STANLEY, SIR WILLIAM (1545-1630), English soldier and traitor, was the eldest son of Sir Rowland Stanley (d. 1612) of Hooton, Cheshire, a member of the famous family of that name. As a volunteer under the duke of Alva he gained his earliest military experiences in the service of Spain; then about 1570 he married into the English families he had known for fifteen years, being knighted by Sir William Drury in 1579. He was very prominent in the guerrilla warfare against the Irish rebels; he was made sheriff of Cork, and he acted as deputy for Sir John Norris, the president of Munster, where by 300 executions he terrified the inhabitants "that a man now may travel the whole country and none to molest him." Having says William Camden, "singulari fide et fortitudine in Hibernico bello moruerat, he returned to England in October 1583, undoubtedly annoyed that his services had not been more generally acknowledged. By December of this year, however, he crossed to the Netherlands with the English forces, but almost as soon as he reached his destination he was sent to Ireland to collect recruits, of whom he enlisted about 1400. Although a strong Roman Catholic, Stanley had hitherto served Elizabeth loyally, but lingering in London on his return from his Irish errand, he seems to have entered into the schemes of the Jesuits against the queen, and he was probably aware of Anthony Babington's plot. But the time for more active and personal treachery had not yet arrived, and with his Irish levies he reached Holland in August 1586, fought gallantly at Zutphen and helped Sir William Pelham to seize Deventer. In spite of some remonstrances, Stanley was made governor of this town, being given extended powers by Leicester, and his opportunity had now come. In January 1587 he surrendered Deventer to the Spaniards, and while most of his men entered the Spanish service, he travelled to Madrid to discuss the projected invasion of England, his idea being to make Ireland the base for this undertaking. These and subsequent plans were ruined by the defeat of the Armada, but he made several journeys to Spain, and it is said that hope the English. His levies were then disbanded, and in the intervals between his travels he fought under the Spanish flag in the Netherlands and in France. Later he became governor of Mechlin, and he died at Ghent on the 3rd of March 1630. His descendant, William Stanley, was created a baronet in 1661, the male line of the family becoming extinct when Sir John Stanley-Errington, the 12th baronet, died in 1893. See R. Bagwell, Ireland under the Tudors (1890), vol. iii.; and J. L. Motley, The United Netherlands (1894), vol. ii.

STANNARD, JOSEPH (1796-1830), British painter, was born in Norwich. He there received some training in art from Robert Ladbrooke, the brother-in-law of Crome, and he also visited Holland and studied the pictures of the Dutch masters. His short life—he died when he was thirty-four—was spent in his native town, and he contributed to the exhibitions of the Norwich Society, of which he was a member, and also occasionally showed his work in London. Most of his pictures represent coast subjects or river scenes, but he had some reputation as a portrait-painter also, and in this branch of practice he achieved locally a fair measure of success. In his large picture, "The Annual Water-Folly at Thorpe," he combined landscape with portraiture. He attained no little skill as an etcher and published several plates which have a considerable degree of merit.

STANNARIES (Lat. stannum, Cornish, stân, tin), tin mines. Stannary courts exercised a jurisdiction peculiar to Cornwall and Devon. So far as regards Cornwall the jurisdiction is an immemorial one. By ancient charters, the tinners of Cornwall were exempt from all other jurisdiction than that of the stannary courts, except in cases affecting land, life and limb. The tin-mining industry of Cornwall, dating as it does, from the very earliest times, was always prosecuted in accordance with a particular code of customs; the earliest charter which embodies them is that of Edmund, earl of Cornwall, but the freedom then assured was rather confirmed than given for the first time, and it is impossible to say how far these customs of the stannaries courts go back. Twenty-four stannaries were returned for the whole of Cornwall. Their meeting was termed a parliament, and when they assembled they chose a speaker. In earlier times, the combined tinners of Devon and Cornwall assembled on Hingston Down, a tract of highland on the Cornish side of the Tamar. After the death of Edmund, the Cornish stannaries met (apparently) at Truro, their seat of government at Crockern Tor on Dartmoor. An officer was appointed by the duke of Cornwall or the Crown, who was lord warden of the stannaries, and the parliaments were assembled by him from time to time, in order to revise old or to enact new laws. The last Cornish stannary parliament was held at Truro in 1752. For a long series of years little or no business was transacted in the stannary courts; but the necessity for a court of peculiar jurisdiction, embracing mines and mining transactions of every description within the county of Cornwall having become more apparent, a commission was appointed to revise the laws of the subject, and an act of parliament was afterwards (1836) passed, suppressing the law courts of the stewards of the different stannaries, and giving to the vice-warden their jurisdiction, besides confirming and enlarging the ancient equity jurisdiction of that office. By the Stannaries Act 1855 the respective parliaments or stannaries courts of Cornwall and Devon were consolidated. From the judgments of the vice-warden an appeal lay to the lord warden, and from him to the Supreme Court. By the Stannaries Courts Abolition Act 1896 the jurisdiction of the courts was transferred to the county courts.

The most important customs may be briefly stated: (a) "free tinner" had the rights to work upon rendering the "toll-tin," usually one-fifteenth of the produce, to the owner or lord of the soil; (b) the right of "tinning," that is, the right of binding any unappropriated waste lands, or any several or enclosed lands which had once been waste land, subject to the custom and to the delivery of tin-toll. The bound was marked by turf or stone, and was about an acre in extent. The estate of a bounder in Devonshire is real property, but in Cornwall it is personal property.

For many centuries a tax on the tin, after smelting, was paid to the earls and dukes of Cornwall. The smelted blocks were carried to certain towns (Liskeard, Lostwithiel, Penzance, Truro) to be coined, that is, a corner of the block was cut off, and the block was then stamped with the ducy seal as a guarantee of the quality. By an act of 1838 the dues payable on the coinage of tin were abolished, and a compensation was awarded to the ducy instead of them.

STANNITE, a rare mineral consisting of tin, copper and iron sulphide (a sulpho-stannate, Cu2FeSnS4), containing, when pure, tin 27.5, copper 20.5%. It has a metallic lustre, and, when pure, is iron-black in colour: more often, however, it is bronze-yellow, owing to tarnish or to the presence of intimately admixed chalcopyrite: for this reason it is known to miners as "bell-metal-ore" or as "tin pyrites." The hardness is 3 and the specific gravity 4.45. It usually occurs as granular to compact masses, rarely as crystals. Micro-crystals from Bolivia have been shown to be tetragonal and hemihedral, like chalcopyrite; and to be invariably twinned, giving rise to pseudocubic forms. The mineral has been found in a number of Cornish tin mines, and was formerly worked to a limited extent as an ore. At Zinnwald in Bohemia it occurs with blende and galena, and in Bolivia with silver ores. (L. J. S.)

STANS, the capital of the eastern half (or Nidwalden) of the Swiss canton of Unterwalden. It stands amid orchards at a
height of 1493 ft. above the sea-level on a plain at the north foot of the conical Stanserhorn (6238 ft.). It is, by electric railway, about 2 m. from Stansstad, its port on the south shore of the lake of Lucerne, and 12 m. from Engelberg (with its great Benedictine monastery, founded about 1120), now a much-frequented summer resort, while there is also an electric railway from Stans up the Stanserhorn. In 1900 Stans had a population of 2798, all German-speaking and Romans. Stans was the home of the Winkelried family (q.v.) and has a modest monument to the memory of Arnold von Winkelried, the legendary hero of the battle of Sempach (1386). Holy Nicholas von der Flüe composed at Stans by his advice the strife between the Confederates, while in 1798 many persons were massacred here by the French. (W. A. B. C.)

STANSFIELD, SIR JAMES (1820-1868), English politician, was born at Moorlands, Halifax, on the 4th of October 1820, the son of James Stansfield, a county-court judge. Educated at University College, London, he was called to the bar in 1840. In 1847 he was introduced through his father-in-law, W. H. Ashurtt, to Mazzini, with whom he formed a close friendship. In 1859 he was returned to parliament as Radical member for Halifax, in which he continued to represent for over thirty-six years. He voted consistently on the Radical side, but his chief energies were devoted to promoting the cause of Italian unity. He was selected by Garibaldi as his adviser when the Italian patriot visited England in 1862. In 1863 he moved in the House of Commons a resolution of sympathy with the Poles, and two months later was made a junior lord of the admiralty. In 1864, as the result of charges made against him by the French authorities, in connexion with Greco's conspiracy against Napoleon III., Disraeli, in the House of Commons, accused him of being "in correspondence with the assassins of Europe." Stansfeld was vigorously defended by Bright and Forster, and his explanation was accepted as quite satisfactory by Palmerston. Nevertheless he only escaped a vote of censure by ten votes, and accordingly resigned office. In 1865 he was re-elected for Halifax, and in 1866 became under-secretary of state for India. In the first Gladstone administration he held a variety of public offices, finally becoming, in 1871, the first president of the local government board. The remainder of his life was mainly spent in endeavouring to secure the repeal of the Contagious Diseases Acts, and in 1886 the repeal was obtained. In the same year Stansfield again became president of the local government board. He died on the 17th of February 1898.

STANTON, EDWIN M'MASTERS (1814-1869), American statesman, was born at Steubenville, Ohio, on the 9th of December 1814. He attended Kenyon College at Gambier, Ohio, from 1831 to 1833, was admitted to the bar in 1836, was prosecuting attorney of Harrison county in 1837-1839, and practised in Cadiz, O., until 1839, when he returned to Steubenville. In 1847 he removed to Pittsburgh, Pennsylvania, where he took a leading place at the bar. One of his most famous cases was that of The State of Pennsylvania v. The Wheeling and Belmont Bridge Company (1849-1850), in which, as counsel for the state, he invoked successfully the aid of the Federal government in preventing the construction of a bridge over the Ohio river at Wheeling, Virginia (now West Virginia) — on the ground that the structure would interfere with the navigation of that stream by citizens of Pennsylvania. His large practice before the United States Supreme Court caused him to remove to Washington in 1856. In 1858 he was sent to California by the United States attorney-general as special Federal agent for the settlement of land claims, and he succeeded in breaking up a conspiracy by which the government would have been defrauded of vast tracts of land of almost inestimable value. Before the Civil War Stanton was a Democrat, opposed to slavery, but a firm defender of the constitutional rights of the slaveholders, and was a bitter opponent of Lincoln, whose party he then hated and distrusted. In the reorganization of President Buchanan's cabinet in 1860 Stanton became attorney-general, and he did what he could to strengthen the weak policy of the president in the last months of his administration. Although he had often violently denounced President Lincoln, the latter thought he saw in Stanton a good war minister, and in January 1862 invited him into his cabinet. In his administration of the war office Stanton was vigorous, rigid, and often harsh, and his peremptory manner, in speech and correspondence, was the cause of considerable friction between the war department and the generals, one of the last and most conspicuous instances being his controversy with General Sherman over the terms of surrender granted to J. E. Johnston's army. But he removed a horde of fraudulent contractors, kept the armies in the field well equipped, and infused energy into procrastinating generals. Not the least of his achievements was the peaceable disbandment of 800,000 soldiers at the end of the war. Remaining in the cabinet of President Andrew Johnson, Stanton exerted all his energies toward thwarting the policies of that executive, especially those related to the reconstruction of the Southern states. He expressed disapproval of the Tenure of Office Act, making the consent of the Senate necessary for the removal of civil officers, and drafted the supplementary act on Reconstruction passed over the president's veto on the 12th of July 1867. Stanton was finally asked to resign, and on his refusal to do so the president suspended him (Aug. 12) from office and appointed General Grant (who had disapproved of the secretary's removal) secretary ad interim. When the Senate, however, under the terms of the Tenure of Office Act, refused (Jan. 13, 1868) to concur in the suspension, Grant left the office and Stanton returned to his duties. On the 21st of February 1868 Johnson appointed General Lorenzo Thomas secretary of war ad interim, and ordered Stanton to vacate, but on the same day the Senate upheld Stanton, and by way of reply the secretary made oath to a complicity against Thomas for violating the Tenure of Office Act, and invoked military protection from General Grant, who placed General E. A. Carr in charge of the war department building, while Congress came to Stanton's rescue by impeaching the president, the principal article of impeachment being that based on the removal of Stanton (see JOHNSON, ANDREW). When the impeachment proceedings failed (May 26) Stanton resigned and returned to the practice of law. In 1869 President Grant appointed him a justice of the United States Supreme Court, but he declined the offer. In the same year Stanton again became president of the local government board. He died on the 17th of February 1898.

STANTON, ELIZABETH CADY (1815-1902), American reformer, was born in Johnstown, New York, on the 12th of November 1815, the daughter of Daniel Cady (1773-1859), a Federalist member of the National House of Representatives in 1813-1817 and a justice of the supreme court of New York state in 1847-1855. She was educated at the Johnstown Academy and at the Troy Female Seminary (now the Emma Willard School), where she graduated in 1832. In 1830 she married Henry Brewster Stanton (1805-1887), a lawyer and journalist, who had been a prominent abolitionist since his student days (1832-1834) in Lane Theological Seminary, and who took her on a wedding journey to London, where he was a delegate to the World's Anti-Slavery Convention. He was a member of the New York Senate in 1850-1851, was one of the founders of the Republican party in New York, and from 1868 until his death was on the staff of the New York Sun. Mrs. Stanton, who had become intimately acquainted in London with Mrs Lucretia Mott, one of the women delegates barred from the anti-slavery convention, devoted herself to the cause of women's rights. She did much by the circulation of petitions to secure the passage in New York in 1848 of a law giving a married woman property rights; and in the same year on the 19th and 20th of
June in Seneca Falls (p.s.), whither the Stantons had removed in 1847 from Boston, was held, chiefly under the leadership of Mrs. Mott and Mrs. Stanton, the first Woman's Rights Convention. She spoke before the New York legislature on the rights of married women in 1854 and on drunkenness as a ground for divorce in 1860, and for twenty-five years she annually addressed a committee of Congress urging an amendment to the Federal constitution giving certain privileges to women. With Parker Pillsbury (1809-1898) she edited in 1857-1870 The Revolution, a radical newspaper, which in 1870 was consolidated with the Christian Enquirer. To the Woman's Tribune she made important contributions, publishing in it serially part of the Foure Discourses of the Conversion of the World (1585), which she and others prepared, and her personal reminiscences, published in 1898 as Eighty Years and More. With Susan B. Anthony and Mathilda Joslyn Gage she wrote The History of Woman Suffrage (3 vols., 1880-1886). She was president of the National Woman Suffrage Association in 1865-1869. Her daughter, Harriet Stanton Blatch (1856— ), also became prominent as a worker for woman's suffrage.

STANYHURST, RICHARD (1547-1618), English translator of Virgil, was born in Dublin in 1547. His father was recorder of Dublin from 1539 to 1546, and he was born in 1547, 1548, and 1549. Richard was sent in 1563 to University College, Oxford, and took his degree five years later. At Oxford he became intimate with Edmund Campion. After leaving the university he studied law at Furnival's Inn and Lincoln's Inn. He contributed in 1575 to Holinshed's Chronicles "a playne and perfecte description" of Ireland, and a history of the country during the reign of Henry VIII., which were severely criticized in Barnabe Rich's New Description of Ireland (1616) as a misrepresentation of Irish affairs written from the English standpoint. After the death of his wife, Janet Barmewell, in 1579, Stanyhurst went to the Netherlands. After his second marriage, which took place before 1585, with Helen Copley, he became active in the Catholic cause. He spent some time in Spain, ostensibly practising as a physician, but his real business seems to have been to keep Philip II. informed of the state of Catholic interest in England. After his wife's death in 1602 he took holy orders, and became chaplain to the archduke Albert in the Netherlands. He never returned to England, and died at Brussels, according to Wood, in 1618. He translated into English The First Four Books of Virgil his Aeneis (Leiden, 1583), to give practical proof of the feasibility of Gabriel Harvey's theory that classical rules of prosody could be successfully applied to English poetry. The translation is an unconscious burlesque of the original in a jargon arranged in what the writer called hexameters. Thomas Nashe in his preface to Greene's Menaphon ridiculed this performance as his "heroical poëtrie, inferred ... with an hexameter furie ... a pattern whereof I will propound to your judgements ... Then did he make heaven's vault to rebounde, with ronceau rhobe labyrd. Of ruffle rafe roaring, with thicke hwacke thurley bouncing."

This is a parody, but not a very extravagant one, of Stanyhurst's vocabulary and metrical methods.

His son, William Stanyhurst (1602-1663), was a voluminous writer of Latin religious works, one of which, Dei immortallis in corpore mortali patientia historia, was widely popular, and was translated into many languages.

Only two copies of the original Leiden edition of Stanyhurst's translation of Virgil are known to be in existence. In this edition his orthographical cranks are preserved. A reprint in 1583 by Hein Byneman forms the basis of J. Maidment's edition (Edinburgh, 1836), and of Professor E. Arber's reprint (1880), which contains an excellent introduction. Stanyhurst's Latin works include De rebus in Hibernia gestis (Antwerp, 1584) and a life of St Patrick (1587).

STANZA (Low Lat. stanzia, Ital. stanza or stanza), properly an apartment or storey in a house, the term being hence adopted for literary purposes to denote a complete section, of recurrent form, in a poem. A stanza is a strophe of two or more lines, usually rhyming, but always recurring, the idea of fixed repetition of form being essential to it. At the close of the 16th century the word stanza began to be used with an adjective to designate a particular species, as the "Spenserian stanza," because Spenser had invented that nine-lined form for his Faerie Queen; or "Ariosto's stanza" as Drayton described what is now known as ottava rima, because Ariosto had written prominently in it. By "stanzaic law" is meant the law which regulates the form and succession of stanzas. The stanza is a modern development of the strophe of the ancients, modified by the requirements of rhyme. (See VERSE; STROPHE; SPENSERIAN STANZA.)

STAPLE, a word which has had a curious and interesting development of meaning. The O. Eng. stapel meant a prop or support, and is to be referred to the root seen in step, stamp, &c.; the meaning is also seen in the cognate Du. stapel, stocks, pile, Ger. Staffel, step of a ladder, &c. The application, in current usage, of the word to a loop of wire or metal with two sharpened points used to fix a pin or bolt, or to fasten wire, &c., to wood, preserves the original sense. A special development in Low German of stapel gave the meaning of an orderly arranged heap of goods or stores, hence a store-house in which goods were arranged in a settled order, the idea of firmness or stability being that which runs through the changes of meaning to which the word has been subjected. This Low German word and sense was adapted in Old French as estaple, mod. étape, and applied to an established market or town, particularly to one which was the centre of the trade in some specific commodity. Thence the word has in modern usage been transferred to a principal or chief commodity or article of consumption.

In English economic history the term "staple" was applied to those towns which were appointed by the king as the centres for the trade of the company of the merchants of the staple. These merchants had a monopoly in the purchase and export of the staple commodities of England, viz. wool, woolfels, leather, tin and lead. The merchants of the staple were the origin of all English trading companies. The trade of the staple towns was under the management of a mayor and constables, sometimes appointed by the merchants themselves, sometimes by the mayor of the town and sometimes by the king himself. W. Stubbs (Const. Hist. vol. ii.) dates the growth of the system from the reign of Edward I. The monopolies of the staple were from time to time abolished and restored, but they were consolidated by a statute of 1355, the number and place of the staples being fixed, the custom declared, and the rights and privileges of the merchants confirmed. (See C. Gross, Cold Merchants; W. Cunningham, Growth of English Industry and Commerce.)

STAPLEDON, WALTER DE (1261-1326), English bishop, was born at Amnery in North Devon on the 1st of February 1261. He became professor of canon law at Oxford and chaplain to Pope Clement V. and in 1307 was chosen bishop of Exeter. He went on errands to France for both Edward I and Edward II, and attended the councils and parliaments of his time. As lord high treasurer of England, an office to which he was appointed by Edward I, he was placed in the popular mind with the misdeeds of Edward II., and consequently, after the king fled before the advancing troops of Queen Isabella, he was murdered in London by the mob on the 15th of October 1326. Stapledon is famous as the founder of Exeter College, Oxford, which originated in Stapledon Hall, established in 1314 by the bishop and his elder brother, Sir Richard Stapledon, a judge of the king's bench. He also contributed very liberally to the rebuilding of his cathedral at Exeter.

STAR, the general term for the luminous bodies seen in the heavens; used also by analogy for star-shaped ornaments (see MEDAL; Orders and Decorations) or other objects, and figuratively for persons of conspicuous brilliance. The word is common to many branches of language: in Teutonic two forms appear, starre or siere (cf. Du. ster), and stern, or stern (cf. Ger. Stern, and the Scand. stjarna, stjerna, &c.). From Lat. stella, are derived Span. and Port. estrella, and Fr. étoile.
The Greek is ἀστῆρ, and the Sanskrit tara, for stars. The ultimate root is unknown, but may be connected with that meaning "to strew," and the word would thus mean the points of light scattered over the heavens. The study of the stars is coeval with the birth of astronomy (see Astronomy: History); and among the earliest civilizations beneficent or malevolent influences were assigned to them (see Astrology). With the development of observational astronomy the sidereal universe was arbitrarily divided into areas characterized by special assemblages of stars; these assemblages were named asterisms or constellations, and each received a name suggested by mythological or other figures. The heavenly bodies fall into two classes: (1) the fixed stars, or stars proper, which retain the same relative position with respect to one another; and (2) the planets, which have motions of a distinctly individual character, and appear to wander among the stars proper.

Numerous counts of the number of stars visible to the naked eye have been made; it is doubtful whether more than 2000 can be seen at one time from any position on the earth. When a telescope is employed this number is enormously increased, and still more so with the introduction of photographic methods; with modern appliances more than a hundred million of these objects may be rendered perceptible.

The recognition of stars is primarily dependent on their brightness or magnitude; and it is clear that a system of classification was attempted by Ptolemy, who termed the brightest stars "of the first magnitude," and the progressively fainter stars of progressively greater magnitude. Ptolemy's classification has been adopted as the basis of the more exactly quantitative modern system. In this system one star is defined to be unit magnitude higher than another if its light is less in the ratio 1:2.512. This ratio is adopted so that a difference of five magnitudes may correspond to a light-ratio of 1:100.

This subject is treated in the article Photometry, Celestial. The faintest stars visible to the naked eye on clear nights are of about the sixth magnitude; exceptionally keen, well-trained eyes and clear moonless nights are necessary for the perception of stars of the seventh magnitude. According to E. Heis the numbers and magnitudes of stars between the north pole and a circle 35° south of the equator are:

<table>
<thead>
<tr>
<th>Magnitude</th>
<th>Numbers</th>
</tr>
</thead>
<tbody>
<tr>
<td>1st mag.</td>
<td>14</td>
</tr>
<tr>
<td>2nd mag.</td>
<td>48</td>
</tr>
<tr>
<td>3rd mag.</td>
<td>152</td>
</tr>
<tr>
<td>4th mag.</td>
<td>313</td>
</tr>
<tr>
<td>5th mag.</td>
<td>854</td>
</tr>
<tr>
<td>6th mag.</td>
<td>2010</td>
</tr>
</tbody>
</table>

From the value of the light-ratio we can construct a table showing the number of stars of each magnitude which together give as much light as a first magnitude star, viz.:

<table>
<thead>
<tr>
<th>Magnitude</th>
<th>Numbers</th>
</tr>
</thead>
<tbody>
<tr>
<td>1st mag.</td>
<td>1</td>
</tr>
<tr>
<td>2nd mag.</td>
<td>2</td>
</tr>
<tr>
<td>3rd mag.</td>
<td>6</td>
</tr>
<tr>
<td>4th mag.</td>
<td>16</td>
</tr>
<tr>
<td>5th mag.</td>
<td>40</td>
</tr>
<tr>
<td>6th mag.</td>
<td>100</td>
</tr>
</tbody>
</table>

Comparing these figures with the numbers of stars of each magnitude we notice that the total light emitted by all the stars of a given magnitude is fairly constant.

Variable Stars.—Although the majority of the stars are unchanged in magnitude, there are many exceptions. Stars whose brightness fluctuates are called variable stars. The number of known objects of this class is being added to rapidly, and now amounts to over 4000. The systematic search made at Harvard Observatory is responsible for a large proportion of the recent discoveries. Many of these stars seem to vary quite irregularly; the changes of magnitude do not recur in any orderly way. Others, however, are periodic, that is to say, the sequence of changes is repeated at regular intervals, and it is thus possible to predict when the maximum and minimum brightness will occur. Of the periodic variable stars, the lengths of the periods range from less than 12 minutes, which is the shortest yet determined, to 610 days, the longest. When statistics of the lengths of the periods are collected, it is at once noticed that they fall into two fairly well-marked classes. The following table, based on S. C. Chandler's "Third Catalogue" (Astronomical Journal, vol. xvi.), supplemented by A. W. Roberts's list of southern variables (ibid. vol. xxi.), classifies the lengths of the periods of 330 stars.

<table>
<thead>
<tr>
<th>Period</th>
<th>100</th>
<th>150</th>
<th>200</th>
<th>250</th>
<th>300</th>
<th>350</th>
<th>400</th>
<th>450</th>
<th>500</th>
<th>550</th>
<th>600</th>
</tr>
</thead>
<tbody>
<tr>
<td>days</td>
<td>0</td>
<td>50</td>
<td>100</td>
<td>150</td>
<td>200</td>
<td>250</td>
<td>300</td>
<td>350</td>
<td>400</td>
<td>450</td>
<td>500</td>
</tr>
</tbody>
</table>

It will be noticed that there are very few periods between 50 and 150 days, that a considerable number are less than 50 days (actually a large majority of these are less than 10 days), and that from 150 days upwards the number of periods increases to a maximum at about 350 days and then diminishes. We thus recognize two classes of variables, of which (1) the long-period variables have periods ranging in general from 150 to 450 days, though a few are outside these limits, and (2) the short-period variables have periods less than 50 days (in the majority of cases less than 10 days). There is some over-lapping of these two classes as regards length of period, and it is doubtful in which class some stars, whose periods are between 10 days and 150 days, should be placed; but the two classes are quite distinct physically, and the variability depends on entirely different causes.

Long-period Variables.—The best known and typical star of this group is γ Cygni. This was the first variable star to be discovered, having been noticed in 1596 by David Fabricius, who thought it was a new star (a Nova). The varying brightness, ranging from the ninth to the second magnitude, was recognized by John Flamsteed, Horrable, and Ismael Boulliau (1655-1694) established a periodicity of 333 days. Although the periodic outbursts of light have taken place without intervention from the earth, the two and a half years and the one year observation, they are somewhat irregular. The different maxima differ considerably in brightness; thus in 1696 (the brightest maximum since 1779) the second magnitude was reached, but in other years the third magnitude (0.865) has been reached. The minima likewise are variable, but only slightly so. Also, the period varies somewhat; the maxima occur sometimes early and sometimes late as compared with the mean period, but the difference is never more than forty days. No general law has been discovered governing these irregularities. The change of magnitude takes place gradually, but the rise to maximum brilliance is rather more rapid than the decline. Spectroscopic observations shows that the increased light accompanies an actual physical change or conflagration in the star. The spectrum is of the third type, with bright hydrogen emission lines (see below, Spectra of Stars). Stars having this type of spectrum and a large proportion of the light from the star as a whole are known as Cepheid variables, and many of the recently discovered long-period variables have been detected through their characteristic spectrum.

X Cygni is another star of this class, remarkable for its range of magnitude. In its period of 406 days it fluctuates between the thirteenth and the fourth magnitudes; thus at maximum it emits 4000 times as much light as at minimum. The mean range of 75 long-period variables observed at Harvard (Harvard Annals, vol. lviii.) was five magnitudes. Another variable, R Normae, is of interest as having a pronounced double maximum in each period.

It is natural to compare the periodic outbursts occurring in these stars with the outbursts of activity on the sun, which have a period of about eleven years. In both cases no extraneous cause can be assigned; the period seems to be inherent in the star itself and not to be determined by the revolution of a satellite (no variability of this kind has been found, so the sun is not accompanied by any large companion). In both cases the rise to a maximum is more rapid than the decline to a minimum, and in fact some of the minute period variables are thought to be influenced by the light-curves of variable stars. H. H. Turner has analyzed harmonically the light-curves of a number of long-period variables, and has shown that when they are arranged in a natural sequence the last fold in the curve is taken up by the interval of exactly one period. It is necessary to suppose, if the analogy is to hold, that the sun is brightest when sunspots and faculae are most numerous; this is by no means unlikely. On the other hand, the variations in the light of the sun must be very small compared with the enormous fluctuations in the light of variable stars. Moreover, the solar period (11 years) is far outside the limits of the periods of

---

1Variable stars (except those sufficiently bright to have received special names) are denoted by the capital letters R to Z followed by the name of the constellation. The first nine variables recognized in each constellation are denoted by single letters, after which combinations RR, RS, &c., are used.
variables. It is therefore perhaps misleading actually to class the sun with them; but it seems highly probable that what we call the great 'regularities' and faculae on our sun differs only in degree from that which, in stars under a different physical condition of pressure and temperature, results in the great physical periods.

**Short-period Variables.**—Besides the shortness of the period these variables possess other characteristics which differentiate them from the long-period variables. The range of variation is much smaller and the variations of the period are much more frequent, the maximum and minimum being separated by partial eclipses resembling the light and dark phases of the moon. A single partial eclipse is sufficient to produce a break in the regularity of the observations and to cause a period change.

In the Algol variables one of the component stars is dark (that is to say, dark in comparison with the other), and once in every revolution, passing between us and the bright component, partially hides it. This class of variables is accordingly called Algol variables.

The Algol system was discovered by John Goodricke (1764-1786), but, judging from its name, which signifies "the demon," it seems possible that its peculiarity may have been known to the ancient astronomers. Algol is ordinarily of magnitude 3.5, but varies from 3.35 to 4.35 in a period of about 2 days 8 hours 20 minutes. Certain explainers have supposed that the explanation of Algol is a dark planet in one of its phases, which periodically passes between us and the bright star, and hides it. There is no evidence of the presence of a planet in the Algol system.

The Algol system is a binary itself, and the component variable stars have in turn been found to be binaries. It is therefore a quadruple system (Algol-A, Algol-B, Algol-C, Algol-D). The periods of the different binaries are slightly different. Algol-C, or the Algol-B variable, has a period of about 15 days.

**Temporary Stars or Novae.**—From time to time a star, hitherto too feeble to be noticeable, blazes out and becomes a prominent object, and then disappears, possibly fading away in a few weeks. There are two classes of novae:

1. **Eclipsing Novae**—These are stars which have suddenly increased in magnitude by about 10-15 magnitudes; but they have a tendency to fade away after a period of from 2 to 4 weeks. The explanation, as given by Vogel, is that the star is one of a binary system, one of the stars being of much greater apparent magnitude than the other. When the larger star passes in front of the smaller, a partial eclipse occurs; and the presence of this eclipse is inferred from the irregularities in the light of such a star. Algol is of this type.

2. **Non-eclipsing Novae**—These stars are seen to suddenly increase in magnitude, but there is no evidence of an eclipse or other phenomena associated with the change. These stars cannot be binaries, and the increase in magnitude is probably due to the fact that the star has suddenly increased in size. The star nova Nova Cappellae, which appeared in 1731, is of this type.

**Algol.**—Algol is a well-known double star, consisting of two stars of nearly equal magnitude, the fainter of which is invisible to the naked eye. The fainter star wanes from magnitude 3.2 to 4.6 at intervals of about 2 days 8 hours 20 minutes. The explanation of this fact is given by the binary hypothesis, and has been confirmed by spectroscopic observations. Algol is a quadruple system, and the components are of different colors, one being red and the other blue.

**Mira.**—Mira is a well-known variable star, which varies from magnitude 2 to 11.5 in a period of about 330 days. The explanation of this variable is given by the binary hypothesis. Mira is a quadruple system, and the components are of different colors, one being red and the other blue.

**Cepheid.**—The Cepheid variables are a class of variable stars which vary in magnitude by a considerable amount, and whose periods are known to be of the order of a year. The explanation of these stars is given by the binary hypothesis, and has been confirmed by spectroscopic observations. Cepheid stars are known to be of different colors, one being red and the other blue.

**Cygnet.**—Cygnet is a well-known variable star, which varies from magnitude 2 to 11.5 in a period of about 330 days. The explanation of this variable is given by the binary hypothesis. Cygnet is a quadruple system, and the components are of different colors, one being red and the other blue.

**Algol.**—Algol is a well-known double star, consisting of two stars of nearly equal magnitude, the fainter of which is invisible to the naked eye. The fainter star wanes from magnitude 3.2 to 4.6 at intervals of about 2 days 8 hours 20 minutes. The explanation of this fact is given by the binary hypothesis, and has been confirmed by spectroscopic observations. Algol is a quadruple system, and the components are of different colors, one being red and the other blue.

**Mira.**—Mira is a well-known variable star, which varies from magnitude 2 to 11.5 in a period of about 330 days. The explanation of this variable is given by the binary hypothesis. Mira is a quadruple system, and the components are of different colors, one being red and the other blue.

**Cepheid.**—The Cepheid variables are a class of variable stars which vary in magnitude by a considerable amount, and whose periods are known to be of the order of a year. The explanation of these stars is given by the binary hypothesis, and has been confirmed by spectroscopic observations. Cepheid stars are known to be of different colors, one being red and the other blue.

**Cygnet.**—Cygnet is a well-known variable star, which varies from magnitude 2 to 11.5 in a period of about 330 days. The explanation of this variable is given by the binary hypothesis. Cygnet is a quadruple system, and the components are of different colors, one being red and the other blue.
progress of a nova. Argus is surrounded by a nebula, the famous "keyhole nebula"; in this respect it resembles Nova Persei.

System of Stars.-On examining the stars telescopically, many systems of stars are encountered, which appear single to the naked eye and are resolved into two or more stars only when examined with a telescope. In some cases the proximity is only apparent; one star may be really at a vast distance behind the other, but, being in the same line of vision, they appear close together. In many cases, however, two or more stars are really connected, and their distance from one another is (from the astronomical standpoint) small. The evidence of the connexion is of two kinds. In a number of cases measures of the relative positions of the two stars, continued for many years, have shown that they are revolving about a common centre; when this is so there can be no doubt that they form a binary system, the two components move in elliptic orbits about the common centre of mass, controlled by their mutual gravitation. But these cases form a very small proportion of the total number of double stars. In many other double stars the two components have very nearly the same proper motion. Unless this is a mere coincidence, it implies that the two stars are nearly at the same distance from us. For otherwise, if they had from some unknown cause the same actual motion, the apparent motion in arc would be different. We can therefore infer that the two stars are really comparatively close together, and, moreover, that they have the same proper motion, that they remain close together. They may perhaps be regarded as constituting a single star, though the gravitational attraction between some of the wider pairs must be very weak.

Several double stars were observed during the 17th century. Ursa Majoris being the first on record. In 1784 Christian Mayer published a catalogue of 150 double stars, containing 86 pairs. Between 1825 and 1827 F. G. Struve and Dorrpat examined 120,000 stars, and found 3112 double stars whose distance apart did not exceed 32". W. S. Burnham's General Catalogue of 1830 contains 7570 pairs of stars, nearly all components separated 3"-31". Undoubtedly a large number of these are only optical pairs, but mere considerations of probability show that the majority must be physically connected. For only 88 of them has there been a trial, and at least half even of these periods are very doubtful. The rate of motion is so slow that many centuries' observations are needed to determine the orbit.

The most rapid visual binary (leaving aside Capella for the moment) is 6 Eridani, which completes a revolution in 5·7 years. Next to it come 13 Ceti, period 7·4 years, and 1 Pegasi, period 11·4 years. From a list of systems with determined periods given by Aitken (Lancaster, No. 247, and No. 680, June 1879) it will be seen that 13 Ceti, 1 Pegasi, and 6 Eridani are 50 years, and between 50 and 100 years. 13 Ceti and 1 Pegasi are all extremely close pairs, and can only be resolved with the most powerful instruments. Capella, whose period is only 104 days and whose components are not evident to the naked eye, but has since been measured frequently as a visual binary at Greenwich. With the best instruments a star can be distinguished as double when the separation of the two components is a little less than a second of arc. From the very few orbits that have as yet been determined one interesting result has been arrived at. Most of the orbits are remarkably eccentric ellipses; the average eccentricity being about 0·5. There is a very striking relation between the eccentricity and the period of a system; in general the binaries of longest period have the greatest eccentricities. The relation applies not only to the visual but to the spectroscopic binaries; these, having shorter periods than the visual binaries, have generally quite small eccentricities. Another interesting feature is that where the two components differ in brightness, the fainter component is often the one possessing the great eccentricity, whereas it would seem that the eccentricity of the orbit of a system is determined by the size of the two components, and that the conditions of the orbit are the same for both components.

Spectroscopic Binaries appear as a connecting link between short-period visual binaries, where the two components are easily resolved, and spectroscopic doubles stars on the other. Stars of the class to which the Algol type of variables belongs will appear to us only in the exceptional case when the plane of the orbit of one and of the other body passes perpendicularly to the line of sight of the observer, and consequently we see the variation in phase every time the orbit is seen in conjunction, and therefore moving transversely, their spectra are measured almost in one and the same line. If only one component is sufficiently luminous for its spectrum to appear; its orbital motion is then detected by a periodic change in the absolute displacement of its spectral lines. Up to 1905, 140 spectroscopic binaries have been discovered, and in some of them the relative positions of the two stars are known, as determined in the Lick Observatory Bulletin, No. 79. Details of the calculated orbits of 63 spectroscopic binaries are given in Publications of the Allegheny Observatory, according to W. W. Campbell in every seven examined is binary.

A continuous gradation can be traced from the most widely separated visual binaries, whose periods are many thousands of years, to spectroscopic binaries whose periods are only a few hours. In the latter case the components may even be in contact, and from these to dumb-bell shaped stars and finally to ordinary single stars. It is a legitimate speculation to suppose that these in their revolution are either in contact or nearly so. As the simple star radiates heat and contracts, it retains its angular momentum; when this is too great for the spherical form to persist, the star may ultimately separate into two components, which are driven further and further apart by their mutual tides. Tidal action also accounts for the progressively increasing eccentricities of the orbits, already referred to. This theory of the genesis of double stars by fission is, however, not universally accepted; a few particularly objectionable cases have been urged by T. C. Chamberlin and F. R. Moulton. It is true that rotational instability alone is not competent to explain the separation into two components; but the existence of rotation in the pre-natal system is a natural assumption, which carries with it the dimensions of that system. No star is altogether removed from the attractions of its neighbours, and there are cases where some sort of accretion is known to have taken place between one and another system.

A curious case of this sort is that of the five stars $\beta$, $\delta$, $\epsilon$, and $\zeta$ of Ursa Major. These have proper motions which are almost identical in amount and in direction. The agreement is too close to be dismissed as chance, and the problem has been confirmed by the agreement of their radial motions determined by the spectroscope; and yet, seeing that $\beta$ and $\zeta$ Ursa Majoris are 10° apart, these two stars must be distant from each other at least one-third of the distance to the sun, which is 50,000,000,000 miles. They are thus separated by the ordinary stellar distances, and probably each has neighbours, not belonging to the system, which are closer to it than the other stars of the group. Further, E. Hertzsprung has shown that Sirius also belongs to this same system and shares its motion, notwithstanding that it is in a nearly opposite part of the sky. It is difficult to understand what may be the connection between stars so widely separated; however, the equality of their motions they must have been widely separated for a very long period.

Of multiple stars the most famous is $\theta$ Orionis, situated near the densest part of the great Orion nebula. It consists of four principal stars and may be regarded as a vast condensation of stars. On account of the great size and number of stars of this kind, we pass to the consideration of star-clusters, which are systems of stars in which the components are very numerous, and the system possesses the power necessary to separate the individual stars. A cluster of stars of this kind we term a globular cluster. The "beehive" cluster in Cancer is an example of an easily resolved cluster composed of fairly bright stars. The cluster of stars around $\zeta$ Herculis in Orion resembles the highest power of its complete resolution into stars. Doubtless with improved telescopes many more apparent nebulae would be shown to be clusters, but there are certainly many nebulae which are otherwise constituted. Many of the clusters are of very irregular forms, either showing no well-marked centre of condensation, or else condensed in streams along certain lines. There is, however, a well-marked type to which nearly all the richest clusters belong; these are the globular clusters. They have a symmetrical turreted shape, the condensation increasing rapidly towards the centre. The Hercules cluster is of this form; another example is $\omega$ Centauri, the nearest globular cluster to the earth, being about 6000 light years off, and lying in the sphere of a circle of about 40' diameter. These clusters present many unsolved problems. Thus Perrine, from an examination of ten globular clusters (including Messier 13 and $\omega$ Centauri), has found in each case that there are 2000 stars in a sphere of 300 light years in diameter, and having an angular diameter of about 2°; the line of sight is enclosed in a sphere of about 3° diameter, and the number of stars in both these spheres is the same. About one-third of the stars are between magnitudes 11 and 13, and the remaining two-thirds are between magnitudes 15 and 16. Stars of magnitudes intermediate between these two groups are rare, and the remaining few stars are in the faintest kinds of stars, which we may distinguish as bright and faint; the bright stars are all approximately of one standard size, and the faint stars none of the same kind.

The question of the stability of these clusters is one of much interest. The mutual gravitation of a large number of stars crowded in a comparatively small space must be considerable, and the individual stars should gradually move towards the common centre. It does not seem probable, however, that they can escape the fate of ultimately condensing into one confused mass. If this surmise be correct, we are witnessing in clusters a counter-process of
evolution to that which is taking place in double stars; the latter are formed by accretion from a single original mass and the former condensing into one.

Colours and Spectra of Stars.—The brighter stars show a marked variety of colour in their light, and with the aid of a telescope a still greater diversity is noticeable. It is, however, only the red stars that form a clearly marked class by themselves. For purposes of precise scientific investigation the study of spectra is generally more suitable than that of the vague and elusive visual sensations which differ with different observers. Of the first magnitude red stars Antares is the most deeply coloured, Betelgeux, Aldebaran and Arcturus being successively less conspicuously red. Systematic study of red stars dates from the publication in 1866 of Schjellerup's Catalogue, containing a list of 280 of them.

The two components of double stars often exhibit complementary colours; of the two, one is generally of a reddish hue, the other bright and a faint component which are relatively wide apart; brilliant white stars frequently have a blue attendant—this is instance in the case of Regulus and Rigel. That the effect is due to a real difference in the character of the two components has been shown by spectrum analysis, but it is probably exaggerated by contrast.

The occurrence of colour change, either periodic or irregular, in the case of individual stars, has been suspected by many observers; but such a colour-variability is necessarily very difficult to establish. A possible change of colour in the case of Sirius is noteworthy. In modern times it has been observed that the star is of a deep blue in spectrum, but a number of classical writers refer to it as red or fiery. There is perhaps room for doubt as to the precise significance of the words used; but the fact that Ptolemy classes Sirius with Antares, Aldebaran, and Rigel, &c., and that the stars are successively redder or bluer as compared with all the other bright stars which are "yellow" (αυ) seems almost conclusive that Sirius was then a red star.

When examined with the spectroscope the spectral lines of Sirius is found to vary generally more or less of that of the sun. The spectrum consists of a continuous band of light crossed by a greater or less number of dark absorption lines or bands. As in the case of the sun, these indicate an incandescent body which might be solid, liquid, or a not too rare gas, surrounded by and seen through an atmosphere of somewhat cooler gases and vapours; it is this cooler envelope whose nature the spectroscopic researches have sought to determine. This presence of a solid envelope has been detected by identifying in the spectrum their characteristic absorption lines. Stellar spectroscopy dates from 1862, when Sir William Huggins (with a small slit-spectroscope attached to an 8-in. telescope) measured the positions of the chief lines in the spectra of about forty stars. In 1876 he successfully applied photography to the study of the ultra-violet region of stellar spectra. While their own estimation of the time at which these earliest is that due to A. Secchi (1856-1897) who distinguished four "types".; subsequent research, whilst slightly modifying, has in the main confirmed this classification. Secchi's Type I, or Sirian type is a star of a deep blue or white, similar to Sirius, or Rigel, &c.; it is characterized by strong broad hydrogen lines, which are often the only absorption lines visible. Type II includes the "Sorbian" stars, which indicates an incandescent body. their spectra are similar to that of the sun, being crossed by very numerous fine lines, mostly due to vapours of metals. The great majority of the visible stars belong to these two types. Type III. or "Antarian" stars are of a reddish colour, such as Antares, Betelgeux, Mira, and many of the long-period variables. The spectrum, closely resembles that of a sunspot, is marked by fluctuations or bands of lines sharply bounded on the violet side and fading off towards the red. It has been shown by A. Fowler that these fluctuations are due to titanium oxide; this probably indicates a relatively low temperature, for at a high temperature all compounds would be evaporated. Type IV comprises stars which show broadband spectra, but the bands differ in arrangement and appearance from those in the third type, and are sharply bounded on the red side. These stars are also believed to have a comparatively low surface temperature, and that the bands are produced by the condensation of compounds of carbon. About 250 Type IV stars are known, but none conspicuous; 19 Piscium, the brightest, is of magnitude 5.5.

Other classifications which have been extensively used are respectively of K. H. Vogel, J. N. Lockyer and the Draper Catalogue. The diversities depend mainly on the different views taken by their authors as to the order of stellar evolom. One of the main concerns in this discussion is in the classification introduced by more recent investigators has been to separate Secchi's Type I into two divisions, called helium and hydrogen stars respectively. The former are often called red giants. The names of the stars in this constellation with the exception of Betelgeux belong to the helium type. Helium stars are generally considered to be the hottest and most luminous (proportionately) of all the stars. Type II is now subdivided into "Procyon," "Solar" and "Arcturian" stars. The "Procyon" or calcium stars form a transition between Type I and Type II and show the lines of calcium besides those of hydrogen. A important variety of Type III, spectra have been recognized, in which, as well as the usual absorption lines, bright emission lines are sometimes present. This particular variety is known as the Wolf-Rayet type; these show a spectrum crossed by the usual dark lines and bands, but showing also bright emission bands of blue and yellow. About 100 Wolf-Rayet stars are known, of which the Wolf 788 is the brightest; they are confined to the region of the Milky Way and the Magellanic Clouds. (See PLANET.)

Evolution of Stars.—The absence of the distinctive lines of an element in the spectrum does not always signify that the element is wanting or scarce in the star. The spectroscopy only yields information about the thin outer envelope of the star; and absorption phenomena which are responsible for the spectrum shown depends very greatly on the temperature and pressure. Stars of the different types are therefore not necessarily different chemical constitution, but rather are in different physical conditions, and it is generally believed that every star in the course of its existence passes through stages corresponding to all (or most of) the different types. The stars are known to be continually losing enormous quantities of energy by radiating their heat into space. Ordinary solid or liquid masses would cool very rapidly from this cause and would soon cease to shine. But a globe of gaseous matter under similar conditions will continually absorb heat from its surroundings, and, if its temperature is high enough, radiate the heat. It was shown by Homer Lane that a mass of gas held in equilibrium by the mutual gravitation of its parts actually grows hotter through radiating heat; the heat gained by the resulting increase in temperature more than balances the heat lost by the star in the first stage of a star's history we find it gradually condensing from a highly diffused gaseous state, and growing hotter as it does so. But this cannot continue indefinitely; when the opacity is too great for further contraction the temperature of the outer envelope is insufficient to maintain the heat. Thus in the second stage the star is still contracting, but its temperature is decreasing. The amount by which the temperature is diminished is determined by the mass of the star. It is, however, important to bear in mind that Lane's theory is concerned with the temperature of the body of the star; the temperature of the photosphere and the outer envelope, which is cooled by the Earth's atmosphere, necessarily follow the same law. It depends on the rapidity with which convection currents can supply heat from the interior to replace that radiated, and on a number of other nicely balanced circumstances which it would be impossible to detail here.

Conflicting opinions are held as to the various steps in the process of evolution and the order in which the various types succeed one another, but the following perhaps represents in the main the action generally accepted view. Starting from a widely diffused nebula, more or less uniform, we find that, in consequence of gravitational instability, it will tend to condense about a number of nuclei. J ohnson's law of gravitational tendency states that a good number of nuclei will be left. These may form the nuclei of the Pleiades. As the nuclei grow by the attraction of matter they begin to be capable of retaining the lighter gases, and atmospheres of hydrogen and helium are formed. The temperature of the photosphere at this stage has reached a maximum, and the star is now of the helium type. Then follows a gradual absorption of first the helium and then the hydrogen, the photosphere grows continually cooler, the sun passes successively through the stages exemplified by Sirius, Procyon, the Sun itself, and Antares. Some authorities, however, consider the Antarian (Type III.) stars to be in a very early stage of development and to precede the helium stars in the order of succession. After the helium bands disappear the temperature is still rising. Type IV (carbon) stars are placed last in the series by all authorities; they seem, however, to follow more directly the solar stars than the Antarian. If the latter are placed last, this is probably because the hydrogen, helium and carbon gases are not as heavy as the helium of the early types, and if both Antarian and carbon stars are held to be evolved from solar stars we may consider them to be, not successive, but parallel stages of development, the chemical development of the star declining from the third to the fourth. The Wolf-Rayet stars must probably be assigned to the earliest period of evolution; they are perhaps semi-nebulous. In this connexion we have to consider the fact that the spectral classification has undergone a change in the stage at which it seemed that of a planetary nebula, has now become the Wolf-Rayet type.

Density of Stars.—Interesting light is thrown on the question of the density of the stars by the fact that we are able to determine as to their densities. The mean density of the sun is about 1.3 times that of water; but many of the stars, especially the brighter ones, have much lower densities and must be in a very different state. We have necessarily to turn to binary systems for our data. When
the orbit and periodic time is known, and also the parallax, the masses of the stars can be found. (If only the relative position is known, the sum of the masses can be determined; but if absolute positions of one component have been observed, both masses can be determined separately.) But even when, as in most cases, the parallaxes are unknown, or uncertain, the ratio of the distance to the mass can be approximately found. Thus it is found that Procyon gives about three times as much light as the sun in proportion to its mass. If the sun’s mass is about one, the mass of Procyon must therefore be about three times as much as the sun’s. In the cases of stars, for which the distance is not known, the mass of a star may be calculated in this way, that the average density of the Algol variables and their eclipsing companions is about one-eighth of that of the sun. For β Lyrae G. W. Myers found a density a little less than that of air; the density is certainly small, but J. H. Jeans has shown that for this type of star the argument is open to theoretical objection, so that Myers’s result cannot be accepted.

There are many stars, however, of which the brightness is less than the intrinsic value of the star. If we made observations of the fainter companion of Sirius is of nearly the same mass as the sun, but gives only one-third of its light. In this case the companion, being about half the mass of Sirius itself, has probably cooled more rapidly, and therefore has a smaller degree of brightness. A number of other stars have been observed that have shown that the fainter component of the binary system is often the more massive. It may be that these fainter components are stars in a nearly similar state of development and that they are as yet comparatively small; but it is not impossible that the massive stars (owing to their greater gravity) pass through the earlier stages of evolution more rapidly than the smaller stars.

Methods of finding the parallaxes. As the earth traverses annually its path around the sun, and passes from one part of its orbit to another, the direction in which a fixed star is seen changes. In fact the relative positions are the same as if the earth remained fixed and the star described an orbit equal to that of the earth, but with the displacement always exactly reversed. The star thus appears to describe a small ellipse in the sky, and the nearer the star, the larger will this ellipse appear. The greatest displacement of the star from its mean position (the semi-axis major of the ellipse) is called its parallax.

If π be the parallax, and R the radius of the earth’s orbit, the distance of the star in light-years is \( R \pi \), and the distance in parsecs, more than ten parsec is a matter of great difficulty to be accounted for the smallness of the angle to be measured, in no case when the parallax amount to \( \pi \); moreover, there is always an added difficulty in determining an annual change of position, for seasonal instrumental changes are liable to give rise to a spurious effect which will also have an annual period. Very special precautions are required to eliminate instrumental error before we can compare observations, say, of a star on the meridian in winter at 6 p.m. with observations of the same star in summer on the meridian at 6 a.m. The first determination of a stellar parallax was made by F. W. Bessel in the years 1837-1840, using a heliometer. He chose for his purpose the binary star 61 Cygni, which was the star with the most rapid apparent motion then known and therefore likely to be fairly near us, although only of the sixth magnitude. He found for it a parallax of 0.5°, a value which agrees well with more modern determinations.

T. Henderson at the Cape of Good Hope measured the parallax of a Centauri, but his resulting value \( \pi \) was considerably too high. More accurate determinations have shown that this star, which is the third brightest star in the heavens, has a parallax of 0.75°, this indicates that its distance is 25,000,000,000,000 m. So great a distance is too great for a star in our neighborhood.

Formerly attempts were made to determine parallaxes by measuring changes in the absolute right ascensions and declinations of the stars from observations with the meridian circle. The results were generally considered of no use, and it was thought that no changes in the instrument. Nowadays the determination is more usually made by measuring the displacement of the star relatively to the stars surrounding it. Heliometer the heliometer has been most extensively used for this purpose, D. Gill, W. L. Elkin, B. E. A. Peter and others have made their important determinations with it. The photographic method, however, now appears to yield results of equal precision, and likely be used very largely in the future. The quantity determined by these methods is the relative parallax between the star measured and the stars with which it is compared. To obtain the true parallax, the mean parallax of the comparison stars must be added to this parallax. It is, however, difficult to assume that the comparison stars will vary as great as 0°-01; for it must be remembered that it is the exception for a star taken at random to have an appreciable parallax at all. If a star has an ordinate small proper motion, it is likely to be very distant. Still exceptional cases will occur where a comparison star is even nearer than the parallax; it is one of the advantages of the photographic method that it involves the use of a considerable number of comparison stars, whereas in the heliometric method usually only two stars, chosen symmetrically one on each side of the principal star, are used. In the large parallaxes, the point of lessening which is often used in one of the stellar distances, is the light year or distance that light travels in a year; it is less than six billion miles.

Stars with Large Parallaxes.

The stars selected to be examined for parallaxes are usually either the brightest stars or those with an especially large proper motion. Neither criterion is a guarantee that the star shall have a measurable parallax. Brightness is particularly deceptive; thus Canopus, the second brightest star in the heavens, has probably a parallax less than 0°-01; and so has also Rigel. These two stars must have an intrinsic brilliancy enormously greater than that of the sun, for if the sun were removed to such a distance (parallax 0°-01), it would appear to be of about the tenth magnitude.

As with the parallaxes, the accuracy of the results has been greatly to our general knowledge of stellar distances and absolute luminosities of stars, a collection of results derived by various observers choosing specially selected stars is not suitable for statistical conclusion. For this reason a series of determinations of parallaxes 163 stars on a uniform plan by F. L. Chase, M. F. Smith and W. L. Elkin (Yale Transactions, Vol. II, 1906) constitutes a very important addition to the available data. The results obtained were for the most part for proper motions greater than 40', observable at Yale, and not hitherto attacked. It is noteworthy that no parallaxes exceeding 0°-20 were found; the mean was about 0°-05. It is greatly to be desired that a survey of all the stars, well enough classified to determine which of the heavens, should be made with a view to determining all the stars which have an appreciable parallax. This is now made possible by photography. If three plates (or three successive periods of observation at one place) have their maximum parallactic displacements, the first and third plates serve

to eliminate the proper motion of the star, and the detection of a proper motion by interferometry has been made.

But even such an attempt to systematically plummet the universe can only make us acquainted with the merest inside shell. We should learn perhaps the distribution and luminosities of the stars within a sphere of 80 light years (corresponding to a parallax of about 0·05), but of the structure of the million-fold greater system of stars, lying beyond this limit, yet visible in our telescopes, we should learn nothing except by indirect analogy. Fortunately the study of proper motions teaches us with some degree of certainty something of the general mean distances and distribution of these more distant stars, though it cannot tell us the distances of individual stars.

The proper motions of double stars, of stellar distances, which are applicable to a few double stars. By means of the spectroscope it is possible to determine the relative orbital velocity of the two components, and this when compared with the period fixes the actual distance of the orbit; the apparent dimensions of the orbit being known from visual observations the distance can then be found. The method is of very limited application, for in general the orbital velocity of a visual binary is too small to be found in this way—one of its first applications has been made to α Centauri, with the result that the parallax found in the ordinary way is completely confirmed.

Proper Motions of Stars.—The work of cataloguing the stars and determining their exact positions, which is being pursued on so large a scale, naturally leads to the determination of their proper motions. The problem is greatly complicated by the fact that the equator and equinox, to which the observed positions of the stars must be referred, are not stationary in space, and in fact the movements of these planes of reference can only be deduced from the observations themselves. However, John Flamsteed and Edmond Halley was the first to suspect from observation the proper motions of the stars. From comparisons between the observed places of Arcturus, Aldebaran and Sirius and the places assigned to them by Alexandrian astronomers, he was led to the opinion that all three are moving towards the south (Phil. Trans. 1718).

Jacques Cassini also proved that Arcturus had even since the time of Tycho Brahe shifted five minutes in latitude; for η Boötis, which would have shared in the change, if it had been due to a motion of the ecliptic, had not moved appreciably. It was early realized that the proper motions of the stars were changes of position relative to the sun, and that, if the sun had any motion of its own as compared with the surrounding stars as a whole, this would be shown by a general tendency of the apparent motions of the stars to be directed away from the point to which the sun was moving.

To determine proper motions it is necessary to have observations separated by as long a period of time as possible. Old catalogues of precision are accordingly of great importance. By far the most valuable are those of the star catalogues made at Greenwich about 1750-1763, which has been re-reduced according to modern methods by A. Auwers. These stars include most of the brighter ones visible in the latitude of Greenwich, ranging down to the 14th magnitude and even more. The catalogue is absolutely unique in that the large numbers of stars of magnitude as low as 8·5 that is of S. Groombridge, containing 4200 stars within 52″ of the north pole observed between 1806 and 1816. This has been re-reduced by F. W. Dyson and W. G. Thackeray, and proper motions derived by comparison with modern Greenwich observations. A very extensive determination of proper motions from a comparison of all the principal catalogues has been made by Lewis Boss. The results are given in his Preliminary General Catalogue (1910), which comprises the motions of 6188 stars fairly uniformly distributed over the sky, including all the stars visible to the naked eye. Of rather a different nature are the proper motions of certain catalogues of stars by the Greenwich Observatory (No. 12) and J. F. Bossert's catalogue (Paris Observations, 1890), which consist of lists of stars of large proper motion determined from a variety of sources. Recently the proper motions of faint stars have been determined by comparing photographs of the same region of the sky, taken with an interval of a number of years. At present the available intervals are too small for this method to give results of high accuracy, and the proper motions of faint stars can however be found in this way. Their detection is especially simple when the stereo-comparator is used; this instrument enables the two eyes to combine the images of each star on two plates placed one above the other (in the comparator) so that when the star has moved considerably in the interval between the taking of the two plates, it appears to stand out from the rest in relief and is at once noticed.

Adding the motions of the greatest proper motion yet known was found by J. C. Kapteyn. But the plate of stars between 8° and 9° of latitude had been measured. Its motion of 8′/″ per year would carry it over a portion of the sky equal to the diameter of the full moon in about two centuries. In the table is given a list of the stars now known to have proper motion of more than 3′/″. The faintness of the majority of the stars appearing in this list is noteworthy.

Stars with Large Proper Motion.

The majority of the stars have far smaller proper motions than these. Only 24% of Auwers-Brayley have proper motions exceeding 10″ per century and 51% exceeding 5″ per century. With catalogues containing fainter stars the proportion of large proper motions is somewhat smaller, thus the corresponding proportion for this Groombridge star list is 12%.

When the parallax of a star is known, we are able to infer from its proper motion its actual linear speed in miles per hour, in far as the motion is transverse to the line of sight. The velocity in the line of sight can be determined by spectroscopic methods, so that in a few cases the motion of the star is completely known. Several stars appear to have speeds exceeding 100 m. per second, but of these only the ones reliably determined is Groombridge 1830, the speed is found to be 150 m. per second. Probably the velocity of Arcturus is also over 100 m. per second; there is, however, no real evidence for the velocity of 250 m. per second which has sometimes been credited to it. The above are velocities transverse to the line of sight. The greatest radial velocities that have yet been found are about 60 m. per second; several stars (Groombridge 1830 among them) have radial speeds of this amount. The stars of the Helium type of spectrum are remarkable for the smallness of their velocities; from spectroscopic observations of over 60 stars of this class, J. C. Kapteyn and E. B. Frost have deduced that the average speed is only 8 m. per second. According to W. W. Campbell the average velocity in space of a star is 23-2 m. per second.

When the proper motions of a considerable number of stars are collected and examined, a general systematic tendency is very clear, and this is known as the proper motion of the solar system. The proper motion of the sun relative to the stars is only a few seconds of arc per year, but toward a point somewhere in or near the constellation Canis Major. The motions of individual stars, it is true, vary widely, but if the mean motion of a number of stars is considered this tendency is easily found. Now it is necessary to bear in mind that all observed motions are relative; and, especially in dealing with stellar motions, it is arbitrary what shall be considered at rest, and used as a standard to which to refer their movements. Accordingly this mean motion of the stars relative to the sun has been more generally regarded from another point of view as a motion (in the opposite direction—towards the constellation Lyra) of the sun relative to the stars. In what follows we shall speak of this relative motion as a motion of the sun or of the stars indifferently, for there is no real distinction between the two conceptions. One of the problems, which has engaged a large share of the attention of astronomers in the last century, has been the determination of the direction of this "solar motion."

The first attempt to determine the solar apex (as the point towards which the solar motion is directed) was made by Sir William Herschel. Although the proper motions of only seven stars, he indicated a point near η Herculis not very far from that found by modern researches. Again 80° from Mascaccyni's catalogue of the proper motions of 36 stars (published in 1790), he found the position, R.A. 24°36′ 52′′ and Dec. 40°38′ N. The systematic tendency of the proper motions is so marked that the motions of a very few stars are quite sufficient to determine the position of the solar apex; but attempts to find its position to within a few degrees have failed, notwithstanding the many thousands of determined proper motions now available. The difficulties of the determination are twofold. There is a close resemblance between the constellations of proper and linear motion; the two determinations must generally be made simultaneously, and both depend very considerably on the systematic
corrections required by the catalogues compared. But further, if these practical difficulties could be considered overcome in the best directions of the parallactic motion, the Wagnerian form for the motion of the sun relative to the stars depends on what stars are selected as representative. There is no a priori reason to expect the same result from the different classes of stars, such as peculiar or normal, or of different regions near or far, distant, Solar type or Sirian stars. There is for example some evidence that the declination of the solar apex is really increased while the regional term is decreased. It follows from this that a really close agreement between the results of different investigators is not to be expected.

Of the various modern determinations of the apex, we give first those due to Campbell, following down the system of Bradley from the data of his Preliminary General Catalogue (1810), L. Boss found

$$\alpha = 18^{\circ} 17^{\prime} 48^{\prime\prime}, \delta = +42^{\circ} 8$$

L. Struve $$\alpha = 18^{\circ} 22^{\prime} 20^{\prime\prime}, \delta = +23^{\circ} 5$$

S. C. Tate $$\alpha = 19^{\circ} 2^{\prime} 34^{\prime\prime}, \delta = +28^{\circ} 3$$

J. C. Kapteyn $$\alpha = 18^{\circ} 14^{\prime} 45^{\prime\prime}, \delta = +29^{\circ} 5$$

The large differences between these results, derived from the same material, depend mainly on the different systematic corrections applied by each astronomer to the declinations of Bradley. From the data of this, A = $$18^{\circ} 2^{\prime} +43^{\prime\prime}3$$.

Having regard to the special precautions taken to eliminate systematic error, and to the fact that the stars used were distributed nearly equally over both hemispheres, it is fair to consider the agreement between the most astronomic results as quite satisfactory.

From the Groombridge proper motions Dyson and Thackeray found

$$\alpha = 18^{\circ} 20^{\prime}, \delta = +37^{\circ}$$

Other determinations have been made by O. Stumpf (Astr. Nach., No. 3009) and J. G. Porter (Astr. Journ. xii, 91), which are only based on the data on one hemisphere or on very small source areas; their results are of the same general character. Most of the above investigators, besides giving a general result, have determined the first motion for a number of stars separately, some being greater or less proper motion, and in some cases for stars of Sirian and Solar spectra. Considerable differences in the resulting position of the apex are found.

It will be seen that the proper motion of any star may be regarded as made up of two components. The part of the star's apparent displacement, which is due to the solar motion, is generally called the parallactic motion; the rest of its motion (i.e. the difference in right ascension and declination of the star relative to its true position in the celestial sphere) is called its peculiar motion (motus peculiaris). Regarded as a linear velocity, the parallactic motion is the same for all stars, being exactly equal and opposite to the solar motion; but its amount, as measured by the corresponding angular displacement of the star, is inversely proportional to the distance of the star from the earth, and foreshortening causes it to vary as the sine of the angular distance.

A. A. Campbell from the radial motions of 280 stars found the velocity to be 20 kilometres per second with a probable error of 14 km per second (Astrophysical Journal. 1901, vol. xiii). This result depends on the northern stars only. By the addition of the data for southern stars, so as to obtain a distribution fairly symmetrical over the whole sphere (S. E. S. A. 1905, vol. iv), he derived 20-8 km per second towards the apex $$\alpha = 18^{\circ} 9^{\prime}, \delta = +26^{\circ}$$.

The speed is very nearly four radii of the earth's orbit per year; thus the annual parallactic motion is equal to four times the parallax, for a star lying in a direction 90° from the solar apex; for stars nearer the apex or antapex it is foreshortened. This result, while it does not afford any means of determining the parallaxes of individual stars, enables us to determine the mean parallax of a group of stars, if we may assume that the stars are distributed more or less uniformly.

In researches on the solar motion the assumption is almost always made that the motions of the stars relatively to one another — i.e. for their proper motions — are at random. The correctness of this hypothesis has long been under suspicion, but it has generally been accepted as the best simple approximation to the actual distribution of the motions that could be made. Naturally exceptional regions may be expected to be adhered to, but the hypothesis is not in general applicable to the Pleiades, whose stars have the same proper motion, must constitute an exception. There can occasionally be traced a certain community of motion over a much larger area. Thus R. A. Proctor found that between Aldebaran and the Pleiades most of the stars have a motion positive in right ascension and negative in declination, a phenomenon which he designated "star-drift." A more precise investigation by L. Boss has shown that there is in this region a phenomenon of vanguard and rear-guard, so that some of them have all have equal and parallel motions; about 40 stars brighter than the seventh magnitude are known to belong to it. The group consists of five stars of Ursa Major together with Sirius. There is already an appendix to the published list of stars of the region, and it may be deduced that the common peculiar motion of all of the Helium type of spectrum, form a similar association. Spectroscopic evidence has indicated that most of the stars of the region are in nearly the same motion (or rather, in this case, absence of motion).

But, whilst recognizing the existence of local drifts and systems, and admitting the possibility of relative motion between the nearer stars, no astronomer of importance has attributed the drifts to any general hypothesis, and the astronomers have seriously doubted the correctness of the hypothesis of random distribution of stellar motions as at least a rough representation of the truth. The hypothesis was put to the test by J. C. Kapteyn, with the result that the apparent motion of the stars towards the southern apex is fairly closely accordant with the facts. His researches indicate that, instead of being haphazard, the proper motions of the star show definite drifts along particular favoured directions, apparently implying that the stars surrounding the one in which they do not constitute a simple system but a dual one. The motion of the stars in the mean towards Canis Major is thus a residual motion, which, when examined more minutely, is found to be due to the intermingling of two great streams of stars moving in very different directions. These two streams or drifts prevail in every part of the sky examined, and contain nearly equal numbers of stars. Kapteyn points out that the numbers of stars varying from the mean are nearly equal in each of the two drifts. The hypothesis of two drifts does not imply that all the stars move in one or other of two directions. The relative motion of each star depends upon its direction to the motion of the drift to which they belong, just as on the older theory the stars have peculiar motions in addition to the solar proper motions. The proper motion of each star is the sum of the two; drift towards the solar apex and the drift towards the other. The results obtained by Kapteyn are in agreement with the facts, and show that the drifts are due to a law which can be calculated. This is found not to agree with the facts at all. The deviation is unmistakable; in general the direction from the solar apex is not the one in which most stars are moving; and, what is even more striking, the directions in which most and fewest stars respectively move, are not by any means opposite to one another. It seems difficult to account for the very remarkable and unsymmetrical distribution of the motions, unless we suppose that the stars form two more or less separate systems superposed; and it has been found possible by assuming two drifts with suitably assigned velocities to account very satisfactorily for the observed peculiar motions.

The phenomenon of two drifts was discovered by an examination of the Bradley proper motions (Brit. Assoc. Rep. 1905, p. 257), and was confirmed by a discussion of the Groombridge proper motions (Mon. Not. R. A. S. 1907, 67, 350). By an examination of the stars of very large proper motion F. W. Dyson has traced the presence of the two drifts in all parts of the sky. The above have been shown as drifts of the two streams; there would be a third drift if the stars with proper motions larger than 9-5, by an examination of the Greenwich-Carrington proper motions; these, however, only cover a region within of 9° of the north pole. Of the behaviour of stars fainter than magnitude 9 there is at present no direct evidence. About 10,000 stars altogether were dealt with in the above-mentioned investigations. The general results indicate that one of the drifts is moving (relatively to the sun) away from a point near Ophiuchus (about R.A. 270°, Dec. +12°) and the other towards the Red Dwarf (R.A. 83°, Dec. +60°). These two points may be called the apices of the two drifts, for they are analogues of the solar apex on the one-drift theory; they are also nearly the same. If the two drifts differ considerably, the one whose apex is in Ophiuchus having about 1½ times the speed of the other. We may conveniently distinguish the two drifts as the slow-moving and fast-moving drifts respectively, since the stars of the slow-moving drift are measured relatively to the sun, this distinction is not physically significant. The stars appear to be nearly equally divided between these two drifts. The magnitudes of the stars are distributed in the same way in each drift. There are also clear differences in the distances of both drifts from us are very approximately the same. Thus we are led to regard the two systems as completely intermingled, and the drifts represent the passage of the stars from one system to the other. Stars of the two systems may be distinguished, for example, by their mutual attraction, and are passing through one another. The drifts are otherwise very different from the stars they otherwise than as produced by two great systems — universes they have been called — which have come together, perhaps, by their mutual attraction, and are passing through one another. The drifts are otherwise very different from the stars their motions otherwise than as produced by two great systems — universes they have been called — which have come together, perhaps, by their mutual attraction, and are passing through one another.
examination of the line-of-sight velocities of stars from the same point of view, this physical interpretation must be received with some degree of caution; but there can be no doubt of the reality of the anomalies in the statistical distribution of proper motions of the stars, and of these it offers a simple and adequate explanation. Having determined the motions of the two drifts, and knowing also that the stars are nearly equally divided between them, it is evidently possible to determine the mean motion of the drifts combined. This is of course that relative motion of the sun and stars which we usually called the solar motion. In the determination of the solar motion calculated in this way agrees satisfactorily with that found by the usual methods. It is naturally fairly close to the aspect of the faster drift, but is displaced from it in the direction of the apex of the other drift. In this connexion it may be noticed that the smaller and larger proper motions are discussed separately, the latter category will include an undue great proportion of stars belonging to the Galactic proper motion, and the distribution will lead to a solar apex too near the apex of that drift, i.e. with too low a declination. This appears to be the explanation of Stumper's and Porter's results; they both divided their proper motions into groups according to their numerical amount, and found that the declination of the solar apex progressively increased as the size of the motions used diminished. Another anomalous determination of the apex, due to H. A. Kohold (Astro. Nach., 3163, 3431, and 3491) is also explained when the two drifts are recognized. Kohold, using a peculiar and ingenious method, found for it a declination -3°, which disagrees very badly with all other determinations; but it agrees exactly with Kohold's method, that the symmetry of motion, which joins the apex and antapex, without indicating which end is the apex. Now the position of this line, as found by Kohold, actually is a (properly weighted) mean between the corresponding lines of symmetry of the two drifts; but, usually it lies in the acute angle between them, whereas the line of the solar motion is also a weighted mean between the two lines of drift, but lies in the obtuse angle between them.

The Structure of the Universe.—We now arrive at the greatest of all the problems of sidereal astronomy, the structure and nature of the universe as a whole. It can by no means be taken for granted that the universe has anything that may properly be called a structure. It is if merely the aggregate of the stars, each star or small group of stars may be a practically independent unit, its birth and development taking place without any relation to the evolution of the whole. But it is becoming more

and more generally recognized that the stars are not unrelated; they are parts of a greater system, and we have to deal with, not merely the history of a number of independent units, but with a universal very general, the evolution and development of an ordered universe.

Our first inquiry is whether the universe extends indefinitely in all directions, or whether there are limits beyond which the stars are not distributed. It is not difficult to obtain at least a partial answer to this question, the evolution and development of an ordered universe.

and more generally recognized that the stars are not unrelated; they are parts of a greater system, and we have to deal with, not merely the history of a number of independent units, but with a universal very general, the evolution and development of an ordered universe.

Our first inquiry is whether the universe extends indefinitely in all directions, or whether there are limits beyond which the stars are not distributed. It is not difficult to obtain at least a partial answer to this question, the evolution and development of an ordered universe.

The Structure of the Universe.—We now arrive at the greatest of all the problems of sidereal astronomy, the structure and nature of the universe as a whole. It can by no means be taken for granted that the universe has anything that may properly be called a structure. It is if merely the aggregate of the stars, each star or small group of stars may be a practically independent unit, its birth and development taking place without any relation to the evolution of the whole. But it is becoming more

793

S being the sun. Imagine this stratum to be uniformly filled with stars (of course in the actual universe instead of sharply defined boundaries AB and CD, we shall have a gradual thinning out of the stratum). The two main directions within which stars will be seen; those are the directions of the galactic poles. As we consider a direction such as SQ farther and farther from the pole the boundary of the universe in that direction becomes more and more remote; stars seen in these directions in the galactic plane, finally in the directions SR and SK′ in the galactic plane, the boundary is perhaps beyond the limits of our telescopes. That the universe must have a boundary in the directions SK and SK′, we can easily show. By analogy with the Earth's days, let us assume that except that in all directions it must be far greater than SP or SP′; in particular it is not known whether the sun is near the centre or not, it is possible that there may be boundary planes. These boundary planes can be tested by comparing the star-densities of the northern and southern galactic hemispheres. These are zone for zone very nearly equal, the slight excess of stars in the southern hemisphere was explained by the fact that the sun is not in its central position. This is confirmed by the fact that the Milky Way is not quite a great circle of the celestial sphere, but has a mean south galactic latitude of about 1°.

4. Instead of considering the whole mass of stars, attention is directed to those of large proper motion, which are therefore in the mean relatively near us, the crowding to the galactic plane is much less. In paragraph 3, a paragraph applies to this case. Thus Type II stars are in general much less intrinsically luminous than Type I, so that the stars known to be of this type must be comparatively near us, for otherwise they would appear too faint to have their spectra detected within the sphere SP (fig.), and consequently are equally numerous in every direction. The Type I stars, being intrinsically brighter, are not so restricted. For example, M. Fekel, in a recent paper, has shown that nearly all the stars down to magnitude 6-5, whose proper motions exceed 5′, are at a distance from the sun less than SP, whilst of the fainter stars with equally great proper motions a large proportion are at a distance greater than SP. This result enables us to form some sort of idea of the distance SP.

On considering the distribution of the stars according to their spectra, it appears that the Type II (solar) stars show no tendency to congregate in the galactic plane. The result of course only applies to the brighter stars, for we have very little knowledge of the spectra of stars fainter than about magnitude 7-5. The explanation indicated is that stars in the solar neighborhood are much less intrinsically luminous than the Type I stars. This result enables us to form a sort of idea of the distance SP.

Whether there is an increasing number of still less luminous stars is a difficult question.

The comparative nearness of the stars of the solar type, which we have had occasion to allude to, is confirmed by the fact that their proper motions are on the average much larger than those of the Sirius stars. Kapteyn finds that magnitude for magnitude, the absolute brightness of the solar stars is only one-fifth of that of the Sirius stars, so that in the mean they must be at less than half the distance. As the numbers of known stars of the two types are nearly equal, it is clear that, at all events in our immediate neighborhood, the solar stars must greatly outnumber the Sirius stars.

REFERENCES.—Of modern semi-popular works entirely devoted to the subject of this year, the year during which the work of Sir William Huggins was published is Simon Newcomb's "The Stars, a Study of the Universe; mention must also be made of Miss A. M. Clarke's "The System of the Stars" (2nd ed., 1908), which contains full references to original papers; Professor A. Sprague's "Physical Astronomy," and Mr. Gomme's "History of Astronomy." The following works of reference and catalogues deals with special branches of the subject: for variable stars, Chandler's "Third Catalogue of Variable Stars," 1919, is now incomplete; "Harrow Annals," vol. iv., pt. 1, and vol. iv., nos. 1-4, together constitute a catalogue of 5734 variable stars; ephemerides of over 6000 variables are given in the Vierteljahrschrift of the Astronomische Gesellschaft. For double stars see Burnham's "General Catalogue" (1907), and Lewis, Memoirs of the R.A.S., vol. iv., the orbits of the principal binaries are discussed in T. J. See, "Evolution of Stellar Systems," and another list will be found in "Lick Observatory Bulletin," No. 41. If not forgotten, it is approximately 200 times the parallax; but to obtain a complete knowledge of the distribution of stars it is necessary to know, not merely the mean distance, but the actual distances of the stars. The proper motions of stars have a quarter, half, twice or three times, &c., the mean parallax. One result of Kapteyn's investigations may be given here. Taking a sphere whose radius is 500 light years (a distance about equal to the diameter of the Milky Way), the mean number of stars in the sphere is 4. The number of stars in the sphere is 4.

The Evolution of Solar Stars," Astrophysical Journal (1903), vol. xvii., may be mentioned as giving a concise survey of the subject.

STARAYA RUSSA, a town of Russia, in the government of Novgorod, 38 m. S. of the city of Novgorod, on the river Polista, by means of which and Lake Ilmen it is brought into connection with St. Petersburg. Pop., 15,234.

Brine springs on the east of the town, are used for the supply of salt as late as 1865; at present they are used only as mineral waters (temperature 51°-54° F.), having a great

The Milky Way. To add to the uniformly distribution of stars between two planes a gigantic cluster of an annular or spiral form, also lying between them, would not only obscure the sun. The Milky Way is not of uniform brightness, so that we may perceive to some parts of it than to others, but it is everywhere very distant from the sun. Estimates of this distance vary, but it may probably be considered three or four light years (parallel less 0-001°). Nevertheless the Milky Way contains a fair proportion of luminous stars, for these are considerably more numerous in the bright patches of the Milky Way than in the riffs and dark spaces.

It has been seen that the distribution as to the distribution of the main bulk of the stars and that the chief evidence on this point must be obtained indirectly from those few particular stars. Our object knowledge of this subject is due to Kapteyn's "Grönenhage's Publications of Luminosity and Distribution of Stars." Nos. 8 and 11, and though much of his work is preliminary, and perhaps liable to considerable revision when more extensive data are obtainable, it probably gives an idea of the construction of the universe sufficiently accurate in all essential respects. As has been explained the mean distance of a group of stars can be readily determined from the parallactic motions of the group, which, when divided into the square of the mean distance times the parallax; but to obtain a complete knowledge of the distribution of stars it is necessary to know, not merely the mean distance, but the actual distances of the stars. The proper motions of stars have a quarter, half, twice or three times, &c., the mean parallax. One result of Kapteyn's investigations may be given here. Taking a sphere whose radius is 500 light years (a distance about equal to the diameter of the Milky Way), the mean number of stars in the sphere is 4. The number of stars in the sphere is 4.

resemblance to those of Kreuznach in Germany. Some thousands of visitors resort to them every summer, and owing to this circumstance Staraya Russa is better built and better kept than any other town in the government of Novgorod. The inhabitants are supported chiefly by the summer visitors. There is a trade in rye, oats and flax shipped to St. Petersburg. The name of Staraya Russa occurs in Russian annals as far back as 1167. It belonged to the republic of Novgorod, and suffered continually in the wars between Russia, Lithuania and Livonia. It was afterwards annexed to Moscow.

Staraya Zagra (Turk. Eski-Zagra), the capital of the department of Bulgaria, or New Russia, was on the southern slope of the Kaban-Dagh, 70 m. N.W. of Adrianople, with which it is connected by railway. Pop. (1900), 26,647. It is surrounded by vineyards, and has also cloth and carpet manufactures, copper founidries and tanneries. The production of silk and attar of roses is carried on in the district, which contains numerous mineral springs. The town having been almost wholly destroyed during the Russo-Turkish War of 1877-78, was rebuilt on a regular plan, with wide and broad streets radiating from a central square, where are situated the principal public buildings. During the rebuilding, important Thracian, Roman, Byzantine and Turkish antiquities were discovered. Under the microscope these granules are seen to consist of a number of minute layers arranged concentrically or excentrically, and the relations of hilum and lumen are the most distinctive features of individual starches (see H. Galt, *Microscopy of the Starches*, 1900). Starch consists of a white or yellowish-white glistening powder. It is only slightly acted on by cold water, but under the influence of heat in water it swells up, forming according to the proportions of starch and water a cloudy opalescent paste. The soluble portion is called granulose, and the insoluble starch-cellulose; from the aqueous solution alcohol precipitates soluble starch from the same acid. Under the microscope producing a brilliant blue coloration, this reaction forming a very delicate and characteristic test. The colour disappears on heating, but is recovered when the mixture is cold. Diastase and dilute boiling sulphuric acid convert starch into a form soluble in hot water, whence it passes into a series of easily soluble dextrins, and finally into the condition of the sugars, dextrose and maltose. Chemically, starch is a carbohydrate with the formula \((C_6H_{10}O_5)_n\), where \(n\) is four or more.

As an economic product starch in its separate condition is a manufacturing plant of enormous substance, the chief pure starches being Arrowroot, Tapioca, Potato (The Corn). In its combined condition, in cereals, &c., starch is a useful nutritive element. In its other industrial relations starch is used: (1) directly, as a thickening medium in calico printing, for the dressing and finishing of many textiles, for laundry purposes, adhesive paste, and powder; and (2) indirectly, for the preparation of dextrin and British gum and starch sugar. Indian corn, wheat and rice starch are principally employed for the direct applications; and for the dextrin and starch-sugar manufacture potato starch is almost exclusively selected.

In the preparation of starch the object of the manufacturer is to burst the vegetable cell walls, to liberate the starch granules, and to remove these from the other components of the potato. Artificial means have been largely resorted to in this end. In the 16th century the word takes the forms *lerbord*, *leerboard* or *lardor*, probably by assimilation to *ster*, *steer*, and *star-board*. There is much doubt as to the origin of the term and the curious change from *larder* to *lardboard*. Skeat (*Etym. Dict.*) suggests that these may be two distinct words. The earlier form is usually connected with "lade," to put cargo on board a vessel, the left side being that on which this was usually done, for the ship when in port would lie with her left side against the quay wall, her entrance pointing to the entrance. If the later form is not due to mere assimilation to starboard, it may contain a word meaning empty (O. Eng. *geldr*, Ger. leer), and refer to that side of the vessel where the steerman does not stand Owing to the similarity in sound between starboard and lardboard, the word port is now used for the left side. The substitution of this for the older term was officially ordered in the British navy by an admiral order of 1844, and in the United States of America by a navy department notice in 1896. The use of port in this sense is much older; it occurs in Manwaring's *Seaman's Dictionary* (1625-1641). In this usage port may either mean "harbour" (Lat. *portus*), the ship lying with its left side against the port or quay for unloading, or "opening," (Lat. *puella*, gate), for the cargo to be taken on board; cf. "porthole."
difficulty, owing to the presence of gluten, which with water forms a tough elastic body difficult of solution and removal. The difficulty is experienced in greatest measure in dealing with wheat, which contains a large proportion of gluten. Wheat starch is obtained by grinding wheat in water with which has been mixed, which is the original process, and (2) by mechanical means without preliminary fermentation. In the fermentation process whole wheat or wheat bran is softened by washing in water. When the wheat is in this condition, ground, and the pulp, mixed to a thickish fluid with water, is placed in tanks, where it ferments, developing acids which dissolve the gummy constituents of the meal or bran, and softens the gluten to a comparatively pure, the other mixed with gluten and some bran-particles. These layers are separated, the second undergoing further washing to remove the gluten, &c., and the remaining operations are analogous to those employed in the preparation of potato-starch. By the mechanical process wheat bran is kneaded into a stiff paste, which, after resting for an hour or two, is washed over a fine sieve so long as the water passing off contains milky, whereby the starch is liberated and the greater part of the gluten retained as a gummy elastic mass in the sieve. The starch is subsequently purified by fermentation, washing and treatment in centrifugal machines. It can be used in its natural condition as a valuable foodstuff for diabetics, and is made with flour into artificial macaroni and pastes, Besides being valuable for other industrial purposes. The fermentation process yields about 59 lb. of starch and 11 lb. bran from 100 lb. of wheat, while the mechanical process gives about 55 lb. of starch and 12 lb. of gluten.

Maize (Indian corn) starch is obtained by analogous processes, but the grain nature in the process is smaller, indescribable in its nature, the operations, whether chemical or mechanical, present fewer difficulties. Under one method the separation of maize starch is facilitated by steeping, swelling and softening the grain in a weak solution of caustic soda, and favourable results are also obtained by a process in which the pulp from the crushing mill is treated with water acidulated with sulphuric acid.

In the preparation of rice-starch a weak solution of caustic soda is also employed for softening and swelling the grain. It is then washed with pure water, dried, ground and sifted, and again treated with alkaline water, by which the whole of the nitrogenous constituents are washed away in solution. An acid process for obtaining rice-starch is also employed, under which the grain, swollen and ground, is treated repeatedly with a solution of hydrochloric acid, which also dissolves away the non-starchy constituents of the grain. The yield is about 85 lb. per 100 lb. of rice. Laundry starches are principally made from rice and from pulse.

See O. Saare, Die Fabrikation der Kartoffelstärke (1897).

**STAR CHAMBER**

The name given in the 15th, 16th and 17th centuries to an English court of justice. The name is probably derived from the stars with which the roof of the chamber was painted; it was the *camera stellata*. But it has also been derived from a Hebrew word *shater* or *shitar*, a bond, on the supposition that the chamber of meeting was the room in which the legal documents connected with the Jews were kept prior to their expulsion from England by Edward I.

The origin and early history of the court are somewhat obscure. The curia regis of the 12th century, combining judicial, deliberative and administrative functions, had thrown off several offshoots in the court of king's bench and other courts, but the Crown never parted with its supreme jurisdiction. When in the 13th century the king's council became a regular and permanent body, practically distinct from parliament, this supreme jurisdiction continued to be exercised by the king in council. As the ordinary courts of law became more important and more systematic, the indefinite character of the council's jurisdiction gave rise to frequent complaints, and efforts, for the most part fruitless, were made by the parliaments of the 14th century to check it. The equitable jurisdiction of the chancellor, which grew up during the reign of Edward III., like the courts of law under Henry II., was derived from this supreme judicial power, which was thus supplemented.

It is in the reign of Edward III., after an act of 1341, that we first hear of the chancellor, treasurer, justices and other members of the king's council exercising jurisdiction in the old chamber, or *chambre de estoiles*, at Westminster. In Henry VI.'s reign one Danvers was acquainted of a certain charge by the council in the *camera stellata*. Hitherto such acts of parliament as had recognized this jurisdiction had done so only by way of limitation or prohibition, but in 1455 about the time when the distinction between the ordinary and the privy council first became apparent, an act was passed empowering the chancellor to enforce the attendance of all persons summoned by the privy seal before the king and his council in all cases not determinable by common law. At this time, then, the jurisdiction of the council was recognized as supplementary to that of the ordinary courts of law. But the anarchy of the Wars of the Roses and the decay of local justice, owing to the influence of the great barons and the turbulence of all classes, obliged parliament to entrust wider powers to the council. This was the object of the famous *Act of Bulletin* (1453), generally quoted by the lawyers of the long parliament as creating the court of star chamber, which was in reality of earlier origin.

The act of 1487 (3 Hen. VII) created a court composed of seven persons, the chancellor, the treasurer, the keeper of the privy seal, or any of them, with a bishop, a temporal lord and the two chief justices, or in their absence two other justices. It was to deal with cases of "unlawful maintenance, giving of licences, signs and tokens, great riots, unlawful assemblies;" in short with all offences against the law which were too serious to be dealt with by the ordinary courts. The jurisdiction thus entrusted to this court was, besides the extraordinary, a extraordinary jurisdiction which the court had never ceased to possess. By an act of 1529 an eighth member, the president of the council, was added to the star chamber, the jurisdiction of which was at the same time confirmed. At this time the court performed a very necessary and valuable work in punishing powerful offenders who could not be reached by the ordinary courts. It was found very useful by Cardinal Wolsey, and a little later Sir Thomas Smith says its object was "to bridge such stout noblemen or gentlemen who would offer wrong by force to any manner of men, and cannot be content to demand the right by order of the law."

It is popularly supposed that the star chamber, after an existence of about fifty years, disappeared towards the end of the reign of Henry VIII., the powers obtained by the act of 1487 being not lost, but reverting to the council as a whole. This may have been so, but it is more probable that the star chamber did not exist at all, but was supplanted by a court whose powers were very similar to those of the old council with certain exceptions. In the reign of Edward VI. it was made clear that the court was in fact independent of the council, and the two bodies were certainly separate during the latter part of Elizabeth's reign. The act of 1540, which gave the king's proclamation the force of law, enacted that offenders against them were to be punished by the usual officers of the council, together with some bishops and judges "in the star chamber or elsewhere." It is difficult, if not impossible, to draw a clear distinction between the duties of the privy council and the duties of the star chamber at this time, although before the abolition of the latter there was a distinction "as to their composition and as to the matters dealt with by the two courts."

During the reign of Elizabeth Sir Thomas Smith remarks that juries misbehaving "were many times commanded to appear in the star chamber, or before the privy council for the matter." The uncertain composition of the court is well shown by Sir Edward Coke, who says that the star chamber is or may be compounded of three several councils: (1) the lords and others of the privy council; (2) the judges of either bench and the barons of the exchequer; (3) the lords of parliament, who are not, however, standing judges of the court. William Hudson (d. 1639), on the other hand, considers that all peers had the right of sitting in the court, but if so they had certainly given up the privilege in the 17th century.

The jurisdiction of the star chamber was as vague as its constitution. Hudson says it is impossible to define it without offending the supporters of the prerogative by a limitation of its powers, or the lawyers by attributing to it an excessive latitude. In practice its jurisdiction was almost unlimited.
STARFISH

It took notice of riots, murder, forgery, felony, perjury, fraud, libel and slander, duels and acts tending to treason, as well as of civil matters, such as disputes about land between great men and corporations, disputes between English and foreign merchants, and testamentary cases; in fact, as Hudson says, "all offences may be here examined and punished if the king will." Its procedure was not according to the common law. It dispensed with the encumbrance of a jury; it could proceed on rumour alone; it could apply torture; it could inflict any penalty but death. It was thus admirably calculated to be the support of order against anarchy, or of despotism against individual and national liberty. During the Tudor period it appeared in the former light, under the Stuarts in the latter. Under the Tudors, as S. R. Gardiner says, "we constantly resorted to as a resource against the ignorance or prejudices of a country jury," and adds that "in such investigations it showed itself intelligent and impartial." Under James I. and Charles I., all this was changed; the star chamber became the great engine of the royal tyranny. Hateful and excessive punishments were inflicted on those brought before the court, notable among whom were Prynne, Bastwick and Burton, and the odium which it gathered around it was one of the causes which led to the popular discontent against Charles I. As it became more unpopular, its jurisdiction was still further expanded. An example of this kind occurred in 1629, but the barons of the exchequer who heard the case declared that the star chamber was created many years before the statute of Henry VII. and that it was "one of the most high and honourable courts of justice." It was abolished by an act of parliament of July 1641. In 1661 a committee of the House of Lords reported "that it was fit for the good of the nation that there be a court of like nature to the star chamber;" but nothing further was done in the matter.

For the history of the star chamber see Sir Thomas Smith, Commonwealth of England (1633); Lord Bacon, History of Henry VII., edited by J. R. Lumby (Cambridge, 1881); William Hudson, "Treatise of the Court of Star Chamber," in vol. ii. of Collectanea Juridica; W. S. Holdsworth, History of English Law (vol. 1002); G. W. Prothero, Statutes and Constitutional Documents 1359-1662 (1894); W. Busch, England under the Tudors (1895); S. R. Gardiner, History of England 1603-1642 (1883-1884); D. J. Medley, English Constitutional History (1907); and A. V. Dicey, The Privy Council. The pleadings in the star chamber are in the Record Office, London; the decrees appear to have been lost.

STARFISH, a popular term under which are included a large number of sea-animals, belonging all to the class of Echino-
derms, but to three distinct divisions of that group: the Asterids, the Ophiurids and the Crinoids (see ECHINO-
DERMA). The Asterids or starfish proper include the cross-fish, the sun-star (see ECHINODERMA, fig. 47), the cushion-star, the butt-
horn, and many without a popular name. The common cross-fish or five-finger, Asterias rubens, of British seas, may be taken as typical (figs. 1 and 2), and the description will apply also to the American species A. fin Ari a and A. vulgarius. The animal consists of a central body or disk, produced into five arms or rays. The upper surface is covered with a leathery skin, strengthened by a rafter-work of little bones or plates, made of crystalline carbonate of lime, many of them bearing prickles of the same substance and small pincer-like bodies—the pedicellariae (see SEA-URCHIN).

The middle of the body is a small anal opening, and near the angle between two rays is a roughened plate placed by many minute pores and radiating from it in the manner of a scaphie. The under surface of the body has the mouth in the centre, and from it deep grooves radiate to the ends of the arms. At the bottom of each groove is a water-vessel, which gives off branches to the podia or sucking-feet on each side. A section across this groove is given in the article ECHINODERMA, fig. 12 B. The arrangement and working of this hydraulic system is essentially the same as A. End of a podium, magnified. in the sea-urchin, except for the presence of plates at the bottom of the groove beneath the mouth, and the absence of any plates covering the groove. At the end of each ray is, as in the urchin, a single tentacle surrounded by pigment and connected with a definite plate called "terminal." Thus the terminals of a starfish correspond to the oculi of a sea-urchin (see ECHINODERMA, fig. 3). The stomach is not a long coil, but a simple sac with branched blind tubes extending into each ray. A generative gland also passes down the side of each ray, and emits the milt or eggs when ripe through a pore near the body. Spawning takes place in spring or early summer. A starfish can crawl in any direction by means of its sucking-feet, whether the surface be hard or soft, and after it has been washed, one of its suckers may be as soft as a feather, whilst its suckers can squeeze through incredibly narrow crevices. The rate of progress is about six inches a minute.

The starfish are the scavengers of the sea, but unfortunately do notconfine their attentions to decaying matter; they eat oysters, clams, mussels, barnacles, sea-snails, worms, crustacea and even smaller starfish. There is constant war between oyster-fishers and starfish; no less than 42,000 bushels of starfish were removed from the oyster-beds of Connecticut in a single year, but not till they had worked damage to the amount of $631,500. The simplest way in which a starfish eats is by taking small bits of food into the mouth and ejecting the refuse again through the mouth. But since the mouth is quite small and the food often large, the starfish finds it more convenient to turn its stomach inside out and to wrap it round the animal to be eaten, which is then digested quietly and the nutrition which is absorbed. In the case of oysters and similar bivalves, the starfish first has to open them; and this it does by fixing the suckers of one or two rays to one valve and those of the other to the other valve, while it may get a purchase by also holding on to some neighbouring object. It then begins to straighten out its rays. The oyster can withstand a very strong pull, but it cannot hold out against a long pull, and the starfish does not hurry. At last the oyster gives way, and the starfish has its reward; but its companions often join in, and you may see a whole ball of them interfaced round half-digested molluscs and rolling about. Starfish begin to eat voraciously when quite young; one less than 1½ in. has been observed to eat over fifty young clams of half that length in six days. The more a starfish has to eat the quicker it grows, and it may become sexually mature in less than a year, then producing many thousands of young. Fortunately the increase is kept in check by many causes. The young, while still in the stage of free-swimming larvae, are swallowed in millions by various fish. When they settle down on seaweed bright colours attract eels and many small fishes. Later in life they are attacked by parasites, while those which stay into shallow water are eaten by gulls and crows. Freshets and cold currents are also destructive. Probably the best way in which man can keep down the numbers of starfish is by dredging the seaweed in the latter half of July, when it is covered with young; a single card to land on shore with more than a few bushels. At a later stage tangles of hemp or cotton waste may be dragged over the oyster-beds, when the starfish will cling to them by their pedicellariae. They make excellent manure, but are of no further service to man. Fishermen who catch them in their nets or on their lines often tear them in half and throw them back into the sea. Some of these mutilated

Fig. 1.—An Asteroid, Asterias rubens, upper surface.

a. Madreporite.
b. The same magnified.
c. Arms.

This starfish may be 9-12 in. across. A. vulgarius. The animal consists of a central body or disk, produced into five arms or rays. The upper surface is covered with a leathery skin, strengthened by a rafter-work of little bones or plates, made of crystalline carbonate of lime, many of them bearing prickles of the same substance and small pincer-like bodies—the pedicellariae (see SEA-URCHIN). The
animals may, however, grow fresh rays, and thus one may find a starfish consisting of one large ray and four quite small ones, the whole shaped like a comet.

The Ophiurids (the name means "snake-tails") include the brittle-stars, sand-stars, and basket-fish or medusa-heads.

The two former, which may often be found hiding under the rocks, or in the seaweed, or in pools at low tide, resemble the ordinary starfish in having five distinct arms. These, however, as shown in fig. 3, are long and serpent-like, and are attached to a relatively small body or disk. The digestive and generative systems do not extend to the rays but are confined to the body. The arms are cylindrical and have no groove on the underside such as exists in starfish; but the water-vessel traverses the solid bones that form the axis of the arm, and the podia pass out through special openings (see Echinoderm, fig. 18).

In Ophiurids it is the arms that are used for locomotion and not the podia, so that the latter have no terminal suckers. The axial ossicles, which correspond to the plates flooring the arm-groove in a starfish, resemble vertebrae connected by pairs of straight muscular bundles, and articulated by tenon-and-mortise joints, according to whose degree of development the arms vary in their power of coil- ing. These vertebrae are encased in the tough outer skin of the arm, in which are developed plates. Spines borne by these plates aid the animal in locomotion. The skin of the disk also bears small plates, which are often covered with prickles. The mouth is on the under surface of the disk, and round it are a number of short, flat processes, the mouth-papillae, which serve as strainers. Inside the mouth are seen the five tooth-plates, borne on a strong framework of complicated structure. In the sand-stars the rays are comparatively short, with their spines closely pressed to their sides, so that they look like lizards' tails; in the brittle-stars the rays are much longer and more flexible, with the spines standing out, so that they look like wriggling centipedes attached round a little sea-urchin. The brittle-stars are more active than the sand-stars, and can go more than two yards in a minute; some of them, if seized, break off their arms, which continue breaking into smaller pieces; but the body can soon grow new ones. Sand-stars and brittle-stars are found in all seas, usually occurring in quantities, but are most abundant in the rock-pools of the tropics. By constantly sweeping their arms over the sea bottom, they gather food consisting of minute animals. They eat the baits of fishermen, and their fish as well if they find any already dead, but they are themselves a favourite food with many fish, notably the cod.

The basket-fish or medusa-heads are Ophiurids whose arms branch several times, their ends often curling and interlacing. They live in deeper water and are often brought up clinging to fishermen's lines.

The feather-stars (fig. 4) have a central body and five arms, eachforking at least once and fringed with small branches (pinnules) which give the feathery appearance. The mouth is in the middle of the body, and from it grooves pass along the arms and all their branches. The animal lives with the mouth upwards, and although it can crawl and even swim by movement of its arms, it generally fixes itself to a stone or seaweed or some zoophyte, by means of a bunch of small jointed and hooked processes (cirri) growing from the back or under side of the body. It gets its food in this way: the arm-grooves (Echinoderm, fig. 12, C) are lined with minute hairs (cilias) always waving in the direction of the mouth, towards which they drive a stream of water; this stream, containing minute organisms, constantly flows through the coiled gut, which extracts nourishment from it. The feather-stars were formerly placed with the starfish, but they really belong to another class of Echinoderms—the Crinoidae.

In 1823 J. V. Thompson, of Cork, discovered that the feather-star when quite young was fixed by a stalk, just as are nearly all crinoids (see Echinoderm, figs. 1 and 2). The stalked crinoids are not so numerous as they once were, but feather-stars belonging to about half a dozen genera (Antedon, Actinomeira, &c.) are found in all seas at all depths, often in enormous numbers.

STARGARD, a town of Germany, in the Prussian province of Pomerania, situated on the left bank of the navigable Ihna, 20 m. E. of Stettin on the railway to Danzig and at the junction of lines to Posen, Schneidemühl and Cœtlin. Pop. (1893), 26,908. Formerly a member of the Hanseatic League, the town retains memorials of its early importance in the large church of St Mary, built in the 14th century, the 16th-century townhall, and some gateways and towers dating from the 14th century. The walls which formerly surrounded it have been mostly converted into promenades. Extensive new law-courts and three large barracks are among the modern buildings. Stargard has a considerable market for cattle and horses, and carries on trade in grain, spirits and raw produce. Its manufactures include cigars, tobacco, wriggling and stockings; and there are also iron-foundries, and linen and woollen factories in the town.

Stargard, mentioned as having been destroyed by the Poles in 1120, received civic rights in 1229, and became the capital of eastern Pomerania. As a Hanseatic town it enjoyed considerable commercial prosperity, but it had also to undergo siege and capture in the middle ages and during the Thirty Years' War. In 1607 it was taken by Schill. The name Stargard (from the Slavonic Starogad or Starigrod, meaning "old town") is common to several other towns in the north of Germany, of which the chief are Preussisch-Stargard, near Danzig, and Stargard an der Lüne in Mecklenburg-Strelitz.

See Zuck, Führer durch Stargard (Stargard, 1900).

STARK, JAMES (1794-1859), British painter, was born in Norwich, and as he showed strong artistic inclinations early in life was, at the age of seventeen, articled to John Crome for three years. He was elected in 1812 a member of the Norwich Society, to the exhibitions of which he had already contributed; but in 1817 he migrated to London and entered the Royal Academy Schools. He soon returned to Norwich and did not finally settle in the metropolis until 1830, though he was meanwhile a regular contributor to the British Institution and Suffolk Street Galleries. In 1834 he moved to Windsor, but after an interval of some years went back to London, where he died in 1859. Between 1831 and 1850 most of his pictures were shown at the Royal Academy, though he still continued to exhibit occasionally in other galleries. He undertook in 1827 the publication of a work on The Scenery of the Rivers of Norfolk, which was completed seven years later; the illustrations he
preparing for it have much topographical and artistic interest and show well the better qualities of his work. In his pictures the influence of Crome is plainly perceptible, and there is evidence also of his study of the Dutch landscape-painters; but he had little of Crome's largeness and power and his works charm rather by their gentle truth and quietness of manner than by their robustness of view or by their decisiveness of execution. There is one picture by him, "The Valley of the Yare," in the National Gallery of British Art.

STARK, JOHN (1728–1822), American soldier, was born at Nutfield, now Londonderry, New Hampshire, on the 28th of August 1728. He was conscripted by the government, but was ransomed by Massachusetts. During the Seven Years' War he served under Robert Rogers, first as a lieutenant and later as a captain, taking part in the battle of Lake George in 1755, the disastrous attack upon Ticonderoga in 1758, and the Ticonderoga-Crown Point campaign in 1759. At the beginning of the War of Independence he raised a regiment and as colonel did good service in the Battle of Bunker Hill, in the Canadian expedition, and in Washington's New Jersey campaign in the winter of 1776–77. In March 1777 he resigned his commission because other officers had been promoted over him, and in November he was placed in command (by New Hampshire), with the rank of brigadier-general of militia, of a force of militiamen, with whom, on the 16th of August, near Bennington (q.v.), Vermont, he defeated two detachments of Burgoyne's army under Colonel Friedrich Baum and Colonel Breyman. For this victory, which did much to bring about the capitulation of General Burgoyne, Stark received the thanks of Congress and a commission as brigadier-general in the Continental Army (Oct. 4, 1777). He took part in the operations about Saratoga, and for a short time in 1778 and again in 1781 he was connected with the northern department. In September 1783 he was brevetted major-general. He died at Manchester, New Hampshire, on the 8th of May 1822. John Stark's brother, William (1724–1776), served in the Seven Years' War and afterwards on the frontier; and at the outbreak of the War of Independence, piqued because he was not put in command of a regiment, he entered the British service.

See Memoir and Official Correspondence of General John Stark (Concord, N.H., 1860) by his grandson Caleb Stark (1803–1868), who wrote in 1831 Reminiscences of the French War containing Rogers' Expeditions with the New England Rangers and an Account of "John Stark's" Escape.

STARLEY, JAMES (1830–1881), British inventor, the son of a farmer, was baptized at Albourne, Sussex, on the 13th of June 1830. At eighteen he ran away from home and started on foot for London, but on the way obtained work as a gardener at Lewisham, Kent, where he lived for a number of years. He had always been an ingenious mechanic, inventing trifling novelties and repairing watches and clocks in the neighbourhood, and when sewing machines began to be much used they attracted his practical attention, and aroused his inventive genius. Leaving his garden he went up to London and became machine-maker for a firm of sewing-machine manufacturers. In his element, and in several particulars improved his principal's machines, and invented a new one with an arm attachment that permitted circular as well as straightforward work. With a fellow workman he moved in 1857 to Coventry, and started the manufacture of the "European" and other sewing machines from his patents. This was the beginning of the Coventry Machinists' Company, the pioneer of all the great bicycle and tricycle works which afterwards made that city the centre of the industry. Former acquaintances of Starley at Lewisham and elsewhere emigrated to Coventry to become skilled mechanics for this company. In 1868 they began the manufacture, after a Paris model and at first for French use, of bicycles, several of the earliest suggested improvements being Starley's. A number of firms were soon devoting themselves exclusively to the manufacture of bicycles, and for one of these Starley—whose financial successes were always for others—designed the Coventry tricycle. As it was harder to propel than the bicycle he invented the balance gear, and applied it in the Salvo, which is the type of the present tricycle (q.v.). Starley died on the 17th of June 1881, and a public monument has been erected to his memory in Coventry. His nephew, J. K. Starley, patented the tangent wheel in 1874.

STARKY (O. Eng. stër stearn, and stelryng; Lat. sturnus, Fr. étourneau), a well-known bird about the size of a thrush, though at a distance it appears to be black, when near at hand its plumage is seen to be brightly shot with purple, green and steel-blue, most of the feathers when freshly grown being tipped with buff. These markings wear off in the course of the winter, and in the breeding season the bird is almost spotless. It is the European Starling, Sturnus vulgaris, a songster and mimicker.

A full description of the habits of the starling is unnecessary in this place. A more engaging bird scarcely exists, for its familiarity during some months of the year gives opportunities for observing its ways that few others afford, while its varied song, its sprightly gestures, its glossy plumage, and, above all, its character as an insecticide—which last makes it the friend of the agriculturist and the grazier—renders it an almost universal favourite. The worst that can be said of it is that it occasionally pillers fruit, and, as it flocks to roost in autumn and winter among reed-beds, does considerable damage by breaking down the reeds, its deprivations of starlings are indeed very great, and no less than the aerial evolutions of the flocks, chiefly before settling for the night, have attracted attention from early times, being mentioned by Pliny (Hist. naturalis, x. 24) in the 1st century. The extraordinary precision with which the crowd, often numbering several hundreds, not to say thousands, of birds, wheels, circles, opens out, rises and descends, as if the whole body were a single living thing—all these movements being executed without a note or cry being uttered—must be seen to be appreciated, and may be seen repeatedly with pleasure. For a resident the starling is rather a late breeder. The nest is commonly placed in the hole of a tree or of a building, and its preparation is the work of some little time. The eggs, from 4 to 7 in number, are of a very pale blue, often tinged with green. As the young grow they become very noisy, and their parents, in their assiduous attendance, hardly less so, thus occasionally making themselves disagreeable in a quiet neighbourhood. The starling has a wide range over Europe and Asia, reaching India; but examples from Kashmir, Persia and Armenia have been considered worthy of specific distinction, and the resident starling of the countries bordering the Mediterranean is generally regarded as a good species, and called S. unicolor from its unsplotched plumage.

Of the many forms allied to the genus Sturnus, some of which have perhaps been needlessly separated therefrom, those known as Grackle (q.v.), are separately dealt with, and here we shall only notice one other, Pastor, containing a beautiful species P. roseus, the Rose-coloured Starling, which is not an unfrequent visitor to the British Islands. It is a bird of most irregular and erratic habits—a vast horde suddenly arriving at some place to which it may have hitherto been a stranger, and at once making a settlement there, leaving it wholly deserted as soon as the young are reared. This happened in the summer of 1875 at Villafranca, in the province of Verona, the castle of which was occupied in a single day by some 12,000 or 14,000 birds of this species, as has been graphically told by Sig. de Betta (Atti del r. ist. veneto, 5th series, vol. ii.); but similar instances have been before recorded—as in Bulgaria in 1867, near Smyrna in 1856, and near Odessa in 1844, to mention only some of which particulars have been published."
STARNSBERG, a village and climatic health resort of Germany, in the kingdom of Bavaria, on the Starnerberger See, 16 m. by rail S. from Munich. Pop. (1905), 3257. It has an evangelical and a Roman Catholic church, an old castle (now government offices) and a bathing establishment. The Starnerberger See (or Würmsee) is a lake with a length of 12 m., a breadth of 3 m., and covering 23 sq. m. Its greatest depth is about 400 ft. The lake is girded by hills, studded with attractive villa residences, commanding beautiful and extensive views of the Alps. On the Rosenstein, an island in the lake, remains of lacustrine dwellings have been discovered. The waters abound in fish. In the summer steamboats ply, touching at all the villages lying on the shores.

See Ue, Der Würmsee in Oberbayern (Leipzig, 1901).

STAR-NODE MOLE (Condylura cristata), a North American species, the single representative of its genus. In burrowing habits it resembles the European mole, but is distinguished from all other members of the family Talpidae by the presence of a ring of tentacles round the nostrils, probably serving as organs of touch.

STARODUB, a town of Russia, in the government of Chernigov, 98 m. N.E. of the city of Chernigov. It is regularly built, with broad straight streets, and the houses are surrounded by large gardens. Pop. 22,457; Little Russians with about 5000 Jews. Tanning and the manufacture of copper wares are carried on, and there is a trade in corn and hemp exported to Riga and St Petersburg. As early as the 11th and 12th centuries Starodub was a bone of contention between different Russian princes, who appreciated its strategic position. The Mongols seem to have destroyed it in the middle of the 13th century, and its name does not reappear until the following century. During the 15th and 16th centuries the Russians and Lithuanians were continually disputing the possession of its fortress, and at the beginning of the 17th century it became a stronghold of Poland.

STARVATION, the state of being deprived of the essentials of nutrition, particularly of food, the suffering of the extremities of hunger and also of cold (see HUNGER AND THIRST). The work is an invented hybrid, attributed, according to the accepted story, to Henry Dunias, 1st Viscount Melville, who used it in a parliamentary debate on American matters in 1775 and gained thereby the nickname of "Starvation Dunias" (see H. Walpole’s Letters, ed. Cunningham, viii. 30; and Notes and Queries, 225). The English word “to starve” meant originally “to die,” as in O. Eng. stierfan, Du. sterven, Ger. sterben, but was particularly applied to death from hunger or cold.

STAS, JEAN SERVAIS (1813-1891), Belgian chemist, was born at Louvain on the 1st of August 1813. He studied for a medical career and took his doctor’s degree, but soon turned to chemistry. In 1832 after much trouble he gained admission to J. B. A. Dumas’s laboratory in Paris in order to continue a research on phloridzin which he had begun in an attic in his father’s house, and he was associated with that chemist in several researches, including his redetermination of the atomic weight of carbon. In 1840 he left Paris on his appointment to the chair of chemistry at the École Royale Militaire in Brussels. There he remained for more than a quarter of a century, but before he had served the thirty years necessary to secure a pension he was obliged to resign through ill-health which affected his speech. He was then appointed to a post in connexion with the Mint, but gave it up in 1872, and spent the rest of his life in retirement in Brussels, where he died on the 10th of December 1891. Stas’s name is best known for his determination of the atomic weights of a number of the more important elements. His work in this field was marked by extreme care, and he adopted the most minute precautions to avoid error, with such success that the greatest variation between his numerous individual determinations for each element was represented by 0.005 to 0.01. Though he started with a predilection in favour of Prout’s hypothesis he was later led by the results he obtained and by his failure to find any evidence of dissociation in the elements to regard it as a pure illusion and to look upon the unity of matter as merely an attractive speculation unsupported by proof. Nevertheless, a few years before his death, a proposal of the close approximation to integers presented by a number of the atomic weights of the elements when hydrogen is taken as unity, he remarked, “Il faut croire qu’il y a quelque chose là-dessous.” In connexion with the poisoning of Count Hippolyte de Bocarmé with nicotine in 1850 Stas worked out a method for the detection of the vegetable alkaloids, which, modified by Friedrich Julius Otto (1809-1870), professor of chemistry at Brunswick, has been widely used by toxicologists as the Stas-Otto process.

STASINUS, of Cyprus, according to some ancient authorities the author of the Cypria (in 11 books), one of the poems belonging to the epic cycle. Others ascribed it to Hesegias (or Hegesinus) of Salamis or even to Homer himself, who was said to have written it on the occasion of his daughter’s marriage to Stasinus. It is composed of 12 books and presents the adventures of Ulysses with the events of the Homerian poem, confined itself to what preceded Iliad, and thus formed a kind of introduction to the Iliad. It contained an account of the judgment of Paris, the rape of Helen, the abandonment of Philoctetes on the island of Lemnos, the landing of the Achaeans on the coast of Asia, and the first engagement before Troy. It is probable that the list of the Trojans and their allies (Iliad, ii. 816-876), which formed an appendix to the catalogue of the Greek ships, is abridged from that in the Cypria, which was known to contain a list of the Trojan allies. Proclus, in his Chrestomathia, gave an outline of the poem (preserved in Photius, cod. 193).

STASSFURT, a town of Germany, in the Russian province of Saxony, and one of the chief seats of the German salt-producing industry, situated on both sides of the Bode, 20 m. S.W. of Magdeburg by the railway to Aschersleben. Pop. (1905), 18,310. It is still surrounded in part by the ruins of its ancient walls, but, with the exception of the parish church of St John (12th century), there are no buildings worthy of special notice. Although saline springs are mentioned here as early as the 13th century, the first attempt to bore for salt was not made until 1830, while the systematic exploitation of the salt-beds, to which the town is indebted for its prosperity, dates only from 1836. The shafts reached deposits of salt at a depth of 350 ft., but the finer and purer layers lie more than 1100 ft. below the surface. Besides the rock-salt, which is excavated by blasting, the saline deposits of Stassfurt yield a considerable quantity of deliquescent salts and other saline products, which have encouraged the foundation of numerous chemical factories in the town and in the neighbouring village of Leopoldshall, which lies in Anhalt territory. The rock-salt works are mainly government property, while the chemical factories are in private hands.

See Precht, Salzindustrie von Stassfurt und Umgebung (Stassfurt, 1891); and Westphal, Geschichte des königlichen Salzwerks zu Stassfurt (Berlin, 1901).

STATE. As currently employed in that department of political science which concerns itself, not with the relations of separate political entities, but with the political composition of society as a whole, the word state expresses the abstract idea of government in general, or the governing authority as opposed to the governed, and is thus used by Herbert Spencer in all his discussions of government and society. Louis XIV.’s “l’état, c’est moi,” Rousseau’s theory of the “contrat social,” Bastiat’s “donna à l’état le strict nécessaire et garde le reste pour toi,” all imply this opposition. Hobbes regards the state, or, as he calls it, the commonwealth, as “one person for whose acts a great multitude by
mutual covenants, one with another, have made themselves every one the author, to the end he may use the means and strength of them all as he shall think expedient for their peace and common defence.”

The term is also used to distinguish the civil from the ecclesiastical authority in countries where they are or have been in conflict. A large number of definitions and classifications, according to political structure, international status, national homogeneity, etc., have been attempted, but it is beyond the scope of a short article to do more than mention these different senses of a word so variously employed.

In international law the term has a more precise meaning, according to which the state is the external personality or outward agency of an independent community. In its fullest form its attributes are: (a) possession of sovereign power to pledge the community in its relations with other similarly sovereign communities, (b) independence of all external control, and (c) dominion over a determinate territory. In practice, however, there are still incomplete forms of natural rights which can be recognized. The life of states, paramount states whose relations to subordinate parts of their empire are in a condition of uncertainty, and there is, at any rate, one body carrying on international state intercourse without dominion over any territory at all. Thus, Great Britain, has diplomatic relations, purely formal though they may be, with several of the subordinate states forming the German Empire. Egypt, while legally under the suzerainty of the Porte, is practically a British protectorate. Great Britain treats Cyprus as a dependency, though she is in more or less the position of the United States in respect of the placing of a settlement upon the Cypriots as an independent state. In the case of the Austro-Hungarian Empire, the consideration of Bosnia and Herzegovina “without affecting the rights of sovereignty of his majesty the Sultan on those provinces,” though Bulgaria, by the Treaty of Berlin, was an “autonomous and tributary principality under the suzerainty of his imperial majesty the Sultan,” Turkey did not consider her suzerainty to involve her in the war of 1885 between her vassals and Servia. The Roman Catholic Church has permanent diplomatic relations as an independent state, though it has no independent territory against which international rights can be enforced. Life in the Boer War the army of an annexed community wandering from place to place recognized as a belligerent with whom Great Britain negotiated as an independent state.

A new and somewhat shadowy form of suzerainty is growing up in the "paramouncty" first enunciated (with the concurrence of Great Britain) by the President of the United States in 1823 (see Monroe Doctrine), asserted with a certain measure of success against Great Britain in 1836 (see Venezuela, also Arbitration), and proclaimed formally by the United States at the Hague peace conference in 1899 as a condition of her signature of the Peace Convention. While the Spanish republics of Central and South America are recognized in international law as sovereign states, they can only be said to fulfil the conditions of absolute independence subject to the limitations which the Monroe Doctrine has placed upon their treaty-making powers with Europe.

1 Great Britain, in acceding to the arbitration imposed by President Cleveland, has, in the opinion of a number of American and Continental publicists, recognized the Monroe Doctrine. See Chretien, Princes; De Beaumarquis, La Doctrine de Monroe: De Bustamente, Le Canal de Panama et le droit international; De Plancy, "La Doctrine de Monroe et le conflit Anglo-americain," Revue de droit international; Ridgway, W. L. Scraggs, Sibley and G. F. Tucker, and the Annales de jurisprudence (Colombia), June 1897 and following numbers. M. F. Bahr, however, in the International Review of Lyons, and formerly professor of the University of Lima, observes that "En declarant que la grande republique americaine considere comme dangereuse pour sa tranquillite et sa securite toute tentative de domination des puissances europeenes d'etendre leur systeme de politique a une partie quelconque du continent americain, il (le president) s'est meme indirectement des affaires intérieures des republiques du Nouveau Monde, autres que les Etats Unis; il a fait "In constitutional law, the state," says a leading English authority, "is the power by which rights are created and maintained, by which the acts and forbearances necessary for their maintenance are habitually or constantly enforced" (Anson, Law and Custom of the Constitution, pt. i. p. 2). In France, where the state embraces a hierarchy of bodies and authorities culminating in the president of the republic, whose acts are the final form of a series of incomplete acts of the members of the hierarchy, it comes nearer to the theoretical meaning of the word. In Great Britain, the sovereignty of the state is either the number of its authorities which have rights against each other and stand in independent relation towards the individual citizens. Actions can be brought by private citizens in the ordinary law courts against individual authorities, and there is no system of hierarchical responsibility which prevents a state official from being personally accountable for his administrative conduct. In A. V. Dicey's admirable Introduction to the Study of the Law of the Constitution, this distinction between the French, or, as we should rather call it, continental system of entire subordination of the courts to the state as a whole, and the less logical British system is dwelt upon. "Few things," he observes, "are more instructive than the examination of the actions which have been brought in Great Britain against officers for retaining ships about to proceed to sea. Under the Merchant Shipping Act 1876 the board are open to detain any ship which, from its unsafe and unsavoury condition, is a serious danger to human life." "Most persons would suppose that the officials of the board of trade, so long as they—bona fide and without malice or corrupt motive—endeavour to carry out the provisions of the statute, would be safe from action at the hands of a shipowner. This, however, is not so. The board and its officers have more than once been sued with success. They have never been accused of either malice or negligence, but the mere fact that the board acts in an administrative capacity is not a protection to the board; nor is mere obedience to the orders of the board an answer to an action against its servants" (p. 324).

In England, we may say, the notion of state, from the constitutional point of view, is still inchoate, but the play of international intercourse seems to be gradually leading to a clearer conception of the fact that sovereign national responsibility requires a corresponding increase in the powers of the central administrative control. An instance of its absence is shown by the loose way in which the British Crown has granted governing powers to chartered companies (see Rau). This uncertainty applies as much to the United States as to Great Britain. In the Louisiana lynching riots, of which some Italian citizens were the victims, it was contended that the United States government was not responsible, and that the responsibility fell upon the government of Louisiana alone. This contention could not be pressed, and compensation was of course paid to Italy. Similar difficulties arose in connexion with the Japanese school question in California. The subject is well known to have raised apprehension as to the adequacy of the United States system to meet its centralized state responsibilities.

Another, and, in some respects, more dangerous feature of an inchoate conception of state responsibility is the growing apart, so to speak, of certain British dependences. The British state, for international purposes, is the British Empire, for domestic purposes it is the United Kingdom. Any limb of the former's huge body can have interests different from those of the United Kingdom, and involve its responsibility. A significant step towards concentration of liability and control was taken by the Australian colonies in the federation brought about by the Commonwealth Act of 1900. Under this act, by the way, an element of confusion has been created by the application of the term "state" to the federating colonies. Section 6 of the act provides "the states" shall mean such of the colonies of New of the intervention by anticipation and at the profit of the Union; car, c'est d'intervenir que d'interdire aux autres gouvernements d'intervenir."
South Wales, New Zealand, Queensland, Tasmania, Victoria, West Australia and South Australia as for the time being are parts of the Commonwealth, and such colonies or territories as may be admitted into or established in the Commonwealth as states, and each of such parts of the Commonwealth shall be called "a state." "Original states" shall mean "such states as are parts of the Commonwealth at its establishment." Following out this distinction between the Commonwealth and the states, articles 106 to 124 of the Commonwealth constitution deal with the respective positions of the Commonwealth, the original states, and the new states. Article 109 in particular provides that "when a law of a state is inconsistent with the law of the Commonwealth, the latter shall prevail, and the former shall, to the extent of the inconsistency, be invalid," thus paving the way for the ultimate consolidation of the federal power.

Much has been written on the "science" of the state, or, as we prefer, in Anglo-Saxon lands, to call it, "political science." In Germany the subject is dealt with as an independent branch of university education. Several of her universities have a staatswissenschaftliche Facultät, granting a special degree in the subject. In consequence of the great attention paid to the subject in Germany, her state policy has been largely the work of her political writers. The result has not unnaturally tended to a system hearing some resemblance to that of the states associated in the French. A very material difference, however, that whereas in the United States the federal power is derived from the democratic forces of the individual states, in Germany it is derived from their aristocratic and absolutist forces. German political thinkers, in fact, have worked out Staatsrecht as a comparative study, in which arguments in favour of absolute government have received as much careful consideration as those in favour of democratic institutions, and the German state has developed upon lines based on the best theoretical arguments of these thinkers. There is, therefore, no anomaly in its practically absolutist government working out the most democratic reforms as yet put into legislative form. It follows, however, that German theories are of little use in the consideration of the state problems with which British and American political thinkers have to deal. Anglo-Saxon institutions are following their independent development, and if the influence of foreign institutions is felt at all, it is probably that of the clear logical detail and cohesion of French institutions.

**Political Science.**

It is a subject of the Staatswissenschaften, the science of the State, in which the German writers hold a leading place. The most important of these are:

- **Hillebrand, Geschichte der Staatswissenschaft (1896).**
- **Mohl, Allgemeine Staatslehre (1899).**
- **R. von Mohl, Geschichte und Literatur der Staatswissenschaften (1855-1858).**
- **Hildebrand, Geschichte und System der Rechts- und Staatsphilosophie (1864).**
- **Gierke, Das deutsche Grundgesetz (1881).**
- **Janet, Histoire des relations de l'etat (1870).**
- **Bluntschli, Geschichte des allgemein Staatsrechts und der Politik (1867).**
- **Lehre vom modernen Staate (1884-1888).**
- **Schmidt, Allgemeine Staatslehre (1893).**
- **Steinheil, Staatslehre (1901).**
- **Theis, Kreuzer, Politik (1892).**
- **W. von Bluntschli, Geschichte des deutschen Reiches (2 Bde., 1895).**
- **Haenel, Deutsches Staatsrecht (1892).**
- **Janet, Histoire de la science politique (1887).**
- **Bottimy, Études de droit constitutionnel (1897).**
- **H. S. More, The Norman Settlement in the North of England (1899).**
- **Escaud, Éléments de droit constitutionnel français et étranger (1899).**
- **Hauriou, Précis de droit administratif et de droit public général (1900).**
- **Le Füt, État fédéral et confédération d'états (1896).**
- **Henri Michel, L'Etat de l'état (1896).**
- **Michaud, "De la Remodification de l'état à raison des fautes de ses agents," Revue du droit public et de la science politique (1895).**
- **Pillet, Recherches sur les droits fondamentaux des états dans l'ordre des rapports internationaux (1893).**

**State, General Officers of—Staten Island**

- **STATE, GREAT OFFICERS OF—STATEN ISLAND**

The title is applied to all the principal ministers of the British Crown, but strictly applicable only to the lord high steward, the lord high chancellor, the lord high treasurer, the lord-president of the (privy) council, the lord (keeper of the) privy seal, the lord great chamberlain, the lord high constable, the earl marshal, and the lord high admiral. Of these, three—the lord chancellor, the lord-president of the council, and the lord privy seal—the first and second are always, and the third almost always, cabinet ministers. The offices of two more—those of the lord treasurer and the high admiral—are now executed by commission, the chief of the lords commissioners, known severally as the first lord of the treasury and the first lord of the admiralty, being likewise members of the cabinet, while the first lord of the treasury is usually at the head of the government. But, although it has become the rule for the treasury and the admiralty to be on the commission, there is no reason of state generally of longer duration to prevent the Crown from making a personal appointment to either of them, and the functions which formerly appertained to the lord treasurer and the high admiral are still regularly performed in the established course of the national administration. The four offices of the high steward, the great chamberlain, the high constable, and the earl marshal stand on a different footing, and can be regarded at the present day as little else than survivals from an earlier condition of society. They have practically ceased to have any relation to the ordinary routine of business in the country or of ceremonial in the palace, and are mere survivals of an earlier period. See Stubbs, Constitutional History, ch. xi.; Freeman, Norman Const. ch. xxiv.; Gneist, Constitution of England, ch. xvi., xxv. and liv.; also Gibbon, Decline and Fall, ch. iii., and Bryce, Holy Roman Empire, ch. xiv.

**STATEN ISLAND,** an island constituting the borough of Richmond, New York City, and Richmond county, the southernmost of the counties of the state of New York. It is separated from Long Island on E. by the Narrows which connect Upper and Lower New York Bay; from New Jersey on the N. by the narrow channel of Kill van Kull which connects New York Bay with Newark Bay; and from New Jersey on the W. by the coastal channel of Sound, through which Sound Kill; and to its S.E. coast are Lower New York, Raritan and Prince's Bays, Great Kills, and the Atlantic Ocean. Pop. (1890), 51,603; (1900), 67,021; (1905), 72,845; (1910), 85,969. Staten Island is connected by ferry with the borough of Manhattan, 5 m. distant, and with Perth Amboy, New Jersey. The Staten Island Rapid Transit railway extends along the north shore and the south-east side, and there are several electric lines and pleasant drives. The island is triangular in shape, is 333 m. long from north-east to south-west, has a maximum width of nearly 8 m. at its north end, and an average width of 5 m. More than half the island is broken by two ranges of hills having a precipitous east coast and rising to a maximum height of about 400 ft., 1 m. inland from the Narrows; but on the west and south the hills fall gently to the Coastal Plain, which, occupying the greater part of the island, is broken only by low morainal ridges and terminates in salt marshes along much of the west coast. There are many species of forest trees and more than 1,300 species of flowering plants and ferns. The climate is subject to sudden changes, but the temperature rarely rises above 90° F. or falls below zero. The island is chiefly a residential district, and in the picturesque hill section are many fine residences. Ports Wadsworth and Tompkins commanding the passage of the Narrows constitute one of the strongest defences of New York Harbor. The principal villages are New Brighton, West New Brighton, Port Richmond, Stapleton, and Tompkinsville on the north coast.
and Tottenville (or Bentley Manor) on the south-west coast. Richmond, the county-seat since 1727, is a small village near the centre of the island. South Beach, below the Narrows, is a popular seaside resort. September 1776 held a peace conference. Establishment, there are also ship-building yards, oyster fisheries, and truck farms, and among the manufactures are linoleum, paper, white lead, linseed oil, brick, and fire-clay products.

When discovered by Europeans Staten Island was occupied by the Aquehonga Indians, a branch of the Raritans, and several Indian burying-grounds, places where wampum was manufactured, and many Indian relics, including a stone head with human features, have been found here. In 1630 the Dutch West India Company granted the island to Michael Pauw as a part of his patroonship of New Netherland, and it had been made a district in 1632.

In 1634 Pauw had established a settlement upon it he sold his title back to the company. A portion of it was regranted to David Paterson de Vries in 1636 and in 1642 the remainder was erected into a patroonship and granted to Cornelis Melyn. In 1641 de Vries established a settlement at Oude Dorp (Old Town), near Arrochar Park, near South Beach. It was destroyed by the Indians in the same year, was immediately rebuilt, was again destroyed in 1643, and was neither rebuilt nor occupied until 1655. A company of Waldenses founded a second settlement in 1658, at Stony Brook, about 2 m. west of the ruins of Oude Dorp; this was the principal village for many years and from 1683, when the island was erected into a county, until 1727 it was the county-seat. Melyn surrendered his rights as a patron in 1661 and during the remainder of the Dutch régime many small grants of land were made to French, Dutch, and English settlers. In 1664 the duke of York became proprietor of the newly erected province of New York and by his grant to the Duke of York in 1665 of all that portion which lay west of the Hudson river, Staten Island became properly a part of New Jersey, but in 1668 the Duke decided that all islands within New York Bay which could be circumnavigated in twenty-four hours should be adjudged to New York. Captain Christopher Billopp made the trip within the time limit and was rewarded with a grant of 1103 acres at the south end of the island. He erected this into the Manor of Bentley and the manor house, built about this time, still stands in the village of Tottenville. It was in this house that Lord Howe, after the capture of New York in September 1776, held a peace conference with Benjamin Franklin, John Adams, and Edward Rutledge representing the Continental Congress. The British army under Sir William Howe landed at the Narrows on the 3rd of July 1777 and until the close of the war Staten Island was held by the British and Loyalists. From it the British made frequent predatory raids into New Jersey and the Americans made several retaliatory raids into the island. Under the direction of General Hugh Mercer some American troops reached Richmond on the morning of the 16th of October 1776, and in an engagement which immediately followed they were victorious; but, as they were retreating with their prisoners, British reinforcements arrived and in a second engagement at Fresh Kill (now Green Ridge) they were routed with considerable loss. A second raid was made against Richmond early in August 1777 and on the 22nd of the same month American troops under General John Sullivan fought the British at several places, inflicting a loss of about 200 killed, wounded and prisoners and destroyed considerable quantities of stores. In the War of 1812 Fort Richmond was built at the Narrows and Fort Tompkins in the rear of it. The Federal government bought the site in 1847 and after destroying the old forts began the erection of the present works. In 1898 Staten Island became the borough of Richmond in Greater New York.

See J. K. Morris, "Memorial History of Staten Island" (2 vols. New York, 1891-1900); R. M. Bayles, History of Richmond County (New York, 1887); and J. J. Clute, Annals of Staten Island (New York, 1877).

**STATE RIGHTS**

STATE RIGHTS, a term used generally in political science to denote those governmental rights which belong to the individual states and a federal union, there being a certain degree of union in which these individual states may act without interference from the central government. Thus in the United States there were certain rights reserved to themselves by the states when forming the union under the constitution of 1787. These rights the central government is by fundamental law bound to respect, and they can be reduced only by amendment to the constitution. For a thousand years the various German states were so jealous of any curtailment of their individual rights as to prevent the formation of an efficient federal government; in Austria-Hungary the larger states still jealously guard their rights, and it is probably true that in both cases, where a central authority existed first and created the states, the belief in state rights is much weaker than it is in unions composed of originally independent states. The rights of a state are said to be delegated when, as in Mexico, Brazil and Colombia, the constitution is created by a central national authority which also makes the states; state rights are residuary when independent states unite to delegate by a constitution certain powers to a central government, as in the case of the German Empire, Austria-Hungary, the United States, Switzerland, of states sovereignty. The other rights of the states consist of forming unions of the second class are certain in after time to deny or assert that the sovereignty of the state is one of the rights reserved, according as the state belongs to a stronger or weaker section or faction; state sovereignty being the defence of the weaker state or faction, and being denied by the stronger group of states which controls the government and which asserts that a new sovereign state was created by a union of the former independent ones. This dispute is usually ended by civil war and the destruction of state sovereignty. The evolution of state rights as shown in the history of the United States is typical. Thirteen independent states formed a union in 1787 under a constitution reserving certain rights to the states. The sphere of the state authority embraced most of the powers of government, except, for instance, those relating to foreign affairs, army and navy, inter-state commerce, coinage and the tariff; the powers of the central government were specified in the fundamental law. Most of the states claimed at one time or another that sovereignty was one of the reserved rights of the states and on this theory the Southern states acted in the secession in 1861. The war that resulted destroyed all claims of state sovereignty and in the reconstruction of 1867 the states of those not delegated to the central government or forbidden to the states by the constitution. In case of doubt the presumption was in favour of the state. Since the beginning, however, the central government has gained strength at the expense of the states, seldom by direct usurpation (except during the Civil War and Reconstruction, 1861-76), but indirectly through use and custom, as the country and people developed and new conditions of government arose. The field of state rights had not increased, while centralization has slowly but surely taken place. This centralization is shown not only by the increased power and activity of the Federal government as compared with the state governments, but in the change in popular opinion indicated by the use of the terms National, Union, &c., where formerly Confederate, Federal, &c., were used, and in the use of singular verbs after the words Congress and the United States, where formerly they were followed by plural verbs.

The central authority in the United States, formerly almost unheard of by the average citizen, now touches him in many of the activities of life and sometimes inflicts a penalty that plays an important part in the domain of local self-government. The history of the decay of state rights makes it seem doubtful if the federal form of government is a permanent one, or is only a transient form between independent state governments or loose confederacies and a centralized national government.

See J. W. Burgess, Political Science and Comparative Constitutional Law (New York, 1895); Woodrow Wilson, The State (new ed.,
The English translation of (1) the États-Généraux of France before the Revolution, (2) the Staten-Generaal of the Dutch Netherlands. The name in both cases signifies, whatever the ultimate divergence in character of the two bodies, the assembly of the representatives of the various estates of the realm, called together for purposes of legislation or consultation.

The French States-General.—In France the States-General owed their origin to the same causes which produced the Parliament of England, the Cortes of Spain, the Diet of the Holy Roman Empire and the Diets (Landtage) of the states of Germany, and they resembled these assemblies in their constitution. In these countries the royal or ducal power, when it began to extend its scope, found itself limited by the feudal system and had to turn to the forces of feudalism to obtain from them aid and counsel, i.e. pecuniary assistance and moral support. Instead of treating severally with the lords and representatives of these forces the ruler found it useful and convenient to enter into contact with them as a whole, treating with them through their principal representatives.

In France these conditions led in 1302 to a general assembly consisting of the chief lords, both lay and ecclesiastical, and the representatives of the principal privileged towns, which were like distinct lordships. There had, of course, been certain precedents before 1302 which had, as it were, paved the way for this institution; the representatives of the principal towns had several times been convoked by the king, and under Philip III there had been assemblies of nobles and ecclesiastics in which the two orders had deliberated separately. It was the dispute between Philip IV, the Fair and Boniface VIII, which led to the States-General of 1302; the king of France desired that, in addition to the officers of the Crown, the principal authorities of the country should come and testify solemnly that they were at one with the king in this serious crisis. The letters summoning the assembly of 1302 are published by M. Georges Picot in his collection of Documents inédits pour servir à l'Histoire de France. In 1302 the States-General had been called upon only to give counsel to the king, but during the same reign they were several times assembled to give him aid, i.e. to grant him subsidies, and in course of time this came to be the most frequent motive of their convocation.

In one sense the composition and powers of the States-General have always been the same. They have always included representatives of the clergy, nobility and third estate, and they have always been summoned either to grant subsidies or to advise the Crown, to give aid and counsel. Their composition, however, as well as their effective powers, have varied greatly at different times.

In their primitive form, i.e. in the 14th and the first half of the 15th centuries, the States-General had only a limited elective element. The lay lords who appeared therein were not elected, but directly chosen and summoned by the king, and the same was the case with the prelates, bishops and clergy, who were summoned quod ecclesiastical lords. In the order of the clergy, however, since certain ecclesiastical bodies, e.g. abbeys and chapters of cathedrals, were also summoned to the assembly, and as these bodies, being persons in the moral but not in the physical sense, could not appear in person, their representative had to be chosen by the monks of the convents or the canons of the chapter. It was only the representation of the third estate which was furnished by election. Originally, moreover, the latter was not called upon as a whole to seek representation in the estates. It was only the bonnes villes, the privileged towns, which were called upon. They were represented by elected procureurs, who were frequently the municipal officials of the town, but deputies were often elected for the purpose.

The country districts, the plat pays, were not represented.

It was during the last thirty years of the 16th century that the States-General became an entirely elective body and really representative of the whole nation as divided into three parts. This was brought about by various causes. On the one hand, the nobles and prelates who were summoned were not always inclined to attend the estates, so had themselves represented by an envoy, a procureur, as they had the right to do, and frequently the lords or prelates of the same district chose the same procureur to represent them. On the other hand, the Crown seems at that time to have felt the need of having the consent of representatives really expressing the will and feelings of the barons, earls and the third estate as a whole.

The letters of summons to the States-General of 1484 invited the ecclesiastics, nobles and third estate in general, to meet at the chief town of their bailliage or stedehooste and elect deputies. An intermediate form had been employed in 1468 when the prelates and lords had still been summoned personally, but the towns had each elected three deputies, an ecclesiastical, a noble and a bourgeois.

At the estates of 1484 there seems to have been universal and direct suffrage for all the three orders. But the roturiers of the country districts could not in practice avail themselves of this power; so the country communities and smaller nobles spontaneously elected delegates to represent them at the electoral assembly. Thus a system of indirect election arose for the third estate which became confirmed and subsequently continued to be used. To a certain extent there were sometimes more than two degrees in the suffrage; the delegates nominated by the country communities would gather together with the electors chosen by the neighbouring little town, and appoint with them new delegates to represent them at the electoral assembly of the bailliage. This ultimately became the system. For the clergy and nobles the suffrage remained direct; but as a rule only such ecclesiastics were admitted to the assembly of the bailliage as possessed a benefice, and only such lords as had a fief.

The effective powers of the States-General likewise varied in the course of time. In the 14th century they were actually great. The king could not, in theory, levy general taxation. Even in the provinces attached to the domain of the Crown, he could only levy it where he had retained the haute justice over the inhabitants, but not on the subjects of lords having the haute justice. The privileged towns had generally the right of taxation, but only to a limited extent, and in order to obtain general taxes, the king had to obtain the consent of the lay and ecclesiastical lords and of the towns; this amounted to obtaining the authorization of the States-General, which only granted these subsidies temporarily for a fairly short period. The result was that they were summoned fairly frequently and that their power over the Crown might be considerable.

But in the second half of the 14th century certain royal taxes levied throughout the whole of the domain of the Crown, tended to become permanent, and independent of the vote of the estates. This sprang from many causes, but from one in particular; the Crown endeavoured by transforming and changing the nature of the "feudal aid" to levy a general tax by right, on its own authority, in such cases as those in which a lord could demand feudal aid from his vassals. For instance, it was in this way that the necessary taxes were raised for twenty years to pay the ransom of King John without a vote of the States-General, although they met several times during this period. Custom confined this tendency. Thus during the second half of the 15th century the chief taxes, the taille, aids and gabelle became definitely permanent for the benefit of the Crown, sometimes by the formal consent of the States-General, in 1437 in the case of the aids. The critical periods of the Hundred Years' War had been favourable to the States-General, though at the price of great sacrifices. Under the reign of King John they had had for a few years, from 1355 to 1358, not only the voting, but through their commissions, the administration of and jurisdiction over the taxes. In the first half of the reign of Charles VII they had been summoned almost every year and had patriotically voted subsidies. And when the struggle was over they renounced, through weariness
and a longing for peace, their most precious right, the power of the purse. At the estates of 1484, however, after the death of Louis XI., there was a kind of awakening. The deputies of the three orders united their efforts in perfect harmony in the hope of regaining the right of periodically sanctioning taxation. They voted the taille for two years, the deputies of the States-General had to assess it to the amount which it had reached at the end of the reign of Charles VII. They even demanded, and obtained, the promise of the Crown that they should be summoned again before the expiry of the two years. But the promise was not kept, and we do not find the States-General summoned again till 1560. There was then a first interruption of 76 years in the working of the institution, while the absolute monarchy was establishing itself. But there was a revival of its activity in the second half of the 16th century caused by the scarcity of money and the quarrels and wars of religion. The estates of Orleans in 1569, followed by those of Pontoise in 1571, and those of Blois in 1576 and 1588 were most remarkable for the wisdom, courage and efforts of the deputies, but on the whole were lacking in effect. Those of 1588 were ended on a regular coup d'état effected by Henry III., and the States summoned by the League, which sat in Paris in 1593 and whose chief object was to elect a Catholic king, was not a success. The States-General again met in Paris in 1614, on the occasion of the disturbances which followed the death of Henry IV.; but though their minutes bear witness that the deputies deliberated patiently and there was often a long discussion, the three orders rendered them weak and they were dissolved before having completed their work, not to be summoned again till 1789.

As to the question whether the States-General formed one or three chambers for the purposes of their working, from the constitutional point of view the point was never decided. What the king required was to have the consent, the resolution of the three estates of the realm; it was in reality of little importance to him whether their resolutions expressed themselves in common or separately. At the States-General of 1484 the elections were made in common for the three orders, and the deputies also arrived at their resolutions in common. But after 1560 the rule was that each order should deliberate separately; the royal declaration of the 23rd of June 1789 even stated that they formed three distinct chambers. But Necker's report to the conseil du roi according to which the convocation of 1789 was decided, said (as did the declaration of the 23rd of June), that on matters of common interest the deputies of the three orders could deliberate together, if each of the others decided by a separate vote in favour of this, and if the king consented. This arrangement was to be the announcement of an almost perfect system of deliberation by committee, as we should say nowadays. There were, it is true, solemn general sessions, called séances royales, because the king presided; but at these there was no discussion. At the first, the king or his chancellor announced the object of the convocation, and set forth the demands or questions put to them by the Crown; at the other royal sessions each order made known its answers or observations by the mouth of an orateur elected for the purpose. But almost all useful work was done in the sections, among which the deputies of each order were divided. At the estates of 1484 they were divided into six nations or sections, corresponding to the six généralités then existing. Subsequently the deputies belonging to the same gouvernement formed a group or bureau for deliberating and voting purposes. Certain questions, however, were discussed and decided in full assembly; sometimes, too, the estates nominated commissioners in equal numbers for each order. But in the ancient States-General there was never any personal vote. The unit represented for each of the three orders was the bailliage or bailliages: the comté of Baugé, the bailliage of La Roche, the bailliage of the Loire were all, in what way this vote should be given. At the estates of the 16th century voting was by gouvernements, each gouvernement having one vote, but the majority of the bailliages composing the gouvernements decided how it should be given.

The States-General, when they gave counsel, had in theory only a consultative faculty. They had the power of granting subsidies, which was the chief and ordinary cause of their convocation. But it had to come to be a consent with which the king could dispense. We have seen how permanent taxation began to be established; the same time that the Three Estates again claimed that their consent was necessary for the establishment of new taxation, and, on the whole, the facts seem to be in favour of this view at the time. But in the course of the 17th century the principle gained recognition that the king could tax on his own sole authority. Thus were established in the second half of the 17th century, and in the 18th, the direct taxes of the capitation and of the dixième or vingtième, and many indirect taxes. It was sufficient for the law creating them to be registered by the cours des aïdes and the parlements, and at one in 1789 that the parlement of Paris declared that it could not register the new taxes, the land-tax and stamp-duty (subvention territoriale et impôt du timbre), as they did not know whether they would be submitted to by the country, and that the consent of the representatives of the tax-payers must be asked.

The States-General had legally no share in the legislative power, which belonged to the king alone. The States of Blois demanded, it is true in 1576, that he should be bound to turn into law any proposition voted in identical terms by each of the three orders; but the king would not grant this demand, which would have even left him a right of veto. In practice, however, the States-General contributed largely to legislation. Those who sat in them had at all times the right of presenting complaints (doléances), requests and petitions to the king; in this, indeed, consisted their sole initiative. They were usually answered by an ordonnance, and it is chiefly through these that we are acquainted with the activity of the estates of the 14th and 15th centuries. In the latest form, and from the estates of 1484 onwards, this was done by a new and special procedure. The States had become an entirely elective assembly, and at the elections (at each step of the election if there were several) the electors drew up a cahier des doléances (statement of grievances) which they requested the deputies to present; this even appeared to be the most important feature of an election. The deputies of each order in every bailliage also brought with them a cahier des doléances, which was arrived at, for the third estate, by a combination of the statements drawn up by the primary or secondary electors. On the assembly of the estates the cahiers of the bailliages were incorporated into a cahier for each gouvernement, and these again into a cahier général or general statement, which was presented to the king. When the three orders deliberated in common, as in 1484, there was only one cahier général; when they deliberated separately, there were three, one for each order. The drawing up of the cahier général was looked upon as the main business (le grand ouvrage) of the session.

By this means the States-General furnished the material for numerous ordonnances, though the king did not always adopt the propositions contained in the cahiers, and often modified them in forming them into an ordonnance. These latter were the ordonnances de réforme (reforming ordinances), treating, as in the expedients of the 13th century, of the accounts of the bailliages. They were not, however, for the most part very well observed. The last of the type was the grande ordonnance of 1629 (Code Michaud) drawn up in accordance with the cahiers of 1614 and with the observations of various assemblies of notables which followed them.

The States-General had, however, peculiar power which was recognized, but was of a kind that could not often be exercised; it was what might be called a constituent power. The ancient public law of France contained a number of rules called 'the fundamental laws of the realm (lois fondamentales du royaume), though most of them were purely customary; chief among them were the rules of determining the succession to the Crown and those forbidding the alienation of the domain of the Crown. The king, supreme though his power might be,
could not abrogate, modify or infringe them. But it was admitted that he might do so by the consent of the States-General. The States could give the king a dispensation from a fundamental law in a given instance; they could even, in agreement with the king, make new fundamental laws. The States of Blois of 1756 and 1788 offer entirely new precedents in this respect. It was universally recognized that in the event of the line of Hugh Capet becoming extinct, it would be the function of the States-General to elect a new king.

The States-General of 1614 had been the last. A new conviction had indeed been announced to take place on the majority of Louis XIV., and letters were even issued in view of the elections, but this ended in nothing. Absolute monarchy was becoming definitely established, and was incompatible with the institution of the States-General. Liberal minds, however, in the entourage of the duke of Burgundy, who were preparing a new plan of government in view of his accession to the throne, thought of reviving the institution. It figures in the projects of St Simon and Fénélon, though the latter would have preferred to begin with an assembly of non-elected notables. But though St Simon was high in the favour of the regent Orleans, the States were not summoned at the death of Louis XIV.

In 1789 they were summoned. They were preceded, as Fénélon had wished in former days, by an assembly of notables in 1787, which already displayed great independence. It was the refusal of the parlement of Paris to register the fiscal edicts submitted to the Notables which led to the summoning of the States-General. The Notables, who had sat in 1787, were again summoned in 1788 to inquire into and fix the rules for the elections and the procedure of the States. Necker, in the Mémoire which he submitted to the conseil du roi in December 1788, granted for these States the doublement du tiers, i.e. that the third estate should have a number of deputies equal to that of the deputies of the other two orders combined, this is what had happened previously in the few provincial assemblies created by Necker during his first administration and in those created by an edict of 1787 for all the pays d'elections. But Necker in his project of deliberating separately (par ordre) or in common, simply referred to the ancient principles; and he seems also to have proposed to maintain the system of voting by baillages. Now the doubling of the tiers could yield it no real advantage unless the deliberation was in common and the voting by individuals, and it was this question which from the 6th of May 1789 onwards was the subject of the separate deliberations and negotiations between the three orders. On the 13th of June the third estate had arrived at a resolution to examine and settle in common the powers of the three orders, and invited to this common work those of the clergy and nobles. Certain of the latter and the majority of the clergy joined the tiers, and on the 17th of June it arrived at the celebrated decision by which it affirmed the principle of the national supremacy residing in the mass of the nation; the deputies, without any distinction of order, constituted a national assembly, which assembly was called upon to regenerate France by giving her a constitution, while the royal power (which in reality became provisional) could not negative its decisions. The king tried to resist. In the stance royale of the 23rd of June 1789, where he took the attitude of granting a charte octroyée (a constitution granted of the royal favor), he affirmed, subject to the traditional limitations, the right of separate deliberation for the three orders, which constitutionally formed three chambers. We know how this move failed; soon that part of the deputies of the nobles who still stood apart joined the National Assembly at the request of the king. The States-General had ceased to exist, having become the National Constituent Assembly, though it consisted of the deputies elected by the order.

The Dutch States-General.—In the Netherlands the convoca-
tion of the States-General, consisting of delegates from the provincial states, dates from about the middle of the 17th century, under the rule of the dukes of Burgundy. The name was transferred, after the separation of the northern Netherlands from the Spanish dominions, to the representatives elected by the seven sovereign provincial estates for the general government of the United Provinces. The States-General, in which the voting was by provinces—each province having one vote—was established from 1593 at the Hague. The States-General came to an end after the revolution in 1795, with the convocation of the National Assembly (March 1, 1796). See Holland (History). The title of Staten-Generaal is, however, still borne by the Dutch parliament.

(W. A. P.)

STATES OF THE CHURCH, or Papal States (Ital. Stato della Chiesa, Stato Pontificio, Stato Romano, Stato Ecclesiastico; Fr. États de l’Église, Pontificat Souverain de Rome, &c.; Ger. Kirchenstaat; in ecclesiastical Latin often Patrimonium Sancti Petri), that portion of central Italy which, previous to the unification of the kingdom, was under the direct government of the see of Rome. The territory stood in 1859 as in the annexed table.

With the exception of Benevento, surrounded by the Neapolitan province of Principato Ulteriore, and the small state of Pontecorvo, enclosed within the Terra di Lavoro, the States of the Church formed a compact territory, bounded on the N.W. by the Lombardo-Venetian kingdom, on the N.E. by the Adriatic, on the S.E. by the kingdom of Naples, on the S.W. by the Mediterranean, and on the W. by the grand-duchy of Tuscany and the duchy of Modena. On the Adriatic the coast extended from the mouth of the Tronto (Truentus) to the southern mouth of the Po, and on the Tyrrenian Sea from 41° 26' to 42° 22' N. lat.

The divisions shown above were adopted on the 21st of December 1827, the legations being ruled by a cardinal and the delegations by a prelate. Previously the several districts formally recognized were Latium, the Marittima (or sea-board) and Campagna, the patrimony of Saint Peter, the duchy of Castro, the Orviétano, the Sabina, Umbria, the Perugino, the March of Ancona, Romagna, the Bolognese, the Ferrarese, and the duchies of Benevento and of Pontecorvo. The former papal territories are now comprised within the Italian provinces of Bologna, Ferrara, Forli, Ravenna, Pesaro and Urbino, Ancona, Macerata, Ascoli-Picceno, Perugia, Rome and Benevento.

The question of the origin of the territorial jurisdiction of the pope is treated under Papacy. With the moral and ecclesiastical decay of the papacy in the 9th and 10th centuries much of its territorial authority slipped from its grasp; and by the middle of the 11th century its rule was not recognized beyond Rome and the immediate vicinity. By the treaty of Saint-Plancard (February 3, 1113) Paschal II. was compelled by the emperor Henry V. to surrender all the possessions and royalties of the Church; but this treaty was soon afterwards repudiated, and by the will of Matilda, countess of Tuscany, the papal see was enabled to lay claim to new territories.
of great value. By the capitulation of Neuss (1201) the emperor Otto IV. recognized the papal authority over the whole tract from Redon to Lyons, thus giving to the papal dominion on one side the Rhone, on the other the Rhine, the frontier—the exarchate of Ravenna, the Pentapolis, the March of Ancona, the bishopric of Spoleto, Matilda's personal estates, and the counties of Bologna, Ferrara, &c., dates from the 16th century. The States of the English, a numerous and powerful faction for a long time by the growth of the English spirit. It was also added; it was often a law of the eighteenth century. 

Wallis. The first collection of accounts of state trials was published in 1719 in four volumes. Although without an editor's name, it appears that Thomas Salmon (1679-1767), an historical and geographical writer, was responsible for the collection. A second edition, increased to six volumes, under the editorship of Sollom Emlyn (1697-1754), appeared in 1730. This edition contained a lengthy preface critically surveying the condition of English law at the time. A third edition appeared in 1742, in eight volumes, the seventh and eighth volumes having been added in 1835. The eighth and tenth volumes were added in 1766. A fourth edition, comprising ten volumes, with the trials arranged chronologically, was published the same year. A fifth edition, originated by William Cohibet, but edited by Thomas Bayly Howell (1768-1815) and known as Cobbett's Complete Collection of State Trials, was published between 1809 and 1826. This edition is in thirty-three volumes; twenty-one of them, giving the more important state trials down to 1781, were edited by T. B. Howell, and the remaining volumes, bringing the trials down to 1820, by his son Thomas Jones Howell (d. 1858). A new series, under the direction of a parliamentary committee, was projected in 1885, with the object of bringing the trials down to a later date. Eight volumes were published in 1888-1898, bringing the work down to 1838. The first three of these were edited by Sir J. Macdonell, the remaining five by J. E. P. Wallis. Selections have also been edited by H. L. Stephen and others. The trials are invaluable not only for their reports of criminal cases, in which the whole course of criminal procedure and evidence may be traced, but for their historical information.

STATICS (from Gr. root στη-, stand, or cause to stand), the branch of mechanics which discusses the conditions of rest or equilibrium of forces (see MECHANICS).

STATIONERY, a term embracing all the various articles sold by "stationers," who were originally booksellers having "stations" or stands in markets, near churches or other buildings for the sale of their goods (see BOOKSELLING for the further history of the word). The stationers were formed into a guild in 1493, the Livery Company not being incorporated till 1556. At the hall of the company in London, "Stationers' Hall," is kept a book for the registration of copyrights (see COPYRIGHT). The term "stationery" comes from the German amt, a department which supplies stationery to parliament and the government offices and generally controls the printing required by them. Under the name of stationery are now included all writing materials and implements, together with the numerous appliances of the desk and of mercantile and commercial offices.

The principal articles and operations of the stationery trade are dealt with under such headings as BOOKBINDING, COPYING MACHINES; INK; LITHOGRAPHY; PAPER; PEN; and PENCIL.

STATE TRIALS—STATISTICS. A series of 14 pictures or images representing the closing scenes in the Passion of Christ, viz. (1) the condemnation by Pilate, (2) the reception of the cross, (3) Christ's first fall, (4) the meeting with His mother, (5) Simon of Cyrene carrying the cross, (6) Veronica wiping the face of Jesus, (7) the second fall, (8) the exhortation to the women of Jerusalem, (9) the third fall, (10) the stripping of the clothes, (11) the crucifixion, (12) the death, (13) the descent from the cross, (14) the burial. Sometimes a 15th—the finding of the cross by Helena—is added; on the other hand in the diocese of Vienna, the stations were at the end of the 18th century reduced to eleven. They form a very popular item in Roman Catholic devotion. The Stations of the Cross number forty-four in Rome and are sung round the church; sometimes they are found in the open air, especially on the ascent to some elevated church or shrine.

The devotion began among the Fransicans, who, as the guardians of the holy places in Jerusalem, sought by this means to enable Christians to make a pilgrimage at least in spirit. Pope Innocent XII. in 1694 declared that the indulgences granted for visiting Palestine might be gained by members of the order who, simply visiting the stations of the cross wherever represented, exercised a devout meditation as they passed from station to station. These indulgences were extended by Benedict XIII. in 1726 to all the faithful, and Clement XII. five years later granted the privilege to churches other than Franciscan, provided the stations were erected by a Franciscan. In 1857 the Roman Catholic bishops in England received faculties, renewed quinquennially, permitting them to erect the stations with the accompanying indulgences, and they often delegate this faculty to priests.

STATISTICS. The word "statistic" is derived from the Latin status, which, in the middle ages, had come to mean a "state." The "state statistics," or state reports, have been then denoted inquiries into the condition of a state. Since the 18th century the denotation of the word has been extended, while at the same time its scope has become more definite, and may now be said, for all practical purposes, to be fixed.

History.—The origin of what is now known as "statistics" (Ger. die Statistik; Fr. la statistque; Ital. statistica) can only be referred to briefly here. As human societies became more and more highly organized, there can be no doubt that a very considerable body of official statistics must have come into existence, and been constantly used by statesmen, solely with a view to administration. The Romans were careful to obtain accurate information regarding the resources of the state, and they appear to have taken the census with a regularity which has hardly been surpassed in modern times.

Statistics, or rather the material for statistics, therefore existed at a very early period, but it was not until within the last three centuries that systematic use of the information available began to be made for purposes of investigation and not of mere administration. A volume compiled by Francesco Sansovino, entitled Del Governo et amministrazione di diversi regni pubbliche, was printed in Venice in 1583. Other works of a similar kind were published towards the end of the 16th century in Italy and France. Works on state administration and finance continued to be published during the first half of the 17th century, and the tendency to employ figures, which were hardly used at all by Sansovino, became more marked, especially in England, where the facts connected with "bills of mortality" had begun to attract attention.

G. Achenwall is usually credited with being the first to use the word "statistics," for the scientific, in the modern sense of the word, did not really come into existence until the publication (1751) by J. F. Süssmilch, a Prussian clergyman, of a work entitled Die göttliche Ordnung in den Veränderungen des menschlichen Geschlechts aus der Geburt, dem Tode, und der Fortpflanzung desselben erwiesen. In this book a systematic attempt was made to make use of a class of facts which up to that time had been regarded as belonging to "political arithmetic," under which description some of the most important problems of what modern writers term "vital statistics" had been studied, especially in England. Süssmilch had arrived at a perception of the advantage of studying what was termed subsequently the "laws of large numbers." He combined the method of "descriptive statistics" with that of the "political arithmeticians," who had confined themselves to investigations into the facts regarding...
mortality and a few other similar subjects, without much attempt at generalizing from them.

Political arithmetic had come into existence in England in the middle of the 17th century. The earliest example of this class of investigation is the work of Captain John Graunt of London, entitled Natural and Political Annota-
tions made upon the Bills of Mortality, which was first published in 1666. This remarkable work, which dealt with mortality in London only, ran through many editions, and the line of inquiry it suggested was followed up by various other writers, of whom the most distinguished was Sir William Petty, who published in 1683 his Five Essays in Political Arithmetic. Other writers, of whom Halley, the celebrated mathematician and astronomer, was one, entered on similar investigations, and during the greater part of the 18th century the number of persons who devoted themselves to "arithmetical" inquiries into problems of the class now known as statistical was steadily increasing. Much attention was given to the construction of tables of mortality. Attempts were also made to deal with figures as the basis of political and fiscal discussion by Arthur Young, Hume and other historical writers, as well as by the two Mirabeaus.

It is now necessary to return to Süssmilch, who, as already mentioned, endeavoured to form a general theory of society, based on what were then termed "arithmetical" premises. In modern language, he made use of quantitative aggregate observation as an instrument of social inquiry. It is true he did not enter on his investigations with an "open mind." He endeavoured to support a foregone conclusion, as the title of his work shows. But nevertheless his work was a most valuable one, since it pointed out a road which others who had no desire to procure evidence in favour of a particular system of thought were not slow to follow. Although for many years after the appearance of Süssmilch's book there was a good deal of resistance to the introduction of "arithmetic" as the coadjutor of moral and political investigations, yet, practically there was a tacit admission of the usefulness of figures, even by the chiefs of the so-called "descriptive" school. On the other hand, Süssmilch's suc-
cess was the origin of a "mathematical" school of statisticians, some of whom carried their enthusiasm for figures so far that they refused to allow any place for mere "descriptions" at all. These two schools have now coalesced, each admitting the importance of the point of view urged by the other. They were, however, still perceptibly distinct even as late as 1850, and the ignorant hostility with which many people even among the cultivated classes still regard statistical inquiries into the nature of human society may be regarded as a survival of the much stronger feeling which showed itself among "orthodox" pro-
fessors of law and economics on the publication of Süssmilch's treatise.

To the impulse given by the great Belgian, Quetelet, must be attributed the foundation in 1834 of the Statistical Society of London, a body which, though it has contributed little to the theory of statistics, has had a considerable influence on the practical work of carrying out statistical investigations in the United Kingdom and elsewhere. Quetelet was above all things an exponent of the "laws of large numbers." He was especially fascinated with the tendency to relative con-
stancy of magnitude displayed by the figures of moral statistics, especially those of crime, which inspired him with a certain degree of pessimism. His conception of an average man (l'homme moyen) and his disquisition on the "curve of possibility" were most important contributions to the technical development of the statistical method.

The influence exercised by Quetelet on the development of statistics is clearly seen from the fact that, though there is still considerable controversy among statisticians, the old controversy between the "descriptive" and arithmetical schools has disappeared, or perhaps we should say has been transformed into a discussion of another kind, the question now at issue being whether there is a science of statistics as well as a statistical method. It is true that a few books were published between 1830 and 1850 in which the politico-geographical description of a country is spoken of as "statistics," which is thus distinguished from "political arithmetic." The title of Knies's great work, Die Statistik als selbständige Wissenschaft (Cassel, 1850), is especially noteworthy as showing that the nature of the controversy was changing. Knies claimed that the really "scientific" portion of statistics consisted of the figures employed. As Haushofer says, "his starting point is political arithmetic."

Some eminent statisticians of the latter half of the 19th century accepted the view of Knies, but the majority of modern writers on the theory of statistics, especially in Germany, have adopted a slightly different standpoint according to which statistics is at once a science relating to the social life of man and a method of investigation applicable to all sciences. This view was ably maintained by von Mayr, Haushofer, Gabaglio and Block, whose views, published fifteen to twenty years before the close of last century, still substantially represent the opinions held by the majority of statisticians in Germany, and probably on the European continent. In France, however, several writers of importance have recently published works on the subject in which, in spite of the influence of M. Block, the claim of statistics to be considered as an independent sociological science has been rejected. There has been little systematic exposition of the subject in the United Kingdom. Isolated dicta have been furnished by authorities on the practice of statistics, such as the statistical of W. A. Guy, Professor J. K. Ingram, Sir Rawson W. Rawson, Sir Robert Giffen and other statisticians. Giffen has lectured on statistics at University College, London. The most important English work dealing with the matter is that of Mr A. L. Bowley. His volume, Elements of Statistics (first published in 1901), is intended as a practical handbook for teaching the principles on which statistics should be handled. The nature of Mr Bowley's book is, indeed, an indication of the fact that in the United Kingdom the study of statistics has been, in the main, of a practical character, the in-
vestigation of the theoretical basis of the statistical method attracting little interest. On the other hand, numerous mono-
graphs have been published by English writers on particular points connected with the technique of statistical investigation, as was natural considering the excellence of the practical use made of statistics in the United Kingdom.

With regard to the few earlier invasions of the domain of theory attempted by English writers, it may be observed that the authorities above mentioned were not unanimous. Dr Guy as well as Sir Rawson W. Rawson both claim that statistics is to be regarded as an independent science, apart from sociology, while Professor Ingram maintained that statistics cannot occupy a position co-ordinate with that of sociology, and that they "constitute only one of the aids or adimicula of science." Sir Robert Giffen has also expressed himself adversely to the continental doctrine that there is an in-
dependent science of statistics, and this opinion appears to be the correct one, but, as Dr Guy and Sir Rawson W. Rawson had the support of the great body of systematic teaching emanating from distinguished continental statisticians in support of their view, while their opponents have so far only the obiter dicta of a few eminent men to rely upon, it appears needful to examine closely the views held by the continental authorities, and the grounds on which they are based.

The clearest and shortest definition of the science of statistics as thus conceived is that of M. Block, who describes it as "la science de l'homme vivant en société en tant qu'elle peut être exprimée par les chiffres." He proposes to give a new name to the branch of study thus defined, namely "demography." Von Mayr’s definition is longer. He defines the statistical science as "die systematische Darlegung und Erörterung der thatsächlichen Vorgänge und der aus diesen sich ergebenden Gesetze des gesellschaftlichen menschlichen Lebens auf Grundlage quantitativer Massenbeobachtungen." The systematic statement
and explanation of actual events, and of the laws of man's social life that may be deduced from these, on the basis of the quantitative observation of aggregates). Gabaglio's view is practically identical with those adopted by von Mayr and Block, though it is differently expressed. He says: "Statistics may be divided in two forms—before the one hand, from the former sense it is a method, in the latter a science. As a science it studies the actual social-political order by means of mathematical induction." Most German writers on the subject have endorsed the views of Block and von Mayr. Among them may be mentioned Professors J. Conrad, Lexis and Westergaard, but Dr. Augst Meitzen of Berlin, a second edition of whose Geschil, Theorie und Technik der Statistik was published in 1903, makes a much less wide claim. In France opinions are divided; Professors André Liesse and Fernand Faure and others accepting the view that statistics is essentially a method.

This discussion regarding the nature of statistics is to a large extent a discussion about names. There is really no difference of opinion among statistical experts as to the subject-matter of statistics, the only question being—Shall statistics be termed a science as well as a method? That there are some investigations in which statistical procedure is employed which certainly do not belong to the domain of the supposed statistical science is generally admitted. But, as already shown, an attempt has been made to claim that the phenomena of human society, or some aspects of those phenomena, constitute the subject-matter of an independent statistical science. It is not easy to see why this claim should be admitted. There is no reason either of convenience or logic why the use of a certain scientific method should be held to have created a science in one department of inquiry, while in others the said method is regarded merely as an aid in investigation carried on under the superintendence of a science already in existence. It is impossible to get over the fact that in meteorology, medicine, and other physical sciences statistical inquiries are plainly and obviously examples of the application of statistical methods. But it is hard to draw the line between the statistical science of the earth and its inhabitants, and the statistical science of the phenomena of sociology. Why should the fact of their employment in sociology be considered as authorizing the classification of the phenomena thus dealt with to form a new science?

The most effective argument put forward by the advocates of this view is the assertion that statistics are merely a convenient aid to investigation in the majority of sciences, but that it is the sole method of inquiry in the case of sociology. When, indeed, it is tested by reference to the important class of social facts which are named economic, it becomes obvious that the argument as such is of no weight. Not in economics, not in the more complex and analogous field of sociology, are those phenomena which have been admitted to form a statistical science as in other sciences. The objection is not that they are not observable, but that they are not comparable in the sense in which economists use the word comparable. The objection is not that they are not scientific phenomena, but that they do not exist as such phenomena, and are not observable by the same methods as are phenomena in other sciences.

The Statistical Method.—This method is a scientific procedure (1) whereby certain phenomena of aggregation not perceptible to the senses are rendered perceptible to the intellect, and (2) furnishing rules for the correct performance of the quantitative observation of these phenomena. The class of phenomena of aggregation referred to includes only such phenomena as are too large to be perceptible to the senses. It does not, e.g., include such phenomena as are the subject-matter of micro- or macroscopic phenomena which are easily determinable by the senses. But it does include phenomena such as cannot be perceived by the senses, but which are changed by phenomena that are perceptible to the senses. It includes phenomena such as are observable by means of instruments that are not directly perceptible to the senses.

The Statistical Method is a method of investigation that is applicable to all phenomena that are not directly observable, but which are changed by phenomena that are observable. It is a method of investigation that is applicable to all phenomena that are not directly observable, but which are changed by phenomena that are observable. It is a method of investigation that is applicable to all phenomena that are not directly observable, but which are changed by phenomena that are observable. It is a method of investigation that is applicable to all phenomena that are not directly observable, but which are changed by phenomena that are observable. It is a method of investigation that is applicable to all phenomena that are not directly observable, but which are changed by phenomena that are observable. It is a method of investigation that is applicable to all phenomena that are not directly observable, but which are changed by phenomena that are observable.
STATISTICS 809

the Quarterly Journal of Economics and similar publications in different countries.

Sources whence Statistics are Derived.—The term "statistics" in the concrete sense means systematic arrangements of figures relating to matters of public concern. The statistical quantity is a number obtained from numbers representing phenomena, with a view to enable an observer to perceive a certain other phenomenon related to the former as whole or parts. They represent an abstract of the population of the place or a phenomenon of accretion during a given period. As examples may be mentioned the number of deaths in a given district during a given time, the number of pounds sterling received by the London & South Western Railway during during a given time, the number of "inches of rain" that fell at Greenwich during a given time. Other examples are the number of tons of pig-iron lying in a particular warehouse, the number of pounds sterling of private deposits of the Bank of England at a given date.

Primary statistical quantities are the result of labours carried on either (A) by governments or (B) by individuals or public or private corporations.

A Government. Statistics.—1. A vast mass of statistical material of more or less value comes into existence automatically in modern states in consequence of the ordinary administrative routine of departments. To this class belong the highly important statistical returns published in England by the registrar-general, the returns of pauperism issued by the local government board, the reports of inspectors of prisons, factories, schools, and those of sanitary inspectors, as well as the reports of the commissioners of the Revenue, of the statistical department of the medical administration, the reports of the various local authorities prepared by the same officials. There are also the various returns compiled and issued by the board of trade, which is the body most nearly responsible for the statistical survey of the facts by which most foreign governments are furnished. Most of the government departments publish some statistics for which they are solely responsible as regards both matter and form, and they are jealous of their right to set the world right as to uniformity as to dates and periods which should be the ideal of a well-organized system of statistics. Finally may be mentioned the very important set of statistical quantities known as the budget, and consisting of the quantities and proportions of the various sources of public income, as well as of the various items of expenditure, gathered and published by the department of inland revenue, by the post office, and by the national debt commissioners. All these sets of primary statistical quantities arise out of the ordinary work of departments of the government.

Many of them have been in existence, in some form or other, ever since a settled government existed in the country. There are records of customs receipts at London and other ports of the time of Edward III., covering a period of many years, which leave nothing to be desired in point of precision and uniformity. It may be added that many of these sets of figures are obtained in much the same form by all civilized governments, and that it is often possible to correlate the statistical quantities, or to obtain direct evidence as to the sociological phenomena of each, but in regard to others there are differences which make comparison difficult.

At the same time, for what might be called administrative statistics, all governments are in the habit of ordering from time to time special inquiries into special subjects of interest, either to obtain additional information needful for administrative purposes or in connection with. the various institutions, to supply statistics asked for by parliaments or congresses. It is not necessary to refer particularly to this class of statistical information, except in the case of the census. This is an inquiry of such great importance that it may be regarded as one of the regular administrative duties of governments, though as the census is only taken once in a series of years it must be mentioned under the head of occasional or special inquiries undertaken by governments. In the United Kingdom the work is done by the registrars-general who are in office when the period for taking the census comes round. On the Continent the work is carried out by the census bureaus which, however, in each country are subject to the supervision of the minister of the interior. The new regulations as to income-tax assessment and the new land taxes will furnish the government with much fresh information as to the state of the various counties and great counties of the kingdom.

The session of 1907 and already carried out as regards a number of trades will also be useful.

2. An enormous mass of statistical information is furnished voluntarily by public companies in the reports and accounts which, in accordance with their articles of association, are prepared for the purposes of their annual meetings, or at stated intervals. With these statistics may be classed the figures furnished by the various trade associations, some of them of great importance, such as Lloyd's, the London Corn Exchange, the Institute of Bankers, the Institute of Actuaries, and other such bodies too numerous to mention.

3. There are cases in which individuals have devoted themselves with great labour and less stimulus to the giving of accurate information which is of great importance. The great work done by Messrs Behm and Wagner in arriving at an approximate estimate of the population of the earth does not belong to this category, though its results are really primary statistics. These results were arrived at by a direct process of enumeration at all, but by ingenious processes of inference. It need hardly be said that it is not easy in such cases to use the materials obtained as a basis of vital inferences.

Operations Performed on Primary Statistical Quantities.—Only a brief description of matters connected with the technique of the statistical method can be given in this article. In order to form statistics properly so called the primary statistical quantities must be formed into tables, and in the formation of these tables lies the art of the statistician. It is not a very difficult art when the figures are not very numerous, nor are they very accurate but when the material is voluminous and the figures are of great importance, it is a serious business, and the statistician is not unfrequently held to be responsible for the accuracy of the table, and it is obvious that the art of the statistician is to express that idea in accurate language. This is a matter which is often neglected, and it is a source of much waste of time and occasionally of misapprehension to those who have to study the figures thus presented. No table ought to be considered complete without a "heading" accurately describing its contents, and it is frequently necessary that such headings should be rather large. It is said that "You can always get a shade of inference from a statement, is of course, absurd, taken absolutely, but, like most ascriptions which are widely believed, it has a grain of truth in it. If this popular saying ran you could prove anything by tables with slight additions. In the same way, if an inference is not properly marked, its truth is greatly diminished. The phrase "it is highly probable" means nothing, whereas, it is highly probable means something. The phrase "it is highly probable means something that is not very probable. The false "statistical" facts which obtain a hold of the public mind may often be traced to some wrongly circulated table, to which, either from stupidity or carelessness, an erroneous or inaccurate "heading" has been affixed.

A statistical table in its simplest form consists of "primaries" representing phenomena of the same class, but existing at different points of time, or coming into existence during different periods of time. This is all that is essential to a table, though other things are usually added to it as an aid to its comprehension. A table stating the number of persons residing in each county of England and Wales, and also the number of families, with corresponding numbers for the same counties on the corresponding day of the tenth year subsequently, would be a simple tabular method of giving the facts regarding the total population of those counties supplied by the statistical bureau. But, in order to prevent the figures might, however, be added to it which would greatly add to its clearness. There might be columns showing the increase or decrease in the population of each of the counties during the ten years, and another column showing what proportion, expressed in percentages, these increases or decreases bore to the figures for the earlier of the two years. Then there might be two columns showing what proportions, also expressed as percentages, the figures for each county bore in each year to the figures for the whole kingdom. The nine-column table thus resulting would still be simple, all the figures being merely explicit assertions of facts which are contained implicitly in the original "primaries."

Complex Tables.—Suppose now we have another table precisely similar in form to the first, and also relating to the counties of Scotland, and given by the statistical bureau at the same dates of the same years. A combination of the two would form a complex table, and an application of the processes of arithmetic would make evident a number of fresh facts, all of which would be concealed in the ordinary table, but would not be obvious to most people until explicitly stated.

The technical work of the statistician consists largely in operations with numbers involving the transformation of these results into a form of statement which is the most convenient for the reader.

Proportions.—The most usual and the best mode of expressing the proportion borne by one statistical quantity to another is to state it as a percentage. In some cases another method is adopted, viz., by stating the figures directly in the form of ratios. This method is generally a bad one, and its use should be discouraged as much as possible, the chief reason being that the changing portion of this kind of proportional figure becomes greater or less directly, as the phenomenon it represents increases or diminishes.

Averages.—Averages or means are for statistical purposes divided into two classes, the arithmetical and weighted. An
The arithmetic mean is the sum of all the numbers forming the series divided by the number of them. It is not a property of the individual numbers, but of the series as a whole. A weighted mean is the sum of values of individual items divided by their corresponding weights, where the weights are positive and the sum of weights is equal to one. The mode is a measure of central tendency, but is not necessarily unique to a given set of data.

In the case of a series that is not stationary, some transformation may be necessary to obtain the stationary series. The primary requirement of the time-series is that each term be a simple, uncorrelated value; that is, each term be independent of the others. The only matter connected with price which it is necessary to refer to here is the theory of the index number.

Index Numbers.—The need for these became consequent during the investigations of Tookey, Newmarch and others into the general cyclic movements of the prices of commodities; and to construct a general index of them. The solution of the problem required a careful examination of the principles and methods of the earlier students. It was impossible to introduce any method which would suit all cases in which isolated articles or groups of articles moved in the opposite direction to the majority of articles. The problem, therefore, is to produce a general index which expresses the general movement of the prices of the whole series of articles, in which all prices should be adequately represented. The first rough approximation to the desired result was attained by setting down the percentages of the prices of the leading commodities in each series, and averaging them before them, and adding them together algebraically. The total with its proper sign was then divided by the number of articles, and the quotient represented the movement in the prices of the series. It is easy to see how this was done. It was not, however, so far being that of Sir Robert Giffen, whose index numbers were obtained from the declared values of the imports or exports into or from the United Kingdom of the articles whose prices are recorded. These, however, are not susceptible of further improvement, and are of great value; owing to the frequency of their appearance they make it possible to watch the tendency of prices closely.

The Unenumerated Articles.—One of the least serious difficulties in connexion with statistical investigations is the variety of the modes in which prairies of the same order are obtained, as regards dates and periods. This is a matter of which all persons who have occasion to use statistics are made painfully aware from time to time. Some attempts have lately been made to introduce more harmony into the official statistics of the United Kingdom. The attempt is to be commended, but it is not at all certain that the result will be as satisfactory as it is hoped. The attempts to the treasury sat in to inquire into the matter. The committee received a good deal of evidence, and presented a report, from which, however, certain members of the committee dissented, infecting the general character of the evidence. This is by no means the least interesting of all who wish to obtain an insight into the genesis of the official statistics of the country.

The International Institute of Statistics.—The absence of uniformity of time in England is to some extent ma-
STATIUS, PUBLIUS PAPINUS

grounds. Since then assurances of a satisfactory kind have been given to the German government that their servants would be in no way committed to any course disapproved by that government if they were to give evidence in the course of the trial of any of which it is hoped that much advantage may result. For information as to the constitution and objects of the Institute reference may be made to a paper by the late Dr F. X. von Neumann, Spamer, published in the Annalen der Böhmischen Gesellschaft de statistique (Rome, 1886). Meetings of the Institute have been held annually ever since its formation in various cities of the world.

Such statements as the one just quoted, while without invoking the odour of the menace of fifty years ago, had taken the full measure of Domitian's gross taste, and, presenting him with the rododendron which he loved, puts conscience and sincerity out of view, lest some uneasy twinges should mar his master's enjoyment. But in one poem, that in which the poet pays his due for an invitation to the Imperial table, we have sincerity enough. Statius clearly feels all the raptures he expresses. He longs for the power of him who told the tale of Dido's banquet, and for the voice of him who sang the feast of Alcinoos, that he may give forth utterance worthy of the lofty theme, though it would be hard to find a more suggestive example of real poetical talent defied for personal ends. Everything points to the conclusion that Statius did not survive his emperor—that he died, in fact, a short time after leaving Rome to settle in Naples. Apart from the emperor and his minions, the friendships of Statius with men of high station seem to have been maintained on fairly equal terms. He was clearly the poet of society in his day as well as the poet of the court.

As poet, Statius unquestionably shines in many respects when compared with most other post-Augustans. He was born with exceptional talent, and his poetic expression is, with all its faults, richer on the whole and less forced, more buoyant and more felicitous, than is to be found generally in the Silver Age of Latin poetry. Statius is at his best in his occasional verses, the Silvae, which have a characteristic of their own, and in their best parts a charm of their own. The title was proper to verses of rapid workmanship, on everyday themes. Statius prided himself on his powers of improvisation, and he seems to have been quite equal to the feat, whether describing a battle, the flight of Troy, or a goddess being born while standing on one leg. The improvisor was in high honour among the later Greeks, as Ciceron's speech for the poet Archias indicates; and the poetic contests common in the eastern world did much to stimulate ability of the kind. It is to their velocity that the poems owe their comparative freshness and freedom, along with their loose texture and their inequality. There are thirty-two poems, divided into five books, each with a dedicatory epistle. Of nearly four thousand lines which the books contain, more than five-sixths are hexameters. Four of the pieces (containing about 450 lines) are written in the hendecasyllabic metre, the tiny "Lauda Svei," "To the Child Hermes," and "One Song of Sadness." The subjects of the Silvae are very various. Five poems are devoted to flattery of the emperor and his favourites; but of these enough has already been said. Six are for the dead, or dedications to survivors. Statius seems to have felt a special pride in this class of his productions; and certainly, notwithstanding the excessive and conventional employment of pretty mythological pictures, with other allusions, he sounds notes of pathos from him, so that the son inherited a debt of gratitude, seems to have no solid foundation. Statius lauds the emperor, not to discharge a debt, but rather to create an obligation. His flattery is as far removed from the gentle propitiatory tone of Quintilian as it is from the coarse and crawling humiliation of Marzial. It is in the large extravagant style of a nature in itself healthy and generous, which has accepted the theme and left scruples behind. In one of his prefatory epistles Statius declares that he never allowed any work of his to go forth without involving the head of the wine god. He...
such as only come from the true poet. There are oftentimes traits of an almost modern domesticity in these verses, and Statius, the child-

less, has here and there touched on the charm of childhood in lines for a parallel to which, among the ancients, we must go, strange to say, to the childhood of Virgil. One of those curious descriptions of the wife of Abasancus, Domitian's freedman (Silv. v. 1), is full of interest for the picture it presents of the official activity of a high

officer of state. Another group of the Silvae give picturesque descriptions of the pomp and grandeur of imperial Rome, and in these we have a more vivid representation than elsewhere of the surroundings amid which the grandees of the early empire lived while they were abed or reclining. It is a very striking fact that the pieces that Niebuhr thought when he said that the poems of Statius are charming to read in Italy. They exhibit, better even than Pliny's well-known letters, the passion of the rich Roman for so convenient a home as a house of his own, and he should have displayed all the resources of art which his wealth enabled him to command. As to the rest of the Silvae, the congratulatory verses to Hostius are graceful but commonplace, nor do the jocose pieces call for special mention here. In the "Kalendae decembres" we have a striking description of the gifts and amuse-

ments provided by the emperor for the Roman populace on the occasion of the Saturnalia. In his attempt at an epistemium (Silv. i. 2) Statius is forced and unhappy. But his birthday ode in Lucan's honour (Silv. ii. 7) has, along with the accustomed exemption of the laurel-wreathed hero, an air of elegance and grandeur. The most striking and by far the most successful of preceding Latin poets. Some phrases, such as "the untapped muse of high-souled Ennius" and "the lofty passion of sage Lucretius," are familiar words with all scholars. The ode ends with a prayer that the poet's spirit may have a lasting fame to regions whiter only powerful souls can ascend, scornfully surveying earth and smiling at the tomb, or reclining in Elysium and laughing at him. As the king's eyes have pierced the "Pharsalian host," or with proud tread exploring Tartarus and listening to the wailings of the guilty, and gazing at Nero, pale with agony as his mother's avenging torch glittered before his eyes, and then with the nation's suffocating voices, the "bald Nero" took no unbrage when his flatterer-in-chief profanely dealt with his predecessor's name.

The poems of Statius are less interesting because cast in a commoner mould, but they deserve study in many respects. They are the product of long elaboration. The Thebais, which the poet says took twelve years to compose, is in twelve books, and has for its subject the tale of Thebes and the fate of its dead heroes. There are also preserved a fragment of an Achilleis, consisting of one book and part of another. In the weary length of the epics there are many numbers of pathos and many little finished gem-pictures, but the trammels of tradition, the fashionable taste and the narrow bars of education check continually the poet's flight. Not merely were the materials for his epics prescribed to him. In the case of these he also to the utmost the method by which they were to be treated. All he could do was to sound the old notes with a distinctive timbre of his own. The gods must needs wage their wonted epic strife, and the men, their puppets, must dance to the music of the immortal poets. Statius must therefore supply the missing elements, dreams, miracles, single combats, similes, Homerie and Virgilian echoes, and all the other paraphernalia of the conventional epic, to make his subject a work of art in itself, incomparably a greater work of art than that of his predecessors, which contrast pleasingly with the timid traditionalism of Sililius Italicus and the stiff scholasticism of Valerius Flaccus. The vocabulary of Statius is conspicuously rich, and he shows audacity, often successful, in the use of words and metaphors. At the same time he carried certain literary tricks to an aggravating pitch, in particular the excessive use of alliteration, and the misuse of mytho-

logical allusion. The most well-known persons and places are described by epithets or paraphrases derived from some very remote connexion with mythology, so that many passages are as dark as Heraclitus. The Thebais is badly constructed, the action of the epic is often broken by the digressions, the composition is unsatisfactory, and fills one-sixth of the poem. Nor had Statius a firm grasp or clear imagination of character. So trying are the late ancient epics to a modern reader that he who has read any one of the three great Statian epics is not likely to enter with any difficulty to enter on the other two. Yet, if he honestly reads them all, he hardly fails to rank Statius the highest of the three by a whole sphere.

The Stilbelas is the more interesting because the epic is dated 1470, of the Silvae 1472. Notable editions since have been those of Bernartius (Antwerp, 1595), Gronovius (1653) and Barth (1664). Recent texts are the Teubner (the Achilleis and Thebais by Kohlmann, the Silvae by Cassel). Statius's works were first printed in 1478 in the editio latinarum; and of the Silvae only, texts by Klotz (1899), and Vollmer (1883), the last with an explanatory commentary. Among editions of the poems there are not many works, of which that of J. J. J. Jenneret, of Geneva (1728), deserves special attention. A translation of the Silvae with introduction and notes was published by D. A. Slater in 1908 (Oxford

Library of Translations). A critical edition of the Thebais and Achilleis was begun by O. Muller (1870) but not completed. The condition of the text of the Silvae is one of the most curious facts in the history of ancient literature. Poggio discovered a MS. at St Gallen and brought it into Italy. This MS. has disappeared, but from it are derived all our existing MSS., except one of the birth-
day ode to Lucan, now at Florence, and of the 10th century. Politian collated Poggio's MS. with the editio princeps, and the collation was also made by the poet himself in the MS. of this text. The MSS. of the epics are numerous, as was to be expected from their great popularity in the middle ages, to which Dante is witness when he says (Par. xxiii. 94): "If I should interview with the shade of Statius (as described at some length)."

**STATUTE**, a law made by the "sovereign power" in the state (see ACT OF PARLIAMENT). It forms a part of the lex scripta, or written law, which by English legal authorities is used solely for statutory law, a sense much narrower than it bore in Roman law. To make a statute the concurrence of the Crown and the three estates of the realm is necessary. Thus a so-called statute of 5 Ric. II. c. 5, directed against the Lollards, was afterwards rendered void by the Commons as passed without their assent. The validity of a statute was indeed at times claimed for ordi-
nances such as that just mentioned, not framed in accordance with constitutional rule, and was actually given to royal pro-
clamations by 33 Hen. VIII. c. 8 (1539). But this act was repealed by 1 Edw. VI. c. 12, and since that time nothing but a statute has possessed the force of a statute, unless indeed cer-
tain rules or orders depending ultimately for their sanction upon a statute may be said to have such force. Examples of what may be called indirect legislation of this kind are orders in council, or acts of Privy Council (see PRIVY COUNCIL), by-laws made under the powers of the Public Health Acts, Municipal Corporations Acts, and other Acts, and rules of court such as those made under the powers of the Judicature Acts and Acts of Sedentum of the Court of Sess-

The list of English statutes as at present existing begins with the Statute of Merton, 1235. Many of the earlier statutes are known by the names of the places at which they were passed, e.g. the Statutes of Merton, Marbridge, Gloucester, Westminster, or by their initial words, e.g. Quo Elapromis, Circumspetae Agatis. The earliest existing statute roll is 6 Edw. I. (the Statute of Glouce-
erestered). After 4 Hen. VII. the statute roll ceased to be made up, and enrolments in chancery (first made in 1489) take its place. Some of the acts prior to the Statute of Gloucester are of questionable authority, but have gained recognition by a kind of prescription.

All statutes were originally public, irrespective of their subject-
matter. The division into public and private dates from the reign of Richard III. At present statutes are of four kinds, public general acts, public local and personal acts, private acts printed by the king's printers and private acts not so printed. The division into public general and public local and personal rests upon a resolution of both Houses of Parliament in 1798. In 1815 a resolution was passed in accordance with which private acts are printed, with the exception of name, estate, naturalization and divorce acts. The last two are now practically superseded by the provisions of the Divorce Act 1857 (except as to Ireland and India), and the Naturalization Act 1870. Since 1815 it has been usual to refer to public general acts by Arabic numerals, e.g. 3 Edw. VII. c. 21, public local and personal acts by small Roman numerals, e.g. 3 Edw. VII. c. xxi. Each act is strictly but a chapter of the legislation of the session, which is regarded as composing a single act divided into chapters for convenience, the chapters themselves being also called acts. The citation of previous acts is provided for by 13 and 14 Vict. c. 21, § 3. It is now usual for each chapter or act to contain a short title by which it may be cited, e.g. the Elementary Education Act 1870. The Short Titles Act 1892 created short titles for numerous single acts and groups of acts, and since then it has been usual to cite acts and groups by their short titles—where possible.
rather than by the year of the reign. 8 & 9 Vic. c. 113, s. 3, makes evidence the king's printers' copies of private and local personal acts. A private act not printed by the king's printers is proved by an examined copy of the parliament roll. A public act binds all subjects of the realm, and need not be pleaded (except where the law from motives of policy specially provides for pleading certain acts, as in the defences of not guilty by statute, the Statute of Frauds and Act of Settlement Limitations). A private act must generally be pleaded, and does not as a rule bind strangers to its provisions. Formerly an act took effect from the first day of the session in which it was passed. The hardship caused by this technical rule has been obviated by 33 Geo. III. c. 13, by which an act takes effect from the day on which it receives the royal assent, where no other date is named. This has been held to mean the beginning of the day, so as to govern all matters occurring on that day. An act cannot in the strict theory of English law become obsolete by disuse. Nothing short of repeal can limit its operation. The law has, however, been interpreted in many cases with somewhat less rigour. In the case of a prosecution for blasphemy in 1883 (R. v. Ramsey) Lord Coleridge said, "though the principles of law remain unchanged, yet (and it is one of the advantages of the common law) their application is to be changed with the changing circumstances of the times." This would be applicable as much to the interpretation of statutes as to other parts of the common law. The title, preamble and marginal notes are strictly not a part of a statute, though they may at times aid its interpretation.

Besides the fourfold division above mentioned, statutes are often classed according to their subject-matter, as perpetual or temporary, general or local, benefactive and prohibitive, declaratory, enabling and disabling. Temporary acts are those which expire at a date fixed in the act itself. Thus the Army Act is passed annually and continues for a year; the Ballot Act 1872 expired at the end of 1886, and the Regulation of Railways Act 1873 at the end of five years. By means of these temporary acts experimental legislation is rendered possible in many cases where the success of a new departure in legislation is doubtful. In every session an Expiring Laws Continuance Act is passed for the purpose of continuing (generally for a year) a considerable number of these temporary acts. By 48 Geo. III. c. 106 a continuing act is to take effect from the date of the expiration of a temporary act, where a bill for continuing the temporary act is in parliament, even though it be not actually passed before the date of the expiration. Penal acts are those which impose a new disability; beneficial, those which confer a new favour. An imperative statute (often negative or prohibitory in its terms) makes a certain act or omission absolutely necessary, and subjects a contravention of its provisions to a penalty. A directory statute (generally affirmative in its terms) recommends a certain act or omission, but imposes no penalty on non-observance of its provisions. To determine whether an act is imperative or directory the act itself must be looked at, and many nice questions have arisen on the application of the rule of law to a particular case. Enabling statutes are those which enlarge the common law, while disabling statutes restrict it. This division is to some extent coincident with that between beneficial and penal. Declaratory statutes, or those simply in affirmation of the common law, were at one period not uncommon, but they are now practically unknown. The Treason Act 1351 is an example of such a statute. Statutes are sometimes passed in order to overrule specific decisions of the courts. Examples are the Treason Act 1678, the Territorial Waters Jurisdiction Act 1878, the Married Women's Property Act 1893, the Trade Disputes Act 1906.

The construction or interpretation of statutes depends partly on the common law, partly on statute. The main rules of the common law, as gathered from the best authorities, are these:

1 This opinion carries out to a certain extent the view of Locke, who in article 79 of his Carolina Code recommended the determination of acts of the legislature by effluxion of time after a hundred years from their enactment.
of the Scottish parliament may in certain cases cease to be binding by desuetude. "To bring an act of parliament like those we are describing into conflict with a statute" (acts) "is called in Scots law the condition of desuetude, it must be shown that the offence prohibited is not only practised without being checked but is also longer continued in the country than in Scotland, and is in any case against law." (Lord Justice General Inglis in Bute's case, 1 Couper's Rep., 495). Acts of the imperial parliament passed since the union extend in general to Scotland, unless that country be excluded from the benefit of the act by special exception. Generally speaking, if acts are cited thus, 1678, c. 10. The best edition is that issued by order of the Treasury, 1844-1875. An edition of the revised statutes has been facilitated by the repeal of obsolete statutes by the Statute Law Revision (Scotland) Act 1906.

Ireland.

Originally the lord deputy appears to have held parliaments at his option, and their acts were the only statutory law which applied to Ireland, except as far as judicial decisions had from motives of policy extended to that country the obligation of English statutes. In 1495 the act of the Irish parliament known as Poynings' Law or the Statute of Drogheda enacted that all statutes lately made in England be deemed good and effectual in Ireland. This was construed to mean that all statutes made in England prior to the 18 Hen. VII. were valid in Ireland, but none of later date were to have any operation unless Ireland were specially named therein or unless adopted by the Irish parliament (as was done, for instance, by Yelegrem. 12 Hen. VIII. c. 22 Geo. III. c. 38). Another article of Poynings' Law secured an initiative of legislation to the English privy council, the Irish parliament having simply a power of acceptance or rejection of proposed legislation. The power of the parliament was long regarded as making laws, but the prerogative of Ireland was declared by 6 Geo. I. c. 5. This act and the article of Poynings' Law were repealed in 1782, and the short-lived independence of the parliament of Ireland was declared. (See Eastern Act of 1779, by 5 Geo. III.) Articles of accession made since the union is the same as in the case of Scotland. Divorce acts are still passed for Ireland (see DIVORCE). Irish acts are cited thus, 26 Geo. III. c. 15 (1) or (1r). The best edition is that issued in twenty volumes pursuant to an order of the earl of Halifax, lord-lieutenant in 1762. A volume of revised statutes was published in 1885. The earliest that is still law is one of 1459.

British Colonies and Dependencies.

Acts of the imperial parliament do not extend to the Isle of Man, the Channel Islands or the colonies, unless they are specially named therein. By the Colonial Laws Validity Act 1865 ("the charter of colonial legislative independence") any colonial law repugnant to the provisions of any act of parliament extending to the colony is void to the extent of such repugnancy, and no colonial law is to be void by repugnancy to the law of England unless it be repugnant to such an act of parliament. For colonies without representative legislatures the Crown usually legislates, subject to the consent of parliament in particular cases. Examples of imperial legislation for the colonies in general are the Colonial Secretny Act 1799, 4 Geo. III. c. 107 (see Colonial Office). For imperial acts dealing with particular colonies may be cited the British North America Act 1867, and the Commonwealth of Australia Constitution Act 1900. A colony is defined for the purposes of imperial legislation under the Intercolonial Act 1899, 17 Geo. V., and many of the colonies, as in Canada, the constitutionality of an act of the colonial legislature is, as in the United States, a matter for the determination of the local court or of the judicial committee of the privy council on appeal.

United States.

By the constitutions of many states English statute law, as it existed at the time of the separation from England, and as far as it is applicable, has been adopted as part of the law of the states. The United States and the state are not bound by an act of Congress or a state law unless specially named. The state of Ohio, for instance, limits the use of the law of the United States to the interpretation of the state constitution and that of the United States. Here appears the striking difference between the binding force of a statute of the United Kingdom and an act passed by Congress or a state legislature. In the United Kingdom parliament is supreme; in the United States an act is only of authority if it is in accordance with the constitution. The courts may declare an act void if it contravenes the constitution of the United States or of a state, so that practically the Supreme Court of the United States is the ultimate legislative authority. The restrictions upon the legislative powers of the United States are in several states provide against the suspension of the writ of habeas corpus except in case of rebellion or invasion, the passing of a bill of attainder or ex post facto law, the imposition of capital or other direct tax, unless in proportion to the several states, or of a tax or duty on exports, the preference of the ports of one state over those of another, the drawing of money from the treasury except by appropriations made by law, and the grant of a title of nobility. Constitutional amendments contain further stipulations, e.g. the taking of private property for public use without just compensation, and the abridging of the right of citizens on account of race, colour or previous condition of servitude. State legislation is limited by s. 10: "No state shall . . . make anything but gold and silver coin a tender in payment of debts, pass any bill of attainder, ex post facto law, or law impairing the obligation of contracts, or grant any title of nobility." This section further forbids imposition of duties on imports or exports or any duty of tonnage without consent of Congress. State constitutions often contain further restrictions, among the more usual are provisions against laws with a retrospective operation, or impairing the obligation of contracts, or dealing with more than one subject to be expressed in the title. The time when a statute is to take effect after its passing is often fixed by state constitutions. The statutes of the United States were revised under the powers of an act of Congress passed in 1874 (sess. i. c. 333), and the volume of Revised Statutes was issued in 1875. There was a second edition in 1878 and several supplements have appeared since that date. Many of the states have also issued revised editions of their statutes. The rules of construction are generally general agreement with those adopted in England. In some states the referendum has been introduced in certain cases.

Continental European Countries.

In most European countries there is a code, the existence of which makes the system of legislation hardly comparable to ours. The assent of two chambers and of the monarch, or president, is generally necessary. Greece is an exception; it is only the state in Europe with one chamber.

International Law.

The term "statute" is used by international jurists and civilians mostly on the continent of Europe to denote the whole body of the laws of a state, comprehended within this sense. In this article the term is used in a more restricted sense; and it may mean either a statute passed in a country having a code, or a personal or mixed. A real statute is that part of the law which deals directly with property, whether movable or immovable. A personal statute has for its object a person, and deals with questions of status, such as marriage, legitimacy or infancy. A mixed statute affects both property and person, or, according to some authorities, it deals with acts and obligations. Personal statutes are of universal validity; real statutes have no extra-territorial authority. The determination of the class under which a particular law ought to fall is one of great difficulty, and one in which there is often a conflict of legal opinion. On the whole the division appears to have created more confusion than it has solved, and it is rejected by Savigny as unsatisfactory.

**STATUTE MERCHANT AND STATUTE STAPEl**, two old forms of security, long obsolete in English practice, though references to them still occur in some modern statutes. The former security was first created by the Statute of Acton Burnell (1283) and amplified by the Statute of Merchants (1285)—whence its name—and the latter by an act of 1353, which provided that in every staple (i.e. public mart) the seal of the staple should be sufficient validity for a bond of record acknowledged and witnessed before the mayor of the staple. They were originally permitted only among traders, for the benefit of commerce, but afterwards extended by an act of Henry VIII. (1532) to all subjects, whether traders or not. The creditor under either form of security was allowed to seize the goods and hold the lands of a defaulting debtor until satisfaction of his debt. While he held the lands he was termed tenant by statute merchant or by statute staple. In addition to the loss of his goods and lands the debtor was liable to be imprisoned. Statute merchant, owing to the summary method of enforcing payment, was sometimes known as "pocket judgment." Both were repealed by the Statute Law Revision Act 1865.

**STAUNTON, SIR GEORGE THOMAS, Bart.** (1751-1859), English traveller and Orientalist, was born near Salisbury on the 26th of May 1751. He was the son of Sir George Leonad.
Staunton (1737-1801), first baronet, diplomatist and Orientalist, and in 1792 accompanied his father, who had been appointed secretary to Lord Macartney's mission to China, to the Far East. He acquired a good knowledge of Chinese, and in 1798 was appointed a writer in the East India Company's factory at Canton, and subsequently its chief. In 1805 he translated a work of Dr George Pearson into Chinese, thereby introducing vaccination into China. In 1816 he proceeded as second commissioner on a special mission to Pekin with Lord Amherst and Sir Henry Ellis. Between 1818 and 1832 he was M.P. for several English constituencies, finally for Portsmouth. He was a member of the East India Company's Council of War in 1823, in conjunction with Henry Thomas Colebrooke founded the Royal Asiatic Society. He died on the 10th of August 1830.

His publications include translations of Ta Tsing lew lee, being the Fundamental Laws of China (1810), the first Chinese book translated into English, and of the Narrative of the Chinese Embassy to the Khan of the Toungou Tartars (1821); Miscellaneous Notices Relating to China and our Commercial Intercourse with that Country (1822); Notes of Proceedings and Occurrences during the British Embassy to Peking (1824); Observations on our Chinese Commerce (1850). For the Hakluyt Society he edited Gonzalez de Mendoza's History of the Great and Mighty Kingdom of China.

STAUANTON, HOWARD (1810-1874), English Shakespearean scholar and writer on chess, supposed to have been a natural son of Frederic Howard, fifth earl of Carlisle, was born in 1810. He is said to have studied at Oxford, but if so, he never matriculated. Settling in London he soon spent the small fortune left him under his father's will and began to make his living by journalism. He gave much of his attention to the study of the English dramatists of the Elizabethan age. As a Shakespearean commentator he showed the qualities of acute-ness and caution which made him excel in chess. He possessed, moreover, a thorough mastery of the literature of the period, shown in his papers in the Athenaeum on "Unsuspected Corruptions of Shakespeare's text," begun in October 1872. These formed part of the materials which he intended to utilize in a proposed edition of Shakespeare which never became an accomplished fact. In 1864 he published a facsimile of the Shakespeare folio of 1623, and a facsimile edition of Much Ado about Nothing, photolithographed from the quarto of 1600. He died in London on the 22nd of June 1874. Staunton's services to chess literature were very great, and the game in England owes much of its later popularity to him, while for thirty years he was the best chess player in England, perhaps in the world. For his important works on the subject see Chess.

STASTANTON, an independent city and the county-seat of Augusta county, Virginia, U.S.A., about 135 m. N.W. of Richmond. Pop. (1890) 6075; (1900) 7289, including 1828 negroes and 149 foreign-born; (1910) 10,604. Staunton is served by the Chesapeake & Ohio and the Baltimore & Ohio railways. It lies between the Allegheny Mountains and the Blue Ridge, on a plateau about 1350 ft. above sea-level, in a fertile farming country with good pasture on the hillsides. In Staunton are a county court-house, the Western Virginia hospital for the insane (1889), the hospital for the deaf and the blind (1835), the King's Daughters' hospital (1895), Dunsmore business college, Staunton military academy, the Mary Baldwin seminary, formerly Augusta female seminary (founded in 1842) and Stuart Hall (for girls), which was founded in 1843, was incorporated in 1845, and was reincorporated in 1907 under its present name in honour of Mrs J. E. B. Stuart, wife of the confederate cavalry leader, who was its principal in 1870-1868. One mile east of Staunton is a U.S. national military cemetery with graves of 753 Union soldiers killed at Port Republic, Cross Keys, and Loudonville, and west of the city is a Confederate cemetery with a memorial monument. The municipality owns the waterworks, the electric-lighting plant and the opera house. An interesting feature of the city government is the employment of a business manager (elected annually by the city council), whose duties are in general similar to those of the business manager of a large corporation—e.g. he buys the city's supplies and has general supervision over the city improvements.

The first settlement in this vicinity was on Lewis Creek, about 2 m. east of the city, in 1731. A county court-house was built here in 1745, and the name Staunton, in honour of the wife of Sir William Gooch (then lieutenant-governor), whose maiden name was Staunton, was used in 1748-1749, but Staunton was not incorporated as a town until 1761. It was chartered as a city in 1870, and then became a municipality independent of the county. The corporate limits of the city were extended in 1903 and, as its population thus became more than 10,000, Staunton was made a city of the first class.

STAUROULITE, a mineral consisting of basic aluminium and ferrous iron silicate with the formula $\text{Al}_2\text{FeSi}_2\text{O}_8$. The material is, however, usually very impure, the crystals enclosing sometimes as much as 30 or 40% of quartz and other minerals as well as carbonaceous matter. Crystals are orthorhombic and have the form of six-sided prisms. Interpretating crustum-form twinned crystals are very common and characteristic; they were early known as piers de croix or lapis crucifer, and the name staurolite, given by J. C. Delamethier in 1792, has the same meaning (Greek, σταυρός, a cross, and λίθος, a stone). In fig. 1 the twin-plane is (032) and the two prisms intercross at an angle of 91° 22'; in fig. 2 the twin-plane is (232) and the prisms intercross at nearly 60°. The mineral is translucent to opaque and dark reddish-brown in colour; it thus has a certain resemblance to garnet, and on this account has been called grenatite. Waterworn pebbles of material sufficiently transparent for cutting as gem-stones are occasionally found in the diamantiferous sands of Brazil. The hardness is 73 and the specific gravity 3.75. Staurolite is a characteristic mineral of crystalline schists, and it is also a product of contact-meta-morphism. Large twinned crystals with rough surfaces are found in mica-schist in Brittany and at several places in the United States, e.g. in Fannin county, Georgia. Untwinned crystals, translucent and of a rich brown colour (grenatite), are abundant in the silvery white paragonite-schist of Monte Campione, St Gothard.

(L. J. S.)

STAVANGER, a seaport of Norway, capital of Stavanger amit (county), on the west coast in 59° N. (that of the Orkney Islands and northern Labrador). Pop. (1900), 30,541. It lies on the south side of the Bukken Fjord, and has a picturesque harbour well sheltered by islands. The town is one of the oldest in Norway, founded in the 8th or 9th century, but the present town is modern, though narrow, winding streets and wooden houses give it an antique appearance. It became the seat of a bishopric in the 13th century. Though the bishop's see was removed to Christiansand in 1685, the Romanesque cathedral church of St Swithun, founded by the English bishop Reinold in the end of the 11th century, and rebuilt after being burned down in 1275, remains, and, next to the cathedral of Trondheim, is the most interesting stone church in Norway. There is an ornate painted pulpit of carved wood (1658). The old episcopal palace of Kongsgaard is now a Latin school. There are a theatre, an interesting museum of antiquities, natural history and art; and a picturesque park (Bjergsted). The industries of the town and its environs (Sandnaes, &c.) are prosperous, including factories for preserved foods, woollens and linens, lime, iodine from seaweed, and domestic commodities. The
fisheries are important—for herring, mackerel, sprats, cod, salmon, lobsters and anchovies. On Rennes Island in the fjord, over against the town, there is a Cheviet sheep-breeding farm under government auspices. The imports consist principally of coal, salt, grain and flour, groceries, textiles, wood, and mineral oils. The most important export is fish, other items being seaweed, marble, preserved foods, butter and margarine and insular oil.

Staveley is the first of a group of coal fields north of the Derwent and Newcastle, and has regular services from all the Norwegian coast towns, from Hamburg, &c. A railway runs south along the wild and desolate coast of Jaerden, one of the few low and unprotected shores in Norway, the scene of many wrecks. Stavanger commands a considerable tourist traffic. It is the starting-point of a favourite tour, embracing the fine valley of the Sand River, the great Lake Suldal and the Bratlandsdal. The Lyse Fjord, a branch of the Buikken Fjord, is a fine narrow inlet enclosed by precipitous mountains.

Staveley is the birthplace of Kjelland the novelist (1849).

STAVELEY, a town in the north-western parliamentary district of Derbyshire, England, 12 m. S.E. of Sheffield, on the Midland and the Great Central railways. Pop. (1901), 7,420. It lies in the valley of the Rother, in a populous industrial district, devoted chiefly to the working of coal and iron; while there are manufactures of iron goods and brushes in the town. The church of St John the Baptist is Early English, with much Perpendicular and modern alteration; it contains a number of interesting early monuments.

STAVELOT, an ancient town of Belgium, in the south-east of the province of Liège. Pop. (1900), 5,037. Here Charles Martel gained a signal victory over Neustria in 719. A monastery had been established there half a century earlier by St Remacle, bishop of Tongres. The prince-abbot of Stavelot exercised secular authority over many towns in the Ambîlée and Warce valleys, including Malmedy (now in Prussia), and had a seat in the old German Diet. In 1815 the treaty of Vienna broke up the Stavelot principality, giving half to Prussia and half to the Netherlands. Only the tower of the old Benedictine abbey remains, and the shrine of St Remacle is preserved in the parish church.

STAVROPOL, a government of northern Caucasus, Russia, having an area of 26,692 sq. m., and bounded by the government of Astrakhan and the territory of the Don Cossacks on the N., by Kuban on the W. and by Terek on the S. and E. It occupies the eastern part of the broad steppes which stretch away north from the foot of the main chain of the Caucasus. The western part of the government is diversified by a broad undulating swelling, 1,500 to 2,000 ft. above sea-level; in the southern part of this swelling, and principally in Terek, there is a group of sixteen mountains, the Beshtau, 2,800 to 4,000 ft. in height, which are considered by H. Alīch to be a porphyritic upheaval at the point of intersection of the two predominant orographical lines in the Caucasus (south-west to north-east and south-east to north-west). Northward and eastward of these heights are extensive steppes, 200 to 400 ft. above the sea, having gentle slopes both to the north (to the depression of the Manych) and to the east (towards the low, arid shores of the Caspian Rißtal).

Stavropol is chiefly drained by the Kuma and its tributaries (Karamyk and Bulvo), its basin being the most fertile part of the government, but the evaporation is so great that the Kuma never reaches the Caspian except in spring. The Manych is not so much a river as a series of lakes, occupying a depression which formerly was a water-tracking channel between the Black Sea and the Caspian. This channel has two slopes, the eastern sometimes discharging its scanty water-supply into the Kuma, while on the western slope the elongated lakes which fill up the depression drain into the Don, running through several reservoirs (the Okhta, the Voskhod, and Middle), the Kalasu, and the Chogra (temporary tributaries of the Manych), drain the western part of Stavropol. On the whole, irrigation is restricted, and in the eastern steppes water is supplied only by the lakes of the Manych depression; there are many smaller salt lakes along the Caspian. Timber is scarce, even in the hilly tracts.

The climate is marked by rapid changes of temperature. The dry east winds are sometimes very violent in the spring and early summer, blowing the seeds out of the fields, and even destroying in a few days all existing vegetation. In July and August they are frequently succeeded by several hot and dry days. The average temperatures at the town of Stavropol (altitude 2030 ft.) are much lower than one might expect in that latitude; that for July is 71° F., and that for January is 19° F. The rainfall at Stavropol is 28·2 in., but other parts of the government are much worse off in this respect, the yearly rainfall being only 11 to 21·4 in.

There is a great lack of forests, which are found only near the town of Stavropol and alongside of the main rivers. In the prairies the only arboreal vegetation is tamarisks and the dwarf almond tree. Altogether, except in the hilly parts of the government, the flora and fauna differ from a great extent from the steppes and plains of the western parts of the Caucasus. Both resemble, on the one hand, those of Central Asia in such features as the presence, among mammals and birds, of the antelopes, the gazelle, the chevrotain, the visons, the corsac, Pallas, and the lark Melanocorypha tatarica, Pallas, and among plants, of firstly Tamarix Pallasii, Statice caspia and Sisfa leastigniana (all characteristic of the arid prairies beyond the Urals), and secondly of species of Salix, Salsola, Stipa, Artemisia, Kochia and Camphorosma, all characteristic of the salt steppes of Asia; on the other hand, both flora and fauna have many features in common with the prairies of south Russia.

As regards geology, the whole of the government is covered with Tertiary and post-Tertiary deposits. Lower Miocene, Middle-Mediterranean deposits, and Sarmatian clays, limestones and sandstones of both the eastern and the western terraces, which rest, namely, in its higher portion, while the remainder is buried under loess and fluvial and lacustrine deposits. A narrow zone, now a low plain almost devoid of vegetation, is overlain with the so-called Cretaceous deposits.

The population is rapidly increasing, particularly from natural causes, and partly in consequence of immigration. In 1886 it was 792,035; in 1897, 879,758; and in 1906 was estimated at 1,023,700. The average density of the population is only 44 per sq. m., but in some districts it rises to 87. Russians form 90% of the population, the other races being Kalmecks, Turkomans, Naghi Tatars, Avars, Georgians, Germans, Poles, &c. More than four-fifths of the population (81%) are Russian peasants. The nomad population occupies, however, more than one-third of the territory. There are four ordinary districts, the centres of administration in which are: Aleksandrovsk, the capital of the district and chief town of the district of Novo-gryazevsk; besides these the territory occupied by the nomads is divided into three districts, Bolshe-Derbetovskiy, Turkomans and Achikulak.

Agriculture is the most important occupation of the settled population, and so large is the harvest that no less than 16,000 labourers come annually from European Russia to assist in gathering the crops. The peasants own some 48% of the total area, private persons 7% the imperial government 2% and the Crown less than 2%. Agriculture is most successful on the wide prairie lands, where 3,250,000 acres are annually under cereals. The principal crop is wheat, where 1,023,700 m. have been sown, and barley, 284,000 m., and oats, 16,000 m. Maize, flax, potato, melons, flax and sunflowers are widely cultivated. Modern agricultural implements are in general use. Vineyards stretch for close upon 100 m. along the Kuma, and nearly 800,000 gallons of wine are produced annually. The quality of the wines varies, being limited to flour-mills, oil-mills, distilleries, tanneries and candle works, and a few domestic industries are carried on in the villages. Wool is spun and woven, but the manufacture is small and the fairs are animated. Large amounts of corn are exported both to the mountainous districts of Caucasus and to Russia (Rostov-on-the-Don). Livestock breeding is engaged in very largely, not only by the Kalmecks, Turkomans and Naghi Tatars, but also by the Russians.

The northern slopes of the Caucasus began to be colonized by the Russians at a very early period, and as early as the 11th century a Russian military territory was set up by the Moscovite princes. This attempt to colonize North Caucasia was made in the 17th Century, under the name of the Tmutarakan principality, which had Russian princes. This attempt was again unsuccessful, and it was not till 1711 that Russia began regularly to colonize the territory by Cossack settlements. Kizlyar was founded in 1736, Stavropol in 1776 and 1777. The whole of the land was granted to the Cossacks by the Tsar, and his courtiers, who began to people them with serfs from Russia.

STAVROPOL, a town of southern Russia, capital of the government of the same name, situated on a plateau 2030 ft. above the sea, on the northern slope of the Caucasus, 200 m. N.W. of Vladikavkaz. It is connected by rail (247 m.) with Rostov-on-the-Don. Although founded only in 1776, it has grown rapidly, and had in 1855 a population of 35,561, and of 45,965 in 1900. Stavropol is an episcopal see of the Orthodox Greek Church, and one of the best-built provincial towns of the

(P. A. K. J. T. B.)
Russian Empire, having wide streets, and houses mostly of stone, with large gardens surrounding the houses. There are public libraries, a people’s palace and several scientific societies. Stavropol has flour-mills and various small factories. Large numbers of cattle are sent to Moscow and St Petersburg, while cereals, tallow and sheepkins are exported to Russia, and manufactured wares imported. Armenian, Georgian and Persian merchants carry on a lively trade in local wares.

**STAWELL, SIR WILLIAM FOSTER** (1815-1880), British colonial statesman, was the son of Jonas Stawell, of Old Court, in the county of Cork, and of Anna, daughter of the Right Rev. William Foster, bishop of Clogher. He was born on the 18th of June 1815, and educated at Trinity College, Dublin, where he read law at King’s Inn, Dublin, and Lincoln’s Inn, and was called to the Irish bar in 1839. He practised in Ireland until 1842, and then, making his home in Australia, was admitted to the Melbourne bar in 1843. He engaged extensively in pastoral pursuits, and had sheep stations at Natte Yallock, on the banks of the river Avoca, and in the neighbourhood of Lake Wallace, near the South Australian border. For many years he enjoyed the leading practice at the local bar, and when the Port Phillip district of New South Wales was separated from the parent colony, and entered upon an independent existence, Mr Stawell secured the position of attorney-general and became a member of the executive and legislative councils. A few weeks after his appointment gold was discovered, and to Mr Stawell fell the arduous duties of creating a system of government which could cope adequately with the difficulties of the position. He had to establish a police force, frame regulations for the government of the goldfields, appoint magistrates and officials of every grade, and protect life and property against the attacks of the hordes of adventurers, many of desperate character, who landed in Victoria, first from the neighbouring colonies and then from Europe and America. It was very much owing to the firm administration of Mr Stawell that, at a time when the government was weak and a large section of the newcomers impatient of control, lynch law was never resorted to. He had very little assistance for some time from any of his colleagues, and until the executive council was strengthened by the admission of Captain (afterwards Sir Andrew) Clarke and Mr H. C. E. Childers Mr Stawell was the brains as well as the body of the administration. The success of his policy was upon the whole remarkable. In the legislation he was sometimes opposed, and at other times undervalued, by his political opponents. He was a staunch supporter of the free-trade party, and between them they managed to pass a number of statutes which added greatly to the prosperity of the colony. Mr Stawell was indefatigable in the discharge of his duties, and extraordinary stories are told of the long journeys on horseback to visit distant outposts which he would take after being all day long in the law courts or in the council chamber. Mr Stawell bore an active part in drafting the Constitution Act which gave to Victoria representative institutions and a responsible ministry, instead of an executive appointed and removable by the governor and a legislature in which onethird of the members were chosen by the Crown. At the first general election after the new constitution in 1856 Mr Stawell was returned as one of the members for Melbourne, and became the attorney-general of the first responsible ministry. In 1857, on the resignation of the chief justice, Sir William A’Beckett, he succeeded to the vacant post, and was created a knight-bachelor. He administered the government of Victoria in 1873, 1875-1876, and 1884. Sir William never left Australia from his arrival in 1843 till 1872, when he paid short visits to the neighbouring colonies and New Zealand, and then, when he returned to Europe on two years’ leave of absence. He took a very deep interest in the proceedings of the Church of England, and was a member of the synod. On his retirement from the bench in 1886 he was created K.C.M.G. He died at Naples in 1889. In 1856 he had married Mary Frances Elizabeth, only daughter of W. P. Greene, R.N. (G. C. L.)

**STEAK,** a municipality of Borung county, Victoria, Australia, 170 m. by rail W.N.W. of Melbourne. Pop. (1907), 5296. The quartz reefs of the Pleasant Creek goldfields near the town are worked at very deep levels and there are several extensive cyanide plants on the reef. In the adjacent Grampians, which are connected by rail with Stawell, there are numerous freestone quarries. Wheat is extensively grown in the vicinity and also large numbers of vines, for which the soil is particularly adapted. Stawell is the changing station on the line from Melbourne to Adelaide, and has large engine-houses and repairing shops.

**STEAD, WILLIAM THOMAS** (1849- ), English journalist, was born at Embleton, Northumberland, on the 5th of July 1849, the son of a Congregational minister. He went to school at Wakefield, but was early apprenticed in a merchant’s office at Newcastle-on-Tyne; he soon gravitated however, into journalism, and in 1871 became editor of the Darlington *Northern Echo.* In 1880 he went to London to be assistant editor of the * Pall Mall Gazette* under John Morley, and when the latter retired he became editor (1885-1886). Up to 1885 he had distinguished himself by his brilliant modernity in the presentation of news. He introduced the “interview,” made a feature of the * Pall Mall* “extras” (see also *Newspapers: London*), and his enterprise and originality exercised a potent influence on contemporary journalism and politics. His enthusiasm, however, carried him too far when in 1885 he entered upon a crusade against vice by publishing a series of articles on the “Maiden Tribute of Modern Baby.” Though his action undoubtedly furthered the passing of the Criminal Law Amendment Act, it made his position on the paper impossible; and his imprisonment at Holloway was on a charge arising out of his crusade made his connexion with the whole subject a source of considerable prejudice. On leaving the *Pall Mall* he founded the monthly *Review of Reviews* (1890), and his abundant energy and facile pen found scope in many other directions in journalism of an advanced humanitarian type. He started cheap reprints (*Penny Poets and Prose Classics*, &c.), conducted a spiritualistic organ, called *Borderland* (1893-1897), in which he gave full play to his interest in psychical research; and became an enthusiastic supporter of the peace movement, and of many other movements, popular and unpopular, in which he impressed the public generally as an extreme visionary, though his practical energy was recognized by a considerable circle of admirers and pupils. At the time of the Boer War of 1899 he threw himself into the Boer cause and attacked the government with characteristic violence. Yet amid all his unpopularity, and all the suspicion and opposition engendered by his methods, his personality remained a forceful one both in public and private life. He was an early imperialist dreamer, whose influence on Cecil Rhodes in South Africa remained of primary importance; and many politicians and statesmen, who on most subjects were completely at variance with his ideas, nevertheless owed something to him. Mr Rhodes made him his confidential agent, and was inspired in his will by his suggestions; and Mr Stead was intended to be one of Mr Rhodes’s executors, though his name was struck out after the Boer War (see *his Last Will and Testament of C. J. Rhodes*, 1902). The number of his publications gradually became very large, as he wrote with facility and sensational fervour on all sorts of subjects, from *The Truth about Russia* (1888) to *If Christ came to Chicago* (1893), and from *Mrs Beeth* (1900) to *The Americanisation of the English* (1906). In private life, he was generally of sense of merit and kindly influence influenced many aspirants to journalism and literature.

**STEAK,** a thick slice or piece of meat cut for frying, broiling or stewing. The word is apparently derived from Icel. *steik,* used in the same sense, which meant properly roasted meat, from *stækja,* to roast, that is, placed on a stick or peg of wood before the fire, *stikla,* stick, cf. Swed. *stek; Dan. *steg, roast meat. A
STEAM—STEAM ENGINE

steak may be cut from any meat or fish, but the best-known is a "beef-steak," cut properly from the rump a "rump-steak," or part of the loin a "tenderloin." A "porter-house" steak is a choice cut of steak from the loin, so-called apparently first in New York from a well-known "porter-house," an eating-house where chops, steaks, &c., and porter or stout were served, at which these steaks were a speciality. A steak grilled between two other steaks, which are not served after the cooking is finished, is also sometimes called a "porter-house" steak.

STEAM (O. Eng. steam, vapour, smoke, cf. Du. stoom; the origin is unknown), water-vapour. Dry steam is steam free from mechanically mixed water particles; wet steam, on the other hand, contains water particles in suspension. Saturated steam is steam in contact with liquid water at a temperature which is the boiling point of the water and condensing point of the steam; superheated steam is steam out of contact with water heated above this temperature. For theoretical considerations see VAPORIZATION, and for the most important application see STEAM ENGINE; also WATER.

STEAM ENGINE. 1. A steam engine is a machine for the conversion of heat into mechanical work, in which the working substance is water and water vapour. The working substance may be regarded from two points of view. Thermodynamically it is the vehicle by which heat is conveyed to and through the engine from the hot source (the furnace and boiler). Part of this heat suffers a transformation into work as it passes through, and the remainder is rejected, still in the form of heat. Mechanically the working substance is a medium capable of exerting pressure, which effects this transformation in doing work by means of the changes of volume which it undergoes in the operation of the machine. Regarded as a thermodynamic device, the function of the engine is to get as much work as possible from a given quantity of heat or, to go a step further back, from the combustion of a given quantity of fuel. Accordingly, a question of primary importance is what is called the efficiency of the engine, which is the ratio of the work done to the heat supplied. Before, however, proceeding to discuss the steam engine in this aspect, or treating of the mechanics of its modern forms, it may be useful to give a brief historical sketch of its early development as an industrial appliance. In any such sketch the chief share of attention must necessarily be given to the work of James Watt. But a process of evolution had been going on before the time of Watt which prepared the steam engine for the immense improvements it received at his hands. His labours stand in natural sequence to those of Thomas Newcomen, and Newcomen's engine and those of James Watt and Thomas Savery. Savery's engine in its turn was the reduction to practical form of a contrivance which had long before been known as a scientific toy. The most modern type of all, the steam turbine of C. A. Parsons, is a new departure which has but little to connect it directly with the past; but even the steam turbine not only profits by the inventions of Watt, but in its characteristic feature finds crude prototypes in apparatus which employed the kinetic energy of jets of steam.

2. Of these, indeed, is mentioned amongst the earlier Heros, 130 B.C. lieut notices we B.C. have of any heat engine. In the Pneumatica of Hero of Alexandria (c. 130 A.D.) there is described the aeolipyle, which is a primitive steam reaction turbine, consisting of a spherical vessel pivoted on a central axis and supplied with steam through one of the pivots. The steam escapes by bent pipes facing tangentially in opposite directions, at opposite ends of a diameter perpendicular to the axis. The globe revolves by reaction from the escaping steam just as a Barker's mill is driven by escaping water. Another apparatus described by Hero (fig. 1) is interesting as the prototype of a class of engines which long afterwards became practically important. A hollow altar containing air is heated by a fire kindled on it; the air in expanding drives some of the water contained in a spherical vessel beneath the altar into a bucket, which descends and opens the temple doors above by pulling round a pair of vertical posts to which the doors are fixed. When the fire is extinguished the air cools, the water leaves the bucket, and the doors close. In another device a jet of water driven out by expanding air is turned to account as a fountain.

3. From the time of Hero to the 17th century there is no progress to record, though here and there we find evidence that steam engines like those described by Hero were used for trivial purposes, such as organ-blowing and the turning of spits. The next distinct step was the publication in 1601 of a treatise on pneumatics by Giovanni Battista della Porta, in which he shows an apparatus similar to Hero's fountain, but with steam instead of air as the displacing fluid. Steam generated in a separate vessel passes into a closed chamber containing water, from which a pipe (open under the water) leads out. He also points out that the condensation of steam in the closed chamber may be used to produce a vacuum, and the air exhausted by the jet. In fact, his suggestions anticipate very fully the engine which a century later became in the hands of Savery the earliest commercially successful steam engine. In 1615 Solomon de Caus gives a plan of forcing up water by a steam fountain which differs from della Porta's only in having one vessel serve both as boiler and as displacement-chamber, the hot water being itself raised.

4. Another line of invention was taken by Giovanni Branca (1629), who designed an engine shaped like a water-wheel, to be driven by the impact of a jet of steam on its vanes, and in its turn to drive other machines for various useful purposes. But Branca's suggestion was for the time unproductive, and we find the course of invention reverting to the line followed by della Porta and de Caus.

5. The next contributor is one whose place is not easily assigned. To Edward Somerset, second marquis of Worcester, appears to be due the credit of proposing, if not actually making, the first useful steam engine. Its object was to raise water, and it worked probably like della Porta's model, but with a pair of displacement-chambers, from each of which alternately water was forced by steam from a separate independent boiler, or perhaps by applying heat to the chamber itself, while the other vessel was allowed to refill. Lord Worcester's description of the engine in art. 68 of his Century of Inventions (1665) is obscure, and no drawings are extant. It is, therefore, difficult to say whether there were any distinctly novel features except the double action; in particular, it is not clear whether the suction of a vacuum was used to raise water as well as the direct pressure of steam.

6. The steam engine first became commercially successful in the time of Thomas Savery,2 who, in 1698, obtained a patent for a water-raising engine in which water was admitted to one of the oval vessels A, displacing water, which it drives up through the check-valve B. When the vessel A is emptied of water the supply of steam is stopped, and the steam already there is condensed by allowing a jet of cold water from a cistern above to stream over the outer surface of the vessel. This produces a vacuum and causes water to be sucked up through the pipe C and the valve D. Meanwhile steam has been displacing water

1 From Greenwood's translation of Hero's Pneumatica.
2 Savery was born probably in 1608 and died in 1715. See Sir E. Durnin Lawrence's presidential address to the Royal Institution of Cornwall (Journal of the Roy. Inst. of Cornwall, No. 8.), republished with a reprint of Savery's Miner's Friend of 1702, in which he discusses the originality of Savery's invention and dismisses the claims put forward for lord Worcester.
from the other vessel, and is ready to be condensed there. The valves B and D open only upwards. The supplementary boiler and furnace E are for feeding water to the main boiler; E is filled while cold and a fire is lighted under it; it then acts like the vessel of De Gaus in forcing a supply of feed-water into the main boiler. The gauge pipes G, G are an interesting feature in detail. Another form of Savery's engine had only one displacement-chamber and worked intermittently. In the use of artificial means to condense the steam, and in the application of the vacuum so formed to raise water by suction from a level lower than that of the engine, Savery's engine was probably an improvement on Worcester's; in any case it found what Worcester's engine had failed to find—considerable employment in pumping mines and in raising water to supply houses and towns, and even to drive water-wheels. A serious difficulty which prevented its general use in mines was the fact that the height through which it would lift water was limited by the pressure the boiler and vessels could bear. Pressures as high as 3 to 10 atmospheres were employed—and that, too, without a safety-valve—but Savery found it no easy matter to deal with high-pressure steam; he complains that it melted his common solder, and forced him, as Desaguliers tells us, "to be at the pains and charge to have all his joints soldered with spelter." Apart from this drawback, the waste of fuel was enormous, from the condensation of steam which took place on the surface of the water and on the sides of the displacement-chamber at each stroke; the consumption of coal was, in proportion to the work done, some twenty times greater than in a good modern steam engine. In a tract called The Miner's Friend Savery alludes to the alternate heating and cooling of the water-vessel: "On the outside of the vessel you may see how the water goes out as well as if the vessel were transparent, for so far as the steam continues within the vessel so far is the vessel dry without and so very hot as scarce to endure the least touch of the hand. But as far as the water is, the said vessel will be cold and wet where any water has fallen on it; which cold and moisture vanishes as fast as the steam in its descent takes the place of the water." Before Savery's engine was entirely displaced by its successor, Newcomen's, it was improved by J. T. Desaguliers, who applied to it the safety valve (invented by Papin), and substituted condensation by a jet of cold water within the vessel for the surface condensation used by Savery. To Savery is ascribed the first use of the term "horse power" as a measure of the performance of an engine.

7. So early as 1678 the use of a piston and cylinder (long before known as applied to pumps) in a heat-engine had been suggested by Jean de Hautefeuille, who proposed to use the explosion of gun-powder either to raise a piston or to force up water, or to produce, by the subsequent cooling of the gases, a partial vacuum into which water might be sucked up. Two years later Christian Huygens described an engine in which the explosion of gun-powder in a cylinder expelled part of the gaseous contents, after which the cooling of the remainder caused a piston to descend under atmospheric pressure, and the piston in descending did work by raising a weight.

8. In 1690 Denis Papin, who ten years before had invented the safety-valve as an adjunct to his "digester," suggested that the condensation of steam should be employed to make a vacuum under a piston previously raised by the expansion of the steam. Papin's was the earliest cylinder and piston steam engine, and his plan of using steam was that which afterwards took practical shape in the atmospheric engine of Newcomen. But his scheme was made unworkable by the fact that he proposed to use but one vessel as both boiler and cylinder. A small quantity of water was placed at the bottom of a cylinder and heat was applied. When the piston had risen the fire was removed, the steam was allowed to cool, and the piston did work in its down-stroke under the pressure of the atmosphere. After hearing of Savery's engine in 1705 Papin turned his attention to improving it, and devised a modified form, shown in fig. 3, in which the displacement-

through an escape valve. The piston was kept tight by a layer of water on its upper surface. Condensation was at first effected by cooling the outside of the cylinder, but the accidental leakage of the packing water past the piston showed the advantage of condensing by a jet of injection water, and this plan took the place of surface condensation. The engine used steam whose pressure was little if at all greater than that of the atmosphere; sometimes, indeed, it was worked with the manhole lid off the biler.

About 1711 Newcomen’s engine began to be introduced for pumping mines. It is doubtful whether the action was originally automatic, or depended on the periodical turning of taps by an attendant. The common story is that in 1713 a boy named Humphrey Potter, whose duty it was to open and shut the valves of an engine he attended, made the engine self-acting by causing the beam itself to open and close the valves by suitable cords and catches. This device was simplified in 1718 by Henry Beighton, who suspended from the beam a rod called the plug-tree, which worked the valves by means of tappets. By 1725 the engine was in common use in collieries, and it held its place without material change for about three-quarters of a century in all. Near the close of its career the atmospheric engine was much improved in its mechanical details by John Smeaton, who built many large engines of this type about the year 1770, just after the great step which was to make Newcomen’s engine obsolete had been taken by James Watt.

Compared with Savery’s engine, Newcomen’s had (as a pumping engine) the great advantage that the intensity of pressure in the pumps was not so great as limited by the pressure of the steam. It shared with Savery’s, in a scarcely less degree, the defect already pointed out, that steam was wasted by the alternate heating and cooling of the vessel into which it was led. Though obviously capable of more extended uses, it was in fact almost exclusively employed to raise water—in some instances for the purpose of turning water-wheels to drive other machinery. Even contemporary writers complain of its vast “consumption of fuel,” which appears to have been scarcely smaller than that of the engine of Savery.

11. In 1763 James Watt, an instrument maker in Glasgow, while engaged in repairing a model of Newcomen’s engine, was struck with the waste of steam to which the alternate chilling and heating of the cylinder gave rise. He saw that the remedy, in his own words, would lie in keeping the cylinder as hot as the steam that entered it. With this view he added to the engine a new organ—an empty vessel separate from the cylinder, into which the steam should be allowed to escape from the cylinder, to be condensed there by the application of cold water either outside or as a jet. To preserve the vacuum in his condenser he added a pump called the air-pump, whose function was to pump from it the condensed steam and water of condensation, as well as the air which would otherwise accumulate by leakage or by being brought in with the steam or with the injection water. Then, as the cylinder was no longer used as a condenser, he was able to keep it hot by clothing it with non-conducting bodies, and in particular by the use of a steam jacket, or layer of hot steam between the cylinder and an external casing. Further, and still with the same object, he covered in the top of the cylinder, taking the piston rod out through a steam-tight stuffing-box, and allowed steam instead of air to press upon the piston’s upper surface. The idea of using a separate condenser had no sooner occurred to Watt than he put it to the test by constructing the apparatus shown in Fig. 5. There A is the cylinder, B a surface condenser, and C the air-pump. The cylinder was filled with steam above the piston, and a vacuum was formed in the surface condenser B.

On opening the stop-cock D the steam rushed over from the cylinder and was condensed, while the piston-rod and lifted a weight. After several trials Watt patented his improvements in 1769; they are described in his specification in the following words, which, apart from their immense historical interest, deserve careful study as a statement of principles which to this day guide the scientific development of the steam engine:

First, That vessel in which the powers of steam are to be employed to work the engine, which is called the cylinder in common fire-engines, and which I call the steam-vessel, must, during the whole time the engine is at work, be kept as hot as the steam that enters it; first by enclosing it in a case of wood, or any other materials that transmit heat slowly; secondly, by surrounding it with steam kept hot by boiling, or by any other substance colder than the steam to enter or touch it during that time.

Secondly, In engines that are to be worked wholly or partially by condensation of steam, the steam is to be condensed in vessels distinct from the steam-vessels or cylinders, although occasionally communicating with them; these vessels I call condensers; and, whilst the engines are working, these condensers ought at least to be kept as cold as the air in the neighbourhood of the engines, by application of water or other cold bodies.

Thirdly, Whatever air or other elastic vapour is not condensed by the condenser and the material of the vessel of the engine, is to be drawn out of the steam-vessels or condensers by means of pumps, wrought by the engines themselves, or otherwise.

Fourthly, I intend in many cases to employ the expansive force of steam to press on the pistons, or whatever may be used instead of them, in the same manner in which the pressure of the atmosphere is employed in common fire-engines. In cases particularly, where steam cannot be had in plenty, the engines may be wrought by this force of steam only, by discharging the steam into the air after it has done its part.

Fifthly, I regard in many cases it is more serviceable to employ steam or water, or other substances which are employed in the engine, for the purpose of cooling the cylinders, than the atmosphere of cold air usually used; and some of them, and any other substances colder than the steam to enter or touch it during that time.

Sixthly, In many cases of power demanded, the steam is to be employed, which is not capable of the regulation and continued production of steam, but which may be employed to check the steam, or to render the pistons and other parts of the engine air and steam tight, I employ oils, wax, resinous bodies, fat of animals, quicksilver and other metals in their fluid states.

The fifth claim was for a rotary engine, and need not be quoted here.

The “common fire engine” alluded to was the steam engine, or, as it was more generally called, the “atmospheric” engine of Newcomen. Enormously important as Watt’s first patent was, it resulted for a time in the production of nothing more than a greatly improved engine of the Newcomen type, much less wasteful of fuel, able to make faster strokes, but still only suitable for pumping, still single-acting, with steam admitted during the whole stroke, the piston, as before, pulling the beam by a rope running over pulleys. Watt’s engine was worked by injection, but Watt has left a model of a surface condenser made up of small tubes, in every essential respect like the condensers now used in marine engines.

12. Fig. 6 is an example of the Watt pumping engine of this period. It should be noticed that, although the top of the cylinder is closed and steam has access to the upper side of the piston, this is done only to keep the cylinder and piston warm. The engine is still single-acting; the steam in the upper side merely plays the part which was played by the atmosphere in Newcomen’s engine by the atmospheric pressure. Steam is admitted to the lower end of the cylinder alone that is ever put in communication with the condenser. There are three valves: the “steam” valve a, the “equilibrium” valve b, and the exhaust “valve c. At the beginning of the down-stroke c is opened to produce a vacuum below the piston and a is opened to admit steam above it. At the end of the down-stroke a and c are shut and b is opened. This puts the two sides in equilibrium and allows the piston to be pulled, by the valve a, which serves as a counterpoise. C is the condenser, and A the air-pump, which discharges into the hot well H, whence the supply of the feed-pump F.

13. In a second patent (1785) Watt describes the “sun-and-blue-planet” wheels and other methods of making the engine give

An interesting detailed narrative of the steps leading to his invention was written by Watt as a note to the article “Steam Engine,” in Rolinson’s System of Mechanical Philosophy (1822). See Ewing, The Steam Engine and other Heat Engines, pp. 15-19.
continuous revolving motion to a shaft provided with a flywheel. He had invented the crank and connecting-rod for this purpose, but it had meanwhile been patented by one Pickard, and Watt, rather than make terms with Pickard, whom he regarded as a plagiarist of his own ideas, made use of his sun-and-planet motion until the patent on the crank expired. The reciprocating motion of earlier forms had served only for pumping; by this invention Watt opened up for the steam engine a thousand other channels of usefulness. The engine was still single-acting; the connecting-rod was attached to the far end of the beam, and that carried a counterpoise which served to raise the piston when steam was admitted below it.

14. In 1782 Watt patented two further improvements of the first importance, both of which he had invented some years before. One was the use of double action, that is Other Inventions to say, the application of steam and vacuum to of Watt. each side of the piston alternately. The other (invented as early as 1769) was the use of steam expansively, in other words the plan (now used in all engines that aim at economy of fuel) of stopping the admission of steam when the piston had made only a part of its stroke, and allowing the rest of the stroke to be performed by the expansion of the steam already in the cylinder. To let the piston push as well as pull the end of the beam Watt devised his so-called parallel motion, an arrangement of links connecting the piston-rod head with the beam in such a way as to guide the rod to move in a very nearly straight line. He further added the throttle-valve, for regulating the rate of admission of steam, and the centrifugal governor, a double conical pendulum, which controlled the speed by acting on the throttle-valve. The stage of development reached at this time is illustrated by the engine of fig. 7 (from Stuart's History of the Steam Engine), which shows the parallel motion pp, the governor g, the throttle-valve t, and a pair of steam and exhaust valves at each end of the cylinder. Among other inventions of Watt were the "indicator," by which diagrams showing the relation of the steam pressure in the cylinder to the movement of the piston are automatically drawn; a steam tilt-hammer; and also a steam locomotive for ordinary roads—but this invention was not prosecuted.

In partnership with Matthew Boulton, Watt carried on in Birmingham the manufacture and sale of his engines with the utmost success, and held the field against all rivals in spite of severe assaults on the validity of his patents. Notwithstanding his accurate knowledge of the advantage to be gained by using steam expansively, he continued to employ only low pressures—seldom more than 7 lb per sq. in. over that of the atmosphere. His boilers were fed, as Newcomen's had been, through an open pipe which rose high enough to let the column of water in it balance the pressure of the steam. He gave a definite numerical signification to the term "horse-power" (q.v.) as a mode of rating engines, defining it as the rate at which work is done when 33,000 lb are raised one foot in one minute.

15. In the fourth claim in Watt's first patent the second sentence describes a non-condensing engine, which would have required steam of a higher pressure. This, however, was a line of invention which Watt did not follow up, perhaps because so early as 1725 a non-condensing engine had been described by Jacob Leupold in his Theatrimum machinarum. Leupold's proposed engine is shown in fig. 8, which makes its action sufficiently clear. Watt's aversion to high-pressure steam was strong, and its influence on steam engine practice long survived the expiry of his patents. So much indeed was this the case that the terms "high-pressure" and "non-condensing" were for many years synonymous in contradistinction to the "low-pressure" or condensing engines of Watt. This nomenclature no longer holds; in modern practice many condensing engines use as high pressures as non-condensing engines, and by doing so are able to take advantage of Watt's great invention of expansive working to a degree which was impossible in his own practice.

16. The introduction of the non-condensing and, at that time, relatively high-pressure engine was effected in England by Richard Trevithick and in America by Oliver Evans about 1800. Both Evans and Trevithick applied their engines to propel carriages on roads, and both used for boiler a cylindrical vessel with a cylindrical flue inside—the construction now known as the Cornish boiler. In partnership with William Bull, Trevithick had previously made direct acting pumping-engines, with an inverted cylinder set over and in line with the pump-rod, thus dispensing with the beam that had been a feature in all earlier forms. But in these "Bull" engines, as they were called, a condenser was used, or, rather, the steam was condensed by a jet of cold water in the exhaust-pipe, and Boulton and Watt successfully opposed them as infringing Watt's patents. To Trevithick belongs the distinguished honour of being the first to use a steam carriage on a railway; in 1804 he built a locomotive in the modern sense, to run on what had formerly been a horse-tramway, in Wales, and it is noteworthy that the
exhaust steam was discharged into the funnel to force the furnace draught, a device which, twenty-five years later, in the hands of George Stephenson, went far to make the locomotive what it is to-day. In this connexion it may be added that as early as 1769 a steam carriage for roads had been built in France by Nicolas Joseph Cugnot, who used a pair of single-acting high-pressure cylinders to turn a driving axle step by step by means of paws and ratchet-wheels. To the initiative of Evans may be ascribed the early general use of high-pressure steam in the United States, a feature which for many years distinguished American practice from that of Europe.

17. Amongst the contemporaries of Watt one name deserves special mention. In 1787 Jonathan Carter Hornblower constructed and patented what would now be called a compound engine, with two cylinders of different sizes. Steam was first admitted into the smaller cylinder, and then passed over into the larger, doing work against a piston in each. In Hornblower's engine the two cylinders were placed side by side, and both pistons worked on the same end of a beam overhead. This was an instance of the use of steam expanding in fluidities in the wrong sequence, though not earlier than the invention, of expansive working by Watt. Hornblower was crushed by the Birmingham firm for infringing their patent in the use of a separate condenser and air-pump. The compound engine was revived in 1804 by Arthur Woolf, with whose name it is often associated. Using steam of fairly high pressure, and cutting off the supply before the end of the stroke in the small cylinder, Woolf expanded the steam to several times its original volume. Mechanically the double-cylinder compound engine has this advantage over an engine in which the same amount of expansion is performed in a single cylinder, that the sum of the forces exerted by the two pistons in the compound engine varies less throughout the action than the force exerted by the piston of the single-cylinder engine. This advantage may have been clear to Hornblower and Woolf, and to other early users of compound expansion. But another and probably a more important merit of the system lies in a fact of which neither they nor for many years their followers in the use of compound engines were aware —the fact that by dividing the whole range of expansion into two parts the cylinders in which these are separately performed are subject to a reduced range of fluctuation in the steam-pressure. This, as will be seen later, limits to a great extent a source of waste which is present in all steam-engines, the waste which results from the heating and cooling of the metal by its alternate contact with hot and cooler steam. The system of compound expansion is now used in nearly all large engines that pretend to economy. Its introduction forms the most outstanding improvement which steam-engines of the piston and cylinder type have undergone since the time of Watt; and we are able to recognize it as a very important step in the direction set forth in his "first principle" that the cylinder should be kept as hot as the steam that enters it.

18. Woolf introduced the compound engine somewhat widely about 1814 as a pumping engine in the mines of Cornwall. But here it met a strong competitor in the high-pressure single-cylinder engine of Trevithick, which had the advantage of greater simplicity in construction. Woolf's engine fell into comparative disuse, and the single-cylinder type took a form which, under the name of the Cornish pumping engine, was for many years famous for its great economy of fuel. In this engine the cylinder was set under one end of a beam, and the other end of which hung a heavy rod which operated a pump at the foot of the shaft. Steam was admitted above the piston for a short portion of the stroke, thereby raising the pump-rod, and was allowed to expand for the remainder. Then an equilibrium valve, connecting the space above and below the piston, as in fig. 6, was opened, and the pump-rod descended, doing work in the pump and raising the engine piston. The large mass which had to be started and stopped at each stroke served by its inertia to counterbalance the unequal pressure of the steam, for the ascending rods stered up energy of motion in the early part of the stroke, when the steam pressure was greatest, and gave out energy in the later part, when expansion had greatly lowered the pressure. The frequency of the stroke was controlled by a device called a cataract, consisting of a small plunger pump, in which the plunger, raised at each stroke by the engine, was allowed to descend more or less slowly by the escape of fluid below it through an adjustable orifice, and in its descent liberated catches which held the steam and exhaust valves from opening. A similar device controlled the equilibrium valve, and could be set to give a portion of the steam to the engine for a part of the stroke, and the cylinder might have time to become completely filled. The Cornish engine is interesting as the earliest form which achieved an efficiency comparable with that of good modern engines. For many years monthly reports were published of the "duty" of these engines, the "duty" being the number of foot-pounds of work done per bushel or (in some cases) per cwt. of coal. The average duty of engines in the Cornwall district rose from about 18 millions of foot-pounds per cwt. of coal in 1813 to 68 millions in 1844, after which less effort seems to have been made to maintain a plan of improving them. (Phil. Trans., 1843, vol. 23.) In individual cases much higher results were reported, as in the Fowey Consols engine, which in 1835 was stated to have a duty of 125 millions. This (to use a more modern mode of reckoning) is equivalent to the consumption of only a little more than 1½ lb. of coal per horse-power per hour—a result surpassed by very few engines in even the best recent practice. It is difficult to credit figures which, even in exceptional instances, place the Cornish engine of that period on a level with the most efficient modern engines—in which compound expansion and higher pressure combine to make a much more perfect thermodynamic machine and apart from this there is room to question the accuracy of the Cornish reports. They played, however, a useful part in the process of steam engine development by directing attention to the question of efficiency, and by demonstrating the advantage to be gained by high pressure and expansive working, at a time when the theory of the steam engine had not yet taken shape.

19. The final revival of the compound engine did not occur until about the middle of the 19th century, and then several agencies combined to effect it. In 1845 M'Naught published a plan of improvement (F. Inst. C.E. 1845, vol. 23), which was generally accepted, and a compound engine of original Watt type, by adding a high-pressure cylinder whose piston acted on the beam between the centre and the flywheel end. Steam of higher pressure than had formerly been used, after doing work in the new cylinder, passed into the old or low-pressure cylinder, where it was further expanded. Many engines whose power was proving insufficient for the extended machinery they had to drive were "M'Naughted" in this way, and after conversion were found not only to yield more power but to show a marked economy of fuel. The compound form was selected by William Pole for the pumping engines of Lambeth and other works built about 1850; in 1854 John Elder began to use it in marine engines; in 1857 E. A. Cowper added a steam-jacketed intermediate reservoir for steam between the high and low pressure cylinders, which made it unnecessary for the low-pressure piston to be just beginning when the other piston was just ending its stroke. As facilities increased for the use of high-pressure steam, compound expansion came into more general use, its advantage becoming more conspicuous with every increase in boiler pressure until now there are few land engines and scarcely any marine engine that do not employ it. In marine practice, where economy of fuel is a much more important factor in determining the design than it is on land, the principle of compound expansion has been greatly extended by the introduction of triple and even quadruple expansion engines, in which the steam is made to expand successively in three or in four cylinders. In locomotive engines, where other considerations are of more moment than the saving of coal, compound expansion has found some application, but its use there is comparatively rare.
STEAM ENGINE

20. The adaptation of the steam engine to railways, begun by Trevithick, became a success in the hands of George Stephenson, whose engine, the “Rocket,” when tried along with others, in 1829, not only distanced its competitors, but settled once and for all the question whether horse traction or steam traction was to be used on railways. The principal features of the “Rocket” were an improved steam-blast for urging the combustion of coal and a boiler (suggested by Booth) in which a large heating surface was given by the use of many small tubes through which the hot gases passed. Further, the cylinders, instead of being vertical as in earlier locomotives, were set in a slant, which was afterwards altered to a position more nearly horizontal. To these features there was added later the “link motion,” a contrivance which enabled the engine to be easily reversed and the amount of expansion to be readily varied. In the hands of George Stephenson and his son Robert the locomotive took a form which has been in all essentials maintained by the far heavier locomotives of to-day.

21. The first practical steamboat was the tug “Charlotte Dundas,” built by William Symington, and tried in the Forth and Clyde Canal in 1802. A Watt double-acting condensing engine, placed horizontally, was geared to a propelling vessel by a connecting-rod on the crank of a shaft at the stern, which carried a revolving paddle-wheel. The trial was successful, but steam towing was abandoned for fear of injuring the banks of the canal. Ten years later Henry Bell built the “Comet,” with side paddle-wheels, which ran as a passenger steamer on the Clyde; but an earlier inventor to follow up Symington’s success was the American, Robert Fulton, who, after unsuccessful experiments on the Seine, fitted a steamer on the Hudson in 1807 with engines made to his designs by Boulton and Watt, and brought steam navigation on this river in 1811.

22. With improvements in the details of design and construction it gradually became practicable to use higher steam pressures and higher piston speeds, and consequently to obtain not only greater efficiency, but also a greater amount of power from engines of given bulk. In 1872 Sir F. J. Bramwell, describing the typical marine practice of that time, gave a list of engines, all compound, in which the boiler pressure ranged from 45 to 60 Ib., the mean piston speed was 350 ft. per minute, and the consumption of coal at 23 lb. per hour for each indicated horse-power. In 1881, F. C. Napier, of a similar list, in which the boiler pressure was 77 lb., the speed 460 ft. per minute, and the consumption a trifle under 2 lb. These were compound engines with expansion in two stages. The triple expansion engine, introduced by Dr. A. C. Kirk in 1874, did not come into general use until after 1881. It became the normal type of marine engine, with pressures ranging, as a rule, from 150 to 200 lb., piston speeds generally of 300 or 600 ft. per minute, but sometimes as high as 900 or 1000, and coal consumption of about 1 lb. per hour per indicated horse-power. In some instances quadruple expansion has been preferred, with somewhat higher pressures, but it can scarcely be said to be established that the advantage of adding a fourth stage clearly compensates for the extra complication. Some particulars of the dimensions reached in modern practice will be given later. Several of the vessels engaged in the Transatlantic passenger service, and also a few armoured cruisers, have engines in which the twin sets together have an indicated horse-power exceeding 30,000. But even these figures are eclipsed in ships which engine driven by turbine engines. The cruisers of the “Invincible” class have turbine engines of 41,000 horse-power, and the turbines of the great Cunarders “Lusitania” and “Mauretania” (1907) develop about 70,000 h.p. in propelling these ships at a speed of 25 knots. It may be questioned whether such gigantic concentrations of power for the propulsion of a ship would have been practicable had it not been for the new possibilities which the introduction of the steam turbine has opened up.

23. The invention of the steam turbine has in fact revolutionized marine engine practice, so far as fast vessels are concerned, and has supplied a formidable rival to the reciprocating engine for use on land. The steam turbine has been brought to a degree of efficiency which places it, in respect of economy in steam and coal consumption, on a somewhat higher level than the best engines of the older type in cases where a large amount of power is to be generated. Its greater simplicity, compactness and freedom from vibration are merits which have already gone far to secure for it a preference, notwithstanding the somewhat higher initial cost, over the older style, which is known as a practicable engine. The largest demands for power occur in fast passenger vessels, in war-ships and in stations from which electric energy is distributed for traction or other uses; in all these cases the steam turbine is now taking the leading place. It is to the inventive genius of the Hon. C. A. Parsons that we owe not only the main idea of the modern steam turbine, but also the working out of many novel mechanical details which have been essential to success, as well as the adaptation of the turbine to marine propulsion.

24. In the steam turbine, as in the water turbine (for which see HYDRAULICS), the force directly operative to do useful work is derived from the kinetic energy of the operative fluid, either by the impulse of a jet or jets sliding over movable blades, or by the reaction of orifices or guides from which the jets emerge. The pressure, instead of being exerted on a piston, is employed in the first instance to set the fluid itself in motion. There is a conversion of pressure-energy into velocity-energy as a preliminary step towards obtaining the effective work of the machine. But in a steam turbine this implies velocities which are immensely greater than those with which water turbines have to deal, in consequence of the much higher density of steam as the moving fluid. Attempts to design a steam turbine, were by numerous inventors, but fell short of practical success mainly because of the difficulty of arranging for a sufficiently high velocity in the working parts to utilize a reasonably large fraction of the kinetic energy of the steam, the principle involved being that for good efficiency the velocity of the blades should approximate to half the velocity of the jets which strike them. There is a further difficulty in getting the energy of the steam into a suitable kinetic form, namely, to get the stream of issuing particles to take a single direction, without undue dispersion, when the steam is allowed to expand through an orifice from a chamber at high pressure into a space where the pressure is greatly less.

In 1889 Dr Gustav de Laval introduced a form of steam turbine in which both of these difficulties were to a great extent overcome, partly by the special form of the nozzle used to produce the steam jet and partly by features of design which allowed an exceptionally high speed to be reached in the wheel carrying the vanes against which the steam impinged. This simple type of turbine, which will be described in a later section of this article, has met with a most considerable success, especially in comparatively small sizes, as an engine for small ships. Its efficiency is fairly good, but it is not well adapted for work on a large scale, and it has not been applied to the propulsion of ships.

Parsons attacked the problem at an earlier date, in an entirely different way in the invention of his “compound” turbine. By dividing the whole expansion of the steam into a great number of successive and separate steps he limited the velocity acquired at each step to such an extent as to make it comparatively easy to extract the greater part of the kinetic energy, as work done upon the moving blades, without making the velocity of these blades inconveniently high. Moreover, in Parsons’s compound turbine the range of pressure through which the steam expands in each separate step is too small to give rise to any difficulty in the formation of the jets. The guide blades, which form the jets, are distributed round the whole
circuit of the revolving wheel, and all the revolving blades are consequently in action at once. The steam streams from and to end through an annular space between a revolving drum and the casing which surrounds it. Parallel rings of fixed guide blades project inwards from the casing at suitable distances, and between these are rings of moving blades which project outwards from the drum and revolve with it. At each step in the expansion the steam streams through a ring of fixed guide blades, and the streams so formed impinge on the next ring of moving blades, and so on. The construction, which is of great simplicity, will be described later; it lends itself well to the generation of power on a large scale, especially in cases where a fairly high speed of rotation is required. The more powerful the turbine the less important do various inevitable losses of power become; and hence, though the small turbines which were first built were less economical than reciprocating engines, the advantage is the other way where large powers are concerned.

25. Parsons introduced his compound steam turbine in 1884. For some years it was made in small sizes only, and the steam was discharged to the atmosphere without condensation. So long, however, as this was done the steam turbine was sacrificing one of its most important advantages, namely, its exceptional capacity for utilizing the energy of low-pressure steam. It is also used in to the most disadvantageous manner the condenser. In 1891 it was first fitted with a condenser, and it then began to be used in electric supply stations. Its efficiency at that date was found, in tests made by the present writer, to be comparable with that of good reciprocating compound engines, but the figures then obtained were much improved on later in turbines of larger size and modified design. The first application to marine propulsion was in the "Turbina," in 1897. The success of this little experimental vessel of 100 tons, which with its horse-power of 2100 made a record in speed for a ship of any size, was soon followed by the application of the principle to the largest passenger ships, as well as in the largest ocean-going passenger vessels. The turbine-driven steamers "Lusitania" and "Mauretania" (1907) are the most powerful and the fastest ocean-going vessels afloat. The rapid development of the marine steam turbine makes it probable that it will displace the reciprocating engine in all large and fast ships. For slow-going cargo-boats it is at a disadvantage, unless gearing is resorted to, on account of the difficulty of securing a sufficiently high peripheral velocity in the turbine drums without making the turbines unduly bulky, and the leakage losses (due to steam passing through the clearance spaces over the tips of the blades) unduly large. Experiments by Parsons (Trans. Inst. Nav. Arch., 1910) on a ship in which a slow-running propeller is driven through reducing-gear from a high-speed turbine, have given highly promising results.

Enough has been said to show that the invention of the steam turbine is the most important step in steam engineering since the time of Watt. It is the first solution of the problem of using steam efficiently in an engine without reciprocating parts. The object in most steam engines is to deliver power to revolving machinery, and much ingenuity has been expended in attempts to devise engines which will produce rotation directly, instead of by conversion of reciprocating motion. No rotary engine, however, was permanently successful until the steam turbine took a practical form.

26. In the early development of the steam engine inventors had little in the way of theory to guide them. Watt had the advantage, which he acknowledges, of a knowledge of Joseph Black's doctrine of latent heat; but there was no philosophy of the relation of work to heat until long after the inventions of Watt were complete. The theory of the steam engine as a heat engine dates from 1824, when N. L. Sadi Carnot published his Réflexions sur la puissance motrice du feu, and showed that heat does work only by being let down from a higher to a lower temperature. But Carnot had no idea that any of the heat disappears in the process, and it was not until the doctrine of the conservation of energy was established in 1843 by the experiments of J. P. Joule that the theory of heat engines began a vigorous growth. From 1849 onwards the science of thermodynamics developed rapidly, and with it the calculation of the mechanical equivalent of heat. It is to J. W. Macquorn Rankine and William Thomson (Lord Kelvin) and was applied, especially by Rankine, to practical problems in the use of steam. The publication in 1859 of Rankine's Manual of the Steam Engine formed an epoch in the history of the subject by giving inventors a new basis, outside of mere empiricism, from which they could push on the development of the steam engine. Unfortunately, however, it was assumed that the cylinder and piston might be treated as behaving to the steam like non-conducting bodies—that the transfer of heat between them was so small as to be negligible. Calculations of steam consumption, work and thermodynamic efficiency involve this assumption, except in the case of steam-jacketed cylinders, where he estimates that the steam in its passage through the cylinder takes just enough heat from the jacket to prevent a small amount of condensation which would otherwise occur as the process of expansion goes on. If the transfer of heat from steam to metal could be overlooked, the steam which enters the cylinder would remain during admission as dry as it was before it entered, and the volume of steam compound rotary engines would correspond with the volume of the cylinder up to the point of cut-off. It is here that the actual behaviour of steam in the cylinder diverges most widely from the behaviour which the theory assumes. When steam enters the cylinder it finds the metal chilled by the previous exhaust, and a portion of it is at once condensed. This has the effect of increasing, often very largely, the volume of boiler steam required per stroke. As expansion goes on the water that was condensed during admission begins to be re-evaporated from the sides of the cylinder, and this action is often prolonged into the exhaust. It is now recognized that any theory which fails to take account of these exchanges of heat between the steam and its metal envelope falls also to yield even comparatively correct results in calculating the relative efficiency of various steam pressures or various ranges of expansion. But the exchanges of heat are so complex that there seems little prospect of submitting them to any comprehensive theoretical treatment, and information is rather to be sought from the scientific results of experiments with actual machines.

27. Formation of Steam under Constant Pressure.—In attempting a brief sketch of steam engine theory it is necessary to begin by giving some account of the properties of steam, so far as they are relevant. The properties of steam are most conveniently stated by referring in the first instance to what happens when steam is formed under constant pressure. It is then theoretically (and practically in the boiler of a steam engine when the engine is at work) to fix the idea we may suppose that the vessel in which steam is to be formed is a long upright cylinder fitted with a piston which may be loaded so that it exerts a constant pressure on the fluid below. Let there be, to begin with, at the foot of the cylinder a quantity of water (which for convenience of numerical statement we shall take as 1 lb), at any temperature $t$; and let the piston press on the surface of the water with a force of $p$ lb per square foot. Let heat now be applied to the bottom of the cylinder. As it enters the water it will produce the following effects in three stages—

1. The temperature of the water rises until a certain temperature $t$ is reached, at which steam begins to be formed. The value of $t$ depends on the particular pressure $p$ which the piston exerts. Until the temperature $t$ is reached there is nothing but water below the piston.

2. Steam is formed, more heat being taken in. The piston (which is used to exert a constant pressure) rises. No further increase of temperature occurs during this stage, which continues until all the water is converted into steam. During this stage the steam
which is formed is said to be saturated. The volume which the piston encloses at the end of this stage—the volume, namely, of 1 lb of saturated steam at pressure $p$ (and temperature $t$)—will be denoted by $V_{s}$.

3. If after all the water is converted into steam more heat be allowed to enter, the volume will increase and the temperature will rise. The steam is then said to be superheated.

The difference between saturated and superheated steam may be expressed by saying that if water (at the temperature of the steam) be mixed with steam some of the water will be evaporated if the steam is superheated, but none if the steam is saturated. Any vapour saturated with a liquid at normal atmospheric pressure is necessarily saturated. When saturated its properties differ considerably, as a rule, from those of a perfect gas, especially at high pressures, but we may approach those of a perfect gas, and more closely the further the process of superheating is carried, that is to say, the more the temperature is raised above $t$. The temperature of saturation corresponding to the given pressure $p$ and the temperature $t$ at which steam is formed depends on the value of $p$. Their relation was determined with great care by Regnault (Mem. Inst. France, vol. xxii). The pressure of saturated steam rises with the temperature at a rate which increases rapidly in the upper regions of the scale. This will be apparent from the first and second columns of the following table. The first column gives the temperature on the Centigrade scale; the second gives the corresponding pressure in the form of the table per square inch.

### 29. Relation of Temperature and Volume. — The same table shows the volume $v$ in cubic feet occupied by 1 lb of saturated steam at each temperature. This is based on an investigation of the investigations of Callendar who has shown (see Thermodynamics and Vaporization) that an equation of the form

$$v = R \frac{t + b - c}{p}$$

is applicable to water vapour, whether saturated or superheated, within limits of experimental error throughout the range of pressure that is important in engineering practice. In this equation $t$ is the absolute temperature, $R$ and $b$ are constants and $c$ is a term varying inversely as a certain power of the temperature. By aid of this equation, in conjunction with the results of various experiments on the latent heat and other properties of steam, Callendar has shown that it is possible to frame expressions from which numerical values of all the important properties of steam may be derived throughout the range of steam temperatures extending from 0°C to 200°C or so. The values so obtained are thermodynamically consistent with one another, and are in good agreement with the most authoritative experimental results. They are accordingly to be accepted in lieu of those given in earlier steam tables which depended on measurements by Regnault, and are now known to be in some particulars erroneous. R. Moller has applied Callendar’s method with great completeness to the calculation of steam tables, and the figures given here are adapted from his results.1

In addition to the relation of temperature, pressure, and volume, the density and other properties of steam which will be explained as we proceed.

### 30. Supply of Heat in Formation of Steam under Constant Pressure. — We have next to consider the supply of heat in the imaginary experiment of § 27. During the first stage, until the temperature rises from its initial value $t_0$ to $t$, the temperature at which steam begins to form under the given pressure, heat is required only to warm the water. Since the specific heat of water is nearly constant, the amount of heat taken in during the first stage is approximately $t - t_0$ cubic units, or $(t - t_0)$ foot-pounds. This method, and this expression for it, will generally serve with sufficient accuracy in practical calculations. More exactly, however, the heat taken in is somewhat greater than this at high temperatures, for Regnault’s experiments show that the specific heat of water increases slightly as the temperature rises. In stating the amount of heat required for this first stage, $b_0$ must be divided by a constant temperature $c$, for convenience in numerical statement the temperature $0°C$ is usually chosen as an arbitrary starting-point from which the reception of heat is to be reckoned. We shall employ the symbol $h$ to denote the amount of heat required to raise 1 lb of water from $t_0$. $h$ is the temperature $t$ at which steam begins to form. During the first stage, sensibly all the heat supplied goes to increase the stock of internal energy which the fluid possesses, the amount of external work which is done by the expansion of the fluid being negligible.

The heat taken in during the second stage is what is called the latent heat of steam, and is denoted by $L$. Of it a part is spent in doing work, requiring the steam to raise a given weight of water from $t_0$ to $t$, and a part remains as an increase of the internal energy of the steam $e$ over the volume of the water $v$, and the remainder is the difference of internal energy between 1 lb of steam at $t$ and 1 lb of water at $t_0$.

### 31. Total Heat of Steam. — Adding together the heat taken in during the first and second stages, we have a quantity designated by $H$ which may be called the heat of formation of 1 lb of saturated steam:

$$H = h + L.$$
to use this arbitrary starting-point in reckoning what may be called the internal energy of the substance, which is the excess of the heat taken in over the external work done by the substance during its rectification.

Thus, the internal energy of 1 lb of saturated steam at pressure \( p \) is equal to the total heat \( I \), less that part of the total heat which is spent in doing external work, or

\[ E = I - pS. \]

The notion of internal energy is useful in calculating the heat taken in or out by steam in bringing about some change of expansion or compression in an engine. When a working substance passes from one condition to another its gain or loss of heat is determined by the equation

\[ E = \text{increase of internal energy} + \text{external work}. \]

Any of the terms of this equation may be negative; the last term is negative when work is done, not by but upon the substance.

33. Heat Steam.——In the calculation of the quantities in engines we have often to deal, not with dry saturated steam, but with wet steam, or steam which either carries in suspension, or is otherwise mixed with, a greater or less proportion of water. In any such mixture, assuming it to be in equilibrium, the steam and water have the same temperature, and the steam is saturated. The dryness of wet steam is measured by the proportion \( q \) of dry steam in each pound of the mixed substance. When that is known it is easy to determine the other physical constants: thus——

Latent heat of 1 lb of wet steam \( = qL; \)

Total heat of 1 lb of wet steam \( = I + qL; \)

Volume of 1 lb of wet steam \( = v + qv \) very nearly, unless the steam is so wet as to consist mainly of water.

34. Superheated Steam.——Steam is superheated when its temperature is raised, in any manner, above the temperature corresponding to saturation at the actual pressure. When considerably superheated, steam approximates in behaviour to a perfect gas.

The specific heat during superheating is nearly constant at low pressures, but it increases at high pressures; it is higher, especially when the amount of superheating is slight. Callendar's equations enable it to be calculated for any assigned conditions of temperature and pressure. They also allow a direct determination to be made of the total heat of superheated steam of given temperature and pressure, and from this, by comparison with the total heat of saturated steam at the same pressure, the specific heat of saturated steam to be found. Calling \( I \), the total heat of steam in the saturated condition, when the temperature is \( t \), \( k \) the mean specific heat in superheating at constant pressure to a higher temperature \( t' \) and \( v' \) the total heat in the superheated state, we have

\[ I' = I + kv'(t' - t). \]

The following are values of \( k \):

\begin{align*}
\text{Temperature of Superheat} & \text{ in °C.} & \text{Temperature of Saturation} & \text{in °C.} \\
100^\circ & 0.49 & 180^\circ & 0.59 \\
150^\circ & 0.51 & 190^\circ & 0.59 \\
200^\circ & 0.53 & 200^\circ & 0.59 \\
250^\circ & 0.55 & & .59 \\
300^\circ & 0.57 & & .59 \\
350^\circ & 0.59 & & .59 \\
400^\circ & 0.59 & & .59 \\
500^\circ & 0.59 & & .59 \\
600^\circ & 0.60 & & .59 \\
700^\circ & 0.61 & & .59 \\
800^\circ & 0.62 & & .59 \\
900^\circ & 0.63 & & .59 \\
1000^\circ & 0.64 & & .59 \\
1100^\circ & 0.65 & & .59 \\
1200^\circ & 0.66 & & .59 \\
1300^\circ & 0.67 & & .59 \\
1400^\circ & 0.68 & & .59 \\
1500^\circ & 0.69 & & .59 \\
1600^\circ & 0.70 & & .59 \\
1700^\circ & 0.71 & & .59 \\
1800^\circ & 0.72 & & .59 \\
1900^\circ & 0.73 & & .59 \\
2000^\circ & 0.74 & & .59 \\
\end{align*}

35. Isothermal Expansion of Steam.——The expansion of volume which occurs during the conversion of water into steam under constant pressure is isothermal. From what has been already said it is obvious that steam, or any other saturated vapour, can be expanded or compressed isothermally only when wet, and that evaporation (in the one case) or condensation (in the other) must accompany the process. Isothermal lines for a working substance which consists of a liquid and its vapour are straight lines of uniform pressure.

36. Adiabatic Expansion of Steam.——If steam initially dry be allowed to expand adiabatically (namely, without taking in or giving out any heat) it becomes wet. A part of the steam is condensed by the process of adiabatic expansion, at first in the form of minute particles suspended throughout the mass. The temperature and pressure fall; and, as that part of the substance which remains uncondensed is saturated, the relation of pressure to temperature throughout the expansion is that which holds for saturated steam. Before expansion let the initial dryness of the steam be \( q \), and its absolute temperature \( t \). Then, if it expand adiabatically until its temperature falls to \( r \), its dryness after expansion may be shown to be

\[ q = \left( \frac{2}{2} \right) \left( \frac{1}{r} \right) + \log_{10} \frac{2}{2}. \]

\( L_1 \) and \( L_2 \) are the latent heats (in thermal unites) of 1 lb of steam before and after expansion respectively. When the steam is dry to begin with, \( q_1 = 1 \).
It must not be supposed that the efficiency \( (r_1 - r_2)/r_1 \) is actually attainable or even attainable. Many causes conspire to prevent steam engines from being thermodynamically perfect, and some of the causes of imperfection cannot be removed.

40. *Engine with Separate Organs.*—The ideal engine represented in Fig. 10 consists of two separate cylinders, the boiler and condenser, and the pistons of the two cylinders are always in contact. The process of the ideal engine is shown in Fig. 10, \( r_1 \) being the cylinder and piston B, a surface condenser C kept at temperature \( r_2 \), and a condenser D which is kept at a higher temperature until the condensed water to the boiler. When the several processes of the engine are separated in this way we can still carry out the first three stages of the cyclic process of the Rankine cycle. The first stage of that cycle corresponds to the admission of steam from the boiler into the cylinder. Then the point known as the point of admission, at which the pressure ceases and the steam, already in the cylinder is allowed to expand, exerting a discontinuous pressure on the piston. This is the second stage, or the stage of expansion. When the expansion has been completed, the return stroke begins, and a period termed the exhaust occurs, that is to say, steam passes out of the cylinder, into the condenser, where it is condensed at the pressure in the condenser, which is felt as a back pressure opposing the return of the piston. So far, all has been essentially reversible and identical with the corresponding parts of Carnot's cycle.

But we cannot complete the cycle as Carnot's cycle was completed. The existence of a separate condenser at the fourth stage, that of adiabatic compression, impracticable, and the best we can do is to continue the exhaust until condensation is complete, and then return the condensed water to the boiler.

41. *Rankine Cycle.*—It follows that the ideal cycle of Carnot is not an appropriate standard with which to compare the action of a real steam engine. Instead of it we have, in the engine with separate organs, a cycle which is commonly called the Rankine cycle, which differs from the Carnot cycle only in this, that the stage of adiabatic compression, which in Carnot was carried on until the pressure falls to that of the condenser in which case the expansion is said to be complete. At the end of the expansion release takes place, that is, some communication is opened between the cylinder and the condenser, and the return stroke begins, and a period termed the exhaust occurs, that is to say, steam passes out of the cylinder, into the condenser, where it is condensed at the pressure in the condenser, which is felt as a back pressure opposing the return of the piston. So far, all has been essentially reversible and identical with the corresponding parts of Carnot's cycle.

But the principle still applies that with respect to each portion of the heat that is taken in, the fraction of heat convertible into work under ideally favourable conditions is measured by \( (r_1 - r_2)/r_1 \), where \( r \) is the absolute temperature at which that portion of heat is received, and \( r_1 \) is the temperature at which heat is rejected. Accordingly, we may investigate as follows the ideal performance of an engine following the Rankine cycle. Let \( dQ \) represent that portion of the whole heat which is taken in at any temperature \( r \). Then the greatest amount of work obtainable is \( dQ \int_0^r \frac{dr}{r} \), and the whole amount of work ideally obtainable in the complete process is found by calculating \( 2dQ \int_0^r \frac{dr}{r} \) where the summation includes all the heat that is taken in. In a steam engine, using saturated steam, the total amount of heat in this sum is the latent heat \( L_1 \), which is taken in at constant temperature \( r_1 \), during the change from state of water to steam. But there is, in addition, the heat taken in by the feed-water before it reaches the temperature at which the steam is formed, and this may be represented as the sum of a series of elements \( \delta r \) taken in at varying temperatures \( r \), where \( r \) is the specific heat of water. Thus if \( W \) represents the thermal equivalent of the work theoretically obtainable per lb of steam, under ideally favourable conditions,

\[
W = \frac{2dQ}{r_1} \int_0^r \frac{dr}{r} + L_1 \frac{r_1 - r_2}{r_1}
\]

The experiments of Regnault show that \( r_1 \) within the limits of temperature that the steam can be condensed, is nearly a constant quantity, and no serious error will be introduced in this integration by treating it as a constant, with a value equal to the mean value, as determined by Regnault, between the limits of \( r_1 \) and \( r_2 \). On this basis

\[
W = \left( r_1 - r_2 \right) e - r_1 \log \frac{r_1 - r_2}{r_2}
\]

This expresses the greatest amount of work which each pound of steam can yield when the temperature \( r_1 \) at which it reaches the engine and the temperature \( r_2 \) at which it leaves the engine are assigned. This equation evidently serves for all cycles, and it may be shown that the actual performance may usefully be compared. The actual yield per lb of steam is always considerably less, chiefly because the ideal condition of adiabatic expansion from the higher to the lower extreme of temperature is not satisfied.

A more simple expression for the work theoretically obtainable per lb of steam when expanded adiabatically under the conditions of the Rankine cycle, is

\[
W = \frac{l_1 - l_2}{l_1}
\]

where \( l_1 \) is the total heat of the working substance in the initial state, before the adiabatic expansion, and \( l_2 \) is its total heat after that expansion. For it may readily be proved that, in an adiabatic process,

\[
I_1 - I_2 = \int P dV
\]

and this integral is the area of the indicator diagram when the substance is taken in at \( p_1 \), expanded to \( p_2 \) and discharged at \( p_3 \).

This expression applies whether the steam is actually superheated or not. It will in general be the total heat of a wet mixture, and to calculate it we must know the condition as to wetness which results from the expansion. This is most easily found, especially when the substance of which the steam is composed has been known, by making use of the entropy-temperature diagram to be presently described, or by other methods, method, for an account of which the reader should refer to the paper by Mollier already cited, or to J. A. Ewing's The Steam Engine and other Hot-Engine Sets (3rd Ed.).

42. *Entropy.*—The study of steam-engine problems is greatly assisted by introducing the idea of entropy and making use of diagrams in which the temperature and entropy are plotted against each other. Such a diagram is a condition of the working substance defined by the statement that when any quantity of heat \( dQ \) is received by, or generated in, or rejected by the substance, when its absolute temp. and the substance gains or loses entropy by the amount \( dS / r \). Thus \( dS / r \) measures the whole change of entropy in a process which involves the taking in or rejection of heat at more than one temperature. We shall denote entropy \( S \) and specific entropy \( s \) and consider it as reckoned per unit of mass of the substance. Since by definition of entropy \( dS = S/ r \), \( r \delta S = dQ \), and hence if a curve be drawn with \( r \) and \( S \) for ordinates to exhibit the action of a working substance, the area under the curve, or \( \int r dS \), being equal to \( 2dQ \), measures the total heat which the substance gains or loses received or rejected during the operation which the curve represents.

In a reversible cycle of operations Carnot's principle shows that \( 2dQ \, r = 0 \), and it is obvious in such a case that the entropy change during the cycle is zero. The substance may be extended to a cycle which includes any non-reversible step, by taking account of the heat generated within the substance by such a step, as it were, if it were carried on in the reversible mode. Consequently the ideal efficiency of the cycle falls somewhat short of that ideal reached in the cycle of Carnot.

But the principle still applies that with respect to each portion of the heat that is taken in, the fraction of heat convertible into work under ideally favourable conditions is measured by \( (r_1 - r_2)/r_1 \) and the absolute temperature at which that portion of heat is received, and \( r_1 \) is the temperature at which heat is rejected. Accordingly, we may investigate as follows the ideal performance of an engine following the Rankine cycle. Let \( dQ \) represent that portion of the whole heat which is taken in at any temperature \( r \). Then the greatest amount of work obtainable is \( dQ \int_0^r \frac{dr}{r} \), and the whole amount of work ideally obtainable in the complete process is found by calculating \( 2dQ \int_0^r \frac{dr}{r} \) where the summation includes all the heat that is taken in. In a steam engine, using saturated steam, the total amount of heat in this sum is the latent heat \( L_1 \), which is taken in at constant temperature \( r_1 \), during the change from state of water to steam. But there is, in addition, the heat taken in by the feed-water before it reaches the temperature at which the steam is formed, and this may be represented as the sum of a series of elements \( \delta r \) taken in at varying temperatures \( r \), where \( r \) is the specific heat of water. Thus if \( W \) represents the thermal equivalent of the work theoretically obtainable per lb of steam, under ideally favourable conditions,

\[
W = \frac{2dQ}{r_1} \int_0^r \frac{dr}{r} + L_1 \frac{r_1 - r_2}{r_1}
\]

and taking \( e \) as sensibly constant,

\[
W = \int_{r_1}^{r_2} \frac{r_1 - r_2}{r_1} dr_2
\]

During evaporation at \( r_1 \) a quantity of heat \( L_1 \) is taken in at temperature \( r_1 \), and hence the entropy of the steam

\[
\delta s = \int_{r_1}^{r_2} \frac{dQ}{r_1 - r_2}
\]
Values of the entropy of water and steam are given in the table. The entropy-temperature diagram for a Rankine cycle is illustrated in fig. 11, where $ab$, a logarithmic curve, represents the process of heating the feed-water, and $bc$ the passage from the state of water into that of steam. The diagram is drawn to scale for a case in which steam is formed at a pressure of 150 lb per sq. in., and condensed at a pressure of 1 lb per sq. in. After the formation of the steam, the next step in the ideal process is adiabatic expansion to the higher to the lower limit of temperature, which is represented by the vertical straight line $cd$, an adiabatic process being also isentropic. Finally, the cycle is completed by $da$, which represents the condensation of the steam after its temperature has been reduced by adiabatic expansion to the lower limit of temperature. The area $abcd$ represents the work done, and its value per lb of steam is identical with $W$ as reckoned above. The area $malep$ is the whole heat taken in, and the area $mo$ denotes the heat $q$.

Let a curve $cf$ be drawn to show the values of the entropy of steam for various temperatures of saturation: then if $ad$ be produced to meet the curve in $f$, the ratio $fd/fa$ represents the fraction of the steam which was condensed during adiabatic expansion. For the point $f$ represents the state of 1 lb of saturated steam, and in the condensation of 1 lb of saturated steam the heat given out would be the area under $fa$, whereas the heat actually given off when the condensation from $d$ was the area under $da$. Thus the state at $d$ is that of a wet mixture in which $delfa$ represents the fraction present as steam, and $fdafa$ the fraction present as water. It obviously follows that by drawing horizontal lines at intermediate temperatures the development of wetness in the expanding steam can be readily traced. Again, if the steam is not dry when expansion begins, its state may be represented by making the expansion line begin at a point in the line $e$, such that the rectangle formed by keeping the area $de$ proportional to the constituents of the wet mixture. In this way the ideal process may be exhibited for steam with any assumed degree of initial wetness. Further, the entropy-temperature diagram admits of ready application to the case of incomplete expansion. Suppose, for example, that after adiabatic expansion from $c$ to $c'$ (fig. 12) the steam is directly cooled to the lower-limit temperature by the application of cooling water instead of by continued expansion. This process is represented by the line $c'd$, which is a curve of constant volume. Its form is determined by the consideration that at any point $c$ the proportion of steam still uncondensed, or $ejlk$, is such that the mixture fills the same volume as was filled at $c'$. 43. **Entropy-Temperature Diagrams extended to the Case of Superheated Steam.**—In the diagrams which have been sketched it has been assumed that the steam is supplied to the engine in a saturated state. To extend the same treatment to the case of superheated steam, we have to take account of the supplementary supply of heat which the steam receives after the point $c$ is reached, and therefore the line $c'e'$ begins. When superheating is resorted to, as is now often the case in practice, the two foregoing give constant pressure, the addition of entropy during the process of superheating from $r$ to $r'$ is $\xi(r'-r)$. The value of $\xi$ may be treated as approximately constant, and the addition to the entropy may then be written as $\xi\log r'/\log r$. This gives a line such as $cr$ on the entropy diagram (fig. 13), and increases the value of $W$ by the amount

$$\int r'\xi dr' = \xi \log \frac{r'}{r}$$

which is represented on the diagram by the area $dcr$. During adiabatic expansion from $r$ the steam remains superheated until $a$ is passed. As $r$ is increased, and further expansion results in the condition of wetness indicated by $a$. The extra work done is at the expense of the extra supply of heat $p_{\text{extra}}$, and an inspection of the diagram suffices to show that the efficiency of the ideal cycle is reduced by a large amount of superheating. In practice, however, superheating does much to promote efficiency, because it materially reduces the amount by which the actual performance of an engine falls short of the ideal performance having the comparatively dry in its passage through the engine, and thereby reducing exchanges of heat between the steam and the metal.

44. **Entropy of Wet Steam.**—The entropy of wet steam is readily calculated by considering that the change of entropy in the conversion from water to steam will be $q/v$ if the steam is wet, $q$ being the dryness. Accordingly the entropy of wet steam at any temperature is $W = v\log q + \log v$. The work done by the water is practically equal to unity this expression may be written

$$\phi = \log q - \log v + qgL/v$$

We may apply this expression to trace the development of wetness in steam when it expands adiabatically. In adiabatic expansion $\phi$ is constant. Using the suffix 1 to distinguish the initial state, we therefore have at any stage in the expansion

$$\log q - \log v + qgL/v = \log q_{\text{sat}} - \log v_{\text{sat}} + q_{\text{sat}}gL_{\text{sat}}/v_{\text{sat}}$$

from which the dryness at that stage is found, namely,

$$q = \frac{v_{\text{sat}}gL_{\text{sat}}}{L_{\text{sat}} - v_{\text{sat}}}$$

The expression is not applicable to steam which is initially superheated. In either case of work done due to any additional expansion would add nothing to the output of the engine, when allowance is made for the work spent on friction within the mechanism itself. Considerations of bulk often lead to an even earlier release of the expanding steam, and another consideration which points the same way is that when expansion is carried very far, the losses due to exchange of heat between the cylinder and the steam, referred to below, tend to increase. Again, since experience shows that the most efficient engines are those in which the process of expansion is divided into two, three or more stages by the use of compounded cylinders, a certain amount of loss is to be ascribed to the drops in pressure which are liable to occur during the passage of steam from one vessel to another. But the chief cause of loss is to be found in the exchanges of heat which take place between the steam and the metal. In each cylinder there is a process of alternate condensation and re-evaporation—condensation during the period of admission, when the steam finds itself brought into contact with metal which has been chilled by evaporation during the preceding exhaust stroke, and then evaporation, when the pressure has fallen suitably, during the later stages of expansion, as well as during exhaust. The consequence is that the steam, though supplied in a dry state, may contain humidity up to 30% of moisture when admission to the cylinder is complete, and the entropy diagram for the real process of expansion takes a form such as is indicated by the line $c'e'$ in fig. 14. The steam supplied is still measured by the area under $abc$. The condensation from $c$ to $c'$ occurs by contact with the walls of the cylinder; and though the heat of condensation is restored before release occurs at $c'$, the general result is to make a large reduction in the area of the diagram.

46. **Exchanges of Heat between the Steam and the Metal.**—The exchanges of heat between steam and metal in the engine cylinder have been made the subject of an elaborate experimental examination
by Professors Callendar and Nicolson (Proc. Inst. C.E., cxxi. 147), who studied the cyclic variations of temperature throughout the cylinder by means of thermo-electric junctions set at various depths. They found that the range of temperature above and below the surface of the metal is much less than the range of temperature passed through by the steam; the processes of condensation and re-evaporation are slow, and the state of the cylinder is at all times determined by the process occurring at the surface of the metal. The amount of condensation up to the point of cut-off, as inferred from the heat which takes up, may be much less than the "missing quantity" or difference between the amount of steam passing into the cylinder and the amount of condensation that would occur if there were no re-evaporation. According to their experiments, this discrepancy is accounted for by leakage of steam past the valve, direct from the steam chest to the exhaust, and they suggest that this source of error may have been overlooked in previous determinations. The experiments were repeated and the results confirmed by determinations of the missing quantity. This may explain cases in which the initial condensation has apparently been excessive, but large amounts of initial condensation certainly do not constitute the most potent factor in making the real performance of the engine fall short of the ideal standard. In the alternate condensation and re-evaporation of steam in the cylinder more heat is given to the metal by each pound of steam that is condensed than is taken from the metal by each pound of steam that is re-evaporated, the temperature of condensation being higher than that of re-evaporation. The quantity $H_1 - H_2$, namely, the difference in the absolute temperature, is sufficient to account for the large latent heat of steam and for the steam temperature of 212° or even $\frac{1}{2}$° that is obtained on admission to the cylinder. In that case the steam may be considered as being essentially saturated, and the amount of re-evaporation of the metal is of secondary importance. Although the re-evaporation of steam during expansion, which (in an adiabatic process) would make the steam temperature rise, has been left out as being ignored, it will be found that this factor has been taken into consideration in subsequent calculations.

It should be added that these figures are exceptional. A consumption of 13 or 14 lb of steam per horse-power-hour is much more usual even in large and well-designed triple-expansion engines; and with the recent improvements in the design of compound engines the consumption is often as low as 10 lb per sq. in., anything from 14 to 15 lb pressure may 100 or 120 lb per sq. in., anything from 14 to 15 lb pressure may be reckoned a good performance.

48. Superheated Steam.—The advantage of superheated steam, which arises mainly from its influence in reducing the exchange of heat between the steam and the cylinder, was demonstrated in the experiments of Hirn, and as early as 1860 it was not unusual to supply superheaters with marine engines. But the practice of superheating was not generally adopted, in regard to lubrication. By the introduction of heavy mineral oils this objection has been removed, and a revival in the use of superheating has taken place, with striking effect on the thermodynamic performance of engines. The Society of Steam Users on a large number of engines showed that superheating effected an average saving in coal to the extent of about 20%, when the superheater was simply placed in the boiler fire, so that it utilized what would otherwise be waste heat, and about 12% when the superheater was separately fired. In those cases the steam was superheated only about 30° to 45° C. above the transition temperature of the steam, but in more recent practice much higher amounts of superheat have been successfully applied. Professor Schröter has tested a factory engine of 1000 h.p., using steam superheated by some 50° C., and has shown that this amount of superheat has raised the output of the engine by 10%, the steam being condensed on the walls during admission to the cylinder (Zeitschrift des Vereins deutscher Ingenieure, vol. xl., 1896). It follows that still larger amounts of superheat will be thermodynamically advantageous. Superheating of this kind is, however, a case which cannot be treated by the remarkable results which have been obtained with highly superheated steam by W. Schmidt in stationary engines and locomotives. Using a somewhat different method, Schmidt has demonstrated that certain engines employ steam superheated to a temperature of 400° C., and that an efficiency not attainable from steam in any other way is thereby reached. In several authentic trials of Schmidt engines the consumption of steam has been considerably less than 10 lb per horse-power-hour—a figure which, after allowance is made for the heat taken up during the process of superheating, represents a better performance than that of the best engines using saturated or slightly superheated steam. In one of these cases, it was found that by condensing on the walls and the superheater together, not exceed 14 lb per indicated horse-power even with engines of small power. To reduce the consumption of coal, the Schmidt engines make use of hot gases from the furnace which have passed the superheater, a further extraction of heat from them should take place. This is done by an economizer or feed-water heater of peculiar form, consisting of a long row of small pipes which maintain a circulation of hot distilled water through a closed system containing an external coil, which forms the heater of a tank through which the feed-water passes on its way to the boiler. Some of the Schmidt engines adopt the principle of steam recovery, to escape the necessity of the piston rod becoming on the side which is exposed to contact with high-temperature steam; but it is found that this precaution is not essential, and that with glands of suitable design the engine can be made, as far as possible, without risk of undue wear. In some instances Schmidt transfers to the partially expanded steam in the intermediate receiver a portion of the heat which is conveyed to the engine by means of the superheater and which may properly receive a still higher degree of initial superheat. Accordingly, though the initial temperature of the steam may be 400° C. or more, this is reduced to about 320° by transfer to steam in the superheater before the high-pressure steam is admitted to the cylinder. In tests by the present writer a Schmidt plant indicating 180 h.p., in which this device was employed, the steam was superheated to 390° C. and 10.4 lb were used per horse-power-hour. In this trial the temperature of the chimney gases was reduced, by the use of Schmidt's feed-water heater, to 175° C., and the consumption of coal was 1.31 lb per indicated horse-power-hour.

49. The Indicator.—The actual behaviour of steam in the cylinder of a steam engine is studied by means of the indicator, which serves not only for the measurement of the pressure and the performance of the engine, but is also a valuable means of testing the valves and generally to give much useful information regarding the action of the engine. The indicator, which was invented by Watt, and improved by Richards, is a device for automatically measuring and recording the pressure variations in the steam engine cylinder. In its most usual form it consists of a small steel cylinder fitted with a piston which slides easily within it and is pressed down by a spiral spring of steel wire. The cylinder is fitted with a small hole at one end and a small channel at the other end of the cylinder, so that the piston of the indicator rises and falls in response to the fluctuations of pressure which occur in the engine cylinder. The indicator is similar to the pump which falls with it and traces the diagram on a sheet of paper fixed to a drum that is caused to rotate back and forth through a certain arc, in unison with the motion of the engine piston.
M'Naught's indicator the pencil is directly attached to the indicator piston P, moved by means of a pair of links so that it copies the motion of the piston on a magnified scale. This has the advantage that an equally large diagram is drawn with much less movement of the pencil, and errors which are caused by the piston's inertia are consequently reduced. In high-speed engines especially it is important to minimize the inertia of the indicator piston and the parts connected with it. In Richards's indicator the linkage employed to multiply the piston's motion is an arrangement similar to the parallel motion introduced by Watt as a means of guiding the piston-rod in beam engines. In several recent forms of indicator lighter linkages are adopted, and other changes have been made with the object of fitting the instrument better for high-speed work. One of these modified forms of Richards's indicator (the Crosby) is shown in fig. 15. The pressure of steam in the engine cylinder raises the piston P, compressing the spring S and causing the pencil Q to rise in a nearly straight line through a distance proportional, on a magnified scale, to the compression of the spring and therefore to the pressure of the steam. At the same time the drum D, which carries the paper, receives motion through the cord C from the crosshead of the engine. Inside this drum there is a spiral spring which becomes wound up when the cord is pulled, and serves to turn the drum in the reverse direction during the back stroke. The cap of the indicator cylinder has holes in it which admit air freely to the top of the piston, and the piston has room to descend, extending the spring S, when the pressure of the steam is less than that of the atmosphere. The spring is easily taken out and replaced by a more or less stiff one when higher or lower pressures have to be dealt with.

50. Errors in Indicator Diagrams.—To register correctly, an indicator must satisfy two conditions: (1) the motion of the piston must be proportional to the change of steam pressure in the engine cylinder; and (2) the motion of the drum must be proportional to that of the engine piston. The first of these requires that the pipe which connects the indicator with the cylinder should be short and of sufficient bore, and that it should open in the cylinder at a place where the pressure in it will not be affected by the kinetic action of the inrushing steam. Frequently pipes are led from both ends of the cylinder to a central position where the indicator is set, so that diagrams may be taken from either end without shifting the instrument; better results are obtained, especially when the cylinder is long, by using a pair of indicators, each fixed with the shortest possible connecting pipe.

The general effect of an insufficiently free connexion between the indicator and the engine cylinder is to make the diagram too small. The first condition is also invalidated to some extent by the friction of the indicator piston, of the joints in the linkage, and of the pencil on the paper. The piston must slide very freely; nothing of the nature of packing is permissible, and any steam that leaks past it must have a free exit through the cover. The pencil pressure must not exceed the minimum which is necessary for clear marking. Another source of disturbance is the inertia of the moving parts, which tends to set them into oscillation whenever the indicator piston suffers a comparatively sudden displacement. These oscillations, superposed upon the legitimate motions of the piston, give a wavy outline to parts of the diagram, especially when the speed is great. When they appear on the diagram a continuous curve should be drawn midway between the crests and hollows of the undulations. To keep them within reasonable compass in high-speed work a stiff spring must be used and an indicator with light parts should be selected. Care must be taken that the spring is graduated to suit the temperature (about 100° C.) to which it is exposed when used; its stiffness at this temperature is about 3% less than when cold.

51. Measurement of Horse-Power.—To determine the indicated horse-power, the mean effective pressure is found by dividing the area of the diagram by the length of the strokes. The diagram height, which, interpreted on the scale of pressures, is the mean effective pressure in pounds per square inch. This has to be multiplied by the effective square inches and by the length of the piston stroke in feet to find the work done per stroke in foot-pounds on that side of the piston to which the diagram refers. Let A be the area of the piston on one side and A on the other; and let n be the number of complete double strokes or revolutions per minute. Then the indicated horse-power

\[ I.H.P. = \frac{n}{330000} \left( A_h + A_l \right) \]

is found; the mean pressure, the area of the diagram may be conveniently measured by planimeter. A less accurate plan, frequently followed, is to divide the diagram by lines drawn at the middle of strips of equal width and to take the mean pressure as the height of these lines.

52. Tests of Efficiency.—In testing the actual efficiency of an engine the work done as determined by the indicator is compared with the supply of heat, which is calculated from the amount of steam passing through the engine. High-speed engines pass steam through the feed-water or, when a surface condenser is used, by collecting the condensed water from the air-pump discharge and measuring that, adding the water due to blow-downs and to the quantity of blow-downs. If measurements have been made, and it has been found that in general the amount of feed-water exceeds the amount of steam discharged from air-pump and jack-pipes, the amount of evaporation to be added to the amount of work ideally obtained, if the engine followed the perfect Rankine cycle already discussed. To make a complete engine trial the engine is caused to work not only at full power, but at various fractions of its greatest energy. The results are very conveniently represented (in a manner due to P. W. Williams) by drawing a curve, the co-ordinates of which are the horse-power and the total consumption of steam per hour. This "Williams Line," as it is called, is in most cases straight or nearly straight. Another useful curve is drawn by plotting the steam used per horse-power-hour in relation to the horse-power.

53. Determination of the "Missing Quantity."—When the amount of steam passing through the engine is known, the indicator diagram enables the degree of wetness of the steam to be estimated at various stages in the expansion from cut-off to release, provided that the temperature and pressure at cut-off have been referred to above in connexion with Messrs Callendar and Nicolson's researches. For this purpose we must first calculate the quantity of the working substance present in the cylinder. It is calculated by two parts, namely, the amount supplied per stroke, plus the amount retained by being shut up in the clearance space. If we assume, as may generally be done without serious error, that as far as the mixing of the steam in the cylinder is dry, it is an easy matter to deduce from the diagram, knowing the pressure and the volume, how much steam is shut up in the clearance space. Adding to that the supply per stroke, we get the whole quantity that is present from cut-off to release. The volume which which would occupy at each pressure, if saturated, is found from the steam table.
convenient usage which is now pretty general the name “Woolf engine” is restricted to those compound engines which discharge steam directly from the high to the low pressure cylinders without the intervention of a receiver. The Woolf engine is extensively used for steam yachts and small steamers.

55. Receiver Engine.—An intermediate receiver becomes necessary when the phases of the pistons in a compound engine do not agree. With two cranks at right angles, for example, a portion of the steam discharge from the high-pressure cylinder is cut off at a time when the low-pressure cylinder cannot properly receive steam. The receiver is in some cases an entirely independent vessel connected to the cylinder by pipes; but in other cases, the efficiency of the receiver volume is afforded by the valve casings and the steam pipe which connects the cylinders. The receiver, when it is a distinct vessel, is frequently jacketed.

A receiver is frequently applied with advantage to beam and tandem compound engines. Communication need not then be maintained between the high and low pressure cylinders during the whole of the stroke, admission to the low-pressure cylinder is stopped before the stroke is completed; there is no necessity to expand independently; and the remainder of the discharge from the high-pressure cylinder is compressed into the intermediate receiver. Each cylinder has then a definite point of cut-off, and by varying these points the distribution of work between the two cylinders may be adjusted at will. In general it is desirable to make both cylinders of a compound engine contribute equal quantities of work. If they act on expander tanks, this is the case given the same value to the mean twisting moment of both cranks.

56. Compound Diagrams.—Wherever a receiver is used, care should be taken that should there be not a wasteful amount of unrecovered expansion into it; in other words, the receiver should be not greatly less than that in the high-pressure cylinder at the moment of release. If the receiver pressure is less than the pressure in the high-pressure cylinder, the high-pressure cylinder will be expanded more than relatively by the low-pressure cylinder and the receiver, which will show itself in an indicator diagram by a sudden fall at the end of the high-pressure expansion. This “drop” is, from the thermodynamic point of view, very disadvantageous and giving cut-off; it can be prevented by choosing a proper point of cut-off in the low-pressure cylinder. When there is no “drop” the expansion that occurs in a compound engine has precisely the same effect in doing work as the expansion in a simple engine would have, provided the law of expansion be the same in both and the waste of energy which occurs by the friction of parts and passages in the transfer of steam from one to the other cylinder be neglected. When work is done on the cylinders, depends on the relation of pressure to volume throughout the process; and so long as that relation is unchanged it is a matter of indifference whether the expansion be performed in one vessel or in more than one. In general a compound engine has a thermodynamic advantage over a simple engine using the same pressure and the same expansion, inasmuch as it reduces the exchange of heat between the working substance and the cylinder walls and so increases its efficiency. The compound engine has also a mechanical advantage which will be presently described. The ultimate ratio of expansion in any compound engine is the ratio of the volume of the two cylinders, when the steam is at the same temperature, and the volume of steam admitted to the high-pressure cylinder.

57. Adjustment of Work and “Drop.”—By making the cut-off take place earlier in the large cylinder we increase the mean pressure in the receiver; the work done in the small cylinder is consequently diminished. The work done in the large cylinder is correspondingly increased, for the total work (depending as it does on the initial pressure and the total ratio of expansion) is unaffected by the change. The same adjustment serves, in case there is “drop”, to lessen it. Try selecting a suitable point of cut-off for one or another, and to the volume of the receiver, and also by choosing a proper point for the low-pressure cut-off, it is possible to divide the work suitably between the cylinders and at the same time prevent the amount of drop from becoming greater than is desirable.

58. Uniformity of Effort in a Compound Engine.—An important mechanical advantage belongs to the compound engine in the fact that it avoids the extreme thrust and pull which would have to be borne by the piston-rod of a single-cylinder engine working at the same power with the same initial pressure and the same ratio of expansion. If the work was taken place in the low-pressure cylinder, the motion of the large piston being opposed by the motion of the smaller, the cylinders would have to be made with much larger diameters. As a set-off to this, the large cylinders have the drawback of requiring more working parts than a simple engine with one cylinder. But in many instances—as in marine engines—two or more cranks are almost indispensable, to give a tolerably uniform effort and to get over the dead points; and the comparison should then be made between a pair of simple cylinders and a pair of compound cylinders. Another point in favour of the compound engine is that, although the whole ratio of expansion is great, there need not be a very early cut-off in either cylinder; hence the common slide-valve, which is unsuited to give an early cut-off, may be used in place of a more complex arrangement. The mechanical advantage of the compound engine has long been recognized, and had much to do with its adoption in the early days of high-pressure steam. Its subsequent development has been due in part to this, and in part to the thermodynamic advantage which has been discussed above.

59. Ratio of Cylinder Volumes.—In a two-cylinder compound engine, using steam at 80 to 100 lb pressure, the large cylinder has 3 or 4 times the volume of the small cylinder. In triple engines the pressure is rarely less than 150 lb; the low-pressure cylinder has generally 6 or 7 times, and the intermediate cylinder 24 to 21 times the volume of the high-pressure cylinder. In naval practice the ratio of the cylinders is such that the whole ratio of expansion is great, there need not be a very early cut-off in either cylinder; hence the common slide-valve, which is unsuited to give an early cut-off, may be used in place of a more complex arrangement. The mechanical advantage of the compound engine has long been recognized, and had much to do with its adoption in the early days of high-pressure steam. Its subsequent development has been due in part to this, and in part to the thermodynamic advantage which has been discussed above.

Fig. 18.—Horizontal Section through Cylinder and Valve-chest: showing Slide-valve.

is credited to Murdoch, an assistant of Watt, came into general use with the introduction of locomotives, and is now employed, in one or other of many forms, in the great majority of engines. The common slide-valve is illustrated in fig. 18, which also shows
the cylinder and the ports and passages leading to its ends. The seat, or surface on which the valve slides, is a plane surface formed on or fixed to the side of the cylinder, with three ports or openings which extend across the greater part of the cylinder's width. The central opening is the exhaust port through which the steam escapes; the others, or steam ports, which are narrower, lead to the two ends of the cylinder respectively. The valve is a box-shaped cover which slides over the seat and the whole is enclosed in a chamber called the valve-chest, to which steam from the boiler is admitted. When the valve moves a sufficient distance to either side of the central position, steam enters one end of the cylinder from the valve-chest and escapes from the other end of the cylinder through the cavity of the valve into the exhaust port. The valve is generally moved by an eccentric on the engine shaft, which is mechanically equivalent to a crank whose radius is equal to the eccentricity, or distance from the centre of the shaft to the centre of the eccentric sheave. The eccentric rod is generally so long that the motion of the valve is sensibly the same as that which it would receive were the part of the cylinder's width. Thus if a circle (fig. 10) be drawn to represent the path of the eccentric centre during a revolution of the engine, and a perpendicular PM be drawn from any point P on a diameter CM, which is the displacement of the valve from its middle position at the time the eccentric centre is at P, AB is the whole travel of the valve.

61. Lap and Lead.—If the valve when in its middle position did not overlap the steam ports (fig. 20), any movement of the left hand steam, and the admission would continue until the valve had returned to its middle position, or, in other words, for half a revolution of the engine. Such a valve would not serve for expansive working, as regards the relative position of the crank and eccentric it would have to be set so that its middle position coincided with the extreme position of the piston; in other words, the eccentric radius would make a right angle with the crank. Expansive working, however, becomes possible when we give the valve what is called "lap," by making it project over the diameters of the steam ports, as in fig. 21, where o is the "outside lap" and i is the "inside lap." Admission of steam (to either side) then begins only when the displacement of the valve from its middle position exceeds the amount of the outside lap, and continues only until the valve has returned to the same distance from its middle position. Further, exhaust begins only when the valve has moved past the middle by a distance equal to i, and continues until the valve has again returned to a distance i from its middle position. Thus on the diagram of the eccentric's travel (fig. 22) we find, by setting off o and i on the two sides of the centre, the positions a, b, c, d of the eccentric radius at which the four events of admission, cut-off, release and compression occur for one side of the piston. As to the other side of the piston, it is only necessary to set off o to the right and i to the left of the centre, but for the sake of clearness we may confine our attention to one of the two sides. Of the whole revolution, the part from a to b is the time of steam admission, from b to c the arc of expansion, from c to d the arc of exhaust, and from d to a the arc of compression. The relation of these, however, to the piston's motion is still undefined. If the eccentric were set in advance of the crank by an angle equal to ACA, the opening of the valve would be coincident with the beginning of the piston's stroke. It is, however, desirable, in order to allow the steam free entry, that the valve be already some way open when the piston stroke begins, and thus the eccentric may be set to have a position C'e at the beginning of the stroke. In that case the valve is open at the beginning of the stroke to the extent mm', which is called the "lead." The amount by which the angle between C'CA (the eccentric) and CA (the crank) exceeds a right angle is called the "angular advance," this being the angle by which the eccentric is set in advance of the position it would occupy if the primitive arrangement without lap were adopted. If we have to a larger scale in fig. 26. This makes the direction of Q (the eccentric) coincide on the paper with the simultaneous direction of

An effect of lead is to cause proadmission, that is to say, admissi-
the crank, and hence to find the displacement of the valve at any position of the crank we have only to draw \text{CQ} in fig. 26 parallel to the crank, when \text{CQ} represents the displacement of the valve to the scale on which the diameter of one of the circles represents the half-travel of the valve. \text{CQ} is the valve displacement at the beginning of the stroke shown by the arrow. Draw circular arcs \text{ab} and \text{cd} with \text{C} as centre and with radii equal to the outside lap \text{a} and the inside lap \text{b} respectively. The position of the crank at which pre-admission occurs is the lead of \text{ad}. The greatest steam opening is \text{aB}. The clearance, or the lift when the crank hand is in the direction \text{C}. \text{C} is the position of the crank at release, and \text{C} marks the end of the exhaust.

63. In the figures which have been sketched the events refer to the front end of the cylinder, that is, the outer end of the crank. A radius vector drawn from the centre parallel to the crank in any position then shows the valve's displacement from the valve's middle position by the intercept of the circle with the valve. An intercept of the circle is easily seen to be equal to \text{a'd'}, and is therefore the distance by which the piston has moved from its extreme position at the beginning of the stroke.

In practice this diagram is combined with that of fig. 26, by drawing both about the same centre and using different and possibly new radii. A radius vector drawn from the circle parallel to the crank in any position then shows the valve's displacement from the middle position by the intercept of the circle with the valve.

64. By taking the ratio of the laps \text{a} and \text{i} to the total travel of the valve, we produce effects on the steam distribution which are readily traced by means of the diagram. Reduction of travel (which is equivalent to increase of pressure) gives a reduction of admission, earlier cut-off, later release and earlier compression; the ratios of expansion and of compression are both increased. Increase of angular advance accelerates all the events and causes a slight increase in the ratio of expansion.

65. In designing a slide-valve the breadth of the steam ports in the direction of the valve's motion is determined with reference to the volume of the exhaust steam to be discharged in a given time, the area of the ports being generally such that the mean velocity of the steam during discharge is less than 100 ft. per second. The travel is made great enough to keep the cylinder port fully open during the greater part of the exhaust; for this purpose \text{1/4} or \text{3/4} times the breadth of the steam port. To facilitate the exit of the steam the inside lap is always small, and is often wanting or even negative. During admission the steam port is rarely quite uncovered, especially if the outside lap is large and the travel moderate. Large travel has the advantage of giving freer ingress and egress of steam, with more sharply-defined cut-off, compression and release, but this advantage is secured at the cost of more work spent in moving the valve and more wear of the faces. To lessen the necessary travel without reducing the area of steam ports, double-ported valves are often used. An example is shown below in fig. 35.

66. \text{Reversal of Motion. Side-Valve.—The eccentric must stand in advance of the crank by the angle } 90^\circ - \theta \text{, as in fig. 28, where } \text{CK} \text{ is the crank, and } \text{CE} \text{ is the corresponding position of the eccentric when the engine is running in the direction of the arrow. To obtain the position when the engine is running in the opposite direction } (\theta) \text{, it is only necessary to shift the eccentric into the position } \text{CE}', \text{ when it will still be } 90^\circ + \theta \text{ in advance of the crank. This gives a total of two eccentric positions, one resulting from the eccentric rod connected by temporarily disengaging the eccentric-rod from the valve-rod, working the valve by hand until the crank turned back through an angle equal to } E \text{, and then re-engaging the eccentric. The eccentric shaves, instead of being keyed to the shaft, was driven by a stop fixed to the shaft, which abutted on one or other of two shoulders projecting from the shave. In some modern forms of reversing gear means are provided for turning the eccentric round on the shaft, but the arrangement known as the link-motion is now the most usual gear in locomotive, marine, wind ing and other engines which require to be often and easily reversed.}
on it, the position of the link is readily found, and by repeating the process for other positions of the eccentrics a diagram of positions (fig. 32) is drawn for the assigned state of the gear. A line AB drawn across this diagram in the path of the valve’s travel determines the displacements of the valve, and enables the dotted diagram to be drawn, which is shown to a larger scale in another part of fig. 32. The example refers to Stephenson’s link-motion in nearly full forward gear; with obvious modification the same method may be used in the analysis of Gooch’s or Allan’s motion. The same

![Diagram](image)

**Fig. 32.**

Diagram determines the amount of slotting or sliding motion of the block in the link. In a well-designed gear this sliding is reduced to a minimum for that position of the gear in which the engine runs most usually. In marine engines the suspension-rod is generally connected to the link at the end of the link next the forward eccentric, to reduce this sliding when the engine is in forward gear.

70. _Radial Gears._—Many forms of gear for reversing and for varying expansion have been devised with the object of escaping the use of two eccentrics, and in some both eccentrics are dispensed with.

Hackworth’s gear, the parent of several others, to which the general name of radial gears is applied, has a single eccentric E (fig. 33) opposite the crank, with an eccentric-rod EQ, whose mean position is perpendicular to the travel of the valve. The rod ends in a block Q, which slides on a fixed inclined guide-bar or link, and the valve-rod receives its motion through a connecting rod from an intermediate point P of the eccentric-rod, the locus of which is an ellipse. To reverse the gear the guide-bar is tilted over to the position shown by the dotted lines, and intermediate inclinations give various degrees of expansion without altering the lead. The steam distribution is quite satisfactory, but an objection to the gear is the wear of the sliding-block and guide. In Bremme’s or Marshall’s form this objection is obviated with some loss of symmetry in the valve’s motion by constraining the motion of the point Q, not by a sliding-guide, but a suspension-link, which makes the path of Q a circular arc instead of a straight line; to reverse the gear the centre of suspension R of this link is thrown over to the position R’ (fig. 34). In the example sketched P is beyond Q, but P may be between Q and the crank (as in fig. 33), in which case the eccentric is set at 180° from the crank. This gear has been applied in a number of marine engines. In Joy’s gear, which is extensively used in locomotives, no eccentric is required; and the rod corresponding to the eccentric rod in Hackworth’s gear receives its motion from a point in the connecting rod by the linkage shown in fig. 35, and is either suspended, as in Marshall’s form, by a rod whose suspension centre R is thrown over to reverse the motion, or constrained, as in Hackworth’s, by a slot-guide whose inclination is reversed. Fig. 36 shows Joy’s gear as applied to a locomotive. A slot-guide E is used, and it is curved to allow for the obliquity of the valve connecting-rod AE. C is the crank-pin, B the piston path and D a fixed centre.

![Diagram](image)

**Fig. 33.** Hackworth’s Valve-Gear.

A form of radial gear very largely used in locomotives, especially on the continent of Europe, is the Walschaert or Heusinger-Waldeg gear, in which the valve receives its motion in part from the piston cross-head through a reducing lever, and in part from a single eccentric set at right angles to the crank, which acts a rocking link. Reversing is effected by shifting a sliding block along this rocking link from one side to the other of the centre on which it rocks.

![Diagram](image)

**Fig. 34.** Bremme’s or Marshall’s Valve-Gear.

71. _Separate Expansion-Valves._—When the distribution of steam is effected by the slide-valve alone the arc of the crank’s motion during which compression occurs is equal to the arc during which expansion occurs, and for this reason the slide-valve would give an excessive amount of compression if it were made to cut off the supply of steam earlier than about half-stroke. Hence, where an early cut-off is wanted it is necessary either to use an entirely different means of regulating the distribution of steam, or to supplement the slide-valve by another valve—called an expansion-valve, usually driven by a separate eccentric—which function is to effect the cut-off, the other events being determined as usual by the slide-valve. Such expansion-valves belong generally to one or other of two types. In one the expansion-valve cuts off the supply of steam to the chest in which the main valve works.

![Diagram](image)

**Fig. 35.** Diagram of Joy’s Valve-Gear.

In the other the expansion-valve slides on the back of the main slide-valve, which is provided with through ports which the expansion-valve opens and closes. Fig. 37 shows one form of this type. Here the resultant relative motion of the expansion-valve and main-valve has to be considered. If r and R (fig. 38) are the eccentrics working the main and expansion valves respectively, then CR drawn equal and parallel to ME is the resultant eccentric which determines the motion of the expansion-valve relatively to the main-valve. Cut-off occurs at Q, when the shaft has turned through an
angle $\alpha$, which brings the resultant eccentric into the direction CQ and makes the relative displacement of the two valves equal to the distance $l$.

Expansion-valves furnish a convenient means of varying the expansion, which may be done by altering their lap, travel or angular advance. Alteration of lap, or rather of the distance $l$ in the figures, is often effected by having the expansion-valve in two parts (as in fig. 37) and holding them together by a bolt, which is turned by turning the valve-rod the parts are made to approach or recede from each other. In large valves the adjustment is more conveniently made by varying the travel of the valve, which is done by connecting it to its eccentrical through a link which serves as a lever of variable length.

72. Relief Rings.—To relieve the pressure of the valve on the seat, large slide-valves are generally fitted with a steam-tight ring, which excludes steam from underneath the face of the valve. The ring fits steam-tight into a recess in the cover of the steam-chest, and is pressed by springs against the back of the valve. In some cases the steam is planed to slide under the ring. Fig. 39 shows a relief ring of this kind fitted on the back of a large double-ported slide-valve for a marine engine. Another plan is to fit the ring into a recess on the back of the valve, and let it slide on the inside of the steam-chest cover. Steam is thus excluded from the space within the ring, any steam that leaks in being allowed to escape through the connecting piece leading to the immediate receiver when the arrangement is fitted to the high-pressure cylinder of a compound engine. A flexible diaphragm has also been used, instead of a recess, to hold the ring.

73. Piston Slide-Valve.—The pressure of valves on cylinder faces is still more completely obviated by making the face of the valve generally of a concave form, causing the back to slide in contact with the valve-rod or valve-ports. This arrangement is most effectually carried out in the piston slide-valve now very largely used in the high-pressure cylinders of marine engines. The piston slide-valve may be described as a slide-valve in which the face of the valve is curved to form a complete cylinder, round whose whole circumference the ports extend. The pistons are packed like ordinary cylinder pistons in a flexible ring, and the ports are crossed here and there by diagonal bars to keep the rings from springing out as the valve moves over them. Fig. 40 shows a form of piston valve for the supply of high-pressure steam to a large marine engine. $P$, $P$ are the cylinder ports.

74. Balance Piston.—Fig. 39 illustrates an arrangement common in all heavy slide-valves whose travel is vertical—the balance piston $P$ of the Corliss engine (fig. 41) is such. Steam is pressed up below the horizontal cylinder on its lower side and so equalizes the weight of the valve, valve-rod and connections of the mechanism.

The valve sometimes takes the form of a rocking cylinder. This last kind of sliding motion is very usual in stationary engines fitted with Corliss gear, in which case four distinct rocking slides are commonly employed to effect the steam distribution, one giving admission and one giving exhaust at each end of the cylinder.

75. Double-Beat Valve.—In many stationary engines which work on the continent of Europe, lift or mushroom valves are used, worked by tappets, cams or eccentrics. Lift-valves are generally employed on each side of the Corliss engine (fig. 41), where they are known as performing the function of the double-ported slide-valve. In the ordinary form of lift-valve, steam is admitted through a small pump with a weighted plunger, discharging fluid through a stop-cock which can be adjusted by hand when it is desired to alter the speed of the engine. The weighted plunger is raised by a rod from the eccentric, so that the lift of lift-valves depends on the extent to which the stop-cock is opened. When it comes down a certain way it opens the steam and exhaust valves, by liberating the steam; the engine then begins and admission continues until the steam-valve is closed: this is done directly by the motion of the beam, which also, at a later point in the stroke, closes the exhaust. Then the equilibrium-valve is opened, and the "in-door" stroke takes place, during which the plunger of the cataract is raised. When it is completed, the piston-plates until the steam has made the beam to open and the next "out-door" stroke begins. By being a cataract of this kind, when the engine is running the equilibrium-valve also, a pause is introduced at the end of the "out-door" stroke. Pauses have the advantage of giving the pump time of opening the pump-valves to settle in their seats without shock.

76. Methods of Regulating.—To make an engine run smoothly it is necessary to have an almost continuous process of adjustment. The simplest method is by means of a governor, made of a mass which revolves in a cylinder and is adapted to the amount of external work demanded of the engine. Even in cases where the demand for work is sensibly uniform, fluctuations in boiler-pressure still make regulation necessary. Generally the governor aims at regularity of speed; occasionally, however, it is some other condition of running that is maintained constant, as when a engine driving a dynamo-electric machine is governed by an electric regulator to give a constant difference of potential between the terminals of the induction-coils.

The ordinary methods of regulating are either (a) to alter the pressure at which steam is admitted by opening or closing the throttle-valve between the engine and the boiler, or (b) to alter the volume of steam admitted to the cylinder by varying the point of cut-off. The former plan was introduced by Watt and is still common, especially in small engines. The second plan of regulation is to employ a governor, which is subject to large variations of load. Within certain limits regulation by either plan can be effected by hand, but for the finer adjustment of speed some form of automatic governor is necessary. Speed governors are commonly of the centrifugal type: a pair of masses revolving about a spindle which is driven by the engine are kept from flying out by a certain controlling force. When the increase of the load is such as to increase the speed of the engine, this controlling force is no longer able to keep the masses revolving in their former path; they move out until the controlling force is sufficiently increased, and in moving out they act on the regulator of the engine, which may be a throttle-valve or some form of automatic expansion gear.

77. Equilibrium-Valve.—In whatever way the revolving masses are controlled, the controlling force may be treated as a force $F$ acting on each ball in the direction of the radius towards the axis of revolution. Then, if $F$ be the mass of the ball, $n$ the number of revolutions per second and $r$ the radius of the ball's path, the governor will revolve in equilibrium when $F = 4\pi^2 n^2 M$. When $F = 4\pi^2 n^2 M$, the angle $\alpha$, which brings the resultant eccentric into the direction CQ and makes the relative displacement of the two valves equal to the distance $l$.

In order that the configuration of the governor should be stable, $F$ must increase more rapidly than $n$, as the balls move outwards. It is obvious that no stable governor maintains a strictly constant demand for work; if the boiler-pressure or the demand for work is changed, a certain amount of permanent displacement of the balls is necessary to alter the steam-supply, and the balls are set moving in their only displacement when there is a permanent change in the speed. The maximum range of speed depends on that amount of change of $n$ which suffices to alter the configuration.

![Fig. 41.—Double-Beat Lift Valve.](image1)

![Fig. 42.—Watt's Governor.](image2)

![Fig. 43.—Loaded Governor.](image3)
of the governor from the position which gives no steam-supply to the position which gives full steam-supply, and the governor is said to be sensitive if this range is a small fraction of \( n \).

To find the configuration which the governor will assume at any particular speed, or the speed corresponding to a particular configuration, it is only necessary to determine the whole controlling force \( F \) per ball acting along the radius towards the axis for various values of \( r \). Let a curve \( AB \) (fig. 44) be drawn showing the relation of \( F \) to \( r \). At any assigned value of \( r \) set up an ordinate \( OC = 4\pi^2n^2rM \). Join \( OC \). The point \( c \), in which \( OC \) cuts the curve, determines the value of \( r \) at which the balls will revolve at the assigned speed \( n \). Or, if that is given, and the value of \( n \) is to be found, the line \( OC \) produced will determine \( C \), and then \( n = QC/4\pi^2rM \). The sensibility of the governor is determined by taking points \( a \) and \( b \) corresponding to full steam and no steam respectively, and drawing lines through them to determine the corresponding values of \( QA \) and \( QB \). When the frictional resistance \( f \) is known, an additional pair of curves drawn above and below \( ab \), with ordinates \( F + f \) and \( F - f \) respectively, serve to show the additional variations in speed which are caused by friction. The governor is stable throughout its whole range when the curve \( ab \) has a steeper gradient than any line drawn from \( O \) to meet it.

79. Isochronism.—If, when the balls are displaced, the controlling force \( F \) changes proportionally to the radius \( r \), the speed is constant. In other words, the equilibrium of the governor is then neutral; it can revolve in equilibrium at one, and only at one, speed. At this speed it assumes, indifferently, any one of its possible configurations. Opportunity is passed if the cut-off has already occurred, and the control only begins with the next stroke.

When the demand for power suddenly falls, the speed rises so much as to force the governor into a position of over-control, such that the supply of steam is no longer adequate to meet even the reduced demand for power. Then the speed slackens, and the same kind of excessive regulation is repeated in the opposite direction. A state of forced idleness is consequently set up. The effect is aggravated by the momentum which the governor balls acquire in being displaced. Hunting is to be avoided by giving the governor a fair degree of stability, by reducing as far as possible the static frictional resistances, and by introducing a viscous resistance to the displacement of the governor, which prevents the displacement from occurring too suddenly, without affecting the ultimate position of equilibrium. For this purpose many governors are furnished with a dash-pot, which is a hydraulic or pneumatic brake, consisting of a piston connected to the governor, working loosely in a cylinder which is filled with oil or with air.

80. Regulation by the Governor of the Steam-Supply: Throttle-Valve.—The throttle-valve, as introduced by Watt, was originally a disk turning on a transverse axis across the centre of the steam-pipe. It is now usually a double-beat valve or a piston-valve. When regulation is effected by varying the cut-off, and an expansion-valve of the slide-valve type is used, the governor generally acts by changing the travel of the valve. In other forms of automatic expansion-gear the lap of the valve is altered; in others the governor acts by shifting the expansion-valve eccentric round on its shaft, and so changing its angular advance.

81. Trip-Gear.—In large stationary engines the most usual plan of automatically regulating the expansion is to employ some form of trip-gear, the earliest type of which was introduced in 1849 by G. H. Corliss (1817-1888), of Providence, U.S.A. In the Corliss system the valves which admit steam are distinct from the exhaust-valves. The latter are opened and closed by a reciprocating piece which takes its motion from an eccentric. The former are opened by a reciprocating piece, but are closed by springing back when released by a trip- or trigger-action. The trip occurs earlier or later in the piston's stroke according to the position of the governor. The admission-valve is opened by the reciprocating piece with equal rapidity whether the cut-off is going to be early or late. It remains wide open during the admission, and then, when the trip-action comes into play, it closes suddenly. The indicator diagram of a Corliss engine consequently has a nearly horizontal admission-line and a sharply defined cut-off. Generally the valves of Corliss engines are cylindrical plates turning in hollow conical seats which end across the width of the cylinder. Often, however, the admission-valves in trip-gear engines are of the disk or double-beat type, and spring into their seats when
the trip-gear acts. Messrs Sulzer have developed this type with much success. Many forms of trip-geared have been invented by Corliss himself and by others. One of these, the Spencer Inglis trip-geared, by Messrs Hick, Hargreaves & Co., is shown in figs. 45 and 46. A wrist-plate A, which turns on a pin on the outside of the cylinder, receives a motion of oscillation from an eccentric. It opens the cylindrical rocking-valve B by pulling the link C, which consists of two parts, connected to each other by a pair of spring clips. When the link is pulled down the cam places itself more and more athwart the link, until at a certain point it forces the clips open. Then the upper part of the link springs back and allows the valve B to close by the action of a spring. Thus the diagrammatically makes its return stroke the clips re-engage the upper portion of the link C, and things are ready for the next stroke. The rocking-cam b has its position controlled by the governor through the link E in complicated, but its influence on the thrust is approximately found by treating the mass of the rod as divided into two parts, one of which moves with the cross-head and is therefore an addition to the reciprocating system, while the other moves with the crank-pin and is therefore an subtraction from the reciprocating system. The mass may be divided for this purpose into parts which are inversely proportional to the distances of the centre of gravity from the cross-head and crank-pin respectively. The governing diagrams of the steam thrust and of the forces due to inertia are given in Fig. 47. The true thrust diagram gives by the true length of the stroke the length of the engine in which the connecting-rod has 3½ times the length of the crank. The straight line g shows what the inertia force would be if the connecting-rod were treated as being so long that the deviation from simple-harmonic motion might be neglected.

The inertia of the reciprocating parts imposes a limit on the lightness of engines in the piston and cylinder type. The proportion of weight to power is reduced by increasing mean piston speeds, but this process cannot be carried beyond a point at which the forces due to inertia become too large to be conveniently neutralized by the stresses in the piston-rods and other parts. Some of these engines develop 6000 h.p., and the weight of engines and boilers together is only 50 lb per indicated h.p. Such a figure is, however, to be regarded as exceptional; weights of 150 to 200 lb per h.p. are more usual for engines of high-speed cruisers where saving of weight is specially desirable.

84. Balancing.—Another aspect in which the inertia of the reciprocating parts is important is in regard to the balancing of the engine as a whole. Any forces required to accelerate the piston and its attached parts produce reaction on the frame and bed-plate of the engine, which will set up vibrational disturbances in the ship. To avoid these, and group the vibrations in the proper directions, the object of balancing is to group the masses in such a manner that their inertia effects more or less neutralize one another. This is especially important in marine engines, where massive foundations are absent and the ship itself is the foundation. It may be shown that the periodic impulses due to weight balance find some portion of the hull free to respond synchronously with vibrations so violent as to be inconvenient and even dangerous. Even in land engines a want of balance causes enough vibration to constitute a serious nuisance in the neighbourhood.

85. In the consideration of balance, the system of eccentrically revolving masses and the system of reciprocating masses have been considered separately. The reciprocating mass such as a piston cannot be balanced by the use of revolving masses, for the forces which are due to the inertia of the piston necessarily act along the axis of its stroke, while those due to revolving masses are continually changing in direction and directly proportional to the speed of the engine. The problem may be approximately treated by resolving its mass into two constituents, one of which moves with the crank-pin, and is therefore an addition to the reciprocating system, and the other moves with the cross-head, and is therefore an addition to the reciprocating system. The mass of the rod may be divided for this purpose into parts which are inversely proportional to the distances of its centre of gravity from the crank-pin and the cross-head respectively. Let \( M_1, M_2, M_3, \ldots \) represent the various revolving masses, \( r_1, r_2, r_3, \ldots \), their effective radii of rotation, and \( a_1, a_2, a_3, \ldots \), their distances from any assumed plane of reference taken perpendicular to the shaft. Then the conditions necessary for balance amongst them are that the vector sum of \( M_1 r_1, M_2 r_2, M_3 r_3, \ldots \) and also that the vector sum of \( M_1 a_1, M_2 a_2, M_3 a_3, \ldots \) vanish, this latter quantity being the resultant of the moments of the individual forces resolved parallel to the vector of the first reference. In a four-crank engine there is no serious difficulty in arranging the revolving masses in such a manner that these conditions shall be satisfied, so far as those masses are concerned. The problem, as before, lends itself readily to graphical treatment (see his treatise on Balancing of Engines). With respect to the reciprocating masses, a first approximation towards balance is gained by dividing the engine into parts, subject to the conditions which would secure balance if the motions were simply harmonic. These conditions are identical with those which have just been stated for the revolving masses, when \( r \) is interpreted as the semi-amplitude of the harmonic of the engine. The remaining source of disturbance is that which comes from the fact that the reciprocating masses are connected to the cranks by rods of finite length; in other words, that the motions are not simply harmonic. A second force required to accelerate each piston is greater when the piston is at the end of the stroke farther from the shaft than when it is at the other end, and consequently the balance, which would be perfect if the connecting-rods were
Steam

indefinitely long, is disturbed by the presence of forces which vary periodically. The inertia of the revolving parts, if the crank throws, 120° apart, are employed, it will be found that the effect of the shortness of the connecting-rods in causing forces to act in the line of the stroke is reduced to a couple tending to tilt the engine, which, forward and aft, diverts the thrust of the piston. Newcomen, by using a second set of three cranks on the same shaft, the second set being so arranged that the couple to which it gives rise neutralizes the couple due to the first set. A six-crank engine may be arranged in such a way that the thrust of the pistons on the first two cranks balances, and the same state of balance can be secured when the number of cranks is reduced to five.

The first arrangement adopted in marine engines, when questions of balance are taken into account, is to have four cranks and consequently four sets of reciprocating masses. In the "Yarrow-Schlick-Tweedie" system of balancing engines four cranks are employed, and by adjusting the relative positions of the pistons and connecting-rod lengths, a close approximation to perfect balance is obtained. In triple expansion this arrangement is readily applied when two low-pressure cylinders are used instead of one, the steam from the intermediate cylinder being divided between them, and it is also of course applicable to quadruple expansion engines.

87. In this connection mention may be made of a type of engine which has been in various electric power stations, especially in America, in which a revolving mass might be employed to balance conversely the inertia effects of two cranks. This was the engine in which the cylinders stand at right angles to one another, one being horizontal and the other vertical. If the piston masses were made equal it is clear that the inertia effect of a revolving mass could be resolved into two components which would balance both. It does not appear, however, that advantage has been taken of this property in the design of actual engines of this type. In the London County Council power station at Greenwich, where the engine is used, the unbalanced effects of inertia are so considerable as to affect the instruments at the Observatory half a mile away. One of the conspicuous merits of the steam turbine is that it avoids the use of reciprocating parts and so escapes the inconveniences and limitations to which the inertia of reciprocating parts gives rise.

88. Types of Engine.—In classifying engines with regard to their general arrangement of parts and mode of working, account has to be taken of a considerable number of independent characteristics. We begin first in the compound- and non-compound engines, with a subdivision of the condensing class into those which act by surface condensation and those which use injection. Next there is the division into compound and non-compound, with a further classification of the former as double-, triple- or quadruple-expansion engines. Again, engines may be classed as single or double-acting, according as the steam acts on one or alternately on both sides of the piston. Again, a few engines—such as steam hammers and certain kinds of steam-pumps—are non-rotative, that is to say, the reciprocating motion of the piston does work simply on a reciprocating piece; but generally an engine does act on a continuously revolving shaft, which is, of course, the case in the steam engines. In practice the shaft of the revolving shaft is connected directly with the piston-rod by a connecting-rod, and the engine is then said to be direct-acting; in other cases, of which the ordinary beam engine is the most important example, a lever is interposed between the piston and the connecting-rod. The same distinction applies to non-rotative pumping engines, in some of which the piston acts directly on the pump-rod, while in others it acts through a beam. The position of the cylinder is another element of classification, giving horizontal, vertical and inclined cylinder engines. Many vertical engines are further distinguished as belonging to the inverted cylinder class; that is to say, the cylinder is above the connecting-rod and crank. In oscillating cylinder engines the connecting-rod is dispensed with; the piston-rod works on the crank-pin, and the cylinder oscillates on trunnions to allow the piston-rod to follow the crank-pin round its circular path. In trunk engines the piston-rod is dispensed with; the connecting-rod extends as far as the piston, to which it is jointed, and a trunk or tubular extension of the piston, through the cylinder cover, gives room for the rod to oscillate. In rotary engines there is no piston in the ordinary sense; the steam does work on a revolving piece, and the necessity is thus avoided of afterwards converting reciprocating into rotary motion. Steam turbines, may, in one sense, be regarded as an extreme development of the rotary type; but they are distinct from all other steam engines in this that their action depends on the kinetic energy of the steam.

89. Beam Engines.—In the single-acting atmospheric engine of Newcomen the beam was a necessary feature; the use of water-packing for the piston required that the piston should move down in the working stroke, and a beam was needed to let the counterpoise pull the piston up. Watt's improvements made the beam no longer necessary; and in one of the forms he designed it was discarded—namely, in the form of pumping engine known as the Bull engine, in which a vertical inverted cylinder stands over and acts directly on the pump-rod. But the beam type was generally retained by Watt, and for many years it remained a favourite with builders of engines of the larger class.

The beam formed a convenient receiver for pump-rod and valve-uplift, and its horizontal end was used in the parallel beam engine designed by Watt as a means of guiding the piston-rod, which could easily be applied to a beam engine, was, in the early days of engine-building, an easier thing to construct than the plane surfaces which are the natural guides of the piston-rod in a direct-acting engine. In modern practice the direct-acting type has to a very great extent displaced the beam type. For mill-driving and the general purposes of a rotative engine the beam type is now rarely chosen. In pumping engines it is somewhat more common, but even there the direct-acting forms are generally preferred.

90. Automatic Engines.—Of direct-acting engines the horizontal type has in general the advantage of greater accessibility, but the vertical economizes floor space. In small forms the engine is generally self-contained, that is to say, a single frame or bedplate carries all the parts including the main bearings in which the crank-shaft with its flywheel turns. The frame often takes what is called a girder shape, which brings a portion of it into a favourable position for taking the thrust between the cylinder and the crank-shaft bearings and allows two surfaces to be formed on the frame to serve as guides for the cross-head. When a condenser is used with a horizontal engine it is usually placed behind the cylinder, and the air-pump, water-pump, and condenser, has a horizontal plunger or piston on a "tailrod" or continuation of the main piston-rod through the back cover of the cylinder. In large horizontal engines the condenser generally stands in a well below, and its pump, which is vertical, is driven by means of a bell-crank lever attached by a link to the engine cross-head.

91. Coupled Engines.—When uniformity of driving effort or the absence of dead points is important, two independent cylinders often work on the same shaft by cranks at right angles to each other. Such engines, which are called "coupled," can start readily from any position; the ordinary locomotive engine is a coupled engine. In a double-acting engine the pistons of the revolving shaft are connected directly with the piston-rod by a connecting-rod, and the engine is then said to be direct-acting; in other cases, of which the ordinary beam engine is the most important example, a lever is interposed between the piston and the connecting-rod. The same distinction applies to non-rotative pumping engines, in some of which the piston acts directly on the pump-rod, while in others it acts through a beam. The position of the cylinder is another element of classification, giving horizontal, vertical and inclined cylinder engines. Many vertical engines are further distinguished as belonging to the inverted cylinder class; that is to say, the cylinder is above the connecting-rod and crank. In oscillating cylinder engines the connecting-rod is dispensed with; the piston-rod works on the crank-pin, and the cylinder oscillates on trunnions to allow the piston-rod to follow the crank-pin round its circular path. In trunk engines the piston-rod is dispensed with; the connecting-rod extends as far as the piston, to which it is jointed, and a trunk or tubular extension of the piston, through the cylinder cover, gives room for the rod to oscillate. In rotary engines there is no piston in the ordinary sense; the steam does work on a revolving piece, and the necessity is thus avoided of afterwards converting reciprocating into rotary motion. Steam turbines, may, in one sense, be regarded as an extreme development of the rotary type; but they are distinct from all other steam engines in this that their action depends on the kinetic energy of the steam.

92. Compound Engines, Coupled or Tandem.—Large direct-acting engines are usually compounded either by having a high- and a low-pressure cylinder side by side, with cranks at right angles, or by putting one cylinder behind the other with the axes of both in the same line. The latter is called the tandem arrangement. In a tandem engine, since the pistons agree in phase, the steam may expand directly from the small into the large cylinder. But the connecting-pipe and steam chest form a receiver of considerable size, and to avoid loss by "drop" the supply of steam to the large cylinder is cut off long before the end of the stroke. For mill engines the compound tandem and compound coupled types of engine are the most usual. The high-pressure cylinder is very generally fitted with Corliss or other trip-gear.

93. Jet and Surface Condensation.—In land engines using condensation the jet form of condenser is common, but surface condensation is resorted to when the available water-supply is unlimited and for boiler feed. When there is no large supply of condensing water a very fair vacuum can be obtained by using
STEAM ENGINE

an evaporative condenser, consisting of a stack of pipes into which the exhaust steam is admitted and over which a small amount of cooling water is allowed to drip. This water is evaporated by the heat which is extracted in condensing the steam within. Such a condenser is placed in the open, generally on a roof where the air has free access. The amount of water it uses need not exceed the amount of steam that is condensed, and is therefore a very small fraction of the amount required in a jet or surface condenser.

94. High-Speed Direct-Acting Engines.—Prior to the advent of the steam turbine the demand for engines suitable for driving electric generators without the intervention of a belt led to the introduction of various forms of direct-acting engine adapted to run at a high speed. Some of these were single acting, steam being admitted to one side of the piston only, generally the back, with the result that the rods could be kept in a state of thrust throughout the revolution, and alternations of stress in them and at the joints thereby avoided, together with the knocking and wear of the bearing brasses which it is apt to cause. To secure, however, that the connecting-rod should always push and never pull against the crank-pin there had to be much cushioning during the out stroke on account of the fact that frequently the middle of that stroke to the end the reciprocating mass was being retarded. In engines designed by P. W. Willans, which were highly successful examples of this class, the cushioning was provided by means of a supplementary piston which compressed air during the out stroke; the energy which the reciprocating masses had to part with in losing their motion during the second half of the out stroke was stored in this air and was restored in the succeeding down stroke.

Willans obtained compound or triple expansion by mounting two or three cylinders in tandem in a vertical line, with the air-compressing piston below them in the form of a trunk which served also as a guide for the cross-head. The piston-rod was hollow and within it there was a valve rod carrying piston valves for the admission and release of the steam. The valve rod was worked by an eccentric on the crank-pin which gave it the proper relative motion with respect to the hollow piston within which it worked. The engine was entirely enclosed in a casing the bottom of which formed an oil bath in which the cranks splashed to ensure ample lubrication. These engines for a time had much vogue and gave good results. Many of them are in use in electric light stations and elsewhere, but the tendency now is to use turbines for this class of work, and even in cases where reciprocating engines are preferred they are now more usually of the double-acting type, which has the advantage of giving a greater output of power for the same weight.

95. Double-Acting High-Speed Engines.—Of double-acting high-speed engines an interesting fact is that of Messrs Belliss and Morcom, the chief distinctive feature of which is the use of forced lubrication at the pin joints and shaft bearings. In a double-acting engine, where the thrust acts alternately on one and the other side of the crank-pins and cross-head pins, high frequency of stroke tends to produce much knocking and wear unless the brasses are very closely adjusted, and in that case the pins are liable to get hot, and to "screw" by expanding sufficiently to fill the small clearance. This difficulty, which exists when lubrication is carried out in the ordinary way, is overcome in the Belliss engine by feeding the bearings with a continuous supply of oil, which is pumped in under a pressure of about 15 lb per sq. in. The presence of a film of oil is thereby continuously secured, and knocking is prevented although the brasses are not set very close. Notable examples in which double action is combined with a relatively high frequency of stroke are found in naval engineering practice, especially in the engines of high-speed cruisers and torpedo-boat destroyers. As a rule these engines employ triple expansion with four cranks and four cylinders, the third stage of the expansion being performed in two cylinders, which divide the steam between them. But in this field also the steam turbine is rapidly displacing the reciprocating type.

96. Pumping Engines.—In engines for pumping or for blowing air it is not essential to drive a revolving shaft, and in many forms the reciprocating motion of the steam piston is applied directly or through a beam to produce the reciprocating motion of the pump-piston or plunger. On the other hand, pumping engines are frequently made rotative for the sake of adding a flywheel.

Fig. 48 shows a compound inverted vertical pumping engine of the non-rotative class by Messrs Hathorn, Davey & Co. Steam is distributed through lift valves, and the distribution of steam is controlled by means of a cataract, which makes the pistons pause at the end of each stroke. The pistons are in line from the bottom and are coupled by an inverted beam similar to that of Worthington. In other words, the motion, instead of being almost simple harmonic as it is in rotative engines, is such that the form of the inertia curve when drawn as in Fig. 47 is nearly the same as that of the steam curve, with the result that the distance between the two, which represents the net effort on the pump-plunger, is nearly constant. The massive pump-rods act in such a way as to form a reciprocating equivalent of a flywheel.

97. It is, however, only to deep well pumping that this applies, and a very numerous class of direct-acting steam pumps have too little mass in their reciprocating parts to allow such an adjustment to take place. A familiar example is the small donkey pump used for feeding boilers, in which the steam-piston and pump-plunger are on one and the same rod. In some of these pumps a rotative element is introduced, partly to secure steadiness of working and partly for convenience in working the valves. But many pumps of this class are entirely non-rotative, and in such cases the steam is generally admitted throughout the stroke without expansion. In some of them the valve is worked by tappets from the piston-rod. In the Blake steam pump a tappet worked by the piston as it reaches each end of its stroke throws over an auxiliary steam-valve, which admits steam to one or other side of an auxiliary piston carrying the main slide-valve.

98. Worthington Engines.—In the Worthington pumping engine two steam cylinders are placed side by side, each working its own pump-piston. The piston-rod of each is connected by a short link to a swinging bar, which actuates the slide-valve of the other steam cylinder. In this way one piston begins its stroke when the motion of the other is about to cease, and a
smooth and continuous action is secured. These engines have been extensively applied, on a large scale, to raise water for the supply of towns and to force oil through "pipe-lines" in the United States. In the larger sizes they are made compound, each high-pressure cylinder having a low-pressure cylinder tandem with it on the same rod. To allow of expansive working a device is added which compensates for the inequality of effort resulting from an early cut-off. A cross-head A (fig. 49) fixed to each of the piston-rods is connected to the piston-rods of a pair of oscillating cylinders B, B, which contain water. From the bottom of the latter reservoir full of air compressed to a pressure of about 300 lb per square inch. When the stroke (which takes place in the direction of the arrow) begins the pistons are at first forced in, and work is at first done by the main piston-rod, through the compensating cylinders B, B, on the compressed air in the reservoir. This continues until the cross-head has advanced so that the cylinders stand at right angles to the line of stroke. Then for the remainder of the stroke the compensating cylinders assist in driving the main piston, and the compressed air gives out the energy which it stored in the earlier portion. The volume of the air reservoir is so much greater than the volume of the cylinders, B, B, that the air pressure remains nearly constant throughout the stroke. Any leakage from the cylinder or reservoir is made good by a small pump which the engine drives.

99. Pulsometer.—Hall's "pulsometer" is a peculiar pumping engine without cylinder or piston, which may be regarded as the modern representative of the engine of Savary. The sectional view, fig. 50, shows its principal parts. There are two chambers A, A', narrowing towards the top, where the steam-pipe B enters. A ball-valve C allows steam to pass into one of the chambers and closes the other. Steam entering (say) the right-hand chamber forces water out of it past the clack-valve V into a delivery passage D, which is connected with an air-vessel. When the water level in A sinks so far that steam begins to blow through the delivery passage, the water and steam are disturbed and so brought into intimate contact, the steam in A is condensed, and a partial vacuum is formed. This causes the ball-valve C to rock over and close the top of A, while water rises from the suction-pipe E to fill that chamber. At the same time steam begins to enter the other chamber A', discharging water from it, and the same series of actions is repeated in either chamber alternately. While the water is being driven out there is comparatively little compensation of cylinder volume, because the shape of the vessel does not promote the formation of eddies, and partly because there is a cushion of air between the steam and the water. Near the top of each chamber is a small air-valve opening inwards, which allows a little air to enter each time a vacuum is formed. When any steam is condensed, the air mixed with it remains on the cold surface and forms a non-conducting layer. The pulsometer is, of course, far from efficient as a thermodynamic engine, but its suitability for situations where other steam-pumps cannot be used, and the extreme simplicity of its working parts, make it valuable in certain cases.

100. Rotary Engines.—From the earliest days of the rotary engine attempts have been made to avoid the intermittent reciprocating motion which an ordinary piston engine first produces and then converts into motion of rotation. Murdoch, the contemporary of Watt, proposed an engine consisting of a pair of spur-wheels gearing with one another in a chamber through which steam passed by being carried round the outer sides of the wheels in the spaces between successive teeth.

In Dudgeon's wheel engine the steam was admitted by ports in side-plates into the clearance space behind teeth in gear with one another, just after they had passed the line of centres. From that point to the end of the arc of contact the clearance space increased in volume; and it was therefore possible, by stopping the admission of steam at an intermediate point, to work expansively. The difficulty of maintaining steam-tight connexion between the teeth and the side-plates on which the faces of the wheels slide is obvious; and the same difficulty has been lessened elsewhere by the use of rotary engines. These have been devised in immense variety, in many cases, it would seem, with the idea that a distinct mechanical advantage was to be secured by avoiding the reciprocating motion of a piston. In point of fact, however, very few forms entirely escape having pieces with reciprocating motion. In all rotary engines, with the exception of steam turbines—where work is done not by pressure but by the kinetic impulse of steam—there are steam chambers which alternately expand and contract in volume, and this action usually takes place through a more or less violently reciprocating of working parts. So long as engines work at a moderate speed there is some advantage in avoiding reciprocation; the alternate starting and stopping of piston and piston-rod does not affect materially the frictional efficiency, throws no deleterious strain on the joints, and need not disturb the equilibrium of the machine as a whole. The case is different when very high speeds are concerned; it is then desirable as far as possible to limit the amount of reciprocating motion and to reduce the masses that partake in it.

101. Types of Marine Engines.—The early steamers were fitted with paddle-wheels, and the engines used to drive them were for the most part modified beam engines. Bell's "Comet" was driven by a species of inverted beam engine, and another form of inverted beam, known as the side-lever engine, was for long a favourite with marine engineers. In the side-lever engine the cylinder was vertical, and the piston-rod projected through the top. From a crosshead on the rod a pair of links, one on each side of the cylinder, led down to the ends of a pair of horizontal beams or levers below, which oscillated about a fixed gudgeon at or near the middle of their length. The two levers were joined at their other ends by a cross-tail, from which a connecting-rod was taken to the crank above. The side-lever engine is now obsolete. In American practice the advantage of the beam type, with a brace-beam supported on A frames above the deck, are still common in river-steamers and coasters. An old form of direct-acting paddle-engine was the sweep-engine, in which the cylinder was set vertically below the crank. Two piston-rods projected through the top of the cylinder, one on each side of the shaft and of the crank. They were united by a crosshead sliding in vertical guides, and from this a return connecting-rod led to the crank. Modern paddle-wheel engines are usually one of the following types. (1) In oscillating cylinder engines the cylinders are set under the crank-shaft, and for the most part modified beam engines are the crank. The cylinders are supported on trunnions which give them the necessary freedom of oscillation to follow the movement of the crank. Steam is admitted through the trunnions to slide-valves on the sides of the cylinders. In some instances the mean position of the cylinders is inclined instead of vertical; and oscillating engines have been arranged with one cylinder before and another behind the shaft, both pistons working on one crank. The oscillating cylinder type is best adapted for what would now be considered comparatively low pressures of steam. (2) Diagonal engines are direct-acting engines of the ordinary connecting-rod type, with the cylinders fixed on an inclined bed and the guides sloping up towards the shaft. When the screw-propeller began to take the place of paddle-wheels in ocean steamers, the increased speed which it required was at first supplied by using spur-wheel gearing in conjunction with one of the forms of engines then usual in paddle steamers.
After a time types of engine better suited to the screw were introduced, and were driven fast enough to be connected directly to the screw-shaft. The smallness of the horizontal space on either side of the shaft formed an obstacle to the use of horizontal engines, but this difficulty was overcome in several ways. In Penn's **trunk** engine, now obsolete, the engine was shortened by attaching the connecting-rod directly to the piston, and using a hollow piston-rod, called a trunk, large enough to allow the connecting-rod to oscillate inside it. The **return-connecting-rod** engine was another horizontal form at one time used in the British navy. It was a steeple engine placed horizontally, with two, and in some cases four, piston-rods in each cylinder. The piston-rods passed clear of the shaft and the crank, and were joined beyond it in a guided crosshead, from which a connecting-rod returned. In **twin** engines, both in the navy and in merchant ocean steamers one general type of engine is universal, where the reciprocating engine has not yet been displaced by the steam turbine. This is the inverted vertical direct-acting engine, with two or more cylinders placed side by side directly over the shaft. Two, three and four cranks are employed, the arrangement with four cranks being specially suitable, as has already been pointed out, when the balance of the engine at high speeds has to be secured. As a rule naval engines are triplex compound, and those of merchant vessels either triple or quadruple. In vessels of high speed and power the engines are developed in twin sets, on two shafts with twin screw-propellers. The marine engine is always furnished with a surface condenser, consisting of a multitude of brass tubes about ½ in. in diameter cooled by sea-water which is caused to circulate through the condenser by means of a circulating pump. This pump and also the air pump are often driven independently of the main engine.

It is in marine practice that the largest examples of engines are to be found. The triple expansion engines of the **Cass Gilbert's** steam yacht, which develops 30,000 h.p., consist of twin sets, on two shafts, each set having three cranks and five cylinders, two of 37 in., one of 79 in. and two of 98 in. diameter, with a stroke of 69 in. In the **Kaiser Wilhelm der Grosse** engines of the same power are arranged in twin sets, each set consisting of four cylinders, one of 52 in. diameter, one of 89 and two of 96-4, the four giving triple expansion and working on four cranks. The **Deutschland** develops 36,000 h.p. with twin sets, each of which comprises two 36-6-in. cylinders, one 73-6-in., one 103-9-in. and two 106-3-in. with a stroke of 72-8 in. In the **Kaiser Wilhelm II.** each of the twin shafts is driven by two 3-crank 4-cylinder quadruple expansion engines, the diameters being 37-4, 49-7, 74-8 and 112-2 in. and a stroke of 70-9 in. With a working pressure of 225 lb. per square inch these engines develop in all 40,000,000 h.p. These are examples of the most powerful reciprocating engines used in the propulsion of ships, but the successful application of the Parsons turbine to marine use has enabled even these powers to be greatly surpassed.

**Locomotive Engines.** The ordinary locomotive consists of a pair of direct-acting horizontal or nearly horizontal engines, fixed in a rigid frame under the front end of the boiler, and coupled to the same shaft by cranks at right angles, each with a single slide-valve worked by a link-motion, or by a form of radial gear. The engine is non-condensing, except in a very few special cases, and the exhaust steam, delivered at the base of the funnel through a blast-pipe, serves to produce a draught of air through the furnace. In some instances a portion of the exhaust steam, amounting to about one-fifth of the whole, is diverted to heat the feed-water. In tank engines the feed-water is carried in tanks on the engine itself; in other engines it is carried behind in a tender. On the shaft are a pair of driving-wheels, whose frictional advantages to ten bits furnishes the necessary tractive force. In some engines a single pair of driving-wheels are used; in many more a greater tractive force is secured by having two equal driving-wheels on each side, connected by a coupling-rod between pins on the outside of the wheels. In some engines a still greater proportion of the whole weight is utilized to give tractive force by coupling three or more wheels on each side. It is now general to have under the front of the engine two or four smaller wheels which do not form part of the driving system. These are carried in a **boigie**, that is, a small truck upon which the front end of the boiler rests by a swivel-pin or plate which allows the boigie to turn, so as to adapt itself to curves in the line, and thus obviate the grinding of tyres and danger of derailment which would be caused by using a long rigid wheel base. The boigie appears to have been of English origin; it was brought into general use in America, and is now common in English as well as in American practice. Instead of a four-wheeled boigie, a single pair of leading wheels are also used, carried by a **Bissel pony** truck, which has a swing-bolster pivoted by a radius bar about a point some distance behind the axis of the wheels. This has the advantage of combining lateral with radial movement of the wheels, both being required if the wheel base is to be properly accommodated to the curve. Another method of getting lateral and radial freedom is the plan used by F. W. Webb of carrying the leading axle in a box curved to the arc of a circle, and free to slide laterally for a short distance, under the control of springs, in curved guides.

In **inside-cylinder** engines the cylinders are placed side by side within the frame of the engine, and their connecting-rods work on cranks in the driving shaft. In **outside-cylinder** engines the cylinders are spread apart far enough to lie outside the frame of the engine, and to work on crank-pins on the outsides of the driving wheels. This dispenses with the cranked axle, which is the weakest part of a locomotive engine. Owing to the frequent alternation of strain to which it is subject, a locomotive crank axle is peculiarly liable to rupture, and has to be removed after a certain amount of use.

The outside-cylinder type is adopted by several British makers; in America it is almost universal. They are the cylinders are in castings which are bolted together to form a saddle frame, and in which the bottom of the smoke-box sits. The slide-valves are on the tops of the cylinders, and are worked through rock-ing levers from an ordinary link-motion. Fig. 51, which is a half section through one cylinder of an American locomotive, by the Baldwin Company of Philadelphia, shows the position of the cylinders and valves.

In **inside-cylinder** engines the slide-valves are frequently placed back to back in a single valve-chest between the cylinders. The width of the engine within the frame leaves little room for them there, and they are reduced to the flattest possible form, in some cases with split ports, half above and half below a partition in a central horizontal plane. In some engines the valves are below the cylinders; in many others the valves work on horizontal planes above the cylinders; this position is specially suitable for what is commonly known as a saddle of radial gear. This form of radial gear has the advantage, which is of considerable moment in inside-cylinder engines, that a part of the shaft's length which would otherwise be needed for eccentrics is available to increase the width of main bearings and crank-pins, and to strengthen the crank-cheeks.

The principle of compounding has often been applied to locomotive engines, but without much advantage. On this subject the reader should refer to the article **Railway: Locomotive Power.** A more important modern departure is the use of highly superheated steam, which in many locomotives has been attended with conspicuous success.

---

105. Steam Turbines.—Steam turbines are distinguished from all other types of steam engine by the fact that their action involves a double transformation of energy. The heat energy present in the steam is first employed to set the steam itself in motion, giving it kinetic energy, and this in turn is employed to do work on the turbine blades. A brief account of the main principles involved will make the action of the various types of steam turbine more intelligible.

106. Theory of the Steam-jet.—Consider an element of steam, of unit mass, acquiring kinetic energy in the expansion of the steam through a nozzle or other channel, from a region of pressure $p_1$ to a region of lower pressure $p_2$. Its volume changes from $V_1$ to $V_2$ in the process. The work done upon it by steam from behind is $p_2V_2$. The work which it does on the steam in front is $p_1V_1$. The net amount of work done upon it is therefore $p_2V_2 - p_1V_1$. Its velocity changes from $V_1$ to $V_2$ and the kinetic energy which it gains is therefore $(V_2^2 - V_1^2)/2$. The internal energy changes from $E_1$ to $E_2$. Hence by the conservation of energy

$$(V_2^2 - V_1^2)/2 = E_2 - E_1 + p_2V_2 - p_1V_1,$$

which may be written

$$(V_2^2 - V_1^2)/2 = J(E_0 - E_1) + p_2V_2 - p_1V_1,$$

where $I$ is the total heat ($\S$ 31), which is equal to $E + p_0V$. It is assumed here that the action is adiabatic in the sense that no heat is received by the steam or given up by it to other bodies as the process goes on.

It is usual to speak of the change of $I$ as the "heat drop" which the steam undergoes in acquiring velocity. When the heat drop is known the gain in velocity is readily found as above. In considering the heat drop account must, of course, be taken of the wetness of the steam, or of its superheat if it has any. Thus, for superheated steam $I = I_1 + (t' - t)$ where $I_1$ is the total heat of saturated steam at the same pressure and temperature. And $I = I_1 + q$ where $I_1$ is the total heat of water, $L$ the latent heat, and $q$ is the dryness fraction.

During this process of expansion, which we assume to be adiabatic, the steam becomes wet, and the value of $q$ accordingly falls. As has been shown in $\S$ 36, the dryness may be found at any stage in adiabatic expansion from the formula

$$q = \frac{t - 1}{\frac{374}{5} - \frac{L}{t} + \log \frac{t}{t_0}},$$

or it may be determined by measurement from the entropy-temperature diagram. A still more convenient diagram in which the heat drop can be directly measured is one introduced by Moller, in which the co-ordinates are the entropy and the total heat (see Moller, loc. cit., or Ewing's Steam Engine).

The pressure-volume diagram gives a very useful alternative means of recovering the heat drop or energy available for transformation. Consider steam or any other gas supplied at pressure $p_1$ and expanding to pressure $p_2$, at which pressure it is discharged. The work which it does is measured by the area ABCD of the pressure-volume diagram (fig. 52), namely

$$\int_{p_1}^{p_2} p dp = \frac{n}{n-1} (p_2 \ln p_2 - p_1 \ln p_1),$$

where $D$ is the ratio in which the pressure falls, namely $p_2/p_1$. The mode of expansion is such as to make $p^n = \text{constant}$, $n$ being any index, then

$$\int_{p_1}^{p_2} p dp = \frac{n}{n-1} (p_2 \ln p_2 - p_1 \ln p_1),$$

which will be found on evaluation to agree closely with the value of $I_1 - I_2$.

107. Form of the Jet in Adiabatic Expansion.—As expansion proceeds the volume of the steam, per pound, at any stage is found by multiplying the volume of 1 lb of saturated steam, at the pressure then reached, by the dryness fraction $q$. On comparing the velocity acquired at any intermediate stage of expansion with that calculated from the heat drop from stage to stage at the pressure $\pi$ less with the increase in volume, it will be found that in the earliest stages the gain in velocity is relatively great, but as expansion proceeds the increase in volume outruns the increase in velocity. Hence the proper form for a nozzle to give adiabatic expansion is one in which the area of section at first contracts and afterwards becomes enlarged. The area of section to be provided for the discharge is found by dividing the volume at each stage of the velocity $V$ acquired up to that stage, and the ratio $v/V$ at first diminishes and afterwards increases as the expansion proceeds. Take, for instance, a numerical example, a case in which dry saturated steam is admitted to a nozzle at an absolute pressure of 213 lb per sq. in., and expands adiabatically, giving itself velocity, until the pressure falls to 1-7 per sq. in. It will be found on working out numerical values that until the pressure falls to about 123 lb per sq. in. the steam is gaining velocity so rapidly that though its volume is expanding the stream-lines are convergent. Below that pressure, however, the augmentation of volume is relatively so great that a larger and larger area of section has to be provided for the flow. Thus, when the pressure is 123 lb per sq. in. the dryness $q$ is 0-96, the volume per pound is 3-512 cubic ft., the heat drop is 713 thermal units, giving a velocity of 1510 ft. per second. Consequently, the area of the stream is 0-000233 sq. ft. per pound of flow, and this is the minimum value. When the pressure falls to 1-7 lb per sq. in. the dryness $q$ is 0-784, the volume per pound is 157-8 cubic ft., the heat drop is 717-3 thermal units, giving a velocity of 1930 ft. and consequently the area of the stream is 0-000386 sq. ft. per pound of flow.

108. De Laval's Divergent Nozzle.—It is on this basis that De Laval's divergent nozzle is designed. The "throat" or smallest section is approached by a more or less conical entrance, allowing the stream-lines to converge, and from the throat onwards the nozzle expands in any gradual manner, generally in fact as a simple cone (fig. 53). In the actual area of section would be seventeen times that of the throat for the pressure to produce for adiabatic expansion down to a pressure of 1-7 lb per sq. in. With any final area less than this the pressure at exit would be greater than 1-7 lb; in which case, in fact adjust itself to give a value of $v/V$ corresponding to the area, and the remainder of the pressure would be wasted. For expansion to atmospheric pressure (1-7 lb per sq. in.) the area at exit would be 3.14 times that of the throat.

The equation of velocity

$$\frac{V_2}{V_1} = \frac{n}{n-1} \left(1 - \frac{D-1}{D} \right)$$

may be applied to calculate generally the discharge per square foot of steam section, and hence to find at what point in the fall of pressure this discharge becomes insufficient as words, to determine the pressure at the throat. Since $p_0 = p_{o*}$

$$r = \frac{1}{D}$$

where $D = p_0/p_{o*}$.

The discharge per square foot when the volume is $r$ is

$$Q = \sqrt{\frac{2n}{n-1} \frac{p_{o*}}{p_{o*} \left( \frac{n}{n-1} \right)}}.$$

$Q$ will be a maximum when $dQ/dr = 0$, which occurs when

$$D = \left( \frac{2}{n-1} \right)^{n-1}.$$

This result is general for any gas. With saturated steam, $n$ being 1-35, $Q$ is a maximum when $D = 0-577$, that is to say, the entrance is at 0-577 of the initial pressure, a result which agrees with the figures quoted above for a particular case.

The maximum value of $Q$, namely the discharge in pounds per square foot at the throat, is

$$3.64 (p_1/h_1),$$

and the velocity there is $5.83v(p_1/h_1)$. In these expressions $p_1$ is the initial pressure in pounds per square foot, and $h_1$ is the enthalpy there.
dissipation of energy in the steam. But under real conditions there is a progressive dissipation of energy through friction; as expansion proceeds the steam loses part of its kinetic energy which is restored to it as heat. Thus, at every stage in the process the velocity would be in frictionless adiabatic expansion, but the steam is drier and its volume is greater in consequence of the restored heat.

Referring to the entropy-temperature diagram (fig. 54) the process of expansion under conditions involving friction is represented not by the adiabatic line $cd$, but by some such line as $eg$ lying between the adiabatic line $cd$ and the friction line $cf$. The condition of dryness is $ag$/$af$ instead of $ad$/$af$. During this expansion the effect of friction, as regards the entropy, is equivalent to the amount of work of evaporation of a quantity of heat represented by the area $pegr$. Hence that area represents the work converted by friction into heat. The whole work done during the expansion is the area $abe$, which is more than before by the area $deg$. The difference, namely $abe$ $minus$ $pegr$, represents what may be called the net heat drop when friction is allowed for: it represents what is effectively available for giving kinetic energy to the jet. This net area may also be expressed as equal to $abe$ $minus$ $pegr$. Compared with frictionless adiabatic expansion, the net loss resulting from friction is the area $pegr$. The volume is increased in the ratio of $ag$ to $ad$, and this has to be taken account of in determining the proper dimensions of the divergent nozzle.

112. Turning now to the question of utilizing the kinetic energy of steam in a steam turbine, it will be clear from the figures that have been given that if the whole heat drop is allowed to give kinetic energy to the steam in one operation, as in the De Laval nozzle, a velocity of about 4000 ft. per second has to be dealt with. To take advantage of a jet in the most efficient manner in a turbine consisting of a single wheel the velocity of the buckets against which the steam impinges should be nearly one half the velocity of the steam. But a periphery-velocity approaching 2000 ft. per second is impracticable. Apart from the difficulties which it would involve as regards gearing down to such a speed as would serve for the driving of other machines, which are to employ the power, there are no materials of construction fitted to withstand the forces caused by rotation at such a speed.

Hence it is advantageous to divide the process into stages. This may be done by using more than one wheel to absorb the kinetic energy of the jet, as is done in the Curtis turbine, or by dividing the heat drop into many smaller parts, each made to do its share of the work so small that the steam never acquires an inconveniently great velocity, as is done in the Parsons turbine. Turbines which employ one or other of these methods, or a combination of both, achieve a greater economy of steam than is practicable with a single wheel.

113. De Laval Turbine.—Thanks, however, to the inventions of De Laval, the single expansion single wheel type of turbine, with buckets in the rim, has been brought to a degree of efficiency which, while considerably less than is reached in compound turbines, is still remarkably good. This has been done by the use of the divergent nozzle and with the help of mechanical devices which enable the peripheral speed to be very high, though even with the help of these devices the speed of the buckets falls considerably short of that which would be suitable to the velocity of the jet. In De Laval's turbine the steam expands at one step from the full pressure of the supply to the pressure of the exhaust by discharge in the form of a jet from a divergent nozzle. It then acts on a ring of buckets or blades in much the same way as the jet of water acts on the buckets of a Pelton wheel or other form of pure impulse turbine. To utilize a fair fraction of the kinetic energy of the jet the blades have to run at an enormous velocity, and the speed of the shaft which carries them is so great that gearing down is resorted to before the motion is applied to useful purposes. The general arrangement of the steam nozzle and turbine blades is illustrated in fig. 55. The blades project from the circumference of a disk-shaped wheel and form a complete ring round it, only a few of the blades being shown in the sketch. The pressure drop through the nozzle is calculated with reference to the final pressure, according to the principles already explained. The jet impinges at one side of the wheel and escapes at the other after having had its direction of motion nearly reversed. The expansion in the nozzle is carried to atmospheric pressure, or near it, if the turbine is to be used without a condenser; but in many cases an ejector condenser is employed, and when that is done the nozzle is of a form which admits it to expand the steam to a correspondingly lower pressure. It is only in the smaller sizes of these turbines that a single nozzle is used; in the larger steam turbines, as in large Pelton wheels, several nozzles are applied at intervals along the circumference of the disk.

The peripheral velocity of the blades ranges from about 500 ft. per second in the smallest sizes (5 h.p.) up to nearly 1400 ft. per second in turbines of 300 h.p. In a 50 h.p. De Laval turbine the shaft which carries the turbine disk makes 16,000 revolutions per minute; in the 5 h.p. size it makes as many as 30,000 revolutions per minute. A turbine developing 300 h.p. uses a wheel 30 in. in diameter, running over 10,000 revolutions per minute, with a peripheral speed of nearly 1400 ft. per second. These enormous speeds are made possible by the ingenious device of using a flexible shaft, which protects the bearings and foundations from the vibration which any want of balance would otherwise produce. The elasticity of the shaft is such that its period of transverse vibration is much longer than the time taken to complete a revolution. The high-speed shaft which carries the turbine disk is geared, by means of double helical wheels with teeth of specially fine pitch, to a second-motion shaft, of a more moderate speed, at the periphery of which the motion is taken, by direct coupling or otherwise, to the machine which the turbine is to drive. The wheel carrying the buckets is much thickened towards the axis to adapt it to withstand the high stresses arising from its rotation. Turbines of this class in sizes up to 300 or 400 h.p. are now in extensive use for driving dynamos, fans and centrifugal pumps. Compared with the Parsons turbine, De Laval's lends itself well to work where small amounts of power are wanted, and there it achieves a higher efficiency, but in large sizes the Parsons turbine is much more efficient. In 1882 De Laval turbine used with a condenser, and developing about 63 h.p., have shown an average steam consumption at the rate of about 20 lb per brake-horse-power-hour, and even better results are reported in turbines of a larger size.

114. Action of the Jet in De Laval's Turbine.—In entering the turbine the jet is inclined at an angle $\alpha$ to the plane of the wheel. Calling its initial velocity $V_i$, and the velocity of the bucket $\eta$, we have, as in fig. 56, $V_1$ for the velocity of the steam relatively to the wheel on admission. A line $AB$ parallel to $V_1$ therefore determines the proper angle of the blade or bucket on the entrance side if the steam is to enter without shock. As the steam passes through the blade channel the magnitude of this relative velocity does not change, except that it is a little reduced on account of friction. The action is one of pure impulse; there is no change of pressure during the passage, and consequently no acceleration of the steam through the divergent nozzle after once it has left the nozzle. Hence $V_2$, the relative velocity at exit may (neglecting friction) be the same as $V_1$. The direction of $V_1$ or $BC$ is tangent to the exit side of the bucket.
Compounding \( V_t \) with \( u \) we find \( V_4 \), which is the absolute velocity of the steam after exit, and this should be no greater than is required to get the steam clear of the wheel. The most favourable condition of running would be when the bucket velocity \( u \) is such that \( V_4 \) is perpendicular to the plane of the wheel, for \( V_4 \) would then have its least possible value. Assuming the angle of discharge \( \beta \) to be equal to \( \theta \), we should have \( V_4 = \sqrt{V_1^2 - \sin^2 \theta} \), which approximates more and more closely to \( V_1 \) the smaller \( u \) is made. The ideal efficiency would be \( (V_4^2 - V_1^2)/V_4^2 \) or \( 1 - \sin^2 \theta \) in a turbine in which the jet enters the buckets without shock and travels over them without friction. In practice \( \theta \) is about 20°. Owing to the impossibility of making the bucket speed so high as the above condition implies the steam enters the buckets of a De Laval turbine with some shock and leaves them with a velocity inclined to the plane of the wheel, with a backward component, and the turbine loses something in efficiency through this exit velocity being greater than the ideal minimum.

Taking a test of a De Laval turbine of 300 h.p, in which the steam consumed was 15-6 lb per horse-power-hour, Stodola estimates that the losses in the nozzle amount to about 15% of the available energy or total heat drop, the losses in the buckets (due to friction and to eddy currents set up by shock) to 21% and the losses due to the velocity retained by the steam at exit to nearly 5%. The losses due to friction in the mechanism consume about 5% more, leaving a net return of about 54% of the available energy.

115. Curtis Turbine.—The Curtis turbine, like that of De Laval, is a pure impulse turbine, but the velocity of the jet is extracted not by one ring of buckets but by a series of rings, each of which extracts a certain part. Between the first and second rings of buckets there are fixed guide blades which serve to turn the remaining motion of the steam into a direction proper for its action on the second ring, and so on. The jet, having acquired its velocity in a nozzle in the first place, often acts on three successive rings of moving buckets, with two sets of fixed guide blades between, the three co-operating to extract its kinetic energy. But the Curtis turbine is generally compound in the further sense that the total drop from admission to condenser pressure is itself divided into two, three or more stages, the steam acquiring velocity anew at each stage and then giving up that velocity in passing through a series of impulse turbine rings generally either two or three in number before undergoing the next drop in pressure.

116. Action of the Steam in the Curtis Turbine.—In this division of the heat drop or pressure drop into stages Curtis follows Parsons. The distinctive feature in Curtis is the multi-impulse action which occurs at each pressure stage. This is illustrated in the diagram (fig. 57), which shows the nozzle and blades of a two-stage Curtis turbine, with three rings of moving blades or buckets in each stage, arranged, of course, round the periphery of a wheel. The velocity acquired in the nozzles is extracted as the steam pursues its sinuous course between moving and fixed blades, and it leaves the third ring in each case with only a small residual velocity, the direction of which is approximately parallel to the axis of the wheel. The changes of velocity are illustrated in fig. 58, which, for the sake of simplification, is drawn for the ideal case of no friction. There \( u \) is the velocity of the buckets, \( V_1 \) the initial velocity of the jet, and \( V_2 \) the initial relative velocity on entrance to the first moving ring. \( V_3 \) is the absolute velocity on entering the second moving ring, and \( V_4 \) the relative velocity. \( V_4 \) is the absolute velocity on entering the third moving ring and \( V_5 \) the relative velocity. Finally, \( V_6 \) is the absolute velocity on leaving the third moving ring, and this in the example here drawn is parallel to the axis of the turbine. The first moving blades have sides parallel to OB, BC; the first fixed blades have sides parallel to CP, PD. The second moving blades have sides parallel to PE, EQ; the second fixed blades to FQ, QG, and the third moving blades to QH, HR.

The steam then passes on to a second set of divergent nozzles in which it undergoes a second drop in pressure, acquiring velocity afresh, which it loses as before in passing through a set of three rings of moving buckets. In some Curtis turbines this is followed by a third and often a fourth similar process before the condenser is reached. In a four-stage Curtis turbine the speed of the buckets is usually about 400 ft. per second; the steam issues from each set of nozzles with a velocity of about 2000 ft. per second, and each set of moving rings reduces this by something like 400 ft. per second. The losses due to steam friction are somewhat serious, although the blade speed in each set is sufficient to let the steam enter without shock; on the other hand, the Curtis turbine escapes to a great extent losses due to leakage which are present in the Parsons type. The velocity diagram shown in fig. 58 may readily be modified to allow for effects of friction. Owing to the progressive reduction of velocity in passing from ring to ring a larger and larger area of blade opening is required, and this is provided for by making the height of the blades increase in the successive rings of each series.

117. Performance of Curtis Turbines.—Curtis turbines have been successfully applied in large sizes, especially in America, to drive electric generators, with outputs of as much as 9000 kilowatts, and in a few instances they have been adapted to marine propulsion. In large sizes, and using moderately superheated steam, the Curtis turbine has achieved a high degree of efficiency. The advantage of superheating, in any type of turbine, is to reduce the wetness which the steam develops as it expands during work. The prejudicial effect of wetness is chiefly that it increases friction, especially in the later stages of the expansion. Tests of Curtis turbines show that they maintain a very uniform efficiency throughout a wide range of loads, and are capable of being much overloaded without
material increase in the ratio of steam consumption to output. In tests of a 9000 kilowatt Curtis turbine using steam of about 200 lb pressure and 80° C. superheat, with a vacuum of 29½ in. the consumption of steam is reported to have been only 13 lb per kilowatt-hour, and this figure remained almost constant for loads ranging from 8000 to 12,000 kilowatts. In a 9000 kilowatt turbine under very similar conditions the consumption is reported to have been 13½ lb per kilowatt-hour. In the usual arrangement of the Curtis turbine the shaft is vertical and the wheels lie in horizontal planes, the weight of the revolving parts being taken by a footstep bearing with forced lubrication, and the electric generator is mounted on the top. There are usually in the large sizes four stages of expansion, each stage being separated from the one above it by a diaphragm plate containing the nozzles in which the next step in velocity is acquired. The expansion has been divided into as many as seven stages in a Curtis turbine for marine use, the shaft being then horizontal, and in all except the first stage in that example the pressure drop is so comparatively small as not to require divergent nozzles.

118. Parsons Turbines.—In the turbines of De Laval and Curtis the action on the moving blades or buckets is entirely one of impulse. No drop of pressure occurs while the steam is passing the moving blades, and its velocity relative to the blade surface undergoes no change except such as is brought about by friction. In the Parsons turbine, on the other hand, there is a reaction effect. The steam acquires relative velocity and loses pressure as it passes each ring of moving blades: in this respect the action in the moving blades is like the action in the fixed blades. Each pair of fixed and moving rings makes up what is called a “stage” and may be said to constitute a separate turbine; the whole is a series of many such stages. In each stage the drop in pressure and in heat is divided equally between the fixed and moving element, the exit and entrance angles and the form of the blades generally being alike in both. The number of stages depends on what peripheral speed it is convenient to use. Where comparatively high blade speeds are practicable, as in turbines for driving electric generators, the steam is allowed to acquire a fairly high velocity at each ring of blades, and in such cases so few as 45 stages may be suitable. In large marine turbines, on the other hand, where the number of revolutions per minute has to be kept low in the interests of propeller efficiency, the blade speeds cannot be kept high without making the diameters unduly great, and consequently more stages are required: in such turbines the number of stages may be from 100 to 200. The general relation of fixed to moving blades and the characteristic form of both will be seen from fig. 59.

Fig. 60 shows a complete Parsons turbine of 1000 kilowatts capacity in longitudinal section through the casing. The fixed blades are caulked with separating distance-pieces into grooves turned on the inner surface of the case and project inwards: the moving blades are similarly secured in grooves which are turned on the surface of the rotating drum. Between drum and case there is an annular space fitted in this way with successive rings of fixed and moving blades. There is considerable longitudinal clearance from ring to ring, but over the tips of the blades the clearance is reduced to the smallest possible amount consistent with safety against contact (generally from 13 to 30 thousandths of an inch in turbines of moderate size). Steam enters at A, expands through all the rings of blades in turn and escapes to the condenser at B. To provide for the increase in its volume the size of the blade passages enlarges progressively from the high to the low pressure end. In the example shown this is done partly by lengthening the blades and partly by increasing the circumference of the drum, which has the further effect of increasing the blade velocity, so that the expanded steam not only has a larger area of passage open to it but is also allowed to move faster, and consequently each unit of the area is more effective in giving it vent. Instead of attempting to make the change in passage area continuous from ring to ring, as the ideal turbine would require, it is done in a limited number of steps and the several rings in each step are kept of the same size. Thus in the example shown in the figure the first step consists of seven pairs of rings or stages, the next two also of seven each, the next three of four each, the next of two and so on. This is convenient for constructive reasons and gives a sufficiently good approximation to the ideal conditions as regards the relation of steam volume to blade-passage-area and velocity.
119. Balance of Longitudinal Forces:—Drivers.—Since the pressure of the steam falls progressively from left to right, there is a resultant longitudinal thrust on the drum forcing it to the right, which is balanced by means of "dummy" rings C, C', C''. These correspond in diameter with the several portions of the bladed drum and are connected with them by steam passages which secure that each dummy shall have the same pressure forcing it to the left as tends on the corresponding part of the drum to force it to the right. No steam-tight fit is practicable at the dummies, but leakage of the steam past them is minimized by the device of furnishing the circumference of each dummy with a series of rings which revolve between a corresponding series of fixed rings projecting inwards from the case. The dummy rings do not touch but the clearance spaces are made as fine as possible and the whole forms a labyrinth which offers great resistance to the escape of steam. Substantially the same device is employed to guard against leakage in the glands DD where the shaft leaves the turbine case. There is a "thrust block" E at one end of the shaft which maintains the exact longitudinal position of the revolving part and allows the fine clearances between fixed and moving dummy rings to be adjusted.

120. Lubrication.—The main bearings LL are supplied with oil under pressure kept in circulation by a rotary pump which draws the oil from the tank G. The pump shaft H, which carries the pump rotor, is driven by a worm on the main shaft. The same oil is circulated and over again and very little of it is consumed. No oil mixes with the steam, and in this point the turbine has a marked advantage over piston and cylinder engines, which is especially important in marine use. In small fast-running turbines each bearing consists of a bush on which three concentric sleeves are slipped, fitting loosely one over another with a film of oil between. The whole acts as a cushion which damps out any vibration due to want of balance or alignment. In large engines this device is dispensed with and a solid brass bearing lined with white metal is employed.

121. Blades.—The blades are generally of drawn brass, but copper is used for the first few rows in turbines intended for use with superheated steam. In the most usual method of construction they are put one by one into the grooves, along with distance pieces which hold them at the proper angle and proper distance apart, and the distance pieces are caulked to fix them. The length of the blades ranges from a fraction of an inch upwards. In the longest blades of the largest marine steam turbines it is as much as 22 in. When over an inch or so long they are strengthened by a ring of stout wire let into a notch near the tip and extending round the whole circumference. Each blade is "laced" to this by a fine copper binding wire, and the lacing is brazed. For long blades two and even three such rings of supporting wire are introduced at various distances between root and tip. The tips are fined down nearly to a knife-edge so that in the event of contact taking place at the tips between the "rotor" or revolving part, and the "stator" or case, they may grind without being stripped off. The possible causes of such contact are wear of bearings and unequal expansion in heating up. With a proper circulation of oil the former should not take place, and the clearances are made large enough to provide for the latter. Various plans have been devised to facilitate the placing and fixing of the blades. In one method they are slung on a wire which passes through holes in the roots and in the distance pieces and are assembled beforehand in a curved chuck so as to form a sector of the required ring, and are brazed together along with the supporting wires before the segment is put in place. In another method the roots are fixed in a brass rod in which cuts have been machined to receive them; in another the rod in which the roots are secured has holes of the right shape formed in it to receive the blades, by being cast round a series of steel cores of the same shape as the blades; the cores are then removed and the blades fixed in the holes.

122. Drums.—In small turbines the drums carrying the revolving blades are solid forgings; in large turbines they are also of forged steel but in the form of hollow cylinders turned true inside as well as out. These are supported on the shafts by means of wheel-shaped steel castings near the ends, over which they are shrunk and to which they are fastened by screws the heads of which are riveted over. The case is of cast iron with a longitudinal joint which allows the upper half to be lifted off.

123. Governing.—The governor regulates the turbine by causing the steam to be admitted in a series of blasts, the duration of each blast being so adjusted as to suit the demand for power. When working at full power the admission is practically continuous; at lower powers the steam valve is opened and closed at rapidly recurring intervals. Each revolution of the governor shaft causes a cam, attached to the governor, to open and close a relay valve which admits steam to a cylinder controlling the position of the main steam valve, which accordingly opens and closes in unison with the relay. The position of the governor determines how long the relay will admit steam to the controlling cylinder, and consequently how long the main valve will be held open in each period. In turbines driving electric generators the controlled of the relay-valve is sometimes made to depend on variations of the electric pressure to a number of variations in the speed. In either case the arrangement secures control in a manner remarkably free from frictional interference, and therefore secures a high degree of uniformity in speed or in electric pressure, as the case may be.

To admit of overloading, that is, of working at powers considerably in excess of the full power for which the turbine is designed, provision is often made to allow steam to enter at the full admission pressure beyond the first set of rows of blades; this increases the quantity admitted, and, though the blades are somewhat less efficient, more power is developed. An orifice will be seen in fig. 60 a little to the right of the main steam admission orifice, the purpose of which is to allow steam to enter direct to the second set of blades, missing the first seven stages, so that the turbine may cope with overloads.

124. Absence of Wear.—Owing to its low steam velocities the Parsons turbine enjoys complete immunity from wear of the blades by the action of the steam. A jet of steam, especially when wet, impinging at very high velocity against a metal surface, has considerable cutting effect, but this is absent at velocities such as are found in these turbines, and it is found that after many years of service there are no signs of wear and the efficiency of the turbine is unimpaired.

125. Blade Velocity.—Experience has shown that the most economical results are obtained when the velocity of the steam through the blades is about twice the velocity of the blades themselves, and the Parsons turbine is accordingly designed with, as far as possible, a constant velocity ratio of about this value. As already explained, it is convenient in practice to divide the expansion into a comparatively small number of steps (about twelve steps is a usual number), giving a constant area of steam passage to the first few rows, a larger area to the next few, and so on. An effect of this is that the velocity ratio varies slightly above and below the value of two to one, but if the steps are not too great this variation is not sufficient materially to affect the efficiency.

If the spindle or drum carrying the moving blades were of the same diameter throughout, the blades at the exhaust end would have to be exceedingly long in order to give passage to the rarefied steam. By increasing the diameter towards the exhaust end the peripheral velocity is increased, and hence the proper velocity for the steam is also increased. The amount of heat drop per ring is consequently greater towards the low-pressure end; in other words, the number of rings for a given drop is reduced. Taking the turbine as a whole, the number of rings will depend on the blade velocity at each step, the relation being such that \( \frac{\Delta V}{\Delta S} = \text{constant} \), for a given drop from admission to exhaust, \( n \) being the number of rings whose blade velocity is \( \Delta V \).

It appears that a usual value of this constant is about 1,500,000,000 for the whole range from an admission pressure which may be nearly 200 lb per sq. in. down to condenser pressure.

The increased diameter at the low-pressure end not only allows the steam velocity to be increased but by enlarging the annulus enables a sufficient area of passage to be provided without unduly lengthening the blades. In the very last stages of the expansion, however, the volume becomes so great that it is not practicable to provide sufficient area by lengthening the blades, and the blades there are accordingly shaped so as to face in a nearly axial direction and are spaced more widely apart.

The area of the steam passage depends on the angle of the blade. If the blades were indefinitely thin it would be equal to the area of the annulus multiplied by the sine of the angle of discharge, and in practice this is subject to a deduction for the thickness of the blade on the discharge side, as well as to a correction for leakage over the tips. Generally the angle of discharge is about $22.5^\circ$.

The effective area for the passage of steam is about one-third of the area of the annulus.

**Fig. 61.** A shows a representative pair of fixed and moving blades of a Parsons turbine, and **Fig. 61 B** the corresponding velocity diagram for the steam, neglecting effects of friction. $V_1$ is the exit velocity from the fixed blades, the delivery edge of which is tangent to the direction of $V_2$. The blade velocity is $u$ which is $W_1$. $V_2$ is consequently the relative velocity with which the steam enters the moving blades. Approximately, the back surface of these blades is parallel to $V_3$, but the blades are so thick near the entrance side that their front faces have a considerably different slope and there is therefore some shock at entrance. In passing through the moving blades the relative velocity of the steam over the blades changes from $V_3$ to $V_4$. Allowing for the velocity $u$ of the blades themselves, this corresponds to an absolute velocity $V_4$, with which the steam enters the next set of fixed blades. In these blades it is again accelerated to $V_5$ and so on.

127. Calculation of Velocity at each Stage.—The acceleration of the steam in each row of blades results from a definite heat drop. Or, if we look at the matter from the point of view of the pressure-volume diagram, the acceleration results from the work done on the steam by itself during a drop $dp$ in its pressure. The amount of this work per pound is $w dp$ where $w$ is the actual volume per pound. It is convenient in practice to write this in the form $(p v) dp / p$, for the product $p v$ changes only slowly as expansion proceeds. In designing a turbine a table of the values of $p v$ throughout the range of pressures from admission to exhaust is prepared, and from these numbers it is easy to calculate the work done at each stage in the expansion, the pressure $p$ and drop in pressure $dp$ being known. In the ideal case with no losses we should have

\[
V_1^2 - V_2^2 = \frac{2}{p} W_1 \Rightarrow V_1 = \sqrt{V_2^2 + \frac{2}{p} W_1}
\]

where $V_1$ is the velocity before the acceleration due to the drop $dp$ and $V_1$ is the velocity after.

But under actual conditions the gain of velocity is less than this, owing to blade friction, shock and other sources of loss. The actual velocity depends on the efficiency and on the shape and angles of the blades. It appears that under the conditions which hold in practice in Parsons turbines it is very nearly such that

\[
V_1^2 = 2g(pv)dp/p + V_0^2
\]

In this formula, which serves as a means of estimating approximately the velocity for purposes of design, it is to be understood that in calculating the product $pv$ the volume to be taken is that which is actually reached during expansion. The actual volume is affected both by friction and by leakage and is intermediate in value between the volume in adiabatic expansion and the volume corresponding to saturation. In the case of a turbine of 76% efficiency the actual wetness of the steam is, according to Mr. Parsons' experience, about 55% of that due to adiabatic expansion in the early stages and 60% in the latest stages. In preparing the table of values of $pv$ figures are accordingly to be taken intermediate between those for saturated steam and for steam expanded adiabatically, and from these is found as above the velocity for any given drop in pressure, and also the volume per pound, for which at each stage in the expansion provision has to be made in designing the effective areas of passage.

The blade speeds used in Parsons turbines rarely exceed 150 ft. per second and are generally a good deal less. In marine forms, where the number of revolutions per minute is limited, by considerations of efficiency in the action of the screw propeller, the blade speeds generally range from about 150 to 150 ft. per second, though speeds as low as 60 ft. per second have been used.

127. Parsons Marine Turbines.—Marine turbines are divided into distinct high and low pressure parts through which the steam passes in series, each in a separate casing and each driving a separate propeller shaft. The most usual arrangement is to have three propeller shafts; the middle is driven by the high pressure portion of the turbine, and the steam which has done duty in this is then equally divided between two precisely similar low pressure turbines, each on one of two wing shafts. The rotor drum of each turbine has a uniform diameter throughout its length, but the casing is stepped to allow the lengths of the blades to increase as the pressure falls.

The casing which contains each of the two low pressure turbines contains also a turbine for running astern, so that either or both of the two wing shafts may be reversed. Steam is admitted to the reversing turbine direct from the boiler, the centre shaft being then idle. Each astern-driven turbine consists of a comparatively short series of rings of blades, set for running in the reversed direction, developing enough power for this purpose but making no pretensions to high efficiency. The astern turbine, being connected to the condenser, runs in vacuo when the ahead turbine is in use and consequently wastes little or no power.

Figs. 62 and 63 are sections of the high pressure and low pressure portions of a typical Parsons marine steam turbine, as designed for the three-shaft arrangement in which the low pressure portion is duplicated. In each figure A is the fixed casing and B is the revolving drum. Steam enters the high pressure turbine (Fig. 62) through J and passes out through H. There are 4 "expansions" or steps, with 9 stages or double rows of blades in the first, 9 in the
Each Fig. 4 steps ship close the total high This The shown followed leaves wing very In of stages steps. The "84 STEAM ENGINE..." Fig. 64.

Fig. 65.

requires a different form because some longitudinal play is necessarily brought about there by differences in expansion of the rotor and stator. Accordingly, the astern dummy is of the "radial" form shown in fig. 65 where the fine clearance is round the circumference of the brass rings set in the rotor and stator alternately. The whole dummy includes about sixteen of these rings.

129. Shaft Arrangement of Marine Turbines.—Fig. 66 shows the usual three-shaft arrangement, with two low pressure turbines in parallel on the wing shafts, and one high pressure turbine, with which they are joined in series, on the middle shaft. In very large vessels four shafts are used, and the turbines form two independent sets one on each side of the ship. The outer shaft on each side carries a high pressure turbine, and the inner shaft carries the corresponding low pressure turbine and also a turbine for reversing. This arrangement is followed in the "Lusitania" and "Mauretania" where the low pressure turbines have drums 188 in. in diameter, are about 174 ft. in diameter over all and 50 ft. long, and weigh 300 tons. Each turbine has 8 steps with about 16 stages in each step in the high pressure turbine and 8 in the low. They run at 180 revolutions per minute.

130. Cruising Turbines in War-Ships.—In turbines for the propulsion of war-ships it is necessary to secure a fairly high economy at speeds greatly short of those for which the turbines are designed when working at full power, for the normal cruising speed of such vessels is usually from half to two-thirds of the speed at full power. To counterbalance the reduced blade velocity, when running under these conditions, the number of rows of blades has in some cases been augmented by adding what are called cruising turbines, which are connected in series with the main turbines when the ship is to run at cruising speed. In the three-shaft arrangement the cruising turbines are fitted on the wing propeller shafts, which carry also the low pressure and astern turbines. They form a high and intermediate pressure pair through which the steam may pass in series...
features of the Parsons turbine with those of the De Laval. He divides the whole drop into some twelve or twenty-four stages and at each stage employs an impulse wheel substantially of the De Laval type, the steam passing from one stage to the next through a diaphragm with nozzles. This form can scarcely be called an independent type. It has been applied as an exhaust steam turbine in conjunction with a regenerative thermal accumulator, which is utilized by the steam delivered steadily to the turbine although supplied from an independent boiler. The Zolly turbine, which has found considerable application on a large scale, acts in a precisely similar manner to that of Rateau: it differs only in mechanical details.

133. Combined Reciprocating and Turbine Engines.—The combination of a reciprocating engine with a turbine is suggestedy by Parsons for the propulsion of cargo or other low-speed steamers where the speed of the screw shafts cannot be made high enough to admit of a sufficient blade velocity for the efficient treatment in the turbine of high-pressure steam.

134. Consumption of Steam in the Parsons Turbine.—In large sizes the Parsons turbine requires less steam per horse-power-hour than any form of reciprocating engine using steam under similar conditions. For example, a turbine of the Laval type, driven by a 2000 h.p. turbine coupled to an electric generator showed a consumption of 183 lb per kilowatt-hour, with steam at 155 lb per sq. in. superheated 84°F. Since 1 kilowatt is 1.34 h.p. this consumption is equal to 45 lb per horse-power-hour. The best piston engines when driving dynamos convert about 84% of their indicated power into electric power. Hence the above result is as good, in the relation of electric power to steam consumption, as would be got from a piston engine using only 11.4 lb of steam per indicated horse-power-hour. An important characteristic of the steam turbine is that it retains a high efficiency under comparatively light loads. The figures below illustrate this by giving the results of a series of trials of the same machine under various loads.

Still better results have been obtained in more recent examples, in turbines of greater power. A Parsons turbine, rated as of 3500 h.p. working up to 8000 kilowatts tested in 1907 at the Carville power station of the New-York on-Tyne Electric Supply Company, showed a consumption of only 13-19 lb of steam per kilowatt-hour, with steam of 200 lb pressure by gauge and 67°C. superheat (temperature 264.5°C.), the vacuum being 20-04 in. (barometer 26-37 in.) It is interesting to compare this performance with the ideal amount of work obtainable per pound of steam, or in other words with the ideal heat drop. At the temperature and pressure of supply the total heat h is 7080. After expansion to the pressure corresponding to the stated vacuum (0-66 in.) the total heat of the wet mixture would be 485, the dryness being then 0-792. If the expansion took place in an ideal adiabatic cylinder the heat drop 1-6 is 273 units, and this represents the work ideally obtainable under the actual conditions as to temperature and pressure of supply and exhaust. Since 1 kilowatt-hour is 1867 thermal units (lb-degree C.), each pound of steam was generating an amount of electrical energy equivalent to 1867 or 143.7 thermal units, and the electric output consequently corresponds to 64.4% of the ideal work. If we allow for the loss in the electric generator by taking the electrical efficiency as only 92% of the mechanical efficiency, this reduces that 70% of the ideal work in the steam was mechanically utilized.

135. Torsion Meters for Power.—No measurement corresponding to the "indicating" of a piston engine is possible with a
STEAMSHIP LINES. The shipping company is the outcome of the
development of the steamship. In former days, when
the packet ship was the mode of conveyance, there were com-
binations, such as the well-known Dramatic and Black Ball
lines, but the ships which were run in them were not necessarily
owned by those who organized the services. The advent of the
steamship changed all that. It was in the year 1815 that the
first steamship began to ply between the British ports of
Liverpool and London. In the year 1836 the two light-gunned, metal-shafted
steamers, the "Constitution" and the "Lawrence," first
pressed into service, were built for the Liverpool and London
Steam Navigation Company, which made
the Thames its headquarters; the Atlantic Steam Navigation
Company of London; and the Great Western Steamship
Company of Bristol. Each company set to work to build a wooden paddle
steamer in its own port. The first to be launched was the
"Great Western," which took the water in the Avon on the 19th of
July 1837. On the 14th of October following the "Liverpool
was launched by Messrs Humble, Milcrest & Co., in the port
from which she was named, and in May 1838 the Thames-
built "British Queen" was successfully floated. The "Great Western
was the first to be made ready for sea. When the British Line of
steamers were first established, they were not to be deterred by
gaps in delivering their specially built ships. The London company chartered the "Siriuss a 700-ton steamship,
from the St George Steam Packet Company, and despatched her
from London on the 28th of March 1838. She was thus the
first to put to sea. She eventually left Cork on the 4th of April,
and reached New York on the 22nd, after a passage of 17 days.
The "Great Western" did not leave Bristol till the 8th of April,
and but the command of James Hosken, R.N. (1798-1885) she
reached New York only a few hours after the "Siriuss. The Liverpool people, fired by the action of the other two ports,
chartered the "Royal William" from the City of Dublin Steam
Packet Company, and despatched her on the first steam voyage
from the Mersey to Sandy Hook on the 5th of July in the same
year. The "Liverpool" made her maiden voyage in the follow-
ing October. But the "British Queen" did not make her initial
attempt till the 1st of July 1839. Trouble overtook all three of
these early Atlantic lines, and they soon ceased to exist.
Perhaps the most serious factor against them was the success of Mr. Samuel Cunard in obtaining the government contracts
for the conveyance of the mails from Liverpool to Halifax and
Boston, with a very large subsidy. The Cunard Line was
enabled, and indeed, by the terms of its contract, obliged, to
run a regular service with a fleet of four steamships identical
in size, power and accommodation. It thus offered conveyance
at well-ascertained times and by vessels of known speed.
The other companies, with their small fleets of isolated ships
and their irregular departures, could not compete with the
Atlantic Steamship Company of Liverpool found that the
port could not then maintain two steamship lines, and the
steamship "Liverpool," with another somewhat similar vessel
which they had built, fell into the hands of the P. & O. Company.
The Great Western Steamship Company proceeded to build the
"Great Britain," an iron screw steamship, which in every way
was before her time, and were swamped by financial difficulties,
their "Great Western" being sold to the West India Royal Mail
Company, to whom she became a very useful servant. The
"Great Britain" (which was stranded in Dundrum Bay in
September 1846, owing to her captain, Hosken, being misled
by a faulty chart and mistrusting the lights) eventually drifted
better accommodation for the passenger, with the captainship,
the "President," on their station. She was lost with all
hands, no authentic information as to her end ever being
obtained. Her mysterious fate settled the fortunes of her
owners, and the "British Queen" was transferred to the Belgian
flag. Steam navigation across the Atlantic was now an accom-
dished fact. But all the three pioneers had been borne down by
the difficulties which attend the carrying out of new departures,
even when the general principles are sound.
Constant Improvement has been the watchword of the ship-
owner and the ship-builder, and every decade has seen the ships
of its predecessor become obsolete. The mixed paddle and
screw steamer, the "Great Eastern," built in the late fifties,
was so obviously before her time by some fifty years, and was so
under-powered for her size, that she may be left out of our
reckoning. Thus, to speak roughly, the fifties saw the iron
screw replacing the wooden paddle steamer; the late sixties
brought the compound engine, which effected so great an economy
in fuel that the steamship, previously the conveyance of mails
and passengers, began to compete with the sailing vessel,
in the carriage of cargo for long voyages; the seventies brought
the screw steamer with the saloon, improved sanitation, better
accommodation for the passengers, with the captainship," President,"
the enclosed saloon, improved state-rooms, and covered access to smoke-
rooms and ladies' cabins; the early 'eighties saw steel replacing
iron as the material for ship-building, and before the close of
that decade the introduction of the twin-screw rendered break-
downs at sea more remote than they had previously been, at
the same time giving increased safety in another direction, from
the fact that the duplication of machinery facilitated further
subdivision of hulls. Now the masts of the huge liners in vogue
were no longer useful for their primary purposes, and degenerated
into mere decorative iron prongs and finally into mere signal poles, while
the introduction of boat decks gave more shelter to the pro-
menage of the passengers and removed the navigators from the
distractions of the social side. The provision of train-to-
boat facilities at Liverpool and Southampton in the 'nineties
did away with the incompatibilities of the tender and the cab.
The introduction of the turbine engine at the beginning
of the century gave further subdivision of machinery and
increase of economy, whereby greater speed became possible and
comfort was increased by the reduction of vibration. At the
same time the introduction of submarine bell signalling tends
to diminish the risk of standing and collision, whilst wireless
telegraphy not only destroys the isolation of the sea but tends
to safety, as was seen by the way in which assistance was called out of the fog when the White Star liner "Republic" was sinking as the result of a collision off Fire Island (1900).

In the following pages some of the ships which first embodied these improvements are mentioned, a brief history of the principal lines is attempted, and reference is made to some of the milestones on the road of improvement.

Allan Line.—The story of the Allan Line is that of the enterprise of one family. Captain Alexander Allan, at the time of the Peninsular War, purchased a cargo of cattle to Lisbon for Wellington's army. After 1815 he began to run his vessel between Liverpool and Canada, and as years went on he employed several vessels in the service. Till 1837 the ships ran from Greenock to Montreal, but in that year the Clyde Line was taken over by the Allan Line, and they continued to run to Glasgow, as they have continued to do ever since. Captain Allan and his five sons devoted all their energies to the development of the Canadian trade, and for about forty years the line ran sailing ships alone. So great was the demand for emigrant traffic that in 1852 the Canadian government requested tenders for a weekly mail service between Great Britain and Canada. That of Sir Hugh Allan of Montreal, on which Captain Allan's sons were accepted, and the Canadian mail line of steamships came into existence. It may be noted that the Allan Line inaugurated the steering of the "spare-deck" type, i.e. with a clear promenade deck above the main deck. This meant an important step in the development of shipping, as it signified the beginning of the steamship's large frontage.

Transatlantic trade was developing under the auspices of the Australian steamship "London" in the Bay of Biscay in the year 1866. The company may claim, that their steamship "Buenos Ayres," built for them in the year 1879 by Messrs. Wailes, of Dumbarton, was the first of her kind to attempt the crossing of the Atlantic. Thenceforward the lines of ships between New York and Liverpool were taken in hand.

The beginning of the Allan Line was marked by the introduction of the "Caledonia," the first of the Allan Line's twin-screw steamers. This vessel was built at the William Denny & Brothers shipyard, Dumbarton, and was launched on October 10, 1860. She was a 1,600-ton vessel, with a speed of 12 knots. She was the first of the Allan Line's ships to be built at the Denny yard, and the first of the line's vessels to be provided with twin screws.

In 1861, the Allan Line introduced the "City of Glasgow," which was the first of the line's vessels to be fitted with a steam engine. The "City of Glasgow" was built at the William Denny & Brothers yard, and was launched on October 10, 1861. She was a 1,600-ton vessel, with a speed of 12 knots. She was the first of the Allan Line's ships to be fitted with a steam engine, and the first of the line's vessels to be provided with twin screws.

In 1862, the Allan Line introduced the "City of Liverpool," which was the first of the line's vessels to be provided with a screw propeller. The "City of Liverpool" was built at the William Denny & Brothers yard, and was launched on October 10, 1862. She was a 1,600-ton vessel, with a speed of 12 knots. She was the first of the Allan Line's ships to be fitted with a screw propeller, and the first of the line's vessels to be provided with twin screws.

American Line.—That is to say, the American Line is the successor of the old American Line, which was, as we have seen, the forerunner of the modern American Line. The old American Line was established in 1831, and was the first of the American Line's vessels to be provided with a screw propeller.

In 1831, the American Line introduced the "City of Charleston," which was the first of the line's vessels to be provided with a screw propeller. The "City of Charleston" was built at the William Denny & Brothers yard, and was launched on October 10, 1831. She was a 1,600-ton vessel, with a speed of 12 knots. She was the first of the American Line's vessels to be fitted with a screw propeller, and the first of the line's vessels to be provided with twin screws.

In 1832, the American Line introduced the "City of New York," which was the first of the line's vessels to be provided with a screw propeller. The "City of New York" was built at the William Denny & Brothers yard, and was launched on October 10, 1832. She was a 1,600-ton vessel, with a speed of 12 knots. She was the first of the American Line's vessels to be fitted with a screw propeller, and the first of the line's vessels to be provided with twin screws.

The "Great Eastern," The "City of Paris," was the first vessel (1889) to cross the Atlantic in less than six days. The year 1893 was an important one in the history of the company, and indeed of the United States. The two vessels above mentioned were admitted to American registry by the act of Congress, a step which was hailed as an important one by the shipping world. The "Great Eastern" and the "City of Paris" were two of the new ships of at least equal tonnage and speed to the pair should be ordered by the company from American firms, and that they should be capable of being employed by the United States government as auxiliary cruisers in case of war. The "Great Eastern" and the "City of Paris" were built over the "New York" in 1893 by President Harrison, and in the same year the British headquarters of the company were transferred from London to New York. The "Great Eastern" and the "City of Paris" were the first of the new vessels to be launched, and were named the "St. Louis." In 1898 the American Line had the distinction of supplying the navy of its country with cruisers for use in war. The "St. Paul" and the "St. Louis" are the last survivors of war-time cruisers, which have been constructed of the emigrant traffic. In addition to the weekly express service between Southampton and New York, the company also operated a large number of steamers between Boston, Philadelphia, Quebectown and Liverpool, and Philadelphia and Antwerp.

London Steam Navigation Company.—This company was started in 1837 at Trieste, where its headquarters are still situated. It commenced operations with seven small wooden paddle-boats for the voyage to Constantinople and the Levant. The Royal Navy, as it was a British company, had taken the initiative, and the line was taken in hand.

In 1867 the line had its beginnings. In the year 1867, the line had a large fleet of steamers, with a gross tonnage of about a quarter of a million tons. The whole eastern coast of the Adriatic and the Levant is visited by them with frequent service. There is a line to the west which is run by the company and which includes the lines of the British and American companies between the Mediterranean and Brindisi and Bombay. There is also a monthly ordinary service between Trieste, Bombay, China and Japan, and a monthly branch to New York is open for the trade with Japan.

Bibby Line.—The name of Bibby has long been known and respected in the shipping world. The first undertaking of the family was the institution of a service from Liverpool to Mediterranean ports about the middle of last century. When (subsequently Sir Edward) Harland took over the ship-building works at Belfast, which he afterwards made famous, Mr Bibby was one of his earliest customers. He was the man who gave him practically carte blanche in the building of the "Great Eastern," and the "City of Paris," and the "Great Eastern," and the "City of Paris," was the first of the line's vessels to be provided with a screw propeller. The "Great Eastern," and the "City of Paris," was the first of the line's vessels to be provided with twin screws. In 1867 the line had a large fleet of steamers, with a gross tonnage of about a quarter of a million tons. The whole eastern coast of the Adriatic and the Levant is visited by them with frequent service. There is a line to the west which is run by the company and which includes the lines of the British and American companies between the Mediterranean and Brindisi and Bombay. There is also a monthly ordinary service between Trieste, Bombay, China and Japan, and a monthly branch to New York is open for the trade with Japan.

The "Booth Line" is essentially a Liverpool company. It was founded in the year 1866 by Messrs. Alfred Booth & Co., who in that year instituted a service to north Brazil. Three years later from the ship "City of London" the "City of Liverpool" was launched by Messrs. Booth & Co. to carry on a similar service. In 1901 the two lines were amalgamated under the title of the Booth Steamship Company Limited. Since the year 1868 there has been a connexion by the "City of Liverpool" and the "City of London" with the "Parahyba" and "Maranhao," and "Parahyba" and "Ceara" are the chief Brazilian ports served by the company, while the steamers make calls on the eastern side of the Atlantic at Cardiff and Hull as well as at Spanish and Portuguese ports. The company carries the British mails to Para.
and Manos, whilst it also takes the United States mails between New York and north Brazil. In addition to its transatlantic passenger traffic the Booth Line is largely developing a tourist trade to Vigo, Oporto and Lisbon in the Peninsula, as well as to Madeira. The Young America of 1876, with its 2,628 register tons, carries its trade a couple of thousand miles up the River Amazon; a further development will extend to River Plate ports.

The story of the Dublin Steam Packet Company (Dublin Steam Packet Co.) and its connection with the British and Irish Steam Navigation Company maintains, perhaps, the largest network of communications and serves a greater number of ports difficult of access than any in the world. The Persian Gulf, Burmah, the Straits of Malacca, and the entire littoral of the East Indies and the coasts of Southern China and the scenes of the Chinese war all formed part of its system, and the Indian navy, the government, by which the former agreed to convey troops and stores and to perform other services. Under this arrangement the company ran both a period of order and as a separate line from the navigation to the coast of India.

The company's infrastructure, which was a matter of great importance, and the government, by which the company was allowed to convey troops and stores and to perform other services. Under this arrangement the company ran both a period of order and as a separate line from the navigation to the coast of India.

The company was for a time the only line of communication between the East Indies and the coast of India, and while the northern and southern routes were still maintained, they were of little importance.

Under the Mutiny in 1857 the company rendered important service by bringing up from Ceylon to Calcutta the first detachment of European troops which came to the assistance of India from outside. It was a great development of the company’s fleet.

The S.S. “India” with cargo was waiting at Suez when the canal opened to traffic, and was the first steamer to arrive in London through the newly opened Suez Canal in 1869. It also extended its operations to the east coast of Africa, and by an arrangement among the British government began to run a service every four weeks between Aden and Zanzibar. Upwards of one hundred ports are served by the company, and its lines are with additional services. They may be classified roughly as those running to ports in (i.) India, Burma and Straits Settlements; (ii.) Straits Settlements and Philippines; (iii.) East Coast of Africa; (iv.) Persian Gulf; (v.) Dutch East Indies and Queensland, and the Atlantic.

The Canadian Pacific Railway is now one of the big shipping companies of the world, owning, as it does, just under 200,000 tons of steam shipping. Its services divide themselves into several sections. The first of these is run from Vancouver via Yokohama and other Japanese ports to Hong-Kong. Sailings are made at about three-weekly intervals. This service is maintained by the company’s vessels of forced draught, the “Empress of China,” the “Empress of Japan,” the “Empress of India,” and the “Empress of British India,” the sister ships of the S.S. “Empress of India.”

The second section of the company’s services is the line between the United States and South America, known as the Compagnie Générale Transatlantique, which was under taken by Messrs Laird, and in 1897 the new fleet assumed the duties. They were the “Leinster” and the “Munster,” which undertook the carriage of carrying these important mails again needed revision, and in that year the House of Commons approved of a new contract, under which the whole of the work of during the period of about thirty-eight years. The contract time was now decreased by half an hour, and this meant naturally a very great increase in the speed of the vessels employed. The present ships, capable of a speed of about 24 knots, maintain however with regularity, and the duties were accepted by the various companies. The night and day services with the mails the company also maintains its old line between Liverpool and Dublin.

The “Leinster” and the “Munster” went on working under the company’s service at the time of the shipping companies, and the ship was to be extended to South Africa during the 1890-1902 previous campaigns. By a resolution passed at a meeting of shareholders held on the 15th of February 1900 the company was amalgamated with the Union Line. The fleet had grown from two ships in 1876 to twenty ships in 1900, and from a total tonnage of 3,800 to one of about 110,000 gross register.
STEAMSHIP LINES

a great movement towards the acceleration and improvement of the New York service, and a new fleet was begun with the single-screw steamship "La Normandie," launched at Barrow-in-Furness in 1883. Four larger vessels of much the same class followed, three of them being purchased for the British Post Office. Thus for the first time a British company to build still larger and faster vessels. Eventually four such ships were to be provided. These vessels are of 22 knots speed on trial, and are among the fastest on the Atlantic. The company maintains a weekly service, as well as lines to the West Indies and Mexico in the Atlantic. There are also communications with British and Algerian ports.

Cunard Line.—The company derives its name from Samuel Cunard of Halifax, Nova Scotia, an owner of sailing vessels trading from Boston and Newfoundland to Bermuda. He first conceived the idea of a regular despatch of royal mail steamers across the Atlantic, to take the place of the government brigs which often took six or seven weeks in the transport of mails. This idea he realized with the help of Mr George Burns of Glasgow and Mr David MacIver of Liverpool. On the 4th of July 1840 the first Cunard, the " Britannia," started on her voyage across the Atlantic with thirty-six passengers, landing them at Boston in a fortnight. The experiment of using the screw for the Atlantic service was made with several cargo steamers of from 2250 to 3500 tons. In 1856 the first Cunard line was inaugurated by the " Cathay," and the first Cunard screw steamer for the mail line made her début in 1856. This was the " China," the gross tonnage of which was 2539, her l.t.p. 2250, and her average speed 13.9 knots. In 1858 the " Britannia" and the " Scotia," the first fitted screw steamers for the "Cunard" line, were launched for a mail service. At the present time the contract is for a weekly mail to the United States, via Liverpool and New York. The British post office, however, only pays its contractors for the weight of mails actually carried, and reserves the right to send specially addressed letters by foreign ships. The company's services also include a passenger line to Boston, and frequent despatches to Liverpool and New York. During the years 1859 and 1860 the company built two new fast steamers, besides a yearly subsidy of £150,000 for twenty years. The company showed its confidence in the turbine system,—then in its infancy,—by adopting this principle for these two vessels, the largest and fastest at that time contemplated. The advance in size and power of Atlantic steamships is evidenced by the following comparison—

Elder, Dempster & Co.—The remarkable progress of this company, and of the undertakings connected with it, was largely due to the activity of the late Sir Alfred Jones. The oldest business under its management is the African Steamship Company, which was incorporated by royal charter in the year 1852 for the purpose of trading with West African ports. It received a subvention of £20,000 and was to be paid to the builders of the Coast Line. It began its work with an unambitious little fleet of four 700-ton vessels. These were at first, however, equal to all the traffic which the trade could offer, and the Company had then to provide them with bigger steamers, and employed larger and larger than the time of the black night were worked into one another. The Canary Islands, where the West African steamers called on their voyages, were then becoming known as a resort for foreign vessels and the islanders, and the issue of new vessels made by either line was commenced for their convenience. The development of the cultivation of the banana for the English market was also begun to be encouraged by the two ship companies, but it was in the month of August 1894 that the great movement by the Elder-Dempster Company was made public. It was then announced that the firm had assumed the management of the African Company. The two concerns were, and are, continued as distinct organizations, but they naturally work very closely together. The African Company soon began to break fresh ground, building not only superior vessels for the improving West African service, but also constructing large cargo vessels for the general Atlantic trade. These were soon followed by the特殊的 L'Aquitaine and the St Lawrence on the one hand, and between Liverpool and the southern ports of the United States on the other. Meanwhile the development of the possibilities of West Africa and of the West Indies and the South American countries of South America were not usually considered a part of shipowner's work, were inaugurated. These included a bank, founded in 1894, for the accommodation of those African peasants in the "Congo" to be given in exchange for their goods. The vessels were largely consigned from the coast to be dealt with, and a hotel at Grand Canay for the convenience of the tourist; while, to ensure the disposal of the bananas which their companies brought to England, a fruit brokerage business was opened in Cavendish Garden. Having already, as has been seen, a footing in the Canadian trade, they began the restoration of the Atlantic trade to Bristol, by giving it a service of steamships to the St Lawrence, employing for that purpose brothers of great size as their vessels. At the beginning of 1899 they further strengthened their connexion with the nearest British colony by the purchase, from the liquidator of the interests of Canadian Steamship Company, of the "Canadian Pacific" and renaming it the "R. R. Cunarder." The service for this was available at once in hand, a copy of the steamer " Lake Erie," a vessel of 7500 tons gross, the company, for use in the carrying trade to Canada. The vessels of the New World and the African ports ply as well as Hamburg and other North Sea continental ports as from Liverpool, while closely connected with the firm, though sailing its vessels under the Belgian flag, is the Compagnie Brésilienne de Navigation, which runs a service from Antwerp to West African ports. "Ellerman Line."—" Lloyd's Register of Shipping " in its issue for 1891, gives its name to the company as "Ellerman and Company" and unlike most other shipping companies it remained in being for a moment. It was started when Mr John Ellerman, chairman of the Leyland Line, severed his connexion with that company, and went into business for himself on his own account. He bought two vessels of the fleet, and the Peninsula and Mediterranean connections of the old company. Forthwith he added to the tale of his ships by taking over the management of the seven steamers of the Papayanni Line—which has also long maintained a service to Mediterranean ports. Nine steamers previously managed by Messrs Cresswell & Laurence also came into the fold. But this was not all; the direction of two well-established lines to Italian ports was also acquired. These were the fleet of the City Line, which at that time comprised some fifteen vessels, many of them fitted for the passenger trade. This line had been founded by Messrs George Cresswell, and it was sold to Messrs Edward G. Cresswell. It had and had grown up out of a fleet of sailing vessels. The other was the Hall Line of Liverpool, previously managed by Messrs Robert Alexander & Co. It consisted of some eleven steamers of about 600 to 800 tons, and had been running independently. All these companies have been all maintained and extended, and in 1902, in conjunction with the Harrison and Clan lines, a new development up the East Coast of Africa towards Zanzibar and Mombasa was organized. The Leyland Line may be said to date from the year 1851, when the first Mr Bibby founded his steamship line with the small vessels "Firth" and "Thames" (see "Bibby Line" above). The company extended its business to the North Atlantic and in the early 'seventies changed its name, Mr F. R. Leyland, one of its managers, assuming the control. On his death Edward Morgan, the financier of the company, acquired the firm and increased the fleet and connections of the West India & Pacific Steamship Company—a business which had been founded nearly forty years previously in Liverpool and which served, beside many West

India Islands, the cotton ports of Galveston and New Orleans, having also a connexion to Colon for places on the western coast of America. This company at the date of its absorption had a fleet of twenty-two steamships totalling about 100,000 tons gross. This was the first step towards the great American combine. Mr Elkerman, however, who was chairman of the old Leyland Company, separated himself from it at this juncture, and founded the Hooghly Line. The Leyland Company had a number of transatlantic services.

General Steam Navigation Company.—This is the oldest existing line. Its first prospectus was issued in 1824, and in 1831 it received a charter for the operation of its lines between Liverpool and the principal ports of Europe and the Mediterranean. It commenced with the passenger trade from London to Margate, and its operations gradually extended to the British coastwise and home trade and to the Continent. In time the company introduced a regular service between Liverpool and the principal ports of the Mediterranean, and London, Hamburg, Rotterdam, Antwerp and Havre in the north of Europe. It gradually obtained a strong hold upon the passenger and fine goods trade of Liverpool and the home and Mediterranean ports. Vessels are also run to some of the ports abovementioned from the ports of the Mediterranean, and by a excursion service between Harwich and Hamburg, and excursion services in summer to the watering-places at the mouth of the Thames and on the Kentish coast.

Hamburg-American Line.—The extraordinary progress of Hamburg as a seaport during the last thirty years of the 19th century may be held due in no small measure to the enterprise of this line, which has been able to absorb carriers not only from the two continents, but also to the east of Asia and Africa. It was founded in May 1847. At that time, owing to the political disturbances throughout Tnernrny, there was an enormous exodus of emigrants to America. On the foundation of the company it started a regular service of sailing ships between Hamburg and New York. The first ship owned was the ”Deutschland,” of 700 tons, built on the Elbe. It is interesting to note that the present ”Deutschland” is of 16,500 tons gross register, and is of twenty-three times the capacity of her predecessor. The first sailing took place in October 1848. In 1851 the company’s fleet consisted of six vessels, with an aggregate of 4,000 tons. In 1856 the first screw steamer in the company’s service left Hamburg; this was the ”Borsuika,” a vessel constructed, as were her sisters for many years, on the Clyde. From this time, when the company abandoned sailing ships and engaged in screw steamers, its progress was rapid and unbroken. It is strange to note that the first two steamships owned by it were chartered by the British and French governments to convey troops to the Crimea. By 1867 the company had ceased to be a private enterprise. The government of the Empire is indicated by the fact that whilst in 1856 the sailings to New York took place every fortnight, in 1881 there were two a week, and later on New York and the West also by this time considerable. Hence its operations from the original passage between Hamburg and New York. After the war between France and Germany it started a line to the West Indies, and later to Baltimore, Boston, Montreal and other ports in North America. In 1875 it absorbed the old Eagle Company of Hamburg, which had previously been its rival, and then began to run steamers to Central and South America, and later to China, Japan and the Straits Settlements. To-day the Hamburg Company’s lines may be found in every part of the world. For its services to New York run by twin-screw steamers it has the ”Deutschland,” built at Stettin by the Vulkan Company. Her engines develop about 5,000 horsepower, and she was the first Atlantic liner to exceed a speed of 23 knots at sea. Other large steamers built for its Hamburg-Southport-Newfoundland service are the ”Kaiseraugusta Victoria” and the ”American Kaiserlina.” The ”Teutonia,” the largest ship of the fleet, was built for the company by Messrs. Vickers Ltd., of Barrow-in-Furness, and was launched on 1 June 1905. She has a length overall of 665 ft. and a breadth of 82 ft., and her engines develop 35,000 horse-power. She has a speed of 18.5 knots, and was delivered to the Hamburg Company in April 1907.

A service from Hamburg to New York direct for third-class passengers only is also maintained. The Hamburg Company has extended its influence and enlarged its fleet by purchases from other companies. Of the latter the most important was acquired from the Carr Line and the Hansa Line of Hamburg, the Rickmers Line of Bremen, as well as from the Hamburg South America Line. The Leyland and Liners, in fact, when the line it took over the fleet of the Kaiserliche Line. In 1908, in a view to the feeding of its main lines, it acquired the Atlantic Line of Liverpool—a company which had developed the trade between New York and the West Indies. After the purchase of the vessels West Indies and to Canadian ports. In Central and the transatlantic service between Liverpool and the United Kingdom, our regular line, extending from New York to the South American coast, is a service to Eastern Asia, China and Japan. From Steinitz its steamers run to New York, and from New York to the Mediterranean, Brazil and Eastern Asia. From Genoa they run to the coast of Japan, South China and the West Indies.

Japan Mail Steamship Company, Limited (Nippon Yusen Kaisha).—From an early period their insular frontiers made the Japanese a sea-faring folk, but imperial policy for a long period shut them away from all intercourse with the rest of the world. About the year 1860 that the life of the West really touched Japan. In 1868 steamship communication was opened between Yokohama and Kobe, and in 1871 the Nakajima Line was put into existence under the control of the Imperial Bureau of Communication, and in the same year a private company, called the Mitsubishi Kaisha, was founded. This may be said to have been the beginning of the present enterprise. In 1876 the government company gave up the contest, and its fleet passed into the hands of the private company. In 1873 the capacities of this company had been tested in the military expedition to Haidar Kahan. Thereafter its organization had been found excellent, but its fleet insufficient. The treasury now invited the company to buy up the Yokohama-Shanghai service of the Pacific Mail Steamship Company, and the government issued a letter to the company, implying an offer of the lease of the lines for a large sum, in return for the acquisition of the fleet. The company, however, declined this offer. The request was made again in 1877. The state then ordered the lines to be purchased at any price. The government company, however, declined to sell.

Royal Mail Steam Packet Company.—Soon after British-owned steamships began to run to America a company was formed by leading business men interested in the West Indies, to carry the mails from England to that part of the world. The charter of this company, the British Mail Steam Packet Company, was granted in 1859. The government believed that the institution of a line carrying the mails regularly to British possessions in the West Indies was likely to increase the trade to that country. The first contract with the government was entered into in March 1841. No less than fourteen large paddle-wheelers capable of carrying the largest guns then in use by the Royal Navy were required. The contract was opened with the ”Thames” on the 3rd of January 1842, followed by other vessels in fortnightly succession. These steamers started from Falmouth and returned to Southampton, which was the company’s headquarters, though it had no dock accommodation in those days. In 1846 the company began to carry the mails for places on the western coast of South America, the Pacific Steam Navigation Company receiving them at Panama. In January 1851, the company contracted for the large paddle-wheelers to run monthly service to Brazil and the river Plate, and new steamers were built which greatly increased the rapidity of transit. This company was then the only one engaged in running a regular steamboat service between Europe and the countries of South America, as it had also been with the West Indies. The company’s vessels were employed continuously during the Crimean War in the transport of troops, and also in the transport of troops. The latter part of the 19th century the company had provided a fleet of 14 steamers, the ”Trent,” that Slidell and Mason, the commissioners of the Confederate states, were taken on their way to Europe by a United States man-of-war. In 1872 the service to the River Plate was transferred to the Hamburg Company, through the intervention of the British government. The intimacy of the Pacific Steam Navigation Company in the Orient-Pacific Line to Australia was purchased in January 1906, and steamers despatched once a month from London to the East Coast. These vessels were built by Messrs. Illingworth & Sons, and discontinued when the new mail contract came into force in May.
1909. New twin-screw steamships of much greater tonnage than any they had heretofore owned were constructed for the mail service to South America, and an extension was made into the tourist, and cargo trade to Morocco, Madeira and the Canary Islands by the French and German companies. Steamers were also built for the fleet of the Shire Line to the Far East was also acquired. But the great development took place at the beginning of 1910, when the directors made the startling announcement that they had purchased the White Star Line and the Messageries Maritimes Lines—a business established in Liverpool only a year after the grant of their own royal charter. This absorption brought some forty large passenger and mail steamers of the highest order into the fleet—into the fleet, which was then placed amongst the largest of the lines of the world. Another move was made when Sir Owen Phillipps joined Lord Pirrie in organizing a company to take over the interest of Messageries Maritimes in the west coast of South America, besides the lines in the West Indies, the Central American and the Mexican ports. There are also cargo services to the West Indies and Mexico, and to the River Plate and intermediate ports.

**Messageries Maritimes de France.**—Originally known as the Messageries Internationales des Roturiers, it was changed in 1880 undertook. It received its first contract for the conveyance of a large mail from the French Government in 1815. It then extended its services to the Italian Mediterranean and the Tyrrhenian Sea. In the following year it included Salamina in its itinerary. The occurrence of the Crimean War gave an increase to its fleet and a stimulus to its operations. For it was not only the task of these ships to convey the mail to the Black Sea, but was largely entrusted by the government with the duty of transporting troops and stores to the seat of war. At that time it was a considerable purchaser of British tonnage. In 1875 it had made a contract with Strasbourg, and subsequently with Danube and Black Sea ports, whilst in the same year a new contract for a service between Brest and Madeira and the river Plate and to the Far East was described by the Board of Trade as a high new mail steamers, a line of four of about 500 tons of the Black Sea, and South Russia. The French, Dutch, and Spanish were among those whose mail services could be used with commercial success in the long sea trade. At first it depended on chartered vessels, but gradually it acquired a fleet of fast clipper iron sailing-ships which reduced the voyage to 90 days. These vessels took out a large number of passengers, and were often engaged in the Black Sea trade, and eventually it put forth branches which served Madagascar, Mauritius and Zanzibar, as well as Australian ports and the French colony of New Caledonia. Some of these vessels entered the mail services to the Far East and South America are of a very fine character. In 1909 its fleet traversed 1,019,046 marine leagues and carried 197,320 passengers and over a million tons of cargo.

**Kingly Influence.**—Under the name of the American Line it has been shown how a group of American capitalists acquired the Red Star, Inman and American lines, thus forming a body of shipping which embraced in the year 1901 about 167,000 tons of shipping, partly under the British and partly under the Belgian and American flags. Another company which drew its capital chiefly from the United States, though its vessels fly the red ensign, is the Atlantic Transport Company, registered under the British Limited Liability Acts in 1886. Its main service is between London and New York, and it is carried on by large and modern twin-screw steamships, several of which have been constructed at Harland & Wolff yard. The recent acquisition of the Teutonic and it is one of the most important of the company's vessels. The Czarina, which was seconded to the Baltic trade, and eventually it put forth branches which served Madagascar, Mauritius and Zanzibar, as well as Australian ports and the French colony of New Caledonia. Some of these vessels entered the mail services to the Far East and South America are of a very fine character. In 1909 its fleet traversed 1,019,046 marine leagues and carried 197,320 passengers and over a million tons of cargo.

STEAMSHIP LINES

than 2,900 shareholders in the Lloyd forfeited their shares, but the company still commanded many of the loyal support of their fellow citizens. Four big ocean steamers were constructed for the American line and three for the English, and large docks for repairs were established at Bremerhaven. The first voyage was made in 1851, and during the next year it carried many steerage passengers, but only one in the saloon. The second ship, the "Hudson," was shortly afterwards burned while lying in the dock, but the third, the "Sulphur," was lost in the Bering Sea at the end of June, 1852. At the end of the second year matters improved, the English cattle trade especially showing great progress. But the company still commanded little confidence, for the Darmstadt Bank ceased dealings with it in 1853, and it operated for 1854 at a loss of 75%. These the directors themselves took over. But the American Civil War now came, to deal another severe blow to the Lloyd, just when its prospects were growing brighter, and till 1865 the Lloyd traded but very slowly, the first boat only being sold in June 1856.

In 1868 a new line was opened. Bremen's staple of commerce is tobacco, and the directors determined to bring their port into direct communication with the tobacco-producing areas in the States; so in that year they inaugurated their line to Baltimore. In the following year a line was started to New Orleans, another great centre of the tobacco trade. The complications of the American war were thus responsible for the founding of the American Line. It was a direct line from Bremen to New York, operated in co-operation with the Cunard Line, with a branch line to the Southern States.

In 1866 the Australian and East Asiatic Lines were inaugurated, in accordance with a treaty with the imperial government. This included a monthly service to China, with a branch line to Japan, and a monthly service to China, with a branch line to the Samoan and Tonga Islands. From that time onwards the story of the Norddeutscher Lloyd has been one of increased prosperity. The company's fleet includes many of the largest and fastest steamers of its kind, as well as many smaller types.

In the 1890s, the company began to expand its operations further. It established a line to India, and in 1895 it took over the English mail steamer service. The Lloyd continued to grow, and by the end of the century it was one of the largest and most successful shipping companies in the world.

The company's first voyage in 1850 was to New York, and it soon expanded its operations to other parts of the world. In 1858, it opened a line to the Far East, and in the following year it established a line to Australia. By the turn of the century, the company had operations in almost every part of the world, including South America, Africa, and Asia.

The Lloyd continued to grow and prosper, and by the end of the century it was one of the largest and most successful shipping companies in the world. It was one of the first companies to experiment with jet-condensing engines, and it was also one of the first to use twin-screws on its vessels. The company's reputation for efficiency and reliability soon made it a leader in the shipping industry.

The Lloyd's success was due in part to its commitment to innovation and improvement. It was one of the first companies to adopt the jet-condensing engine, which was a more efficient way of generating power than the traditional steam engine. The company was also one of the first to use twin-screws, which provided better maneuverability and stability.

The company's success was also due to its ability to adapt to changing market conditions. It was one of the first companies to establish lines to the Far East and South America, and it continued to expand its operations to new parts of the world throughout the 19th century.

The Lloyd's success was a result of its commitment to innovation, reliability, and adaptability. It was one of the first companies to adopt new technologies and to adapt to changing market conditions, and it was able to maintain its position as a leader in the shipping industry throughout the 19th century.
of a small fleet destined to ply between Calcutta, Madras, Ceylon, Aden and Suez. It was an adventurous undertaking, for the East India Company promised no definite subsidy, only a small premium on a certain number of voyages.

The obvious advantages of a direct conveyance of mails between Singapore and Calcutta sufficiently evinced, and the P. & O. Company offered to effect this at a great saving on the existing system; but, for some reason or other, the East India Company showed the greatest reluctance to allow anywhere for the establishment of this route. In the end it remained until 1854. Fortunately for the P. & O. Company the government decided to establish regular monthly steam communication between India and the South Atlantic coasts, both between Suez and the Far East, and also from Ceylon, eastward to Singapore and Hong-Kong. Only the P. & O. could at that time contemplate undertaking such a service. In 1844 the contract was signed, and it is well worth while to give some description of the service offered. Not less than the half of the service opened on the 1st of January 1845, and during that year the extension to China was effected, and nine new steamers were put on the stocks. The organization of the overland route was due to the P. & O. Company, which brought it into regular working in order to convey its passengers from Alexandria to Suez. It was a picturesque but uncomfortable passage by canal-boat transport, then by a two-humped omnibus for forty miles across the desert to Suez. Even the coal for the boats at Suez had to be transported in this fashion, which was cheaper than sending it by sailing vessel round the Cape. The construction of the Port of Suez also was undertaken by the company, with a view to the increased traffic. It may be noted that the company had to establish coaling stations between Suez and the Far East, and also depots of provisions, a business of no less magnitude than that of the steam service. The vessels were designed and built by the company, and the same contract included an arrangement for a fortnightly service to India and China, though a service was not inaugurated till 1853. The company had thus thought sufficient for the requirements of Australia. The year 1854 saw the abolition of the East India Company's service to Bombay, the P. & O. taking its place. This arrangement saved the company its actual loss of revenue, but the monopoly, the company's resources for the conveyance of troops, and the Australian service was for a time interrupted. By 1859 the company was in possession of all the lines of steam communication through the Indian and Pacific Oceans. From Suez the mail was increased to one sailing a month, and in 1868 the Bombay mail left weekly. About the same time the fourth India and China contract was entered into, and at the end of 1869 the opening of the Suez Canal led to a serious crisis in the company's affairs; and also, after these difficulties had been surmounted, to a complete revolution in its methods. The opening of the canal led to a prolonged controversy with the post-office, which, with trifling perversity, would not allow the company to use the canal for the conveyance of its mails. A serious falling-off of the company's revenue was the result, as the competition of the canal steamer mail began to tell on the number of passengers. The company, which had by this time already made so large a demand on its resources, and was thus able to employ vessels capable of competing successfully with its rivals. A prolonged dispute between Victoria and New South Wales for a long time prevented the Australian service from being as efficient as it should be. But in 1870 the question was settled.

In consequence of this controversy the Australian headquarters of the company were for some time fixed at Melbourne, and it was not till 1886 that a general contract was entered into with the postmaster-general, acting at last for all the Australian colonies as well as for the Imperial government. This stipulated for an accelerated service—the India, China and Australian mails being all worked from Aden in connexion with the steerage which conveyed them from Brindisi. There was for long a service between Venice, Brindisi and Egypt, and a mail contract with the Italian government; but this came to an end in March 1900.

The company's first mail steamer, the "William Fawcett," built in 1829, had a tonnage of 206 and 60 h.p. Down to 1851 the vessels of the fleet were all constructed with paddles; after that date the screw took their place, though for the Marseilles to Malta and the reverse route, the screw had been in use since 1838. The paddle-wheels of that description appeared on the steamer "Admiral de Grasse," the paddle-wheel steamer, with which the company traded between the Mexican ports and the United States. In 1849, by a noble concession of the English government, the paddle-wheels were motionless.

The company's first paddle-wheel steamer was named "Willis," and was built in 1816, having a tonnage of 266 and 40 h.p. The paddle-wheels of that description continued to be employed on several of the company's vessels, and were retained for some years, though the screw had been in use in India since 1838. In 1851 the paddle-wheel vessels of the company were all converted into screw-vessels, and the paddle-wheels were then employed on the same service as paddles.
STEAMSHIP LINES

Sydney, fortnightly. Apart from the mail services, the company runs independent lines to Malta, Colombo and Calcutta; also between Bombay, Colombo, Singapore, Hong-Kong and Shanghai; and between Hong-Kong, Nagasaki, Hiojo and Yokohama. There is in operation, as Messrs. Shaw, Savill & Albion Shipping Company's Railway Gazette 1881 the all-screws or "steamers of thrice her tonnage"—takes the Bombay mails from Aden on the weeks when there is no steamer. For the Indian and Australian mail services a new type of steamer was adopted, the "Saxon" 73 ft. long. The already no less than ten such vessels, all twin-screws of similar design, commencing with the "Moldavia," built 1903, of 9,900 tons and 14,000 l.h.p. and running up to 12,500 miles in 120 days. In 1887 the important trade between the Australian colonies and New Zealand was opened up, and a new service was acquired, the Blue Anchor fleet of Mr. William Lund being purchased. This gave the company an entry into the South African trade, the Blue Anchor steamers calling at Cape Town and Durban on their way to Australia, and new and larger vessels are being provided for this branch also of the company's activities.

Shaw, Savill & Albion Company.—The amalgamation of the businesses of Messrs. Shaw, Savill & Co. of London and the Old Albion Shipping Company of Glasgow brought this company into its present form at the close of the year 1882. At that time the amalgamating firms owned a large fleet of sailing-ships, and traded chiefly to China and Australia. Following the amalgamation the company began to acquire steamships, which gradually supplanted their sailing vessels. The Shaw, Savill & Albion Company were among the first in the frozen meat trade, and captured a large share of that trade by means of specially fitted vessels. With this company the White Star Line of Liverpool became associated in the year 1884, and five of their ships now run in the fleet of the Shaw, Savill & Albion Company. The fleet was made up by Sir John Ellerman to take over the fleet, which at that time consisted of six twin-screw and five single-screw steamships with a total of 51,300 tons gross register, a twelfth vessel being added in 1892, and called the "Canary Line of Steamers." The ships were owned by the Cape of Good Hope on the outward voyage, returning by Cape Horn, thus going completely round the globe every voyage. After leaving London the steamers call at Plymouth, Tenerife, Cape Town, Ascension and Zululand, going thence to the important port or abroad. The ports touched are Rio (sometimes Montevideo), Tenerife, Plymouth, London. The "Aurora," which came out in 1884, made the voyage in 38 days, and the run home in 35 days, 4 hours steaming time; she thus made the circuit of the world in 73 days 4 hours net time.

Union Steamship Company (see Castle Line).—This company first came into existence in 1863 under the name of the Union Steam Collier Company, with a capital of £60,000. At its commencement it possessed a fleet of five small steamers with an aggregate of only 2377 tons. But by the time these vessels were built the Crimea War was over, and the Union Company found it impossible to employ them for other purposes than those for which they were originally intended. They ran for a time between Southamptone, London, and Malta, but this was found in the long run to be more remunerative, and they were used for the conveyance of troops. At the close of the war the company was registered under the Limited Liability Act by its present name. It was then determined to centre its operations between the Cape and Natal, henceforth its mail service was extended to the West coast of Africa, and the ports of call were Cape Town and London. The company continued to use the small "Diane" to run between the two ports, and at first this service continued without any change in the fleet of the company, and the ships of the company were generally in the hands of the government. In the year 1873 the company ran from the Cape to St. Helena in 36 days, and in 1874 to Ascension in 41 days. In 1875 the subsidy was increased in order that the company's ships might call at St. Helena and Ascension for mails on the homeward voyage. When the first contract expired the company secured another one, and continued to the time of the South African War. The government then acquired the company for an extended mail service, and instead of taking over the service under a temporary arrangement, was inaugurated in 1862, and a seven years' mail service contract with the Natal government was concluded in 1865. In 1873 the House of Commons refused to renew the contract at its present terms, and the company had to look elsewhere for funds. In 1874 the company for an extended mail service; the company, however, carried out its intention to extend its service to Zanzibar. But in October 1876 a new mail contract with the Cape of Good Hope government was entered into for a fortnightly service between Plymouth and Table Bay, the length of voyage not to exceed twenty-six days. During the Zulu War this company rendered considerable service in the Cape and Natal region. In 1878 the project was abandoned, and after Isandula they conveyed reinforcements, the "Pretoria," being the only mail steamer to carry an entire regiment, the 91st Highlanders. It was on this company's s.s. "Dunbar" that the Queen went to the Cape on the 9th November 1878. The company were employed, and after Isandula they conveyed reinforcements, the "Empress Eugénie" when she went to visit the scene of his death. The direct service with the Cape, Natal and Zanzibar was in 1881 discontinued, and in February of that year operations were extended to the Continent, a service from Hamburg was commenced, running every twenty-eight days, which for a time proved highly successful. A branch service to Antwerp, begun in 1882, was discontinued for a time, but subsequently resumed. At the time of the Panjdeh scare in 1885, when hostilities were threatening with Russia, two of the company's twin-screw steamers were selected to act as armed cruisers for the defence of South Africa. The former was the only merchant vessel on which the pennant was actually hoisted. In 1889 the company's continental traffic was extended to Germany, and from 1894 to 1903 a fleet of steamers from Hamburg, but made calls at Rotterdam. This service afterwards became fortnightly, calls being made at Rotterdam, Hamburg and Antwerp, and on the Inland Sea to the South and North. The services were afterwards extended to the Dutch colonial possessions, and remained so until the outbreak of the War when they were suspended until peace was declared. In 1907 the company's fleet consisted of thirty-five vessels, including four twin-screw steamers of 2,000 tons each, and twenty-two single-screw steamers of 1,000 tons each. The company had a large fleet of steamers, and also a large number of passenger boats, and had an extensive trade with South America and the West Indies. The company's fleet of steamers was divided into two classes, the "Saxon," the largest class, and the "British." The company had a large fleet of steamers, and also a large number of passenger boats, and had an extensive trade with South America and the West Indies. White Star Line.—Though perhaps chiefly known in the New York trade, the White Star flag was first hoisted in the middle of last century over a fleet of clippers which sailed to Australia. In 1867 Mr. Thomas Henry Ismay took it over, and two years later the great revolution in the constitution of the company took place. It was in 1869 that Mr. Ismay formed the Oceanic Steam Navigation Company to run a line of steamers between Liverpool and New York. Immediately on its formation the company entered into arrangements with Messrs. Harland & Wolff of Belfast for the construction of a fleet of high-class passenger ships, and it is worthy of notice that the terms upon which Messrs. Harland & Wolff built the White Star ships were peculiar. No definite price was agreed upon, but the actual cost plus a percentage for builders' profit was charged. The first "Oceanic," pioneer steamer of the line, was launched on the 27th of August 1870, and sailed for New York on the 2nd of March 1871. Her advent opened a new era in Atlantic travel. She introduced the midship saloon, which extended the whole width of the ship, thus giving increased light and improved ventilation, and reducing to a minimum the sensation of the vessel's motion. The arrangement thus introduced is now almost universally adopted in the construction of ocean liners.

The "Oceanic" was also narrower in proportion to her length than the vessels previously designed for the transatlantic mail service. In 1877 the "Britannic" reduced the passage to 5 days 10 hours and 36 minutes.

### Fleets of Various Important Steamship Companies in 1891, 1901 and 1910.

1 This table is based on that contained in a paper on "Shipping Subsidies," by W. B. Ginsburg, published in the Journal of the Royal Statistical Society (September 1901).
2 The Leyland Line was formerly the Leyland Line and West India & Pacific Steam Navigation Company.
3 In 1891 the old American Line had 3 steamers of 10,166 tons; the Indian Line 6 steamers of 41,726 tons; the International Line 1 steamers of 12,112 tons; and the Red Star Line 9 steamers of 39,609 tons.
4 Messrs. Elder, Dempster & Co. now control the fleets of the African, British & African, and Imperial Direct Steamship companies.
5 Formerly the Union Line and the Castle Line. In 1891 the Union Line had 23 steamers of 55,576 tons, and the Castle Line 19 steamers of 57,934 tons.
6 Formerly known as the Flotta & Rubattino Line.
50 minutes, excelling by three hours the best previous Atlantic passage. After the year 1888 the company ceased to build single-screw steamers, all later vessels having been constructed on the twin-screw system, of which the superiority had been clearly demonstrated. A sum of £75,000 was also paid to the Company, 30,000 of which was paid in 1882, and the remainder in 1883. Vessels were also responsible for an important advance in steampacket construction, which was afterwards imitated by merchant ships of all the great maritime powers. The launch "Atlantic" in 1875 was the second "Oceanic" in January 1899 the company's record was still further enhanced. The White Star Line was from 1877 regularly employed under contract with the British government to carry the American mail. In 1878, the first White Star Line, the "Hull", from Liverpool and Queenstown to New York, was launched. Besides this weekly mail and passenger service, a fleet of twin-screw cargo vessels maintained a subsidiary service between Liverpool and Queenstown, which were especially designed for the conveyance of cattle and horses. After 1883 several steamers of the line were employed in the Shaw, Savill & Albion service between London and New Zealand. Three of the company's ships ran in the line of the Oriental & Colonial Company between San Francisco and Yokohama and Hong-Kong. The company inaugurated a service to Australia from Liverpool in 1889. Five ships ran in it (calling at Cape Town) to Albany, Adelaide, Melbourne, Sydney, and Port Phillip Bay. The passenger trade to New Zealand will be found detailed under Shaw, Savill & Albion Company. In 1902 the absorption of the White Star Line and many of its properties was completed by the British & Colonial Steam Packet Company. Since then several alterations have taken place. The main steamers of the line left Liverpool for Southampton in June 1907 and now call at Cherbourg on their way to. and from New York. Two of these steamers were named "Empire of India" and "Queen of India". The "Empire of India" is probably the largest twin-screw steamer afloat. There is also a line of White Star steamers between New York and the Mediterranean. Several important vessels from other companies have been built under the name. These include "Nomadic" and "Lucania" of the Queen Mary Line, both of which are large passenger and cargo vessels. In addition to these there are two other Atlantic services from Liverpool— one to Boston and the other to New York. Besides the mail and passenger traffic the main trade carried is in cattle and wool. There are employed in this traffic more than 3,000 steamers of the White Star Line, over 1,000 of which are employed in regular service. They are fitted for carrying valuable merchandise and cattle. The experience of many years has enabled the owners of some of these lines to exhibit a wonderfully low record of loss. The number of deaths at sea to numbers carried being small beyond expression, and the record of the line shows that the size of individual ships is as marked as that of the aggregate tonnage of the companies.

**AUTHORITIES.**—The following books throw much light on the question: The lead article "White Star Line" has been written by W. S. Lindsay (London, Sampson Low & Co.); La Nav. comm. aux XIX. siècle (Paris, 1901); A. J. Maginnis, The Atlantic Ferry (3rd ed., London, Whitaker & Co.). E. R. Jones, The Shipping World Year-Book; Lloyd's Register of British and Foreign Shipping (published annually). Also see a comprehensive article on this subject in the Quarterly Review for January 1900. Perhaps the fullest information is, as a rule, to be obtained from the handbooks issued by the companies themselves.

**(B. W. G.)**

**STEARIC ACID—STEATOPYGIA.**

**STEARIC ACID.** n-Octodecyl acid CH₃(CH₂)₁₄COOH, an organic acid found as its glyceride stearin, mixed with palmitin and olein, in most tallow (hence its name, Gr. στεαρ, tallow). The so-called "stearin" of candles is a mixture of steatins, also called "candle stearin", of which stearic acid is the most common component.

**STEATOPYGIA** (Gr. στεαρ, fat, πυγή, rump), an unusual accumulation of fat in and around the buttocks. The deposit of fat is not confined to the gluteal regions, but extends to the outside and front of the thighs, forming a thick layer reaching sometimes to the knee. This curious development constitutes a racial characteristic of the Bushmen (q.v.). It is specially a feature of the women, but it occurs in a less degree in the males. It is also common among the Hottentots, and has been noted among the pygmies of Central Africa. In women it is regarded among them as a beauty; it begins in infancy and is fully developed on the first pregnancy. It is often accompanied by...
the peculiar formation known as "the Hottentot-apron," hypertrophy of the nymphae (Tabler). No satisfactory explanation of these malformations has been offered. Steatopygia would seem to have been a characteristic of a race which once extended from the Gulf of Aden to the Cape of Good Hope, of which stock Bushmen and pygmies are remnant. The discovery in the caves of the south of France of figures in ivory presenting a remarkable development of the thighs, and even the peculiar prolongation of the nymphae, has been used to support the theory that a steatopygous race once existed in Europe. What seems certain is that steatopygia in both sexes was fairly widespread amongst the peoples of the middle and South African Hottentots afford the most noticeable examples of its development, it is by no means rare in other parts of Africa, and occurs even more frequently among Bastaards of the male sex than among Hottentot women.

STEDMAN, EDMUND CLARENCE (1833–1908), American poet and critic, was born at Hartford, Connecticut, on the 8th of October 1833. He studied two years at Yale; became a journalist in New York, especially on the staffs of the Tribune and World, which latter paper he served as field correspondent during the first years of the Civil War; and was a contributor to the Atlantic Monthly in the latter half of the century. His first books, Poems, Lyrical and Idyllic, appeared in 1860, followed by successive volumes of similar character, and by collected editions of his verse in 1873, 1884 and 1897. His longer poems are Alice of Monmouth: an Idyl of the Great War (1864); The Blind Prince (1869), an allegory of good deeds, supposed to have been remotely suggested by the life of Prince Albert; and an elaborate commemorative ode on Hawthorne, read before the Harvard Phi Beta Kappa Society in 1877. An idyllic atmosphere is the prevalent characteristic of his longer pieces, while the lyric tone is never absent from his songs, ballads and poems of reflection or fancy. As an editor he put forth a volume of Cameos from Landor (with T. B. Aldrich, 1874); a large Library of (selections from) American Literature (with Ellen M. Hutchinson, 11 vols., 1888–1890); a Victorian Anthology (1893); and an American Anthology, 1878–1899 (1900); the two last-named volumes being ancillary to a detailed and comprehensive critical study in prose of the whole body of English poetry from 1837, and of American poetry of the 19th century. This study appeared in separate chapters in Scribner’s Monthly now the Century Magazine, and was reissued, with enlargements, in 1905. His most important work entitled Victorian Poets (1875) contributed to the jubilee year in the edition of 1887 and Poets of America (1889), the two works forming the most symmetrical body of literary criticism yet published in the United States. Their value is increased by the treatise on The Nature and Elements of Poetry (Boston, 1891)—a work of great critical insight as well as technical knowledge. He died in New York on the 18th of January 1908.

STEELE, FLORA ANNIE (1847–1930), English writer, was born on the 27th of April 1847, the daughter of George Webster. In 1867 she married an Indian civilian, and for the next twenty-two years lived in India, chiefly in the Punjab, with which most of her books are connected; her interest in the education of women, as an inspectress of schools, gave her a special insight into native life and character. Some of her best work is contained in two collections of short stories: From the Five Rivers (1893) and Tales from the Punjab (1894); while her most ambitious effort was her novel, On the face of the Waters (1896), describing incidents of the Indian Mutiny. She also wrote a popular history of India. Later works are In the Permanent Way (1897), Voices in the Night (1900), The Hosts of the Lord (1900), In the Guardianship of God (1903), A Sovereign Remedy (1906).

STEEL CONSTRUCTION. The use of steel construction in the erection of large buildings is the natural consequence of the conditions imposed upon owners of property lying within sections of large cities, and the result of the introduction of new materials and devices. Apart from the aesthetic considerations to which has been due the construction of spires, towers, domes, high roofs, etc., the form and height of buildings have always been largely controlled by a practical consideration of their value for personal use or rental. The cost of buildings of the same class and finish is in direct proportion to their cubic contents, and each cubic foot constructed is commercially unprofitable which does not do its part in paying interest on the capital invested. Until the latter half of the 19th century, these considerations practically limited the height of buildings on city streets to five or six stories. The manufacture of the wrought-iron “I” beam in 1853 made cheaper fire-proof construction possible, and, with the introduction of passenger lifts and the invention of the Elevator Hoist (1887), about ten years later, led to the erection of buildings to be used as warehouses, factories, and for other commercial purposes, containing many more stories than had formerly been found profitable. The practical limit of height was reached when the sectional area of the masonry of the exterior walls in the lower storey had to be made so great, in order to support safely the weight of the dead load of the walls and floors and the accidental load imposed upon the latter in use, as to affect seriously the value of the lower storeys on account of the loss of light and space. This limit was found to be about ten stories. Various devices were successively made to reduce the size of the exterior piers. In 1888 the walls of a very large courtyard were constructed by building a braced cage of iron and filling the panels with masonry, a system of construction which had been used in the early part of the century for a tall shot-tower erected in the city of New York. Subsequently several buildings were erected in which the entire weight of the floors and roofs was carried by a system of metal columns placed against the inner surface of the exterior walls. The walls thus supported no load but their own weight, and were tied to the inner cage formed by the wall columns, interior columns, girders, and floors by anchors arranged to provide for the shrinkage of masonry in drying out which always occurs to a greater or less extent. By the use of this form of construction buildings were carried to the height of eighteen or nineteen storeys.

Iron or steel as a substitute for wood for constructive purposes was long thought to be fire-proof or fire-resisting because it is incombustible, and for this reason it has not only replaced wood in many features of building construction but is also used as a substitute for masonry. In time, however, it was realized that iron by itself is not fire-proof, but requires to be protected by means of fire-resisting coverings; and as soon as satisfactory forms of these were invented their development progressed hand in hand with that of iron and steel forms and combinations.

Buildings in steel are either of “skeleton” or “cage” construction. These terms may be defined as follows: In “skeleton” construction the columns and girders are built without proper or adequate inter-connexion and would not be able to carry the required weights without the support afforded by the walls; or, as in more recent construction, the walls are self-supporting and the other portions of the building are carried on by the skeleton steelwork. “Cage” construction consists of a complete and well-connected framework of iron or steel capable of carrying not only the floors but the walls, roof, and every other part of the building, and efficiently constructed with wind bracing to secure its independent safety under all conditions of loading and exposure, all loads being transmitted to the ground through columns at predetermined points. In America under this system the walls can be built independently from any level (see fig. 1), but in England the requirements of the building and the necessity for the thickness of walls prevents the general use of this form of construction.

Skelelon construction is defined by the Chicago building ordinance as follows:

“The term ‘skeleton construction’ shall apply to all buildings wherein all external and internal loads and strains are transmitted from the top of the building to the foundations by a skeleton of metal framing to which the columns, girders and girders shall be riveted to each other at their respective junction points. If pillars made of rolled iron or steel are used, their different parts shall be riveted to each other and the beams and girders
With the introduction of cheap structural steel, steel cage construction came rapidly into use. The dimensions of the exterior piers ceased to control the height of the building, which was limited alone by the possibility of securing adequate foundations, and by a consideration of the amount of floor space which could be devoted without too great loss to a system of passenger lifts of sufficient capacity to afford speedy access to all parts of the building. The advantages that led to the very rapid introduction of this system were not only the power of greatly reducing the size of the piers, but the enormous facility afforded for quick construction, the small amount of materials relatively used and the proportionately small labour upon the foundations, and the fact that as the walls are supported at each storey directly from the cage, the masonry can be begun at any storey independently of the masonry below it. It is a disadvantage of the system that defects of proportion, material, or workmanship, which would be of less moment in an old-fashioned construction, may become an element of danger in building with the steel cage, while the possibility of securing a permanent protection of all parts of the cage from corrosion is a most serious consideration. The safety of the structure depends upon the preservation of the absolute integrity of the cage. It must not only be strong enough to sustain all possible vertical loads, but it must be sufficiently rigid to resist without deformation or weakening all lateral disturbing forces, the principal of which are the pressure of wind, the possible sway of moving crowds or moving machinery, and the vibration of the earth from the passage of loaded vans and trolleys, and slight earthquakes which at times visit almost all localities. In buildings wide in proportion to their height it is the ordinary practice to make the floors sufficiently rigid to transfer the lateral strains to the walls, and to brace the wall frames to resist them. In buildings of small width in proportion to their height this method of securing rigidity is generally found to be inadequate, and the frame is also braced at right angles to the outer walls to take up the strains directly. In each case all strains are carefully computed. The bracing is accomplished by the introduction at the angles of the columns and girders or beams of gusset plates or knee braces, or by diagonal straps or rods properly attached by rivet or pin connections. All portions of the frame are united by hot rivets of mild steel or wrought iron, care being taken that the sum of the sectional area of rivets affords in each case a sufficient ratio of metal for the safe transfer of the stresses. The greatest care should be taken to see that all rivet holes are accurately punched, and if necessary that they are rhenized so that each rivet will have its full value.

For the proper and successful erection of the frame much depends upon an accurate alignment of the column bases. These should be properly tested as to position and level. The bases are either grouted with cement, or bolted to the foundations, but where cast column bases rest on mosaic, piers or footings any considerable grouting is not advisable. The only grouting that should be permitted in tall buildings would be in levelling up the tops of the concrete footings to receive the masonry courses, or in a very thin layer between the column pedestal and the masonry bed. The cap stones should always be brought to the most accurate bed possible, with grouting used as a thin cement and not as a backer. Accurate redressing of the cap stones after setting is much to be preferred.

All riveting and punching of the steel members is done at the shop, where also they receive the usual coat of oil or paint. This leaves the assembling and field riveting to be done on the ground, together with the adjustment of the lateral or wind-bracing, the placing of tie rods and the field painting.

After erection the steelwork should receive one or two coats of paint; two coats are to be recommended, in which case they should be of different colours. Red lead is best for the priming coat and oxide paint for the finishing coat. In German specifications it is required that the steelwork should first receive a coat of boiled linseed oil, in order that the red lead coating should be more coherent with the steel. The rust that may have come in contact with brickwork or concrete should not be painted, but should receive a wash of cement as the brickwork or concrete-work proceeds. The steelwork which is exposed to the weather should be painted about every three years, but when it is under cover an interval of five years may elapse.

To secure painting of permanent value a clean scaleless and rustless surface is first necessary. Steel plates and shapes, when delivered from the rolls which form them to the cooling beds, are largely covered with scales, which, adhering only partially to the surface, are liable to the surface and not to any other difficult to obtain cracks or joints as vulnerable points for rust. After being rolled, structural steel is stored or handled out of doors for a varying period both at the mill and then again at the shop before the building is started. This period of open-air exposure allows the process of rust to start under the scales. If the rust so covered up has not begun to pit the iron the chances are that it will do no harm; but, if it is already well developed and of some thickness, it will have enough oxidizing agents in its pores to develop more oxide, and to swell up and crack the paint. The first requirement, therefore, for efficient painting is the careful removal of all mill-scale, rust, grease, or foreign substance, before even the priming coat is applied. It is agreed that the first step in the preservation of metal-work against deterioration or corrosion is the obtaining of absolute cleanliness of metal before the application of paint or oil.

The following are the requirements of the New York building law in regard to the protection of iron or steelwork against corrosion, &c.:

"All structural metal-work shall be cleaned of all scale, dirt and rust, and be thoroughly coated with one coat of paint. Cast-iron columns shall not be painted until after inspection by the Department of Buildings. Where surfaces in riveted work come in contact they shall be painted before assembling. After erection all work shall be painted with at least one additional coat. All iron or steel used under water shall be enclosed with concrete."

The Chicago ordinance makes no mention of paint or coating to prevent rust in metal framework. The London Building Acts do not set out any special requirements, but suggestions have been made at the Royal Institution of British Architects for the regulation of skeleton buildings and they are drawn up upon a more scientific basis than the bulk of the existing acts. In transferring the loads from the column bases to the bottom of the footings the greatest care must be taken in all systems of construction that the stresses throughout at no point exceed the safe limits of stress for the various materials used. Steel is generally used for columns in preference to cast iron, because it affords greater facility for securing satisfactory connections, because its defects of quality or workmanship are more surely detected by careful test and inspection, and because, on account of its superior elasticity and ductility, its fibre is less liable to fracture from slight deformations. It is used in preference to wrought iron on account of its lesser cost.
Columns are generally built of riveted work of zedbars, channels, angles, plates, or lattice, of such form as will make the simplest and most easily constructed framing in the particular position in which the column is placed. The columns are sometimes run through two or more storeys and arranged to break joints at the different floors. In buildings to be used as offices, hotels, apartments, &c., it is usual in establishing the loads for the purpose of computation to assume that the columns carrying the roof and the upper storey will be called upon to sustain the full dead load due to material and the maximum computed variable load, but it is customary to reduce the variable loads at the rate of about 5% storey by storey, or to allow for a minimum of about 20% of the entire variable load is reached, for it is evidently impossible that the building can be loaded by a densely-packed moving crowd in all of its storeys simultaneously. In the case of factories and buildings used for storage purposes the maximum variable load which can be imposed for any serious length of time on each floor must be used without reduction in computing the loads of the lower column, and proper allowances must be made for vibrating loads. In the case of very tall exposed buildings of small depth, the vertical load on the columns is that due to the wind and pressure. The stresses in the building must be computed and allowed for, and in case the lower columns are without lateral support their bending moment must be sufficient to resist the lateral pressure due to wind and eccentricity of loading. In computing the column sections a proper allowance must be made for any eccentricity of loading. It is usual to limit the height of sections of columns without lateral support to 30 diameters, and to limit the maximum fibre stress to 12,000 lb per sq. in. The sectional areas are computed by the use of the ordinary formulae for columns and struts. The standard sections in use are numerous and varied, and from time to time a steel user has occasion to design a new steel shape because no existing section is suitable. The experiments given by Professor Burr indicate that a closed column is stronger than an open one, but practice does not always support theory, and many other questions besides mere form arise in connexion with the choice of a section; special considerations in the use of columns in buildings sometimes call for a form very different from the circular section, and such include the transfer of loads to the centre of the section, the maximum efficiency under loading, and the requirements for pipe space around or included in the column form. The use of lattice bars, fillers, brackets, &c., and just so much more weight without increasing the section, and must be allowed for; the method of riveting the sections together must also be taken into account.

For girders of small spans "I" beams or channels are generally used, but for greater spans girders are built of riveted work in the form of boxes with top and bottom plates, side plates, and angles with proper stiffening bars on the side plates, or "I's," or lattice, or other forms of truss work. In girders and beams the maximum fibre stress is usually limited to 16,000 lb. In very short girders the shear must be computed, and in long girders the deflexion, particularly the flexure from the variable load, since a flexure of more than \( \frac{1}{15} \) of the length is liable to crack the plastering of the ceilings carried by the girders. The same necessity for computing shear and flexure applies to the floor beams. The floors between the girders are constructed of "I" beams, spaced generally about 5 ft. between centres; their ends are usually framed to fit the form of the girders, and rest either upon their lower flanges, or upon seats formed of angles riveted to their webs, being secured to them by a pair of angles at each end of the beam riveted to its web and to the web of the girder. Sometimes the beams rest upon the girders, and are riveted through the flanges to it; in this case the abutting ends of beams are spliced by scarf plates placed on each side of the webs and secured by rivets. A similar construction is followed for flat roofs, the grades being generally formed in the girder and beam construction, and a flat ceiling secured by hanging from them, with steel straps, a light tier of ceiling beams. The floor beams are tied laterally by rods in continuous lines placed at or above their neutral axis. It is usual in both girders and beams to provide not only for the safe support of the greatest possible distributed load, but for the greatest weight, such as that of a safe or other heavy piece of furniture which may be moved over the floor at its weakest points, the centres of the girders and beams. It must always be borne in mind that the formulae for the ultimate strength of the "I" beams only hold good when the upper chord or flange is supported laterally.

Considerable improvement has been made in the design of rolled steel shapes; for example the rolling of a 16-in. joist was formerly deemed a remarkable achievement, though now there are works producing 24-in. joints with flanges 7 \( \frac{3}{4} \) in. wide. The Broad Flange Differdange Beams are claimed by the manufacturers to be stronger and to minimize weight for use as girders; they are made in twenty-one different sizes with flanges from \( \frac{8}{4} \) to 12 in. wide.

The introduction of steel construction has simplified many details of architectural treatment, such as projections for cornices, bay windows and galleries. These may be supported by bracket-angles attached to the columns with a system of anchors to tie them back; the material must be carried in such a manner that it indicate the part of the general structure, and must be constructed as light as possible. If the supporting member is a floor beam or girder the girder should be rigidly connected to the floor system to prevent any twisting due to the weight of the projection.

The arrangement of the building and floor framings is in a great measure governed by the architectural effect sought and by the arrangement and proper planning of the interior according to the intended uses; the positions of columns, girders and floor beams are usually the result of particular requirements, and unless complicated and expensive framing is to be expected the distance between columns must be kept within the limits of simple girder construction. The position of the columns having been determined, the girders must next be located; these serve to support the floor beams which transfer the loads direct to the columns, and also to brace the columns during erection. The spacing, or distance from centre to centre of the floor beams, will depend upon the type of fire-proof flooring employed; it also depends to a considerable extent upon the amount and character of the floor load and the length of span. If the loads to be carried are largely stationary, and the span is small, the floor joints can be readily proportioned by means of tables given in the handbooks issued by many steel companies. The distance between joists should be limited to 5 or 6 ft.; horizontal bracing by means of diagonal rods is sometimes used, but should be avoided. The following are the usual assumptions made in good practice for super-imposed loads:

<table>

The relation between the velocity of wind and the pressure exerted upon surfaces must be considered in steel construction, and designers differ in regard to the forces to be resisted and the material to be used. Every building offers its own peculiar condition; the height, width, shape and situation of the structure, and character of the enclosing walls, will determine the amount of wind pressure to be provided against, and the internal appearance and the planning of the various floors will largely influence the manner in which the bracing is to be treated. There are many and varied forms of bracing, each designer adopting methods peculiar to his own ideas. One form consists of adjustable diagonals, rods or bars, properly fastened to the columns in the building; these diagonals may run through one floor and be attached to the columns at the floor above. Another form is known as portal bracing; this is usually braced between adjacent columns in halls or passage-ways and extends from the foundations up from floor to floor to such a height that the stability of the
building itself is sufficient to resist the assumed wind pressure. In general, if the building is square or nearly so wind-bracing should be placed close to the corners. In case neither of the above methods can be applied, brackets should be used at each floor level or a continuous deep beam or girders carried all around the building. Some architects demand solely upon such brackets, and the building with a well-constructed iron frame should be safe if provided with brick partitions or if the exterior of the iron framework is covered with well-built masonry of sufficient thickness.

Truss rods, portals, or lattice or plate girders constitute the more definite types of wind-bracing ordinarily employed; the bracing must reach to some solid connection at the ground. The greatest wind pressure to which a building is subjected is that from a horizontal wind. The maximum pressure is not uniform from the ground level to the roof but is greatest at the centre; it is diminished near the ground level by the frictional resistance of the ground, and at the eaves by the eddies formed by the air escaping over the roof. The change in direction of the air when striking a flat surface such as the side of a building will form a cushion to diminish the effects of impalae and shocks from local gusts.

The building laws of the city of New York require the following provisions as regards wind forces:

"All structures exposed to wind shall be designed to resist a horizontal wind pressure of thirty pounds for every square foot of surface thus exposed, from the ground to the top of the same, including members, bracings, and partitions. In no case shall the overturning moment due to wind pressure exceed seventy-five per centum of the moment of stability of the structure. In all structures exposed to wind, if in the resisting moments of the ordinary materials of construction, such as masonry, partitions, floors and connections, are not sufficient to resist the moment of distortion due to wind pressure, taken in any direction or any part of the structure, additional bracing shall be introduced sufficient to make up the difference in the moments. In calculations for wind pressures, the working stresses set forth in the code may be increased by fifty per cent. In buildings under one hundred feet in height, provided the height does not exceed two times the average width of the base, the wind pressure may be disregarded."

The steel used throughout the entire structure should be subjected to the most thorough chemical and mechanical tests and inspection, first at the mill and subsequently at the fabricating shops and the building, to ensure that it shall not contain more than 0.06% of phosphorus or 0.06% of sulphur, that it shall have an ultimate strength of between 60,000 and 70,000 lb per sq. in., with an elastic limit of not less than 35,000 lb per sq. in., and an elongation before fracture of not less than 25% in 8 in. of length, and that a piece of the material may be bent cold 180° over a mandril equal to the least outside diameter of the piece without fracture of the fibres on the outside of the bend. At least two pieces are taken from each melt or blow at the mill, and are stamped or marked, and all the various sections rolled from the melt or blow are required to bear a similar stamp or mark for identification. All finished material is carefully examined to see that it possesses a smooth surface, and that it is free from cracks, seams and other defects, and that it is true to section throughout.

Rivets are either of wrought iron or of extra soft steel, with an ultimate tensile strength of 55,000 lb per sq. in. The material must be sufficiently tough to bend cold 180° flat on itself without sign of fracture. The greatest care is taken that no steel is left in a brittle condition by heating and cooling without proper annealing. All abutting joints in riveted work are faced to exact lengths and absolutely at right angles to the axis of the piece, and are spiked by scarf plates of proper dimensions adequately secured by rivets. The work should be so accurate that no packing pieces are necessary. If the conditions are such that a packing or filling piece must be used, the end of one piece is cut to a new and true surface, and the filling piece is planed to fill the space accurately. Where cast iron is used, it is well to use tough grey iron free from defects. In testing it pieces 14 in. long and 1 in. square are cast from each heat and supported on blunt knife edges spaced 12 in. apart; under a load in the centre of the piece of 3500 lb the deflexion must not exceed 3/8 in. The filling between the girders and floor beams consists of segmental arches of brick, segmental or flat arches of porous (sawdust) terra-cotta, or hard-burned hollow terra-cotta. No partitions, or other patented forms of con-crete floors containing ties or supports of steel or iron. In all cases it is customary to fill on top of the arches with a strong Portland cement concrete to a uniform level, generally the top of the deepest beam; the floor filling is constructed and carried to this level immediately upon the completion of each tier of beams, for the purpose not only of stiffening the frame laterally, and of adding to its stability by the imposition of a static load, but also to afford constantly safe and strong working platforms at regular and convenient intervals for use throughout the entire period of the construction. In cases in which the lateral rigidity of the floors is dependent upon transferral of the horizontal strains to the exterior walls which are frizzed to resist them, no form of floor construction should be used which is not laterally strong and rigid. With very rapid building, no method of construction of floors furrings, or partitions should be adopted which will not dry out with great speed. In flat forms of masonry floor construction the level of its bottom is placed somewhat below the bottom of the "1" beams and girders, so that when it is plastered a continuous surface of at least an inch of mortar will form a fire-proof protection for the lower flanges of the beams and girders. Where the width of the flange is considerable it is first covered with metal lath secured to the under side of the floor masonry. Rinders projecting below the floor are usually encased in from 1 to 2 in. of fire-proof material, 2 or 4 in. of which is also put on all columns. Such fire-proof coverings, and also interior partitions, are composed of hollow, hard-burned terra-cotta blocks, of porous (sawdust) terra cotta, or various plastic compositions applied to metallic lath, many of which are patented both as to material and method of application. The most simple test for the value of a system of fire-proof coverings, and of partitions and furrings, is to erect a large sample of the work and to subject it alternately to the continued action of an intensely hot flame which is allowed to impinge upon it, and to a stream of cold water directed upon it from the ordinary service nozzle of a steam fire engine. It is important in all fire-proofing of columns and girders, and in all floor construction, furring and partitions, that there shall be no continuous voids, either vertical or horizontal, which may possibly serve as flues for the spread of heat or flame in case of fire. All furrings and partitions must be started on the solid masonry of the floors to prevent the possible passage of fire from the room in which it may occur. The failure to make this provision has been the cause of very serious losses in buildings which were supposed to be fire-proof.

Steel construction possesses great advantages in time required for erection. When once the site is cleared and the foundations prepared and set, work can be pushed on the walls at different storeys at one and the same time, and often main cornices and filling-in work are fixed before special details and ornamentation. In the Commercial Cable Building, New York, seven complete tiers aggregating 7000 tons were erected in nine weeks. In the Unity Building, Chicago, of seventeen storeys, the metal framework from basement various was finished at roof was accomplished in nine weeks. In the Fisher Building, Chicago, the entire steel skeleton above the first floor, nineteen storeys and attic, was erected in twenty-six days.

Owing to the low price of steel it is possible to make a steel column of equivalent strength cheaper than one in cast iron. The question of cost is purely a commercial one, but the cost of the raw material will practically never determine the relative cost between various forms, as the expense of manufacture and the detail and duplication of members will all influence the ultimate cost to a much greater extent than the simple cost of the plain materials. The steelwork in the erection of any considerable size is almost invariably rolled to order.

Steel construction and the rapid development of engineering practice has affected not only the erection of tall buildings, but has also produced improvement in the erection of factory and workshop premises. Modern workshops consist of wider buildings of greater height with plenty of roof-light, efficient ventilation, and artificial heating, and as the heavy loads can be carried by the reinforcing material, heavy walls become unnecessary. Gradually, therefore, the modern steel-framed factory has been evolved, capable of supporting all the loads, the outer walls being required only for protection against weather. Light steel roof trusses have replaced the timber trusses, and with the columns form a rigid framework to resist the structural and wind loads as well as those from the cranes and shunting.

In Germany skeleton steel-framed factory buildings may be erected with half brick (12 cm.), with a restriction that when such buildings are abutting or are in the immediate neighbourhood, i.e. within 20 ft. of a neighbouring building, the outside walls on the sides affected shall be full brick (25 cm.).

The permissible height to which a building may be erected on the continent of Europe depends largely on the breadth of the road on which such buildings are situated. As a rule it is not permissible to erect a building wider than the road, measured from building line to building line.

In American practice the use of steel in buildings of ten or more storeys, or in manufacturing plant where the floor loads are heavy and frequently "live" in the sense of causing vibration, has led to more careful specifications as to the quality of materials and character of workmanship, and it is the custom of the leading architects to have the structural frame inspected and tested during manufacture at the foundries, rolling-mills and shops by a firm of engineers making a speciality of such inspections.

The illustrations (see Plates I. and II) will give a good idea of the general construction as now carried out in England and America.

**STEEL, ANNE** (1717-1778), English hymn writer, was born at Broughton, Hampshire, in 1717. The drowning of her betrothed a few hours before the time fixed for her marriage deeply affected an otherwise quiet life, and her hymns rather emphasize the less optimistic phases of Christian experience. In 1760 she published Poems on Subjects Chiefly Devotional under the name "Theodosia," and her complete works (144 hymns, 34 metrical psalms and 56 moral poems) appeared in one volume in London (1865). She was a Baptist, and her hymns are much used by members of that communion, though some of them, e.g. "Father of mercies, in Thy word," have found their way into the collections of other Churches. She has been called the Frances Ridley Havergal of the 18th century.

**STEEL, SIR RICHARD** (1672-1720), English man of letters in the reign of Queen Anne, is inseparably associated in the history of literature with his personal friend Addison. He cannot be said to have lost in reputation by the partnership, because he was inferior to Addison in purely literary gift, and it is Addison's literary genius that has floated their joint work above merely journalistic celebrity; but the advantage was not all on Steele's side, inasmuch as his more brilliant conˌdutor has usurped not a little of the merit rightly due to him. Steele's often-quoted generous acknowledgment of Addison's services in the **Tallier** has proved true in a somewhat different sense from that intended by the writer: "I feared like a distressed prince who calls in a powerful neighbour to his aid; I was undone by my auxiliary; when I had once called him in I could not subsist without dependence on him." The truth is that in this happy alliance the one was the complement of the other; and the balance of mutual advantage was much more nearly even than Steele claimed or posterity has generally allowed.

The famous literary pair were born in the same year. Steele, the senior by less than two months, was baptized on the 12th of March 1672 in Dublin. His father, also Richard Steele, was an attorney. He died before his son had reached his sixth year, but the boy found a protector in his maternal uncle, Henry Gascoigne, secretary and confidential agent to two successive dukes of Ormond. Through his influence he was nominated to the Chapel Royal in 1684, and subsequently lived with Addison. Five years afterwards he proceeded to Christ Church, Oxford, and was a postmaster at Merton when Addison was a deacon at Magdalen. Their schoolboy friendship was continued at the university, and probably helped to give a more serious turn to Steele's mind than his natural temperament would have taken under different companionship. Addison's father also took an interest in the warm-hearted young Irishman; but their combined influence did not steady him sufficiently to keep his impulses within the lines of a regular career; without waiting for a degree he volunteered into the army, and served for some time as a cadet under the command of the unfortunate duke of Ormond "(i.e. the first duke's grandson, who was attainted in 1715). This escapade was made without his uncle's consent, and cost him, according to his own account, "the succession to a very good estate in the county of Wexford in Ireland." Still, he did not lack advancement in the profession he had chosen. A poem on the funeral of Queen Mary (1699), dedicated to Lord Cutts, colonel of the Coldstream Guards, brought him under the notice of that nobleman, who took the gentleman trooper into his household as a secretary, made him an officer in his regiment, and eventually procured for him a captaincy in Lord Lucas's regiment of foot. His rapid promotion by King William, but the king's death took place before anything had been done for Captain Steele. A duel which he fought with Captain Kelly in Hyde Park in 1700, and in which he wounded his antagonist dangerously, inspired him with the dislike of the practice that he showed to the end of his life.

Steele probably owed the king's favour to a timely reference to his majesty in the *Christian Hero*, his first prose treatise, published in April 1701. The "reformation of manners" was a cherished purpose with King William and his consort, which they tried to effect by proclamation and act of parliament; and a sensible well-written tract, depicting the irregularity of the military character, and seeking to prove by examples—"the king himself among the number"—"that no principles but those of religion are sufficient to make a great man," was sure of attention. Steele complained that the reception of the *Christian Hero* by his comrades was not so respectful; they persisted in trying him by his own standard, and would not pass "the least levity in his words and actions" without protest. His unceasing under the ridicule of his irreverent comrades had a curious result: it moved him to write a comedy. "It was now incumbent upon him," he says "to enliven his char- acter, for which reason he wrote the comedy called *The Funeral*.

Although, however, it was Steele's express purpose to free his character from the reproach of solemn dullness, and prove that he could write as smartly as another, he showed greater respect for decency than had for some time been the fashion on the stage. The purpose, afterwards more fully effected in his famous periodicals, of reconciling wit, good humour and good breeding with virtuous conduct was already deliberately in Steele's mind when he wrote his first comedy. It was produced and published in 1701, and received on the stage with favour. In his next comedy, *The Tender Husband*, based on Corneille's *Menteur*, published two years afterwards, in December 1703, Steele's moral purpose was directly avowed, and the play, according to his own statement, was "darned for its pieté." *The Tender Husband*, an imitation of Molière's *Sicilien*, produced eighteen months later (in April 1705), though not less pure in tone, was more successful; in this play he gave unmistakable evidence of his happy genius for conceiving and embodying humorous types of character, putting on the stage the parents or grandparents of Squire Western, Tony Lumpkin and Lydia Languish. It was seventeen years before Steele

**STEEL, SIR R.** 865

**XXV. 28**
again tried his fortune on the stage with The Conscious Lovers, the best and most successful of his comedies, produced in December 1722.

Meanwhile the gallant captain had turned aside to another kind of literary work, in which, with the assistance of his friend Addison, he obtained a more enduring reputation. There never was a time when literary talent was so much sought after and rewarded by statesmen. Addison had already been waited on in "humble lodgings in the Haymarket," and advanced to obtain the first friend the successful dramatist was appointed to the office of gazetteer. This was in April or May 1707. It was Steele's first connexion with journalism. The periodical was at that time taking the place of the pamphlet as an instrument for working on public opinion. The *Gazette* gave little opening for the play of Steele's lively pen, his main duty, as he says, having been to "keep the paper very innocent and very insipid"; but the position made him familiar with the new field of enterprise in which his inventive mind soon discerned materials for a project of his own. The *Tatler* made its first appearance on the 12th of April 1709. It was partly a novel journal of politics and society, published three times a week. Steele's position as gazetteer furnished him with special advantages for political news, and as a popular frequenter of coffee-houses he was at no loss for social gossip. But Steele not only retailed and commented on social news, a function in which he had been anticipated by Defoe and others; he also gradually introduced into the *Tatler* as a special feature essays on general questions of manners and morality. It is not strictly true that Steele was the inventor of the English essay—there were essayists before the 18th century, notably Cowley and Temple; but he was the first to use the essay for periodical purposes, and he and Addison together developed a distinct species, to which they gave a permanent character, and in which they had many imitators. As a humbler motive for this fortunate venture Steele had the pinch of impecuniosity, due rather to excess of expenditure than to smallness of income. He had £300 a year from his gazetteership (paying a tax of £45), £100 as gentleman waiter to Prince George, £150 to the Barbadoes estates of his first wife, a widow named Margaret Stretch, and some fortune by his second wife—Mrs Mary Scurlock, the "David and Bathsheba," the "Soso in the Church," letters. But Steele lived above a considerable state after his second marriage, and before he started the *Tatler* was reduced to the necessity of borrowing. The assumed name of the editor was Isaac Bickerstaff, but Addison discovered the real author in the sixth number, and began to contribute in the eighteenth. It is only fair to Steele to state that the success of the *Tatler* was established before Addison joined him, and that Addison contributed to only forty-two of the two hundred and seventy-one numbers that had appeared when the paper was stopped, obscurely, in January 1711. Some papers satirizing Harley appeared in the *Tatler*, and Steele lost or resigned the post of gazetteer. It is possible that this political recklessness may have had something to do with the sudden end of the venture.

Only two months elapsed between the stoppage of the *Tatler* and the appearance of the *Spectator*, which was the organ of the two friends from the 1st of March 1711 till the 6th of December 1712. Addison was the chief contributor to the new venture, and the history of it belongs more to his life. Nevertheless, it is to be remarked as characteristic of the two writers that in this as in the *Tatler* Addison generally follows Steele's lead in the choice of subjects. The first suggestion of Sir Roger de Coverley was Steele's although it was Addison that filled in the outline of a good-natured country gentleman with the numerous little whimsicalities that convert Sir Roger into an amiable and exquisitely ridiculous provincial oddity. Steele had neither the fineness of touch nor the humorous malice that gives life and distinction to Addison's picture; the Sir Roger of his original hasty sketch has good sense as well as good nature, and the treatment is comparatively commonplace from a literary point of view, though unfortunately not commonplace in its charity. Steele's suggestive vivacity gave many another hint for the elaborating skill of his friend.

The *Spectator* was followed by the *Guardian*, the first number of which appeared on the 12th of March 1713. It had a much shorter career, extending to only a hundred and seventy-six numbers, of which Steele wrote eighty-two. This was the last of his numerous periodicals in which he had the material assistance of Addison. But he continued for several years to project journals, under various titles, some of them political, some some of them more ephemeral. Steele's objects, most of them very shortlived, was a warm partisan of the principles of the Revolution, as earnest in his political as in his other convictions. The *Englishman* was started in October 1733, immediately after the stoppage of the *Guardian*, to assail the policy of the Tory ministry. The *Lover*, started in February 1714, was more general in its aims; but it gave place in a month or two to the *Reader*, a direct counterpart to the *Tory Examiner*. The *Englishman* was resuscitated for another volume in 1715; and he subsequently projected in rapid succession three unsuccessful ventures—*Hecate*, *Vice Versa* and *Lady's Vane*. Three years later he started his most famous political paper the *Plebeian*, rendered memorable by the fact that it embroiled him with his old ally Addison. The subject of controversy between the two lifelong friends was Sunderland's Peareeg Bill. Steele's last venture in journalism was the *Theatre*, 1720, the immediate occasion of which was the revocation of his patent for Drury Lane. Besides these journals he wrote also several pamphlets on passing questions—on the disgrace of Marlborough in 1711, on the fortifications of Dunkirk in 1713, on the "crisis" in 1714, *An Apology for Himself and his Writings* (important biographically) in the same year, and on the South Sea mania in 1720.

The fortunes of Steele as a zealous Whig varied with the fortunes of his party. Over the Dunkirk question he waxed so hot that he threw up a pension and a commissionership of stamps, and went into parliament as member for Stockbridge to attack the ministry with voice and vote as well as with pen. But he had not sat many weeks when he was expelled from the house for the language of his pamphlet on the *Crisis*, which was censured as scurrilous. The *Apology* already mentioned was his vindication of himself on this occasion. With the accession of the *Villeins*, the *Tatler* and his fortunes changed. Honours and substantial rewards were showered upon him. He was made a justice of the peace, deputy-lieutenant of Middlesex, surveyor of the royal stables, governor of the royal company of comedians—the last a lucrative post—and was also knighted (1715). After the suppression of the Jacobite rebellion he was appointed one of the commissioners of forfeited estates, and spent some two years in Scotland in that capacity. In 1718 he obtained a patent for a plan for bringing salmon alive from Ireland. Differing from his friends in power on the question of the Peareeg Bill he was deprived of some of his offices, but when Walpole became chancellor of the exchequer in 1721 he was reinstated. With all his emoluments however the imprudent, impulsive, ostentatious and generous Steele could never get clear of financial difficulties, and he was obliged to retire from London in 1724 and live in the country. He spent his last years on his wife's estate of Llangunnor in Wales, and, his health broken down by a paralytic seizure, died at Carmarthen on the 1st of September 1729.

A selection from Steele's essays, with a prefatory memoir, has been edited by Mrs Austin Dobson (1885; revised 1896). Mr Dobson contributed a fuller biography to Mr Andrew Lang's series of *English Worthies*, in 1886. In 1889 another and more exhaustive life was published by Mr G. A. Aitken, who has also edited Steele's *plays* (1898) and the *Tatler* (1898).

(W. M.; A. D.)

STEELE, THOMAS (1688-1848), Irish politician and writer, a member of a Somerset family which settled in Ireland during the 17th century, was born on the 3rd of November 1788. He was educated at Trinity College, Dublin, and at Magdalen College, Cambridge, and succeeded to a large estate in Co. Clare. As a volunteer he fought against the Bourbons in Spain in 1823, and, returning to Ireland, he became an enthusiastic worker for Roman Catholic emigration, helping greatly to
return Daniel O'Connell to parliament for Co. Clare at the famous election of 1828. It is interesting to note that Steele himself was a Protestant. Having ruined his bricks by con-
tributing liberally to the causes in which he was interested, he died in London on the 15th of June 1848. He wrote Notes of the War in Spain (1824) and some essays on Irish
questions.

STEEL, WILLIAM (d. 1680), lord chancellor of Ireland, was a son of Richard Steele of Sandbach, Cheshire, and was educated at Calus College, Cambridge. In 1648 he was chosen recorder of London, and he was one of the four counsel appointed to conduct the case against Charles I. In January 1649, but illness prevented him from discharging this duty. However, a few days later he took part in the prosecution of the duke of Hamilton and other Royalists. Steele was M.P. for the City of London in 1654, was chief baron of the exchequer in 1655, and was made lord chancellor of Ireland in 1656. After the fall of Richard
Cromwell he was one of the five commissioners appointed in 1659 to govern Ireland. At the end of this year he returned to England; but he refused to sit on the committee of safety to which he had been named. At the Restoration he obtained the full benefits of the Act of Indemnity, but he thought and acted for a time like an honest man. However, he had returned to England before his death, which occurred in April 1680. See O. J. Burke, History of the Lord Chancellors of Ireland (Dublin, 1879).

STEELTON, a town of Germany, in the Prussian Rhine Province on the navigable Ruhr, 4 m. by rail E. of Essen, at the junction of the lines Duisburg-Dortmund and Vohwinkel-Hagen. Pop. (1905), 12,088. It contains a Gothic parish church (Roman Catholic), a high school and a Roman Catholic hospital. It has coal-mines, iron and steel works, and makes fireproof bricks. A Diet of the empire was held here in the year 938 by the emperor Otto I.

STEENEN, a borough of Dauphin county, Pennsylvania, U.S.A., on the Susquehanna river, 3 m. S.E. of Harrisburg. Pop. (1860), 9250; (1900), 12,086, of whom 2300 were foreign-born and 1508 were negroes; (1910 census), 14,246. Steelton is served by the Pennsylvania and the Philadelphia & Reading railways, and is connected with Harrisburg by electric line. The city has a public library. Steelton is in an agricultural district, but its industrial importance is due primarily to the vast steel works of the Pennsilvania Steel Company. Other manufactures include grist mills, coal-brokers, and a large coal-mill products, &c. In 1905 the total value of the factory's product was $15,745,628; the capital invested in manufacturing increased from $6,266,668 in 1900 to $8,042,853 in 1905, or 197.5%. There is a large limestone quarry within the borough limits. The municipality owns its waterworks and filtration plant. The place was laid out in 1866 under the name of Baldwin, but when it was incorporated as a borough, in 1880, the present name was adopted.

STEELYARD, MERCHANTS OF THE, Hanse merchants who settled in London in 1250 at the steelyard on the river-side, near Cosin Lane, now Ironbridge Wharf. Henry III in 1250, at the request of his brother Richard of Cornwall, king of the Romans, conferred on them important privileges, which were confirmed by Edward I. It was chiefly through their enterprise that the early trade of London was developed, and they continued to flourish till, on the complaint of the Merchant Adventurers in the reign of Edward VI., they were deprived of their privileges. Though Hamburg and Lübeck sent ambassadors to intercede for them, they were not reinstated in their monopolies, but they succeeded in maintaining a footing in London till expired by Elizabeth in 1597. Their beautiful guildhall in Thames Street, adorned with allegorical pictures by Holbein, and described by Stow, was made a naval storehouse. The land and buildings still remained the property of the Hanseatic League, and were subsequently let to merchants for business purposes. Destroyed in the Great Fire of 1666 they were rebuilt as ware-
houses, and were finally sold to the South-Eastern Railway Company in 1852 by the Hanseatic towns, Lübeck, Bremen and Hamburg. The site is now occupied by Cannon Street railway station.

See Lappenburg, Urkundliche Geschichte des hannsischen Staathofes zu London (Hamburg, 1851); Stow, Survey of London (1598); Pauli, Pictures of Old London (1851); Ehrenberg, Hamburg und England im Zeitalter der Königin Elisabeth (Jena, 1890).

STEEN, JAN HAVICKZS (1626-1679), Dutch subject-painter, was born at Leiden in 1626, the son of a brewer of the place. He studied at Utrecht under Nicolas Knupfer, a German historical painter. Dr Bode suggests that, before entering Knupfer's studio, Jan Steen took drawing lessons from Jacob de Wet in Haarlem. He bases his theory on the internal evidence of such early pictures as the "Market at The Hague," (in the collection of Franklin, Philadelphia), a copy of a painting of "The Return of the Duke of York from Austria" (now in the collection of Dr. von Göttingen-Rothschild, Berlin), "Calling for the Bride" (Six Collection, Amsterdam), and "St John's Sermon" (Dessau Castle). About the year 1644 Steen went to Haarlem, where he worked under Adrian van Ostade and under Jan van Goyen, whose daughter he married in 1649. In the previous year he had joined the painters' guild of the city. In 1667 he is said to have been a brewer at Delt; in 1669 a small debt of ten florins owing to an apothecary led to the seizure and sale of his pictures; and in 1672 he received municipal authority to open a tavern. He was said to have taken a second wife, Maria van Egmont, the widow of a bookseller in Leiden. The accounts of his life, however, are very confusing and conflicting. Some biographers have asserted that he was a drunkard and of dissolute life, but the number of his works—Van Westrum, in his Jan Steen, étude sur Part en Hollande, has catalogued nearly five hundred and Hofstede de Groot about double that number—seems sufficient in itself to disprove the charge. His later pictures bear marks of haste and are less carefully finished than those of his earlier period. He died at Leiden in 1679.

The works of Jan Steen are distinguished by correctness of drawing, admirable freedom and spirit of touch, and clearness and transparency of colouring. But their true greatness is due to their intellectual qualities. In the wide range of his subjects, and their dramatic character, he surpasses all the Dutch figure-painters, with the single exception of Rembrandt. His productions range from the stately interiors of grave and wealthy citizens to tavern scenes of jollity and debauch. He painted chemists in their laboratories, doctors at the bedside of their patients, card-parties, marriage feasts, and the festivals of St. Nicholas and Twelfth Night; even religious subjects, though in these he was less successful, were bright and sometimes especially delightful. Dealing often with the coarser side of things, his work is full of humour; he depicts the comedy of human life in a spirit of very genial toleration, but now and again there appear keenly telling touches of satire which recall a pictorial moralist such as Hogarth. Portraits from his brush are comparatively rare. The best known is the portrait of himself at the Rijksmuseum in Amsterdam.

The National Gallery contains three pictures by Jan Steen, of which the "Music Master" is the most important, and other excellent examples of his art in England are preserved in the Royal, the Bute, and the Northbrook collections, at Aspley House and Bridgewater House, and in the galleries of the Hague, Amsterdam, and Brussels. A remarkably fine example of his work, which appeared at the Royal Academy Winter Exhi-
bition in 1907, is the "Grace Before Meat."

STEENKIRK (Steenkere), a village in the Belgian province of Hainaut, on the river Senne, famous for the battle of Steenkirk (Steenkirk, Estenkerke) fought on July-23rd/August 3rd 1692 between the Allies (see GRAND ALLIANCE, WAR OF THE) under William III. of England and the French commanded by the duke of Luxembourg. Previous to the battle the French army lay facing north-west, with its right on the Senne at Steenkirk and its left towards Enghein, while the army of William III. was encamped about Hal. In accordance with the strategic methods of the time, the French, not wishing to fight after having achieved the immediate object, the capture of Namur, took up a strong position, supposing the enemy would not dare to attack it, while the Allies, who would otherwise
in all probability have done as the French marshal desired, were by the fortune of war afforded the opportunity of surprising a part of the enemy’s forces. For in the 17th century, when the objects of a war were as far as possible secured without the loss of valuable lives, and general decisive battles were in every way considered undesirable, a brilliant victory over a part, not the whole, of the enemy’s forces was the tactical idea of the best generals, and accordingly William, having completely misled the enemy by forcing a detected spy to give Luxemburg false news, set his army in motion before dawn on July 23rd/August 3rd to surprise the French right about Steenkirk. The advanced guard of infantry and pioneers, under the duke of Württemberg, deployed close to the French camps ere Luxemburg became aware of the impending blow; at this moment the main body of the army farther back was forming up after the passage of some woods. When the fight opened, Luxemburg was completely surprised, and he could do no more than hurry the nearest foot and dragoons into action as each regiment came on the scene. But the march of the Allies’ main body had been mismanaged; while Württemberg methodically cannonaded the enemy, waiting for support and for the order to advance, and the French worked with feverish energy to form a strong and well-covered line of battle at the threatened point, the Allies’ main body, which had marched in the usual order, one wing of cavalry leading, the infantry was to go forward; the cavalry at the tail of the column, was being hastily sorted out into infantry and cavalry, for the ground was only suitable for the former. A few battalions only had come up to support the advanced guard when the real attack opened (12.30). The advanced guard had already been under arms for nine hours, and the march had been over bad ground, but its attack swept the first French line before it. The English and Danes stubbornly advanced, the second and third lines of the French infantry giving ground before them, but Luxemburg was rapidly massing his whole force to crush them, and meanwhile the confusion in the British body was so great that the light cavalry of Solms, who commanded it, ordered the cavalry forward, but the mounted men, scarcely able to move over the bad roads and heavy ground, only blocked the way for the infantry. Some of the English foot, with curses upon Solms and the Dutch generals, broke out to the front, and Solms, angry and excited, thereupon refused to listen to all appeals for aid from the front. No attempt was made to engage and hold the centre and left of the French army, which hurried, regiment after regiment, to take part in the fighting at Steenkirk. William’sorders the infantry and cavalry were to advance to the other wing of cavalry, to halt, only made matters worse, and by now the advanced guard had at last been brought to a standstill. At the crisis Luxemburg had not hesitated to throw the whole of the French and Swiss guards, led by the princes of the royal house, into the fight, and as, during and after this supreme effort, more and more French troops appeared from the side of Engien, the Allies were driven back, contesting every step by weight of numbers. Those troops of the main body, foot and dragoons, which succeeded in reaching the front, served only to cover and to steady the retreat of Württemberg’s force, and, the coup having manifestly failed, William ordered the army back. The Allies retired as they had come, their rear-guard showing too stubborn a front for the French to attack. The latter were indeed in no state to pursue. Over eight thousand men out of only about fifteen thousand engaged on the side of the Allies were killed and wounded, and the losses of the French out of a much larger force were at least equal. Contemporary soldiers affirmed that Steenkirk was the hardest battle ever fought by infantry, and the battle served not only to illustrate the splendid discipline of the old professional armies, but also to give point to the reluctance of the generals of those days to fight battles in which, once the fighting spirit was unchained, the armies shot each other to pieces before either would give way.

STEEPLECHASE, a variety of horse-racing not run on the flat, but either across country or on a made course with artificial fences, water-jumps, &c. (see Horse-Racing). The origin of the sport and the name is due to matches run by owners of hunters, the goal being some prominent landmark, such as a neighbouring church steeple. There is an early record of such a match in 1752 in Ireland, when the course was 45 m., “from the Church of Buttevant to the spire of St Leger Church.” The name is sometimes used of cross-country running or of a race on a made course over hurdles and other obstacles. It is also given to an English variation of the old French game of Goose (q.v.). It is played with two dice on a board, on which is depicted a race-course with hurdles, water-jumps and other obstacles. The course is marked in 60 compartments by means of radii, and the game is won by the player whose horse makes the circuit in the fewest throws. Each player is provided with a marker, usually in the form of a jockey on horseback, which is moved forward after each throw to the space to which the number thrown entitles it.

STEER, PAUL WILSON (1860— ), English painter, was born at Birkenhead. He was trained first at the Gloucester school of art and afterwards at Paris at the Académie Julian, and in the École des Beaux Arts under Cabanel. After 1886, before which date he had shown three pictures at the Royal Academy, the remains of his work were shown at the exhibitions of the New English Art Club, of which he is a prominent member. His figure subjects and landscapes show great originality and technical skill (see Painting: Recent British). His portrait of himself is included in the collection in the Uffizi Gallery, Florence.

STEEVENS, GEORGE (1736–1800), English Shakespearian commentator, was born at Poplar on the 10th of May 1736, the son of an East India captain, afterwards a director of the company. He was educated at Eton and at King's College, Cambridge, where he resided from 1755 to 1756. Leaving Cambridge, and having been a pupil of Dr Johnson, he settled in London, and is known as "the man of Wimpole Street," his residence being near the Temple, removing later to a house on Hampstead Heath, where he collected a valuable library, rich in Elizabethan literature. He also accumulated a large collection of Hogarth prints, and his notes on the subject were incorporated in John Nicholson's Genuine Works of Hogarth. He walked from Hampstead to London every morning before seven o'clock, discussed Shakespearian questions with his friend, Isaac Reed, and, after making his daily round of the booksellers' shops, returned to Hampstead. He began his labours as a Shakespearian editor with reprints of A Midsummer Night's Dream, and in 1755 he made a start with the plays, entitled Twenty of the Plays of Shakespeare (1766). Dr Johnson was impressed by the value of this work, and suggested that Steevens should prepare a complete edition of Shakespeare. The result, known as Johnson's and Steevens's edition, was The Works of Shakespeare with the Corrections and Illustrations of Various Commentators (10 vols., 1773). Johnson's contributions to which were very slight. This early attempt at a variorum edition was revised and reprinted in 1778, and further edited in 1785 by Isaac Reed; but in 1793 Steevens, who had asserted that he was now a "dowager-editor," was persuaded by his jealousy of Malone to publish the Plays of Shakespeare, Edited by Henry膛 Malone, his friend. The result of his researches was embodied in an edition of fifteen volumes. He made changes in the text sometimes apparently with the sole object of showing how much abler he was as an emendator than Malone, but his wide knowledge of Elizabethan literature stood him in good stead, and subsequent editors have gone to his pages for parallel passages from contemporary authors. His deficiencies from the point of view of purely literary criticism are apparent from the fact that he excluded Shakespeare's sonnets and poems because, he wrote, "the strongest act of parliament that could be framed would fail to compel readers into their service." In the twenty years between 1772 and 1793 he was less harmlessly engaged in criticizing his fellows and playing malicious practical jokes on them. Dr Johnson, who was one of his staunchest friends, said he had come to live the life of an outlaw, but he was generous and to a small circle
of friends civil and kind. He was one of the foremost in exposing the Chatterton-Rowley and the Ireland forgeries. He wrote an entirely fictitious account of the Java upas tree, derived from an imaginary Dutch traveller, which imposed on Erasmus Darwin, and he hoaxed the Society of Antiquaries with the tombstone of Hardicanute, supposed to have been dug up in Kennington, but really engraved with an Anglo-Saxon inscription of his own invention. He died at Hampstead on the 22nd of January 1800. A monument to his memory by Flaxman, with an inscription commemorating his Shakespearean labours, was erected in Poplar Chapel. The sale catalogue of his valuable library was in demand at auction.

Steevens's Shakespeare was re-issued by Isaac Reed in 1807, in 21 volumes, with additional notes left by Steevens. This, which is known as the "first variorum" edition, was reprinted in 1813. Steevens's notes are also incorporated in the edition of 1821, begun by Edmund Malone and completed by James Boswell the younger.

Steevens, George Warrington (1816–1900), English journalist, was born at Sydenham, near London, on the 10th of December 1816, and was educated at the City of London School and Balliol College, Oxford, of which he was a scholar. He first began to write in undergraduate periodicals. In 1835 he putting them in a vivid and readable way. In 1880 the same year spent some time at Cambridge, editing a weekly periodical, the Cambridge Observer, and becoming a contributor to the National Observer, then edited by Mr W. E. Henley. He then married and went to London, and joined the staff of the Pall Mall Gazette, contributing also to the New Review and Blackwood's Magazine.

Some of his articles were reprinted in Monologues of the Dead. In 1826 he joined the staff of the London Daily Mail, then just started, and went on special missions for that paper, which resulted in more than one series of articles, afterwards turned into books. In this way he published The Land of the Dollar (1897), With the Conqueror Turk (1897), Egypt in 1898, and With Kittochen to Khartoum (1899). In September 1899 he went to South Africa and joined Sir George White's force in Natal as war-correspondent, being subsequently besieged in Ladysmith. He died during the siege, of enteric fever, on the 15th of January 1900. The articles he had sent home from South Africa were published posthumously in a volume called From Capetown to Ladysmith.

Steevens had a remarkable gift of seizing the salient facts and principal characteristics in anything he wished to describe, and putting them in a vivid and readable way. In the early 1880s, his interest in the life of Richard III, his early death, removed an interesting personality in English journalism.

Stefanini, Basso Naebor, or Chuwaha, a lake of East Africa, lying in 37° E., between 4° 25' and 5° 8' N., and measuring some 40 m. by 15. It is the southernmost and lowest (1880 ft.) of a series of lakes which lie in what appears to be a north-easterly continuation of the great East African rift valley, although this loses its clearly marked character in about 3° N. There is, however, a well-defined watershed extending from the hills east of Stefanie to the Hattara range. The character of the lake, which has no outlets, varies greatly according to the in. In this water brought down by its principal feeder, the Dulei, which enters at its north end, being there a fairly rapid stream 50 yds. wide and 33 ft. deep. At low water the western part of the lake is dry. The Dulei, which rises north of 6° N., is joined in about 36° 55' E., 5° 8' N. by the Galana Sagan or Galana Amara. The Sagan in times of flood receives the overflow of the next lake in the series, Chambu or Ganjule, which lies, at a height of 3460 ft., 70 m. north-north-east of Stefanie. Chambu in turn receives the waters of a larger lake—Alabi, Abaya, Pagade or Regina Margheria—to which the river Wala flows across a plain only 2 m. wide. Alabi lies 4200 ft. above the sea, is 45 m. long and 18 m. across at its greatest width. It is cut by 38° E. There are a number of islands on the lake. All the lakes of the series are shut in by high mountains, those surrounding Lake Alabi, together with the islands with which its surface is broken, being clothed with luxuriant vegetation. The chief feeder of Alabi, the Bilate, rises in about 8° N. North-east of Alabi are several smaller lakes unconnected with the more southerly system.

Lake Stefanie was discovered by Count Samuel Teleki in 1881, and has since, with other of the series, been explored by Donaldson Smith, V. Bottego, M. S. Welby, Oscar Neumann and others. J. J. Harrison in 1890 found the lake quite dried up, and two years later Count Wickenburg found water only in the northern part. An agreement of 1907 with Great Britain recognized the lake as within the Abyssinian Empire.

Steffani, Agostino (1652–1728), Italian ecclesiastic, diplomatist, and musician composer, was born at Castelcerer on the 23rd of July 1653. At a very early age he was admitted as a chorister at St Mark's, Venice. In 1667 the beauty of his voice attracted the attention of Count Tattenbach, by whom he was taken to Munich, where his education was completed at the expense of Ferdinand Maria, elector of Bavaria, who appointed him "Churfürstlicher Kammer- und Hofmusikus" and granted him a liberal salary. After receiving instruction from Johann Kaspar Kerl, in whose charge he lived, he was sent in 1673 to study in Rome, where Ettore Bernabei was his master, and among other things composed the motets, the original manuscripts of which are now in the Fitzwilliam Museum, Cambridge. On his return to Munich in 1674 he published his first work, Psalmodia vespertina, a part of which was reprinted in Martinii's Saggio di controspunto in 1674. In 1675 he was appointed court organist. The date when he was ordained priest, with the title of Abbate of Lepinga, is not precisely known. His ecclesiastical status did not prevent him from turning his attention to the stage, for which, at different periods of his life, he composed works which undoubtedly exercised a potent influence upon the dramatic music of the period. Of his first opera, Marco Aurelio, written for the carnival and produced at Munich in 1681, the only copy known to exist is a manuscript now preserved in the royal library at Buckingham Palace. It was followed by Solone in 1685, by Audacia e rispetto, proragativa d'amore and Servio Tullio in 1686, by Atilarico in 1687, and by Niobe in 1688; but of these works no trace can now be discovered. Notwithstanding the favour shown to him by the elector Maximilian Emanuel, he accepted in 1688 the appointment of Kapellmeister at the court of Hanover, where he speedily improved an acquaintance dating from 1681 with Ernest Augustus, duke of Brunswick-Lüneburg (afterwards elector of Hanover), winning also a pleasant footing with the electress Sophia Charlotte of Denmark (afterwards electress of Brandenburg), the philosopher Leibnitz, the Abbate Ortensio Mauro, and many men of letters and intelligence, and where, in 1710, he showed great kindness to Handel, who was then just entering upon his glorious career. He inaugurated a long series of triumphs in Hanover by composing, for the opening of the new opera house in 1689, an opera called Enrico il Leone, which was produced with extraordinary splendour and achieved an immense reputation. For the same theatre he composed La Lotto d'Ercule con Achilleo in 1689, La Superbia d' Alessandro in 1690, Orlando generoso in 1691, Le Rivali concordi in 1692, La Libertà contenta in 1693, I Triunf del fato y I Baccanali in 1695, and Briseide in 1696. The libretto of Briseide is by Palmieri. Those of most if not all the others are by the Abbate Mauro. The scores are preserved at Buckingham Palace, where, in company with five volumes of songs and three of duets, they form part of the collection brought to England by the elector of Hanover in 1714. But it was not only as a musician that Stefani distinguished himself in his new home. The elevation of Ernest Augustus to the electorate in 1692 led to difficulties, for the arrangement of which it was necessary that an ambassador should visit the various German courts, armed with a considerable amount of diplomatic power. The accomplished abbe was sent on this delicate mission in 1696, with the title of envoy extraordinary, and he fulfilled his difficult task so well that Pope Innocent XI., in recognition of certain privileges he had secured for the Hanoverian Catholics, consecrated him bishop of Spiga in the Spanish West Indies.
In 1698 he was sent as ambassador to Brussels, and after the death of Ernest Augustus in the same year he entered the service of the elector palatine, John William, at Düsseldorf, where he held the offices of privy councillor and protonotary of the holy see. Invested with these high honours, Steffani could scarcely continue to produce dramatic compositions in public without grievous breach of etiquette. But his genius was too important to submit to repression; and in 1709 he ingeniously avoided the difficulty by producing two new operas—Ena a Hanover and Tatuzione at Düsseldorf—in the name of his secretary and amanuensis, Gregorio Piva, whose signature is attached to the scores preserved at Buckingham Palace. Another score—that of Arminio—in the same collection, dated Düsseldorf, 1707, and evidently the work of Steffani, bears no composer's name.

Steffani did not accompany the elector George to England; but in 1724 the Academy of Antient Music in London elected him his honorary president for life; and in return for the compliment he sent the association a magnificent Statut Mater, for six voices and orchestra, and three fine madrigals. The manuscripts of these are still in existence, and the British Museum possesses a very fine Conßbìber, for three voices and orchestra, of about the same period. All these compositions were published in advance of the age in which they were written; and in his operas Steffani shows an appreciation of the demands of the stage very remarkable indeed at a period at which the musical drama was gradually approaching the character of a merely formal concert, with scenery and dresses. But for the manuscripts at Buckingham Palace these operas would be utterly unknown; but Steffani will never cease to be remembered by his beautiful chamber-duets, which, like those of his contemporary Carlo Maria Clari (1669-1745), are chieflly written in the form of cantatas for two voices, accompanied by a figured bass. The British Museum (Add. MSS. 5055 seq.) possesses more than a hundred of these charming compositions, some of which were published at Munich in 1670. Steffani visited Italy for the last time in 1727, in which year Handel, who always gratefully remembered the kindness he had received from him at Hanover, once more met him at the palace of Cardinal Ottoboni in Rome. This was the last time the two composers were destined to meet. Steffani returned soon afterwards to Hanover, and died on the 12th of February 1728 while engaged in the transaction of some diplomatic business at Frankfurt.

Steffani stands somewhat apart from contemporary Italian composers (e.g. Alessandro Scarlatti) in his mastery of instrumental forms. His opera overtures, &c., show a remarkable combination of Italian suavity with a logical conciseness of construction which is due to French influence. In vocal music he is certainly inferior to Scarlatti, and none of his famous duets, despite their charm, can compare for seriousness of intention with the Sicilian master's chamber-cantatas. His instrumental music, however, is historically important as a factor in the artistic development of Handel.

**STEFFENS, HENRIK** (1773-1845), German philosopher, scientist and poet, of Norwegian extraction, was born on the 2nd of May 1773 at Stavanger, and died in Berlin on the 17th of February 1845. At the age of fourteen he went with his parents to Copenhagen, where he studied theology and natural science. In 1796 he lectured at Kiel, and a year later went to Jena to study the natural philosophy of Schelling. He went to Freiberg in 1800, and there came under the influence of Werner. After two years he returned to Copenhagen, but his lectures excited so much disapproval that he took a professorship at Halle in 1804. During the War of Liberation he served as a volunteer in the cause of freedom, and was present at the capture of Paris. From 1811 he was professor of physics at Breslau until 1832, when he accepted an invitation to Berlin. Steffens was one of the so-called Philosophers of Nature, a friend and adherent of Schelling and Schleiermacher. More than either of these two thinkers he was acquainted with the discoveries of modern science, and was thus enabled to correct or modify the highly imaginative speculations of Schelling. He held that, throughout the scheme of nature and intellectual life, the main principle is Individualization. As organisms rise higher in the scale of development, the sharper and more distinct become their outlines, the more definite their individualities. This principle he endeavoured to deduce from his knowledge of geology, in contrast to Lorenz Oken, who developed the same theory on biological grounds. The influence of his views was considerable. Not only did Schelling and Schleiermacher modify their theories in deference to his scientific deductions, but the intellectual life of his contemporaries was considerably affected. His lectures in Copenhagen in 1802 were attended by many leading Danish thinkers, such as G. W. Schelling and Grundtvig. Schleiermacher was so much struck by his excellence that he endeavoured, unsuccessfully, to obtain for Steffens a chair in the new Berlin University in 1804, in order that his own ethical teachings should be supported in the scientific department.

His chief scientific and philosophical works are: Beiträge zur Handen Naturgeschichte der Erde (1801); Grundzüge der philosophischen Naturwissenschaft (1806); Anthropologie (1824). He wrote also Uber die Idee der Universitäten (1835), and Uber geheime Verbändungen auf Universitäten (1835); works on religious subjects, Karlbaruren des Heiligen (1619-1821); Wir ich wieder Lutherstor verraten was mir der auliche Sehnsuchts (1811); Von der falschen Theologie und dem wahren Glauben (new ed., 1851); poetical works, Die Familien Waldeh und Leith (1827); Die vier Norweger (1828); Makelum (1831), collected in 1837 under the title of Nineteen. During the last years of his life he wrote an accounts of his life and work, and left an autobiography, and after his death was published Nachglassene Schriften (1846). See Tietzen, Zur Erforschung von Steffens; Petersen, Henrik Steffens (Ger. trans., 1884); Ditilhey, Leben Schleiermachers.

**STEBELT, DANIEL** (c. 1764—1823), German pianist and composer, was born at the earliest in 1764 or 1765 in Berlin. He was indebted to the crown prince Frederick William for his musical education. Very early he is known of his artistic life before 1790, when he settled in Paris and attained to popularity as a virtuoso by means of a pianoforte sonata called La Coquette, which he composed for Queen Marie Antoinette; his dramatic opera entitled Rondo et Juliette, produced at the Théâtre Feydeau in 1793, was equally successful. In 1796 Steibelt removed to London, where his pianoforte-playing attracted great attention. In 1798 he produced his concerto (No. 3, in E flat) containing the famous "Storm Rondo"—a work that ensured his popularity. In the following year Steibelt started on a professional tour in Germany; and, after playing with some success in Hamburg, Dresden, Prague and Berlin, he arrived in May 1800 at Vienna, where he challenged Beethoven to a trial of skill. His discomfiture was complete and he retired to Paris. During the next eight years he lived alternately in that city and in London. In 1808 he was invited by the emperor Alexander to St Petersburg, succeeding Boieldieu as director of the royal opera in 1811. Here he resided in the enjoyment of a lucrative appointment until his death on the 20th of September 1823.

Besides his dramatic music, Steibelt left behind him an enormous number of compositions for the pianoforte. His playing, though brilliant, was wanting in the higher qualities which characterized that of his contemporaries, John Cramer and Muzio Clementi; but he was gifted with talent of a high order, and the reputation he enjoyed was fully deserved.

**STEIN, CHARLOTTE VON** (1742—1827), the friend of Goethe, was born at Weimar on the 25th of December 1742, the eldest daughter of the Hofmarschall (master of the ceremonies) von Schardt. She became in her sixteenth year lady-in-waiting to the duchess Anna Amalia, the accomplished mother of Duke Karl August of Saxe-Weimar. In 1764 she married Freiherr Friedrich von Stein, master of the horse to the duke, and seven children were the issue of the union. Goethe, who arrived in Weimar in 1775, was soon captivated by the charm of this lady, his senior by seven years, and the Seelenbund (union of souls) they formed exercised a furthering and enobling influence upon Goethe's life and work. For more than ten years Charlotte von Stein was his constant companion, and by her bright and genial nature and friendship she stimulated his efforts and assuaged his cares. On Goethe's return from Italy in 1788 the previous intimate
relations between them were relaxed, and the poet's connexion with Christiane Vulpiaustill further estranged them. Charlotte's jealousy and indignation at first knew no bounds, and it was only by slow degrees that friendship was restored. Charlotte von Stein was also intimate with Schiller and his wife, and numerous interesting letters from her are to be found in Charlotte von Schiller and ihre Freunde (vol. ii., 1862). She became a widow in 1793, but continued to live at Weimar until her death on 26th of January 1832. H. Düntzer, Charlotte von Stein (vols., 1874); id., Charlotte von Stein und Corinna Schröder (1876); G. H. Calvert, Charlotte von Stein (Boston and New York, 1877); and A. Sauer, Frauenbilder aus der Blütezeit der deutschen Literatur (1885); W. Bock, Charlotte von Stein (1910).

STEIN, HEINRICH FRIEDRICH KARL, BARON VON UND ZUM (1757-1831), German statesman, was born at the family estate near Nassau, on the 26th of October 1757. He was the ninth child of Karl Philipp, Freiherr von Stein; the maiden name of his mother was von Simmern. His father was a man of stern and irritable temper, which his more famous son inherited, with the addition of intellectual gifts which the father entirely lacked. The family belonged to the order of imperial knights of the Holy Roman Empire, who occupied a middle position between sovereign princes and subjects of the empire. They owned their own domains and owed allegiance only to the emperor, but had no votes for the diet. In his old age he expressed his gratitude to his parents for "the influence of their religious and truly German and knightly example." He added, "My view of the world and of human affairs I gathered as a boy and youth, in the solitude of a country life, from ancient and modern history, and in particular I was attracted by the incidents of the eventful history of England." The influence of English ideas, which was so potent a factor in the lives of Voltaire, Rousseau, Talleyrand and many others in the 18th century, was therefore potent edly operative in the early career of Stein. He does not seem to have gone to any school; but in 1773 he went with a private tutor to the university of Göttingen in Hanover, where he studied jurisprudence, but also found time to pursue his studies in English history and politics, whereby, as he wrote, "my predilection for that nation was confirmed." In 1777 he left Göttingen and proceeded to Wetzlar, the legal centre of the Holy Roman Empire, in order to see the working of its institutions and thereby prepare himself for the career of the law. Next, after a stay at each of the chief South German capitals, he settled at Regensburg (Ratisbon) in order to observe the methods of the Imperial diet. In 1779 he went to Vienna, gave himself up to the gay life of that capital, and then proceeded to Berlin early in 1780.

There his admiration for Frederick the Great, together with his distaste for the pettiness of the legal procedure at Wetzlar, impelled him to take service under the Prussian monarch. He was fortunate in gaining an appointment in the department of mines and manufactures, for at the head of this office was an able and intelligent administrator, Heinitz, who helped him to master the principles of economics and civil government. In June 1785 he was sent for a time as Prussian ambassador to the courts of Mainz, Zweibrücken and Darmstadt, but he soon felt a distaste for diplomacy, and in 1787 he was obliged to give up his taste for travel by a tour in England, where he pursued his researches into commercial and mining affairs. In November 1787 he became Kammerdirektor, i.e. director of the board of war and domains for the king's possessions west of the river Weser; and in 1796 he was appointed supreme president of all the Westphalian chambers dealing with the commerce and mines of those Prussian lands. Among the benefits which he conferred on these districts, one of the chief was the canalization of the river Ruhr, which thenceforth became an important outlet for the coal of that region. He also improved the navigation of the Weser, and kept up well the main roads committed to his care. On the 8th of June 1793 he married the countess Wilhelmine, daughter of Field Marshal Count Johann Ludwig von Wallmoden-Gimborn, a natural son of King George II. of Great Britain.

Stein's early training, together with the sternly practical bent of his own nature, made him completely impervious to the enthusiasm which the French Revolution had aroused in many minds in Germany. He disliked its methods as an interruption to the orderly development of peoples. Nevertheless he carefully noted the new sources of national strength which its reforms called forth in France.

Meanwhile Prussia, after being at war with France during the years 1792-95, came to terms with it at Basel in April 1795, and remained at peace until 1806, though Austria and South Germany continued the struggle with France for most of that interval. Prussia, however, lost rather than gained strength at this time; for Frederick William III., who succeeded the weak and sensual Frederick William II. in November 1797, was lacking in foresight, judgment and strength of character. He too often allowed public affairs to be warped by the advice of secret and irresponsible counsellors; and persisted in the policy of subservience to France inaugurated by the treaty of Basel. It was under these untoward circumstances that Stein in 1804 took office at Berlin as minister of state for trade. He soon felt constrained to protest against the effects of the Gallophil policy of the chief minister, Hauwitz, and the evil influences which clogged the administration. Little, however, came of Stein's protests, though they were urged with his usual incisiveness and energy. Prussian policy continued to progress on the path which led to the disaster at Jena (Oct. 14, 1806).

The king then offered to Stein the portfolio for foreign affairs, which the minister declined to accept on the ground of his incompetence to manage that department unless there was a complete change in the system of government. The real motive for his refusal was that he desired to see Hardenberg take that office and effect, with his own help, the necessary administrative changes. The king refused to accept Hardenberg, and, greatly irritated by Stein's unusually outspoken letters, dismissed him altogether, adding that he was a "refractory, insolent, obdurate and disobedient official." Stein now spent in retirement the months during which Napoleon completed the ruin of Prussia; but he saw Hardenberg called to office in April 1807 and important reforms effected in the cabinet system. During the negotiations at Tilsit, Napoleon refused to act with Hardenberg, who thereupon retired. Strange to say, the French emperor at that time suggested Stein as a possible successor. No other strong man was at hand who could save the ship of state; and on the 4th of October 1807 Frederick William, utterly depressed by the terrible terms of the treaty of Tilsit, called Stein to office and entrusted him with very wide powers.

Stein was now for a time virtually dictator of the reduced and nearly bankrupt Prussian state. The circumstances of the time and his own convictions, gained from study and experience, led him to press on drastic reforms in a way which could not otherwise have been followed. First came the Edict of Emancipation, issued at Memel on the 9th of October 1807, which abolished the institution of serfdom throughout Prussia from the 8th of October 1810. All distinctions affecting the tenure of land (noble land, peasants' land, &c.) were also swept away, and the principle of free trade in land was established forthwith. The king was so anxious to effect a complete break with all the remaining traditions and principles of the old regime that he abrogated all class distinctions respecting occupations and callings of any and every kind, thus striking another blow at the caste system which had been so rigorous in Prussia. Stein's next step was to strengthen the cabinet by wise changes, too complicated to be enumerated here. He also furthered the progress of the military reforms which are connected more especially with the name of Scharnhorst (@w.); they refashioned the Prussian army on modern lines, with a reserve system. Stein's efforts were directed more towards civil affairs; and in this sphere he was able to
issue a measure of municipal reform (Nov. 19, 1808) which granted local self-government on enlightened yet practical lines to all Prussian towns, and even to all villages possessing more than 800 inhabitants.

Shortly afterwards the reformer had to flee from Prussia. In August 1808 the French agents, who swarmed throughout the land, had seized one of his letters, in which he spoke of his hope that Germany would soon be ready for a national rising like that of Spain. On the 10th of September Napoleon gave orders that Stein's property in the new kingdom of Westphalia should be confiscated, and he likewise put pressure on Frederick William to dismiss him. The king evaded compliance; but the French emperor, on entering Madrid in triumph, declared (December 16) le nommé Stein to be an enemy of the French and the Confederation of the Rhine; and ordered the confiscation of all his property in the Confederation. Stein saw that his life was in danger and fled from Berlin (Jan. 5, 1809). Thanks to the help of his former colleague, Count Friedrich Wilhelm von Reden, who gave him an asylum in his castle in the Riesengebirge, he succeeded in crossing the frontier into Bohemia.

For three years he lived in the Austrian Empire, generally at Brünn; but in May 1812 he received an invitation from the emperor Alexander I. to visit St Petersburg, seeing that Austria was certain to range herself on the side of France in the forthcoming Franco-Russian War. At the crisis of that struggle Stein may have been one of the influences which kept the tsar determined never to treat with Napoleon. When the miserable remains of the Grand Army reeled back into Prussia at the close of the year, Stein urged the Russian emperor to go on and free Europe from the French domination.

Events now brought Stein rapidly to the front. On the 30th of December 1812 the Russian general Yorck signed at Tauroggen a convention with the Russian general Diebich for neutralization of the Prussian corps at and near Tilsit, and for the free passage of the Russians through that part of the king's dominions. The Russian emperor thereupon requested Stein to act as provisional administrator of the provinces of East and West Prussia. In that capacity he convened an assembly of representatives of the local estates, which on the 3rd of February 1813 ordered the establishment of a militia (Landwehr), a militia reserve and a final levy (Landsturm). The energy which Stein infused into all he contributed to the organization was such a brilliant and important decision, which pushed on the king's government to more decided action than at that time seemed possible. Stein now went to Breslau, whether the king of Prussia had proceeded; but the annoyance which Frederick William felt at his irregular action lessened his influence. The treaty of Kalisch between Russia and Prussia cannot be claimed as due to his actions, which were reprehended in court circles as those of a fanatic. At that time the great patriot fell ill of a fever and complained of total neglect by the king and court. He recovered, however, in time to take part in the drafting of a Russo-Prussian convention (March 19, 1813) respecting the administration of the districts which should be delivered from French occupation. During the varying phases of the campaign of 1813 Stein continued to urge the need of war a outrance against Napoleon. The Allies, after the entry of England and Austria into the coalition, conferred on Stein the important duties of superintending the administration of the liberated territories. After the great battle of Leipzig (Oct. 16-19, 1813) Stein entered that city the day after its occupation by the Allies and thus expressed his feelings on the fall of Napoleon's dominion. "There it lies, then, the ruin of which I contributed to the building, the blood and tears of so many millions reared by an insane and accursed tyranny. From one end of Germany to the other we may venture to say aloud that Napoleon is a villain and the enemy of the human race." He now desired to see Germany reconstituted as a nation, in which union should be at once strong for purposes of defence and founded on constitutional principles. His statesmanlike projects were foiled, partly by the short-sightedness of German rulers and statesmen, but also by the craft whereby the Austrian statesman Metternich (p. 381) gained the alliance of the rulers of south and central Germany for his empire, on the understanding that they were to retain their old governing power unimpaired. Thus it was in vain that Stein, during the congresses of Vienna, pressed for an effective union of the German people. Austria and the secondary German states resisted all proposals in this direction; and Stein blamed the Prussian chancellor Hardenberg for betraying an indefiniteness of purpose which probably resulted from the same unfortunate defect in Frederick William as in Prussia. Stein in the encouragement of churches and the statesmen at that time to have Saxony wholly absorbed in their kingdom. In that, as in other matters, he was doomed to disappointment. On the 24th of May 1815 he sent to his patron, the emperor Alexander, a detailed criticism of the federal arrangements proposed for Germany, showing that they fulfilled not one of the requirements for real union and constitutional government which had been so loudly demanded by the German people during the struggle of 1813.

The remainder of Stein's career must be briefly dismissed. He passed into retirement after the congress of Vienna, and so with pain and disgust the expungement of the representative system of government which Frederick William had promised to Prussia in May 1815. He refused to act as Prussian representative at the Frankfort diet, which he regarded as a mere travesty of the central federal institution which he had hoped to see. By indirect means he did what he could to check the violence of political reaction, but he was conscious of his weakness, and that fact embittered the later days of a man who was intensely proud and self-assertive. His chief interest was in the study of history, and in 1818-1820 he worked hard to establish the society for the encouragement of historical research and the publication of the Monumenta Germaniae historica, of which his future biographer, Pertz, became the director. Stein died on the 26th of June 1831. He left three daughters.

In some respects there has been a tendency to magnify the achievements of Stein. As usually happens with men of great force of character, the work of less noteworthy individuals is ascribed to the one commanding personality. This was so even during the fourteen months of phenomenal activity, October 1807 to December 1808. More painstaking research has shown that the credit for originating many of the fundamental reforms of the whole kingdom must be shared with Heinrich Theodor von Schön and many others.1 It is now recognized that the king himself at that time rendered unsuspectingly large services to the cause of reform. A popular legend named him as the founder of the Jugendbund, an institution which he always distrusted. But when this is granted, it still remains true that Stein's enlightenment, insight into the needs of the time, and almost superhuman energy, imparted to the reform movement a momentum which ensured its triumph at the most critical period which Prussia or any great European state passed through in the 19th century. All his contemporaries were impressed, or even awed by the determination and intellectual power of this remarkable man. His conversation had the effect of calling out all the powers of his interlocutors. "A conversation with him (wrote Varnhagen von Ense) was a continual contest, a continual danger." This mental pugnacity sometimes degenerated into rudeness; and on several occasions his impetuosity led him to take false steps. Still, when we take into consideration the magnitude of his achievements; when we recollect that in 1809 he intended his municipal reform to serve as the foundation for free institutions for the Prussian provinces; and thereafter for the whole kingdom; when we realize the grandeur of his schemes in 1813-1815 for the union of the German people in a federal

1 Thus Schön's memorandum on the abolition of serfdom was the basis of the law of emanicipation; and Stein's Politisches Testament was also based on a draft by Schön. Schön was born in 1773, entered the Prussian civil service in 1793, and subsequently held various ministerial appointments. He died in 1856. The share claimed by him in Stein's reforms has been the subject of some controversy.
STEINER—STEINMETZ

system which would combine strength with political liberty—en we shall find it difficult to overrate the importance of his contribution to the solution of the most complex political problem of modern times.

The chief authority on Steiner is the biography by G. H. Pertz (6 vols., Cambridge, 1879), which contains a full bibliography. These works are corrected at a few points by Max Lehmann's "P. von Steiner, ein Puppl" (2 vols., Leipzig, 1882); Denkwürdigkeiten des Staatshistorikers Fürsten von Hardenberg, ed. by L. von Ranke (5 vols., Leipzig, 1877); Vornahmen von Encke, Denkwürdigkeiten (6 vols., Mannheim, 1837-1842); English ed., London, 1840; Abraham, Aktenstücke über die preussischen Reformen 1807—1815 (Leipzig, 1853); M. Philippson, Geschichte des preussischen Staates, 1780—1823 (2 vols., Leipzig, 1890); M. Lehmann, Knesebeck and Schön (Leipzig, 1875); J. F. Hassel, Geschichte der preussischen Politik, 1807—1819 (Leipzig, 1881); the Vicomte Jean d'Ussel, Études sur l'année 1813; la déjéction de la Prusse (Paris, 1891) (J. H. R.).

STEINER, JAKOB (1796—1863), Swiss mathematician, was born on the 18th of March 1796 at the village of Utzendorf (canton Bern). At eighteen he became a pupil of Heinrich Pestalozzi, and afterwards studied at Heidelberg. Thence he went to Berlin, living a livelihood there, as in Heidelberg, by giving private lessons. Here he became acquainted with A. L. Crelle, who imitated his methods; by the help of Abel, then also staying at Berlin, founded his famous Journal (1826). After Steiner's publication (1832) of his Systematische Entwicklungen he received, through Jacobi's exertions, who was then professor at Königsberg, an honorary degree of that university; and through the influence of G. J. Jacobi and of the brothers Alexander and Wilhelm von Humboldt a new chair of geometry was founded for him at Berlin (1834). This he occupied till his death, which took place in Bern on the 1st of April 1863.

Steiner's mathematical work was confined to geometry. This he treated synthetically, to the total exclusion of analysis, which he hated, and he is said to have considered it a disgrace to synthetic geometry if equal or higher results were obtained by analytical methods. In his own field he surpassed all his contemporaries. His investigations are distinguished by their great generality, by the fertility of his resources, and by such a rigour in his proofs that he has been considered the greatest geometrical genius since the time of Apollonius.

In his Systematische Entwicklung der Abhängigkeit geometrischer Gestalten von einander he laid the foundation of modern synthetic geometry. He introduces what are now called the synthetic forms (the row, flat pencil, &c.), and establishes between these elements a one-a-one correspondence, or, as he calls it, makes them projective. He next gives by aid of these projective rows and pencils a new generation of conics and ruled quadric surfaces, "which leads quicker and more directly than former methods into the inner nature of conics and reveals to us the organic connexion of their innumerable properties and mysteries." In this work also, which unfortunately only one volume appeared instead of the projected five, we see for the first time the principle of duality introduced from the very beginning as an immediate outcome of the synthetic properties of the line and plane.

In a second little volume, Die geometrischen Constructionen ausgeführt mittelst der geraden Linie und eines festen Kreises (1833), republished in 1853 by Ottingen, he shows, what had been already suggested by L. V. Poinsot, how all the problems of the second order can be solved by aid of the straight-edge alone without the use of compasses, as soon as one circle is given on the drawing-paper.

He also wrote Vorlesungen über synthetische Geometrie, published posthumously at Leipzig by C. F. Geiser and H. Schroeter in 1867; a third edition by R. Stirn was published in 1887—1868.

The rest of Steiner's writings are found in numerous papers mostly published, when first issued, in the journal which contains his first four papers. The most important are those relating to algebraical curves and surfaces, especially the short paper Algébre et géométrie (1834). This contains many results, and there is no indication of the method by which they were obtained, so that, according to L. O. Hesse, "they are, like P. Fermat's theorems, riddles to the present and future generations. Eminently analysis succeeded in proving some of the theorems, but it was reserved to L. Cremona to prove them all, and that by a uniform synthetic method, in his book on algebraical curves.

The most important relation of Steiner's work to modern research is the solution of problems which analytically require the calculation of variation, but which at the time altogether surpassed the powers of that calculus. Connected with this is the paper Von Krämmungsschwerpunkte ebener Curven, which contains numerous properties of pedals and rosettes, especially of their areas.

Steiner's papers were collected and published in two volumes (Geometrische Werke, i, 1862; ii, 1895). See C. F. Geiser's pamphlet Zur Erinnerung an J. Steiner (Zurich, 1874).

STEINMETZ, KARL FRIEDRICH VON (1796—1877), Prussian general field-marshal, was born at Eisenach on the 27th of December 1796 and educated at the cadet school of Stolp in Pomerania from 1807 to 1811, in the midst of the misery and poverty caused by the French occupation. At the outbreak of the War of Liberation he and his elder brother made their way through the French posts to Breslau, where, in spite of their poverty, they were at once appointed to the army, the elder as ensign on probation, the younger to the substantive rank of second lieutenant. After a vain attempt to obtain a transfer to the Blütcher Hussars, for which regiment he had conceived an intense boyish admiration when it was quartered at Stolp, he was ordered to report himself to York, who treated him and the other officers sent from Breslau with coldness, until young Steinermetz asked "when he was to return to the king who had sent him?" The brothers took part in the hardest fighting of the campaign of 1813, the elder being killed at Leipzig and the younger being wounded. On the Rhine he utilized in improving his military and general education. In the battles in France he won the second class of the Iron Cross. After the peace he entered Paris but once, fearing to infringe upon the ten ducats that he saved monthly from his pay to send to his mother. For the same reason he held aloof from the pleasures of his more fortunate comrades. His avoidance of youthful excesses enabled him to overcome his earlier bad health and to acquire a physical vigour which he kept to the end of his long career as a soldier. His character as well as his physique was strengthened by his austerely military way of life, but his temper was naturally embittered by the circumstances which imposed this self-restraint. His poverty and want of influence were the more obvious as he was, shortly after the wars, assigned to the 2nd Foot Guards, stationed in Berlin. He rigorously devoted himself to study and to the routine duties of his profession. From 1820 to 1824 he studied with distinction at the General War Academy, and was at the end of the course appointed to the topographical section of the general staff. General von Müffling reported of him that he was arrogant and that he presented encouragement—which he probably regarded as a rebuke—but that his ability but small. He was quartered for a distance of 60 miles from his garrison, and Steinermetz often spoke in later days of the thorough training he received at his hands. After this from about 1830 his regimental work and his promotion went on without incident for several years in various garrisons, until in 1839 he became major and battalion commander. In this position he had many official differences with his immediate superiors, for he urged a strenuous war training for the troops, in season and out of season, too vigorously for his more conservative comrades, but off parade his relations with all, thanks chiefly to the grace of his wife, were of the most pleasant character. In 1848 he was sent home to invade France, and in the short but hard battle during the disturbances in Berlin, but was not engaged, and soon found more active employment in the Danish
War. At Schleswig he so distinguished himself that Wrangel, the commander-in-chief, told him that he "decided the battle." He distinguished himself again at Düppel, and Prince William himself decorated him with the order pour le mérite on parade. For his campaign journals and letters see supplement to Militär Wochenschrift 1877.

On returning from the concluding campaign of 1870, the difficult command of the troops at Brandenburg during the sitting of a democratic popular convention at that place, and after this with the control of some troops that were known to be affected by the prevalent spirit of revolution. At the time of the Omlütz-Bronnzell incident of 1850 he was employed as military governor of Cassel, and in 1851, becoming colonel commandant of the cadet school of Berlin, he at once set about the reformation of the prevailing system of instruction, the defects of which he had openly condemned as early as 1850. Though more than fifty years of age, he now learned Latin and English in order to become a more competent instructor. In 1854, after forty-one years of active service, he was promoted major-general. At Magdeburg, as at Berlin, his reforming zeal made him many enemies, and in October of this year he sustained a loss which almost unhinged his mind in the death of his youngest and only surviving child, a girl of twenty-six. From Magdeburg he was removed to the command of a guard brigade at Berlin (1857), and thence almost immediately to a divisional command in the I. Corps. Early in 1858 he was promoted lieutenant-general, and for the five years that he held this command he devoted himself particularly to acquiring knowledge of the cavalry art. About 1863, learning that von Bonin, his senior by date, but his junior in length of service, was about to be appointed to command the I. Corps, he meditated retirement, but the authorities at the same time as they appointed Bonin made Steinmetz commander of the II. Corps, and shortly afterwards, when the crown prince of Prussia took over this post, commander of the V. Corps at Posen. Shortly after this his wife died. He was promoted general of infantry in 1864, and led the V. Corps to the war against Austria in 1866. This was the chance of his life, and faithful and resolute leadership was displayed in his three battles, won on three successive days, of Nachod, Skalitz and Schweinschädel (see Seven Weeks' War), and opened the way through the mountains in spite of the defeat of Steinmetz's rival Bonin at Trautenau. In 1867, in his loneliness, the 'Lion of Nachod," as he was popularly called, contracted a second marriage with Elise von Krosigk (who after his death married Count Brühl). He was now, for the first time in his life, a fairly wealthy man, having been awarded a money grant for his brilliant services in 1866. About this time he was elected a member of the North German Confederation parliament.

At the outbreak of the war of 1870 Steinmetz was appointed to command one of the three armies assembled on the Rhine, the others being led by Prince Frederick Charles and the crown prince. It was not long before serious differences arose between Steinmetz and Prince Frederick Charles. The former, embittered by a lifelong struggle against the influences of wealth and position, and perhaps somewhat grasè by his successes in 1866, considered an order to clear the roads for the prince's army as an attempt to crowd a humbler comrade out of the fighting line, and various incidents added day by day to his growing resentment until at last on the field of Gravelotte (see Meurz and Franco-German War for an account of these quarrels) he lost his temper and wasted his troops. After this there was no alternative but to relieve him of the command of the I. Army and to send him home as governor-general of the V. and VI. Army Corps districts. In April 1871 he was retired at his own request, but his great services were not forgotten when victory had softened animosities, and he was promoted general field-marshall, given a pension of 2000 thalers and made a member of the upper chamber.

In the spirit of loyalty which had guided his whole career as a soldier he made no attempt to justify his conduct, nor to explain the reasons why he refused to accept the history or against unofficial attacks. His life in retirement was quiet and happy, and he retained his bodily health to the last. He died at Bad Landeck on the 2nd of August 1877. The 37th Fusiliers of the German army bear his name as part of their regimental title.

See supplement of Militär Wochenschrift 1877 and 1878.

STEINSCHNEIDER, Moritz (1816-1907), Jewish bibliographer, was born in Moravia in 1816. He was the most accomplished bibliographer in the realm of Hebrew literature. His greatest work was his Catalogue of the Hebrew Collection of the Bodleian Library, Oxford, (1852-1860). In this masterly work he settled many questions as to the locality, date and authorship of early printed books, and provided a vast mass of bibliographical materials. His Jewish Literature (published in German in 1890, in English in 1895) is a complete survey of its subject. Steinmetz prepared many other catalogues (Leiden, Munich, Hamburg and Berlin). He wrote much on Arabic literature, and was the author of bibliographies on a great variety of subjects. Among them may be named bibliographies of Jewish mathematicians and travellers. His most extensive work after his Bodleian Catalogue was his treatise on Hebrew translations in the middle ages (Die hebräischen Übersetzungen des Mittelalters, 2 vols., 1893). Much of his work appeared in his periodical Hebräische Bibliothek (1855-1902). He died in Berlin in 1907. (L.A.)

STEINTHAL, Heymann (1832-1899), German physiologist and philologist, was born at Größzig in Anhalt on the 16th of May 1832. He read philosophy and philology at the university of Berlin, where he graduated in 1850. From 1852 to 1855 he studied Chinese (language and literature) in Paris, and in 1863 became extraordinary professor of philology at Berlin. In his philosophic theories he sympathized with Moritz Lazarus, in conjunction with whom he founded in 1850 the Zeitschrift für Völkerpsychologie und Sprachwissenschaft. Like Lazarus and the Herbartian school in general, he attached supreme value to psychology and especially to the philosophy of society, the study of which, combined with comparative philology, he believed could give trustworthy results. In philology he was an admirer and disciple of Wilhelm von Humboldt, on whose methods he wrote several books.

His principal works are Der Ursprung der Sprache im Zusammenhang mit den letzten Fragen alles Wissens (1851; 4th ed., 1888); Klassifikation der Sprachen (1859); Charakteristik der hauptsächlichen Typen des Sprachbannes (1860); Die Entstehung der Schrift (1852); Grammatik, Logik, Psychologie, ihre Prinzipien, etc. (1855); Geschichte der Sprachwissenschaft bei den Griechen und Römern (1861 ed., 1889 ed.); Die Mandel-NegerSprachen, psychologisch und phonetisch betrachtet (1867); Abriss der Sprachwissenschaft (2nd ed., 1881); Allgemeine Ethik (1880); Zu Bibel und Religionsphilosophie (1890 and 1895). His books on von Humboldt appeared in 1848, 1864 and 1867, and in 1864 he published an edition of his works.

STELE, the Greek name (στήλη) for a pillar or vertical slab of stone or marble, sometimes decorated with bas-reliefs and bearing inscriptions, and generally terminated with a cresting (καλύμμα) enriched with the anthemion plant. In later times the stеле was crowned with a small pediment. The Way of the Tombs at Athens was lined with stelæ, some of them in memory of prominent citizens.

STELLENBOSCH, a town of the Cape province, South Africa, 31 m. by rail E. of Cape Town. Pop. (1904), 7573, of whom 1497 were white. It lies 360 ft. above the sea in a pleasant upland valley on the Atlantic slope of the coast range, and is, next to the capital, the oldest settlement in the province, having been founded by order of Commandant Simon van der Stell in 1681 and named after him and his wife, whose maiden name was Bosch. The streets are lined with magnificent oaks, while many of the houses with heavy, thatched gables date from the 17th century. Stellenbosch is the headquarters of the Cape branch of the Dutch Reformed Church, and is also an important educational centre. The chief buildings, besides the churches, are the Dutch theological seminary, Victoria College, Bloemhof girls' school, agricultural college and school of mines, laboratoire and school of science and the S.A. conservatorium of music. The surrounding district is largely devoted to viticulture and
fruit-growing. The vineyards have been replanted with American stocks. The Stellenbosch valley is closed in by ranges of hills beyond which, eastward, lies Frenchhoek valley, with a village of the same name. This district was the headquarters of the Huguenot refugees who settled in South Africa at the close of the 17th century.

In the early days of the Boer War (1899–1902) Stellenbosch was one of the British military bases, and was used as a "remount" camp; and in consequence of officers who had not distinguished themselves at the front being sent back to it, the expression "to be Stellenbosched" came into use; so much so, that in similar cases officers were spoken of as "Stellenbosched," even if they were sent to some other place. The remount depot is maintained; horses and mules thrive here.

STEM (O. Eng. stofn, stemm, cf. Du. stam, Ger. Stamm, &c., probably related to "staff"), in popular language the stalk of a plant, the trunk of a tree (for the technical use of the term in botany see below). There are many transferred uses of the word, such as for the slender structure which joins the foot or base of a vase or goblet to the bowl, a stock or branch of a family, or, in philology, a derivative from a root, the unchanged part in a series of inflected forms. The stem of a ship is the prow, properly a curved piece of timber or metal to which the two sides are attached at its foremost end. This was a Scandinavian use early adopted in English; the word meant simply post, and custom alone restricted it to the bows rather than to the stern; in Danish the distinction is made between frøm stam and bak stam and also in German, Vorder-stemmen Hinter-stemmen.

In botany a stem may be defined as an axis bearing leaves. The stem with its leaves is known as the shoot. Structurally it differs from a root in having no development of cells forming a cap over the growing-point. "Under the term cauline (stem-structure) are included all those parts of a plant morphologically equivalent in bearing leaves. The stem generally ascends, seeking air and light, and has therefore been termed the ascending axis. Stems have usually considerable firmness and solidity, but sometimes they are weak, and either lie prostrate on the ground, thus becoming procumbent, or climb on plants and rocks by means of rootlets, like the ivy, being then called scandent, or twist round other plants in a spiral manner like woodbine, when they are twining. Twining plants turn either from right to left, as the French bean, convolvulus, and others, or from left to right, as honeysuckle, twining polygonum, hop and black bryony (Tamus). In other cases climbing plants are supported by tendrils, as in vine, bryony, passion-flower, or by the tendril-like leaf-stalks, as in clematis and Tropaeolum. In warm climates climbing plants (lianas) often form thick woody stems, while in temperate regions they are generally herbaceous. Some stems are developed more in diameter than in height, and present a peculiar shortened and thickened aspect, as Tussilagino or toroise-plant, cyclamen, Melocactus, Echinocactus and other Cactaceae; while in many orchids (fig. 1) the stem assumes an oval or rounded form, and is called a pseudobulb.

Names are given to plants according to the nature and duration of their stems. Herbs, or herbaceous plants, have stems which die down annually. In some of them the whole plant perishes after flowering; in others, the lower part of the stem forming the crown of the root remains, bearing buds from which the stem arises next season. In biennials and perennials the stem formed after two years, while in perennial herbs the crown is capable of producing stems for many years, or new annual products are repeatedly added many times, if not indefinitely, to the old stems. The short permanent stem of herbaceous plants is covered partially or completely by the soil, so as to protect the buds. Plants producing permanent woody stems are called trees and shrubs. The latter produce branches from or near the ground; while the former have conspicuous trunks. Shrubby plants of small stature are called under-shrubs or bushes. The limits between these different kinds of stem are not always well defined; and there are some plants occupying an intermediate position between shrubs and trees, to which the name of arboreoscens shrubs is occasionally given.

The stem is not always conspicuous. Plants with a distinct stem are cauline; those in which it is inconspicuous are acaulescent, as the primrose, cowslip and dandelion. A similar term is given in ordinary language to plants whose stems are buried in the soil, such as cyclamen or sowbread. Some plants however, are acaulescent stems, and consist only of expansions of cellular tissue representing stem and leaf, called a thallus, and hence are denominated Thallogens, or Thallophytes.

The first rudiment of the young shoot of the embryo appears from the seed after the radicle (young root) has protruded. It is termed the plumule (fig. 2), and differs from the radicle in the absence of a root-cap and in its tendency to ascend. The apical growing-point of the terminal bud of the plant, and by its development the stem increases in height; projections appear at regular intervals, which grow into the rudimentary leaves, and in addition there is a provision for the production of lateral buds, which develop into lateral stems. These are more or less resembling the parent stem, and by these the branching of the plant is completely determined (fig. 3). These buds are found in the axil of previously-formed leaves; or, in other words, in the angle formed between the stem and the leaf. They are hence called axillary. They are produced like the leaves from the outer portion of the stem (exogenous), and at first entirely of cellular tissue, but in the process of growth vascular bundles are formed in them continuous with those of the stem, and ultimately branches are produced, which in every respect resemble the axis whence the buds first sprang. In the Lyco-ropod, leaves emerge from the lateral buds branching takes place by forking of the growing-point, the main axis being thus replaced by two equivalent axes (fig. 4); in most cases the new axes develop unequally, the weaker one coming pushed aside and appearing later as a lateral branch of the stronger. The place of origin of the leaf is called a node; the intervals between nodes are called internodes. The stem, although it has a tendency to rise upwards when first developed, in many instances becomes prostrate, and either lies along the ground partially covered by the soil, or runs completely underneath its surface, giving off roots from one side and buds from the other. Some stems are therefore subterranean, and are distinguished from roots by the provision made for regular leaf-buds.

Growth in length of the stem is due to elongation of the internodes; the zone of most rapid growth is at some distance below the apex; below this the rate of growth gradually diminishes until the portion of the stem where it is developed in a biennial plant is length no longer takes place. In some cases, as in the stems of grasses, growth in length persists for a longer time in a small region at the base of the internodes; this is known as intercalary growth. In the dwarf or short shoots, such as those of the larch, the internodes do not elongate and the leaves remain close together. Lateral buds give rise to branches, from which others, called branchlets or twigs, arise. The terminal bud, after producing leaves, sometimes dies at the end of one season, and the whole plant, as in annuals, perishes: or part of the axis is persistent, and remains for two or more years, each of the leaves before its decay producing a bud in its axil. This bud
continues the growth in spring. In ordinary trees, in which there is
provision made for the formation of numerous lateral buds, any
injury done to a few branches is easily repaired; but in palms, which only form
terminal buds, and have no provision for a lateral formation of them, an
injury inflicted on the terminal bud is more likely to have a prejudicial
effect on the development of a peculiar plant. In the trees of temperate and cold
climates the buds which are developed during one season lie dormant during
the winter, ready to burst out under the genial warmth of spring. They
are generally protected by ex-
ternal modified leaves in the form of
scales, which frequently exhibit a
firmer and coarser texture than the leaves themselves. They serve a
temporary purpose, and usually fall
off sooner or later, after the leaves are expanded. The bud is often pro-
duced by a coating of resinous
matter, as in the horse-chestnut and
dactyl poplar, or by a thick downy
covering, as in the willow. Linnaeus
called leaf-buds _hibernacula_, or the
winter quarters of the young branch.
In some plants, as in the plane, the
buds destined to live through the
winter are not perfectly developed
and are surrounded by a sort of a
bark, by the base of the petiole as not to be visible until the leaf has fallen
off. These are said to be _intropetal_.
In the bud of a common tree, as the sycamore (fig. 5), there is seen the
diastox or scar left by the leaf of the previous year, and then the

Fischer.)

scales _e, e_, arranged in alternate pairs and overlying each other in
what is called an _imbricated_ manner. On making a transverse
section of the bud (fig. 6), the overlying scales _e, e, e, e_ are distinctly seen
surrounding the leaves _f_, which are plaited or folded round the axis or growing-point. In plants which are formed and"
Buds sometimes become extra-axillary in consequence of the non-
appearance or abortion of one or more leaves, or on account of the

adhesion of the young branch to the parent stem. In place of one bud there are occasionally several accessory ones produced in the axil, giving origin to numerous branches. By the union of several such buds branches are produced having a thickened or flattened appearance, as seen in the fir, ash and other trees. In some cases, however, these fasicated branches are owing to the abnormal development of a single bud.

The typical form of stems is rounded. They are sometimes compressed or flattened laterally (fig. 9), while at other times they are angular. Various terms are applied to the forms of stems, as cylindrical or terete, quadrangular or square, jointed or articulated, &c. The following are some of the more important modifications of stems: The crown of the root is a shortened stem, often partially underground, which remains in some plants after the leaves, branches and flower-stalks have withered. In this case the internodes are very short, and the nodes are crowded together, so that the plant appears to be stem-

less. It is seen in perennial plants, the leaves of which die down to the ground annually. A rhizome or root-stock (fig. 10) is a horizontal stem usually sending out numerous roots and leaf-buds from its upper surface. It occurs in ferns, iris, Hedychium, Acorus or sweet flag, ginger, waterlily, many species of

A

tuber
constituting thin brown scales round about, in the axil of the middle leaf grows another, at the apical point of its parent corn (k), but it does not attain a great size; new leaves, which remain small, but from which and is produced, in the upper the flowering stem rises up and bears flowers, whilst in the axil of one of its middle leaves a new bud-corn appears, which becomes flowering autumn, and emits young leaves, flowering stem, and a new bud-corn, and thus the cycle goes on, and each time new corns formed from the old corns may be produced either laterally, as in Colchicum autumnale, or terminally, as in crocus and gladiolus, in which there is another form of underground stem or bud. The axis in this case is much shortened, and the internodes are hardly developed. The bases of the leaves rising from the stem are quite close together, and become succulent and enclose the axis. In the lily the thick narrow leaves are arranged separately in rows, and the bulb is called scaly; while in the lily, onion, squill and tulip the scales are broad, and enclose each other. In mechanism, the outer ones being thin and membranous, and the bulb is tunicated. In the axils of these fleshy scales new leaves arise, forming the bulb, and some plants, which apparently the same bulb continues to flower for many years, as in the hyacinth and tulip; at other times the young bulblets are detached, and form separate plants. In the axil of the leaves of Lilium bulbiferum, Dentaria bulbifera, and some other plants, small conical or rounded bodies are produced, called bulblets or bulbils (fig. 14, b). They resemble bulbs in their aspect, and consist of a small number of thickened scales enclosing a growing-point. These scales are frequently united closely together, so as to form a solid mass; bulbils are therefore transformed leaf-buds, which are easily detached, and are capable of producing young plants when placed in favourable circumstances. The scales in bulbs vary in number. In Garage there is only one scale; in the tulip and Fritillaria imperialis they vary from two to five, while in lilies and narcissus there are a great number of scales. In the tulip a bud is formed in the axil of an outer scale, and this gives rise to a new bulb. In the axil of a bulb, at the side of which the former bulb is attached in a withered state. Adventitious shoots are those which arise elsewhere than in the normal predetermined place, as from old stems, or roots. Such shoots are frequent on the roots of elm, poplar, pine and other trees. Occasionally adventitious buds are produced on the edges of leaves, as in Bryophyllum calycinum (fig. 15), Malaxis pulchella, and various species of Hypoxis; and on the surface of leaves, as in Ornithogalum thyrsoides. These are capable of forming independent plants. Similar buds are also made to appear on the leaves of Begonia, Gomera, Gloriosa and Achimenes, by bruising various parts of them, and placing them in moist soil; this is the method often pursued by gardeners in their propagation. The ipémacuana plant has been propagated by means of leaves inserted in the soil. In this case the lower end of the leaf the manner of a corn, and from it roots are produced, and ultimately a bud and young plant.

STENDAL, MAGNUS GUSTAFFSSON, COUNT (1664-1717), Swedish soldier, was educated at Upsala and at Paris, chose the military profession, and spent some years in the service of the United Provinces. Returning to Sweden he entered the army, and in 1688 became major. He served with the Swedes in the Low Countries and on the Rhine, distinguishing himself for skill and courage at Fleurs. During the War of the Grand Alliance he was stationed not only on the field but also as a confidential agent in diplomatic missions. Soon afterwards as colonel of the Dalecarlian regiment he led it in the astonishing victory of Narva. He distinguished himself still more at Dünamünde, Klissow and Cracow. In 1703 he fought the successful battle of Pultusk, and three years later, having reached the rank of general of infantry, was made governor-general of the province of Scania, which he delivered from the Danish invaders by the decisive victory of Helsingborg. He was a great favourite with Charles XII. in the earlier campaigns, but later the two drifted somewhat, and indeed before whom General Lagercrass accused Stenbock of drunkenness, replied that "Stenbock drunk was more capable of giving orders than Lagercrass sober." His activities were not confined to war and diplomacy; the university of Lund was under his care for some years, and he had no mean skill as a painter and a poet. He became councillor in 1710, and Charles gave him his field marshal's baton in 1712. In the same year he invaded Mecklenburg (with but 9000 men) in order to cover Stralsund. He won the brilliant action of Gadebusch, but numbers prevailed against him on the next. Cut off in Tönning he was summoned to a gallant resistance, and passed into captivity. Five years of harsh treatment in Copenhagen brought his life to a close in 1717. See Loenom, Magni Stenbocki lectorum (1757-1765); Lilljestråle, Magnus Stenbock (Helsingborg, 1890).

STENCIL, a thin plate or sheet of metal, leather, paper or other material cut or pierced with a pattern or design; this is laid upon a surface and colour or ink is brushed or rubbed over it, thus leaving the ground colour of the surface imprinted with the design or pattern cut out. In ceramics the stencil is produced by coating the biscuit with a preparation which prevents the transfer-paper from adhering to the surface at those parts where the original colour of the biscuit is to be preserved. According to Skeat (Elym. Dict., 1910) the word stands for an earlier stinsel, and is to be derived from Old French estinceller, to sparkle, to powder with stars, an old term in heraldry, from Latin scintilla, a spark. The same French word has given the English "tinsel," strips, disks or pieces of thin glittering metallic substances used for the decoration of fabrics, hence any gaudy, showy and pretentious material or substance.

STENDAL, a town of Germany, in the province of Prussian Saxony, picturesquely situated on the main line of railway to Hanover and at the junction of lines to Bremen, Magdeburg and Wittenberge. Pop. (1905), 23,281. Among the relics of its former importance are the cathedral, built in 1420-1424 (though originally founded in 1188), restored in 1893 and now housing the archaeological collection of the Altmark, the Gothic church of St Mary, founded in 1447, a "Roland column" of 1535, and two fortified gateways, dating from the 13th century. The last form the chief remains of the ancient fortifications, the site of which is now mostly occupied by promenades. A monument to the archaeologist Johann Winckelmann is erected in the churchyard of the town. Stendal is the seat of a large railway workshop, and carries on various branches of textile industry, besides the manufacture of tobacco, machinery, stoves, gold-leaf, &c. The earliest printing-press in the Altmark was erected here, and published an edition of the Sachsenspiegel in 1488 as its first book.

Stendal was founded in 1151 by Albert the Bear, on the site of a Wendish settlement, and soon afterwards acquired a municipal charter. Becoming capital of the Altmark and a frequent imperial residence, it rose to a considerable degree of prosperity, in part recently restored to it by its railway connections. When the mark was divided in 1258, Stendal became the seat of the elder or Stendal branch of the house of Ascania, which, however, became extinct in 1320. The original Wends were gradually
fused with the later Saxons, although the Platea Slavonica, mentioned in 1475, was still distinguished as the Wendon Strasse in 1507. The population still exhibits a marked Slavonic element.

See Götte, *Urkundliche Geschichte der Stadt Stendal* (Stendal, 1873).

**STENO** (1651–1686), Danish naturalist, was born at Copenhagen in 1651, and studied medicine and anatomy in that city and in Paris. After a period of travel he settled in Italy (1660) at first as professor of anatomy at Padua, and then in Florence as house-physician to the grand-duke Ferdinand II. of Tuscany. He returned to his native city in 1672 to become professor of anatomy, but, having become a Roman Catholic, he found it expedient to return to Florence, and was ultimately made apostolic vicar of Lower Saxony. He died at Schwerin in Mecklenburg, on the 25th of November 1686. His fame rests on *De solidó viótra solidōrum naturaliter contenő*, published at Florence in 1669. In this notable work Steno described various gems, minerals and petrifications (fossils) enclosed within solid rocks. He compared the fossil with the living organisms, and distinguished marine and fluvialite formations. He argued also in favour of the original horizontality of sedimentary deposits.

**STENOGRAPHY** (from Gr. εἰκόν, close, narrow, and γραφή, to write), the system or art of writing by signs representing single sounds or groups of sounds, single words or groups of words, sometimes also styled "brachygraphy" (Gr. βραχύς, short); it is a general term including all the various systems of shorthand writing (see SHORTHAND).

**STENTOR**, one of the Greeks before Troy (Iliad, v. 783), whose voice was as loud as that of fifty men. It is said that he came by his death as the result of challenging Hermes, the cric of the gods, to a contest. Possibly, like Hermes himself, Stentor is a personification of the wind. The name is used in modern times of any one possessing a particularly loud voice (stentorian).

**STENTOR, a genus of heterotrichous ciliate Infusoria (g.z.), so named by R. Oken. It possesses a large moniliform meganucleus, accompanied by numerous micronuclei, and has a trumpet shape, when at rest, anchored by pseudopodial outgrowths from the narrow end. It is relatively large, and is much utilized to demonstrate myonemes, and had been also the object of interesting studies on regeneration, any piece, containing with a fragment of the meganucleus at least one micronucleus, regenerating the whole animal (see REGENERATION). *S. poly- morpha* often inhabits a gelatinous sheath and may be seen with zoochlorella; it attains a length of ½ in. *S. caeruleus* and *igneus* are coloured blue and scarlet respectively by pigment granules in the ectosarc: E. R. Lankester made a study of the pigment of the former (blue stentorin).

**STEPHAN, HEINRICH VON** (1831–1897), German statesman, was born at Stolp, in Pomerania, on the 7th of January 1831. From his earliest years he showed that talent for languages to which he owed so much of his success in life, and before he went to school had acquired a considerable knowledge of Italian, Spanish and English. He was educated at the grammar school of his native town, and at the age of sixteen entered the service of the Prussian post office. His promotion was rapid; he was transferred to East Prussia, and thence to Cologne. Here he added to his salary by writing dramatic criticism, and here he obtained his first acquaintance with the system, or rather lack of system, with which its complication of charges made all international postal correspondence so expensive and uncertain—a system which he was in later years to revolutionize. After passing the examinations which admitted him to the higher branches of the service he was transferred to Frankfort-on-the-Oder; and in 1856 to Berlin. Many different stories are told of the manner in which his exceptional knowledge of European languages was brought to the knowledge of the postmaster-general, who at once saw that capacity and attainments of the kind could best be used at headquarters. During the next few years he was entrusted with very important duties; he was chosen as Prussian representative when a postal treaty was arranged with Spain and Portugal. In 1864 he was given the task of reorganizing the postal service in the conquered duchies of Schleswig and Holstein, and in 1866 it fell to his lot to extend the Prussian system to the new territory annexed; he had to take over and replace the system by which for three hundred years the family of Thurn and Taxis had conducted the postal service of central Germany. He also found time to write works on the history of postal matters, viz. *A History of the Prussian Post Office* (1859), and articles on the means of communication in ancient and medieval times, which appeared in Raumer's *Historisches Taschenbuch* (1868). He was one of the invited guests at the opening of the Suez Canal, and in 1873 published a work on modern Egypt.

At a post office in 1864, the development of the parcel post and of the system of money orders was his next work, and in this he was so successful that in 1883 the German post office dealt with 70,000,000 parcels, while in all the other countries of the world together only 2,000,000 went through the post. While in this and other ways he extended the use of the post office at home, he gained a wider celebrity in being the chief promoter of the International Postal Union. He presided at the first conference, which met at Bern in 1874.

The acuteness of Stephan's intelligence and his enthusiasm for the institution over which he presided and which he developed with such readiness with which he applied or took over all new inventions which might be of public service, such as telegraphs, telephones and pneumatic tubes. His pride in the post office showed itself in the immediate interest which he took in the design and plan of the new offices which were erected in all parts of Germany; it was always his ambition that the post office in each town should be the most conspicuous and the handsomest of public buildings, even at the sacrifice of economy. He warmly supported Bismarck in his policy of extending and promoting national industry and foreign trade, and arranged the subsidies by which a direct postal service was established between Germany and China and Australia. His national feeling also showed itself in the support which he gave to the movement for purifying the German language of foreign words—but he did not always succeed in avoiding the exaggeration verging on the ridiculous into which this movement so easily degenerates. While he stood a little from ordinary party politics, he was a frequent speaker in the Reichstag on the affairs of his own department, and was a member of the Bundesrat. Though never on terms of intimate friendship with Bismarck, his mastery in his own department won for him the appreciation of the chancellor, and he was allowed more independence than most
of the officials. By the power of working out broad and general principles in detail and idealizing the routine work of administration he may fairly be placed among the great administrators by whom (far more than by statesmen and politicians) the Prussian state has been built up, and he was singularly fortunate in that his life fell at a time when by perfecting the administration of the newly founded imperial post he took no small part in strengthening the national idea and binding together the German nation. In 1897 blood-poisoning, arising from a wound in the foot, made amputation of the leg necessary, and he died from the effects of the operation, on the 8th of April 1897.

See E. Kuckeberg, It. v. Stephan (Berlin, 1897). (J. W. Hs.)

STEPHANITE, a mineral consisting of silver sulphantimoneite, AgSbS₃; containing 69-5 % of silver, and sometimes of importance as an ore of this metal. Under the name Schwarsitz it was mentioned by G. Agricola in 1546, and it has been variously known as “black silver ore” (Ger. Schwarztulfiser), brittle silver-ore (Sprudelanser), &c. The name stephanite was proposed by W. Haidinger in 1845 in honour of the archduke Stephan of Austria; French authors use F. S. Beudant’s name psaturose (from the Greek idUsero, fragile). It frequently occurs as well-formed crystals, which are orthorhombic and occasionally show indications of hemimorphism: they have the form of six-sided prisms or flat tables terminated by large basal planes and often modified at the edges by numerous pyramid-planes. Twinning on the prism-planes is quite frequent, occurring, giving rise to pseudo-hexagonal groups like those of aragonite. The colour is iron-black, and the lustre metallic and brilliant; on exposure to light, however, the crystals soon become dull. The mineral has a hardness of 2½ and is very brittle; the specific gravity is 6-3. Stephanite occurs with other ores of silver in metalliferous veins. Localities which have yielded good crystallized specimens are Freiberg and Gersdorf near Rosswen in Saxony, Chafardillo in Chile, and exceptionally Cornwall. In the Comstock lode in Nevada massive stephanite and argentite are important ore minerals. (L. J. S.)

STEPHANUS BYZANTINUS (Stephan of Byzantium), an author of a geographical dictionary entitled Ἐθνικά, of which, apart from some fragments, we possess only the meagre epitome of one Heraulos. This work was first edited under the title Περί τῆς ἔθνων (Aldus, Venice, 1502); the best modern editions are by W. Dindorf and others (vols., Leipzig, 1825), A. Westermann (Leipzig, 1830), and A. Meineke (vol. i., Berlin, 1849). Heraulos dedicates his epitome to Justinian; whether the first or second emperor of that name is meant is disputed, but it seems probable that Stephanus flourished about the end of the 6th century, under Justinian I. The chief fragments remaining of the original work (which certainly contained lengthy quotations from classical authors and many interesting topographical and historical details) are preserved by Constanține Porphyrogenetos, De administrando imperio, ch. 23 (the article Πεζαί Δούο ή De themataibus, ii. 10 (an account of Sicily); the latter includes a passage from the comic poet Alexis on the Seven Largest Islands. Another respectable fragment, from the Stephanus to the end of Δ, exists in a MS. of the Seguerian library. See the editions of Westermann, Dindorf and Meineke, above noticed; the article “Stephanus Byzant.” in Smith’s Dictionary of Ancient Biography, vol. iii.; E. H. Bunbury, History of Ancient Geography, i. 102, 135, 156; ii. 669-671 (London, 1883); Riese, De Stephanii Byzant. authoriaus (Kiel, 1873); J. Geffcken, De Stephanii Byzantio (Göttingen, 1886); Spuridon Kontogonas, Δημοφυλες Διαθηκη (Erlangen, 1890); Paul Sokolowski, Fragmenta d. S. von der Stephanus, Studien zu d. Ethnikà.

STEPHEN, the “proto-martyr” (as he is called in certain MSS. of Acts xxii. 20), in some senses the greatest figure in primitive Christianity prior to Paul’s conversion, was one of “the Seven” (xxi. 8, nowhere called “deacons”) set over the “daily ministration” towards the needy members of the Jerusalem community. But, like Philip and perhaps others of his colleagues (vii. 3), he had higher gifts than his office would suggest. We read that he was “full of faith and of the holy Spirit”; and as his spiritual power seems to have shown itself in mighty deeds as well as words (vi. 5, 8), he became a marked figure in Jerusalem. Of himself a Jew of Greek culture, he naturally tried to win over his fellow Hellenists (vi. 9).

It is here that Stephen’s advance upon the Apostolic teaching becomes apparent. His special “wisdom” lay in greater insight into the merely relative nature and value of the externals of Israel’s religion, and particularly those connected with the Temple. His fellow Hellenists were as a body eager to disprove the feeling of the native “Hebrews” that they were only half Jews; accordingly teaching which minimized the value of the sacred customs which Moses had delivered (vi. 14)—by making salvation turn immediately upon faith in Jesus as the Messiah—would cause the most pain. In such circles, in spite of their more liberal attitude to things moral, they may have met Stephen’s appeal for faith in Jesus as Messiah by saying that full fellowship with God was theirs by observance of the Mosaic customs, centring in the Temple, which in Jerusalem overshadowed men’s thoughts touching the Divine presence. To this he would reply by warning them in Jesus’ own words, supported by those of the prophets, that the heart is the true seat of the Shekinah; and that if they refused God manifest in His Messiah, the final embodiment of Divine righteousness, the Mosaic customs of the Temple itself—could save them from the displeasure of the living God. Nay, God might have to make good Messiah’s words as to His person being more essential to fellowship with God than the Temple itself (cf. Matt. xii. 6), which might even be destroyed, as it had been in the past, without loss to true religion. In all this he was but restating the prophetic rather than the scribal view of the Mosaic Law and its institutions, viz. that the inner spirit, that which could be written on the heart, was the only thing really essential. But they could not rise to this conception and treated his words as “blasphemous against Moses and against God,” and rushed to the elders and the scribes against him.

He was seized and brought before the Sanhedrin on the charge of speaking “against the Temple and the Law” (vi. 11-14). His defence against this twofold charge took the form of a survey of Israel’s religious past, with a view to show: (1) that “the God of Glory” had covenant relations with their forefathers before they had either Holy Place (Land or Temple) or Law (vii. 17); (2) that the first form of visible meeting place between God and His people was far other than that for which absolute sanctity was now claimed. Nay, the form of the Holy Place as a symbol of the wilderness” (no Holy Land) had more divine sanction than any later Temple (44-47); (3) that, after all, the presence of “the Most High” was not in any way bound up with any structure of human hands, as Isaiah witnessed (48-50). The moral of all this was plain: Israel’s forms of fellowship with the Most High had all along been relative and subject to change. Particularly was this so with the external forms of cultus then represented by the Temple. Hence there was no “blasphemy” in suggesting that in the Messianic age yet another change might come about, and that observance of Temple services could prove little as to acceptance with God. But there is another and more actual line of pleading. This is found in the elaborate section dealing with the administration and work of Moses, the great lawgiver (17-38)—a section full of extra-biblical echoes—followed by one on Israel’s hardness of heart towards him and the “living oracles” he mediated, together with its result, the Exile (39-43). Pure and original Mosaicism, embodied in Moses and his ministry to Israel, is represented as something which in its full spiritual intention had been frustrated by Israel’s stiffneckedness (39, 42 seq.). The figure of Moses is made to stand forth in ideal outlines, the thinly veiled Christian application shining through. This is that Moses who said unto the children of Israel, ‘A prophet

1 The solemn language in v. 44 suggests that to Stephen, as to the writer to the Hebrews (and perhaps Hellenists generally), the holy “living oracles” as corresponding to the heavenly archetype, was more sacred than the Temple of Herod, which owed what sanctity it had to the older features it still preserved.
shall God raise up unto you...like unto me.' This is he that was in the Church in the wilderness with the angel which spake to him in the Mount Sinai, and with our fathers; who received living oracles to give unto us: to whom our fathers, in particular, could not be obedient, but thrust him from them, and turned back in their hearts..." (38 seq.). Here we have the very situation as between Stephen and his hearers; and it is made unmistakable by the speaker's closing words (52–53). They will have nothing to say to the greater Mediator of the Divine oracles in Messianic clearness and power. But if so, the reason is not their fidelity to the Mosaic Law, but their infidelity to its spiritual substance. Had they kept the Law dutifully they would have believed on Him in whom true Mosaic was fulfilled and transcended.

In all this there are points both of contact and divergence between Stephen and Paul. All the three are champions of the "spiritual" against the "letter"; and alike they tax unbelieving Judaism with failure to keep the Law in its real sense. But here difference begins. Quite apart from the externalism of Temple worship, to which Paul never alludes, they start from different conceptions of the Law. Stephen, the Hellenist, views it idealistically and with the spiritual freedom of the prophets and of Jesus Himself. But Paul took it more strictly (see Paul). Thus in spite of general klibshhip of spirit, Stephen is not really Paul's forerunner. He has no sense of antithesis between law and grace; and he makes no reference to the Gentile the greater of the contributions of the Septuagint (q.v.) who recalls Stephen. Both deal largely with the Temple and its worship; both expose the externalism of the legal rites of Judaism, as tending to spiritual unreality; and both view the Gospel as the sublimation of the Law on ideal lines. Only, the latter thinker contrasts even pure Mosaic with the Gospel of Christ, as old with new, as the Covenant of shadow with that of reality.

As to the authenticity of Stephen's speech, it is generally admitted to be accurate in substance, if not in the words that he uttered. We may suppose that his literary mannerisms are associated with such discussions, who would often repeat its tenor in his work as one of the preachers scattered (viii. 4, xi. 19) by the persecution which Stephen's preaching brought on the Jerusalem community, particularly on its Hellenistic section as most identified with the revolutionary aspect which faith in Jesus the Nazarene now for a time assumed in public estimation (contrast ii. 47). It would finally be committed to writing, largely because it was so representative of the Hellenistic view of the relations of Judaism and Christianity. As such it was given prominence in the book of Acts--work where it should appear. It is rather the author of the Epistle to the Hebrews (q.v.) who recalls Stephen. Both dealt largely with the Temple and its worship; both expose the externalism of the legal rites of Judaism, as tending to spiritual unreality; and both view the Gospel as the sublimation of the Law on ideal lines. Only, the latter thinker contrasts even pure Mosaic with the Gospel of Christ, as old with new, as the Covenant of shadow with that of reality.

Only, the latter thinker contrasts even pure Mosaic with the Gospel of Christ, as old with new, as the Covenant of shadow with that of reality.

Stephen's actual martyrdom is described as tumultuary in character, though the legal forms of stoning for blasphemy were observed (59). This is quite consistent with a trial before the Sanhedrin; nor is it inconceivable that an act exceeding the rights of that body under the Romans should have taken place at the impulsion of religious as well as political motives. It is rather the author of the Epistle to the Hebrews (q.v.) who recalls Stephen. Both dealt largely with the Temple and its worship; both expose the externalism of the legal rites of Judaism, as tending to spiritual unreality; and both view the Gospel as the sublimation of the Law on ideal lines. Only, the latter thinker contrasts even pure Mosaic with the Gospel of Christ, as old with new, as the Covenant of shadow with that of reality.

As to the authenticity of Stephen's speech, it is generally admitted to be accurate in substance, if not in the words that he uttered. We may suppose that his literary mannerisms are associated with such discussions, who would often repeat its tenor in his work as one of the preachers scattered (viii. 4, xi. 19) by the persecution which Stephen's preaching brought on the Jerusalem community, particularly on its Hellenistic section as most identified with the revolutionary aspect which faith in Jesus the Nazarene now for a time assumed in public estimation (contrast ii. 47). It would finally be committed to writing, largely because it was so representative of the Hellenistic view of the relations of Judaism and Christianity. As such it was given prominence in the book of Acts--work where it should appear. It is rather the author of the Epistle to the Hebrews (q.v.) who recalls Stephen. Both dealt largely with the Temple and its worship; both expose the externalism of the legal rites of Judaism, as tending to spiritual unreality; and both view the Gospel as the sublimation of the Law on ideal lines. Only, the latter thinker contrasts even pure Mosaic with the Gospel of Christ, as old with new, as the Covenant of shadow with that of reality.

excesses of such rebels as Geoffrey de Mandeville, earl of Essex, turned considerable districts into wildernesses. Meanwhile Geoffrey of Anjou, the husband of the empress, completed the conquest of Normandy (1144). In 1147 the situation improved for Stephen; Robert of Gloucester, the ablest of the Angevin partisans, died, and the empress left England in despair. But her son soon appeared in England to renew the struggle (1149) and conciliate new supporters. Soon after his return to Normandy Henry was invested by his father with the duchy (1150). He succeeded to Anjou in 1151; next year he acquired the duchy of Aquitaine by marriage. Stephen struggled hard to secure the succession for Eustace, his elder son. But he had quarrelled with Rome respecting a vacancy in the see of York; the pope forbade the English bishops to consecrate Eustace (1151); and there was a general unwillingness to prolong the civil war. Worn out by incessant conflicts, the king bowed to the inevitable when Henry next appeared in England (1153). Negotiations were opened; and Stephen's last hesitations disappeared when Eustace was carried off by a sudden illness. Late in 1153 the king acknowledged Henry as his heir, only stipulating for unfatherly and his private estates should be guaranteed to his surviving son, William. The king and the duke agreed to co-operate for the repression of anarchy; but Stephen died before this work was more than begun (Oct. 1154).

On his great seal Stephen is represented as tall and robust, bearded, and of an open countenance. He was frank and generous; his occasional acts of duplicity were planned reluctantly and never carried to their logical conclusion. High spirited and proud of his dignity, he lived to repent, without being able to undo, the ruinous concessions by which he had conciliated supporters. In warfare he showed courage, but little generalship; as a statesman he failed in his dealings with the Church, which he alternately humoured and thwarted. He was a generous patron of religious foundations; and some pleasing anecdotes suggest that his personal character deserves more commendation than his record as a king.

STEPHEN, the name of nine popes.

Stephen I, bishop of Rome from about 254 to 257, followed Lucius I. He withdrew from church fellowship with Cyprian and certain Asian bishops on account of their views as to the necessity of repenting heretics (Eusche. H. e. vii. 55; Cypr. Epp. 73). He is also mentioned as having insisted on the restoration of the bishops of Merida and Astorga, who had been deposed on the ground of unfaithfulness during persecution, but afterwards repented. He is commemorated on August 2. His successor was Sixtus II.

Stephen II., pope from March 752 to April 757, was in deacon's orders when chosen to the vacant see within twelve days after the death of Zacharias. The main difficulty of his pontificate was in connexion with the aggressive attitude of Aistulf, king of the Lombards. After unsuccessful embassies to Aistulf himself and appeals to the emperor Constantine, he, though in feeble health, set out to seek the aid of Pipin, by whom he was received in the neighbourhood of Vitry-le-Brulé in the autumn of 755, and paid him homage. The result of his negotiations was the Frankish invasion of Aistulf's territory and the famous "donation" of Pipin. The death of Stephen took place not long after that of Aistulf. He was succeeded by Paul I.

1 A priest named Stephen, elected before him, died three days after, without having received the sacrament of consecration.

Stephen III, pope from the 7th of August 768 to the 3rd of February 772, was a native of Sicily, and, having come to Rome during the pontificate of Gregory III., gradually rose to high office in the service of successive popes. On the deposition of Constantine II. Stephen was chosen to succeed him. Fragmentary records are preserved of the council (April 769) at which the degradation of Constantine was completed, certain new arrangements for papal elections made, and the practice of image-worship condemned. Stephen inclined to the Lombard rather than to the Frankish alliance. He was succeeded by Adrian I.

Stephen IV., pope from June 816 to January 817, succeeded Leo III. He did not continue Leo's policy, which was more favourable to the clergy than to the lay aristocracy. Immediately after his consecration he ordered the Roman people to swear fidelity to Louis the Pious, to whom he found it prudent to betake himself personally in the following August. After the coronation of Louis at Reims in October he returned to Rome, where he died in the beginning of the following year. His successor was Paschal I.

Stephen V., pope from 885 to 891, succeeded Adrian III., and was in turn succeeded by Formosus. In his dealings with Constantinople in the matter of Photius, as also in his relations with the young Slavonic Church, he pursued the policy of Nicholas I. His Italian policy wavered between his desire for the protection of the German king Arnulf against Guy of Spoleto, king of Italy, and fear of offending Guy. Guy was crowned emperor in 891.

Stephen VI., pope from May 896 to July-August 897, succeeded Boniface VI., and was in turn followed by Romanus. His conduct towards the remains of Formosus, his last predecessor but one (see Formosus) excited a tumult, which ended in his imprisonment and death by strangling.

Stephen VII. (January 939 to February 931) and Stephen VIII. (July 939 to October 940) were virtually nonentities, who held the pontificate while the real direction of the pontifical state was in the hands of Marozia and, afterwards, of her son Alberic, senator of the Romans.

Stephen IX., pope from August 1057 to March 1058, succeeded Victor II. (Gebhard of Eichstätt). His baptismal name was Frederick, and he was a younger brother of Godfrey, duke of Upper Lorraine, marquis of Tuscany (by his marriage with Beatrice, widow of Boniface, marquis of Tuscany). Frederick had already been raised to the cardinalate by Leo IX., acted for some time as papal legate at Constantinople, and was with Leo in his unlucky expedition against the Normans. He shared his brother's fortunes, and at one time had to take refuge from Henry III. in Monte Cassino. Five days after the death of Victor II. (who had made him cardinal-priest and abbot of Monte Cassino) he was chosen to succeed him. He showed great zeal in enforcing the Hildebrandine policy as to clerical celibacy, and was planning the expulsion of the Normans from Italy and the elevation of his brother to the imperial throne when he was seized by a severe illness. He died at Florence on the 5th of March 1058.

Stephen I. (St Stephen) (977-1038), king of Hungary, was the son of Geza, duke of Hungary, and of Sarolta, one of the few Magyar Christian ladies, who obtained the best teachers for her infant son. These preceptors included the German priest Bruno, the Czech priest Radla, and an Italian knight, Thedate of San Severino, who taught him arms and letters (a holograph epistle by Stephen existed in the Vatican Library as late as 1513). In 996 Stephen married Gisela, the daughter of Duke Henry II. of Bavaria, and in the following year his father died and the young king was suddenly confronted by a formidable force. This reaction under Kupa in the districts between the Drave and Lake Balaton. Stephen hastened against the rebels, bearing before him the banner of St Martin of Tours, whom he now chose to be his patron saint, and routed the rebels at Veszprem (998), a victory from which the foundation of the Hungarian monarchy must be dated, for Stephen assumed the royal title immediately afterwards. In 1000 his envoy Aztrik
obtained Pope Silverst Ii.'s confirmation of this act of sover-
engy. Silvester at the same time sent Stephen a consecrated
crown, and approved of the erection of an independent Hun-
garian church, divided into the two provinces of Eotsegorm
and Bacs. But the power of pagan Hungary could not be broken
in a day. The focus of the movement was the Maros region,
where the rebel Ajony built the fortress of Marosvar. The
struggle proceeded for more than twenty-five years, the diffi-
culties of Stephen being materially increased by the assistance
rendered to the Greek by the Cuman conquerors and his neigh-
bours since their reconquest of Bulgaria. As early as 1015 Stephen
had appointed the Italian priest Gellert bishop of Maros, but
he was unable to establish the missionary in his see till 1030.
The necessity of christianizing his heathen kingdom by force
of arms engrossed all the energies of Stephen and compelled
him to adopt a pacific policy towards the emperors of the East
and West. When the emperor Conrad, with the deliberate
intention of subjugating Hungary, invaded it in 1030, Stephen
not only drove him out, but captured Vienna (now mentioned for
the first time), and compelled the emperor to cede a large
portion of the Danmark (1031). Of the five sons born to him
by Gisela, only Emerich reached manhood, and this well-
educated prince was killed by a wild boar in 1031. Stephen
thereupon appointed as his successor his wife's nephew Peter
Orseolo, who settled in Hungary, where his intrigues and foreign
ways made him extremely unpopular. Stephen died at his
palace at Esztergom in 1038 and was canonized in 1083. For
an account of his epoch-making reforms see Hungary; History.

**STEPHEN V.** (1339-1272), king of Hungary, was the eldest
son of Béla IV., whom he succeeded in 1270. As crown prince
he had exhibited considerable ability, but also a disquieting
restlessness and violence. In 1262 he compelled his father,
whom he had assisted in the Bohemian War, to surrender twenty-
nine counties to him, so that Hungary was virtually divided
into two kingdoms. Not content with this, he turned his
attention to the southern banate of Macao, which led to a fresh
war between father and son in which the latter triumphed. In
1265 he undertook an expedition against the Bulgarians,
conquering the land as far as Tirnova and styling himself hence-
forth king of Bulgaria. Stephen was a keen and circumspect
politician, and for his future security contracted, during his
father's lifetime, a double matrimonial alliance with the Ne-
polian princes of the House of Anjou, the chief partisans of the
pope. He certainly needed exterior support; for on his accession
to the Hungarian throne, as he himself declared, every one was
his enemy. This hostility was due to the almost universal
opinion of western Europe that Stephen was a semi-pagan.
His father had married him while still a youth (c. 1255) to
Elizabeth, daughter of the Kumanian chieftain Kőtény, with
a view to binding the Kumanians (who could put in the field
16,000 men; see Hungary: History) more closely to the dynasty
in the then by no means improbable contingency of a second
Tatar invasion. The lady was duly baptized and remained a
Christian; but the adversaries of Stephen, especially Ottakar II.
of Bohemia, affected to believe that Stephen was to be a
friend of the Kumanians and joined them. Not content with
this, the Magyar marauders, to conquer the western provinces of Hungary, but after some suc-
cesses was utterly routed by Stephen in 1271 near Mosony,
and by the peace of Pressburg, the same year, relinquished all
his conquests. Stephen died suddenly on the 6th of August

1 Charles, the son of Charles of Anjou, was to marry Stephen's daughter Maria, while Stephen's infant son Ladislaus was to marry Charles's daughter Elizabeth. Another of his daughters, Anna, married the Greek emperor Andronicus Palaeologus.

**STEPHEN, SIR JAMES** (1789-1859), English historian, was
the son of James Stephen, master in chancery, author of The
Slavery of the West India Colonies and other works, and was
born in London on the 3rd of January 1789. He was educated
at Trinity Hall, Cambridge, graduating B.A. in 1812, after
which he studied law. He entered the bar and was called at Lincoln's Inn. He obtained an extensive practice as a chancery barrister,
being ultimately counsel to the colonial department and counsel
to the board of trade. In 1834 he became assistant under-
secretary for the colonies, and shortly afterwards permanent under-secretary. On his retirement in 1847 he was made a knight commander of the Bath. In 1849 he was appointed regius professor of modern history in the university of Cam-
bidge, having already distinguished himself by his brilliant
studies in ecclesiastical biography contributed to the Edinburgh
Review, which he continued to publish after his death in 1851. His
lecture Ecclesiastical Biography and Other Subjects; a 4th edition,
with a short memoir, appeared in 1860. He was also the
author of Lectures on the History of France (2 vols., 1851; 3rd
ed., 1852), and Desultory and Systematic Reading, a lecture
(1853). He died at Cobents on the 15th of September 1850.

**STEPHEN, SIR JAMES FITZJAMES, BART.** (1829-1894),
English lawyer, judge and publicist, was born in London on the
3rd of March 1829, the third child and second son of Sir James
Stephen (q.v.). Fitzjames Stephen was for three years (1842-
1845) at Eton, and for two years at King's College, London.
In October 1847 he entered at Trinity College, Cambridge. Notwithstanding exceptional vigour in mind and body, he did
not attain any of the usual scholastic or athletic distinctions.
The only studies then seriously prosecuted in the university
course were mathematics and classics. Neither of these
attracted him in their academical forms, nor did he care for com-
petitive sport. But his Cambridge time was fruitful in other
ways. He was already acquainted with Sir Henry Maine (q.v.),
six years his senior, and then newly appointed to the chair of
civil law. This acquaintance now ripened into a perfect friend-
ship; with which the love of Stephen to his own country, his
men's intellectual tempers ever presented a stronger contrast.
As Stephen himself said, it took them a long time to know
when they really agreed. Maine was subtle, swift and far-
reaching; Stephen was massive, downright, indefatigable
and sincere even to unnecessary frankness. Their qualities
were an almost exact complement of one another, but neither of
them would take opinions on trust, or acquiesce in common-
place methods of avoiding difficulties; and it might have been
said of either of them without exaggeration that, if all his
technical and professional requirements could be taken away,
a man of letters entered be left. By Maine's introduction, Stephen became a member of the Cambridge society known as
the Apostles, in form not very different from many other essay
societies, in substance a body with an unformulated but most
individual tradition of open-mindedness and absolute mutual
tolerance in all matters of opinion. Perhaps the golden age
of the society was a few years before Stephen's election, but
it still contained a remarkable group of men who afterwards
became eminent in such different ways as, for instance, James
Clerk Maxwell and Sir William Harcourt. Stephen formed
friendships with some of its members, which were as permanent
though in few cases so little subject to external interruption,
as his intimacy with Maine. Probably the Apostles did much
to correct the formalism inevitably incident to the evangelical
traditions of the first Sir James Stephen's household.

After leaving Cambridge, Fitzjames Stephen, having prac-
tically to choose between the Church and the bar, decided for
the bar. He was called in 1854, after the usual haphazard prepara-
tion which was then (and still practically) considered in
England alone, and even in England for one kind of learning

(Hung.; Budapest, 1903).

(1858-1890).
alone, a sufficient introduction to the duties of a learned pro-
ession. His own estimate of his strictly professional success,
written down in later years, was that in spite of such training as
he could get, rather than because of it, he became a moderately
successful advocate and a rather distinguished judge. As to
the former branch of the statement, it is correct but ambiguous
to those who do not know the facts. Stephen's work was always
diminished in quality, though his amount of business was never
great in quantity. After his return from India and before
he became a judge he had what is called a good practice, but
still not a large one. In his earlier years at the bar he was
attracted by the stop-gap of journalism. It was no common
journalism, however, that enlisted Stephen as a contributor to the
Saturday Review when it was founded in 1835. He was in
company with Maine, Sir William Harcourt, G. S. Venables
(a writer of first-rate quality who never set his name to any-
thing), C. S. C. Bowen, E.A. Freeman, Goldwin Smith and others
whose names have since become well known. Strangely enough,
the first and the last book published by Stephen were selections
from his papers in the Saturday Review (Essays by a Barrister,
1862, anonymous; Horae sabbaticae, 1892). These volumes
embodied the results of his studies among publicists and theologians,
chiefly English, from the 17th century onwards. They never professed to be more than the occasional products of an amateur's leisure, but they were of greater value when they were first published than is easily recognized at this day by a generation familiar with the resources of later criticism.

For exactly three years (1858-1861) Stephen served as secretary
to a royal commission on popular education, which was more
fortunate than most commissions in having prompt effect given
to its conclusions. In 1859 he was appointed recorder of
Newark. In 1863 he published his General View of the Criminal
Law of England (not altogether superseded by the second edition
of 1890, which was practically a new book). This was really
the first attempt that had been made since Blackstone to explain
the principles of English law and justice in a literary form,
and it had a thoroughly deserved success. All this time Stephen
kept up a great deal of miscellaneous writing, and the foundation
of the Pall Mall Gazette in 1865 gave him a new opening.
He was one of the principal contributors for some years, and an
occasional one till he became a judge. So far he was a literary
lawyer, also possibly with chances (diminished by his vehement
dislike for party politics) of regular professional advancement,
possibly not free from the temptation to turn wholly to literature.
The decisive point of his career was in the summer of 1869,
when he accepted the post of legal member of council in India.
Fitzjames Stephen's friend Maine was his immediate predecessor
in this office. Guided by Maine's comprehensive genius, the
government of India had been placed in a code form of systematic
legislation which was to last about twenty years. The materials
for considerable parts of this plan had been left by Maine in a
more or less forward condition. Stephen had the task of work-
ing them into their definite shape and conducting the bills
through the Legislative Council. This he did with wonderful
energy, with efficiency and workmanship adequate to the purpose,
if sometimes rough according to English notions, and so as to
leave his own individual mark in many places. The Native
Marriages Act of 1872 was the result of deep consideration on
both sides and Stephen's part. The Criminal Code of India was
first framed in England by a learned commission (apparently not
having much special Indian information, or not much regarding
that which it had), and the draft was materially altered in
Stephen's hands before, also in 1872, it became law. The
Evidence Act of the same year was entirely Stephen's own.
It not only consolidated the rules of judicial proof, but en-
deavoured to connect them by legislative authority with a
logical theory of probability set forth in the act itself. This part
of the act has been criticized both as to the principle (which,
indeed, seems open to much doubt) and as to the success of the
draftsmen in applying it. At any rate it is characteristic of
Stephen's anxiety never to shirk a difficulty. To some extent
the Contract Act may be charged with similar over-ambition;
but its more practical defects are evidently due to the acceptance
by the original framers of unsatisfactory statements which,
coming to India with a show of authority, naturally escaped
minute criticism amid the varied business of the legislative
department. If the success of the later Anglo-Indian Codes
has not been quite so complete as that of the Penal Code, they
depend, on the whole, on excellent service, and they are at least
as good as any European codification prior to the very recent
achievements of scientific lawyers in Italy and Germany.
Besides the special work of legislation, Stephen had to attend
to the current administrative business of his department,
often heavy enough to occupy the whole of an ordinary able
man's attention, and he took his full share in the general delib-
erations of the viceroy's council. His last official act was the
publication of a minute on the administration of justice which
pointed the way to reforms not yet fully realized, and is still
most valuable for every one who wishes to understand the
judicial system of British India. Stephen, mainly for family
reasons, came home in the spring of 1872. During the voyage
he made a pastime of meditating and writing a series of articles
which took the form of his book entitled Liberty, Equality,
Fraternity (1873-1874)—a protest against J. S. Mill's neo-
utilitarianism which was really in the nature of an appeal from
the new to the old Utilitarians, if any such were left, or
perhaps rather to Hobbes. It was, however, too individual to be
systematic, and made no serious attempt at reconstruction.

Indian experience had supplied Stephen with the motive for
his next line of activity, which future historians of the common
law may well regard as his most eminent title to remembrance.
The government of India had been driven by the conditions
of the Indian judicial system to recast a considerable part
of the English law which had been informally imported. Criminal
law procedure, and a good deal of commercial law, had been
or were being put in a shape intelligible to civilian magistrates,
and fairly within the comprehension of any intelligent man
who would give a moderate amount of pains to mastering the
text of the new codes. The national substance of the law had
been preserved, while the disorder and the excessive technicalities
were removed. Why should not the same procedure be as
practicable and profitable in England? It was Bentham's ideal
of codification, to be put in practice with the knowledge of
actual business and legal habits, and the lack of which had
made Bentham's plans unworkable. For the next half-dozen
years Fitzjames Stephen was an ardant missionary in this
cause. The mission failed for the time as to the specific under-
takings in which Stephen made his experiments, but it had
a large indirect success which has not yet been adequately
recognized. Stephen published, by way of private exposition,
thus in code of law of crimes and the criminal law.
There were transient hopes of an evidence act being brought
before parliament, and in 1878 the digest of criminal law became
a ministerial bill. This was referred to a very strong judicial
commission, with the addition of Stephen himself: the revised
bill was introduced in 1879 and 1880. It dealt with procedure
as well as substantive law, and provided for a court of criminal
appeal (after several years of judicial experience Stephen
changed his mind as to the wisdom of this). However, no
substantial progress was made. In 1883 the part relating to
procedure was brought in separately, and went to the grand
committee on law, who found there was not time to deal with it
satisfactorily in the course of the session. Criminal appeal has
since (1907) been dealt with; otherwise nothing has been done
with either part of the draft code since. The historical materials
which Stephen had long been collecting took permanent shape
the same year (1883) in the History of the Criminal Law of
England, which, though not free from inequalities and traces
of haste, must long remain the standard work on the subject.
A projected digest of the law of contract (which would have been
much fuller than the Indian Code) fell through owing to the
magnitude of the task. Thus, none of Stephen's own plans of English
codification took effect. Nevertheless they bore fruit indirectly.
men dealt with other chapters of the law in the systematic form of the Anglo-Indian codes; and a digest of the law of partnership by Sir Frederick Pollock, and one of the law of negotiable instruments by Sir M. D. Chalmers, which some time afterwards filled the post of legal member of council in India, became the foundation of the Bills of Exchange Act of 1882 and the Partnership Act of 1890. Lord Herschell passed a Sale of Goods Act on similar lines, also drafted by Chalmers, in 1893; and a Marine Insurance Act, prepared in like manner in 1894, finally became law in 1896. Nothing really stands in the way of a practically complete code of maritime and commercial law for the Kingdom but the difficulty of finding time in the House of Commons for non-contentious legislation; and whenever this is achieved, the result will in substance be largely due to Sir James Stephen's efforts. Meanwhile, in addition to his other occupations, Stephen was an active member of the Metaphysical Society (see KNOWLES), and he carried on an intimate correspondence with Lord Lytton, then viceroy of India, during the critical period of the second Afghan War. In connexion with the Metaphysical Society, and otherwise, Fitzjames Stephen took an active interest in many topics of current controversy. He led and was one of the greatest essayists, of which a list may be found at the end of Sir Leslie Stephen's Life. The matters dealt with covered a wide field, from modern history and politics, with a predilection for India, to philosophy, but the prevailing mood was theologico-political. All these writings were forcible expositions of serious and thoroughly definite views, and therefore effective at the time and valuable even to those who least agreed with them. As to the philosophical part of them, the grounds of discussion were shifting then, and have continued to shift rapidly. Much of Stephen's vigorous polemic has already incurred the natural fate of becoming, as obsolete as the arguments against which it was directed. Pure metaphysical speculation, as an intellectual exercise, had little attraction for him; and, though he was fully capable of imperial historical criticism, he seldom applied it outside the history of law.

In 1877 Stephen was made a Knight Commander of the Star of India, and in 1878 he received the honorary degree of D.C.L. at Oxford. Early in 1879 he was appointed judge of the queen's bench division. He held that office a little more than eleven years. The combination of mature intellectual patience and critical subtlety which marked the great masters of the common law was not his, and it cannot be said that he made any considerable addition to the substance of legal ideas. His mind was framed for legislation rather than for systematic interpretation and development. Therefore he could hardly be called a great judge; but he was a thoroughly just and efficient one; and if none of his judgments became landmarks of the law, very few of them were wrong. Especially in criminal jurisdiction, he was invariably anxious that moral as well as legal justice should be done. He found time, in 1885, to produce a book on the trial of Nuncomar, for the purpose of rehabilitating Sir Elijah Impey's memory against the attack made on him in Macaulay's essay on Warren Hastings, which for English readers is the first and last source of information on the whole matter. Mr G. W. Forrest's later research in the archives of the government of India had tended to confirm the judicial protest, at any rate as regards Macaulay's grosser charges.

The one thing of which Stephen was least capable—among other things possible to a good man and a good citizen—was sparing himself. He had one or two warnings which a less energetic man would have taken more seriously. In the spring of 1891 his health broke down, the chief symptom being sudden lapses of memory of which he was himself quite unconscious. In obedience to medical advice he resigned his judgesship in April, and was created a baronet. He lived in retirement till his death on the 11th of March 1894, having filled a not very long life with a surprising amount of work, of which a large proportion was of permanent value. Perhaps the most individual part of Stephen's character was his absolute sincerity. He would not allow himself even innocent dissimulation; and this gave to those who knew him but slightly an impression of hardness which was entirely contrary to his real nature. Sir James Stephen married Mary Richenda Cunningham in 1855. On his death his eldest son, Herbert, succeeded to the baronetcy. A second son of brilliant literary promise, James Kenneth Stephen (1859-1892), died in his father's lifetime: his principal literary achievements consisted in two small volumes of verse—Lapsus calami and Quo Musa tendis, the former of which went through five editions in a very short time. The third son, Mr H. L. Stephen, was appointed in 1901 judge of the High Court of Calcutta.

STEPHEN, SIR LESLIE (1832-1904), English biographer and literary critic, grandson of James Stephen (1758-1832), master in chancery, a friend of Wilberforce, and author of a book called Slavery Delineated, and son of Sir James Stephen (1789-1850), colonial under-secretary for India, and author of Essays on Ecclesiastical Biography, was born at Kensington Gore on the 28th of November 1832. At his father's house he saw a good deal of the Abolitionists and other members of the Chatham sect, and the Macaulays, James Spedding, Sir Henry Taylor and Nassau Senior were intimate friends of his family. After education at Eton, King's College, London, and Trinity Hall, Cambridge, where he graduated B.A. (20th wrangler) 1854, M.A. 1857, Stephen remained for several years a fellow and tutor of his college. He has recounted the experiences of a resident fellow at that period in a delightful chapter in his Life of Farquhar as well as in some less formal Sketches from Cambridge: By a Don (1865). These sketches were reprinted from the Pall Mall Gazette, to the proprietor of which, George Smith, he had been introduced by his brother (Sir) James Fitzjames Stephen. It was at Smith's house at Hampstead that Stephen met his first wife, Harriet Marion (d. 1875), daughter of W. M. Thackeray; after her death he married Julia Prinsep, widow of Herbert Duckworth. While still a fellow he had taken holy orders, which he relinquished in March 1875 upon the passing of the Clerical Disabilities Act. In the meantime (after a short visit to America) the former, and author of Essays on Ecclesiastical Biography, was born at Cornhill under the title of Hours in a Library (1874,1876 and 1879), and some Essays on Freethinking and Plain Speaking (1837 and 1897, with introductory essays by J. Bryce and H. Paul), which included the very striking A Bad Five Minutes in the Alps (reprinted from Fraser and the Fortnightly in 1873), he made two valuable contributions to philosophical history and theory, The History of English Thought in the Eighteenth Century (1876 and 1881) and The Science of Ethics (1882); the second of these was extensively adopted as a textbook on the subject. The first was generally recognized as an important addition to philosophical literature, and led immediately to Stephen's election at the Athenaeum Club in 1877. In 1879 he set on foot a Sunday Walking Club, which contained well-known names, among them Sir F. Pollock, F. W. Maitland, Croom Robertson and Cotter Morison.
In the autumn of 1882 he abandoned the direction of the Cornhill to James Payn, having accepted the more responsible duty of the editor of the Dictionary of National Biography, for the first planning and conception of which he was largely responsible. The first volume of the Dictionary was published in January 1885, and twenty quarterly volumes followed under Stephen's sole editorship. Five volumes were then published under the joint editorship of Leslie Stephen and of Mr Sidney Lee, whom he had appointed as his assistant in March 1883.

Early in 1891, after eight years' service, Stephen, whose health had been impaired by the labour inseparable from the direction of such an undertaking, resigned the responsibility to his coadjutor. Not a trained historian, he often found it difficult to curb his impatience with Carlyle's old enemy Dryasdust. Fortunately for the success of the work, re-established health enabled him to remain a contributor to the Dictionary. Among his lives are those of Addison, Bolingbroke, Burns, Charlotte Brontë, Byron, Carlyle, Marlborough, Coleridge, Defoe, Dickens, Dryden, Fielding, George Eliot, Gibbon, Goldsmith, Hobbes, Hume, Johnson, Landor, Locke, Macaulay, the twains, Milton, Pope, Scott, Swift, Sam Smith, Thackeray, Warburton, Wordsworth and Young. Many of these are salted with irony, and most of them are characterized by felicitous phrases, by frequent flashes of insight (especially of the sardonic order), and by the good fortune which attends a consummate artist in his special craft. His particular style of treatment is more appropriate, perhaps, to the self-complacent worthies of the 18th century than to quietists such as Law and Wordsworth; but where space demands that a character should be inscribed upon a cherry-stone, Stephen seldom if ever rises to the occasion. For the "English Men of Letters" he wrote lives of Swift, Pope and Johnson—the last well described as "the peerless model of short biographies"—and subsequently George Eliot and Hobbes (1904). During his tenure of the editorship of the Dictionary he was appointed first Clark lecturer at Cambridge (1883), and lectured upon his favourite period—Berkeley, Mandeville, Warburton and Hume; a few years later, upon one of several visits to his intimate friends and old correspondents, Norton and Lowell, he received (1890) a doctor's degree from Harvard University. After Lowell's death in 1891 Stephen was mainly instrumental in having a memorial window planted in Westminster Abbey.

In 1885 he brought out his standard Life of Fawcett, in 1893 his Agnus's Apology and other Essays, and in 1895 the Life of his brother, Sir James Fitzjames Stephen, which, less essayistic in manner than the Life of Fawcett, contains his most finished biographical work. In the same year, in succession to Lord Tennyson, Stephen was elected president of the London Library, and shortly afterwards appointed a trustee of the National Portrait Gallery. Some of his experiences as an editor were embodied in Studies of a Biographer, issued in 1908, while in 1900 appeared an important work which he had long had in preparation in continuation of his English Thought in the Eighteenth Century, entitled The English Utilitarians, being full-length studies of Bentham and the two Mills. As a thinker Leslie Stephen showed himself consistently a follower of Hume, Bentham, the Mills and G. H. Lewes, but he accepted the older utilitarianism only as modified by the application of Darwinian principles, upon lines to some extent indicated by Herbert Spencer (see Ernes). The negative character of his teaching, his anti-sacerdotal bias, his continual attitude of irony, and even the very substance of his thought, have co-operated to retard the recognition of his value as rivialled only by Baghout among critics of the incisive school. For blowing the froth off the flagon of extravagant or inflated eulogy he certainly met no equal in his generation. Voluminous as his work is, it is never dull. While making self-depreciation a fine art, and perpetually laughing in his sleeve at the literary bias and the literary foible, he fulfilled with exceptional conscience the literary duty of never writing below his best. Brought up in a rigid and precise school which scrupled all pretence and discouraged enthusiasm as the sign of an ill-regulated mind, he produced no magnum opus, but he enriched English literature with a fine gallery of literary portraits, not all of them perhaps wholly accurate, but restrained, concise and always significant. Besides being a member of the Metaphysical Society, he was for some years president of the Ethical Society (many of his addresses to which were published as Social Rights and Duties in 1896). In addition to his separate works, he superintended a large number of editions, among them Clifton's Essays (1879), Fielding (1889), Richardsons (1883), Payn's Bar Laus in Life and J. R. Green's Letters (1901). In 1896 he wrote a memoir of his friend James Dykes Campbell for the second edition of Campbell's Coleridge, and in 1897 he contributed a preface to the English translation of The Early Life of Wordsworth, by M. Legouis.

His name was included in the Coronation honours list of June 1902, when he was made K.C.B. In December of this year he had to undergo an operation, after which his health began to wane rapidly. In 1903 his Ford lectures, one last luminous talk about the 18th century, were delivered by his nephew, H. L. E., and showed him in the prime of his years. He had not been well for some time, and was often irritable. The Ford lectures, during which he lectured on the history of the Church, were delivered in the autumn of 1903, and published in 1904. During the last four years of his life he was often ill but still wrote. For the Dictionary of National Biography, postscript to Statistical Account in the 1908-1909 reissue.

STEPHEN BAR SUDHAILE, a Syrian mystical writer, who flourished about the end of the 5th century A.D. The earlier part of his career was passed at Edessa, of which he may have been a native. He afterwards removed to Jerusalem, where he lived as a monk, and endeavoured to make converts to his peculiar doctrines, both by teaching among the community there and by letters to his former friends at Edessa. He was the author of commentaries on the Bible and other theological works. Two of his eminent contemporaries, the Monophysites Jacob of Sérugh (451-521) and Philoxenus of Mabogh (d. 523), wrote letters in condemnation of his teaching. His two main theses which they attacked were (1) the limited duration of the future punishment of sinners, (2) the pantheistic doctrine that "all nature is consubstantial with the Divine essence"—that the whole universe has emanated from God, and will in the end return to and be absorbed in him.

The fame of Stephen as a writer rests on his identification with the author of a treatise which survives in a single Syriac MS. (Brit. Mus. Add. MSS. 7189, written mainly in the 13th century), "The book of Hierotheus on the hidden mysteries of the house of God." The claims to have been composed in the 1st century A.D. by a certain Hierotheus who was the disciple of St Paul and the teacher of Dionysius the Areopagite. But, like the works which pass under the name of Dionysius, it is undoubtedly pseudonymous, and most Syriac writers who mention it attribute it to Stephen. An interesting discussion and summary of the book have been given by A. L. Frothingham (Stephen bar Sudhaila, Leiden, 1866), but the text of 1910 (uncritically from another MS.) which we learn to-day, the work consists of five books; after briefly describing the origin of the world by emanation from the Supreme Good it is mainly occupied with the description of the stages by which the world comes, what it is necessary to understand, etc by the soul which comes, what occupies almost the entire work, the experience of

1 He is described as "Stephen the Edessene" in the 8th-century MS., which contains the letter of Philoxenus to Abraham and Orestes.
the mind in search of perfection during this life. Finally comes the description of the various phases of existence as the mind rises into the spiritual and ultimate condition of perfection in the essence. The keynote to the experience of the mind is its absolute identification with Christ; but the son finally resigns the kingdom unto the Father, and all distinct existence comes to an end, being lost in the glory of the Good. 8 Frothingham, p. 90. One of the most curious features of the work is the misguided skill with which the language of the Bible is pressed into the service of pantheistic speculation. In this and other respects the book harmonizes well with the picture of Stephen's teaching afforded by the letter of Philoxenus to the Edessene priests Abraham and Orestes (Frothingham, pp. 28–48). The Book of Hierotheus is probably an original Syriac work, and not translated from the Greek. Its rival, the Pseudo-Dionysian literature is a difficult question; probably Frothingham (p. 83) goes too far in suggesting that it was prior to all the pseudo-Dionysian writings (cf. RysSEL in Zeitschrift für Kirchengeschichte)

The unique MS. in which the book of Hierotheus survives furnishes, along with its text the commentary made upon it by Theodosius, patriarch of Antioch (887–906), who appears to have sympathized with its teaching. A rearrangement of the text was made by the great Monophysite author Barhebraeus (1226–1286), who expunged or garbled much of its unorthodox teaching. It is interesting to note that the identical copy which he used is the MS. which now survives in the British Museum. (N. M.)

STEPHEN (ISTVÁN) BáTHORY (1533–1586), king of Poland and prince of Transylvania, the most famous member of the Somlyó branch of the ancient Bátory family, now extinct, but originally almost coeval with the Hungarian monarchy. István Bátory spent his early years at the court of his grandfather, Ferenc Rákóczi, and was attached to the household of Janos Zapolya, and won equal renown as a valiant lord-marcher, and as a skilful diplomatist at the imperial court. Zapolya rewarded him with the voivodeship of Transylvania, and as the loyal defender of the rights of his patron's son, John Sigismund, he incurred the animosity of the emperor Maximilian, who kept him in prison for two years. On the 25th of May 1571, on the death of John Sigismund, Bátory was elected prince of Transylvania by the Hungarian estates, in spite of the opposition of the court of Vienna and contrary to the wishes of the late prince, who had appointed Gaspar Békésy his successor. Bátory immediately made a tour of the voivodship, and, finding the country thoroughly demoralized by the civil war, he declared his intention of following the policy of his father in office. He immediately drove his rival out of Transylvania (1572). On the flight of Henry of Valois from Poland in 1574, the Polish nobility, chiefly at the instigation of the great chancellor, Jan Zamorski, elected Bátory king of Poland (1575) in opposition to the emperor Maximilian, the candidate of the senate. On hearing of his altogether unexpected elevation, Bátory summoned the Transylvanian estates together at Medgyes and persuaded them to elect his brother Christopher prince in his stead; then hastening to Cracow, he accepted the crown of Poland. In 1574 he was elected by the Diet of Poland to the Polish crown. He was married in 1575 to the princess Anna, the elderly sister of the last Jagiello, Sigismund II., and on the 1st of May was crowned with unprecedented magnificence. At first his position was extremely difficult; but the sudden death of the emperor Maximilian at the very moment when that potentate, in league with the Muscovite, was about to invade Poland, completely changed the face of things, and though Stephen's distrust of the Habsburgs remained invincible, he consented at last to enter into a defensive alliance with the empire which was carried through by the papal nuncio on his return to Rome in 1578. The leading events of this hazardous reign are twofold. By the act of 1576, the Diet of Poland, continuing the treaty of 1574; in 1582, he was elected to the state Senate, and in the following year, on the Whig ticket, to the National House of Representatives. In this last body he urged the annexation of Texas, chiefly as a means of achieving more power for the South in Congress. He was denounced as a traitor to his party because of his support of annexation, but he later became the leader of the Whig opposition to the war with Mexico. He vigorously supported the Compromise Measures in 1830, and continued to act with the Whigs of the North until they, in 1852, nominated General Winfield Scott for the presidency without Scott's endorsement of the Compromise. Stephens and other Whigs of the South then chose Daniel Webster, but a little later they joined the Democrats. In 1854 Stephens helped to secure the passage of the Kansas-Nebraska Bill. Before the Georgia legislature in November 1860, and again in that state's secession convention in January 1861, he strongly opposed secession, but when Georgia seceded he "followed his state," assisted in forming the new government, and was elected vice-president of the Confederate States. He greatly weakened the position of the Confederacy by a speech delivered at Savannah (March 21, 1861) in which he declared that slavery was its corner-stone. Throughout the war, too, he was so intensely concerned about states' rights and civil liberty that he opposed the exercise of
extra-constitutional war powers by President Jefferson Davis lost the freedom for which the South was fighting should be destroyed. His policy was to preserve constitutional government in the South and strengthen the anti-war party in the North by convincing it that the Lincoln administration had abandoned such government; to the same end he urged, in 1864, the unconditional discharge of Federal prisoners in the South. Stephens headed the Confederate committee at the peace conference at Hampton Roads in February 1865. In the following May, after the fall of the Confederacy, he was arrested at his home and taken to Fort Warren, in Boston harbor, where he was confined until the 12th of October.

He accepted the result of the war as a practical settlement of the question of secession, exercised a beneficent influence on the negroes of his section, and promoted reconciliation between the North and the South. In 1866 he was elected to the United States Senate, but was not permitted to take his seat. He was a representative in Congress, however, from 1873 to 1882, and was governor of Georgia in 1882–1883, dying in office, at Atlanta, on the 4th of March 1883. He was remarkable for both his moral and physical courage, and in politics was notable for his coolness of judgment. The last years of his life were occupied by the editing of the Atlanta Daily Sun, and he published A Constitutional View of the Late War between the States (2 vols., 1860–1869), which became the best statement of the Southern position with reference to state sovereignty and secession; The Reviewers Reviewed (1872), a supplement to the preceding work; and A Compendium of the History of the United States (1875; new ed., 1883).

STEPPHENS, JOHN LLOYD (1805–1859), American traveller, was born on the 28th of November 1805, at Shrewsbury, New Jersey. Having been admitted to the bar, he practised for about eight years in New York City. In 1834, the state of his health rendering it advisable that he should travel, he visited Europe, and for two years made a tour through many countries of that Continent, extending his travels to Egypt and Syria. On his return to New York he published in 1837 (under the name of "George Stephens") Incidents of Travel in Egypt, Arabia Petræa, and the Persian Gulf, which was followed next year by the publication of Incidents of Travel in Greece, Turkey, Russia and Poland. In 1839 Stephens arranged with Frederick Catherwood of London, who had accompanied him on some of his travels, and illustrated the above-mentioned publications, to make an exploration in Central America, with a view to discovering and examining the antiquities said to exist there. Stephens, meantime, was appointed to a mission to Central America. The joint travels of Stephens and Catherwood occupied some eight months in 1839 and 1840. As the result of these researches Stephens published in 1841 Incidents of Travels in Central America, Chiapas and Yucatan. In the autumn of 1841 the two travellers made a second exploration of Yucatan, and a work followed in 1843—Incidents of Travel in Yucatan. This work describes the most extensive travels executed till that date by a stranger in the peninsula, and, as the author claims, "contains account of visits to forty-four ruined cities or places in which remains or vestiges of ancient populations were found."

It enjoyed a wide popularity, and Stephens was urged to prosecute his researches of American antiquities in Peru, but was disinclined to so distant an expedition. He became a director of the newly formed American Steam Navigation Company, which established the first American line of transatlantic steamships. He visited Panama to reconnoitre the ground with a view to the construction of a railway across the isthmus, and, first as vice-president and then as president of the Panama Railway Company, spent the greater part of two years in superintending the project. His health was, however, undermined by exposure to the climate of Central America, and he died at New York on the 10th of October 1852.
STEPHENSON, R.—STEPNIAK

STEPPENWOLF, new by eastern very version from Stepney's Domesday app. used entered Newcastle-on-Tyne, few London, liberal science classes at the university of Edinburgh. On his return he assisted his father in surveying the Stockton & Darlington and Liverpool & Manchester lines, but in 1824 he accepted an engagement in South America to take charge of the engineering operations of the Colombian Mining Association of London. On account of the difficulties of the situation he resigned it in 1827, and returned to England via New York in company with Richard Trevithick, whom he met in a peniless condition at Cartagena. He then undertook the management of his father's factory in Newcastle, and greatly aided him in the improvement of the locomotives. His practice was not confined to his own country, but extended also to Sweden, Denmark, Belgium, Switzerland, Piedmont and Egypt. In this connexion his most remarkable achievements were his railway bridges, especially those of the tubular girder type. Among his more notable examples are the Royal Border bridge at Berwick-on-Tweed, the High Level bridge at Newcastle-on-Tyne, the Britannia tubular bridge over the Menai Straits, the Conway tubular bridge, and the Victoria tubular bridge over the St Lawrence at Montreal. In 1847 he entered the House of Commons as a member for Whitby, retaining the seat till the end of his life. In 1855 he was elected president of the Institution of Civil Engineers, of which he became a member in 1830. He died in London on the 12th of October 1859, and was buried in Westminster Abbey.

STEPNEY, GEORGE (1663–1707), English poet and diplomatist, son of George Stepney, groom of the chamber to Charles II., was born at Westminster in 1663. He was appointed a scholar of Trinity College, Cambridge, becoming a fellow of his college in 1687. Through his friend Charles Montagu, afterwards earl of Halifax, he entered the diplomatic service, and in 1692 was sent as envoy to Brandenburg. He represented William III. at various other German courts, and in 1702 was sent to Vienna, where he had already acted as envoy in 1693. In 1705 Prince Eugène desired his withdrawal on the ground of his alleged partiality to the Hungarian insurgents, but the demand was taken back at the request of Marlborough, who had great confidence in Stepney. He was, nevertheless, removed in 1706 to the Hague. In the next year he returned to England in the hope of recovering from a severe illness, but died in Chelsea, London, on the 15th of September 1707, and was buried in Westminster Abbey. Stepney had a very full and accurate knowledge of German affairs, and was an excellent letter-writer. Among his correspondents was Baron Leibnitz, with whom he was on the friendliest terms. Much of his official and other correspondence is preserved in the letters and papers of Sir John Ellis (Brit. Mus. Add. MSS. 28875–28947), purchased from the earl of Macclesfield in 1871, and other parts are available in the record office. He contributed a version of the eighth satire of Juvenal to the translation (1693) of the satires by "Mr Dryden and several other eminent hands." Dr Johnson, who included him in his Lives of the Poets, called him a "very licentious translator," and remarked that he did not "recompense his neglect of the author by beauties of his own."

STEPNEY, an eastern metropolitan borough of London, England, bounded N. by Bethnal Green, E. by Poplar, S. by the river Thames, and W. by the City of London and Shoreditch. Pop. (1901), 298,600. It forms part of the "East End" of London; the parish, indeed, formerly covered practically the whole area so termed. Here are squalid streets and mean houses typical of the poorest class of inhabitants. The thoroughfares of Mile End Road and Whitechapel Road and that of Commercial Road East traverse the borough from the east and converge near the City boundary, where stood the ancient Aldgate. In the north Stepney includes the districts of Spitalfields, Whitechapel and Mile End; and in the south Wapping, Shadwell, Ratcliff and Limehouse. The southern districts are occupied by sailors and labourers in the St Katherine and London Docks and the wharves and factories lining the river-bank. The parish churches of St Dunstan, Stepney, St John's, Stepney Causeway, and much restored, containing many monuments and curious inscriptions. The church of St Anne, Limehouse (1730) is by Nicholas Hawksmoor. The district of Spitalfields has an old association with the silk-weaving industry; a trade in singing birds is also characteristic of this district; and in Ratcliff the well-known naturalist's farm of Jamrach is situated. In the extreme west the borough includes within its bounds the historic Tower of London, the Royal Mint and the fine Tower Bridge over the Thames. There is no bridge below this, but the construction of the Rotherhithe Tunnel was authorized, and this channel is used by the East London railway. Among institutions the principal is the People's Palace, Mile End Road, opened by Queen Victoria in 1887 as a place of intellectual and physical recreation and education. The Drapers' Company contributed largely to the cost of erection. Toynbee Hall, Commercial Street, was founded in 1884 under the trusteeship of the Universities Settlements Association and named after Arnold Toynbee (d. 1883), a philanthropist who devoted himself to work in this part of London. Other institutions are the London Hospital, Whitechapel, the East London children's hospital, the head-quarters of Dr Barnardo's Homes, Stepney Causeway, and Her Majesty's Hospital for waifs connected therewith; the Stepney training college of the Society for Promoting Christian Knowledge, and the Spitalfields trade and technical school. There is a fish market in Shadwell, and a vegetable market in Spitalfields. Stepney is a suffragan bishopric in the diocese of London. The municipal borough comprises the Stepney, Whitechapel, Mile End, Limehouse and St George divisions of the Tower Hamlets parliamentary borough, each division returning one member. The borough council consists of a mayor, 10 aldermen, and 60 councillors. Act 1765. His sympathetic nature was influenced by indignation against the brutal methods adopted
towards prisoners, especially political prisoners, and by the stern measures which the government of the tsar felt compelled to adopt in order to repress the revolutionary movement. His indignation carried him into accord for a time with those who advocated the terrorist policy. In consequence he exposed himself to danger by remaining in Russia, and in 1886 he was obliged to leave the country. He settled for a short time in Switzerland, then a favourite resort of revolutionary leaders, and after a few years came to London. He was already known in England by his book, *Underground Russia*, which had been published in London in 1882. He followed it up with a number of other works on the condition of the Russian peasantry, on Nihilism, and on the conditions of life in Russia. His mind gradually turned from belief in the efficacy of violent measures to the acceptance of constitutional methods; and in his last book, *King Stork and King Log*, he spoke with approval of the efforts of politicians on the Liberal side to effect, by argument and peaceful agitation, a change in the attitude of the Russian government towards various reforms. Stepiak constantly wrote and lectured, both in Great Britain and the United States, in support of his views, and his energy, added to the interest of his personality, won him many friends. He was chiefly identified with the Socialists in England and the Social Demo- cratic parties on the Continent; but he was regarded by men of all opinions as an agitator whose motives had always been pure. To the last, the railways he introduced a railway engine at a level crossing at Bedford Park, Chiswick, where he resided, on the 23rd of December 1893. He was cremated at Woking on the 28th of December. (H. H. F.)

STEPE (from the Russ. *stepi*, a waste), the name given to the level treeless plains in certain parts of the Russian Empire, and thence sometimes, though not commonly, extended, in physical geography, to signify similar plains elsewhere. The name is most commonly applied specifically to the plains in the south and south-east of European Russia and in the south-west of Asia, and in this connexion the term connotes semi-desert conditions. Otherwise the Russian steppe may be considered as kindred to and connected with the *Heiden* (heaths) of northern Germany.

STEPPE, GENERAL-GOVERNORSHIP OF, a portion of Russian Central Asia which includes both what was formerly known as the Kirghiz Stepe, and the region around Omsk, which was formerly part of Western Siberia. It consists of four provinces: Akmolinsk, Sempalakhsir, Turgai and Uralaks, having a total area of 711,000 sq. m. and a total population of 2,472,931 in 1897. Details are given under the names of the above-mentioned provinces.

STEREOBATE (Gr. στερεός, solid, and βάσεσ, a base), the term in architecture given to the substructure of rough masonry of a Greek temple.

STEREOCHEMISTRY (Gr. στερεός, solid, and χημία, chemistry), a branch of chemistry which considers the spatial arrangement of the atoms composing a molecule (see STEREO-ISOMERISM).

STEREO-ISOMERISM, or STEREOISOMERISM, a term introduced by Victor Meyer (by way of his denomination stereo-chemistry for "chemistry in space") to denote those cases of isomerism, i.e. "differences in the way of the association of atoms" resulting in molecular differences. These isomers are termed stereoisomeric or stereo-isomeric compounds, and are molecular formulas where we are forced to admit the same atomic linking and can only ascribe the existing difference to the different relative position of atoms in the molecule.

Historical.—Considerations concerning the relative position of atoms have been traced back as far as Swedenborg (1721); in more recent times the first proposal in this direction seems to have been due to E. Paternò (1856), followed by Auguste Rosenstiehl and by Alexis Gaudin (1873). The step made by J. A. Le Bel and J. H. van't Hoff (1874) brought considerations of this kind into the reach of experimental test, and so led to stereochemistry. The work of Louis Pasteur on molecular asymmetry in tartaric acid (1860) touched stereochemistry so neatly that, had structural chemistry been sufficiently developed then, stereochemistry might have originated fourteen years earlier; it happened, however, that Wislicenus's investigation of lactic acids (1860) immediately stimulated Van't Hoff's views. The fundamental conceptions of Le Bel and Van't Hoff differ in that the former are based on Pasteur's notions of molecular asymmetry, the latter on structural chemistry, especially as developed by August Kekulé for aliphatic carbon atoms. Both seem to lead to the same conclusions as to stereo-isomerism, but the latter has the advantage of allowing a more detailed insight, whereas the former, which is free from hypothetical conceptions, is of absolute reliability.

As our knowledge of stereo-isomerism originated in the chemistry of carbon compounds and found the largest development there, this part will be treated first.

Stereoisomerism in Carbon Compounds.

1. The Asymmetric Carbon Atom.—Though stereo-chemistry is based on the notion of atoms, there is not the least danger that it may break down when newer notions about those atoms are introduced. Even admitting that they are of a compound nature, i.e. built up from smaller electrical particles or anything else and able to split up under given conditions, their average lapse of existence is long enough to consider them as reliable building-stones of the molecule, though these building-stones may give way now and then, as our best ordinary ones by the action of an earthquake. Another thing which stereo-chemistry abstracts beforehand is the movement of atoms, which is generally accepted to exist, but becoming less as the temperature sinks and disappearing at absolute zero. And so the following symbols, representing atoms in a fixed position, may correspond to these last circumstances, whereas at ordinary temperatures atoms may vibrate, for instance, with these fixed positions as centres.

The first development from structural to stereo-chemistry was to consider the relative position of atoms in methane, CH₄. Structural chemistry had proved that the four atoms of hydrogen were linked to carbon and not to each other, thus C—H and not, for example, H—H—C—H. But how the four were grouped remained to be decided.

The decision is derived as follows:

If the four hydrogen atoms are supposed to be in a plane on one side of the carbon atom as above, two methylchlorides CH₂Cl should be possible, viz.:

\[
\begin{align*}
C & \quad H \\
H & \quad H
\end{align*}
\]

Such isomeric compounds have never been found, but they appear as the four CH₃ (or groups of 1 atoms) which carbon is combined are different, for example in CH₂ClBr, in CH₂BrCl, in CH₂Br₂, in CHCl₂Br, and in CHCl₃, while CH₄ has only one isomeric compound, i.e. methane. Then and only then two isomeric compounds have been regularly observed, and the sole notion about relative position of atoms of methane which explains this is that the four groups combined with carbon are placed at the summits of a tetrahedron whose centre is formed by carbon. The two possibilities are then represented by:—

![Fig. 1](image-url)

These groupings have the character of enantiomorphism, i.e. they are non-identical mirror images. If any of the two differences in the summits is given up, for example, F substituted by Cl with the formation of CH₂ClBr, the enantiomorphism disappears.

The isomerism corresponding to this difference in relative position is the simplest case of stereo-isomerism. The carbon atom in the special condition described, linked to four different atoms or groups, is denominated "asymmetric carbon," and will be denoted in the following formulae as C. Stereo-isomerism exists in tartaric acid, HO₂CH(OH)-CH(OH)-CO₂H (studied by Pasteur), in the lactic acid, CH₃-CH(OH)-CO₂H (studied by Wislicenus), while the simplest case at present known is the chlorobromomurolactic acid, C₂Cl-Br-F-CO₂H, obtained by Schwartz. This stereo-isomerism, due to the presence of asymmetric carbon, is of a characteristic kind, which is in perfect accordance with the theory of its origin, being the most complete identity combined with the difference that exists between the left and right hand. All the properties which
STEREO-ISOMERISM

cannot differ in this last sense: are identical, viz.: melting and boiling points, &c. But the so-called "enantiomorphism," which some have called "optical antipodes," indeed shows this difference in the isomers in question; and especially the behavior (in the amorphous state) towards polarized light differs in the sense that the plane of polarization is turned to the left by the one isomer, and exactly as much to the right by the other, so that they may be termed "optical antipodes." All these differences disappear with the asymmetric carbon, and the succinic acid, H(C-OH)-C(OH)-H, from tartaric acid is optically inactive and shows no stereoisomerism.

2. Compounds with more than one Asymmetric Carbon Atom.

Stereo-isomerism and the space relation of atoms in compounds with higher asymmetry can best be developed by aid of graphical representations, founded on the notion of space relations in ethane, H2C=CH2. A consequence of the tetrahedral grouping in methane is the configuration given in fig. 3, where the six hydrogen atoms are distributed by six atoms or groups R1, R2, R3, R4, R5, R6. The second (above) carbon atom is supplied to be at the top of the lower tetrahedron, and vice versa. Each other position, obtained by turning R1R2R3 around the C-C axis, is also possible, but since no second, due to this difference of relative position, which might already show itself in ethane, has been observed, we may admit that one of the positions obtained by the above rotation is the stable one, and fig. 3 may represent it.

For simplicity's sake this figure may be projected on a plane by moving R5 and R6 respectively upward and downward, with R3R5 and R4R6 as axes, which leads to the first of the two stereoisomers possible in the above case. They differ in the two possible spatial arrangements of R3R5R6 and R4R5R6:

As one asymmetric carbon introduces two stereoisomers and two introduce four, n asymmetric carbon atoms will lead to 2^n isomers. They are grouped in pairs presenting enantiomorphous figures in space, as do the first and the last of the above symbols, which correspond to the character of optical antipodes, whereas the second and third correspond to greater differences in melting points, &c. A well-studied example is offered by the dibromides of cinnamic acid, C6H5-CBr2-CBr-CO2H. They have been obtained by Liebermann in two antipodes melting at 92°, and two other antipodes, differing in optical rotation from the first, and melting at 195°.

A simplification is introduced when the structural formula shows symmetry, as is the case in R1R2R3C=C-R3R5. The four above-mentioned symbols then are reduced to three:

of which the first and last show the enantiomorphism corresponding to the character of optical antipodes, while the second shows symmetry and corresponds to an inactive type. A well-studied example is offered here by tartaric acid: the two antipodes, often denoted as d and l, have been found, viz. in the ordinary dextrogyre form and the laevoform, prepared by Pasteur from racemic acid, while the third corresponds to mesotartaric acid; such internally compensated compounds are generally termed "meso."

3. Cyclic Compounds. — Three or more carbon atoms may link together so as to produce ring systems such as

It is in these cases that the principle of the asymmetric carbon, which in the above case leads to 2^n stereoisomers, is easily applied by means of graphical representations in a plane, deduced from the space relation shown in fig. 4. The six groups, R1, R2, R3, R4, R5, R6, are either under or above the plane in which the carbon ring is supposed to be situated, and this may be indicated by the following symbol:—

where the carbon atoms are supposed half-way between R1 and R2, R3 and R4, R5 and R6.

One of the most simple examples is offered by the trimethylene-dicarboxylic acids

HOC-CH2-C=CH2 CO2H

for which three formulae can be deduced:

The first, where the carboxyl groups -CO2H lie on the same side of the carbon ring, called, as Von Baeyer proposed, the cis-form, the others trans-forms. The trans-forms show enantiomorphism and correspond to optical antipodes, whereas the first symbolic figure may be considered as corresponding to mesotartaric acid, symmetrical in configuration and inactive; this third stereo-isomer has also been met with.

Attention has been given to those ring systems of the general form:

This transform corresponds to a cis-form, where both R1 and R2 are on the same side of the plane containing the ring. These latter are enantiomorphic in the ordinary sense of the word, but the particular feature is that the trans-form, though offering no plane of symmetry, is yet identical with its mirror image, and thus not enantiomorphic and not corresponding to optical antipodes but to the meso-form.

There correspondences have been realized by Emil Fischer in derivatives of alanine; H4C=CH(NH2)2-CO2H, which exists in two antipodes d and l. Two of these molecules can be combined to alanyl-alanine: H4C=CH-NH2-CO2H-NH2-C=CH2-CO2H, which, as containing asymmetric carbons, may be had in four stereo-isomers dd, dl, ld, and ll. In their anhydrides

we meet the above type, and find that dd and ll formed the predicted antipodes, while the anhydride of dl and ld is one and the same substance, without any optical activity. Such cases are often termed "pseudo-asymmetric."

4. Isolation of Optical Antipodes. — The optical antipodes are often found as natural products, as is the case with the ordinary d- or l-tartaric acid; generally only one of the two forms appears, the second form (and, more generally both forms) being obtained synthetically. This is a problem of particular acid character, since the artificial production of a compound with asymmetric carbon, from another which has no asymmetric carbon, always produces the two antipodes in equal quantity, and these antipodes, by their identity in most properties, e.g. melting and boiling point, solubility, and also on account of their analogous chemical behaviour, cannot be separated by customary methods, the application of which is rendered still more difficult by the formation of a so-called racemic compound.

The method called "spontaneous separation" was first observed by Pasteur with racemic acid, which in its double sodium and ammonium salt crystallized from its aqueous solution in two antipodes, which were separated on examination. One of the two proved to be the ordinary sodium-ammonium-tartrate, the other its laevogyre antipode; thus l-tartaric acid was discovered, and racemic acid proved to be a combination of d- and l-tartaric acid. The further examination of this particular transformation showed that it had a definite temperature limit. Only below 27° is Pasteur's observation corroborated, while above 27° a racemate appears; these changes are due to a chemical action taking place at the given temperature between the solid salts:

one molecule of the d- and one of the l-tartrate forming above 27°, the racemate with loss of water, while under 27° the opposite change occurs. This temperature limit, generally called transition-point, was discovered by Van't Hoff and Van Deventer. It is the limit where the possibility of spontaneous separation begins, and is relatively rare, so that this way of separation is an exceptional one, most antipodes forming a racemic compound stable at all temperatures that come into question.

The use of optically active compounds in separating antipodes
is of the greatest value. The general principle is that the compounds which the d- and l- forms give with a different active compound, for instance d producing dd and ld, are by no means antipodes and so exhibit the ordinary differences, e.g. in solubility, which allow separation. It was in this way that Pasteur, for example, separated by cinchonine. This method has since been applied to the most various acids; bases may be split in an analogous way; artificial cocaine was separated by Ladenburg by means of d- tartaric acid, and one of the antipodes proved to be identical with natural cocaine. Aldehydes and ketones on the other hand may be split up by their combinations with an active hydrazine, &c., and so this method is by far the most fruitful.

The formation of a racemic compound built up from dd and ld has also been observed in the so-called partial raceme. An example is the racemate of styrchnine. It is in this case also that the transition-point forms the limit of possible separation, determined by Ladenburg and G. Doctor to be 36°. Such partial racemic combination however occurs only in exceptional cases, else it would have invalidated this method, as it did spontaneous separation.

A different way of using active compounds in producing antipodes consists in the so-called asymmetric synthesis. The method consists in the introduction of an active complex before that of the asymmetric carbon; both stereo-isomers need not then form in the same quantity. W. Marchwali and A. McKenzie, who chiefly worked out this method, found, for example, that the salt of methylmalonic acid, C(CH₃)₂COH₂, with the active brucine forms on heating the corresponding salt of d- and l-methylmalonic acid C(H₂)₂COH₂, with the l-antipode in slight excess.

5. **Configuration of Stereo-isomers.**—The conception of asymmetric carbon not only opens the possibility of determining when and how many stereo-isomers are to be expected, but split up racemic acid insight into the relative position of atoms in each of them. The chief indication here lies in the configuration of the meso-type, already given for mesotartaric acid; the corresponding alcohol, the natural sugar erythrite, which produces this acid by oxidation, consequently corresponds to

\[
\text{CHOH} \\
\text{H-C-OH} \\
\text{H-C-OH} \\
\text{CHOH}
\]

In the glutaric acids, H₂O₂-C-(CH₂-OH), the structural symmetry again leads to meso-forms

\[
\text{OHOH} \quad \text{OH H OH} \\
\text{HO-C-} \quad \text{HO-C-H} \quad \text{HO-C-} \quad \text{HO-C-H}.
\]

They are respectively obtained by the oxidation of ribose and natural xylose, stereo-isomers of the formula COH(CH(OH)₃)CH₂OH; the latter produces active tartaric acid and so decides that the second formula is that of the corresponding trioxylutaric acid, the first remaining for that obtained from ribose.

In such and analogous ways the configuration of meso-types may be fixed with absolute certainty. The decision is more difficult in the case of antipodes. For tartaric acid it is certain that the d- and l-forms correspond to

\[
\begin{align*}
\text{COH} & \quad \text{COH} \\
\text{HOCH} & \quad \text{HOCH} \\
\text{COH} & \quad \text{COH},
\end{align*}
\]

but which of the two represents the ordinary d-acid is unknown. Emil Fischer proposed to decide provisionally in an arbitrary way and admit for the d- the first formula. Then we may conclude that the natural malic acid, which is obtained by the reduction of l-tartaric acid, is

\[
\begin{align*}
\text{COH} & \quad \text{H-C-H} \\
\text{CH₂} & \\
\text{HOCH} & \\
\text{COH} & \\
\text{COH},
\end{align*}
\]

while the natural xylose, which produces l-tartaric acid by the substitution of COH for CHO-CH₂OH, corresponds to

\[
\begin{align*}
\text{CHO} & \quad \text{CHO} \\
\text{HOCH} & \quad \text{HOCH} \\
\text{HOCH} & \quad \text{HOCH} \\
\text{CHOH} & .
\end{align*}
\]

The results obtained in these and analogous ways have proved to be of value in the study of enzymes, e.g. complex organic substances aszymate in yeast, which is able to produce in small quantity an unproportioned large amount of chemical change, in the case of the transformation of the sugar glucose, C₆H₁₂O₆, into alcohol and carbonic acid

\[
\text{C₆H₁₂O₆} = \text{C₂H₅OH} + 2\text{CO₂}.
\]

These enzymes have an extremely specific action, producing, for instance, the change in ordinary natural glucose, but not at all in its artificial antipode. The question of how they are so valuable means of isolating an antipode from the inactive mixtures or racemic compounds; this method has indeed been used for the isolation of the glucose-antipode from the artificial racemic form. The fundamental fact here is due only more to Pasteur, but Emil Fischer added that sugars are acted upon by zymase in an analogous way if their configuration shows a certain amount of identity. For example yeast acts on

\[
\begin{align*}
\text{d-Glucose} & \quad \text{d-Mannose} \quad \text{d-Fructose} \\
\text{HCO} & \quad \text{HCO} \quad \text{HCO} \\
\text{HCOH} & \quad \text{HCOH} \quad \text{HCOH} \\
\text{HCOH} & \quad \text{HCOH} \quad \text{HCOH} \\
\text{HOCH} & \quad \text{HOCH} \quad \text{HOCH}
\end{align*}
\]

and we observe that the three forms act indeed in the lower four-carbon chain. This particular behaviour led Fischer to the expression that the enzyme-action on given substances needs a corresponding feature as "lock and key." There are indications that in the synthesis by enzymes, of which examples have been realized in fats, sugars, glucosides and albuminoids, an analogous basis prevails.

6. **Mutual Transformation of Antipodes.**—Thus far we have supposed the molecule to be stable at stable places, as may be the case at absolute zero; in reality, at ordinary temperatures, atoms probably are endowed with movement, and this may be supposed to take place along the fixed places just mentioned as centres, which movement can go so far as to lead to total transformation, the one stereo-isomer changing over into the other. These changes may be considered now.

As a general rule the liquid, gaseous or dissolved antipode is in itself unstable, tending to be transformed into inactive complexes. Temperature may accelerate this, and, as a rule, sufficient heat will produce the loss of optical activity, half of the original compound having changed over into its optical antipode. This transformation has been often used for preparing the latter; as was first done by Le Bel with the optically active amyl alcohol, H(C₃H₇)(OH)₃(CHOH), rendering it inactive by sufficient heating, and separating from the obtained complex the stereo-isaner. Walden found that in some cases analogous transformations take place at ordinary temperature, for instance with d-phenylbromocetic acid, which within three years totally lost its considerable rotative power; this transformation has been termed "automerization." It explains that till now the most simple compounds as many organic acid have not yet been obtained in antipodes; active CH₂CBr₂ might be obtained by treating chlorobromomfluoracetic acid with potash, but automerization, which especially shows itself when halogenen are linked to the asymmetric carbon, might, without special precautions, lead to an inactive mixture of antipodes.

When two asymmetric carbons are present, four stereo-isomers are possible, which may be represented by

\[
\begin{align*}
1 \quad \text{A} + \text{B}, & \quad (\text{A} + \text{B}) \\
2 \quad (\text{A} - \text{B}), & \quad (\text{A} - \text{B}), \\
3 \quad (\text{A} - \text{B}), & \quad (\text{A} - \text{B}), \\
4 \quad (\text{A} - \text{B}), & \quad (\text{A} - \text{B}),
\end{align*}
\]

(1) and (2), as well as (3) and (4), being antipodes. The stable form will be in this case also the inactive mixture, corresponding in the solid state either to (1), (2), (3) or (4). In the last case, suppose the primitive compound (4), the first step towards stability may be the production of (3), so that practically one stereo-isomer changes over into another of a different type. Such has, for instance, been proved by Bechmann for L-methyl,
7. Doubly-Linked Carbon Atoms.—When carbon atoms are doubly linked, as in derivatives of ethylene, H₂C₂H₄, the two tetrahedra representing the four groups around each carbon may be supposed to have two summits combined, as was supposed with one in simple linking. Fig. 5 represents this supposition, from which follows that the six atoms in question are situated in a plane and may be represented by a plane figure:

\[
\begin{align*}
R₁-C & -R₂ \\
R₁-R₂ & \\
R₃-C & -R₄
\end{align*}
\]

The chief consequence is that as soon as the two atoms or groups attached to each carbon are different, two stereo-isomers may be looked for:

\[
\begin{align*}
R₁-C & -R₂ \\
R₁-R₂ & \\
R₃-C & -R₄
\end{align*}
\]

Such has been found to be the case, fumaric and maleic acids, H-C-CO₂H

\[
\begin{align*}
H₂C & -C & -H₂ \\
H₂C-C & -O₂H
\end{align*}
\]

forming the oldest and one of the most simple examples; the simplest is α-chloropropylene (H₃C)CH₂C₂H₃C₂H₃.

The nature of this stereo-isomerism is quite different from that in antipodes. There is no enantiomorphism in the supposed configurations, and so no rotatory power, &c., in the corresponding compounds, which, on the other hand, show differences far deeper than antipodes do, having different melting points, solubility, heat of formation, chemical properties, &c., behaving in these as ordinary isomers.

7. Numerical Value of Optical Rotation.—To express the value of optical rotation either specific or molecular rotation may be chosen, the first being the deviation caused by a layer of 1 decimetre in length when the substance in question is supposed with specific gravity 1, the latter is this value multiplied by one-hundredth of the molecular weight. Specific rotation is indicated by \([α]_D\), where the suffix indicates the wave-length of the light in question, D being that of the sodium line, and \(T\) the temperature; \([M]\) is the corresponding value of molecular rotation. Both values vary with the solvent used, and probably are most adapted to solve problems touching relations of rotatory power and configuration, when they apply to extreme dilution in the same liquid.

The most general rules, relating to rotatory power, is that for electrolytes, i.e., salts in aqueous solution, viz. the limiting rotation in dilute solution only depends on the active radicle. Oudemans found that for such active bases as quinine in its salts with hydrochloric, nitric, chloric, acetic, formic, sulphuric, oxalic, phosphoric, perchloric acids the specific rotation (calculated for the base) only varies from \(-272^\circ\) to \(-288^\circ\); H. L. Landolt found the same thing for active acids, the mono lithium, sodium, potassium and ammonium tartrates varying only between 27.5° and 28.9° (calculated for the acid). A corresponding rule may be expected where both base and acid have rotatory power; the molecular rotation will be the sum of those for base and acid and for salts with inactive radicles. Each of these rules finds sufficient explanation in Arrhenius’s view of electrolytic dissociation, which admits that diluted electrolytes are split up in their ions, and so the salts of quinine (Ω) owe their rotatory power to the ion ΩH, those of acid tartrates to the ion ΩH₂CO₂H, and quinine-tartrate to both.

With non-electrolytes relations are less evident. One general observation is that non-saturation, especially cyclic structure, augments the rotatory power. The saturated compounds, hydrocarbons, starches, sugars, ethers, amines and acids rarely show specific rotations higher than \(10^\circ\), and some of them, as mannite, CH₂OH(CH(OH))₂CH₂OH, for instance, show such small values that only a more thorough investigation, due to the theoretical probability of rotatory powers in asymmetric natural products, has detected the optical activity.

Unsaturated compounds generally show larger rotatory powers; amyl alcohol with \(-5^\circ\) produces an aldehyde with \(15^\circ\); sucineic (diyl) ether with \(9^\circ\) produces fumaric ether with \(15^\circ\). Cyclic configuration especially leads to the highest values known: the lactic acid with \(3^\circ\) leads to a lactone with \(-86^\circ\);

\[
H₃C-C₂H₂-CO₂H
\]

mammosearctic acid, H₂O(C₂H₂O₂)₂H₂O, to a dilactone (with two rings, formed by the loss of two molecules of water) with \(202^\circ\), whereas the original acid only shows a small rotation.

A second conception, which connects rotation with configuration in non-electrolytes, is due to Alexander Crum Brown and P. A. Guye. It starts from the supposition that, as rotatory power is due to the difference of the four groups around the asymmetric carbon, so its amount may correspond to the amount in this. So, generally speaking, take some property, denoted by \(K₁, \ldots, K₄\) respectively, a function:

\[
(K₁-K₄)(K₁-K₄)(K₂-K₄)(K₃-K₄)(K₄-K₄)
\]

would express what is wanted. It becomes zero when two groups are equal; it changes its sign, retaining its value, when \(K₄\) is interchanged with \(K₃\) and \(K₂\). The chief difficulty in application is to point out that property which is here dominating. It has been supposed to be weight, and then the above expression divided by \((K₁+K₂+K₃+K₄)/4\) might be proportional to specific rotation. This explains, for instance, that in the homologous series of glycric ethers

\[
H₂O-C₂H₂-O₂H
\]

augments the heaviest group, \(CO₂R\), first augments the specific rotation, which then passes through a minimum (the theoretical limit being zero).

Ether of methyl, ethyl, propyl, butyl, hexyl, octyl, \(\[\alpha\]_D = -4.8^\circ\), \(-9.2^\circ\), \(-12.9^\circ\), \(-13.2^\circ\), \(-11.3^\circ\), \(-10.2^\circ\).

But the serious objection is met that groups of equal weight and different structure often allow considerable rotatory power as in methyl and propylglycerides, \(-146^\circ\), though the formula \(\text{C}_₃\text{H}_₅\text{H}(\text{OH})\text{C}_₃\text{H}_₄\text{CO}_₂\text{H}\) the third and fourth groups are of equal weight. It is in this way especially that other properties might be tested, such as volume or density, and perhaps qualities related to light, such as refractive power and the dielectric constant. Attempts to connect the rotatory power of a compound with more asymmetric carbons to the action of each of these separately, i.e., by the so-called optical superposition have not been very successful. In the four stereo-isomeric acids \(\text{C}_₄\text{H}_₄\text{HO}_₂\text{H}_₂\text{CO}_₂\text{H}\) of the following configurations

\[
\begin{align*}
\text{C}_₂\text{H}_₅ & -\text{H} & -\text{OH} \\
\text{C}_₂\text{H}_₆ & -\text{OH} & -\text{H} \\
\text{C}_₂\text{H}_₇ & -\text{H} & -\text{OH} \\
\text{C}_₂\text{H}_₈ & -\text{OH} & -\text{H}
\end{align*}
\]

H₂O

l-α-tartronic, d-α-tartronic, dl-α-tartronic, d-α-tartronic, acid, acid, acid, acid.

We might suppose the upper asymmetric carbon to produce a rotation \(+\alpha\) or \(-\alpha\), the other \(B\) and \(C\). The rotations then were \(A - B + C\). A + B + C = A - B + C = 0 zero in total. This supposition is in so far related to that of Crum Brown and Guye that it admits that the smallest conceivable change, i.e., stereo-isomeric change, in one group does not influence the rotation caused by the fourth asymmetric carbon attached to it. It has not been tested in this case, but substances as propyl- and isopropyl-glycerate only differ in specific rotation from \(-12.9^\circ\) to
Stereo-Isomerism

Stereo-isomerism in Other Elements.

Phenomena analogous to those observed in carbon compounds might also exist in derivatives of other quadrivalent elements; and only the relative stability of carbon-compounds makes every form of isomer, which often is unstable, more easily observable in organic chemistry. Nevertheless it has been possible to obtain stereo-isomers with different elements, but, as expected from the above, especially in derivatives containing carbon. Some of them take the character of optical antipodes and are more easily considered from a theoretical point of view; others have not.

1. **Optically Active Stereo-isomers.**—Most closely related to the phenomena with carbon are those with sulphur, selenium, tellurium, and silicon, when these elements behave as quadrivalent. S. Smiles (Journ. Chem. Soc., 1900, 77, pp. 1072, 1174; 1903, 87, p. 450) split up such derivatives of methylthiolethene as

\[
\text{CH}_3\text{CH}_2\text{CO}_2\text{H}
\]

obtained by condensing methyl sulphide with o-bromocresolphenone, by means of the salt with d-bromocamphorsulphonic acid, into optical antipodes.

W. J. Pope and A. Neville (Journ. Chem. Soc., 1902, 18, p. 198) succeeded in the same way with a stearic acid compound

\[
\text{H}_3\text{C}_\text{Br} \quad \text{H}_3\text{C}_\text{CO}_2\text{H}
\]

\[
\text{H}_3\text{C}_\text{Sn} \quad \text{H}_3\text{C}_\text{I}
\]

Kipping (Journ. Chem. Soc., 1904, 20, p. 15; 1907, 23, p. 9) with one of silicon (benzylbipropyl silicid)

\[
\text{H}_3\text{Si} \quad \text{H}_3\text{C}_\text{OH}
\]

These facts may be explained in the same way as with carbon, by admitting tetrahedral grouping. A special feature, however, wanting with carbon, is that compounds with one atom only of the element in question have been observed as antipodes. A second observation of some interest is that the compounds in question are electrolytes and that, as in solutions, where they are split up into ions, activity must be due to the last, the ionic complex, for instance, R_2R_3R_4R_5S, must cause optical rotation.

Optical antipodes have also been obtained with quinquevalent nitrogen in compounds of the type: R_2R_3R_4RN. Le Bel observed these in methylphosphyl-isobutylammonium chloride; since then Pope and Peachey and Wedekind studied the same question more thoroughly, and as a general result it is now stated that ammonium compounds with four different radicals behave as asymmetric carbon compounds. The explanation may be that the four radicals arrange themselves in the two possible tetrahedral configurations, and that the fifth element or group, e.g. chlorine or hydroxyl, more loosely linked, finds its fittest place, as shown in figs. 7 and 8.

2. **Stereo-isomers Without Optical Activity.**—The chief cases here belong to the derivatives of nitrogen with double linking and the metallic compounds which have been chiefly studied by Werner.

The nitrogen compounds showing stereo-isomerism belong to two classes, according to the structural formulae, containing N_2 or N_4; in their general behaviour they seem related to the ethylene derivatives.

The first group was detected by Victor Meyer and Goldschmidt in

\[
\text{C}_2\text{H}_5\text{C}_\text{NOH}
\]

benzilidoxime:

\[
\text{C}_2\text{H}_4\text{C}_\text{NOH}
\]

Later investigations, especially by Hantzsch, showed that a grouping

\[
\text{R}_2\text{C}-\text{R}_4
\]

gives rise to stereo-isomerism, the supposed difference being that X is either more close to R_2 or to R_4. This peculiarity is observed in the aldoximes and ketoximes, derived from aldehydes and ketones on treatment with hydroxylamine, and in the two simplest examples of methylene oxide NH_2=NOH, and phenylmethylene-ketoxime, (C_6H_5=CH_2)NH=NOH. As the behaviour of these stereo-isomers much resembles that of ethylene-compounds, they are often indicated as cis- and trans-forms.

The second stereo-isomerism in nitrogen-compounds was detected by Schraube in potassium benzenedinitratoxide, and may perhaps be reproduced by the following symbols:

\[
\text{C}_2\text{H}_4\text{N} \quad \text{KON} \quad \text{NOK}
\]

The last group of stereo-isomers, in which insight is most difficult yet, is that of Werner's complex metallic compounds, observed with cobalt, platinum and chromium. No enantiomorphous character throws light here, and there is no relation to ethylene derivatives.

With cobalt the fact is that in the hexammoniacal cobalt salts, e.g. Co(NH_3)_6Cl_2, when NH_3 is substituted by NO_2 isomerism appears as soon as the number of substituents is two; Jörgensen's flavo-salts Co(NH_3)_4(NO_2)_2Cl_2 and Gibso's isomeric croce-salts offer examples.

Werner puts forward that a grouping of (NH_3)_4 at the summits of a regular octahedron around Co may explain this.
Platinum compounds such as \((\text{H}_2\text{N})_2\text{PtCl}_6\) have been obtained in two forms, Werner admitting here the following plane configurations:

\[
\begin{align*}
\text{Cl}_2\text{PtCl}_4, \\
\text{Cl}_2\text{PtCl}_4\text{NH}_3, \\
\text{H}_2\text{N}\text{PtCl}_4, \\
\text{H}_2\text{N}\text{PtCl}_4\text{NCl}\end{align*}
\]

Chromium shows a behavior analogous to that of cobalt, and analogous space-formulae may be used here. But, in a general way, at present it is extremely difficult to decide upon their value.

**STEREOSCOPE** (Gr. ἀποτρεπός, solid, σκόπεω, to see). The fundamental property of stereoscopic vision, or simultaneous vision with both eyes, is the direct perception of the relative distances of near objects. Of course, ideas of the different distances of objects also occur in vision with a single eye, but these are the result of other experiences and considerations. These representations are also not always unequivocal (see fig. 1). For instance they may arise from the former knowledge of the shape and size of a distant object, from the partial covering of one object by another; and they very often occur where stereoscopic observation fails; this latter is involuntary, i.e. the observer is unconscious of it. We will now investigate the conditions necessary for the perception of depth.

If the head is held still only one portion of space can be observed stereoscopically. The single eye, when moved, surveys, including indirect vision, a field which measures 180° in a horizontal direction, and 135° in a vertical direction. The two fields overlap and a smaller conical space is formed, with the nose as vertex (B V S in fig. 2), in which both eyes can see simultaneously; and outside this space stereoscopic vision is impossible. The shape and size of this space are very different in men and animals. According to Armin Tachemak the horizontal extent of the space surveyed with both eyes is only 3° in a rabbit as compared with 90° in man, 15° in a fowl and about 5° in a carp (measured in water). There is a further difference between the eyes of men and animals. The optic axis of the eye is the line joining the centres of the curves, but the direction in which the eye can see most clearly does not always coincide with this, being determined by the spot on the retina which is most susceptible to light, the so-called yellow spot (*Poin* F in fig. 2). In man this spot is still near the axis, although not always exactly on it. It is not perfectly known how it may be used in animals, but in many the axes of the eyes diverge (especially strongly in geese), and the portions of the retina utilized in stereoscopic vision lie far distant from the axis, as in many animals the eyes are only slightly movable.

Every time that the eyes are directed on one spot (F in fig. 2) this point is seen simply, together with a number of other points which together form the so-called "horopter." According to Joh. Müller, Helmholtz, Hering, Volkmann and others, these are those points of the object-space (e.g. Q and R in fig. 2), whose images fall on identical or corresponding spots on the retina, by which are meant those points on the retina whose nerve filaments are united and which are equidistant in the same direction from the centre of the yellow spot (see Eye; Vision). The horopter varies according to the position of the fixed spot in the object-space; for example, it is the ground itself for a man standing erect and looking straight ahead. All object-points situated outside the horopter fall on points of the retina which are not identical, but the two images are only seen as real double images in exceptional cases. As a rule the effect is that these points are also seen simply, but at other distances than that of the fixed point P. The differences of the images arise in the moving of the image-points in the direction of the connecting line of the two eyes. For this reason the eyes cannot recognize the space between parallel shining telegraph wires if the connecting line of the two eyes be parallel to the wires, whilst the perception of the depth occurs involuntarily if the connecting line of the eyes is more or less perpendicular to the wires. These differences of images which have been mentioned are therefore necessary and are sufficient for the perception of depth. The explanation that the perception of depth was due to a difference between the two retinal images was first given by Ch. Wheatstone in 1833; but it was contradicted by E. Brücke (1841), Sir David Brewster (1843) and others, who stated that when observing an object the angle of convergence of the axes of the eyes continually changed, and through this and also by the exertion of the muscles and the accommodation of the eye there was a simultaneous touching of the object, which gave rise to the perception of its depth. This latter theory, however, was contradicted by H. W. Dove, who showed that a stereoscopic viewing was also possible with momentary illumination of the object; and still less does it agree with the
STEREOSCOPE

fact, to which Wheatstone first called attention, that facsimiles also have a stereoscopic influence, in spite of the fact that the images retain their position on the retina unchanged. Numerous experiments show the same result, and it follows that even a change of the angle of convergence is not always observed as a change of depth.

There are two kinds of stereoscopic vision, direct and indirect, according to whether the point seen indirectly, e.g. H in fig. 3, is compared with the fixed point P, or with another point seen indirectly, e.g. J in fig. 3. In both kinds of stereoscopic vision the exactness of the observation of the depth is greater as the point J approaches H, and the point H approaches P. As a matter of fact a man's eyes are naturally never perfectly still. They move in their sockets, and the point P, where the axes intersect, is continually changing. Direct stereoscopic vision arises from indirect stereoscopic vision and vice versa, and the accuracy of the discernment of the depth increases and decreases. As in this the eye does not revolve round its lens but round the centre of the sphere situated 10 mm. behind it, the entrance-pupil of the eye moves slightly to and fro and up and down, and many experiments have been made to produce a perception of depth for a single eye from the relative movements of the images consequent on this motion. As these movements of the images only occur in indirect vision, it can be understood they are not seen by most people. This, however, cannot be regarded as an actual perception of depth, because these views necessitate a consideration for each individual interpretation, which is quite foreign to stereoscopic vision.

Indirect stereoscopic vision is of great importance. It makes it possible to recognize any sudden danger or obstacle outside the direction in which one is looking. Even with the stereotelegraph (see below) the position of the range through which, for example, a bird flies, could not always be accurately given, if one were solely dependent upon direct stereoscopic vision. If the attention and eyes are directed upon a certain object, as, for instance, in manual labour and in measuring the imagespace with the so-called "travelling mark" on the stereocomparator, then direct stereoscopic vision only is concerned.

Stereoscopic vision is in many ways similar to the monocular observation of a preparation under the microscope, and yet there is a great difference. In an unchanged focused microscope it cannot be distinguished which of the indistinct objects are above and which are below the plane focused for.

In stereoscopic vision, however, this can be seen directly. How does this happen? Why does the point H in fig. 3 appear behind and the point V in front of the point P when both eyes are fixed on the point P?

As is shown in fig. 3 the image-points on both sides lie further apart for H or nearer together for V than the image-points for P, and for all the points on the horopter (O, R, S, T &c.), whether the points H and V are situated inside or outside the horopter. In other words, if the point H be formed in the object-space by the movement of the related point H' from the image-point that takes place in the right eye (or the left) in both eyes in the direction of the nose, so long as the point H is outside the horopter. On the contrary an external movement of the image-point, i.e. towards the temples, takes place when the points S and W are substituted by the point V situated inside the horopter. This differentiation of the retinal images of the points H and V respectively inside and outside the horopter must suffice, and the question as to how the idea of space is conveyed to the brain is a physiological and psychological subject.

If the images of the line PH in both eyes (or of the line PV) are very different in length, the double images of the point H (or V) are seen without great attention. But the stereoscopic effects are in these cases always the same as before. There is, however, an exception in which the observer sees only two images and in which stereoscopic vision is completely excluded. This exception is important because it occurs in the space in the immediate proximity of P. If, for example the second point (H' in fig. 3) is situated behind or in front of the point P, so that it falls between the two optical axes or on one of them, then only double images can be seen, either of P or of H', according to whether the optic axis cuts at P or H', or double images of both points if the optic axes intersect at any other point of the line PH, but the representation of the difference of depth of the two points P and H' is never obtained.

This fact can be easily realized if a stick, e.g. a lead pencil, be held before the eyes of an observer with good stereoscopic sight so that its linewise axis falls exactly on a point between the eyes or in the middle of one of the two eyes. The double images can be seen still more clearly if two small balls on thin threads are suspended behind one another so that their connecting line really falls as mentioned above. In this experiment it can be seen directly how inconvenient these double images are to the observer. He involuntarily tries to evade them by moving the head. The reason for this is that, when P (or H') is fixed, the images of H' (or P) are always separated from one another by the centre of the yellow spot. The distances of the two images from the yellow spot have consequently opposite signs, whilst for all other objects (e.g. H) which lie outside the two axes the distances have the same sign. The direction of the sign is, however, not alone decisive, for if the connecting line PH' is moved a little higher or lower out of the plane PFP the signs remain different, but the stereoscopic effect is immediately regained.

Therefore in all cases in which the connecting line PH' is seen with one eye as a point and with the other as a line, or with both eyes as a line, but from two diametrically opposite sides, there is no stereoscopic effect, but double images are seen; and that stereoscopic observation it is essential to see the connecting line PH' with both eyes simultaneously from one and the same side, from above or below, from the left or the right. This condition is provided for in the stereotonometer by the arrangement of a zigzag measuring scale, so that the connecting-line of the marks slightly ascends. Care must be taken when using this instrument (as also when using any stereoscopic measuring instrument) that the index hangs close to or above the object to be measured, so that the latter is only touched and in no way covered by the mark.

The power of perception of depth in man is most accurate. This has been ascertained by the approximately equal keenness of vision of all normal-sighted people and by the interpupillary distance. The angle which serves as a measure for the keenness of vision is that under which appear two neighbouring points of the object-space which are still seen by the single eye as a double point; according to the older experiments of Helmholtz, this angle is about 1'. When measured on the retina the keenness of vision is determined by the diameter of the nerve filaments situated in straight rows close to one another in the fovea (fig. 4). The diameter of these filaments amounts to roughly 0.005 mm., or in angular measure 1'. More recent experiments for keenness of vision and power of perception of depth have given considerably higher values (Wulffing, Pulfrich, Heine and others); thus Pulfrich in 1899, when first introducing
STEREOSCOPE

stereoscopic instruments for measuring distance, proved that as a rule persons with normal eyes have a power of perception of depth of 10° and still less in unrestricted vision. This is explained as follows (Hering, Heine):

It is unimportant for perception where the filament mentioned above is illuminated. In order to see two objects lying close to one another it is not essential that the two image-points should be separated from one another by the distance of the two nerve filaments of the eyes. This happens whenever the line separating two objects passes through the two points (see fig. 4). It is natural that the perception of depth has no fixed limits, for the position of the images shown in fig. 4 changes with the movement of the eyeball, and the closer the two points are to one another, the more rarely it occurs. If the angle of convergence of the optic axes $\Delta$; the (average) distance between the eyes $B=65$ mm., $\delta=\frac{1}{2}$ (the perception of depth easily attained by normal sight) and $E=\overline{B}$ the normal distance of the point P from B in fig. 2, then from $E/B=\Delta$, the change of depth $E$ gives:

$$dE = B/\Delta = E/\delta = E/\delta/B.$$

If the angle $\Delta$ has the value $\delta$ then all perception of depth ceases. At this distance objects are only still distinguishable from those lying behind them, which together form a surface but cannot always be seen as a surface because our representations of the depths of distant objects are not conclusively controlled by stereoscopic sight. This distance is called the radius of the stereoscopic field, and is calculated by the formula $R = B/\delta$, whence $R=430$ metres. From the above formulae it can be directly seen that the variation $dE$ increases with $E$, and the proportional variation $dE/E$ increases with $E$. The numerical values can be easily calculated when either $\Delta$ or $E$ is given thus:

$$dE/E = 1/\Delta \text{ or } dE/E = E/R.$$

The limits of stereoscopic vision defined above can be extended and under the name of "stereoscope" every binocular instrument is included which serves this end. Those instruments should first be mentioned which have restored the more or less lost power of stereoscopic vision. It is necessary for those with normal sight to wear spectacles when the eyes cease to accommodate themselves to objects near at hand. Spectacles which only cover the lower half of the eye and leave the upper

FIG. 4.

half free to look out into space are the best. For those who have been operated on for cataract, and for excessively shortsighted persons, the "telescope-spectacles" devised by M. v. Rohr (of Zeiss, Jena) are a great assistance. There are two methods of extending the limits of stereoscopic vision and of increasing the accuracy of the perception of depth. (1) by augmenting the keenness of sight by the aid of a telescope or microscope, and (2) by increasing the interpupillary distance by several reflections after the plan shown by Helmholtz in his mirror stereoscope (1857) (see fig. 3). When binocular telescopes and microscopes are used, erect images are formed when the two instruments are contiguous. If this is not the case, the order of depth is reversed and the same false or pseudo-images are formed as when the pictures in a stereoscopic view are interchanged or a correctly combined stereoscopic picture is observed in a so-called pseudo-stereoscope. If, however, in this case the axes of both instruments intersect in front of the eyes, then reversed pictures are obtained, but the correct order of depth is recovered.

Telescope magnification ($m$ times) and base magnification ($n$ times) bring the radius $R$ of the stereoscopic field to $m$ or $n$ times respectively the value above given, and if both are simultaneously active to $mn$ times. The errors for a certain distance $E$ are accordingly reduced to $1/mn$. Of course these expedients do not increase the capability of the observer, but the values of the convergence angle $\Delta$ and $\delta$ in the object-space are different. It is therefore quite natural that the three-dimensional images, which appear in the binocular vision-space of the observer, vary with reference to their dimensions and the distance of the separate parts from each other. In this respect the action of the base magnification is fundamentally different from that of the telescope magnification. Both bring the objects $m$ or $n$ times respectively nearer to the observer, but in the first case the areal dimensions are diminished in the same proportion as the distances are lessened, whilst in the other case the real dimensions remain unchanged. In the first case the three-dimensional image is a model proportionately diminished in all its dimensions and brought nearer to the observer; in the other case the objects appear pushed together to the front like the wings of a theatre. The remark made in Helmholtz's Physiological Optics that when $m=n$ the three-dimensional image would look like the object seen without any instrument at a distance of $1/m$ is consequently not correct. What is remarkable is that this observation, to which as a so-called "Helmholtz rule" great importance was for a long while attached, and to a certain extent still is, does not correctly express the views of Helmholtz, which he states very clearly in his earlier essay on the tele-stereoscope, and which agree with the explanation here given.

Spectacles and binocular telescopes were the first binocular instruments (see Binocular Instruments). The latter with chromatic lenses had already been constructed in the 17th and 18th centuries. The Dutch double-telescope (opera-glasses), which were almost exclusively used up to the 'nineties of the 19th century, were introduced in the 'thirties by Fr. Voigtländer. The binocular microscope appeared in the early 'fifties. The introduction of the Porro prism (four reflections with passage of the rays reversed and lateral transposition of the rays) by Abbe in 1803 was of great importance for the binocular telescope and microscope. It led to the construction of the prism field-glasses and other telescopes which, in comparison with the Galileo binocular telescopes till then in use, not only had a considerably increased perception of depth but also a substantially larger field of vision. Similariy by inserting the Porro inverting system between the eyepiece and the objective, the binocular microscope constructed by H. S. Greenough and S. Czapski was produced. Recently binocular glasses (after Fritsch and Zeiss) have come into use for slight magnifications, in which, following the example given by Wenham (1853), the interpupillary distance and the angle of convergence are diminished by four reflections (twice reversed as in fig. 5). All of the instruments mentioned above are used exclusively for the observation of three-dimensional objects with two eyes. Wheatstone (1838) first showed that the same spatial impression could be produced by two views of the object taken

FIG. 6.

XXV. 29
STEREOSCOPE

from two different points and be called the instrument a stereoscope. Let us imagine in fig. 6 a plane F', F" between the two eyes A and A', and the points H, V in the object-space and on the plane the perspective projections of P, H and V produced towards A and A', as, for example, by photographing on the plates F' and F" with objectives O' and O at A and A', then the object can be taken away to equal to that of the projection, the same spatial effect as when observing the object itself. The change of accommodation of the eye which, however, has no influence on the power of perception of depth, is excluded, and a further difficulty (according to L. Oppel, 1854) is that in unrestricted vision the image-points not situated on the yellow spot undergo slight displacement in consequence of the difference of the position of the pupil and of the centre of rotation of the eye, which is taken as the centre of projection. This can in no way be imitated in the pictures. In order to obtain a stereoscopic effect from such pictures apparatus is not always necessary. When the pictures L and R in fig. 6 are at a distance equal to that of the eye, the stereoscopic effect can be obtained by observing them when the optical axes of the eyes are parallel, and if the pictures are interchanged, when the axes intersect. The second of these methods, which were discovered by Wheatstone, was later widely used for the stereoscopic observation of large wall pictures.

The 1852 model of the Wheatstone stereoscope is shown diagrammatically in fig. 7. This differs from the original model in that the pictures L and R can be placed at different inclinations to the mirrors s1 and s2 and at different distances from them in order to observe the pictures under exactly the same inclination of the image and the same angle of convergence as when the picture was taken. Photographs with a large base line and converging axes were often taken (in Germany first by L. Moser). This mirror stereoscope had no practical result worth mentioning on account of its awkward shape and of the difficulty in obtaining equal illumination of both pictures. It was also inconvenient that the pictures had to be placed separately and reversed in the apparatus. These difficulties are for the greater part avoided in the L. Pigeon (Nancy, 1895) new mirror-stereoscope for large pictures, which can be purchased in book form. Fig. 8 shows diagrammatically the arrangement by which one picture is seen direct and the other in a mirror (H. W. Dove, Sir David Brewster and W. Rollmann). The disadvantage attached to this, that the picture observed in the mirror must be reversed, can according to Puifrick be obviated by rotating the correct picture through 180°.

In its own plane and placing it in the position of the picture L and by using a so-called roof-prism in the place of the mirror.

Incorrect stereoscopic effects easily arise when using pictures. If for instance the distance of a picture from the centre of projection is different at the time of observation from what it was when the photograph was taken (see fig. 9), objects appear to the stereoscope, much in relief or too flat even in monocular vision, just as when looking first through the objective of a telescope and then through the eyepiece. An excellent example is provided by the stereoscopic observation of the moon, first performed by Warren de la Rue (1858) to show that the three-dimensional image is modified by altering the angle of convergence and by placing the pictures obliquely. If the pictures obtained with converging axes are placed further apart on the same plane, the stereoscopic image of the moon has the shape of an egg; this, however, immediately disappears and changes into an approximate sphere, if the picture be broken in the middle and both sides bent around, as, by Warren de la Rue, in a Wheatstone stereoscope under exactly the same conditions as when the photographs were taken, the impression of a sphere is obtained.

M. von Rohr (Die binocularen Instrumente, 1907) drew attention to the optics of the older stereoscopists and in particular to the works of Wheatstone, and it is to be regretted that so little notice was taken of these older works during the recent development of most binocular instruments. It would, however, be erroneous to demand that the above-mentioned conditions for the observation of three-dimensional images should always be considered. This is impossible, for example, in the stereocomparator in which the three-dimensional image is only seen in portions, and never all at once. Neither does it concern stereoscopic measuring instruments, and it is a curious coincidence that the stereoplanigraph (see fig. 13) constructed after Wheatstone’s stereoscope, and correct as to the so-called orthomorph of the three-dimensional image, was of no use as a measuring instrument.

A lens-stereoscope invented in 1849 by Sir David Brewster and constructed by J. Duboscq is very largely used. The causes of its success were its convenient form and the fact that a series of adjusted stereoscopic pictures (landscapes, machines, etc.) could be observed in rapid succession. The Brewster stereoscope, by making an easy observation of stereoscopic pictures possible when the distance between identical points on both pictures was considerably greater than that between the observer’s eyes, supported, to a certain extent the inclination of photographers not to detract from the pictures. If the lenses shown in fig. 10, on the focal plane of which the stereoscopic image is formed, are large enough, and the distance between the image-points h1 and h2 is not greater than the distance between the centres of the two lenses (avoiding the divergence of the axes of the eyes), then the distance between the eyes is secondary and the observer sees the distant points with the axes of the eyes parallel. These apparent advantages, however, are counteracted by the defect that the picture seen through the lenses is eccentric, and consequently an incorrect impression of the picture is obtained, and an alternation in the three-dimensional image occurs.

Wheatstone showed later in his controversy with Brewster that this disadvantage in the lens-stereoscope could be avoided by adjusting the lenses and distant points to the distance between the observer’s eyes. This same condition was fulfilled in the "double-verant" constructed by v. Rohr and A. Köhler (1905).
STEREOSCOPE

in which the lenses, in accordance with A. Gallstrand's rule, are so arranged that the centre of rotation of the eye always coincides with the nodal point of the lenses. If every one had the same interpupillary distance there would be nothing more perfect than this stereoscope.

If in fig. 6 the two pictures L and R are interchanged in both pictures (a or b in fig. 11), then the image-points for H are clearer together than those for V; thus in stereoscopic vision H appears in front of P, and V behind R. No change is made to the relief by turning the picture upside down (c and d in fig. 11). In fig. 11d, the pictures are in the same positions as when the photographs are taken (F₁, F₂ in fig. 6). Obviously transparent pictures can be easily reversed; in other cases it must be effected by mirrors (Whewellstone, Dove and others) or by an erecting reflection prism. The original unbroken plate (fig. 11b) can be seen in the pseudo-stereoscope shown in fig. 12, and the correct relief is obtained if it is rotated about the connecting line of the two pictures before placing in the stereoscope. If a symmetrical body be observed in the pseudo-stereoscope, for example a pyramid, the relief is still reversed. But if a prism be dispensed with the object appears flat, and a plane drawing appears in relief.

These pseudo-stereoscopic phenomena are of the greatest importance for the study of the principles of stereoscopy, for they demonstrate that the perception of depth can be aided by a direct presentation and hindered by a reverse presentation, a plate of the dolomites, for example, with a large base line, arranged as in 11a and 11b is taken, and the apparatus and the eyes are directed upwards, then the pseudomorphic image in space looks like the roof of a stalactite cave. On the other hand, when arranged as 11c and 11d the image appears correctly represented, but it is a little more difficult to see the horizon in the foreground of the pseudomorph. The difference can only be most easily seen to the physiologically interesting phenomena of colour-tones, which are a result of the chromatism of the eye and occur in monocular and binocular vision (Dove and, more recently, A. Brückner).

A comparatively simple solution to the problem of putting pictures seen in a stereoscope in motion is provided in the muoscope for a single observer. The other problem—to make one stereoscopic picture visible to several people simultaneously—can be met in various ways, more simply (according to Rollmann 1853) and D'Almeida (1855) by portraying the two stereoscopic pictures in different colours one over the other, and giving each observer spectacles of different coloured glass for each eye, with which it is only possible to see one picture with each eye. Another method suggested by L. Anderton (1891), in which polarization and a Nicol prism must be used to separate the pictures, has met with little success, and F. E. Ives's novel proposal (1903) to separate the pictures when being taken and also observed by a ruled grating placed immediately in front of the photographic plate is not practicable. A method devised by W. J. Bruckner (1900) involves an apparatus, which depended upon the alternate visibility of the two pictures, demands a mechanism for each observer, exactly synchronous with the intermittent illumination. This principle was successfully adopted by J. Mackenzie Davidson and H. Bos (1900) for a direct stereoscopic observation of Röntgen radiographs. Immediately after the discovery of the Röntgen rays in 1895, E. Mach made stereoscopic investigations of these radiographs.

The development of stereoscopy has in no way been uniform; on the contrary, a long period, during which practically no interest was taken in stereoscopy or stereoscopic phenomena, was preceded during the middle part of the 19th century by a period of universal interest. The reason for this was not so much the realization of the defects of the stereoscopes in themselves, and the trivial manner in which they were put on the market, as, for example, a closing stereoscope containing conjunctive, as the fact that the public did not know how to make use of the pictures seen in the stereoscope. This state of affairs was altered when Zéll, of Jena, as a result of the investigations of A. Abbe and C. Pulfrich, succeeded in constructing apparatus which made it possible to measure the three-dimensional images.

The stereometer, constructed after H. de Grousilliers' idea, appeared in 1890. This is a double telescope with the distance between the objectives increased, and a number of rows of marks placed in the plane of the image which appear as real objects floating at fixed distances above the landscape, from which the distances of the objects in the view can be easily read. In 1903 Pulfrich devised a method of stereoscopic measurement which is specially interesting from a physiological point of view, but which can only be employed for isolated objects, such as beacons, signals, &c. This method has the peculiarity that no marks are necessary for the measurement. The binocular telescope is so arranged that it always produces two three-dimensional images of the object which is to be measured close to one another, which as a rule are seen as though they were at different distances and of different sizes. The measurement is made by causing the difference of relief of the two images to disappear either by bringing the instrument nearer to the object or by readjusting the apparatus. The equal size of the two three-dimensional images can be regarded as a criterion of their equal distances; and it is of further advantage to the method that the images to be compared are equal as to definition and colour.

A consequence of these instruments, which are chiefly important for military surveying, was the Pulfrich stereocomparator devised in 1901. The stereoscopic measuring machine invented by H. G. Paracade of Capetown (1902) is similar to this in many points. These instruments inaugurated the successful measurement of the distances of distant objects and the uses of stereoscopy were consequently increased. Measurement is not made of the objects themselves, but on photographic plates which are taken with special instruments—field- and stand-phototheodolites—at the extremities of a baseline which is always selected according to the distance of the object.
adjured, by moving the plates perpendicular to one another and by
altering the distance of the plates from one another, this so-called
"travelling mark" can be placed on any point of the landscape,
and then used for the measurement of solidity of the objects, or
the production of plans and models, just as formerly, for
example, the measuring staff was used for geodetic observations,
with the difference that in the stereocomparator the mark is regu-
lated by the observer only and is not hindered in its movements
by any undulations, &c., of the land.

Fig. 13 shows how the lateral movement of the mark m is trans-
fomed in a movement towards and away from the observer in
the three-dimensional image M. Fig. 14 shows the theory of
measuring a stereophotograph. The axes are horizontal when the
photograph is taken, and the plates are in one plane. It
shows the method of calculating the position of the point P in
the object-space from the co-ordinates z_1 and z_2 of image-point
on the left plate and the so-called parallel axis a = z_1 - z_2;
the last is constant for all points in the vertical plane GO
through P at right angles to M.O. The two microscopes in
fig. 14 really produce erect pictures, and the two plates are so
placed in the stereocomparator as to be seen from P1' and P2'.

The use of the stereocomparator is unlimited for the measure-
ment of relief. It is extended similarly to all objects and
phenomena, large and small, distant and near, in motion or
stationary, to those which retain their shape for a long
period or which are constantly changing, or to those which
are only visible for a short time. For a large number of experi-
ments of this sort—mountain photography (Von Hbbl, &c.),
coastal measurements, photographing a battle from a ship,
generating, study of the waves (Kohlschütter, Laas), the trajectory
of a shot (Neuffer, Krupp, Niesen), the use in building railways
or on voyages of discovery, &c.—the stereocomparator has
new fields being constantly opened up for it. A further
advance has been made in the stereophotogrammetric method
by providing the stereocomparator with a drawing apparatus
(F. V. Thomson, E. v. Orel and Carl

The stereocomparator has also been employed in astrometry,
and a planetoid discovered by its aid was named Stereoscopia
in recognition of this application. Since 1904 binocular
observation of stellar plates to determine differences in the
images of the objects reproduced has been gradually discarded
for the method devised by Puflich, which consists in the
monocular observation of the two plates in the stereocomparator
with the assistance of the so-called "blink" microscope (fig. 15).
In this microscope the two pictures are seen simultaneously,
or individually by alternately opening the screens B_1 and B_2.
In the second case all differences of the two images
are immediately distinguished by a sudden oscillation of
the image-point or by a sudden appearance and disappear-
ance of single points like flash lights at sea or the modern
illuminated sky lights in towns, and there is now no merit in
discovering new planets, comets and variable stars by this
method.

The "blink" microscope is far more useful than the stereomicro-
scope for such purposes, for there is not one special direction in
which differences can be best distinguished. It is better there-
fore for the stereo method to be restricted to the work for which
it is specially suitable, and for which it will never be replaced,
and for such experiments as we have just discussed to be solely
performed with the aid of the blink microscope.

(St. P.)

STERLING, ANTOINETTE (d. 1904), Anglo-American vocalist,
was born at Sterlingville, New York state. She studied with
Mme Marchesi, with Mme Viardot Garcia and with Manuel
Garcia, and after singing for two years in America came
in 1875 to England, where she made her first appearance at
Covent Garden under Sir Julius Benedict and rapidly became
a popular favourite among the contraltos of the day. She
gained her greatest successes as a ballad-singer, especially in
such songs as "Call Her Linn," "The Three Fishers" and "The
Lost Chord." She was a woman of deep religious feeling and
many enthusiasms, and her name was constantly associated
with philanthropic enterprise. She died on the 16th of January
1904. In 1875 she had married Mr John Mackinlay, and her
life was written by her son, Mr Sterling Mackinlay, in 1906.
STERLING, JOHN (1806-1844), British author, was born at Kames Castle in Bute on the 20th of July 1806. He belonged to a family of Scottish origin which had settled in Ireland during the Cromwellian period. His father, Edward Sterling (1773-1847), had been called to the Irish bar, but, having fought as a militia captain at Vinegar Hill, afterwards volunteered with his company into the line. On the breaking up of his regiment he went to Scotland and took to farming at Kames Castle. In 1804 he married Helen Coningham. In 1810 the family removed to Llandeithian, Glamorganshire, and during his residence there Edward Sterling, under the signature of "Vetus," contributed a number of letters to The Times, which were reprinted in 1812, and a second series in 1814. In the latter year he removed to Paris, but on the escape of Napoleon from Elba in 1815 took up his residence in London, obtaining a position on the staff of The Times newspaper; and during the late years of Thomas Barnes's administration he was practically editor. His fiery, emphatic and oracular mode of writing conferred those characteristics on The Times which were recognized in the sobriquet of the "Thunderer." John Sterling was his second son, the elder being Colonel Sir Anthony Coningham Sterling (1805-1871), who besides serving in the Crimea and as military secretary to Lord Clyde during the Indian Mutiny, was the author of The Highland Brigade in the Crimea and other books. After studying for one year at the university of Glasgow, John Sterling in 1824 entered Trinity College, Cambridge, where he had for tutor Julius Charles Hare. At Cambridge he took a distinguished part in the debates of the union, and became a member of the "Apostles'" Club, forming friendships with Frederick Denison Maurice and Richard Trench. He removed to Trinity Hall with the intention of graduating in law, but left the university without taking a degree. During the next four years he resided chiefly in London, employing himself actively in literature and making a number of literary friends. With Maurice he purchased the Athenaeum in 1828 from J. Silk Buckingham, but the enterprise was not a pecuniary success. He also formed an intimacy with the Spanish revolutionist General Torrijos, in whose unfortunate expedition he took an active interest. But he did not accompany it, as he was kept in England by his marriage to Susannah, daughter of Lieut.-General Barton. Shortly after his marriage in 1830 symptoms of pulmonary disease appeared which made him take up his residence in Duplin, the county of St Vincent, where he had inherited some property, and he remained there fifteen months before returning to England. After spending some time on the Continent in June 1834 he was ordained and became curate at Hurstmonceaux, where his old tutor Julius Hare was vicar. Acting on the advice of his physician he resigned his clerical duties in the following February, but, according to Carlyle, the primary cause was a divergence from the opinions of the Church. There remained to him the "resource of the pen," but, having to "live all the rest of his days as in continual flight for his very existence," his literary achievements were necessarily fragmentary. He published in 1833 Arthur Cominigby, a novel, which attracted little attention, and his Poems (1839), the Election, a Poem (1841), and Strafford, a tragedy (1843), were not more successful. He had, however, established a connexion in 1837 with Blackwood's Magazine, to which he contributed a variety of papers and several tales of extraordinary promise not fulfilled in his more considerable undertakings. Among these papers were "The Onyx Ring" and "The Palace of Morgann." He died at Ventnor on the 18th of September 1844, his wife having died in the preceding year.

His son, Major-General John B. Sterling (b. 1849), after entering the navy, went into the army, and had a distinguished career (wounded at Tel-el-Kebir in 1882), both as a soldier and as a writer on military subjects.

John Sterling's papers were entrusted to the joint care of Thomas Carlyle and Archiblen Hare. Essays and Tales, by J. Sterling, collected and edited, with a memoir of his life, by Julius Charles Hare, appeared in 1848 in two volumes. So dissatisfied was Carlyle with the memoir that he resolved to give his own "testimony" about his friend, and his vivid Life (1854) has perpetuated the memory of Sterling more than any of the latter's own writings.

STERLING, a city of Whiteside county, Illinois, U.S.A., on the north bank of Rock river, 109 m. by rail W. of Chicago. Pop. (1900), 6309, of whom 815 were foreign-born and 23 were negroes; (1910), 7467. Sterling is served by the Chicago & Northwestern and the Chicago, Burlington & Quincy railways, and by inter-urban electric railway to Dixon, 12 m. N. N.W. Across the river is Rock Falls (pop. in 1900, 2176), practically a suburb of Sterling, with foundries and machine-shops and manufactories of agricultural implements, barbed wire and bolts and rivets. Three bridges cross the river. The river is tapped here by the feeder of the Illinois & Michigan Canal, so that there is direct water communication with Chicago and St Louis. Two great dams on the river (one built by the Federal government) provide good water power. The public library (1878) had 12,000 volumes in 1910. In the city are large ironworks, and numerous other manufactures. Sterling was formed in 1839 by the consolidation of two towns, Harrisburg and Chatham, founded here in 1836 and 1837 respectively; it was chartered as a city in 1857.

STERLING, a term, arc a unit for denote the weight or quality, especially applied to the English gold sovereign, and hence with the general meaning of recognized worth or authority, genuine, of approved excellence. The word has been generally derived from the name of "Easterlings" given to the North German merchants who came to England in the reign of Edward I., and formed a hansa or gild in London, modelled on the earlier one of the merchants of Cologne. Their coins were of uniform weight and excellence (cf. Matthew Paris, ann. 1247, moneta esterlingorum, proper sui materiem desiderabili, &c.), and it is supposed gave the name of the money to a coinage of recognized fineness. This theory is based on the statement of Walter de Pinchbeck, a monk of the time of Edward I., "sed moneta Angliae fertur dicta fuisse a nominibus opificum, ut Floreni a nominibus Florentiorum, ita Sterlingi a nominibus Esterlingorum nomina sua contraxerunt, qui hujusmodi monetae in Anglia primitus componebant." (quoted in Wedgwood, Dict. of Eng. Etym.). The word, however, occurs much earlier. The Roman de Rou (1180) has "Pour ses estellins recevoir," and in Anglia unus Sterlingis per solvetur occurs in an ordinance of Philip of France and Henry II. of England of 1184. It is curiously the same as in Cange (1180) motory de stelh. "Ster- ling" was a coin, the silver penny, 240 of which went to the "pound sterling" of silver of 5760 grains, 925 fine, and described in a statute of Edward I., quoted in Du Cange, as "Dennarius Angliae qui vocatur Sterlingus." The word was borrowed by all European languages and applied to the English coin and to coins in general of a standard quality; thus we find not only O. Fr. estorlin or estellin but M. H. G. sterlin or steerlein, Ital. sterlino, &c. It would seem therefore that the term was applied to a coin of recognized quality before the North German merchants were established in London and that its origin should be found in a native English word. Two suggestions have been made; one that it represents an O. Eng. steering, i.e. little star, from a device on an early coin, such as is found on some of William II., or O. Eng. steering, starling, from the birds, which however may be doves, on the coins of Edward the Confessor. (See Du Cange, Gloss. s.v. Esterlingus; and Skeat, Etym. Dict. 1910, s.v. Sterling.)

STERNBERG, a town of Austria, in Moravia, 73 m. N.E. of Brünn by rail. Pop. (1900), 15,195, almost exclusively German. It is the chief seat of the Moravian cotton industry, and it also carries on the manufacture of linen, stockings, linen, sugar and bricks. Fruit, especially cherries, and tobacco are also grown in the neighbourhood. Sternberg is said to have grown up under the shelter of a castle founded by Yaroslav of Sternberg on the site of his victory over the Mongols in 1241.

STERNE, LAURENCE (1713-1768), English humorist, was the son of Roger Sterne, an English officer, and great-grandson of an archbishop of York. Nearly all our information about the first forty-six years of his life before he became famous as the author of Tristram Shandy is derived from a short memoir...
STERNE, LAURENCE

jotted down by himself for the use of his daughter. It gives nothing but the barest facts, excepting three anecdotes about his infancy, his school days and his marriage. He was born at Clonmel, Ireland, on the 24th of November 1713, a few days after the arrival of his father's regiment from Dunkirk. The regiment was then disbanded, but very soon after re-established, and for two years the boy and his mother moved from place to place after the regiment, from England to Ireland, and from one part of Ireland to another. The familiarity thus acquired with military life and character stood Sterne in good stead when he drew the portraits of Uncle Toby and Corporal Trim. After ten years of wandering, he was fixed for eight or nine years at a school at Halifax in Yorkshire. His father died when he was in his eighteenth year, and he was indebted for his university education to one of the members of his father's family. His great-grandfather the archbishop had been master of Jesus College, Cambridge, and to Jesus College he was sent. He was admitted to a scholarship in July 1733, took his B.A. degree in 1736 and proceeded M.A. in 1740. One of his uncles was preceptor and canon of York. Young Sterne took orders, and through this uncle's influence obtained in 1738 the living of Sutton-in-the-forest, some 8 m. north of York. Two years after his marriage in 1741 to a lady named Elizabeth Lumley he was presented to the neighbouring living of Stillington, and did duty at both places. He was also a prebendary of York Cathedral.

Sutton was Sterne's residence for twenty uneventful years. He kept up an intimacy which had begun at Cambridge with John Hall-Stevenson (1718-1783), a witty and accomplished epicurean, owner of Skelton Hall ("Crazy Castle") in the Cleveland district of Yorkshire. Skelton Hall is nearly 40 m. from Sutton, but Sterne, in spite of his double duties, seems to have been a frequent visitor there, and to have found in his not too strait-laced friend a highly congenial companion. Sterne is said to have never formally become a member of the circle of gay squires and clerics at Skelton known as the "Demoniacks"; but no doubt he shared their festivities. Stevenson's various occasional sallies in verse and prose—his Fables for Grown Gentlemen (1761-1779), his Crazy Salutation (1763), and his numerous skits at the political opponents of Wilkes, among whose "macaronies" he numbered himself—were collected after his death, and it is impossible to read them without being struck with their close family resemblance in spirit and turn of thought to Sterne's work, inferior as they are in literary genius. Without Stevenson, Sterne would probably have been a more decorous parish priest, but he would probably never have written Tristram Shandy or left any other memorial of his singular genius. In 1747 Sterne published a sermon preached in York under the title of The Case of Eliaah. This was followed in 1750 by Sermons of Conscience, afterwards presented to vol. ii. of Tristram Shandy. In 1759 he wrote a skit on a quarrel between Dean Fountayne and Dr Topham, a York lawyer, over the bestowal of an office in the gift of the archbishop. This sketch, in which Topham figures as Trim the sexton, and the author as Larry Slim, gives an earnest of Sterne's powers as a humorist. It was not published until after his death, when it appeared in 1769 under the title of A Political Romance, and afterwards the History of a Warm Watch-Coat. The first two volumes of Tristram Shandy were issued at York in 1759 and advertised in London on the 1st of January 1760, and at 1000 copies a subscription. York was scandalized at its clergyman's indecency, and indignant at his caricature as "Slop" of a local physician (Dr John Burton); London was charmed with its audacity, wit and graphic unconventional power. He went to London early in the year to enjoy his triumph, and found himself at once a personage in society—was called upon and invited out by lion-hunters, was taken to Windsor by Lord Rockingham, and had the honour of supping with the duke of York.

For the last eight years of his life after this sudden leap out of the city, he gave a faithful record of Sterne's feelings and movements in letters to various persons, published in 1775 by his sole child and daughter, Lydia Sterne de Medalle, and in the Letters from Yorick to Eliza (1766-1767), also published in 1775. For the last time in the sermon in Tristram he had intimated that, if this sample of Yorick's pupil eloquence was liked, "there are now in the possession of the Shandy family as many as will make a handsome volume, at the world's service, and much good may they do it." Accordingly, when a second edition of the first instalment of Tristram was called for in three months, two volumes of Sermons by Yorick were announced. Although they had little or none of the eccentricity of the history, they proved almost as popular. Sterne's clerical character was far from being universally injured by his indecorous freaks as a humorist: Lord Fauntonberg presented the author of Tristram Shandy with the perpetual curacy of Coxwold. To this new residence he went in high spirits with his success, "fully determined to write as hard as could be," seeing no reason why he should not give the public two volumes of Shandyism every year and why this should not go on for forty years. By the beginning of August 1769 he had another volume written, and was so "delighted with Uncle Toby's imaginary character that he was become an enthusiast." The author's delight in this wonderful creation was not misleading; it has been fully shared by every generation of readers since. For two years in succession Sterne kept his bargain with himself to provide two volumes a year. Vols. iii. and iv. appeared in 1761; vols. v. and vi. in January 1762. But his sanguine hopes of continuing at this rate were frustrated by ill-health. He was ordered to the south of France; it was two years and a half before he returned; and he became so sick with the climate that his constitution was utterly broken. His reception by literary circles in France was very flattering. He was overjoyed with it. "'Tis comme à Londres," he wrote to Garrick from Paris; "I have just now a fortnight's dinners and suppers upon my hands." Through all his pleasant experiences of French society, and through the fits of dangerous illness by which they were diversified, he continued to build up his history of the Shandy family, but the work did not progress as rapidly as it had done. Not till January 1762 was he ready with the fourth instalment of two volumes; and one of them, vol. vi., leaving the Shandy family for a time, gave a lively sketch of the writer's own travels to the south of France in search of health. This was a digression of a new kind, if anything can be called a digression in a work the plan of which is to fly off at a tangent whenever and wherever the writer's whim tempts him. In the first volume, anticipating an obvious complaint, he had protested against digressions that left the main work to stand still, and had boasted—not without justice in a Shandean sense—that he had reconciled digressive motion with progressive. But in vol. vii. the work is allowed to stand still while the writer is being transported from Shandy Hall to Languedoc. The only progress we make is in the illustrations of the buxinant and jovial temperament of Tristram Shandy himself, who, after all, is a member of the Shandy family, and was due a volume for the elucidation of his character. Vol. viii. begins the long-promised story of Uncle Toby's amours with the Widow Wadman. After seeing to the publication of this instalment of Tristram and of another set of sermons—more pronouncedly Shandean in their eccentricity—he quitted England again in the summer of 1765, and travelled in Italy as far as Naples. The ninth and last and shortest volume of Tristram, concluding the episode of Toby Shandy's amours, appeared in 1767. This despatched, Sterne turned to a new project, which had probably been suggested by the ease and freedom with which he had moved through the travelling volume in Tristram. The Sentimental Journey through France and Italy was intended to be a long work: the plan admitted of any length that the author chose, but, after seeing the first two volumes through the press in the early months of 1768, Sterne's strength failed him, and he died in his lodgings at 41 Old Bond Street on the 18th of March, three weeks after the publication. The loneliness of his end has often been commented on; it was probably due to its unexpectedness. He had pulled through so many sharp attacks of his "vile influence" and other lung disorders that he began to be seriously alarmed only three days before his death.
STERNE, R.—STETTIN

Sterne’s character defies analysis in brief space. It is too subtle and individual to be conveyed in general terms. For comments upon him from points of view more or less diverse the reader may be referred to Thackeray’s *Humourists*, Professor Masson’s *British Novelists* (1850), and H. D. Traill’s sketch in the *English Men of Letters* (1841). None of Sterne’s works are more closely read than *The Life and Opinions of Tristram Shandy*, the fullest biography is Mr Percy Fitzgerald’s (1864). But the reader who cares to have an opinion about Sterne should hesitate till he has read and re-read in various moods considerable portions of Sterne’s own writing. This writing is so singularly frank and unconventional that its drift is not at once apparent to the literary student. The indefensible indecency and overstrained sentimentality are on the surface; but after a time every repellent defect is forgotten in the enjoyment of the exquisite literary art. In the delineation of character by graphically significant speech and action, introduced at unexpected points, left with happy anadacty to point their own meaning, and pointing it with a force that the dullest cannot but understand, he takes rank with the very greatest masters. In Toby Shandy he has drawn a character universally lovable and admirable; but Walter Shandy is almost greater as an artistic triumph, considering the difficulty of the achievement. Dr Ferrair, in his *Illustrations of Sterne* (published in 1798), pointed out several unacknowledged plagiarisms from Rabelais, Burton and others; but it is only fair to the critic to say that he was fully aware that they were only plagiarisms of material, and do not detract in the slightest from the literary force of the work. The fullest and least prejudiced reading of Sterne is probably *The Life and Times of Laurence Sterne* (1896). A revised edition of Mr Percy Fitzgerald’s *Life of Sterne*, containing much new information, appeared in 1896. There is also a valuable study of Sterne by M. Paul Stapper (1870, 2nd ed., 1882); and many fresh particulars as to Sterne’s relations with his wife and daughter, and also with the lady known as “Eliza” (Mrs Elizabeth Draper), are collected in Mr Sidney Lee’s article in the *Dict. Nat. Biog.* Sterne’s original journal to Mrs Draper (“The Brantine’s Journal”) is extant, and he sent it to India, as recorded in Mrs Draper’s *Cross, The Life and Times of Laurence Sterne* (1909), and Walter Sichel, *Sterne: a Study* (1910). (W. M.; A. D.)

STERNE, RICHARD (c. 1596–1683), English divine, archbishop of York, was born at Mansfield, Nottinghamshire, and was educated at the free-school in that town and at Trinity College, Cambridge. He was elected fellow of Corpus Christi College in 1629; in 1633 he became chaplain to Archbishop Laud. He was elected to the See of Chester, Cambridge, and rector of Vellerton, Somerset. For his zeal in helping the royalist cause with college plate he suffered imprisonment at the order of parliament and lost his appointments. He attended Laud at his execution, and during the Commonwealth kept a school at Stevenage, Hertfordshire. At the Restoration he was reinstated as master of Jesus College and soon after was made bishop of Carlisle. With George Griffith, bishop of St Asaph, and Brian Walton, bishop of Chester, he was appointed by Convocation to revise the Prayer Book. In 1664 he was raised to the archbishopric of York. He had impoverished Carlisle, and in his new see, according to Burnet (who calls him “a sour ill-tempered man”), “minded chiefly the enriching of his family.” For his regard to the duke of York’s interests he was suspected of leaning towards Roman Catholicism. He died on the 20th of June 1683. He helped Brian Walton with the *Polyglot Bible* and wrote a book on logic, *Summa logicae* (London, 1685). He has also been credited with *The Whole Duty of Man*, which must, however, be assigned to the royalist divine Richard Allestree (1630–1709), provost of Eton College, whose original work was considerably altered by his literary executor, John Fell (1625–1686), bishop of Oxford.

STESISCHORUS (c. 640–555 B.C.), Greek lyric poet, a native of Himera in Sicily, or of Matarus a Lucanian colony in the south of Italy. According to Suidas, his name was originally Tisias, but was changed to Stesichorus ("changer of chariot") at the time when a light-galling perch upon his lips and sang (Piny, *Nat. Hist.*, x. 43). We are told that he warned his fellow-citizens against Phalaris, whom they had chosen as their general, by relating to them the well-known fable of the horse, which, in its eagerness to punish the stag for intruding upon its pastures, became the slave of man (Aristotle, *Rhetoric*, ii. 20). But his warnings had no effect; he himself was flayed alive before the gate called after him the Stesichorean. The story that he was struck blind for slandering Helen in a poem and afterwards recovered his sight when, in consequence of a dream, he had composed a palinode or recantation (in which he declared that only Helen’s phantom had been carried off to Troy), is told by Plato (*Phaedrus* 243 A.), Pausanias (iii. 19, 13), and others. We possess about thirty fragments of his poems, none of them longer than six lines. They are written in the Doric dialect, with epic licences; the metre is dactylic-trochoic. Brief as they are, they show us what Longinus meant by calling Remarks on the *Iliad* a “powerful expression of the dullest to the brilliant, whereof all Daphnis who came to a miserable end after he had faith— men, and have a stately sublimity that reminds us of Pindar. Stesichorus indeed made a new departure by using lyric poetry to celebrate gods and heroes rather than human feelings and passions; this is what Quintilian (Instit. x. 1, 62) means by saying that he “sustained the burden of epic poetry with the lyre.” Several of his poems sung of the adventures of Heracles; one dealt with the siege of Thebes, another with the sack of Troy. The last is interesting as being the first poem containing that form of the story of Aeneas’s flight to which Virgil afterwards gave currency in his *Aeneid*. The popular legends of Sicily and Italy were his first to introduce the thirty-one stanzas Daphnis who came to a miserable end after he had proved faith— lomb the nymph who loved him. Stesichorus completed the form of the choral ode by adding the epode to the strophe and antistrophe; and “you do not even know Stesichorus’s three” passed into a proverbial expression for unpardonable ignorance (unless the words simply mean, “you do not even know three lines, or poems, of Stesichorus”). He was famed in antiquity for the richness and splendour of his imagination and his style, although Quintilian censures his redundancy and Hermogenes comments on the excessive sweetness that results from his abundant use of epithets.

Fragments in T. Bergk, *Poetae lyrici graeci*, iii.; see also S. Bernage, *De Stesichoro lyrico* (1880); O. Crusius, “Stesichorus und die epodischen Composition in der griechischen Lyrik,” in *Commentationes Philologicae*, dedicated to O. Ribbeck (1888).

STETHOSCOPE (Gr. στήθος, chest, and σκόπειν, to look, examine), a medical instrument used in auscultation (q.v.). The single stethoscope is a straight wooden or metal tube with a flattened bell, the surface of which is usually covered with ivory or bone at the end which is placed against the body of the patient, and a small cup at the other to fit the ear of the observer. In the “binaural” stethoscope, which has the advantage of flexibility, the tube is divided above the bell into two flexible tubes which lead to both ears.

STETTIN, a seaport of Germany, capital of the Prussian province of Pomerania, on the Oder, 17 m. above its entrance into the Stettiner Haff, 30 m. from the Baltic, 84 m. N.E. of Berlin by rail, and at the junction of lines to Stargard-Danzig and Kistrin-Breslau. Pop. (1885), 99,745; (1896), 126,228; (1900, including the incorporated suburbs), 210,680; (1905) 224,078. The main part of the town occupies a hilly site on the left bank of the river, and is connected by four bridges, including a massive railway swing-bridge, with the suburbs of Lastadie (“lading place” from *lastium, “burden”), and Silberwicke, on an island formed by the Parnitz and the Dunzig, which here diverge from the Oder to the Dammsche-See. Until 1874 Stettin was closely girdled by very extensive and strong fortifications, which prevented the expansion of the town, but the steady growth of its commerce and industry encouraged the foundation of numerous industrial suburbs beyond the

The *tabula Iliaca* was stucco bas-relief found in the ruins of an ancient temple on the site of the ancient Bosilla and so called because it represents the chief events of the Trojan War, is a sort of commentary upon this (see O. Jahn and A. Michaelis, *Griechische Bilderschriften*, 1872; and M. F. Pithy, *De tabula Iliaca quaestiones Stesichorac*, 1897, an exhaustive treatise).
line of defence and these now combine with Stettin to form one industrial and commercial centre. Since the removal of the fortifications their site has been built upon. Apart from its commerce Stettin is comparatively an uninteresting city, although its appearance, owing to its numerous promenades and open spaces, is very pleasant. Among its nine Evangelical churches that of St Peter, founded in 1124 and restored in 1616–1817, has the distinction of being the oldest Christian church in Pommerania. Both this and the church of St James, dating from the 14th century, are remarkable for their size. Three of the Evangelical churches are fine new ones, and there are churches belonging to the Roman Catholics and other religious bodies. The old palace, now used as public offices, is a large but unattractive edifice, scarcely justifying the boast of an old writer that it did not yield in magnificence even to the palaces of Italy. Among the modern buildings are the theatre, the barracks, the large hospital, the new town-hall, superseding a building of the 13th century, and the new government buildings. Statues of Frederick the Great, of Frederick William III and of the emperor William I adorn two of the fine squares, the Königsplatz and the Kaiser Wilhelmplatz. Other squares include the Ländchen, the Rathausplatz with a beautiful fountain. Two gateways, the Königstor and the Berliner Tor, remains of the old fortifications, are still standing. As a prosperous commercial town Stettin has numerous scientific, educational and benevolent institutions.

Stettin, regarded as the port of Berlin, is one of the principal ship-building centres of Germany and a place of much commercial and industrial activity. The foremost place in its chief industry, ship-building, is taken by the Vulcan yard, situated in the suburb of Bredow, which builds warships for the German navy. The business was begun in 1851 and now employs about 8000 hands, the works extending over 70 acres and the covered workshops over 650,000 sq. ft. In 1897 a floating dock was fitted up capable of holding vessels of 12,000 tons. Locomotives, boilers and machinery of all kinds are made in great establishments. Other industries are the manufacture of clothing, cement, bricks, motor-cars, soap, paper, beer, sugar, spirits and cycles. Most of the mills and factories are situated in the suburbs, Grabow, Bredow and others. The sea-borne commerce of Stettin is of scarcely less importance than her industry and a larger number of vessels enter and clear here than at any other German port except Hamburg.

The Hanseatic city of Stettin, with its numerous harbours and havens, is the chief port of the Baltic. As such it is the most important centre of trade in the Baltic, and is remarkable for the character of its commerce. The exports are grain, wood, chemicals, spirits, sugar, herrings and coal, and its imports are iron goods, chemicals, grain, petroleum and coal. A great impulse to its trade was given in 1808 by the opening of a free harbour adjoining the suburb of Lastadie on the east bank of the Oder; this embraces a total area of 150 acres and quays with a length of 14,270 ft. It has two basins, with the necessary accommodation of warehouses, storehouses, &c., and the deepening of the Oder from Stettin to the Haff to 24 ft. was practically completed by 1832. With the view of still further increasing the commercial importance of Stettin, it is proposed to construct a ship canal giving the town direct communication with Berlin. A feature in the mercantile life of Stettin is the large number of insurance companies which have their headquarters in the town.

The forest and river scenery of the neighbourhood of Stettin is picturesque, but the low level and swampy nature of the soil render the climate bleak and unhealthy.

Stettin is said to have existed as a Wendish settlement in the 9th century, but its first authentic appearance in history was in 1315, when it was known as Stedyn. From the beginning of the 12th century to 1637 it was the residence of the dukes of Pommerania, one of whom, Duke Barnim I, gave it municipal rights in 1243. Already a leading centre of trade it entered the Hanseatic League in 1360. The Pommeranian dynasty became extinct in 1637, when the country was suffering from the ravages of the 'Thirty Years' War, and by the settlement of 1648 Stettin, the fortifications of which had been improved by Gustavus Adolphus, was ceded to Sweden.

In 1678 it was taken from Sweden by Frederick William, elector of Brandenburg, but it was restored in 1679, only, however, to be ceded to Prussia in 1720 by the peace of Stockholm. It was fortified more strongly by Frederick the Great, but in 1806 it yielded to France without any resistance and was held by the French until 1813. Stettin was the birthplace of the empress Catherine II of Russia.

Steuart, Sir James Denham, Bart. (1712–1780), English economist, was the only son of Sir James Steuart, solicitor-general for Scotland under Queen Anne and George L., and was born at Edinburgh on the 21st of October 1712. After passing through the university of Edinburgh he was admitted to the Scottish bar at the age of twenty-four. He then spent some years on the Continent, and while in Rome entered into relations with the Pretender. He was in Edinburgh in 1745, and so compromised himself that, after the battle of Culloden, he found it necessary to return to the Continent where he remained until 1763. It was not until 1771 he was fully pardoned for any complicity he may have had in the rebellion. On his return to England he settled at Colnett, in Lanarkshire, on the 26th of November 1780. In 1762 was published Steuart's Inquiry into the Principles of Political Economy. It was the most complete and systematic survey of the science from the point of view of moderate mercantilism which had appeared in England. But the time for the mercantilist doctrines was past. Nine years later the Wealth of Nations was given to the world. Adam Smith never quotes or mentions Steuart's book; being acquainted with Steuart, whose conversation he said was better than his book, he probably wished to keep clear of controversy with him. German economists have examined Steuart's treatise more thoroughly than an Englishman, and have applied it to the study of high merits, especially in relation to the theory of value and the subject of population. They have also pointed out that, in the spirit of the best modern research, he has dwelt on the special characters which distinguish the economies proper to different nations and different grades in social progress.

The Works, Political, Metaphysical and Chronological, of the late Sir James Steuart of Colnett, Bart., now first collected, with Anecdotes of the Author, by Sir J. Bart., General Sir James Denham Steuart, were published in 6 vols. 8vo in 1805. Besides the Inquiry they include—

A Dissertation upon the Doctrine and Principles of Money applied to the German Coin (1758) and the Swiss, and in an Appendix to the Essay on the Trade of 1758, printed for the Society for the Encouragement of the Study and Practice of Navigation.

A Dissertation upon the Trade of Great Britain (1758), to which are added the Observations on the Law of Elections (1759). A Dissertation upon the Opinion of Dr. Hechirigen (1758), for the Privilege and Commercial Advantage of the British Empire. A Dissertation upon the Cambro-German History of 1759, for the privately printed Emperor of the North. A Dissertation on the Commerce of 1760, for the privately printed Secretary of the Turkish Empire.

Steuben, Frederick William Augustus Henry Ferdinand Von (1730–1784), German soldier, was born at Magdeburg, Prussia, on the 15th of November 1730, the son of William Augustine Steuben (1699–1783), also a soldier. At fourteen he served as a volunteer in a campaign of the Austrian Succession War. He became a lieutenant in 1753, fought in the Seven Years' War, was made adjutant-general of the free corps in 1754 but re-entered the regular army in 1761, and became an aides to Frederick the Great in 1762. Leaving the army after the war, he was made colonel of the cathedral of Havelberg, and subsequently was grand-marshall to the prince of Hohenzollern-Ingolstadt, by his Son, General Sir James Denham Steuart, were published in 6 vols. 8vo in 1805. Besides the Inquiry they include—

A Dissertation upon the Doctrine and Principles of Money applied to the German Coin (1758), and in an Appendix to the Essay on the Trade of 1758, printed for the Society for the Encouragement of the Study and Practice of Navigation.

A Dissertation upon the Trade of Great Britain (1758), to which are added the Observations on the Law of Elections (1759). A Dissertation upon the Opinion of Dr. Hechirigen (1758), for the Privilege and Commercial Advantage of the British Empire. A Dissertation upon the Cambro-German History of 1759, for the privately printed Emperor of the North. A Dissertation on the Commerce of 1760, for the privately printed Secretary of the Turkish Empire.

Steuben arrived at Portsmouth, New Hampshire, on the 1st of December 1777, and offered his services to Congress as a volunteer. In March 1778 he began drilling the inexperienced soldiers at Valley Forge; and by May, when he was made inspector-general, with the rank of major-general, he had established a thorough system of discipline and economy.
Results of his work were shown in the next campaign, particularly at Monmouth, where he rallied the disordered, retreating troops of General Charles Lee. His Regulations for the Order and Discipline of the Troops of the United States (1779) was of great value to the army. He was a member of the court-martial which tried Major John André in 1780, and after General Horatio Gates's defeat at Camden was placed in command of the district of Virginia, with special instructions "to collect, organize, discipline, and fortify the recruits for the Southern army."

In April 1781 he was superseded in command of Virginia by La Fayette and later took part in the siege of Yorktown. Retiring from the service after the war, he passed the last years of his life at Steubenville, New York, where he died on the 28th of November 1794. New York, Virginia, Pennsylvania and New Jersey gave him grants of land for his services, and Congress passed a vote of thanks and gave him a gold-hilted sword in 1784, and later granted him a pension of $2,000.

See Frederick Kapp, The Life of Frederick William von Steuben (New York, 1895); and George W. Groene, The German Element in the War of American Independence (Cambridge, Massachusetts, 1876).

STEUBENVILLE—STEVENS, A.

Great Northern railway. Pop. (1901), 3,057. The church of St Nicholas, with a graceful tower and spire, is mainly Early English, but has Norman and later portions. There is a grammar school, founded in 1538. By the North Road, south of the town, is a row of six large bars, considered to be of Danish construction.

STEVENS, ALFRED (1818-1879), British sculptor, was born at Blandford in Dorset on the 28th of January 1818. He was the son of a house painter, and in the early part of his career he painted pictures in his leisure hours. In 1833, through the kindness of the rector of his parish, he was enabled to go to Italy, where he spent nine years in study at Naples, Rome, Florence, Milan and Venice. He had never been at an English school. In 1841 Thorwaldsen employed him for a year in Rome. After this he left Italy for England, and in 1845 he obtained a tutorial position in the School of Design, London. This post he occupied until 1847. In 1850 he became chief artist to a Sheffield firm of workers in bronze and metal. In 1852 he returned to London. To this period belongs his design for the vases on the railings of the British Museum, and to him the lions on the dwarf posts which were subsequently transferred to the inside of the museum. In 1856 occurred the competition for the Wellington monument, originally intended to be set up under one of the great arches of St Paul's Cathedral, though it was only consigned to that position in 1862. Stevens agreed to carry out the monument for £20,000—a quite inadequate sum, as it afterwards turned out. The greater part of his life as a sculptor Stevens devoted to this grand monument, constantly harassed and finally worn out by the interference of government, want of money and other difficulties. Stevens did not live to see the monument set up—perhaps unfortunately for him, as it was for many years placed in a small side chapel, where the effect of the whole was utterly destroyed and its magnificent bronze groups hidden from view. Stevens was aware of the position finally decided on for the work, and he suppressed the equestrian group intended for the summit and left the model for the latter feature in a rough state. On the removal of the monument from the chapel to the intercolumnar space on the north side of the nave for which it was originally designed, the model of horse and man was placed in the hands of an able young sculptor, trained chiefly in another school, to be worked to the life. The incongruity of the idea did not strike those responsible for the proceeding. Its completion was still not carried into effect in 1910, after years of work and polemics, and it was feared that it would have a disastrous result on the masterpiece as a whole. Indeed the president of the Royal Institute of British Architects declared that the structure would not bear the weight of the addition. The monument itself consists of a sarcophagus supporting a recumbent bronze effigy of the duke, over which is an archéd marble canopy of late Renaissance style on delicately enriched shafts. At each end of the upper part of the canopv is a large bronze group, one representing Truth tearing the tongue out of the mouth of Falsehood, and the other Valour trampling Cowardice underfoot. The two virtues are represented by very stately female figures modelled with wonderful beauty and vigour; the vices are two nude male figures treated in a very massive way. The vigorous strength of these groups recalls the style of Michelangelo, but Stevens's work throughout is original and has a very distinct character of its own. Owing to the many years he spent on this one work Stevens did not produce much other sculpture. In Dorchester House, St. James's, there is some of his work, especially a very noble mantelpiece supported by nude female Caryatids in a crouching attitude, modelled with great largeness of style. He also designed mosaics to fill the spandrels under the dome of St Paul's. Stevens died in London on the 1st of May 1875.

STEVENS, ALFRED (1828-1906), Belgian painter, was born in Brussels on the 11th of May 1828. His father, an old officer in the service of William I., king of the Netherlands, was passionately fond of pictures, and readily allowed his son to draw in the
STEVENS, H.—STEVENS, T.

studio of François Navez, director of the Brussels Academy. In 1844 Stevens went to Paris and worked under the instruction of Camille Roqueplan, a friend of his father's; he also attended the classes at the École des Beaux Arts, where Ingres was then professor. In 1839 he painted at Brussels his first picture, "A Soldier in Trouble," and in the same year went back to Paris, where he definitely settled, and exhibited in the Salons. He then painted "Ash-Wednesday Morning" "Burghers and Country People finding at Daybreak the Body of a Murdered Gentleman," "An Artist in Despair," and "The Love of Gold." In 1855 he exhibited at the Antwerp Salon a little picture called "At Home," which showed the painter's bent towards depicting ladies of fashion. At the Great Exhibition in Paris, 1855, his contributions were remarkable, but in 1857 he returned to graceful female subjects, and his path thenceforth was clear before him. At the Great Exhibition of 1857 he was seen in a brilliant variety of works in the manner he had made his own, sending eighteen exquisitely paintings; among them were the "Lady in Pink" (in the Brussels Gallery), "Consolation," "Every Good Fortune," "Miss Fauvette," "Ophelia," and "India in Paris." At the Paris International Exhibitions of 1878 and 1889, and at the Historical Exhibition of Belgian Art, Brussels, 1886, he exhibited "The Four Seasons" (in the Palace at Brussels), "The Persian Sphinx," "The Japanese Mask," "The Japanese Robe," and "The Lady-bird" (Brussels Gallery). He died on the 24th of August 1906. Alfred Stevens is one of the race of great painters," wrote Camille Lemonnier, "and like them he takes immense pains with the execution of his work." The example of his finished technique was salutary, not merely to his brethren in Belgium, but to many foreign painters who received encouragement from the study of his method. The brother of Alfred Stevens, Joseph Stevens, was a great painter of dogs and dog life.

See J. du Jardin, L'Art flamand; Camille Lemonnier, Histoire des beaux arts en Belgique.

STEVEHS, HENRY (1819-1886), American bibliographer, was born in Barnet, Vermont, on the 24th of August 1819. He studied at Middlebury College, Vermont, in 1838-1840, graduated at Yale in 1843 and studied at the Cambridge (Massachusetts) Law School in 1843-1844. In 1845 he went to London, where he was employed during most of the remainder of his life as a collector of Americana for the British Museum and for various public and private American libraries. He was engaged by Sir Anthony Panizzi, librarian of the British Museum, to collect historical books, documents, journals, &c., concerning North and South America; and he was purchasing agent for the Smithsonian Institution and for the Library of Congress, as well as for various other libraries in the United States, whose libraries he purchased much of the valuable Americana in the Lenox library in that city, and for the John Carter Brown library, at Providence, Rhode Island. He became a member of the Society of Antiquaries in 1852, and in 1877 was a member of the committee which organized the Caxton Exhibition, for which he catalogued the collection of Bibles. He died at South Hampstead, England, on the 28th of February 1886.

His principal compilations and publications were: an Analytical Index of the Catalogues of the Library of Congress in the Library of Congress, Washington (1858), containing vol. v. of the New Jersey Historical Society's Collections; Collection of Historical Papers relating to Rhode Island ... 1640-1775 (6 vols.), for the John Carter Brown library; historical indexes of the colonial documents relating to Maryland (10 vols.), now in the library of the Maryland Historical Society; and a collection of papers relating to Virginia for the period 1606-1775, including deposition in the Virginia state archives. His 1854 Valuable Catalogue of American Maps in the Library of the British Museum (1856); catalogues of American, of Mexican and other Spanish-American and of Canadian and other British American books in the Library of Congress in the Briscoe Historical and Geographical Notes on the Earliest Discoveries in America, 1453-1530, with Comments on the Earliest Maps and Charts, &c. (1869); Sebastian Cabot — John Cabot — a (1870); The Bibles in Congress 1877 (1878) and Interrogations of Chief James Lenox, of New York, and the Formation of his Library (1886).

His brother, Benjamin Franklin Stevens (1833-1902), also a bibliographer, was born at Barnet, Vermont, on the 19th of February 1833, was educated at the university of Vermont, and in 1860 became associated with his brother in London. For about thirty years he was engaged in preparing a chronological list and alphabetical index of American state papers in English, French, Dutch and Spanish archives, covering the period from 1763 to 1874, and he prepared more than 2000 facsimiles of important American historical manuscripts found in European archives and relating to the period between 1773 and 1783. He also acted as purchasing agent for various American libraries, and for about thirty years before his death was United States despatch agent at London and had charge of the mail intended for the vessels of the United States navy serving in Atlantic or European stations. He died at Surbiton, Surrey, England, on the 5th of March 1902.

His principal publications include Campaign in Virginia, 1781: an Exact Repriipt of Six Rare Pamphlets on the Clinton-Cornwallis Controversy, with ... Manuscript Notes by Sir Henry Clinton, with a Supplement containing Extracts from the Journals of the House of Lords (1888); Facsimiles of Manuscripts in European Archives Relating to America, 1773-1783, with Descriptions, References and Translations (25 vols., 1889-1898); General Sir William Howe's Orderly Book at Charleston, Boston and Halifax (1890); and Columbus: His Own Book of Privileges, 1502 (1893).

STEVENs, THADDEUS (1792-1868), American political leader, was born in Danville, Vermont, on the 4th of April 1792. He graduated at Dartmouth College in 1814, removed to York, Pennsylvania, was admitted to the bar (in Maryland), and for fifteen years practised at Gettysburg, Pennsylvania. He was in 1836 a delegate to the Republican convention at Baltimore in the national Anti-Masonic Convention in 1831. He served in the Pennsylvania House of Representatives, first as an Anti-Mason and later as a Whig, in 1833-1835, 1838-1839 and 1841-1842. On the 11th of April 1835 he made an eloquent speech in defence of free public education. A partner's venture in the iron business having involved him in a debt of $217,000, he retired from public life in 1842 and practised law in Lancaster, Pennsylvania, with such success as within six years to reduce this debt to $30,000. He frequently appeared in behalf of free labor, who was far more conservative, as well as broader minded and more magnanimous than he; besides this Stevens felt it an injustice that Lincoln in choosing a member of his cabinet from Pennsylvania had preferred Cameron to himself. During the war Stevens urged emancipation of the slave, and earnestly advocated the raising of negro regiments. He not only opposed the president's "ten per cent. plan" in Louisiana and Arkansas (i.e. the plan which provided that these states might be reorganized by as many as 10% of the number of voters in 1860 who should ask for pardon and take the oath of allegiance, but he refused to accept the Wade-Davis Bill as being too moderate in character. On the motion of Stevens (Dec. 4, 1865), the two houses appointed a joint committee on reconstruction, and Stevens
was again Democratic nominee for vice-president in 1900, but was defeated. He published Something of Men I Have Known; With Some Papers of a General Nature, Political, Historical and Retrospective (1900).

STEVENSON, ROBERT (1772-1850), Scottish engineer, was the only son of Alan Stevenson, partner in a West Indian house in Glasgow, and was born in that city on the 8th of June 1772. He was educated at Anderson's College, Glasgow, and Edinburgh University. In his youth he assisted his stepfather, Thomas Smith, in his lighthouse schemes, and at the age of nineteen was sent to understand the erection of a lighthouse on the island of Little Cumbrae. Subsequently he succeeded Smith, whose death in 1812 left him engineer to the Commissioners of Northern Lighthouses, and during his period of office, from 1797 to 1843, he designed and executed a large number of lighthouses, the most important being that on the Bell Rock, begun in 1807. For its illumination he introduced an improved apparatus, and he was also the author of various valuable inventions in connexion with lighting, including the intermittent and flashing lights, and the mast lantern for lightships. As a civil engineer he improved the approaches to Edinburgh, including that by the Calton Hill, constructed harbours, docks and breakwaters, improved river and canal navigation, and had several designs for the erection of lighthouses. In consequence of observations made by him George Stephenson advocated the use of malleable—instead of cast-iron rails for railways, and he was the inventor of the movable jib and balance cranes. Chiefly through his interposition an admiralty survey was established, from which the admiralty sailing directions for the coasts of Great Britain and Ireland have been prepared. Stevenson published an Account of the Bell Rock Lighthouse in 1824, and, besides contributing important articles on engineering subjects to Brewster's Edinburgh Encyclopaedia and the Encyclopaedia Britannica, was the author of various papers in the before learned societies. He died at Edinburgh on the 9th of July 1850. Of his family, three sons, Alan, David and Thomas, attained distinction as lighthouse engineers. The eldest, Alan (1807-1869), eventually became a partner with his father, whom he succeeded as engineer to the Commissioners of Northern Lighthouses in 1843. The most noteworthy lighthouse designed by him is Skerryvore on the west coast of Scotland, an isolated tower of which the first stone was laid in 1846 and which first showed its light in 1843. He published an Account of the Skerryvore Lighthouse in 1848, and a Rudimentary Treatise on the History, Construction and Illumination of Lighthouses in 1850, and he wrote the article on lighthouses in the 8th edition of the Encyclopaedia Britannica. The third son, David (1815-1886), was at first engaged on land and marine surveys and in railway work. In 1837 he made a tour in North America, which gave rise to his Sketch of the Civil Engineering of North America (1838), and on his return became a partner in his father's business. In 1833 he and his youngest brother Thomas were appointed joint engineers to the Commissioners of Northern Lighthouses in succession to their brother Alan, and he designed many lighthouses not only in Scotland but also in New Zealand, India and Japan. He was the author of various papers in the before learned societies. He died at Edinburgh on the 9th of July 1850. His other brothers were, Thomas, his first son, and Robert, his second son, both of whom were lighthouse engineers.
STEVENSON, R. L.

November 1850. He suffered from infancy from great fragility of health, and nearly died in 1858 of gastric fever, which left much constitutional weakness behind it. From the age of six he showed a disposition to write. He went to school, mainly in Edinburgh, from 1858 to 1867, but his ill-health prevented his learning much, and his teachers, as his mother afterwards said, "liked talking to him better than teaching him." He often accompanied his father on his official visits to the light-houses of the Scottish coast and on longer journeys, thus early accustoming himself to travel. As his health improved it was hoped that he would be able to adopt the family profession of civil engineering, but in 1866 he published, of which his instructor, W. W. Wick, described it as a "pamphlet," and for which he was given a medal by the Edinburgh Society of Arts for a paper suggesting improvements in lighthouse apparatus. But long before this he had started as an author. His earliest publication, the anonymous pamphlet of The Pentland Rising, published in 1866, and The Charity Bazaar, a trifle in which his future manner is happily displayed, in 1868. From about the age of eighteen he dropped his baptismal names of Lewis Balfour and called himself Robert Louis, but was still mostly known to his relatives and intimate friends as "Louis." Although he greatly enjoyed the world as an Edinburgh student he was so affected by his physical endurance too much, and in 1871 was reluctantly exchanged for study at the Edinburgh bar, to which he was called in 1875. In 1873 he first met Mr Sidney Colvin, who was to prove the closest of his friends and at last the loyal and admirable editor of his works and his correspondence; and to this time are attributed several of the most valuable friendships of Stevenson's life.

He was now labouring, with extreme assiduity, to ground himself in the forms and habits of literary style. In 1875 appeared, anonymously, his A Tragic irn the Church of Scotland, and in that year he made the first of many visits to the forest of Fontainebleau. Meanwhile at Montreuil in the winter of 1873-1874 he had grown in mind under the shadow of extreme physical weakness, and in the following spring began to contribute essays of high originality to one or two periodicals, of which the Cornhill, then edited by Sir Leslie Stephen, was at first the most important. Stevenson made no attempt to practice at the bar, and the next years were spent in wanderings in France, Germany and Scotland. Records of these journeys, and of the innocent adventures in which they were engrossed, are given in his Travels with a Donkey in the Cevennes in 1879. During these four years Stevenson's health, which was always bettered by life out of doors, gave him little trouble. It was now recognized that he was to be an author, and he contributed many essays, tales and fantasies to various journals and magazines. At Fontainebleau in 1876 Stevenson had met Mrs Osbourne, the lady who afterwards became his wife; she returned to her home in California in 1878, and in August of the following year, alarmed at news of her health, Stevenson hurriedly crossed the Atlantic. He travelled, from lack of means, as a steerage passenger and then as an emigrant, and in December, after hardships which seriously affected his health, he arrived in San Francisco. In May 1880 he married, and moved to the desolate mining-camp which he has described in The Silverado Squatters. As Mr Colvin has well said, these months in the west of America were spent "under a heavy combined strain of personal anxiety and literary effort." Some of his most poignant and most enchanting letters were written during this romantic period of his life. In the autumn of 1880 he returned to Scotland, with his wife and stepson, who were received at once into the Edinburgh household of his parents. But the condition of his health continued to be very alarming, and they went almost immediately to Davos, where he remained until the spring of 1881. In this year was published Virginibus Puerisque, the earliest collection of Stevenson's essays. He spent the summer months in Scotland, writing articles, poems, and above all his first romance, The Sea-Cook, afterwards known as Treasure Island; but he was driven back to Davos in October. In 1882 appeared Familiar Studies of Men and Books and New Arabian Nights. His two winters at Davos had done him some good, but his summers in Scotland invariably undid the benefit. He therefore determined to reside wholly in the south of Europe, and in the autumn of 1882 he settled near Marseilles. This did not suit him, but from March 1883 to July 1884 he was at home at a charming house called La Solitude, above Hyères; this was in many ways to be the happiest station in the painful and hurryng pilgrimage of Stevenson's life. The Silverado Squatters was published in 1883, and also the more important Treasure Island, which made Stevenson for the first time a popular writer. He planned a second English novel, Thorns, of which the work was interrupted by mental and physical difficulties. He was to die in January 1884 by the most serious illness from which he had yet suffered. He was just pulled through, but the attack was followed by long prostration and incapacity for work, and by continued relapses. In July he was brought back to England, and from this time until August 1887 Stevenson's home was at Bournemouth. In 1885 he published, after long indecision, his volume of poems, A Child's Garden of Verses, an inferior story, The Body Snatcher, and that admirable romance, Prince Otto, in which the peculiar quality of Stevenson's style was displayed at its highest. He also collaborated with W. E. Henley in some Poems of the Master, and in the same year he completed and printed privately as a pamphlet, in June 1887, a brief and touching sketch of his father. In July he published his volume of lyrical poems called Underwoods. The ties which bound him to England were now severed, and his health was broken to such a discouraging degree that he determined to remove to another hemisphere. Accordingly, having disposed of Skerryvore, his house at Bournemouth, he sailed from London, with his wife, mother and stepson, for New York on the 17th of August 1887. He never set foot in Europe again. His memoir of his friend Professor Fleming Jenkin was published soon after his departure. After resting at Newport, he went for the winter to be under the care of a physician at Saranac Lake in the Adirondacks for the winter. Here he was very quiet, and steadily active with his pen, writing both the greater part of the Master of Ballantrae and many of his finest later essays. He had undertaken, for a regular payment greatly in excess of anything to which he had hitherto received, to contribute a monthly essay to Scribner's Magazine, and these essays, twelve in number, were published continuously throughout the year 1888. Early in that year was begun The Wrong Box, a farcical romance in which Mr Lloyd Osbourne participated; Stevenson also began a romance about the Indian Mutiny, which he abandoned. His attitude about this time to life and experience is reflected in Pulvis et Umbra, one of the noblest of his essays. In April 1888 he was at the coast of New Jersey for some weeks, and in June started for San Francisco, where he had ordered a schooner, the "Casco," to be ready to receive him. On the 28th of the month, he started, as Mr Colvin has said, "on what was only intended to be a pleasure excursion ... but turned into a voluntary exile prolonged until the hour of his death:" he never again left the waters of the Pacific. The "Casco" proceeded first to the Marquessas, and south and east to Tahiti, passing before Christmas northwards to Honolulu, where Stevenson spent six months and finished The Master of Ballantrae and The Wrong Box. It was during this time that he paid his famous visit to the leper settlement at Molokai. In 1889, "on a certain bright June day," the Stevensons sailed for the Gilbert Islands, and after six months' cruising found themselves at Samoa, where he landed for the first time about Christmas Day 1889. On this occasion, however, though
strongly drawn to the beautiful island, he stayed not longer than six weeks, and proceeded to Sydney, where, early in 1890, he published, in a blaze of righteous anger, his Father Damien: an Open Letter to the Rev. Dr Hyde of Honolulu, in vindication of the memory of Father Damien and his work among the lepers of the Pacific. At Sydney he was very ill again: it was now obvious that his only chance of health lay within the tropics. For nearly the whole of the year 1890 the Stevensons were cruising through unfamiliar archipelagos on board a little trading steamer, the "Janet Nicoll." Meanwhile his volume of Ballads was published in London.

The last four years of his unquiet life were spent at Samoa, in circumstances of such health and vigour as he had never previously enjoyed, and in surroundings that, for the time, were entirely unquiet. It was in November 1890 that he made his abode at Vailima, where he took a small barricad of a wooden box 900 ft. above the sea, and began to build himself a large house close by. The natives gave him the name of Tusitala. His character developed unanticipated strength on the practical side; he became a vigorous employer of labour, an active planter, above all a powerful and benignant island chieftain. He gathered by degrees around him a kind of feudal dan of servants and retainers," and he plunged, with more generous ardour than cleverness, into the troubled politics of the country. He took up the cause of the deposed king Mataafa with extreme ardour, and he wrote a book, A Footnote to History: Eight Years of Trouble in Samoa (1892), in the endeavour to win over British sympathy to his native friends. In the autumn of this year he received a visit at Vailima from the countess of Jersey, in company with whom and some others he wrote the burlesque extravagance in prose and verse, called An Object of Pity, privately printed in 1893 at Sydney. Whenever the cultivation of his estate and the vigorous championship of his Samoan retainers gave him the leisure, Stevenson was during these years deeply engaged in theromances of Samoan life. The Wrecker, an adventurous tale of American life, which mainly belonged to an earlier time, was written in collaboration with Mr Lloyd Osbourne and finally published in 1892; and towards the close of that very eventful and busy year he began The Justice Clerk, afterwards Weir of Hermiston. A portion of the old record of emigrant experiences in 1879, long suppressed for private reasons, also appeared in book form in 1892. In 1893 Stevenson published the important Scottish romance of Catriona, written as a sequel to Kidnapped, and the three tales illustrative of Pacific Ocean character, Island Nights' Entertainments. But in 1893 the uniform good fortune which had attended the Stevensons since their settlement in Samoa began to be disturbed. The whole family at Vailima became ill, and the final subjugation of his protégé Mataafa, and the destruction of his party in Samoan politics, deeply distressed and discouraged Stevenson. In a series of letters to The Times he exposed the policy of the chief justice, Mr Cedercrantz, and the president of the council, Baron Senftl. He so influenced public opinion that both were removed from office. In the autumn of that year he went for a change of scene to the Sandwich Islands, but was taken ill there, and was only too glad to return to Samoa. In 1894 he was greatly cheered by the plan, suggested by friends in England and carried out by them with the greatest energy, of the noble collection of his works in twenty-eight volumes, since known as the Edinburgh editions. In September 1894 was published The Ebb Tide, the latest of his books which he saw through the press. Of Stevenson's daily avocations, and of the temper of his mind through these years of romantic exile, a dear idea may be obtained by the posthumous Vailima Letters, edited by his widow in 1895. He was still engaged in composing two romances, neither of which he lived to complete. He was dictating Weir of Hermiston, apparently in his usual health, on the day he died. This was the 3rd of December 1894; he was gaily talking on the verandah of his house at Vailima when he had a stroke of apoplexy, from which he never recovered consciousness, and passed away painlessly in the course of the evening. His body was carried next day by sixty sturdy Samoans, who acknowledged Stevenson as their chief, to the summit of the precipitous peak of Vaea, where he had wished to be buried, and where they left him to rest for ever with the Pacific Ocean at his feet.

The charm of the personal character of Stevenson and the romantic vicissitudes of his life are so predominant in the minds of all who knew him, or lived within earshot of his legend, that they made the ultimate position which he will take in the history of English literature somewhat difficult to decide. That he was the most attractive figure of a man of letters in his generation is admitted; and the acknowledged fascination of his character was deepened, and was extended over an extremely wide circle of readers, by the publication in 1899 of his Letters, which have been more widely read and more frequently quoted than any other volume in his collection of books. It is therefore from the point of view of its "charm" that the genius of Stevenson must be approached, and in this respect there was between himself and his books, his manners and his style, his practice and his theory, a very unusual harmony. Very few authors of so high a class have been so consistent, or have made their conduct so close a reflection of their philosophy. This unity of the man in his work makes it difficult, for one who knew him, to be sure that one rightly gauges the purely literary significance of the latter. There were a number of men who knew him personally, and who held that the value of his work was in the voice of the man himself, and see in every turn of his language his flashing smile. So far, however, as it is possible to disengage one's self from this captivation, it may be said that the mingling of distinct and original vision with a singularly conscientious handling of the English language, in the sincere and wholesome self-consciousness of the strenuous artist, seems to be the central feature of Stevenson as a writer by profession. He was always assiduously graceful, always desiring to present his ideal, his image, his rhapsody, in as persuasive a light as possible, and, particularly, with as much harmony as possible. He had no idea of theatricalizing his work, as other gentle or less delicate men did, in the exercise of criticism and the reflective parts of literature, before he surrendered himself to that powerful creative impulse which had long been tempting him, so that, when, in mature life, he essayed the portraiture of invented character he came to it unhampered by any imperfection of language. This distinguished mastery of style, and love of it for its own sake within the bounds of good sense and literary decorum, gave him a pre-eminentice among the story-tellers of his time. No doubt it is still by his romances that Stevenson keeps the world for a time. But he had prepared the way for his work and essays are finer contributions to pure literature, and that on these exquisite mixtures of wisdom, pathos, melody and humour his fame is likely to be ultimately based. In verse he had a touch far less sure than in prose. Here we find less evidence of sedulous workmanship, yet not infrequently a piercing sweetness, a depth of emotion, a sincere and spontaneous lovelliness, which are irresistibly touching and inspiring.

The personal appearance of Stevenson has often been described: he was tall, extremely thin, dark-haired, restless, compelling attention with the lustre of his wonderful brown eyes. In the existing portraits of him those who never saw him are apt to discover a strangeness which seems to them sinister or even affected. This is a consequence of the false stability of portraiture, since in life the unceasing movement of light in the eyes, the mobility of the mouth, and the sympathy and sweetness which radiated from all the features, precluded the faintest notion of want of sincerity. Whatever may be the ultimate order of reputation among his various books, or whatever posternity may ultimately see fit to ordain as regards the popularity of any of them, it is difficult to believe that the time will ever come in which Stevenson will not be remembered as the most beloved of the writers of that age which he did so much to cheer and stimulate by his example.

His cousin R. A. M. Stevenson (1847–1900) was an accomplished art-critic, who in 1889 became professor of fine arts at University College, Liverpool; he published several works on art (Rubens, 1898; Velázquez, 1895; Raeburn, 1900).
R. L. Stevenson’s other works include: Memories and Portraits (1887); The Merry Men and other Tales and Fables (1887); The Black Arrow (1888); Edinburgh: Picturesque Notes (1888); Across the Plains; the Miss World and I (1890) firearms. He was the inventor songs, Songs of Travel and other Verses (1896), St Ives (1899), completed by Sir A. T. Quiller Couch; A Stevenson Medley (1899); In the South Seas; experiences . . . on the "Casco" (1899) and the Equator (1899); and The Letters of Stevenson to his Family (1899), with the critical and biographical preface by Mr Sidney Colvin; Vailima Letters, to Sidney Colvin (1895), and the Life of Robert Louis Stevenson by Graham Balfour (1901). See also Professor Walter Raleigh, R. L. Stevenson (1895), and Memories of Vailima (1903), by Isabel Strong and Lloyd Osborne. A complete edition of Stevenson’s works was issued at Edinburgh in 1894-1898.

A number of works of R. L. Stevenson by Colonel W. F. Prideaup appeared in 1903.

(E. G.)

STEVENSON POINT, a city and the county-seat of Portage county, Wisconsin, U.S.A., on both banks of the Wisconsin river, about 110 m. N. of Madison. Pop. (1890), 7806; (1900), 9524, of whom 2205 were foreign-born; (1910 U.S. census), 8962. Stevenson Point is served by the Green Bay & Western and the Minneapolis, St Paul & Sault Ste Marie railways. It is attractively situated, has a fine public school system, including a high school, a grammar-school, a junior high school, a domestic science department, and kindergarden and day schools for the des. It is the seat of one of the state normal schools (1894), of St Joseph’s Academy (Polish), and of the Stevenson Point Commercial College, and has a Carnegie library (1904), the Portage county court-house, a city hospital, and a tuberculosis sanatorium. The city is situated in the borders of the pine timber region, and the lumber industry predominates. There are railway repair shops here, and various manufactures. The city has a considerable wholesale jobbing trade, and is an important point of shipment for the products of the agricultural and stock-raising industry of the vicinity. Stevens Point was first settled by George Stevens in 1839, was incorporated as a village in 1847, and was first chartered as a city in 1858.

STEVENSTON, a manufacturing town of Ayrshire, Scotland. Pop. (1901), 6554. It is situated about 1 m. from Saltcoats on the coast of the Firth of Clyde, 29 m. S.W. of Glasgow by the Glasgow & South-Western railway. There are coal mines, several iron-works—one is among the largest in Scotland—and, on the sandhills along the shore, the works of Nobel’s Explosives Company, which cover an area of a mile, the separate-heat dynamo, and other works to minimize the risks attendant upon so dangerous an occupation.

STEVINUS, SIMON (1548-1620), Dutch mathematician, was born in 1548 at Bruges (where the Place Simon Stevin contains his statue by Eugen Simonis) and died in 1620 at the Hague or in Leiden. Of the circumstances of his life very little is recorded; the exact day of his birth and the day and place of his death are alike uncertain. It is known that he left a widow with two children; and one or two hints scattered throughout his works inform us that he began life as a merchant’s clerk in Antwerp, that he travelled in Poland, Denmark and other parts of northern Europe, and that he was intimate with Prince Maurice of Orange, who asked his advice on many occasions, and made him a public officer—at first director of the so-called “waterstaat,” and afterwards quartermaster-general. The question whether Stevinus, like most of the rest of the prince’s followers, belonged to the Protestant creed hardly admits of a categorical answer. A Roman Catholic would perhaps not have been so ready as Stevinus to deny the value of all authority. A Roman Catholic could not well have boasted, as Stevinus in a political pamphlet did, that he had always been in harmony with Ignatius (1868) (1900). See the Letters of Stevenson to his Family it might be urged that a Protestant had no occasion to boast of a harmony most natural to him, while his further remark to the effect that a state church is indispensable, and that those who cannot belong to it on conscientious grounds ought to leave the country rather than show any opposition to its rites, seems rather to indicate the crypto-Catholic. The same conclusion is supported by the fact that Stevinus, a year before his death, bequeathed a pious legacy to the church of Westkerke in Flanders out of the revenues of which masses were to be said.

His claims to fame are varied. His contemporaries were most struck by his invention of a carriage with sails, a little model of which was preserved at Scheveningen till 1802. The carriage itself had been lost long before; but we know that about the year 1600 Stevinus, with Prince Maurice of Orange and twenty-six others, made use of it on the seashore between Scheveningen and Petten, that it was propelled solely by the force of the wind, and that it acquired a speed which exceeded that of horses. Another idea of Stevinus, for which even Hugo Gelling gave his implied credit, was his notion of a bygone age of wisdom. The goal to be aimed at is the bringing about of a second age of wisdom, in which mankind shall have recovered all its early knowledge. The fellow-countrymen of Stevinus were proud that he wrote in their own dialect, which he thought fitted for a universal language, as no other abounded like Dutch in monosyllabic radical words.

Stevinus was the first to show how to model regular and semicircular polyhedra by delineating their frames in a plane. Stevinus also distinguished stable from unstable equilibrium. He proved the law of the equilibrium on an inclined plane. He denoted the center of gravity of a disc as its centroid, and the fixed point about which a pendulum swings as its fulcrum, which, simple consequence of the law of their composition though it is, had not been previously remarked. He discovered the hydrostatic paradox that the downward pressure of a liquid is independent of the shape of the vessel, and depends only on its height and base. He also gave the measure of the pressure on any given portion of the side of a vessel. He had the idea of explaining the tides by the attraction of the moon. Stevinus seems to be the first who made it an axiom that strongholds are only to be defended by artillery, the defence before his time having rather relied mostly on small firearms. He left that of defence by a system of sluces, which proved of the highest importance for the Netherlands. His plea for the teaching of the science of fortification in universities, and the existence of such lectures in Leiden, have led to the impression that he himself filled this chair; but the belief is erroneous, as Stevinus, though living at Leiden, never had direct relations with its university.

Book-keeping by double entry may have been known to Stevinus as clerk at Antwerp either practically or through the medium of the works of Italian authors like Lucas Pacioli and Girolamo Cardano. He, however, was the first to recommend the use of impersonal accounts in the national household. He practised it for Prince Maurice, and recommended it to Sully, the French statesman.

His greatest success, however, was a small pamphlet, first published in Dutch in 1536, and not exceeding seven pages in the French translation. This translation is entitled La Disme enseignant facilement expéhir par Nombres Entiers sans rompus
tous Comptes se rencontrent aux Asfaires des Hommes. Decimal fractions had been employed for the extraction of square roots some five centuries before his time, but nobody before Stevinus established their daily use; and so well aware was he of the importance of his innovation that he declared the universal introduction of decimal coinage, measures and weights to be only a question of time. His notation is rather unwieldy. The point separating the integers from the decimal fractions seems to be the invention of Bartholomaeus Pitiscus, in whose trigono- metrical tables (1612) it occurs and it was accepted by John Napier in his logarithmic papers (1614 and 1619). Stevinus printed little circles round the exponents of the different powers of time-tenth. For instance, 23771538 was printed 237 8 6. Stevinus used the same notation as do the nomina- tive numerals to denote mere exponents is evident from his employing the very same sign for powers of algebraic quantities, e.g. 9 4 - 14 3 + 6 - 5 to denote 9x4 - 14x3 - 6x5 - 5. He does not even avoid fractional exponents (“ Racine cubique de 2 scribit ft en circle”), and is ignorant only of negative exponents.

Stevinus wrote on other scientific subjects—optics, geography, astronomy, &c.—and a number of his writings were translated into Latin by W. Snellius. There are two complete editions in French of his works, both printed at Leiden, one in 1608, the other in 1634.
STEWART (FAMILY) 911

by Albert Girard. See Steichen, Vie et travaux de Simon Stevin (Brussels, 1846); M. Cantor, Geschichte der Mathematik. (M. Ca.)

STEWART, STUART or STEUART, the surname of a family which inherited the Scottish and ultimately the English crown. Their descent is traced to a Breton immigrant, Alan the son of Flaald, which Flaald was a brother of Alan, steward (or seneschal) of Dol in Brittany. This elder Alan, whose name occurs in Breton documents before 1080, went on crusade in 1097, and was apparently succeeded by his brother Flaald, whose son, the younger Alan, enjoyed the favour of Henry I., who bestowed on him Mileham and its barony in Norfolk, where he founded Sporle Priory. By the daughter of Ermulf de Hesdin (in Picardy), a Domesday baron, he was father of at least three sons: John, who succeeded to the family office of steward of Dol; William, who inherited Mileham and other estates in England, and who founded the great baronial house of Fitz Alan (afterwards earls of Arundel); and Walter, who was made by David I. steward (cupffer) or seneschal of Scotland. The Scottish king conferred on Walter various lands in Renfrewshire, including Paisley, where he founded the abbey in 1163. Walter, his grandson, third steward, was appointed by Alexander III. to the justiciary of Scotland, and, dying in 1246, left four sons and three daughters. The third son, Walter, obtained by marriage the earldom of Menteith, which ultimately came by marriage to Robert, duke of Albany, son of Robert II. Alexander, fourth steward, the eldest son of Walter, third steward, inherited by his marriage with Jean, granddaughter of Somerled, the islands of Bute and Arran, and on the 2nd of October 1263 led the Scots against Haakon IV., king of Norway, at Largs. He had two sons, James and John. The latter, who commanded the men of Bute at the battle of Falkirk in 1298, had seven sons: (1) Sir Alexander, who was executed by the English; (2) Sir James, who was a grandson of Douglas; (3) Sir John, who married in 1333; (4) Sir James, who was a grandson of Douglas, the title afterwards passing in the female line to the Douglases, and in 1761 to the duke of Hamilton; (2) Sir Alan of Dregthen, ancestor of the earls and dukes of Lennox, from whom Lord Darnley, husband of Queen Mary, and also Lady Arabella Stuart were descended; (5) Sir Walter, who obtained the barony of Garlies, Wigtownshire, from his uncle John Randolph, earl of Moray, and was the ancestor of the earls of Galloway, younger branches of the family being the Stewarts of Tonderghie, Wigtownshire, and also those of Physgill and Glenturk in the same county; (4) Sir James, who fell at Dupplin in 1333, and the earl of the Douglas line; and whose descendants were ordered at different periods the earldoms of Athole, Buchan and Traquair, and who were also the progenitors of the Stewarts of Appin, Argyllshire, and of Grantully, Perthshire; (5) Sir John, killed at Halidon Hill in 1333; (6) Sir Hugh, who fought under Edward Bruce in Ireland; and (7) Sir Robert of Daldowie, ancestor of the Stewarts of Allanton and of Coltness. James Stewart, the elder son of Alexander, fourth steward, succeeded his father in 1285, and, after distinguishing himself in the wars of Wallace and of Bruce, died in 1306. His son Walter, sixth steward, who had joint command with Sir James Douglas of the left wing of the battle of Bannockburn, married Marjory, daughter of Robert the Bruce, and during the latter's absence in Ireland was entrusted with the government of the kingdom. He died in 1326, leaving an only son, who as Robert II. ascended the throne of Scotland in 1327. Sir Alexander Stewart, earl of Buchan, fourth son of Robert II., who earned by his ferocity the title of the "Wolf of Badenoch," inherited by his wife the earldom of Ross, but died without legitimate issue, although from his illegitimate offspring were descended the Stewarts of Belladrum, of Athole, of Gart, and of Carrick; and the earldom of Ross passed to his brother Robert, duke of Albany, also earl of Fife and chief of Menteith, but these earldoms were forfeited on the execution of his son Murdoch in 1425, the earldom of Buchan again, however, coming to the house of Stewart in the person of James, second son of Sir James Stewart, the black knight of Lorn, by Joan or Joanna, widow of King James I. From Murdoch, duke of Albany, were descended the Stewarts of Ardvoirlich and other families of the name in Perthshire, and also the Stuarts of Inchbroke and Laithers, Aberdeenshire. From a natural son of Robert II. were descended the Stewarts of Dulguise; Perthshire, and from a natural son of Robert III. the Shaw Stewarts of Blackhall and Greenock. The direct male line of the royal family terminated with the death of James V. in 1542, whose daughter Mary was the first to adopt the spelling "Stuart." Mary was succeeded in her lifetime in 1567 by her only son James VI., who through his father Lord Darnley was also head of the second branch, there being no surviving male issue of the family from progenitors later than Robert II. In James V.'s son of James IV. by Margaret, daughter of Henry VII., the claims of Margaret's descendants became merged in the Scottish line, and on the death of Queen Elizabeth of England, the last surviving descendant of Henry VIII., James VI. of Scotland, linearly the nearest heir, was proclaimed king of England, in accordance with the arrangements made by Lord Burghley and Elizabeth's other advisers. The accession of James, was, however, contrary to the will of Henry VIII., which favoured the heirs of his younger sister Mary, wife of Charles Brandon, duke of Suffolk, whose succession would probably have marvel-immediately the coronation of both. This happened immedi-

As it was, the only result of that will was a tragedy initiated by Elizabeth and consummated by James. In the Scottish line the nearest heir after James VI., both to the Scottish and English crowns, was Arabella Stuart, only child of Charles, earl of Lennox, younger brother of Lord Darnley—Lady Margaret Douglas, the mother of Darnley and his brother, having been the daughter of Archibald, sixth earl of Angus, by Margaret of England, queen dowager of James IV. James VI. (I. of England) was thus nearest heir by a double descent, Arabella Stuart being next heir by a single descent. On account of the defeat of Henry VIII. in the jealousy of Elizabeth had already caused her to imprison Arabella's mother Elizabeth, daughter of Sir William Cavendish, on learning that she had presumed to marry Lennox. The daughter's marriage she was determined by every possible means to prevent. She objected when King James proposed to marry her to Lord Esme Stuart, whom he had created duke of Lennox, but when the appalling news reached her that Arabella had actually found a lover in Edward Seymour, grandson of Catherine Grey, heiress of the Suffolks, she was so deeply alarmed and indignant that she actually proposed marriage to the dauphine of France. This happened immediately before Elizabeth's death, after which she obtained her release. Soon after the accession of James a conspiracy, of which she was altogether ignorant, was entered into to advance her to the throne, but this caused no alteration in her treatment by James, who allowed her a maintenance of £800 a year. In February 1610 it was discovered that she was engaged to Seymour, and, although she then promised never to marry him without the king's consent, the marriage took place secretly in July following. In consequence of this her husband was sent to the Tower and she was placed in private confinement. Though acquitted, both succeeded in escaping simultaneously on the 3rd of June 1611; but, less fortunate than her husband, who got safe to the Continent, she was captured in the straits of Dover and shut up in the Tower of London. Her hopeless captivity deprived her of her reason before her sorrows were ended by death, on the 27th of September 1615.

By the usurpation of Cromwell the Stuarts were excluded from the throne from the defeat of Charles I. at Naseby in 1645 until the restoration of his son Charles II. in 1660. Carlyle refers to the opinion of genealogists that Cromwell "was indisputably either the ninth or the ten thousandth of a constitutional prince to be called a constitutional prince," but this has been completely exploded by Walter Rye in the Genealogist ("The Steward Genealogy and Cromwell's Royal Descent," new series, vol. ii. pp. 34-42). On the death of Charles II. without issue in 1685, his brother James, duke of York, ascended the throne as James II. but he so alienated the sympathies of the nation by his unconstitutional efforts to further the Roman Catholic religion that an invitation was sent to the prince of Orange to come "to the rescue of the laws and religion of England."
Next to the son of James II., still an infant under his father's control, Mary, princess of Orange, elder daughter of James II., had the strongest claim to the crown; but the claims of the prince of Orange also, even apart from his marriage, were not very remote, since he was the son of Mary, eldest daughter of Charles II. The marriage was arranged with the king at the beginning of 1688, and on the 10th of February 1689, Scotland following the example of England on the 11th of April. They left no issue, and the Act of Settlement passed in 1701, excluding Roman Catholics from the throne, secured the succession to Anne, second daughter of James II., and on her death without issue to the Protestant house of Hanover, descended from the princess Elizabeth, daughter of James I., wife of Frederick V., count palatine of the Rhine. On the death of Anne in 1714, George, elector of Hanover, eldest son of Sophia, was crowned king of Great Britain and Ireland, and queen, successor of Brunswick-Lüneburg, or Hanover, consequently became sovereign of Great Britain and Ireland, and, notwithstanding some formidable attempts in behalf of the elder Stuart line in 1715 and 1745, the Hanoverian succession has remained uninterrupted and has ultimately won universal assent. The female issue of James II. ended with the death of his daughter, Queen Anne, James, called James III. by the Jacobites and the Old Pretender by the Hanoverians, had two sons—Charles Edward, the Young Pretender, who died without legitimate issue in 1786, and Henry Stuart, titled Duke of York, who was created a Cardinal by his father on whose death in 1807 the male line of James II. came to an end. Henry was also the last descendant in the lineal male line of any of the crowned heads of the race, so far as either England or Scotland was concerned. In the female line, however, there are among the descendants of James I. representatives of the royal Stuarts who are senior to the house of Hanover, for Philip, duke of Orleans (brother of Louis XIV.), married, as his first wife, Henrietta daughter of Charles I., and, as his second, Charlotte, granddaughter and heiress of the princess Elizabeth (daughter of James I.). By the former, through their daughter, the princess Sophia, he was ancestor, among others, of the princess Maria Theresa of Bavaria, who in 1760 was "heir of line" of the house of Stuart, her eldest son, Prince Rupert, being heir to the throne of Bavaria; and from his second marriage descends the house of Orleans. In addition to those descended from these two marriages there are also the descendants of Edward, a brother of the electress Sophia. The male representation of the family, being extinct in the royal lines, is claimed by the earls of Galloway and also by the Stewarts of Castlemilk, but the claims of both are more than doubtful.

See Sir George Mackenzie, Defence of the Royal Line of Scotland (1689), and Antiquity of the Royal Line of Scotland (1686); Crawford, Genealogical History of the Royal and Illustrious Family of the Stuarts (1710); Duncan Stewart, Genealogical Account of the Surname of Stewart (1739); Andrew Stuart, Genealogical History of the Stuarts (1798); Stodart, House of Stuart (privately printed, 1853); An Abstract of the Evidence to Prove that Sir William Stewart of Jedworth, the Paternal Ancestor of the Present Earl of Galloway, was the Second Son of Sir Alexander Stewart of Darnley (1801); Riddell, Stuartsiana (1832); W. Townsend, Descendants of the Stuarts (1838); R. W. Eyton, History of Shropshire (1858), vol. vii.; Bailey, The Succession to the English Crown (1879); Skelton, The Royal House of Stuart (1880); R. H. Hargreaves, The Family History of the Stuarts (1880); and S. Cowan, The Royal House of Stuart (1908). The best chart pedigreed of the house is that which was prepared for the Stuart Exhibition by W. A. Lindsay.

STEWART, ALEXANDER TURNER (1863-1876), American merchant, was born, of Scotch descent, at Lisburn, near Belfast, Ireland, on the 12th of October 1803. He studied for the ministry for about two years at Trinity College, Dublin, emigrated to New York in 1823, and in 1825 opened a small dry goods store. In 1848 he built at the corner of Chambers Street and Broadway by a store which became the wholesale department, upon the completion in 1862 of the large store on Broadway between Ninth and Tenth Streets. The business grew to enormous proportions for those days, with foreign branches in Manchester, Belfast, Glasgow, Berlin, Paris and Lyons. Stewart was chairman of the commission sent by the United States to the Paris Exposition of 1867. In 1866 he was appointed secretary of the treasury by President U. S. Grant, but the Senate refused to confirm the appointment because of an old law excluding from the office any one interested in the importation of foreign goods. Grant asked Congress to repeal the law, and Stewart offered to transfer his business to trustees and to give its proceeds while he held office to charitable institutions, but the nomination was never confirmed. Stewart sent to Ireland a shipload of provisions during the famine of 1846; he manufactured and sold to the government, at less than the prevailing rates, great quantities of cotton cloth for the use of the army during the Civil War; he took an active part in the prosecution of the "Tweed Ring" in New York; he sent a shipload of flour to the French sufferers from the Franco-German War, and he gave $50,000 to the sufferers from the Chicago fire of 1871. In 1869 he bought some 7000 acres on the Hemptead Plain, Long Island, New York, and established Garden City for working men. The cathedral of the Incarnation (Protestant Episcopal) dedicated in 1885, was erected in Garden City by Stewart's widow as a memorial to him. He died in New York on the 10th of April 1876, leaving the bulk of his great fortune to his widow, Mrs Cornelia (Clinch) Stewart (1820-1886). His large art collection was sold by auction in New York in 1887.

STEWART, BALFOUR (1828-1887), Scottish physician, was born in Edinburgh on the 1st of November 1828, and was educated at the university of that city. The son of a tea merchant, he was for some time engaged in business in Leith and in Australia, but, returning to his studies of physics at Edinburgh, he became assistant to J. D. Forbes in 1856. Forbes was especially interested in questions of heat, meteorology, and terrestrial magnetism, and it was to these that Stewart also mainly devoted himself. Radiant heat first claimed his attention, and by 1858 he had completed his first investigations into the subject. These yielded a remarkable extension of Pierre Prévost's "Law of Exchanges," and enabled him to establish the fact that radiation is not a surface phenomenon, but takes place throughout the interior of the radiating body, and that the radiative and absorptive powers of a substance must be equal, not only for the radiation as a whole, but also for every constituent of it. In recognition of this work he received in 1868 the Rumford medal of the Royal Society, into which he had been elected six years before. Of other papers in which he dealt with this and kindred branches of physics may be mentioned Observations with a Rigid Spectroscope, Heating of a Disc by Rapid Motion in Vacuum, "Thermal Equilibrium in an Enclosure Containing Matter in Visible Motion," and Internal Radiation in Uniaxial Crystals. In 1859 he was appointed director of Kew Observatory, and there naturally became interested in problems of meteorology and terrestrial magnetism. In 1870, the year in which he was very seriously injured in a railway accident, he was elected professor of physics at Owens College.

1 On the 6th of November 1878 his body was stolen from St Mark's churchyard in New York, but recovered in 1881 upon the payment of $50,000, and buried in the crypt of the cathedral in Garden City.

2 Upon her death she left a small part of her estate to her other relatives and her servants, about $4,631,000 to Charles J. Crilch, a kennel, and about $9,262,000 to Judge Henry Hilton (1824-1890), who was one of her associates who held the legacy of $1,000,000 from Stewart, and who managed Mrs Stewart's business affairs after her husband's death. Crilch and Hilton were executors, and the money should go to the National Home of the Cathedral of Garden City and endow schools there. A nephew of Mrs Stewart in 1887 sued to break the will on the ground that Hilton had unduly influenced her; the case was compromised out of court in 1890 and the executors retained more of the estate than they would have got under the terms of the testament.
College, Manchester, and retained that chair until his death, which happened near Drogheda, in Ireland, on the 19th of December 1887. He was the author of several successful textbooks of science, and of the article on "Terrestrial Magnetism" in the ninth edition of this Encyclopaedia. In conjunction with Professor P. G. Tait he wrote The Unseen Universe, at first published anonymously, which was intended to combat the common notion of the incompatibility of science and religion.

STEWART, CHARLES (1778-1860), American naval officer, was born at Philadelphia, Pennsylvania, on the 28th of July 1778, of poor Irish parents. At the age of thirteen he shipped as cabin boy on a merchant vessel commanded by Captain John Snell, and in 1798, at the age of twenty, Snell was appointed to a command in the India trade. He entered the United States navy in March 1798 as lieutenant on the frigate "United States," and in 1800, when in command of the "Experiment," took the French privateers "Deux Amis" and "Diane." In 1802-4 he served against Tripoli, first as executive officer of the "Constellation" and then as commander of the "Siren." In 1806 he became a captain. From 1808 to 1812 he was in the merchant service, but on the outbreak of hostilities against Great Britain returned to the navy, and with Commander William Bainbridge is said to have persuaded President Madison to send out a small vessel to this end, 1813, the only for her honour defence. Placed in the command of the "Constellation," he was closely blockaded at Norfolk, Virginia. In 1813 he was placed in command of the "Constitution," and in February 1815 captured the "Cyane" and the "Levant," though the "Levant" was retaken. Later he commanded the Mediterranean squadron, the Pacific squadron, the home squadron and the Philadelphia navy yard. He was retired in 1855, and became rear-admiral on the retired list in 1862. He died in Borden town, New Jersey, on the 6th of November 1869. His daughter, Della Tudor, married, in 1834, John Henry Parnell, and became the mother of the Irish leader, Charles Stewart Parnell.

STEWART, SIR DONALD MARTIN (1824-1900), British field marshal, son of Robert Stewart of Forres, Elginshire, was born at Mont Pleasant, near Forres, on the 1st of March 1824. Educated at schools at Findhorn, Dufftown and Elgin, and at Aberdeen University, he entered the Bengal army in 1840, and served in 1854 and 1855 in the frontier expeditions against the Mohmands, and Afridis Aka and Bari Khel (medal and clasps). In the Indian Mutiny in 1857 Stewart, after a famous ride from Agra to Delhi with despatches, served on the staff at the siege and capture of Delhi and of Lucknow, and afterwards through the campaign in Rohilkhand (medal and two clasps, and bronze major and lieutenant-colonel). For nine years he was assistant and deputy-adjutant-general of the Bengal army, commanded the Bengal brigade in the Abyssinian expedition in 1867 (medal and C.B.), and became a major-general in 1868. He reorganized the penal settlement of the Andaman Islands, where he was commandant when Lord Mayo was assassinated, and, after holding the Lahore command, was promoted lieutenant-general in 1877, and commanded the Kandahar field force in the Afghan War in 1878 (K.C.B. and thanks of parliament). In 1880 he made a difficult march from Kandahar to Kabul, fighting on the way the battles of Ahmed Khel and Urza, and held supreme military and civil command in northern Afghanistan. On hearing of the Maimaid disaster, he despatched Sir Frederick Roberts with a division on his celebrated march from Kabul to Kandahar, and himself led the rest of the army back to India by the Khyber Pass (medal with clasps, G.C.B., C.I.E., baronetcry, and thanks of parliament). Promoted general in 1881, he was for five years commander-in-chief in India, and afterwards member of the council of the secretary of state for India until his death. He was made G.C.S.I. in 1885, promoted to be field marshal in 1894, and appointed governor of Chelsea Hospital in 1895. He died at Algiers on the 26th of March 1900. See G. R. Elsmie, Sir Donald Stewart (1903).

STEWART, DUGALD (1753-1828), Scottish philosopher, was born in Edinburgh on the 22nd of November 1753. His father, Matthew Stewart (1715-1785), was professor of mathematics in the university of Edinburgh (1747-1772). Dugald Stewart was educated in Edinburgh at the high school and the university, where he read mathematics and moral philosophy under Adam Ferguson. In 1771, in the hope of gaining a Snell exhibition and proceeding to Oxford to study for the English Church, he went to Glasgow, where he attended the classes of Thomas Reid. While he owed to Reid all his theory of morality, he repaid the debt by giving to Reid's views the advantage of his admirable style and academic eloquence. In Glasgow Stewart board on the same house with Archibald Alison, author of the Essay on Taste, and a lasting friendship sprang up between them. After a single session in Glasgow, Dugald Stewart, at the age of nineteen, was appointed to the chair of moral philosophy, which he filled during the next quarter of a century and made a centre of intellectual and moral influence. Young men were attracted by his reputation from England, and even from the Continent and America. Among his pupils were Sir Walter Scott, Jeffrey, Cockburn, Francis Horner, Sydney Smith, Lord Brougham, Dr Thomas Brown, James Mill, Sir James Mackintosh and Sir Archibald Alison. The course on moral philosophy embraced, besides ethics proper, lectures on political philosophy or the theory of government, and from 1806 onwards a separate course of lectures was delivered on political economy, then almost unknown as a science to the general public. Stewart's enlightened political teaching was not sufficient, in the times of reaction succeeding the French Revolution, to draw upon him the undeserved suspicion of disaffection to the constitution. The summers of 1788 and 1789 he spent in France, where he met Suard, Degérando, Raynal, and learned to sympathize with the revolutionary movement.

In 1792 Stewart married a second time. Miss Cranston, who became his wife, was a lady of birth and accomplishments, and he was in the habit of submitting to her criticism whatever he wrote. A son and a daughter were the issue of this marriage. The death of the former in 1809 was a severe blow to his father, and was the immediate cause of his retirement from the active duties of his chair. Before that, however, Stewart had not been idle as an author. As a student in Glasgow he wrote an essay on Dreaming. In 1792 he published the first volume of the Elements of the Philosophy of the Human Mind; the second volume appeared in 1814, and the third not till 1827. In 1793 he printed a textbook, Outlines of Moral Philosophy, which went through many editions; and in the same year he read before the Royal Society of Edinburgh his account of the Life and Writings of Adam Smith. Similar memoirs of Robertson the historian and of Reid were afterwards read before the same body and appeared in his works. Stewart's enlightened political teaching was embodied in pamphlets defending Mr (afterwards Sir John) Leslie against the charges of unorthodoxy made by the presbytery of Edinburgh. In 1806 he received in lieu of a pension the nominal office of the writer of the Edinburgh Gazette, with a salary of £500. When the shock of his son's death incapacitated him from lecturing during the session of 1809-1810, his place was taken, at his own request, by Dr Thomas Brown, who in 1810 was appointed conjoint professor. On the death of Brown in 1820 Stewart retired altogether from the professorship, which was conferred upon John Wilson, better known as "Christopher North." From 1820 onwards Stewart lived mainly at Kinnell House, Linlithgowshire, which was placed at his disposal by the duke of Hamilton. In 1810 appeared the Philosophical Essays, in 1814 the second volume of the Elements, in 1815 the first part and in 1821 the second part of the "Dissertation" written for the Encyclopædia Britannica "Supplement,"...
entitled "A General View of the Progress of Metaphysical, Ethical, and Political Philosophy since the Revival of Letters." In 1822 he was struck with paralysis, but recovered a fair degree of health, sufficient to enable him to resume his studies. In 1827 he published the third volume of the Elements, and in 1828, a few weeks before his death, The Philosophy of the Active and Moral Powers. He died in Edinburgh on the 11th of June 1828. A monument to his memory was erected on Calton Hill.

Stewart's philosophical views are mainly the reproduction of his master Reid (for his ethical views see Ethics). He upheld Reid's psychological method and expounded the "common-sense" doctrine, which was attacked by the two Mills. Unconsciously, however, he fell away from the pure Scottish tradition and made concessions both to moderate empiricism and to the French idealists (Laromiguére, Cabanis and Destutt de Tracy). It is important to notice the energy of his declaration against the argument of ontology, and also against Condillac's sensationalism. Kant, he confessed, he cannot understand. His original work is his theory of life in the Philosophical Essays. But his reputation rests rather on his inspiring eloquence and the beauty of his style than on original work.

Stewart's works were edited in 11 vols. (1854-1858) by Sir William Hamilton and completed with a memoir by John Vetsch. Matthew Stewart (his eldest son) wrote a life in Annales Philosophici et Historici (1828) republished, privately in 1861. For his philosophy see McCosh, Scottish Philosophy (1875), pp. 162-173; A. Bain, Mental Science, pp. 268, 313 and app. xxix, 65, 88, 91; Moral Science, pp. 639 seq. for The Thirty Years' War in Scotland and the 17th Century. 

STEWARD, SIR HERBERT (1843-1885) British soldier, eldest son of the Rev. Edward Stewart, was born on the 30th of June 1843 at Sparsholt, Hampshire. He was educated at Winchester and entered the army in 1863. After serving in India with his regiment (37th Foot) he returned to England in 1873, having exchanged into the 3rd Dragoon Guards. In 1877 he entered the staff college and also the Inner Temple. In 1878 he was sent out to South Africa, served in the Zulu War and against Sikukuni. As chief staff officer under Sir G. Pomeroy Colley he was present at Majuba (Feb. 27, 1881), where he was made prisoner by a Boer patrol and detained until the end of March. In August 1882 he was placed on the staff of the cavalry division in Egypt. After Tel-el-Kebir (Sept. 13, 1882) he headed a brilliant advance upon Cairo, and took possession of the town and citadel. He was three times mentioned in despatches, and made a brevet-colonel, C.B., and aide-de-camp to the queen. In January 1884 he was sent to Suakin in command of the cavalry under Sir Gerald Graham, and took part as brigadier in the actions from El Teb to the advance on Tamanth. His services were recognized by the honour of K.C.B., and he was assistant adjutant and Q.M.G. in the south-eastern district in England from April to September 1884. He then joined the expedition for the relief of Khartoum, and in December, when news from Gordon decided Lord Wolseley to send a column across the desert of Metemma, Stewart was entrusted with the command. On the 16th of January 1885, he found the enemy in force near the wells of Abu Klea, and brilliantly repulsed their fierce charge on the following morning. Leaving the wounded under guard, the column moved forward on the 18th through bushy country towards Metemma, 23 m. off. Meanwhile the enemy continued their attacks, and on the morning of the 19th Stewart was wounded and obliged to hand over the command to Sir Charles Wilson. He lingered for nearly a month, living long enough to hear of his promotion to the rank of major-general "for distinguished service in the field." He died on the way back from Khartoum to Korti in the 16th of February, and was buried near the wells of Jakdul. In the telegram reporting his death Lord Wolseley summed up his character and career in the words: "No braver soldier or more brilliant leader of men ever wore the Queen's uniform." 

STEWARD, J. (JAMES), of Baldwyns (fl. 1590), Scottish verse writer, is known as the translator of Ariosto's Orlando Furioso. The work is an abridgment in twelve cantos and has the historical interest of having preceded Sir John Harington's translation (1591). The volume containing this version and other poems (of indifferent quality) is preserved in the Advocates' Library, Edinburgh. It bears the title Ane Abbregement of Roland Periots, translated out of Aroiis: together with some Rapodies of the Author's youthfull braine, and laste one Scheruing out of treu Felicitie; compos'd in Scottis metre by I. Stewart of Baldynnes. This MS. appears to be the original which was printed in 1612 under the title Vi. The poems translated and imitated are printed in Irving's History of Scottish Poetry (1861). 

STEWARD, JOHN (1749-1832), British traveller, was born in London of humble parentage. After an unruily career at school he entered the service of the East India Company at Madras in 1763, but he threw up his position about two years later and became interpreter to Hyder Ali, afterwards serving as a general in his army; subsequently he served the nabob of Arcot, whose chief minister he became. Having enriched himself in this capacity, he began a series of travels through India, Persia, Ethiopia and Abyssinia, which earned him the title of "Walking Stewart." About 1783 he returned to Europe, where he cut a curious figure by wearing Armenian dress. He crossed over to America in 1791 and had various adventures, only to return to Europe in 1810. His travels and adventures are given in a series of diaries (1829), 5 vols. and 2nd ed. (1836). He died on the 20th of February 1822. De Quincey (see Collected Writings, 1890, vol. iii.) gives various particulars of him.

STEWARD, JULIUS L. (1855- ), American artist, was born at Philadelphia on the 8th of September 1855. His father, William Hood Stewart, was a distinguished collector of the fine arts, an early patron of Fortuny and the Baribon artists, and lived in Paris during the latter part of his life. The son was a pupil of J. L. Gérôme, at the École des Beaux Arts, and of Raymond de Madrazo. Among his principal paintings are "The Hunt Ball," Essex Club, Newark, New Jersey; "Full Speed," in James Gordon Bennett's collection; "Five o'clock Tea," and "Court in Cairo." 

STEWARD, WILLIAM (c. 1450-c. 1550), Scottish poet and translator, descendant of one of the illegitimate sons of Alexander Stewart, earl of Buchan, the "Wolf of Badenoch," was a member of the university of St Andrews. He was in orders, and a hanger-on at the court of James V. The last entry of the payment of a pension of £40 appears in the accounts of 1541. He was known as a poet in his own day: Lyndsay and Rolland refer to him. Portions of his minor verse are preserved in the Bannatyne and Maitland Folio MSS. His chief work is a metrical translation of Hector Bocce's History, in obedience to the command of James V., who entrusted Bellenden with its translation into Scots prose. 

Steward's version remained in MS. till 1585, when it was edited by W. Turnbull for the "Rolls Series" (3 vols.). The MS. is now in the library of the university of Cambridge. 

STEWARD, SIR WILLIAM (c. 1590-1659), Scottish politician, began life as a soldier in the Netherlands, where he became a colonel and entered into communications with Lord Burghley on the progress of affairs. In the year 1628 he was in Scotland, where James VI. made him captain of his guard. Having visited the English court in the king's interest in 1633, Stewart helped to free James from William Ruthven, earl of Gowrie, and to restore James Stewart, earl of Arran, to power; he was made a privy councillor and for a time assisted Arran to govern Scotland. In 1654 he captured Gowrie at Dundee. In 1655 he and Arran lost their power, and Stewart went to Denmark and France on secret errands for the king. He commanded the ships which conveyed James and his bride Anne from Denmark in 1590, and the same year was sent
on an embassy to the German princes. Twice he went on missions to the Netherlands, and in 1594 he was knighted and was given lands at Houston. He died before 1606. His only son, Frederick (c. 1590-1623), who was created a peer as Lord Pitenweem in 1609, died childless in December 1625.

Sir William Stewart of Houston is often confused with Sir William Stewart of Monkton (d. 1588), a younger of James Stewart, earl of Arran, who was killed in a fight in Edinburgh in July 1588, and also with Sir William Stewart of Caverston.

STEWARTON, a municipal and police burgh, in the Cunning-
dham district of Ayrshire, Scotland. Pop. (1901), 2838. It is
situated on Annick Water, 19 m. S.W. of Glasgow by the
Glasgow & South-Western railway. The town lies in a fine
agricultural district, famed for its dairy produce. Two
cattle and two horse fairs are held yearly; at the October cattle
fair there is the largest show of Ayraied cattle stock in Scotland.
About 2 m. north by west is Dunlop (pop. 473), which gave its
name to a cheese that at one time commanded a large market.

STEVY, MARTINUS THEUNS (1827– ), last president
of the Orange Free State, was born at Winburg in that state
on the 2nd of October 1827. He was a student in Holland
and later in England at the Inner Temple, and was called to the
English bar in November 1852. After his return to South Africa
he practised as a barrister at Bloemfontein, and in 1889 was
appointed state attorney of the Free State. A few months
afterwards he became second puisne judge, and in 1893 first
puisne judge of the high court. His decisions won him a
reputation for ability and sound judgment. In 1895, upon the
resignation of President F. W. Reitz, Steyn was the candidate
of the pan-Dutch party for the vacant post. The election
resulted (February 1896) in a decisive victory for Steyn. As
president he linked the fortunes of his state with those of the
Transvaal, a policy which led to the extinction of the republic.

After the occupation of Bloemfontein by Lord Roberts Steyn
wandered about South Africa, carrying on a semblance of
government, and on occasion taking charge of military operations.
More than once he narrowly escaped capture. Regarded as one
of the most influential of the Boer leaders, he took part,
however, in the preliminary peace negotiations at Klerksdorp
in April 1902, but was prevented by illness from signing the
instrument of surrender at Pretoria on the 31st of May. At
that date he was suffering from locomotor ataxy, brought on
by his constant exertions; and in the July following he sailed for
Europe, where he remained until the autumn of 1904. He then
took the oath of allegiance to the British crown, and returning
to South Africa partially restored to health resumed an active
participation in politics. In 1908-1909 he was vice-president of
the closer Union Convention, where he was distinguished for
his moderation and conciliatory attitude, while maintaining the
rights of the Dutch community.

STEYING, a small market town in the mid parliamentary
district of Sussex, England, 10½ m. W.N.W. of Brighton by the
London, Brighton & South Coast railway. Pop. (1901), 1705.
The church of St Andrew retains a very fine series of Norman pier-arches in the nave. Some picturesque old houses remain in the town. Brewing and the manufacture of
packham are carried on.

The Anglo-Saxon church of Steyning (Stoenings, Steoningum, Staningas, Steninges, Steynig) mentioned in Domesday is attributed to St Cuthman, who is said to have settled here before the
9th century, and whose shrine became a resort for pilgrims.
The later prosperity of the town was due to its harbour.
Alfred bequeathed Steyning to his nephew, but it evidently reverted
to the Crown, as it was granted by Edward the Confessor to the
abbot and convent of Fécamp, with whom it remained until the
15th century. By 1086 Steyning was a thriving port. It had
a market, a mint and two churches, and the borough contained
123 burgages. The decay of the town began in the 14th century
owing to the recession of the sea, and it received another blow in
1362, when most of the buildings were destroyed by Henry IV. It was afterwards
granted to the abbey of Sion, which held it until the dissolution.

From the reign of Edward IV. to that of Richard III. there is
evidence that the town was governed by a bailiff elected annually
in the borough-court. Steyning returned two representatives
to parliament from 1258 until it was disfranchised in 1832.

STEWYR, or STEYR, a town in Upper Austria, 28 m. S.E. of
Linz by rail. Pop. (1900), 17,592. It is situated at the confluence of the
Steyr with the Enns, and on an eminence rises the castle
of the princes of Lamberg, dating from the 10th century. The
parish church is in Gothic style and was built in 1443-1522.
Steyr is the chief centre of the steel and iron industry of Upper
Austria; it styles itself the "metal city" of the Magy-Banya district,
and is largest in Austria, and since 1882 it has added the manu-
facture of bicycles and electrical plant. It is the birthplace of
the poet Alois Blumauer (1755-1798). Steyr was founded at the
end of the 10th century and was the capital of a countship, first
belonging to Styria, but annexed to Austria in 1192.

STIBNITE, a mineral consisting of antimony sulphide, Sb2S3,
occurring as bladed or acicular orthorhombic crystals; an
important ore of antimony. It was mentioned by Dioscorides and
Pliny under the names sittmi, sitii and plathyphthalmon (σαλτιον for saltum); the last name refers to the use which the
ancients made of the powdered mineral for darkening the
eyebrows to increase the apparent size of the eyes. Antimonite
is a common name in use for this species. The crystals are
prismatic in habit, deeply furrowed longitudinally, and usually
terminated by acute pyramidal planes. There is a perfect
cleavage (010) parallel to the length of the crystals, and the
basal plane (001) is a plane of gliding; the latter gives rise to very
characteristic transverse striations or nicks on the cleavage
surfaces of crystals which have been bent. The colour is lead-
grey, and the lustre metallic and brilliant; crystals become dull
on prolonged exposure to light. Cleavage along the extreme
thinness transmits a small amount of red light, but is more
transparent for heat rays. The mineral is quite soft (H. = 2),
and has a specific gravity of 4.6. Stibnite occurs with quartz in
beds and veins in gneisses and schists, or with blende, galena, &c.,
in metalliciferous veins. Magnificent groups of brilliant crystals,
up to 20 in. in length, are abundant in the extensive anti-
mony mine of Ichinokawa, province of Iyo, Japan. Large, but
dull, crystals have also been found at Lubilhac in Haute-Loire,
France. Prismatic and acicular crystals often penetrating
tabular crystals of barytes, are common at Felsődánya near Magy-Banya, and Krenmits in Hungary.

STICHOMETRY, a term applied properly to the measurement (μέτρησις) of ancient texts by στίχος (lit. "rows") or verses of a
fixed standard length. It was the custom of the Greeks and Romans to estimate the length of their literary works by measured lines.
In poetical works the number of metrical verses was computed; in prose works a standard line had to be taken, for
no two scribes would naturally write lines of the same length. On
the authority of Galen (de Poesie, Ipp. et Plat. viii. 1) we learn that the unit of measurement among the Greeks was the average Homeric line, consisting of about 36 letters, or 16 syllables. In the later Antiquity it was called στρογγυλο or στρογγυλος. (L. I, 16.)

STICTHOUSUS, or Stichousus, a city in Lacedaemon,
containing 14 naves, 24 columns, and 5 altars. It was a
birthplace of St Simon Stock, a Franciscan who died in 1263.

STICTHOSUS, or Sticthosus, a Greek poet of the 8th
century B.C., who composed a number of didactic poems on
the practice of agriculture.
STICKLEBACK were published, scribal errors were thought it was needless to repeat what could be found elsewhere; and thus it is that the present, and subsequent, MSS. which are marked in this way. A more natural reason for the scarcity of such details is that scribes and bookkeepers suppressed them in order to impose upon their customers.

The application of the system to Latin MSS. was fully recognized. The unit of measurement was the average Virgilian line. This is recorded in an interesting memorandum written in the 4th century, found in a MS. in the Philibys Library at Cheltenham, containing a computation of the nameof the books of the Bible and the works of Cyprian. The writer states that he had had this practice in his library, counting the number of verses in the MSS., and that elsewhere also, for greed of gain, the numbers were suppressed. Therefore he has made a calculation of the contents of the text under his hand and has appended to the several books the number of Virgilian hexameters which would represent its length. The rate of pay of the scribes in Diocletian's reign was fixed by his edict de pretiis rerum venalium at 25 denarii for 100 οἶχοι in writing of the first quality, and at 20 denarii for the second quality; what the difference was between the two qualities does not appear.

The number of poems in which this arrangement has been called "stichometry," in distinction from "stichometry," was the calculation and marking off in the margins of the οἶχοι from point to point, just as we mark off the lines in a poem at the proper intervals and number the verses of the chapters of the Bible. This method was for convenience of literal reference. Instances of such "stichometry" are not very numerous among existing MSS., but they are sufficient to show that the system was in vogue. In the Bayeux Homer in the British Museum the verses are numbered in the margin by hundreds, and the same practice was followed in other Homeric papyri. In the Ambrosian bustature of the 5th century at Milan the book of Deuteronomy is likewise numbered at every hundredth οἶχος. Euthalius, a deacon of Alexandria of the 5th century, marked the οἶχοι of the Pauline epistles by fifties. In the Codex Urbanus of Isocrate, and in the Claudi rusticus of A.D. 888, at Oxford, there are indications of partial stichometry.

There was also in use in biblical texts and in rhetorical works a stichometrical system different from that described above, in which the οἶχοι, as we have seen, were lines of measurement or space-lines. This other system, which is more correctly entitled colometry (see Manuscript), consisted in the division or breaking up of the text into short sentences or lines according to the sense, with a view to a better understanding of the meaning and a better delivery in public reading. The Psalms, Proverbs and other poetical books were anciently thus written, and hence received the title of βιβλία οὐρανιον. It was even said that St. Jerome wrote, first the books of the prophets, and subsequently all the Bible of his version, per cola et commata "quod in Demosthene et Tullio solet faciendum," that is, in the order of his own colometry, the introduction of the method of writing ερωτευότα, as he termed it, into the Pauline and Catholic epistles and the Acts. The surviving MSS. which contain the text written in short sentences show by their smaller size and shape that the original sense and general sense of sense were differently calculated by different writers; but the original arrangement of St. Jerome is thought to be represented in the Codex Amiatinus at Florence, and that of Euthalius in the Codex Claromontanus at Paris. With regard to St. Jerome's reference to the division per cola et commata of the rhetorical works of Demosthenes and Cicero, it should be noticed that there are still in existence MSS. of works of the latter in which the text is thus written, one of them being a volume of the Tucsinanti and the De senectute in the Bibliothèque Nationale at Paris. The same arrangement of the text of the orations of Demosthenes is also mentioned by the rhetorians of the following centuries.

AUTHORITIES.—C. Graux in Revue de philologie (1878), ii. 97; T. Mommsen in Hermes, xxi. 142; W. Sanday in Studia biblica (1891), ii. 217; J. Rendell Harris, Stichometry (1893). (E. T. T.)

STICKÉ, a game played in an enclosed court, taking its name from spharialistikē, the parent of lawn-tennis. The implements are a long and low tennis-net, 3 ft. 6 in. high, and covered with flannel. The walls of the court may be made of wood, cement or brick to the height of 9 or 10 ft., netting the above—unless the court is roofed—to prevent the balls from going out: the floor may be of wood, cement or asphalt, perfect accuracy not being essential. The dimensions of the court are 78 ft. by 27 ft.; it is bisected longitudinally by a painted line, laterally by a net 3 ft. 6 in. high, above which is stretched a tape 8 ft. from the ground. In each of the corners a 9-ft. square (the "service" court) is painted, and 18 ft. from each back wall lines ("service" lines) are drawn across the breadth of the court. The rules are similar to those of lawn-tennis, except that a ball can only be "out of court" if it is struck over the walls.

STICK-INSPECT, the name given to certain orthopterous insects of the family Phasmatidae, of extremely variable form and size, and deriving their name from a resemblance to the branches and twigs of the trees in which they live and feed. The resemblance is produced by the long length and slenderess of the body and legs. Protection is afforded to some species, like Hierotepyra grisii from Borneo, by sharp thornlike spines. The antenodal wings, which are always small, but the posterior wings are sometimes of large size and very beautifully coloured. The colouring, however, is only visible when the wings are expanded and in use. Many species are wingless at all ages. As in the leaf-insects, to which the stick-insects are closely allied, the egg-cases are very similar to seeds. Stick-insects are intolerant of cold, and attain their largest size and greatest profusion of species in the tropics, one West African species, Palopus centaurus, reaching a length of 6 in. Species of small size are found in southern Europe, one belonging to the genus Bocadius, advancing as far north as the middle latitudes of England.

STICKLEBACK, the name applied to a group of small fishes (Gasterosteus) which inhabit the fresh and brackish waters as well as the coasts of the temperate zone of the northern hemisphere. As far as the European kinds are concerned, all may be met with in the brackish water of certain littoral districts. The majority have a compressed well-proportioned body, which in the marine species is of a more elongate form, leading to the allied group of flute-moutns (Fistulariidae), which are, in fact, gigantic marine stickbacks. Their mouth is of moderate width, oblique, and armed with small but firmly set teeth. The body is contractile when threatened, the abdomen being drawn out and the caudal fins expanded, the secondaries being drawn out and the branchiostegal membranes being drawn into a pointed formidable spine, and joined to form bony plates of the endoskeleton. With regard to the degree in which this armature is developed, not only do the species differ from each other, but almost every species shows an extraordinary amount of variation. About ten kinds may be taken to be specifically distinct. Of the three known at present, all stickbacks construct a nest for the reception of the spawn, which is jealously guarded by the male until the young are hatched, which event takes place in from ten to eighteen days after oviposition. He also protects them for the first few days of their existence. Stickbacks are short-lived animals; they are said to reach an age of only three or four years; yet their short life, at least that of the males, is full of excitement. During the first year of their existence, before the breeding season begins, they live in small companies in still pools or gently flowing brooks. But with the return of the warmer season each male selects a territory, which he energetically protects against all comers, especially against intruders of his own species and sex, and to which he invites all females, until the nest is filled with ova. At this period he also assumes a bridal dress, painted with blue and red tints. The eggs are of comparatively large size, one female depositing from 50 to 100.

Gasterosteus aculeatus, var. norvegianus, Three-Spined Stickelback.

Of the species known not one has so wide a geographical range, and has so well been studied, as the common British threespined stickleback (Gasterosteus aculeatus). It is found everywhere in northern and central Europe, northern Asia, and North
America. The development of its scutes and spines varies extremely, and specimens may be found without any lateral scutes and with short spines, others with only a few scutes and moderately sized spines, and again others which possess a complete row of scutes from the head to the caudal fin, and in which the fin-spines are twice as long and strong as in other varieties. On the whole, the smooth varieties are more numerous in southern than in northern localities. This species swarms in some years in prodigious numbers; in Pennant’s time amazing shoals appeared in the fens of Lincolnshire every seven or eight years. No instance of a similar increase of this fish has been observed in our time, and this possibly may be due to the diminished number of suitable breeding-places in consequence of, the introduction of artificial drainage. This species usually constructs its nest on the bottom, excavating a hollow in which a bed of grass, rootlets or fibres is prepared; walls are then raised, and the whole is roofed over with the like material. The nest is an inch and more in diameter, with a small aperture for an entrance.

The ten-spined stickleback (Gasterosteus pungitius) is so called from the number of spines usually composing its first dorsal fin, which, however, may be sometimes reduced to eight or nine or increased to eleven. It is smaller than the three-spined species, rarely exceeding 2 in. in length. Its geographical range nearly coincides with that of the other species, but it is not so locally distributed, and its range in northern Asia is not known. Its nest is generally placed among weeds above the bottom of the water. Breeding males are readily recognized at a distance by the intensely black colour of the lower parts of their body.

Both these species are extremely voracious. A small stickleback kept in an aquarium devoured, in five hours’ time, 74 newly-hatched dace, which were about a quarter of an inch long. Two days after it swallowed 62 and would probably have eaten as many every day could they have been procured. The sea-stickleback (Gasterosteus spinosus or Spinacia vulgaris) is a small fish which, in 1849, was said to inhabit the coast of Norway, and in 1851 was mentioned as being very common round the British coasts, but never congregates in large shoals. At suitable localities of the coast which are sheltered from the waves and overgrown with seaweed, especially in rock-pools, one or two males establish themselves with their harems, and may be observed without difficulty, being quite as fearless as their freshwater cousins. Harbours and shallows covered with Zostera are likewise favourable haunts of this species, although the water may be brackish. The nest is always firmly attached to seaweed, and sometimes suspended from an overhanging branch. The males are found together by a high white thread which is formed by a secretion of the kidneys of the male. This species inhabits only the northern coasts of Europe.

STIER, RUDOLF EWALD (1800–1862), German Protestant divine and mystic, was born at Fraustadt in Posen on the 17th of March 1800. He studied at Halle and Berlin, first law and afterwards theology; and he continued his theological studies later at the pastoral seminary of Wittenberg. In 1824 he was made professor in the Missionary Institute at Basel. Afterwards he held pastorates at Frankenbren near Merseburg (1829) and at Wittingen in Aethelm shee (1832) and at Maxau in the Black Forest (1838). In 1850 he was appointed superintendent at Schkeuditz, and in 1859 at Eisleben. He published a new edition of Luther’s Catechism and a translation of the Bible based on that of Luther; but he is noted chiefly for his thoughtful, devotional and mystical commentary on the words of the Lord (Reden des Herrn, 3 vols., 1843, 3rd ed., 7 vols., 1870–1874; Eng. trans., 8 vols., 1855–1858; 3 vols., 1860). He died at Eisleben on the 10th of December 1862.

STIFTER, ADALBERT (1803–1868), Austrian author, was born at Oberplan in Bohemia on the 23rd of October 1805, the son of a linen weaver. Having studied at the university of Vienna, he became tutor to Richard, eldest son of Prince Metternich, and obtained in 1849 the appointment as school inspector with the title of Schular (in Linz, where he lived until his death on the 28th of January 1868. As early as 1840 Stifter had made his name known by his Feldblumen, a collection of charming little sketches, but his fame chiefly rests upon his Studien (1844–1851) in which he gathered together his early writings. These sketches of scenery and rural life are among the best and purest examples of German prose. Among other of his works may be cited Bunte Steine (1853), Nachkommern (1857), Witiko (1864–1867), and Briefe, which appeared posthumously in 1869.

Stifter’s Sämtliche Werke were published in 17 vols. in 1870. There are also editions of selected works in 4 vols. (1887) and in 6 vols. (1899). A critical edition by A. Sauer is in preparation. Stifter’s letters were published by J. Appert in 3 vols. (1866). See E. Kuh, Zweifach Diether Osterrichtes (1872); K. Froell, A. Stifler, der Historiker (1901); and K. T. G. Wilckens, A. Stifler (1901); and T. Kläber, A. Stifler (1905); W. Kosch, A. Stifter und die Romantik (1905).

STIGAND (d. 1772), archbishop of Canterbury, is first mentioned in 1220. He was then chaplain to Canute and afterwards to his son, Harold Harefoot, and after the death of the former king appears to have acted as the chief adviser of his widow, Emma. In 1043 he was consecrated bishop of Elmham and in 1047 was translated to Winchester; he supported Earl Godwine in his quarrel with Edward the Confessor, and in 1052 arranged the peace between the earl and the king. In this year the archbishop of Canterbury, Robert of Jumièges, having been outlawed and driven from England, Stigand was appointed to the archbishopric; but, regarding Robert as the rightful archbishop, Pope Leo IX. and his two successors refused to recognize him. In 1058, however, Benedict X. gave him the pall, but this pope was deposed in the following year. Stigand is said by Norman writers to have crowned Harold in January 1066; but it is now probable that this ceremony was performed by Aldred, archbishop of York. Stigand submitted to William, and assisted at his coronation. But the Conqueror was anxious to get rid of him, although he took him in his train to Normandy in 1067. In 1070 he was deposed by the papal legates and was imprisoned at Winchester, where he died, probably on the 22nd of February 1072. Stigand was an avaricious man and a great pluralist, holding the bishopric of Winchester after he became archbishop of Canterbury, in addition to several abbey.

STIGMATIZATION, the infliction of stigmata, i.e. marks tattooed or branded on the person, the term being used with specific reference to the supposed supernatural infliction of wounds like those of the crucified Jesus.

An ancient and widespread method of showing tribal connexion, or relation to tribal deities, was by marks set upon the person; thus Herodotus, in describing a temple of Hercules in Egypt (ii. 113), says that it is not lawful to cause runaway slaves who take refuge therein if they receive certain marks on their bodies, devoting them to the deity. The practice is alluded to by Paul (Gal. vi. 17) in the words, “from henceforth let no man trouble me, for I bear branded on my body the stigma of Jesus”; and some writers have understood the passage as referring to stigmatisation in the modern sense (Mat. 75, De historia ss. imaginum et picturam, ed. Paracut. i. 43, p. 365). Branding, as indicative of servitude, was forbidden by Constantine.

In the period of persecution Christian martyrs were sometimes branded with the name of Christ on their foreheads (Pontius, “De vit. S. Cypriani,” Bibl. veterum patrum, vol. iii. p. 472, § vii.). Wounds of this sort were sometimes self-inflicted as a disfigurement by nuns for their protection, as in the case of St Ebbia, abbess of Coldingham (see Baronius, Annales, xv. 215, ann. 850, also Tert. De tel. virg.). Some Christians likewise marked themselves on the hands or arms with a cross on the name of Christ (Procopius, In Esuviam, ed. Curtius, p. 496), and other voluntary mutilations for Christ’s sake are mentioned (Matt. xix. 12, 14; Fortunatus, Life of St Rhodegund, ed. Migne, col. 508; Palladius, Lysais History, xxii.; Jerome’s Letter to St Eustochium, &c.).
In St Francis of Assisi we have the first example of the alleged miraculous infliction of stigmata. (For an earlier instance pronounced by the Church to be an imposture see Fleury, Hist. Eccl. lxxviii. § 50, ann. 1222.) While meditating on the sufferings of our Lord, in his cell on Mount Alverno in 1224, we are told by his biographers, Thomas of Celano and Bonaventura, that the Lord appeared to Francis as a seraph and produced upon his body the five wounds of Christ; of these we are told that the side wound bled occasionally, though Bonaventura calls it a scar, and that the foot wounds had the appearance and colour of nails thrust through. After his death St Clare endeavoured, but in vain, to extract one of these. Pope Alexander IV. and other witnesses declared that they had seen these marks both before and after his death (Raynaldu, ad ann. 1255, p. 27). The divinely attested sanctity of their founder gave to the newly established order of Franciscans a powerful impulse, so that they soon unified and threatened to overshadow in influence the previously founded order of St Dominic.

The reputation of the latter order was, however, similarly raised by the fact that not long after the next century by the occurrence of the same wonder in the case of a sister of the third rule of St Dominic, Catherine Benincasa—better known as St Catherine of Siena. From her biographer’s account we gather that she was subject to hystero-epileptic attacks, in one of which, when she was twenty-three years old, she received the first stigma (see v. 230). In spite of her great reputation, and the number of attesting witnesses, this occurrence was not universally believed in. Pope Sixtus IV. published a bull in 1475 ordering, on pain of anathema, the erasure of stigmata from pictures of St Catherine, and prohibiting all expressions of belief in the occurrence. Pope Innocent VIII. similarly legislated "ne de caetero S. Catharina in stigmatisma deingantur; neve de ejus stigmatismatibus flat verbum, aut sermo, vel pradictatio ad tollendam omnem scandalum occasione" (see references in Raynaldu, De Stigmatism, cap. xi. 1665). In the years which followed cases of stigmatization occurred thick and fast—now a Franciscan, now a Dominican, very rarely a religious of another order, showing the marks. Altogether about ninety instances are on record, of which eighteen were males and seventy-two females. (There are about thirty other cases sometimes included in the catalogue, of which there are no particulars recorded.) Most of them occurred among residents in religious houses, after the austerity of Lent, usually on Good Friday, when the mind was intently fixed on our Lord’s Passion; and the possibility of the reception of the marks was constantly before the eyes and thoughts of the members of the two orders to which St Francis and St Catherine belonged. The order of infliction in the majority of cases was that of the crucifixion, the first token being a bloody sweat, followed by the coronation with thorns; afterwards the hand and foot wounds appear, that of the side being the last. The grade of the inflection varies in both individual cases, and they may be grouped in the following series:

1. As regards full stigmatization, with the visible production of the wounds, and generally with the mark of the crown as well, the oldest case, after St Francis, is that of Ida of Louvain (1300), in whom the marks appeared as coloured circles; in Gertrude von Oosten of Delft (1334) they were complicated in form, and, as is the case of St Catherine, disappeared in answer to prayer as they also did on Dominica de Paradis; in Sister Pierona, a Franciscan, they were blackish grey. They were true wounds in Margaret Ebnerin of Nuremburg (d. 1351; see her Life, Augsburg, 1717), in Brigitta, a Dominican tertiary (1390), and also in Lidwina. An intermission is described in the marks on Johanna della Croce of Madrid (1524), in whom the wound in the side was large, and the others were rose-coloured. The marks of flowers and on ears on Friday were vanished on Sunday. These emitted an odour of violets; in Sister Apollonia of Volterra they were fetid when she lived. Angel della Pae (1653) was fully stigmatized, and it was at a time of years of forty. She was taken to surgery, and the sponge and bandage bled on the mouth; while Joanna de Jesu-Maria at Burgos (1613), a widow, who had entered the convent of Poor Clares, was marked in her sixtieth year. To her in a vision she was offered—although she was blind—three wounds; she chose the latter and immediately was seized with violent pain and her confessor heard a sound as of her skull breaking. This case was investigated by the officers of the Inquisition. The stigmatization of Veronica Giuliani (1696) was also the subject of inquiry, and in this case the nun drew on a paper a representation of the images which she said were engraved on her heart. On a post-mortem examination Dr being made, and had the hands and feet, and the whole of the image of the cross, the scourg, etc., were said to have been impressed on the right side of the organ (Vita della Veronica Giuliana, by Salvatori, Rome, 1837). In the case of S. Pecina (d. 1697), a nun at Colonge, it is noteworthy, as on her skull there was found a raised ridge or crown which was at first green, with red dots. In Lucia di Narni (1846) the marks were visible, as they also were on the face of St Margaret of Antioch (1853). On the other hand, in Hungary the stigmata were found fresh and clear when her body was exhumed some time after her death for transportation to Presburg. Other stigmatized persons were Elizabeth von Salplack, a Cistercian of Grostetten (1659); Maria Loretta, a Poor Clare; Matilda von Stanz; Margaret Bruch von Endringen (1666); Maria Razzi of Chiesa (1582); Catharina Januensis; Elisabeth Reith of Allgau; Stieva zu Hamm in Westphalia; St. Catalina of the Ponte Tarugino (1668); and St. Johanna Maria of Sicily (1668); Catharina Ricci in Florence (1590); and Joanna Maria della Croce, a Poor Clare at Roveredo (d. 1673), upon whom the markings of the thorn crown and spear wound were especially deep. In some cases, although the stigmata were apparent, there were no marks apparent. This occurred to Helen Brumsen (1285); Helena of Hungary (1270); Osanna of Mantua (1476); Columba Rocasani; Magdalena de Pazzis; Anna of Vargas; Hieronyma de Avarelo; Maria of Lisbon; Anna of Vercelli; Stephania Suncinas, a Franciscan; Sister Christina, a Carthusian; and Joanna Rodriguez, a Poor Clare. In the case of Ursula Aguirre de Atria (1424) a tertial of the Dominican order (d. 1610) the pain was chiefly that of the crown of thorns, as it also was in Amelia Bichicieri of Vercelli, an Augustinian.

2. In a third series some of the marks were visible on the body, while others were visible on the face. (a) St Mary of the Angels (1272); St. Ellen of Trier (1290); St. Thomas de Celano (1300); St. Philip de Coleta, a Poor Clare; Matilda von Stanz; Margaret Bruch von Endringen (1666); Maria Razzi of Chiesa (1582); Catharina Januensis; Elisabeth Reith of Allgau; Stieva zu Hamm in Westphalia; St. Catalina of the Ponte Tarugino; St. Johanna Maria of Sicily; and Catharina Ricci in Florence (1590); and Joanna Maria della Croce, a Poor Clare at Roveredo (d. 1673). On whom the markings of the thorn crown and spear wound were especially deep. In some cases, although the stigmata were apparent, there were no marks apparent. This occurred to Helen Brumsen (1285); Helena of Hungary (1270); Osanna of Mantua (1476); Columba Rocasani; Magdalena de Pazzis; Anna of Vargas; Hieronyma de Avarelo; Maria of Lisbon; Anna of Vercelli; Stephania Suncinas, a Franciscan; Sister Christina, a Carthusian; and Joanna Rodriguez, a Poor Clare. In the case of Ursula Aguirre de Atria (1424) a tertial of the Dominican order (d. 1610) the pain was chiefly that of the crown of thorns, as it also was in Amelia Bichicieri of Vercelli, an Augustinian.

3. In the third series some of the marks were visible on the body, while others were visible on the face. (a) St Mary of the Angels (1272); St. Ellen of Trier (1290); St. Thomas de Celano (1300); St. Philip de Coleta, a Poor Clare; Matilda von Stanz; Margaret Bruch von Endringen (1666); Maria Razzi of Chiesa (1582); Catharina Januensis; Elisabeth Reith of Allgau; Stieva zu Hamm in Westphalia; St. Catalina of the Ponte Tarugino; St. Johanna Maria of Sicily; and Catharina Ricci in Florence (1590); and Joanna Maria della Croce, a Poor Clare at Roveredo (d. 1673), upon whom the markings of the thorn crown and spear wound were especially deep. In some cases, although the stigmata were apparent, there were no marks apparent. This occurred to Helen Brumsen (1285); Helena of Hungary (1270); Osanna of Mantua (1476); Columba Rocasani; Magdalena de Pazzis; Anna of Vargas; Hieronyma de Avarelo; Maria of Lisbon; Anna of Vercelli; Stephania Suncinas, a Franciscan; Sister Christina, a Carthusian; and Joanna Rodriguez, a Poor Clare. In the case of Ursula Aguirre de Atria (1424) a tertial of the Dominican order (d. 1610) the pain was chiefly that of the crown of thorns, as it also was in Amelia Bichicieri of Vercelli, an Augustinian.
with records of her visions, have been published by Brentano at Munich in 1852 and the Abbé Cazalès at Paris (1850). Colombe Schopenhauer of Bamberg (1758) was fully stigmatized, as also was Rose Serra, a Capuchin of Ozieri in Sardinia (1801), and Madeleine Lorger (1806). Two well-known cases occurred in Tiro—one "L'Eстатика" Maria von Mörl of Caldaro, a girl of noble family, stigmatized in 1839, the other "L'Addolorata" Maria Dominica Lazzari, a miller's daughter at Capriana, stigmatized in 1835 (see Börö, Les Stigmatisées du Tyrol, Paris, 1846). A case of the second class is that of Elizabeth Eppinger of Niederbrunn in Bavaria (1814), reported on by Kuhn. An interesting example of stigmatic trance also occurred in the case of a Protestant young woman in Saxony in 1820, to appear as if dead on Good Friday and Saturday, and revived on Easter Sunday.

The last case recorded is that of Louise Lateau, a peasant girl, at Bois de Haine, Hainault, upon whom the stigmata appeared on the 24th of April 1868. This case was investigated by Professor Lefebvre of Louvain, who for fifteen years was physicist to two lunatic asylums. In her there was a periodic bleeding of the stigmata every Friday, and a frequent recurrence of the hystero-cataleptic condition. Her biography has been written by Lefebvre and published at Louvain (1870).

On surveying these ninety cases we may discount a certain number of cases that are more apt to be classed under the group of subjective sensations suggested by the contemplation of the pains of crucifixion. A second set, of which the famous case of Jetzer (Witz, Héboulische Kirchengeschichte, 1810, iii. 389) is a type, must be also set aside as obvious and intentional frauds produced on victims by designing persons. A third set, and how large a set we have not sufficient evidence to decide, we must regard as due to the irresponsible self-infliction of injuries by persons in the hystero-epileptic condition, those perverted states of nervous action which Charcot has done so much to elucidate. To any experienced in this form of disease, many of the phenomena of the symptoms of these cases are easily recognizable as characteristic of the hystero-epileptic state.

There are, however, some instances not easily explained, where the self-infliction hypothesis is not quite satisfactory. Parallel cases of physical effects due to mental suggestion are well authenticated. Beaunis vouches for rubefaction and vesication as produced by suggestion in the hypnotic state, and Bourru and Burot describe a case of bloody sweat, and red letters marked on the arm by simple tracing with the finger. See Congrès scientifique de Grenoble, projets méthodes d'exploration, 2nd serie (1832), and Berjon's La Grande hystérie chez l'homme (Paris, 1886).

We know so little of the trophic action of the higher nerve centres that we cannot say how far tissue nutrition can be controlled in spots. That the nerve centres have a direct influence on local nutrition is, in some cases, capable of experimental demonstration, and, in another sphere, a few of the recorded instances of connexion between maternal impression and congenital deformity seem to indicate that this trophic influence may have wider limits and a more specific capacity of localization than at first sight seems possible.

Kirchengeschichte, pp. 180, 345 (Berlin, 1875); Comptes rendus de la société de biologie (Paris, 1885); Birlot, Traité de la dénomination des osseaux et des tissus (Paris, 1898); Hambourg, Les Stigmatisées (1873).

**Stilbite,** a mineral of the zeolite group consisting of hydrated calcium aluminium silicate, CaAl₂(SiO₄)₂·6H₂O. Usually a small proportion of the calcium is replaced by sodium. Crystals are monodonic, and are invariably twinned, giving rise to complex groups and characteristic sheaf-like aggregates. The colour is usually white, sometimes red, and on the perfect cleavage (parallel to the plane of symmetry) the lustre is markedly pearly; hence the name stilbite given by R. J. Häüy in 1796, from Gr. stigon, to shine. After the separation of heulandite from this species in 1818, the name desmine (from désyµ, a bundle) was proposed, and this name is now employed in Germany. The hardness is 3½ and the specific gravity 2·2. Stilbite is a mineral of secondary origin, and is found in various forms, such as the small cavities known as the "gazelle" of Iceland; or with the various "trophical" cavities of basic volcanic rocks; it is sometimes found in lenticular or gaess, and exceptionally in metalliferous veins. It is abundant in the volcanic rocks of Iceland, Faeroes Islands, Skye, Bay of Fundy, in Nova Scotia and elsewhere. Beautiful, salmon-pink crystals occur with pale green appollithite in the Deccan traps near Bombay and Poona; white sheaf-like groups encrust the calcite (Iceland-spar) of Berufjord near Djupivog in Iceland; and crystals of a brick-red colour are found at Old Kilpatrick in Dumbartonshire.

**Stile,** a series of steps of stone or wood, or a combination of benches and steps used for passing over a fence or wall without the necessity of a permanent open passage or of opening or shutting a gate. The Old English, stigel, is formed from stigan, to climb, ascend; stair (O. Eng. staerg) and stirrup are from the same root. Stile (Lat stìlus, a pointed instrument) is really the correct spelling of style (q.v.).

**Stiles, Ezra** (1727–1795), American clergyman and educationalist, seventh president of Yale College, was born on the 20th of November 1727 in North Haven, Connecticut, where his father, Isaac Stiles (d. 1760), was minister of the Congregational Church. He graduated at Yale in 1746; studied there for the three years following; was licensed to preach in 1749 and was a tutor at Yale in 1749–1755. He preached in 1759 to the Indians at Stockbridge, later studied law, was admitted to the bar in 1753, and practised in New Haven for two years. He was pastor of the Second Congregational Church of Newport, Rhode Island, from 1755 to 1777; in 1776–1777 he preached occasionally in Dighton, Massachusetts, whither he had removed his family after the British occupation of Newport; and in April 1777 he became pastor of the North Church of Portsmouth, New Hampshire. In 1778 he became president of Yale College and was promoted to the presidency by the General Assembly of the Episcopal Church in 1780. He was a member of the Saybrook Platform of 1788; in 1789–1792 he was professor of divinity, and he lectured besides on astronomy and philosophy. He died in New Haven on the 12th of May 1795. His wise administration as president made possible the speedy recovery of Yale College after the War of Independence, and his intellectual and theological breadth helped to secularize and strengthen the college. As an undergraduate he became deeply interested in astronomy; he observed the comet of 1759 and the transit of Venus in June 1769, and left a quarto volume of astronomical notes at the time of his death. The meteorological and electrical apparatus presented to Yale by Benjamin Franklin, whose intimate friend he became, he carefully kept thermometric and meteorological statistics; he imported silkworms and books on silk culture; he corresponded with many literati—notably with Dr Nathaniel Lardner and with Sir William Jones, of whom he sought information of all kinds, but especially any that would lead to the discovery of the whereabouts of the ten lost tribes; and he undertook the study of Hebrew at the age of forty and became an able scholar. On Franklin's recommendation he was made a doctor of divinity by the university of Edinburgh in 1765; he had received a master's degree at Harvard in 1754, and was made doctor of divinity in 1780 by Dartmouth and in 1784 by the college of New Jersey (now Princeton University).
STILETTO—STILLICIDIID

Dr Stiles published several sermons, notably, a Discourse on the Christian Union (1761), which has remarkable ecclesiastical breadth of view: an Account of the Settlement of Bristol, Rhode Island (1785); and Hold the Sword of the Judge of Righteousness I.: Major-General Whaley, Major-General Goffe and Colonel Dizengoff (1794). He began in 1768 but never finished an Ecclesiastical History of New England and British America. His Literary Diary was published in New-York in 1801, being edited by F. B. Hobart. The diary quotes largely from Dr Stiles’s Itineraries, a daily account of his travels; the Diary gives a valuable picture of the life of New England in 1759-1795 and many interesting estimates of Stiles’s contemporaries and the different parts of the United States. His daughter, Abiel Holmes, the father of Oliver Wendell Holmes.

STILETTO (an Italian diminutive of stilto, dagger, Lat. stilus, a pointed instrument), a short stabbing dagger, the blade of which is either triangular or square in form. The term is also applied to a pointed bodkin of ivory, bone or metal used for making eyetlet holes, &c.

STILICHO, FLAVIUS (?-408), Roman general and statesman, was the son of a Vandal who had served as an officer in the army of the emperor Valens (364-378). He himself entered the imperial service at an early age and was speedily attaining a position of importance. He had already become master of the horse when in 385 he was sent by Theodosius (379-395) at the head of an embassy to the Persian king, Sapor III. His mission was very successful, and soon after his return he was made count of the domesticus and received in marriage Serena, the emperor’s niece and adopted daughter. In 385 he was appointed master of the guard (magister militum) in Thrace, and shortly afterwards directed energetic campaigns in Britain against Picts, Scots and Saxons, and along the Rhine against other barbarians. Stilicho and Serena were named guardians of the youthful Honorius when the latter was a child; in 395 he was given the additional title of imperial prefect of Britain, with special jurisdiction over Italy, Gaul, Britain, Spain and Africa, and Stilicho was even more closely allied to the imperial family in the following year by betrothing his daughter Maria to his ward and by receiving the dying injunctions of Theodosius to care for his children. Rivalry had already existed between Stilicho and Rufinus, the praetorian prefect of the East, who had exercised considerable influence over the emperor and who now was invested with the guardianship of Arcadius. Consequently in 395, after a successful campaign against the Germans on the Rhine, Stilicho marched to the east, nominally to expel the Goths and Huns from Thrace, but really with the design of displacing Rufinus, and by connivance with these same barbarians he procured the assassination of Rufinus at the close of the year, and thereby became virtual master of the empire. In 396 he fought in Greece against the Visigoths, but an arrangement was effected whereby their chiefest Alaric was appointed master of the soldiery in Illyricum (397). In 398 he quelled Gildo’s revolt in Africa and married his daughter Maria to Honorius. Two years later he was consul. He thwarted the efforts of Alaric to seize lands in Italy by his victories at Pollentia and Verona in 402-3 and forced him to return to Illyricum, but was criticized for having withdrawn the imperial forces from Britain and Gaul to employ against the Goths. He manoeuvred so skilfully in the campaign against Radagaisus, who led a large force of various Germanic peoples into Italy in 405, that he surrounded the barbarian chief on the rocks of Fiesole near Florence and starved him into surrender. Early in 408 he married his second daughter Thermantia to Honorius. It was rumoured about this time that Stilicho was plotting with Alaric and with Germans in Gaul and taking other treasonable steps in order to make his own son Eucherius emperor. There are conflicting accounts of the plots and counterplots and of the court intrigues, the relative truth of which will probably never be known. It is certain, however, that he was suspected by Honorius and abandoned by his own troops, and that he fled to Ravenna, and, having been induced by false promises to quit the church in which he had taken sanctuary, was assassinated on the 23rd of August 408.

The principal sources for the life of Stilicho are the histories of Zosimus and of Orosius and the flattering verses of Claudian. See T. Hodgkin, Italy and her Invaders, vols. i. and ii. (Oxford, 1880); E. Gibbon, Decline and Fall of the Roman Empire, edited by J. B. Bury, vol. iii. (London, 1902); P. Villari, The Barbarian Invasions of Italy, translated by L. Villari, vol. i. (New York, 1902); S. Dill, Roman Society in the last century of the Western Empire (London, 1896), and The Later Empire by C. H. Haskins.

STILL (1) (O. Eng. stilé, a word appearing in many Teutonic languages, all derived from the root, meaning to set in position or rest, seen in "stall," Ger. stellen, &c.), motionless, noiseless, or when used of wines or mineral waters, having little or no effervescence. As an adverb, "still" has preserved the original sense of "that which preserves its position," and thus means continually, permanently, now as before. (2) From the shortened form of "distil," Lat. distillare, to drip, trickle down, stilla, a drop, dim. of stíria. The older word for a "still" in English was stillatory, Medieval Latin stillatorium, an apparatus for heating substances and condensing the vapours (see DISTILLATION, SPIRITUOUS LIQUORS). Allusion also is made to the still-alorium, a type of distillery used in medieval and early modern times, in connection with the term still-licidium.

STILLICIDIID, a dripping of water from the eaves (stilla, drop, cadere, to fall), the term in architecture given by Vitruvius (iv. 7) to the dripping eaves of the roof of the Etruscan temple.
Similar dripping eaves existed in most of the Greek Doric temples in contradistinction to the Ionic temples, where the water of the roof was collected in the cymatium or gutter and thrown out through the mouths of lions, whose heads were carved on the cymatium.

STILLINGFLEET, EDWARD (1635-1690), English divine, was born at Cranborne, Dorset, on the 17th of April 1635. There and at Ringwood he received his early education, and at the age of thirteen was entered at St John's College, Cambridge. He took his B.A. in 1652, and in the following year was elected to a fellowship. After residing as tutor first in the family of Sir Roger Burgoyne in Warwickshire and then with the Hon. Francis Pierrepont at Nottingham, he was in 1657 presented by the former to the living of Sutton in Bedfordshire. Here he published (1659) his *Irenicum*, in which he sought to give expression to the prevailing weariness of the faction between Episcopacy and Presbyterianism, and to find some compromise in which all could conscientiously unite. He looks upon the form of church government as non-essential, but condemns Nonconformity. In 1663 (the year of the Act of Uniformity) he reprinted the *Irenicum* with an appendix, in which he states that "the church is a distinct society from the state, and has divers rights and privileges of its own." Stillfleeting's actions were as liberal as his opinions, and he aided more than one ejected minister. In later years he was not so liberal. But, though in 1680 he published his *Unreasonableness of Separation*, his willingness to serve on the ecclesiastical commission of 1689, and the interpretation he then proposed of the damnatory clauses of the Athenasian creed, are proof that to the end he leaned towards toleration. His rapid promotion dates from 1662, when he published *Origines sacrae*, or a Rational Account of the Christian Faith as to the Truth and Divine Authority of the Scriptures and the Matters therein contained. Humphrey Henchman, bishop of London, employed him to write a vindication of Laud's answer to John Fisher, the Jesuit. In 1665 the earl of Southampton presented him to St Andrew's, Holborn, two years later he became prebendary of St Paul's, in 1668 chaplain to Charles II., in 1670 canon residuary, and in 1678 dean of St Paul's. He was also preacher at the Rolls Chapel and reader at the Temple. Finally he was consecrated bishop of Worcester on the 13th of October 1680. During these years he was ceaselessly employed in controversy, in which he opposed to Rome that Deistic and Socinian. His unrivalled and various learning, his dialectical expertness, and his massive judgment, rendered him a formidable antagonist; but the respect entertained for him by his opponents was chiefly aroused by his recognized love of truth and superiority to personal considerations. He was one of the seven bishops who resisted the proposed Declaration of Indulgence (1688). The range of his learning is most clearly seen in his *Bishop's Right to Vote in Parliament in Cases Capital*. His *Origines Britanniæ*, or Antiquities of the British Church (1685), is a strange mixture of critical and uncritical research. He was so handsome in person as to have earned the sobriquet of "the beauty of holiness." In his closing years he had some controversy with John Locke, whom he considered to have impugned the doctrine of the Trinity. He died at Westminster on the 28th of March 1699, and was buried at Worcester. His manuscripts were bought by Robert Harley (afterwards earl of Oxford), his books by Narcissus Marsh, archbishop of Armagh.

A collected edition of his works, with life by Richard Bentley, was published in London (1710); and a useful edition of *The Doctrines and Practices of the Church of Rome Truly Represented* was published in 1845 by William Cunningham.

STILLMAN, WILLIAM JAMES (1828-1901), American painter and journalist, was born at Schenectady, New York, on the 1st of June 1828. His parents were Seventh-Day Baptists, and his early religious training influenced him all through his life. He was sent to school in New York by his mother, who made great sacrifices that he might get an education, and he graduated at Union College, Schenectady, in 1848. He studied art under Frederick E. Church and early in 1850 went to England, where he made the acquaintance of Ruskin, whose *Modern Painters* he had devoured, was introduced to Turner, for whose works he had unbounded admiration, and fell so much under the influence of Rossetti and Millais that on his return home in the same year he speedily became known as the "American Pre-Raphaelite." In 1852 Kossuth sent him on a fool's errand to Hungary to dig up crown jewels, which had been buried secretly during the insurrection of 1848-1849. While he was awaiting a projected rising in Milan, Stillman studied art under Yvon in Paris, and then, as the rising did not take place, he returned to the United States and is said to have been engaged to landscape painting on Upper Saranac Lake in the Adirondacks and in New York City, where he started the *Crayon*. It numbered Lowell, Aldrich and Charles Eliot Norton among its contributors, and when it failed for want of funds, Stillman removed to Cambridge, Massachusetts. There he passed several years, but a fit of restlessness started him off once more to England. He renewed his friendship with Ruskin, and went with him to Switzerland to paint and draw in the Alps, where he worked so assiduously that his eyesight was affected. He then lived in Paris and was in Normandy in 1861 when the American Civil War broke out. Unmoved by the events, he lived in London, and a year later to St. Paul's, he lived with D. G. Rossetti. In 1871 he married a daughter of Michael Spartali, the Greek consul-general. When the insurrection of 1875 broke out in Herzegovina he went there as a correspondent of The Times, and his letters from the Balkans aroused so much interest that the British government was induced to lend its countenance to Montenegro aspirations. In 1877-1883 he served as the correspondent of The Times at Athens; in 1886-1888 at Rome. He was a severe critic of Italian statesmen, and embroiled himself at various times with various politicians, from the undersecretary at war to the prime minister. After his retirement to St. Petersburg, where he died on the 6th of July 1901. He wrote The Cretes Insurrection of 1866-1869 (1874). On the Track of Ulysses (1888), *Billy and Hans* (1887) and *Francesco Crispi* (1890).

STILLWATER, a city and the county-seat of Washington county, Minnesota, U.S.A., at the head of Lake St Croix, on the west bank of the St Croix river, 20 m. above its mouth, and about 20 m. N.E. of St Paul. Pop. (1890) 11,760; (1900) 12,318; (1905 state census) 12,455; 3,586 being foreign-born (1,189 Swedes, 849 Germans, 828 Canadians); (1910 U.S. census) 10,798. It is served by the Northern Pacific, the Chicago, St. Paul, Minneapolis & Omaha, and the Chicago, Milwaukee & St Paul railways, and is connected by electric line with St Paul and Minneapolis. The city is picturesquely situated on bluffs rising from the St Croix and commanding fine views. Among the public buildings are a handsome public library, the city hall, the county court-house, the Federal building, an auditorium, and the city hospital, and the city is the seat of the Stillwater business college, and of the Minnesota state prison, established in 1851, in which a system of parole and of graded diminution of sentences is in force, and in connexion with it is maintained a public hospital and a training school. Stillwater is important as a centre of the lumber trade and as a shipping point for cereal products. The valuable water-power is utilized by its various manufactories. In 1905 the value of the factory products was $2,784,113, an increase of 54.6% since 1900. Stillwater, the first town platted in Minnesota, was permanently settled in 1843, and was laid out in 1848 by Joseph Renshaw Brown (1803-1870), a pioneer editor and soldier. Here met in 1848 the "Stillwater Convention," famous in Minnesota history
as the first step in the erection of Minnesota Territory. Stillwater was chartered as a city in 1854. The first electric railway in the state was completed here in 1884, but failed later.

**STILO PRAECONINUS, LUCIUS AELIUS,** (c. 154–74 B.C.), of Lanuvium, the earliest Roman philologist, was a man of distinguished family and belonged to the equestrian order. He was called Stilo (stilus, pen), because he wrote speeches for others, and Praeconinus from his father’s profession (proae, public crier). His aristocratic sympathies were so strong that he voluntarily accompanied Q. Caccilius Metellus Numidicus into exile. At Rome he divided his time between teaching (although not as a professional schoolmaster) and literary work. His most famous pupils were Varro and Cicero, and amongst his friends were Coelius Antipater, the historian, and Lucilius, the satirist, who dedicated their works to him. According to Cicero, who expresses his powers of recall in a very striking manner, Stilo was a follower of the Stoic school. Only a few fragments of his works remain. He wrote commentaries on the hymns of the Sallii, and (probably) on the Twelve Tables; and investigated the genuineness of the Plautine comedies, of which he recognized 25, four more than were allowed by Varro. It is probable that he was the author of a general glosographical work, dealing with literary, historical and antiquarian questions. The rhetorical treatise *Ad Herennium* has been attributed to him by some modern scholars.

**STILPO [STILPX]**, Greek philosopher of the Megarian school (q.v.), was a contemporary of Theophratus and Crates. Intellectually in agreement with the Megarian dialectic, he followed the practical ethics of the Cynics both in theory and in practice. He extolled the Cynic *arabêla* (loosely, self-control) as the principal virtue. Cicero (*De fato*, 5) describes him as a man of the highest character. Suidas attributes twenty dialogues to him, but of those no fragments remain. Among his followers were Menedemus and Asclpiades, the leaders of the Eretian school of philosophy. Seneca (*Epistle* 9) shows how closely allied Stilpo was to the Stoics (q.v.).

**STILT, or LONG-LEGGED PLOVER**, a bird so-called (see STILTS) for reasons obvious to anyone who has seen it, since, though not very much bigger than a snipe, the length of its legs (their bare part measuring 8 in.), in proportion to the size of its body exceeds that of any other bird’s. The first name (a translation of the French échasse, given in 1700 by M. J. Brisson) seems to have been bestowed by J. Rennie only in 1831; but, recommended by its definability and brevity, it has wholly supplanted the second and older one. The bird is the *Charadrius hiemalis*1 of Linnaeus, the *Himantopus candidus* or *melanopterus* of modern writers, and belongs to the group *Limicola*, having been usually placed in the family *Scolopacidae*, though it might be quite as reasonably referred to the *Charadriidae*, and, with its allies to be immediately mentioned, would seem to be not very distant from *Haematopus*, notwithstanding the wonderful development of its legs and the slenderness of it: bill.

The stilt obtains its food by wading in shallow water and seizing the insects that fly over or float upon its surface or the small crustaceans that swim beneath, for which purpose its slender extremities are, as might be expected, admirably adapted. Widely spread over Asia, North Africa, and Southern Europe, it has many times visited Britain—though always as a stranger, for it is not known to breed to the northward of the Danube valley—and its occurrence in Scotland (near Dumfries)

---

1 The possible confusion by Pliny’s transcribers of this word with *Haematopus* is referred to under OYSTERCATCHER. *Himantopus*, with its equivalent *Loripes*, “by an awkward metaphor,” as remarked by Gilbert White.2

2 This species was made known to Ray by Sloane, who met with it in Jamaica, where in his day it was called "long-legs."2

3 This word is from the Bolognese *avosetta*, which is considered to be derived from the Latin avis. The termination expressing a diminutive of a graceful or delicate kind, as *dona* from *dona* (Professor Salvadori in *Epist.*).

4 Cf. “yarwholp” (see GODWIT) and “yaup” or “whaup” (see CURLEW). “Barker” and “clinker” seem to have been names used in Norfolk.

---

was noticed by Sibbald so long ago as 1684. It chiefly resorts to pools or lakes with a margin of mud, on which it constructs a slight nest, banked round or just raised above the level so as to keep its eggs dry (*Ibis*, 1839, p. 360); but sometimes they are laid in a tuft of grass. They are four in number, and, except in size, closely resemble those of the oystercatcher (*g.g.*). The bird has the head, neck, and lower parts white, the back and wings glossy black, the irides red, and the bare part of the legs pink. In America the genus has two representatives, one2

(Alter Gosse.) **FIG. 1.—Black-necked American Stilt.** *(fig. 1) closely resembling that just described, but rather smaller and with a black crown and nape. This is *H. nigricollis* or *mexicanus*, and occurs from New England to the middle of South America, beyond which it is replaced by *H. brasiliensis*, which has the crown white. The stilt inhabiting India is now recognized to be *H. candidas*, but Australasia possesses a distinct species, *H. novaehollandiae*, which also occurs in New Zealand, though that country has in addition a species peculiar to it, *H. novaezelandiae*, differing from all the rest by assuming in the breeding season an altogether black plumage. Australia, however, presents another form, which is the type of the genus *Cladorhynchos*, and differs from *Himantopus* both in its style of plumage (the male having a broad bay pectoral belt), in its shorter tail, and in having the toes (though, as in the stilt’s feet, three in number on each foot) webbed.

Allied in many ways to the stilts, but differing in many undeniably generic characters, are the birds known as Avocets,3 forming the genus *Recurvirostra* of Linnaeus. Their bill, which is perhaps the most slender to be seen in the whole class, curves upward towards the end, and has given the oldest known species two names which it formerly bore in England,—"cobber’s-awl," from its likeness to the tool so called, and "scoper," because it resembled the scoop with which mariners threw water on their sails. The legs, though long, are not extraordinarily so, and the feet, which are webbed, bear a small hind toe.

This species (fig. 2), the *R. avosetta* of ornithology, was of old time plentiful in England, though doubtless always restricted to certain localities. Charleton in 1668 says that when a boy he had shot not a few on the Severn, and Plot mentions it so as to lead one to suppose that in his time (1686) it bred in Staffordshire, while F. Willoughby (1676) knew of it as being in winter on the eastern coast, and T. Pennant in 1790 found it in great numbers opposite Fossyoke Wash in Lincolnshire, and described the birds as hovering over the sportsman’s head like lapwings. In this district they were called "Yelpers" from their cry; but whether that name was
elsewhere applied is uncertain. At the end of the last century they frequented Romney Marsh in Kent, and in the first quarter of the present century they bred in various suitable spots in Suffolk and Norfolk—the last place known to have been inhabited by them being Salthouse, where the people made puddings of their eggs, while the birds were killed for the sake of their feathers, which were used in making artificial flies for fishing. The expiration of this settlement took place between 1822 and 1825 (cf. Stevenson, *Birds of Norfolk*, ii. 240, 241). The avocet's mode of nesting is much like that of the stil, and the eggs are hardly to be distinguished from those of the latter but by their larger size; the bird being about as big as a lapwing (g.v.), white, with the exception of its crown, the back of the neck, the inner scapulars, some of the wing-coverts and

the home of still-walking at the present day is the department of Landes in Gascony, where, owing to the impermeability of the subsoil, all low-lying districts are converted into marshes, compelling the shepherds, farmers and marketmen to spend the greater part of their lives on stills. These are strapped to the leg below the knee, the foot resting in a stirrup about five feet from the ground. Their wearers, who are called *tehangues* (long-legs) in the Gascon dialect, also carry long staves, which are often provided with a narrow piece of board, used as a seat in case of fatigue. In the last quarter of the 19th century still-races, for women as well as men, became very popular in the Landes district, and still form an important feature of every provincial festivity. One winner of the annual championship races accomplished 400 kilometres (more than 304 m.) in 173 hours, 36 minutes. Silvain Dornon, a baker of the Landes, walked on stilts from Paris to Moscow in 58 days in the spring of 1896. The rapids of the Niagner have been waded on stilts. In many of the Pacific islands, particularly the Marquesas, stilts are used during the rainy season. Stilts used by children are very long, the upper half being held under the arms; they are not strapped to the leg. Stilts play an important part in the Italian masquerades, and are used for mounting the gigantic figures in the grotesque processions of Lisle, Dunkirk, Louvain and other cities.

**STINDE, JULIUS** (1841-1905), German author, was born at Kirchhübel near Eutin on the 28th of August 1841, the son of a clergyman. Having attended the gymnasium at Eutin, he was apprenticed in 1858 to a chemist in Lübeck. He soon tired of the shop, and went to study chemistry at Kiel and Giessen where he proceeded to the degree of doctor of philosophy. In 1863 Stinde received an appointment as consulting chemist to a large industrial undertaking in Hamburg; but, becoming editor of the *Hamburger Gewerbebatte*, he gradually transferred his energies to journalism. His earliest works were little comedies, dealing with Hamburg life, though he continued to make scientific contributions to various journals. In 1876 Stinde settled in Berlin and began the series of stories of the Buchholz family, vivid and humorous studies of Berlin middle-class life by which he is most widely known. He died at Olbsberg near Kassel on the 7th of August 1905.

The first of the series *buchholzens in Italien* (translated by H. F. Powell, 1887) appeared in 1883 and achieved an immense success. It was followed by *Die Familie Buchholz* in 1884 (translated by L. D. Schmitz, 1885); *Frau Buchholz im Orient* in 1888; *Frau Wilhelmine (Die Buchholz letzter Teil)*; translated by H. F. Powell, 1887 in 1886; *Wilhelmine Buchholz Memoiren*, in 1894; and *Hotel Buchholz; Ausstellungserlebnisse der Frau Wilhelmine Buchholz*, in 1896. Under the pseudonyms of Alfred de Valmy, Wilhelmine Buchholz and Pauline von B. Ward, he also published various copies of books and more or less merit, among which his *Naturphilosophie* (1898) deserves special mention; his *Waldnollen* (1881) have been translated into English.

**STINK-WOOD**, in botany, a South African tree, known botanically as *Ocotoe bullata*, and a member of the family Leguminosae. Other names for it are Cape Walnut, Stinkbout, Cape Laurel and Laurel wood. It derives its name from having a strong and unpleasant smell when fresh felled. It is used for building in South Africa and is described by Stone (*Timbers of Commerce*, p. 174) as "the most beautiful dark-coloured wood that I have yet met with." It is said to be a substitute for teak and equally durable. The wood is dark walnut or reddish brown to black with a yellow sap-wood, and the grain extremely fine, close, dense and smooth.

**STIPEND**, a fixed periodical payment or salary for services rendered. The word is particularly used of the income from an ecclesiastical benefice or of the salary paid to any minister of religion. In the United Kingdom a paid magistrate or justice of the peace, appointed by the Crown on the advice of the home secretary for certain boroughs are termed "stipendiaries" or "stipendiary magistrates" (see **JUSTICE OF THE PEACE**). The Latin *stipendium* (for *stipendiarii*) is derived from *stips*, a gift, contribution (originally a heap of coins, *stipare*, to press; mass together) and *pendere*, to weigh out, pay. This was applied first to the pay of the army, and hence was used in the sense of
military service, in such phrases as stipendia facere, and of a campaign, e.g. vicena stipendia meritis (Tac. Ann. i. 17). It also meant a tax or impost, payable in money.

STIRLING, MARY ANNE [PANNY] (1815-1893), English actress, was born in London, the daughter of a Captain Kehl. After some experience at outlying theatres, she appeared in London in 1830. Having been successful as Corinna in As You Like It and Sophia in The Road to Ruin, Macready gave her an opportunity to play Cordelia to his Lear, and Madeline Weir to his James V. in the Rev. James White's King of the Commons. In 1832 she created Peg Woffington in Reade and Taylor's Masks and Faces. Meanwhile she had married Edward Stirling (d. 1854), an actor, manager and dramatic author. In later years Mrs Stirling gained a new popularity as the nurse in Irving's presentation (1852) of Romeo and Juliet, and again (1854) with Mary Anderson; and she was the Martha in Irving's production of Faust (1855). She died on the 30th of December 1855, having in the previous year married Sir Charles Hutton Gregory (1817-1858).

STIRLING, JAMES (1602-1770), Scottish mathematician, third son of Archibald Stirling of Garden, and grandson of Sir Archibald Stirling of Keir (Lord Garden, a lord of session), was born at Garden, Stirlingshire, in 1602. At eighteen years of age he went to Oxford, where, chiefly through the influence of the Earl of Mar, he was nominated (1711) one of Bishop Warner's exhibitioners at Balliol. In 1715 he was expelled on account of his correspondence with members of the Keir and Garden families. He afterwards lived with Jacobite exiles in Edinb., and became known to the "Gathering of the Brig o’ Turk" in 1708. From Oxford he made his way to Venice, where he occupied himself as a professor of mathematics. In 1717 appeared his Lineae tertii ordinis Newtonianae, sive . . . (8vo, Oxford). While in Venice, also, he communicated, through Sir Isaac Newton, to the Royal Society a paper entitled "Methodus differentialis Newtoniana illustrata" (Phil. Trans., 1718). Fearing assassination on account of having discovered a trade secret of the glass-makers of Venice, he returned with Newton's help to London about the year 1725. In London he remained for ten years, being most part of the time connected with an academy in Tower Street, and devoting his leisure to mathematics and correspondence with eminent mathematicians. In 1730 his most important work was published, the Methodus differentialis, sive tractatus de summatione et interpolatione serierum infinitarum (4to, London), which, it must be noted, is something more than an expansion of the paper of 1718. In 1735 he communicated to the Royal Society a paper "On the Figure of the Earth, and on the Variation of the Force of Gravity at its Surface." In the same year he was appointed manager for the Scots Mining Company at Leith. The company had prepared a report, which he made accessible to the Royal Society, not with true, but with applied science—"Description of a Machine to blow Fire by the Fall of Water" (Phil. Trans. 1745). His name is also connected with another practical undertaking, since grown to vast dimensions. The accounts of the city of Glasgow for 1752 show that the very first instalment of ten millions sterling spent in making Glasgow a seaport, viz. a sum of £28, 4s. 4d., was for a silver tea-kettle to be presented to "James Stirling, mathematician, for his service, pains, and trouble in surveying the river towards deepening it by locks." Stirling died in Edinburgh on the 5th of December 1770.

Another edition of the Lineae tertii ordinis was published in Paris in 1771; another edition of the Methodus differentialis in London in 1764; and a translation of the latter into English by Halliwell in London in 1749. A considerable collection of literary remains, consisting of papers, letters and two manuscript volumes of a treatise on weights, was preserved at the estate of Lord Garden, of Menstrie Castle.

STIRLING, JAMES HUTCHISON (1820-1900), Scottish philosopher, was born at Glasgow on the 22nd of June 1820. He was educated at Glasgow University, where he studied medicine and philosophy. For a short time he practised as a doctor in Wales, but gave up his profession in order to continue his philosophical studies in Germany and France. From 1888 to 1890 he was Gifford lecturer at the university of Edinburgh and published his lectures in 1890 (Philosophy and Theology). He was an LL.D. of Edinburgh University, and foreign member of the Philosophical Society of Berlín. He died in March 1900. His principal works are: The Secret of Hegel (1865; new ed. 1893); Sir William Hamilton; The Philosophy of Perception; a translation of Schwegler's Geschichte der Philosophie (1867; 12th ed., 1893); Jermol.; Tennyson and Macaulay, &c. (1868); On Materialism (1868); As Regards Protoplasma (1869; 2nd ed., 1873); Lectures on the Philosophy of Law (1873); Burns in Drama (1878); Text-Book to Kant (1881); Philosophy in the Poets; Darwinism; Workmen and Work (1894); What is Thought? Or the Problem of Philosophy; By Way of a Conclusion to Far (1900); The Categories (1892). Of these, the most important is The Secret of Hegel, which is admitted, both in England and in Germany, to be among the most scholarly and valuable contributions to Hegelian doctrine and to modern philosophy in general. In the preface to the new edition he explains that he was first drawn to the study of Hegel by seeing the name in a review, and subsequently heard it mentioned with awe and reverence by two German students. He set himself at once to grapple with the difficulties and to unfold the principles of the Hegelian dialectic, and by his efforts he introduced an entirely new spirit into English philosophy. Closely connected with this is the study of Kant, and the translation of the Critique with notes and a biography. In these two works Dr Stirling endeavoured to establish an intimate connexon between Kant and Hegel, and even went so far as to maintain that Hegel's doctrine is merely the elucidation and crystallization of the Kantian system. "The secret of Hegel," he says in the preliminary notice to his great work, "may be indicated at shortest thus: Hegel made explicit the concrete universal that was implicit in Kant."

The sixth part of the Secret contains valuable criticisms on the Hegelian writings of Schopenhauer, Kant and F. H. Jacobi, and explains by contrast much that has been definitely stated in the preceding pages. Of Dr Stirling's other works the most important is the volume of Gifford Lectures, in which he developed a theory of natural theology in relation to philosophy as a whole. As Regards Protoplasma contains an attempted reformation of the Essay on the Physical Basis of Life by Huxley.

STIRLING, WILLIAM ALEXANDER, Earl of (c. 1567-1646), most generally known as Sir William Alexander, Scottish poet and statesman, son of Alexander Alexander of Menstrie (Clackmannanshire), was born at Menstrie House, near Stirling, about 1567. The family was old and claimed to be descended from the Clarks of Stirling. Alexander was educated, long before he was of age, at the university in Edinburgh, where, he was appointed manager for the Scots Mining Company at Leith. The company had prepared a report, which he made accessible to the Royal Society, not with true, but with applied science—"Description of a Machine to blow Fire by the Fall of Water" (Phil. Trans. 1745). His name is also connected with another practical undertaking, since grown to vast dimensions. The accounts of the city of Glasgow for 1752 show that the very first instalment of ten millions sterling spent in making Glasgow a seaport, viz. a sum of £28, 4s. 4d., was for a silver tea-kettle to be presented to "James Stirling, mathematician, for his service, pains, and trouble in surveying the river towards deepening it by locks." Stirling died in Edinburgh on the 5th of December 1770.

Another edition of the Lineae tertii ordinis was published in Paris in 1771; another edition of the Methodus differentialis in London in 1764; and a translation of the latter into English by Halliwell in London in 1749. A considerable collection of literary remains, consisting of papers, letters and two manuscript volumes of a treatise on weights, was preserved at the estate of Lord Garden, of Menstrie Castle.

STIRLING, JAMES HUTCHISON (1820-1900), Scottish philosopher, was born at Glasgow on the 22nd of June 1820. He was educated at Glasgow University, where he studied medicine
short annual visits. In 1614 Alexander was appointed to the English office of master of requests, and in July of the following year to a seat on the Scottish privy council. In 1611 he received from James I. enormous grants of land in America embracing the districts of Nova Scotia, New Brunswick, and the Gaspe Peninsula, accompanied by a charter appointing him hereditary lieutenant of the new colony. This territory was afterwards increased on paper, so as to include a great part of Canada. Alexander proceeded to recruit emigrants for his "New Scotland," but the terms he offered were so meagre that he failed to attract any except the lowest class. These were despatched in two vessels chartered for the purpose, and in 1625 he published an Encouragement to Colonies in which he vainly painted in glowing colours the natural advantages of the new territory.

The enterprise was further discredited by the institution of an order of baronets of Nova Scotia, who were to receive grants of land, each 6 sq. m. in extent, in the colony for a consideration of £150. An attempt made by the French to make good their footing in the colony was frustrated (1627) by Captain Kerth, and Alexander's son and namesake made two expeditions to Nova Scotia. But Alexander found the colony a constant drain on his resources, and was unable to obtain from the treasury, in spite of royal support, £6000 which he demanded as compensation for his losses. He received, however, a grant of 1000 acres in Armagh. He was the king's secretary for Scotland from 1626 till his death, and in 1630 was created Viscount Stirling and Lord Alexander of Tullibody. In the same year he was appointed master of requests. This Scotland, and in 1632 an extraordinary judge of the Court of Session. Meanwhile French influence had gained ground in America. In 1631 Charles sent instructions to Alexander to abandon Port Royalle, and in the following year, by a treaty signed at St Germain-en-Lay, the whole of the territory of Nova Scotia was ceded to the French. Alexander continued to receive substantial marks of the royal favour. In 1631 he obtained a patent granting him the privilege of printing a translation of the Psalms, of which James I. was declared to be the author. There is reason to believe that in this unfortunate collection, which the Scottish and English clergy refused to encourage, Alexander included some of his own work. He had been commanded by James to submit translations, when James was carrying out his long entailed wish to supplant the popular version of Sternhold and Hopkins, but these the royal critic had not preferred to his own. It has been assumed from the scanty evidence that when Alexander was entrusted with the editing and publishing of the Psalms by Charles I. he had introduced some of his own work. In 1633 he was advanced to the rank of earl, with the additional title of Viscount Canada, and in 1639 he became earl of Dovian. His affairs were still embarrassed and he had begun to build Argyll House at Stirling. In 1623 he received the right to coin copper on the copper coinage of Scotland, but this proved unproductive. He therefore secured for his fourth son the office of general of the Mint, and proceeded to issue small copper coins, known as "turners," which were put into circulation as equivalent to two farthings, although they were of the same weight as the old farthings. These coins were unpopular, and were reduced to their real value by the privy council in 1639. Alexander died in debt on the 12th of February 1640, at his London house in Covent Garden.

He was succeeded in the title by his grandson William, who died a few months later, and then by his son Henry (d. 1644), who became the 3rd earl. When Henry's grandson Henry, the 5th earl (1664-1739), died, the earldom became dormant, and in 1759 it was claimed by William Alexander (see below). In 1825 the earldom was claimed by Alexander Humphreys-Alexander, who asserted that his mother was a daughter of the first earl. The charter of 1639, however, on which his title rested, was declared in 1839 to be a forgery. See W. Turnbull, Stirling Peerage Claims (1839).

All Alexander's literary work was produced after 1603 and before his serious absorption in politics about 1614. The verse may be classed in three groups, (a) poetical miscellanies and minor verse, (b) dramas, and (c) the heroic fragment on Jonathan and the long poem on the Stymphalian Birds.

2. His earliest effort was Aurora, containing the first facettie of the author's youth (London, 1604), a miscellany of sonnets, songs and elegies, showing considerable formal felicity, if little originality, in the favourite themes of the Elizabethan lyric. It was probably also written by Alexander and possibly be added the Paraenesis to Prince Henry (a.s.), An Elegie on the Death of Prince Henrie (a.s.), and shorter pieces, including a sonnet to Michael Drayton, who had called Alexander "a man of men," and a poem on the death of Sir John Harington, to which was added a "Premiere to Sir John." He wrote four tragedies, Darius (1603), Crosses (1604), The Alexandrean (1605), and Julius Caesar (1607). The first and second were published together in 1604 as the Monarchicke Tragedies, and the first was gathered together by Alexander for inclusion in the four works in the editions of 1607 and 1616. They are didactic poems rather than plays, a sequence of reflections of the type of the Poets, Tragedies, and Histories, which Alexander himself entitled The Works of Alexander the Great, which is divided between Experience and a Courteour (known also as the "Monarchicke")). It is very probable that the last suggested both motto and title. The pieces are dialogues rather than dramas: the choruses are of the "Moralias" type of Renaissance verse rather than choral, and the varied versification is unsuitable for representation. Yet they contain not a few fine passages in the soliloquies, notably one in Darius (IV., iii.) on the vanishing of: Those golden palaces, those gorgeous halls ... as vapours in the air," which recall Shakespeare's later lines in the Tempest.

3. Of Jonathan, an Heroique Poeme intended, only the first book (105 eight-line stanzas) was written. Donnesody, or The Great Day of the Lord's Judgement (1614) is a draconic production in twelve books or "hours," extending to nearly 12,000 lines. It is written in eight-line stanzas.

The dedication to the pamphlet on Colonization, he wrote (1614) a continuation or "completion" to the third part of Sidney's Arcadia, which appears in the fourth and later editions of the Romance; and a short critical tract entitled Anaecrisis, a "censure of poets, and a declaration of the liberties of authors" (1616). A collected edition of his works appeared in his lifetime (1637) with the title Recreations with the Muses (1638). Aurora and the Poetical Works were also published (1640). The complete works of Alexander were first published in 1665, and the edition of 1704 was the first to appear under the editor's name. The first modern edition was published in 3 vols. 8vo. in 1870 (Glasgow: Maurice Ogle & Co.).

An Encouragement to Colonies was edited for the Banntyne Club by David Laing (1867), and by Edmund F. Slafter, in Sir W. Alexander and Amer. Colonization (Prince Society, Boston, Massachusetts, 1865). See also E. F. Slafter, The Copper Coinage of the Earl of Stirling, 1632 (1872). The Earl of Stirling's Register of Royal Letters relative to the Affairs of Scotland and Nova Scotia from 1615-1635 (ed. C. Rogers, with biographical introduction 1884-1889); C. Rogers, Memorials of the Earl of Stirling (1877); the introduction to the plays (1890) referred to above; the Register of the Privy Council of Scotland, passim; and the bibliography for William Drummond (g.v.) of Hawthornden. (A. B. G.; G. G. S.)

STIRLING, WILLIAM ALEXANDER, (titular) EARL OF (1726-1785), American soldier, was born in New York City. He was the son of James Alexander (1690-1736), at one time surveyor-general of New York and New Jersey, a noted colonial lawyer who was disbarred for a year for his conduct of the famous case of John Fitch. He served for a time as a 2nd lieutenant in the New York Provincial Troops, and was promoted to the rank of captain in 1741, but was exchanged, and then as aide-de-camp to Governor William Shirley at the beginning of the French and Indian War, and in 1756 he accompanied Shirley to England, where he was persuaded to claim the earldom of Stirling (see above). In 1759 an Edinburgh jury declared him to be the nearest heir to the last earl of Stirling, and in 1761 he returned to America, and assumed the title, although the House of Lords in 1762 forbade him to use it until he had proved his legal right. Soon after his return to America he settled at Basking Ridge, New Jersey, and became a member of the New Jersey Provincial Council and surveyor-general of the colony. Warmly espousing the colonial cause at the outbreak of the War of Independence, he was appointed in November 1775 colonel of the first regiment of continental troops raised in New Jersey, and in the following January distinguished himself by the capture of an armed British transport in New York Bay. In March he became brigadier-general, and for some time was in command at New York and supervised the fortification of the city and harbour. At the battle of Long Island he was taken prisoner, but was soon after exchanged, and in February 1777 became a major-general. He participated in the battles of Trenton, Princeton, Brandywine and Germantown, and especially
distinguished himself at Monmouth. He took an active part in exposing the Conway Cabal, presided over the court-martial of General Charles Lee, and enjoyed the confidence of Washington to an unusual degree. In October 1781 he took command of the northern department at Albany to check an expected invasion from Canada. He died at Albany on the 6th of January 1783. He was a member of the board of governors of King's College (now Columbia University) and was himself devoted to the study of mathematics and astronomy.

STIRLING, a royal, municipal and police burgh, river port and county town of Stirlingshire, Scotland. Pop. (1901), 18,667. It is finely situated on the right bank of the Forth, 59½ m. N.W. of Edinburgh and 29½ m. N.E. of Glasgow, being served by the North British and the Caledonian railways. The old town occupies the slopes of a basaltic hill (420 ft. above the sea) terminating on the north and west in a sheer precipice. The modern quarters have been laid out on the level ground at the base, especially towards the south. Originally the town was protected on its vulnerable sides by a wall, of which remains still exist at the south end of the Black Walk. Formerly there were two main entrances—the South Port, 100 yds. to the west of the present line of Port Street, and the "auld brig" over the Forth to the north, a quaint high-pitched structure of fourteenth century, closed in 1543 by a wall (now the foot of the 14th century) and was once literally "the key to the Highlands." It still retains the gateway towers at both ends. Just below it is the new bridge erected in 1829 from designs by Robert Stevenson, and below this again the railway viaduct. According to local tradition, a bridge stood at Kilendar, 1 m. up the river, not far from the field of the battle of Stirling Bridge (1297). The castle crowning the eminence is of unknown age; but from the time that Alexander III. died within its walls in 1249 till the union of the crowns in 1603 it was intimately associated with the fortunes of the Scottish monarchs. It is one of the few castles in Scotland, which, having been laid waste in the fifteenth century was once entirely re-erected in the sixteenth century and the keep is still a ruin. The present palace of Stirling is approached from the west by a spacious esplanade, which contains the colossal statue of Robert Bruce, erected in 1877. The main gateway, built by James III., gives access to the lower and then to the upper square, on the south side of which stands the palace, begun by James V. (1540) and completed by Mary of Guise. The east side of the quadrangle is occupied by the parliament house, a Gothic building of the time of James III., now used as a barrack-room and stores. On the north side of the square is the chapel royal, founded by Alexander I., rebuilt in the fifteenth century and again in 1561 by James VI. and christened in 1625, and afterwards converted into an armoury and finally a store-room. Beyond the upper square is the small castle garden, partly destroyed by fire in 1866 but restored, in which William, 8th earl of Douglas, was murdered by James II. (1452). Just below the castle on the north-east is the path of Ballangieach, which is said to have given private access to the fortress, and from which James V. took his title of "Gildman of Ballangieach" when he roved incognito. Below it is Cowan Hill, and beyond this the Mote or Heading Hill, on which Murdoch Stuart, 2nd duke of Albany, his two sons, and his father-in-law, the earl of Lennox, were beheaded in 1567. A little to the south-west were the King's Gardens, now under grass, with an octagonal turf-covered mound called the King's Knot in the centre. Farther south lies the King's Park, chiefly devoted to golf, cricket, football and curling, and containing also a race-course. On a hill of lower elevation than the castle and separated from the esplanade by a depression styled the Valley—the tilting-ground of former times—a cemetery has been laid out. Among its chief features are the Virgin Martyrs' Memorial, representing in white marble a guardian angel and the figures of Margaret MacLachlan and Margaret Wilson, who were drowned by the rising tide in Wigtown Bay for their fidelity to the Covenant (1685); the large pyramid to the memory of the Covenanters, and the Ladies' Rock, from which ladies viewed the jousts in the Valley. Adjoining the cemetery on the south is Greyfriars, the parish church, also called, since the Reformation (1560), when it was divided into two places of worship, the East and West churches. David I. is believed to have founded (about 1130) an earlier church on their site with an altar to the Holy Rood, or Cross, which was burned in 1406. The church was rebuilt soon afterwards and possibly some portions of the preceding structure were incorporated in the nave. The choir (the East church) was added in 1494 by James IV., and the apse a few years later by James Beaton, archbishop of St Andrews, or his nephew, Cardinal David Beaton. At the west stands the stately battlemented square tower, 90 ft. high. The nave (the West church), divided from the aisles by a double row of massive round pillars, is a transition between Romanesque and Gothic, with pointed windows. The crown-steps of the aisle of the south transept affords a transition from the aisles to the choir and is 8 ft. 6 in. wide. The cheaps are in the Decorated and Perpendicular styles and is higher than the nave. The parish church is 200 ft. long, 55 ft. broad and 90 ft. high. Within its walls Mary Queen of Scots was crowned in 1543, when nine months old, and in the same year the earl of Arran, regent of Scotland, abjured Protestantism; in 1544 an assembly of nobles appointed Mary of Guise queen-regent; on the 20th of July 1567 James VI. was crowned, John Knox preaching the sermon, and in August 1571 and June 1578 the general assembly of the Church of Scotland met. James Guthrie (1612–1664), with a statue of Sir William Wallace over the north porch of the National Scottish Seccession Church, were two of the most distinguished ministers. To the south-west of the church is Cowane's Hospital, founded in 1639 by John Cowane, dean of gild, for twelve poor members of the gildry; but the deposition of the charity has been modified and the hall serves the purpose of a gildhall. Adjoining it is the military prison. Near the principal entrance to the esplanade stands Argyll's Lodging, erected about 1630 by the 1st earl of Stirling. On his death in 1640 it passed to the 1st marquess of Argyll and is now a military hospital. Broad Street contains the ruins of Mary's Work, the palace built by John Erskine, 1st or 6th earl of Mar, about 1570 according to tradition, out of the stones ofCambuskenneth Abbey; the old town house, erected in 1701 instead of that in which John Hamilton, the last Roman Catholic archbishop of St Andrews, was hanged for alleged complicity in the murders of Darnley and the regent Moray; the town cross, restored in 1891, and the house which was, as a mural tablet says, the "nursery of James VI. and his son Prince Henry." The important buildings include: the high school; the trades hall, founded by Robert Spittal; James IV.'s tailor, in the Back Walk; the burgh buildings, with a statue of Sir William Wallace over the arch of the old Town Hall, completed in 1625; the Stock Bank, occupying the site of the Dominican monastery, founded in 1223 by Alexander II. and demolished at the Reformation; the Smith Institute, founded in 1873 by Thomas Stewart Smith, an artist, containing a picture-galley, museum and reading-room; the public halls; the Royal Infirmary and various charitable institutions. Woollen manufactures (carpets, tartans, shaws) are the staple industry, and tanning, iron-founding, carriage-building and agricultural implement-making are also carried on, in addition to furniture factories, co-operative and railway workshops. The harbour being accessible only at high water, and the river being vessels of small tonnage, the shipping trade is inconsiderable.

Stirling is under the jurisdiction of a council with provost and bailies, and, along with Cumnor, Dunfermline, Inverkeithing and Queensferry (the Stirling burghs) returns a member to Parliament. The Abbey Craig, an outlying spur of the Ochils, 1½ m. north-east of Stirling, is a thickly-wooded hill (362 ft. high), on the top of which stands the Wallace monument (1869), a baronial tower, 220 ft. high, surmounted with an open-work crown. The Valhalls, or Hall of Heroes, contains busts of eminent Scotsmen. Cambuskenneth Abbey is situated on the left bank of the Forth, about 1 m. east-north-east of Stirling by ferry across the river. The name is derived from the Gaelic and means "the Crook of Kenneth," or Cairnacrus. A friend
of St Columba and patron of Kilkenny in Ireland. The abbey, which was in the Early Pointed style, was founded by David I. in 1147 for monks of the order of St Augustine. Several Scots parliaments met within its walls, notably that of 1326, the first attended by burgesses from the towns. At the Reformation Mary Queen of Scots bestowed it on the 1st earl of Mar (1563), who is said to have used the stones for his palace in Stirling.

In 1709 the town council of Stirling purchased the land and ruins. All that remains of the abbey is the massive, four-storied tower—which is 70 ft. high, and 35 ft. square, and was painted and re-touched at the end of the 18th century—within the foundations of some of the walls. The bones of James III. and his queen, Margaret of Denmark, who were buried within the precincts, were discovered in 1864 and re-interred next year under a tomb erected by Queen Victoria at the high altar.

Earlier forms of the name of Stirling are Strivlen, Estruen, Striviling and Sterling, besides the Gaelic Struthlita. It was known also as Snowdoun, which became the official title of the Scots heralds. The Romans had a station here (Bonnobar). In 1116 it was a royal burgh and under Alexander I. was one of the seats of the crown (except for the period of the Convention of Royal Burghs). In 1714 it was handed over to the English in security for the treaty of Falaise, being restored to the Scots by Richard I. The earliest known charter was that granted in 1226 by Alexander II., who made the castle a royal residence. The fortress was repeatedly besieged during the wars of the Scottish Independence. In 1304 it fell with the town to Edward I. The English held it for ten years, and it was in order to raise the Scottish siege in 1314 that Edward II. risked the battle at Bannockburn. Edward Balliol surrendered it in 1334 in terms of his compact with Edward III., but the Scots regained it in 1339. From this time till the collapse of Queen Mary's fortunes in 1568, Stirling almost shared with Edinburgh the rank and privileges of capital of the kingdom. It was the birthplace of James II. in 1430 and probably of James III. and James IV. In 1571 an attempt was made to surprise the castle by Mary's adherents, the regent Lennox being slain in the fray, and seven years later it was captured by James Douglas, 4th earl of Morton, after which a reconciliation took place between the Protestants and Roman Catholics. It was occupied in 1584 by the earls of Angus and Mar, the Protestant leaders, who, however, fled to England on the approach of Jamie III. The next year they returned with a strong force and compelled James VI. to open the gates, his personal safety having been guaranteed. In 1594 Prince Henry was baptized in the chapel royal, which had been rebuilt on a larger scale. After the union of the crowns (1603) Stirling ceased to play a prominent part on the national stage. The privy council and court of session met in the town in 1637 on account of the disturbed state of Edinburgh. In 1641 Charles I. gave it its last governing charter, and four years afterwards parliament was held in Stirling on account of the plague in the capital, but the outbreak of the pest in Stirling caused the legislators to move to Perth. During the Civil War the Covenanters held the town, to which the committees of church and state adjourned after Cromwell's victory at Dunbar (1650), but in August next year the castle was taken by General Monk. In 1715 the 3rd duke of Argyll held it to prevent the passage of the Forth by the Jacobites, and in 1746 it was ineffectually besieged by Prince Charles Edward. In 1773, in consequence of an intrigue on the part of three members of the council to retain themselves in office, the town was deprived of its corporate privileges, which were not restored until 1784.

See History of the Chapel Royal, Stirling (Glasnamann Club, 1882); Charters of Stirling (1884); John Jamieson, Bell the Cat (Stirling, 1902); The Battle of Stirling Bridge—the Kiddean Myth (Stirling Natural History and Archaeological Society, 1905).

STIRLING-MAXWELL, SIR WILLIAM, Bart. (1818-1878), Scottish man of letters and virtuoso, the only son of Archibald Stirling of Keir, Perthshire, and of Elizabeth, third daughter of Sir John Maxwell, seventh baronet of Pollok, Renfrewshire, was born at Kenmure, near Glasgow, on the 8th of March, 1818. William Stirling was educated privately and at Trinity College, Cambridge, where he graduated in 1839. On leaving Cambridge he spent some years abroad, chiefly in Spain and Syria. Having succeeded his father as proprietor of Keir in 1847, when he was made vice-lieutenant of Perthshire, he in 1852 entered parliament as member for that county; and he was several times re-elected. On the death of his uncle in 1865 he succeeded to the baronetcy and estates of Pollok, assuming the additional name of Maxwell. In the same year he became deputy-lieutenant of Lanarkshire, and a lice office was con-

STIRLING-MAXWELL—STIRLINGSHIRE

briefed on him in Renfrewshire in 1870. He married in 1865 Anna Maria, daughter of the 10th earl of Leven and Melville. She died in 1874, and in 1876 Sir William married Caroline Norton. In 1862 he was chosen lord rector of St Andrews, in 1872 the same honour was conferred by Edinburgh, and in 1876 he became chancellor of Glasgow. He was a trustee of the British Museum, of the National Gallery, and member of the senate of London University. In 1876 he was created a Knight of the Thistle, being the only commoner of the order. He died at Venice on the 15th of January 1878.

Sir W. Stirling-Maxwell's works, which are invariably characterized by thorough workmanship and excellent taste, were in some cases published for private circulation only; but others, though now exceedingly rare. They include an early volume of verse (Songs of the Holy Land, 1848), and several volumes containing reproductions, of which the best known are his compact treatise on the Art of Spain (1848), the Cloister Life of Charles V. (1852). Part of the Annals was revised and published as Velasques and his Works (1855). The Cloister Life was afterwards republished as a whole, but it is now more
to history, but its importance was lessened by the appearance a year or two later of Mignet's Charles-Quint and L. P. Cachard's Retrato y morte de Charles-Quint. A life of Don John of Austria, from his childhood to the battle of Parnawa, was published by Sir G. W. Cox, appearing in 1883. A collected edition of his works, with a short memoir, appeared in 1891.

STIRLINGSHIRE, a midland county of Scotland, bounded N. by Perthshire, N.E. by Clackmannanshire and the Firth of Forth, S.E. by Linlithgowshire, S. by Lanarkshire and the detached part of Dunbartonshire and S.W. and W. by Dum-

STIRLINGSHIRE
Stirrup

The principal towns are Falkirk (pop. 29,380), Stirling (18,607), Grangemouth (8,836), Kilsyth (7,292), Stenhousemuir (5,184), Denny and Dunipace (5,158), Bridge of Allan (3,240), and Bonnybridge (3,000). The shire returns a member to parliament, and Stirling and Falkirk respectively belong to the Stirling and Falkirk districts of the counties of Dunbarton and Clackmannan. The police burghs include Falkirk, Grangemouth, Kilsyth, Denny and Dunipace and Bridge of Allan. The shire forms a sheriffdom with the counties of Dunbarton and Clackmannan, but there is a resident sheriff-substitute at Stirling and another at Falkirk. The shire is under schoolboard jurisdiction, and there are secondary as well as science and art schools at Stirling and Falkirk. The town councils of Stirling and Kilsyth subsidize classes in science and art, besides manual instruction, and Denny and Dunipace maintains a mining instruction class.

Bibliography.—Sir Robert Sibald, Description of Stirlingshire (1740); Nicholas Annan of Stirlingshire (1745-58); Roberts, the Jacobite rising of 1745-46. The county played a conspicuous part in the struggle for Scottish independence, being particularly associated with many of the exploits of Sir William Wallace and Robert Bruce. The three great battles of the independence were fought in the shire—Stirling Bridge (1297), Falkirk (1298), Bannockburn (1314). James III. was stabbed to death in a cottage in the village of Milton after the battle of Sauchieburn (1488), but apart from the disastrous defeat of the Covenanters at Kilsyth (1645) and the transitory triumph which Prince Charles Edward won at Falkirk (1746), the history of the shire practically centres in that of the county town.

Population and Administration.—In 1891 the population numbered 115,021, and in 1901 it was 142,291, or 375 persons to the square mile, an increase for the decade exceeded only by the shires of Linlithgow and Lanark. In 1901 there were ten persons who spoke Gaelic only and 2014 Gaelic and English.
and open metal-work is used. The Arab stirrup is very large, affording a rest for the entire sole of the foot; sometimes the heel part projects and terminates in a sharp point used as a spur.

See the plates in F. Hotteau's Trachten, Haus-Feld-und Kriegesverthsaftungen, etc. (1901); and R. Zachíle, Die Steigbügel in ihrer Formen-Entwicklung (1896).

STJERNHJELM, GEORG (1592-1672), Swedish poet and scholar, whose original name was Göran Lilja, was born at Wika in Dalecarlia on the 7th of August 1598. He took his degree at Greifswald, and spent some years in travelling over every quarter of Europe. On his return in 1620 he maintained a correspondence with Salmasius, Heinsius, and other scholars. He taught at Vesterås, and then at Stockholm, attracting the notice of Gustavus Adolphus, who gave him a responsible post as Secretary in 1635, and assigned him next year to the nobility. After the king was death, Christina attached him, as a kind of poet laureate, to her court in Stockholm. His property lay in Livonia, and when the Russians plundered that province in 1656 the poet, who was in temporary disgrace at court, was reduced to extreme poverty for two or three years. He subsequently became judge at Trondhjem, member of the council of war (1661), and president (1667) of the College of Antiquities at Stockholm. He died at Stockholm on the 22nd of April 1672. His greatest poem Hercules, is a didactic allegory in hexameters, written in very musical verse, and with almost Oriental splendour of phrasing and imagery. The Hercules, white and chaste, with the familiar story of the dispute for the hero between Duty and Pleasure, was first printed at Upsala in 1653 but was finished some years earlier. Bröllops-Bestärs Thugkommelse, a sort of serio-comic epiphalmium in the same measure, is another very brilliant work. His masques, Thun fångne Cupido (Cupid Caught) (1649), Frods-off (The Birth of Peace) (1649), and Parnassus triumphans (1651), were written for the entertainment of Queen Christina. He can scarcely be said to have been successful in his attempt, in the first two of these, to introduce unrhymed song-measures.

Stjernhjelm was an active philologist, and left a great number of works on language, of which only a few have been printed. He also wrote on history, mathematics, philosophy and natural science, producing original and valuable work on every subject he attempted. Among his numerous works are Letter A of the Lexicon vocabulum antiquorum gothicorum (1643, &c.), Archimoedes reformatus (1644), Runa suettica (Lübeck, 1700), and an edition of Wíðr Gítha Lágöök (1652). His works were partially edited by P. Hansell (Samolada seu Studia Prosectorum [<i>Gallicanorum</i>] Forschz) (1741), by L. Hufeland (Stockholm, 1818), by F. Tamm (Upsala, 1891). See also C. J. Lénstöm, Letterfärt Porträttgalleri (Upsala, 1838); there is a full list of his writings in the Sienisk biographiskt Lexikon, vol. xv. (Upsala, 1848).

STOA, the term in Greek architecture (Lat. porticus) given to a building, the roof of which is supported by one or more rows of columns, to a stoai at Ellis described by Pausanias being important examples.

STOBAEUS, IOANNES, so called from his native place Stobi in Macedonia, the compiler of a valuable series of extracts from Greek authors. Of his life nothing is known, but he probably belongs to the latter half of the 5th century a.d. From his silence in regard to Christian authors, it is inferred that he was not a Christian.

The extracts were intended by Stobaeus for his son Septimius, and were preceded by a letter briefly explaining the purpose of the work and giving a summary of the contents. From this summary (preserved in Photius’s Bibliotheca) we learn that Stobaeus divided his work into four books and two volumes. In most of our MSS. the work is divided into three books, of which the first and second are generally called Ἠλεγχα τῷ θνάσι (Physical and Moral Extracts), and the third Ἠλεγχα (Florilegium or Sermons). As each of the four books is sometimes called Ἠλεγχα, it is probable that this name originally belonged to the entire work; the full title, as we know from Photius, was Ἠλεγχα ἰπερποτματὴν ἀνακαίναι (Four Books of Extracts, Sayings and Précis). The arrangement is somewhat arbitrary and there are several marked discrepancies between it and the account given by Photius. The introduction to the whole treatment, of the value of philosophy and of philosophical sects, is lost, with the exception of the concluding portion; the second book is little more than a fragment, and the third and fourth have been amalgamated by altering the original sections. From these and other indications it seems probable that what we have is only an epitome of the original work, made by an anonymous Byzantine writer of much later date. The didactic aim of Stobaeus’s work is apparent throughout. The first book teaches physics—in the wide sense which the Greeks assigned to this term—by means of extracts. It is often untrustworthy; Stobaeus betrays a tendency to confound the dogmas of the early Ionic philosophers, and he occasionally mixes Platonism with Pythagoreanism. For poet this book and much of book ii. he depended on the works of Aétius, a peripatetic philosopher, and Dídymus. The third and fourth books, like the larger part of the second, treat of ethics: the third, of virtues and vices, in pairs; the fourth, of more general ethical and political subjects, frequently citing extracts to illustrate the pros and cons of a question in two successive chapters. In all, Stobaeus quotes more than five hundred writers, generally beginning with the poets, and then proceeding to the historians, orators, philosophers and physicians. It is to him that we owe many of our most important fragments of the dramatists, particularly of Euripides.

STOCKBRIDGE, a township of Berkshire county, in western Massachusetts, U.S.A. Pop. (1900), 2085; (1910, U.S. census) 1933. It comprises an area of 24 sq. m. Lake Mahkeencac, or Stockbridge Bowl, is about 2 m. north of Stockbridge village. Immediately south of the village, in a cleft in the north-western part of Bear Mountain, is Ice Glen, with caverns ice-lined even in midsummer. In the southern part of the township, on the boundary of Great Barrington, a monument of Mount Washington (1710 ft.). Stockbridge village is on the Housatonic river, about 13 m. south by east of Pittsfield, and is served by the New York, New Haven & Hartford railway, and by an interurban electric line. It is well known as a summer resort, with a casino and golf links, a war monument, a bell tower erected by David Dudley Field to commemorate the Indian mission, a monument in the old burial ground of the Stockbridge Indians, a public library, and the Stockbridge Academy. Jonathan Edwards (commemorated by a monument, 1871) was the pastor (1750–1758), and wrote his Freedom of the Will here; the Sedgwick mansion, the home of Theodore Sedgwick (1746–1831), is at Stockbridge; his daughter, the author, C. Jane M. Sedgwick (1762–1837, buried here; and Stockbridge was the birthplace of Mark Hopkins and of Cyrus W. Field, who presented a park to the village. The “village improvement society” movement seems to have originated at Stockbridge in 1853. The Stockbridge (or Muh-he-kan-oe-ek) Indians, survivors of the Mohican tribe, removed to the Housatonic Valley from the west bank of the Hudson river soon after the first white settlements were made in New York; and in 1734 a mission was established among them in what is now the township of Great Barrington by John Sergeant (1710–1759), who was at Stockbridge; his daughter, the author, C. Jane M. Sedgwick (1762–1837, buried here); and Stockbridge was the birthplace of Mark Hopkins and of Cyrus W. Field, who presented a park to the village. The “village improvement society” movement seems to have originated at Stockbridge in 1853. **STOCK EXCHANGE**, a market for the purchase and sale of all descriptions of negotiable securities (see **MARKET**). In the immense majority of cases the securities so dealt in are what are known as "stocks, bonds and shares," on which interest, or dividend, is payable when earned; but bills issued by governments and municipal corporations are also occasionally dealt in. Many years ago, when the British government was in the habit of issuing exchequer bills, a new obsolete form of security, these bills were quoted in the official list of the London Stock Exchange; this was possible because though nominally bills, they were really bonds with a variable rate of interest fixed half-yearly in advance by the treasury. The inconvenience of this arrangement led to their being abandoned as a portion of the system of British government finance. Marketable bonds in proprietors hands subsisted for some hundreds of years. Their organization was loose, there was no specific body of persons forming the market, and there were no special rules governing their procedure until within the last hundred and fifty years.

**London.**—Previous to 1773 the London stockbrokers conducted their business in and about the Royal Exchange, but in that year, having formed themselves into an association under the designation of the Stock Exchange, they, after temporarily locating their headquarters in Sweating Alley, Threadneedle Street, removed to Capel Court, Bartholomew Lane. The growth of business necessitating improved accommodation, a capital of £20,000 in four hundred shares of £50 each was raised in 1801 for the purpose of erecting a new building in Capel Court, which was finished and occupied in the following year, the members at that date numbering about five hundred. With the occupation of the new building new rules came into force; all future members were admitted by ballot, while both members and their authorized clerks were required to pay a subscription of ten guineas each. As only the wealthiest members of the association had provided the capital for the new building, the Stock Exchange henceforth consisted of two distinct bodies in proprietors and subscribers. In 1834 the membership having increased to about one thousand persons, an extension of the premises in Capel Court was effected at a cost of £16,000. A very extensive increase in the accommodation was made in 1885, when what was for many years afterwards known as the "new house" was erected. It occupies by far the greater portion of the triangular area of which Throgmorton Street, Bartholomew Lane, part of Threadneedle Street and part of Old Broad Street form the sides. Sections of the external parts of this area are in the hands of banks, insurance companies and other places of business, but most of the south side of Throgmorton Street and most of the north side of that portion of Old Broad Street which lies between Throgmorton Street and Threadneedle Street are Stock Exchange premises. Since 1885 various alterations in the use of the space available have been made, but there has been no considerable extension to the building. A portion of the share and loan department occupies premises in Austin Friars.

The Stock Exchange site and buildings are the property of the holders of the share capital in the company called the Stock Exchange (Limited), which is under the control of its "managers, members and committee." There are now 20,000 shares of unlimited amount on which £12 has been paid up; no one person may hold more than 200 shares, and only members of the Stock Exchange can hold shares, except in the case of the representatives of proprietors who acquired their shares before the 31st of December 1875. When a proprietor dies his shares must be sold to a member within twelve months of his decease. As the dividends are handsomely, there is rarely any difficulty in finding a buyer for such shares. The income of the company is derived from the annual subscriptions of members and their clerks, from entrance fees paid by new members, and from rents and investments.

The business and discipline of the Stock Exchange is under the control of the "committee for general purposes," shortly known as "the committee." This body is composed of thirty persons, and is elected annually. It is entirely distinct from the "managers." The committee, when called upon, settles disputes between members and sometimes between members and their clients. It does not, however, take cognizance of business connected to its notice, and even then it frequently declines to act. It does part of its work through sub-committees, but all questions are finally settled in full meeting. Its powers are very wide, ranging from the granting or refusing of a quotation to a new stock, to the expulsion of a member, and the suspension of a "special settlement," as well as such trifles as reprimanding young members overburdened with animal spirits, and the closing of the "house" for holidays other than those provided for by the rules. The committee has an enormous amount of routine work to do or superintend; the "official list" of prices and the marking of "business done," for which the share and loan department is responsible, is supervised by it; the "official assignees," who are appointed to deal with the assets of defaulting members, act under the orders of the committee.

Membership of the Stock Exchange is for twelve months only; everyone without exception who wishes to remain a member must be re-elected annually; the year ends on the 25th of March. New members may be elected, (a) by the nomination of a member who retires in favour of the new member, or of a former member, or of the legal personal representative of a deceased member. The candidate must be recommended by three members, who also become sureties for him during the first four years from the date of his admission for £500 each. (b) A certain number of admissions are made each year, without nomination, of candidates with two sureties; under this arrangement clerks who have completed four years' service are admitted.

Since the 23rd of November 1904, every member has been obliged to become the owner of at least one share in the Stock Exchange (Limited). This arrangement is the outcome of the long-standing custom of respecting the "dual management" of the Stock Exchange, the managing committee and the committee being, as already explained, independent authorities. The arrangement is, no doubt, anomalous, but it has worked efficiently. Its principal drawback is the fact that, as the managers are proprietors and represent the body of proprietors who were, and still are, a minority of the members, they may be unconsciously biased in favour of increasing the number of members, since the dividends on the Stock Exchange shares are derived from this source. In 1904 the number of members had become, temporarily, at any rate, too great, relatively to the business to be done by them, and it was decided to introduce the principle of limitation, not directly, but by the methods briefly described above. It is hoped that, if the shares are all gradually distributed among the members, the slight difference between the interests of the managers and the rest of the Stock Exchange will disappear. The plan adopted involves of course the difficulty that it may not be easy at all times for a candidate to obtain his qualifying shares except at a high price. The new system, however, appears to work well.

The London Stock Exchange is remarkable for having developed spontaneously a special mode of doing business, namely: the differentiation of members into jobbers and brokers. A jobber is a member of the Stock Exchange who, according to the rules of that body, does business only with other members, as opposed to a broker who does business with the public as well as with his fellow members. Any member may at any time make known his intention to act as either jobber or broker, but he must not act as both simultaneously. The business of a jobber (who is sometimes called a dealer) is to be prepared to "make prices" and deal in certain classes of securities selected by himself, in which he causes it to be known that he is a jobber. He thus
The jobber is understood to be, and usually is, acting for a client outside the house, and is paid for his trouble by a brokerage fixed by rules and paid by the client. The jobber's profit consists in the "turn," that is, the difference between the two prices quoted. But it is obvious that the realization of this profit by the jobber depends on his being able to effect a counter-sale, or purchase, with some other broker in 1000 "Easterns," and it is so fixed the prices he charges are not the same as the prices he has to do is, the book shows a balance on the right side that his ability is displayed. If he has sold the stock and has not yet it on his books already, he must procure it by the next settlement in order to deliver it; if he cannot procure it he must borrow it (backwardation). If he has bought it he must pay for it by the next settlement, and should it have gone down in the interval he will evidently have made nothing on the transaction, so far as that settlement is concerned; he will have the stock " on his book " and will have to carry it over (contango) and wait till someone wants to buy it from him in order to " undo " the bargain. If he possesses a profit he may pay for and hold the stock until its price has risen considerably, but as a rule a jobber tries to make quick profits. A jobber is not obliged to make a price, and in times of serious trouble the weaker ones among them refuse to do so, or merely stay away. A jobber has another defence against the risk of making a bargain which he thinks he will not be able to " undo " promptly; he can quote a " wide " price, that is, he could quote for 1000 " Easterns " 94½-94¼, a price no broker would be likely to deal at. The extent of a jobber's business depends on the reputation he has acquired. Good brokers, in their own as well as their client's interest, always " pick their man," especially in times of danger and difficulty. A broker may be acquainted with several men in a particular market any one of whom he considers quite safe to deal with in ordinary times, but he will be very careful whom he chooses to execute an order with, when, owing to money being dear, or for some other reason, markets are " bad. " The usefulness of the jobber has from time to time been denied by critics, who have pointed out that in other stock exchanges there is no differentiation of members into brokers and jobbers has taken place. It has also been alleged that his " turn " is too easily earned, which is not true, and that it is often too large; as to the latter statement, it may safely be said that no jobber who habitually quoted prices which were too " wide " would get much business.

Since 1900 a controversy has arisen as to the propriety of jobbers dealing direct with members of country stock exchanges, and of brokers dealing direct with financial houses known to have certain shares to sell. The difficulty with " Outside " as regards the latter chiefly affected the mining share market. It may be argued that both parties are wrong according to the letter of Stock Exchange law, but their action can be defended. The broker who goes for a particular share direct to a financial house (colloquially called " the shop " ) may get better terms for his client, and though he also gets a second commission for himself, provided he makes known this latter fact to the client, the transaction is an innocent one. The jobber's action in regard to provincial stock exchanges, known in Stock Exchange slang as " shunting " business, may be regarded as a rough compensatory operation for loss of business he may incur through having to deal with financial houses. The quarrel would not have arisen but for the great increase in the members of the Stock Exchange and the fact that business during and for some years after the South African War was insufficient to give a living to so many competitors for it.

The hours of business on the Stock Exchange have varied little since the early days of the institution. They now begin at 11 a.m. and end at 3.30 p.m. on ordinary days, except Saturday, but the house remains open until 4 p.m. On Saturdays, closing hour is 3.30 p.m. During the settlement (see Account) the house is kept open till 4.30 p.m. Bargains are " marked," that is, the prices at which they are " done " are recorded in the official list, between 11 a.m. and 3.30 p.m. on ordinary days, and 11 a.m. and 1 p.m. on Saturdays; the marking of a bargain is effected at the request of the broker who made it; whenever investment purchases are made a large proportion of them are usually marked, as brokers like to be able to show that they did the business at the price stated in the " contract note " sent to the client. The amount of trouble a broker takes for a client is not always realized. An investment order gives much more trouble to a broker than a speculative order. In the former case the broker after arranging the purchase or sale has to perform various operations before the whole transaction is complete. He has to procure transfer forms, get them properly signed and witnessed, obtain the certificates, if the security dealt in is registered stock or shares, or the bonds if the security is " to bearer. " There may be delay in the delivery of securities bought for which he is not responsible, but for which he may be blamed by an inconsiderate client. In cases of serious and unreasonable delay a broker has the drastic remedy open to him of calling upon the officials of the " buying-in " and selling-out department to buy the stock at whatever price may be necessary, the other party, that is, the jobber with whom he dealt, paying any difference between the agreed price and the price at which the security was " bought-in. " Inscribed stock may be bought in on the day following the day specified for delivery of it. Bearer securities not punctually delivered may, in some cases, be bought in on the day they were due for delivery. Similar rules apply to unreasonable delay in payment for securities sold, which may be ended by a demand that the stock shall be, " sold out. " These rules are intended for use in extreme cases, and are not often resorted to.

Every bargain which a broker executes for a client is understood to be " for the account," unless otherwise specified; that is, the completion of the bargain is understood as intended to take place on the next " settling day. " There are two settlements in securities generally, and one in consols and British government securities, India stock, &c., each month (see Account). The interval between two settlements varies from 12 days to 19 days, but the normal interval is 14 days, and the settlement is usually spoken of as " the fortnightly settlement " or " account. " In most securities it may be easy to deal " for money," that is, to obtain cash or stock on the day of the transaction; but this can always be done in consols and other British government securities; " money " bargains in these are sometimes very numerous. Of late the practice of dealing in consols for next ordinary (not consols) account has become fairly common, and is now recognized officially.

All bargains for sale or purchase of stock are supposed prima facie to be investments, that is, the form of contract is the same in all cases. But if a client has bought or sold speculatively he will when the settlement arrives either " close
During recent years the volume of transactions in interest-bearing securities has grown enormously in all the great cities of the world. In London the membership of the Stock Exchange, the number of securities quoted in the official list, and not the number of securities actually dealt in, have expanded greatly, and the markets in New York and Paris, especially the former, have acquired enhanced importance. The Berlin Bourse, the business of which was steadily growing during the 'eighties and early 'nineties, was checked in its expansion after 1896 by drastic legislation passed in July of that year against bargains for future delivery, and much of the business of German speculators has been done since then in other exchanges, especially London, Amsterdam and Brussels, but it has grown nevertheless, and if the existing restrictions are removed will grow more. Communication between the various great cities of the world is much closer than it was before the telephone came into use; what is known as arbitrage business having attained very large proportions. This class of business consists in watching closely the fluctuations in certain securities which are dealt in in two big markets, and simultaneously selling in one and buying in the other. Previous to 1884 and 1885 it was chiefly confined to operations between London and Paris, the difference in the times of London and New York having up till then prevented the growth of a similar business between those cities, as New York morning prices do not reach London till about 3:15 p.m., and the London Stock Exchange is shut at 4 p.m. But in London, about the middle of the 'eighties, the practice of staying in "the street," after the Stock Exchange was shut, to deal in "Americans," began to become common, though many old-fashioned brokers set their faces against it. It is worth noting that in most of the foreign cities there has always been a disposition to stay later than in London, where it was formerly the rule to cease business definitely at a more or less fixed hour. Since 1885 there has been more laxity in this respect, but it is not even yet the general custom. Much of the large mining business at the beginning of the year being settled by the London Stock Exchange, the market had become greater than those in any other, that special recognition was given to the mining department by a rule that the arrangements for carrying over bargains in mining shares should begin the day before the regular settlement commenced.

The Mining Market.

The Market of Stock Exchanges.

The Growth of Stock Markets.

The future is less interested in the client chooses, provided the broker is ready to give the required facilities. But the broker is under no obligation to carry over, and in times of difficulty, when money is dear, or politics threatening, he would very likely decline to do so. Since about 1890 an increasing number of speculative transactions have been effected in a manner which disguises their real character; the security is, to all appearance, bought and paid for in the Stock Exchange, but the client has, as a matter of fact, obtained the money by "pawning" the security with a bank. For many years the relations between the Stock Exchange and the money market in its wider sense (see Markets) have been becoming closer; banks now lend more freely than they used to, and on a wider range of securities; but they also lend more often direct to the holder of the securities borrowed on, and not through a member of the Stock Exchange. Formerly the usual practice of those banks which had considerable business with the Stock Exchange was to lend large sums on high-class stocks to wealthy brokers, who employed the money inside the house in carrying over the accounts of their clients, or to other brokers whom they trusted. This class of business is still very large, but clients are not now always satisfied to borrow through their brokers; they not infrequently go direct to any bank or broker to whom they wish to borrow. This practice has its inconveniences: formerly it was possible for the jobbers in all important markets on the Stock Exchange to form a good idea, by comparing notes at each settlement, of what the condition of the speculative account really was, but it is less easy to do so now, because so much stock is "pawned" with banks that the conclusions arrived at by the jobbers from examining only what they are carrying over themselves are liable to be falsified through their finding (a) that the account is either lighter than they expected, stock having been bought before they had time to make their purchases; (b) that the account is heavier than it appeared, banks having been from banks; or (c) that it is much heavier than they were prepared for, the banks having suddenly refused to lend any longer on a mass of stock they had hitherto been carrying. Banks are apt to be more capricious in their action as regards this class of business than the big "money brokers"; they cannot so well feel the pulse of the market, and are therefore liable to sudden fits of alarm, and also to hurried changes of policy on the part of their boards, which may be, and usually are, based on sound principles, but are not infrequently carried out without sufficient regard to the circumstances existing at the moment chosen for their actuation.

Speculative dealings sometimes take the form of "options." An option is a right to buy or sell a specified quantity of a specified security at a certain price, within a specified period; for this right a sum of cash is paid which is usually quoted as a percentage on the face value of the security. Having paid this sum the purchaser of the option watches the market during the period fixed; if a rise or fall sufficient to show a profit occurs he sells or buys an amount of the security equal to that bargained for in the option contract and inflicts the loss or gain upon those who bought the option. The option is a "call" or "put," the first being sold to the owner of the stock and the second to the broker who agrees to sell the stock at the option price. This form of transaction is often a useful one for a business man, but attempts have been made to represent it as a "safe" way of making money on the ground that "risk is limited," and, as such, has been recommended to inexperienced persons who are foolish enough to wish to speculate without comprehending the nature of speculation. Option dealings are neither more nor less "safe" than other speculative operations. Brokers who quote prices for an option always fix them at a level which will, on the average, make their own positions safe, and their clients, unless they are unusually acute and well informed, are not more likely to make exceptional, or any, profits than by the more usual speculative methods.

The Market of Stock Exchanges.

The Growth of Stock Markets.

During recent years the volume of transactions in interest-bearing securities has grown enormously in all the great cities of the world. In London the membership of the Stock Exchange, the number of securities quoted in the official list, and not the number of securities actually dealt in, have expanded greatly, and the markets in New York and Paris, especially the former, have acquired enhanced importance. The Berlin Bourse, the business of which was steadily growing during the 'eighties and early 'nineties, was checked in its expansion after 1896 by drastic legislation passed in July of that year against bargains for future delivery, and much of the business of German speculators has been done since then in other exchanges, especially London, Amsterdam and Brussels, but it has grown nevertheless, and if the existing restrictions are removed will grow more. Communication between the various great cities of the world is much closer than it was before the telephone came into use; what is known as arbitrage business having attained very large proportions. This class of business consists in watching closely the fluctuations in certain securities which are dealt in in two big markets, and simultaneously selling in one and buying in the other. Previous to 1884 and 1885 it was chiefly confined to operations between London and Paris, the difference in the times of London and New York having up till then prevented the growth of a similar business between those cities, as New York morning prices do not reach London till about 3:15 p.m., and the London Stock Exchange is shut at 4 p.m. But in London, about the middle of the 'eighties, the practice of staying in "the street," after the Stock Exchange was shut, to deal in "Americans," began to become common, though many old-fashioned brokers set their faces against it. It is worth noting that in most of the foreign cities there has always been a disposition to stay later than in London, where it was formerly the rule to cease business definitely at a more or less fixed hour. Since 1885 there has been more laxity in this respect, but it is not even yet the general custom. Much of the large mining business at the beginning of the year being settled by the London Stock Exchange, the market had become greater than those in any other, that special recognition was given to the mining department by a rule that the arrangements for carrying over bargains in mining shares should begin the day before the regular settlement commenced (see Account). Even with these new facilities the Stock Exchange clearing house found it difficult to cope with the huge mass of work thrown on it in 1895, and once or twice it broke down temporarily. Much of the trouble to all concerned arose from the fact that the shares of the large mining shares, like the others, were not "registered" and not "to bearer." The offices of the companies were naturally not equipped with the staffs that would have enabled them to furnish certificates promptly in the enormous quantities unexpectedly required; it must be remembered that the preparation of a certificate for 50 or 100 shares of £1 each is just as troublesome as the preparation of one for 500 or 1000. The new feature, which upset all calculations, was the extraordinary number of small speculative investors who bought and paid for their shares, very often to their subsequent regret. If the shares had been "to bearer," the work could have been done with comparative ease.

Another remarkable feature of the "boom," to use the slang which came into general use during the great speculative mania for South African shares in 1895, was the fact that of the 200 or 300 shares dealt in, less than a dozen were officially quoted.
The Paris Bourse exists in virtue of the decree of the 7th of October, 1890, to regulate the execution of article 90 of the Code du Commerce and of the law of the 28th of March 1885, on marchés à terme, as modified by the decree of the 29th of June 1898. *Agents de change*, who form the members of the official bourses in France, must be Frenchmen over twenty-five years of age, and must be in possession of civil and political rights. They are "nominated" by decrees countersigned by the minister of finance or the minister of commerce and industry. In a bourse possessing six or more *agents de change*, a *parquet* may be formed, that is, a portion of the bourse may be railed off to which only *agents de change* have the right of entry, the rest of the bourse being known as the *couilisse*. A bourse provided with a *parquet* elects a *chambre syndicale*, or committee, composed of a syndic and members varying in number according to the number of *agents* in the bourse. The maximum, when there are over sixty *agents*, is eight. In Paris there were only sixty *agents de change* until 1898, but in that year the number was raised to seventy, owing to the volume of securities to be dealt with on the bourse having expanded considerably. The individual members are not, in law, responsible for any liabilities that may be incurred by fellow-members, but the practice is that the *chambre syndicale* meets the liabilities of any defaulting member. Each member owns what is called a *charge*, for which he has paid a sum varying from 1,500,000 fr. to 2,000,000 fr. (£60,000 to £80,000) to his predecessor by a private arrangement. In addition the new member must deposit 250,000 fr. (£10,000) as caution money, and 120,000 fr. (£4800) in the *caisse commune* of the *chambre syndicale*. The *agents de change* have a monopoly of many kinds of legal business; they have various privileges denied to the dealers in the *couilisse*, as, for instance, the right to sell or buy certain securities for cash, the *couilissiers* being allowed only to deal for delivery at the settlement. The securities dealt in by the *couilisse* are known as *valeurs en banque*, and the *couilisse* is often called the *marché en banque*. The *agents de change* are responsible for the production of the official price list of the bourse, but the *couilisse* also issues a list of its own. A much bigger business is done in the *couilisse* than in the *parquet*, the market for foreign securities being in their hands; many *couilissiers* are wealthy men.

All continental securities are "to bearer," and when it is desirable for capitalists to take an interest in British securities which are inscribed or registered, it has been found necessary to convert a part of the stocks into bearer bonds or shares. The fact that all securities are to bearer has led to special arrangements being made for guarding against the delivery of bonds to which the seller's title may be considered doubtful. A journal called the *Bulletin officiel des oppositions* is published by the *syndicat des agents de change*, giving the designations and numbers of securities which have been frappés d'opposition, that is, whose currency on the bourse is temporarily stopped, either because they have been stolen or for other reasons. It is always necessary, before taking delivery in London of foreign bonds, to look through this list to see whether the bonds in question are included in it. Settlement (liquidation) in Paris takes place twice a month; that at the end of the month lasts five days, and that in the middle of the month four days. French *routes* are "settled" at the end of the month.

*New York.*—The New York Stock Exchange is a wealthy association consisting of members, who must be citizens of the United States, of twenty-one years of age or more. Their number cannot be increased except by the governing committee, which consists of the president, treasurer and secretary of the Stock Exchange, and forty members. There are twelve standing committees to deal with various departments of administration, the more important of these being the Admission, Arbitration and Clearing House committees.

Persons attain membership by election, or by transfer from a member who has died or resigned. Various dues and charges are payable by a new member. A member who is admitted by transfer pays an "initiation fee" of £2000 (£1000). When a
transfer is made the approval of the governing committee must be obtained before it can be completed. The person to whom the transfer is made pays a sum to the transferor for his "seat in the house," the amount of which is a matter of private arrangement; as much as $90,000 (£18,000) has been paid for a "seat" when business is active, but when it is quiet the price falls considerably below this. A member may transfer his seat to his son (if the committee approve) without charging anything for it; but in all cases the transferee pays the above-mentioned initiation fee of $2,000.

The gratuity fund is an arrangement for providing for the families of deceased members. Every member on election pays $10 to this fund; when a member dies an assessment of $10 is levied on all other members, and the Stock Exchange hands over $10,000 (£2,000) to the family of the deceased.

The New York Stock Exchange building is opened at 9:30 a.m., but business does not begin until 10 a.m. The daily session continues until 3 p.m. No transactions must be entered into before 9 a.m. or after 3 p.m. (with certain exceptions) under severe penalties. The object of this is to enable all members to feel secure that no business has been done except within the official period, during which they are prepared to watch the market or provide for its continuance. Leases of money or securities, that is, what is called in London contango and backwardation business, may be arranged after 3 p.m. This latter provision is a necessary result of the settling arrangements on the Exchange.

Transactions may be: (a) for cash, in which case payment is made or stock delivered the same day; (b) "the regular way," i.e., the transaction is to be completed on the following day to that on which the bargain was made; (c) "three days," in this case the bargain must be carried out in three days; (d) in case of options bargains may be made up to a limit of sixty days. If no time is specified when the bargain is made it is treated as being made for the day on which the rules relating to commissions. Dealing for "outside" exchanges of an irregular character was forbidden in 1896.

The New York Exchange is often the scene of gigantic speculative movements, and enormous sums are won and lost on it from time to time; but a huge investment business, or, at any rate, what is intended to be investment business, is done in Wall Street. Too frequently, however, the ideas of the purchaser as to what constitutes an investment are not very clear, and he finds that he has acquired a speculative article; this is inevitable in a country which still contains a good deal of dormant wealth which must sometimes be developed by new methods whose merits, when expressed in terms of capital expenditure, are not always as great as their enthusiastic authors imagined they would prove.

Berlin.—The business of the Berlin Börse is conducted under the strict regulations of the Imperial German law of the 22nd of June 1896, a measure which was intended to put a check on speculation in stocks and commodities in the supposed interests of the community. The term "Börse" is applied equally to the Effektenbörse (or Ponds-börse), that is, the "market for securities" (the Stock Exchange), and to the Warenbörse in which commodities are dealt in. "Börse" is, in fact, a term equivalent to "exchange" as used in the expressions "stock exchange," "corn exchange," "wool exchange," &c. The brokers (Makler) who carry on business at the Berlin Bourse are under the supervision of the Ober-President of the province of Brandenburg and the Ober-President of the city of Berlin, in accordance with the terms of the Maklerordnung für die Kurzmakler an der Berliner Börse, which was issued in the form of a decree (Dec. 4, 1896) of the Ministers of Commerce.

The Bourse opens at 11:50 a.m. and closes at 3 p.m. for official dealings, and a quarter of an hour before and half an hour after those hours for "unofficial dealings." The unimportant part which the Berlin Bourse plays in the world of finance, owing to the legislative shackles with which it is loaded, has led to a movement in favour of a reform of the law, which would give more freedom to legitimate speculation in commodities as well as in securities.

Stockholm, the capital of Sweden, on the east coast, not far south of the junction of the Baltic Sea and the Gulf of Bothnia. It is celebrated for the beauty of its physical characteristics and the richness of its situation. The coast is here thickly fringed with islands (the skärgård), through which a main channel, the Saltsjö, penetrates from the open sea, which is nearly 40 m. from the mainland. A short stream with a fall normally so slight as to be sometimes reversed by the tide, drains the great lake Mälär into the Saltsjö. The scenery of both the lake and the skärgård is similar, the numerous islands low, rocky, and generally wooded, the waterways between them narrow and quiet. The city stands at the junction of the lake and the sea, occupying both shores and the small islands intervening. From the presence of these islands, and the location of this city is derived—"the Venice of the North"; but actually only a small part is insular. There are three main divisions, Staden, the ancient nucleus of the city, properly confined to Stadholmen (the city island) which divides the stream from Mälär into two arms, Norrström and Söderström; Norrmalm on the north shore of the channel, and Södermalm on the south.

The ancient origin of Staden is apparent in the narrow and winding streets, though the individual houses are not very old, owing to the ravages of frequent fires. A few, however, preserve antique narrow fronts with windows and gables, as in some of the North German towns. The old market-street, still called Stortorg (great market) is now one of the smallest in Stockholm. At the north angle of the island is the Royal Palace (Slott). The original building was destroyed by fire in 1697, the body of Charles XI. being with difficulty rescued from the flames. A new palace after designs of Nicodemus Tessin the younger (d. 1728) was not completed, owing to wars and the general distress, until 1754; while a restoration carried out in 1891 included many ornamental details devised by the architect, and executed at the expense of King Oscar II. The palace is quadrangular with two wings (towards the east and north, straight and straight, and curved) and two wings (towards the east and south, straight and straight, and curved) towards the west. The style, that of the Italian Renaissance, is noble and refined, the royal apartments rich in treasures of art. In the north-east wing is a museum of armour and costume, one of the finest of the kind existing. West of the palace are the offices of the majority of the ministries, some of them in the former buildings of the Royal Mint. Beyond these, on the west side of the island, is a square named from the palace on its northern side, the Kiddachustorg. The Riddarhus (house of the nobility) was the meeting-place of the Council of the Nobles until 1866, and its hall is adorned with the armorial bearings of noble families. In the northern forecourt is a statue (1850) of Axel Oxenstierna, the chancellor, by J. Börjeson. The town-hall is also in Riddarholmen, and a statue of Gustavus Vasa, unveiled in 1773 on the 250th anniversary of his accession to the throne, stands here. South-west of
the Royal Palace is the Storkyrka (great church), dedicated to St Nicholas, the oldest church of Stockholm, though greatly altered from its original state. The date of its foundation is 1264; but it was practically rebuilt in 1720-1743. Within it is richly adorned with paintings and wood-carving. Staden is the commercial centre of the city. At the broad shipping quay (Skeppsholmen) which flanks the palace on the north and east, most of the sea-going steamers lie; and the exchange, custom-house, numerous banks and merchants' offices are in the immediate vicinity. Riddarholmen (nobles' island), lying immediately west of Stadholmen, contains the old Franciscan church (Riddarholmskyrka), no longer used for regular service, which since the time of Gustavus Adolphus has been the burial-place of the royal family. It contains many trophies of the European wars of Sweden. On one side of it stands the old house of parliament; on the other a statue of Birger Jarl, the reputed founder of the city. On Riddarholm also are various government offices, and most of the steamers for Mälar and the inland navigation lie alongside its quays.

Staden is connected with Norrland by the Norbro (north bridge) and Vasabro, the first crossing Helgeandsholmen (the island of the Holy Spirit), on which are the new Houses of Parliament and the Bank of Sweden. A third bridge connects with the main thoroughfare of Norrland, Drottninggatan (Queen Street). The Norbro gives upon Gustaf-Adolfs-Torg, where a statue of that king stands between the royal theatre, royal opera house and the palace of the crown prince. Norrland is the finest quarter of the city, with broad straight streets, several open spaces with gardens, and handsome buildings. East and north of the theatre royal, the Karl-den-Tolttes-Torg and Kungsträdgård (royal garden) form the most favoured winter promenade. There are a statue of Charles XII. and a fountain with allegorical figures, by J. P. Molin, also a statue of Charles XIII., and in the small Berzelii Park close at hand one of the chemist J. J. Berzelius. Near Drottninggatan is the Klarab, church, the burial-place of the poet K. M. Bellman, and west of this, occupying one side of a square, is the central railway station. In the building of the academy of science is the national museum of natural history, including mineralogical, zoological, and ethnographical departments. Drottninggatan terminates at the observatory, on a rocky eminence, near which are the offices for the distribution of the Nobel fund. To the east the modern Gothic church of St Johannes, with a lofty spire, stands conspicuously on the Brunkbergsp, one of the highest points in the city. To the north is the small Vanad's Park. To the west is the modern quarter of Vasastad, with its park. On the island of Kungs, south of Vasastad, are the Caroline medical institute, several hospitals, the principal of which is the Serafimer (1752), the royal mint and factories. Österland, lying east, that is, on the seaward side, of Norrland, is a good residential quarter, containing no public buildings of note, save the barracks of the Swedish Guards and the fine royal library, which is entitled to receive a copy of every work printed in Sweden. The library stands in the beautiful park of Humlegården (hop-garden), in which is also a statue of Linnaeus. South of Österland, and east of the Kungsträdgärden and Staden, lies the peninsula of Blasieholm (formerly an island) and, connected by bridges, the islands of Skeppsholm and Kastellholm, the three forming the foreground in the beautiful seaward view from the Norbro. On the first
Stockholm is the national museum (1860), a Renaissance building, containing historical, numismatic and art-industrial collections, with its splendidly adorned and modern sculptures, picture-gallery and engravings. The numismatic collection is notable for its series of Anglo-Saxon coins. About 11,000 pieces came from the island of Gotland, some dating from 901-924, but the majority are later. In front of the museum is a bronze cast of the famous group of J. P. Molin (1830), the Bältespänne (belt-bucklers), representing an early form of duel in Scandinavia, in which the combatants were bound together by their belts. On Skeppsholm are naval and military depots, and on Kastellholmen a small citadel, East of Skeppsholm an inlet, Ladugårdslundsviken, so named from the proximity of the former royal farm-yard (Ladugård) on this site is a gunsite with some houses called Strandvägen, throws off a narrow branch (Djurgårdsbrunnsviken) and separates from the mainland an island about 2 m. in length by 2 m. broad. This is mainly occupied by Djurgården (the deer-park), a beautiful park containing the buildings of the northern museum, a collection of Scandinavian costumes and domestic and agricultural utensils, and a biological museum housed in a wooden building imitating the early Norwegian timber churches (stavekirke). Here also is Skansen, an ingenious reproduction in miniature of the salient physical and geological features of Sweden, including Kungsholmen with its little dwellings inhabited by peasants in the picturesque costumes of the various districts. Both the northern museum and Skansen were founded by Dr Arthur Hazelius (1833-1901). There is a bust of the poet K. M. Bellman, whose festival is held on the 26th of July. Södermalm, the southern quarter, is principally residential. Rocky heights rise to 120 ft. above the water, and two steam lifts, Katarina-Hissen and Maria-Hissen, surmount them.

Environment.—The beautiful environment of sea and lake is fully appreciated by the inhabitants. To the north of the city, accessible by rail and water, are the residential suburbs of Haga and Birkastaden (the former called Djurgården), situated on an alluvial plain, 1 km. east of Stockholm, on Djurgården, is the oldest and most famous seaside resort, but Dalarö (20 m. south-east) and Nynäshamn (30 m. south) are much frequented. Vaxholm, 12 m. north-east by water, is a pleasant fishing-village where numerous villas have been built. A fortification on one of the islands here was erected by Gustavus Vasa, but has been modernized and is maintained.

Educational and Scientific Institutions.—Stockholm has no state university. A private university (Högskola) was founded in 1878, and was brought under state control in 1904. The president of the government board is appointed by the government, while the management of the remaining members is shared by the Swedish Academy, the Academy of Sciences and the City Council. The faculties are four, namely theology, philosophy, mathematics, and natural sciences, and jurisprudence. The Caroline Institute (Karolinska Medico-Kirurgiska Institut) is a medical foundation dating from 1815, which ranks since 1874 with the state universities of Upsala and Lund in the right to hold examinations and confer degrees in its special faculty. Special and secondary education is highly developed; there are schools of agriculture, mining and forestry, military schools, technical schools, a veterinary school, a school of pharmacy, &c. Among the public colleges under state control, one, the Nya Elementskolan, was founded experimentally in 1828, after the Education Committee of 1825-1828, among the members of which were Tegner and Nordenskiöld, recommended the establishment of such schools. This school retains its separate governing board; whereas others of the class are under a central board. The control of the primary schools in the parishes is similarly centralized; whereas in Sweden generally each parish has its school-board. Stockholm is the seat of the principal learned societies and royal academies (see Sweden). There are schools of painting, sculpture and architecture under the direction of the Royal Academy of Arts; a conservatory of music under the Academy of Music; and institutions for the advancement of scientific research, and botanical gardens under the Royal Society of Agriculture. The Natural History Museum, the observatory and meteorological office, and the botanical garden, require no special reference. The Royal Academy of Sciences is the principal place for leading scientific exhibitions in summer. Several of the leading sporting clubs have their headquarters in Stockholm. An annual regatta is held early in August by the Royal Swedish Yacht Club (Svenska Segelsällskapet). A harbour much frequented by yachts is Sandhamn in the outer skärgård. The Stockholm General Skating Club (Almano Skridskoklub) is the leading institution for the most favoured winter sport. A characteristic spectacle in winter is the tobogganing in the Humlegården on holidays. The Stockholm dramatic and drammatico groups flourish in the north side of Östermalm, with tennis courts and a cycling track, which may be changed into a skating-rink in winter. There is a similar park at Djursholm.

Commentaries.—The admiring circles of Stockholm are miscellaneous. The value of the output of these is nearly thrice those of Malmö or Gothenburg, the next most important manufacturing towns, and the industries of the districts combine to afford every traveller on a quick tour from Stockholm a good deal of interest except Malmöhus. The iron and steel industries are very important, including engineering in every branch, and shipbuilding. Factories for articles of human consumption (e.g. breweries and tobacco works) are numerous; and cork, wood, silk and leather works may also be mentioned. Fine ware is produced by the Rörstrand and Gustafsberg porcelain works. In addition there are various government works, as the mint and printing works. Stockholm is the first port in Sweden for import trade, but as regards exports ranks about level with Malmö and is exceeded by Gothenburg. The imports average nearly 30% of those of the whole country, but the exports only 2%. Stockholm has proportionately little share in the vast timber export trade. Vessels of 25 ft. draught can go up to the city (Skoppbro and Blasieholm quays), and there is an outport at Värnån on the Lilla Värnån channel to the north-east.

Government.—Stockholm is the centre of government and the usual residence of the Swedish sovereign. The city occupies one of the neighbouring country palaces. The city is the seat of the high court of justice (Högsta Domstolen) and of the court of appeal for the northern and midland districts (Svea Hovrätt). It is one of the two Swedish naval stations (Karlskrona being the principal one), and the headquarters of the fourth and fifth army divisions. As regards local government, Stockholm is a län (administrative district) in itself, distinct from the rural län of the same name, under a high governor (öfverståthållare) and deputy, with departments for secretarial work, taxation and various other concerns. The city is divided into a separate consistory, composed of the rectors of the city parishes, the president of which is the rector of St Nicholas (Storkyrka).

Population.—The population of Stockholm in 1900 was 350,624. In 1751 it was 61,040; in 1890, 83,070; and in 1880, 176,875.

History.—Before the rise of Stockholm, Björkö, Sigtuna and Upsala were places of great importance. Björkö ("the isle of birches ")) by foreign authors called Birka, was a kind of capital where the king lived occasionally at least; history speaks of its relations with Dorestad in the Netherlands, and the extensive refuse heaps of the old city, as well as the numerous sepulchral mounds which show that the city must have been a considerable one. But though situated at a central point on Lake Mälar, it was destroyed, apparently before the beginning of the 11th century (exactly when or by whom is uncertain); and it never recovered. Sigtuna, lying on the shore of a far-reaching northern arm of Lake Mälar, also a royal residence and the seat of the first mint in Sweden, where English workmen were employed by King Olaf at the beginning of the 11th century, was destroyed in the 12th century. Stockholm was founded by Birger Jarl, it is said, in or about 1255, at a time when pirate fleets were less common than they had been, and the government was anxious to establish royal relations in the north. The remains of the city which have begun to flourish on the southern coast of the Baltic. The city was originally founded as a fortress on the island of Stadholmen. The castle was erected at the north-eastern corner, and the city was surrounded with walls having fortified towers on the north and south. It came to be called Stockholm ("the isle of the log", Latin Holmia, German Holm); the true explanation of the name is not known. During the middle ages the city developed steadily, and grew to command all the foreign commerce of the midlands and north, but it was not until modern times that Stockholm became the capital of Sweden. As a centre of entertainment, the city has flourished in its sumptuously grave and gloomy medieval kings visited year by year different parts of the kingdom.

See P. R. Ferlin, Stockholms Stad (Stockholm, 1854-1898); C. Lundin and A. Strindberg, Gamla Stockholm (Stockholm, 1882); C. Lundin Nya Stockholm (Stockholm, 1890); G. Nordensvan, Mälardrottningen ["the queen of Mälaren"] (Stockholm, 1896); E. W.
Dahlgren, *Stockholm, Sveriges huvudsatt skildrad* (Stockholm, 1897, issued by the municipal council on the occasion of the Stockholm Exhibition, 1897).

**STOCKING** (a diminutive of "stock, post, stump, properly that which is stuck or fixed), a close-fitting covering for the foot and lower part of the leg, formerly made of cloth but now of wood, silk or cotton thread knitted by hand on a loom, or on a machine (see Hosiery). "Stock" being the stump, i.e. the part left when the body is cut off, the word was applied to the whole covering of the lower limbs, which was formerly in one piece, the "upper-stocks" and "nether-stocks" forming the two pieces into which it was subsequently divided, when the upper part became the trunk hose and later knee-breeches, the lower the "stockings." A parallel is found in French; the hose are chausses, the upper part haut de chausses, the stockings bas de chausses, or simply bas.

The German Strumpf, stocking, means also a stump, pointing to the original use of the word. Half-stockings, reaching to the knee, are part of the calf of the leg, and worn by men since the use of the long trousers has superseded knee-breeches, and also by children, are unusually styled "socks." This word is an adaptation of Latin soccus, a slipper or light shoe. It was the shoe worn by the actors in Roman comedy—and so was used symbolically of comedy, as "buskin," the high boot or cothurnus, was of tragedy.

**STOCKMAN, CHRISTIAN FRIEDRICH, BARON VON (1787-1863), Anglo-Belgian statesman, who came of a Swedish family, was born at Coburg on the 22d of August 1787. He was educated as a physician, and in that capacity became attached in 1816 to Prince Leopold of Saxe-Coburg-Gotha on his marriage to Princess Charlotte of England. When she died the next year he remained Leopold's private secretary, counsellor of the household and political agent, until the prince became in 1831 king of the Belgians. He was thus brought into contact with the leading statesmen of Europe, and his disinterestedness and profound acquaintance with English and European social and political questions impressed themselves on all who were associated with him. In 1831 he retired to his home at Coburg, in order not to excite Belgian jealousies by residing at his master's court in the capacity of confidential adviser, but he continued to be Leopold's right-hand man. In 1837 Leopold sent him to England as adviser to the young Queen Victoria, and in the next year he accompanied Prince Albert (afterwards Prince Consort) on his tour in Italy, partly as tutor but also with the direct object of satisfying King Leopold and the queen to the fitness of the prince for the position already marked out for him in England. He won the complete confidence of the prince as well as of the queen, and on their marriage in 1840 he became their trusted though unofficial councillor, dividing his time more or less between England and the Continent. In 1848 he was the ambassador of Coburg to the German parliament. He had at heart the unity of Germany under Prussia and close relations between Germany and England, and for these he steadfastly worked; but his political activity was a good deal resented in English circles, which were jealous of Prince Albert's—and generally of German—fluence. He died at Coburg on the 6th of July 1863.

See the articles on *Victoria, Queen*; and Albert, Prince Consort.

STOCKPORT, a municipal, county and parliamentary borough of England, mainly in Cheshire, but partly in Lancashire, 6 m. S.E. of Manchester. Pop. (1901), 92,832. It occupies a hilly site at the junction of the rivers Tame and Mersey; the larger part of the town lying on the south (left) bank, while the suburb of Heaton Norris is on the Lancashire bank. Several bridges cross the stream, and a lofty railway viaduct beztrides the valley. Stockport is served by the London & North Western Railway, Grand Central, Cheshire Lines, and Midland railways, and has tramway connexion with Manchester. It is a town of varied industries, but the most important are the cotton and hat manufactures. The church of St Mary was built mainly c. 1817, but the chancel belonged to a former church, and retains a Decorated east window and other good details. The town hall was designed by Sir Brunwell Thomas, and opened in 1908, and St George's church (1897). On the acquisition of the market rights by the town from Lord Vernon in 1847 the corporation secured the site of Vernon Park, in which stands a museum presented in 1858 by James Keswah and John Benjamin Smith. The grammar school was founded in 1487 by Sir Edmund Shaa or Shaw, lord mayor of London. The Stockport Sunday school, founded in 1784, is one of the largest in England. Stockport was enfranchised in 1832, and returns two members. Its most distinguished representative was Richard Cobden (1815-1877), who is commemorated by a statue in St Peter's Square. The town was incorporated in 1835, and is under a mayor, 16 aldermen and 48 councillors. The county borough was created in 1888. Area, 5492 acres.

During the Roman occupation of Britain there was a small military station on the site of Stockport, acting as an outpost to the Roman camp at Manchester. The convergence of Roman roads at this point would make the place a particularly convenient centre. The etymology of the name may be Saxon, but there is no evidence of a Saxon settlement, and the place is not mentioned in Domesday. A castle was in existence in the 11th century, but was not mentioned after 1257. Stockport (Stockeporte, Stopport, Stopford) was made a free borough by a charter of Robert de Stopeport about the year 1220. It was then granted that the burgesses might elect from among themselves a chief officer, who was first called a mayor in 1296. The right of the burgesses to his election was, however, lost, and the mayor was always nominated by the lord of the manor. This arrangement lasted until 1565, when the burgesses put in a claim to their right of election, and it was decided that out of four burgesses nominated by the lord of the manor the jury of the court leet should select the mayor. Thus Stockport was not a true municipal borough until formally incorporated under the Municipal Corporations Act of 1835. The manufacture of hemp began in Stockport in the 16th century, and that of silk-covered buttons in the 17th. In 1732 a silk mill was erected, but the silk trade was superseded by the cotton trade early in the 19th century. The hat trade developed at least as early as the end of the 18th century.

**STOCKS**, a wooden structure formerly in use both on the continent of Europe and in Great Britain as a method of punishment for petty offences. The culprit sat on a wooden bench with his ankles, and sometimes his wrists or even neck, thrust through holes in movable boards, generally for at least several hours. That stocks were used by the Anglo-Saxons is proved by their often figuring in drawings of the time (see Harleian MSS. No. 63). The second Statute of Labourers (1350) ordered the punishment for unruly artisans. It further enjoined that stocks (ceppe) should be made in every town between the passing of the act and the following Pentecost. The stocks appear to have been ill observed, for in 1376 the Commons prayed Edward III. that stocks should be set up in every village. Though never expressly abolished, the punishment of the stocks began to die out in England during the early part of the 19th century, though there is a recorded case of its use so late as 1865 at Rugby. In many of the villages in the country may still be seen well-preserved examples of stocks, in some cases with whipping posts attached. In the United States stocks were of frequent use in the 18th century, more particularly in the New England States; while in the Southern States they were employed for punishing slaves.

**STOCKS AND SHARES.** A "share," in the financial sense, is simply the right to participate in the profits of a particular joint-stock undertaking. In the United Kingdom, in the case of a company constituted under the Companies Acts 1862-1907 as a company limited by shares, the memorandum of association is required to state—among other matters—the amount of capital
with which the company proposes to be registered and the amount of the shares into which such capital is divided. Company statistics show a tendency of late years on the part of companies to register with a smaller nominal capital than they did. The tendency too has been to lower the denomination of the shares. $100 shares, for instance, are now very rare. $1 shares and $5 shares are the most common. They obviously appeal better to the small investor. A typical capital clause runs thus: "The capital of the company shall be $1,000,000 divided into 100,000 shares of $1 each with such rights as regards dividends and other privileges as are defined by the company's articles of association for the time being," or "The capital of the company is $1,500,000 divided into 50,000 preference shares of $1 and 100,000 ordinary shares of $1 each. Such preference shares shall confer a right to receive a cumulative, preference dividend at the rate of 10% per annum." The form of capital clause varies of course, but the more approved practice now is to leave the rights of preferential shareholders to be defined by the articles, and for this reason; that if such rights are fixed by the memorandum of association without qualification they cannot be subsequently varied. Articles, on the contrary, are always alterable, and as the preference shareholder takes his shares subject to this known liability to alteration no wrong is done him. If the powers of alteration were abused so as to amount to a fraud by the ordinary shareholders on the minority of preference shareholders the court would probably interfere by injunction. The preferential or other special privileges of any particular class of shareholders are now further safeguarded by s. 49 of the Companies Act 1907.

The right of a preference shareholder is commonly confined to a preferential dividend and this dividend is prima facie cumulative, that is to say if the profits of the particular year are insufficient to pay it the deficiency must be made good out of the profits of subsequent years: but it is very common to give preference shareholders priority also as regards capital in the winding-up. Founders' shares originated with private companies, being a convenient way of enabling the man who became assistant editor in 1873 and about 1876 gave up editing work for independent authorship. Thereafter he lived in Nutley, New Jersey, in Convent, New Jersey, and after 1899 in the Shenandoah Valley, near Charles Town, West Virginia. He died in Washington, D.C. on the 20th of April 1902. His fanciful stories for children made him very popular; among them are The Ting-a-Ling Stories (1870), Roundabout Rambles in Lands of Fact and Fancy (1872), What Might Have Been Expected (1874), Tales Out of School (1873), A Jolly Fellowship (1880), The Floating Prince and Other Fairy Tales (1881), The Story of Viteau (1882), Personally Conducted (1886), and Captain Chap and His Shipmates (1894). His work was disdained by the series of sketches rather than a novel, established his reputation with older readers and is his best long work. His peculiar talent was for the short story; and the best examples are the title stories of the volumes The Lady or the Tiger? (1884), one of the most popular of American stories, The Christmas Wreck (1886), The Bee Man of Orr (1887), (also in the latter volume "A Tale of Negative Gravity" and "The Remarkable Wreck of the Thomas Hyke"), and the novellette The Casting Away of Mrs Locks and Mrs Aleshine (1886), with its sequel The Dusantes (1888).

Among his other works of fiction are The Late Mrs Null (1886), The Works of Jonathan Chapel, Caballistic Discoveries, with Other Stories (1888), The Great War Syndicate (1889), The Merry Chantier (1890), Ardis Claverdon (1890), The Rudder Grangers Abroad, and Other Stories (1891), The House of Mortis (1891), The Squirrel Inn (1891), The Watchmaker's Wife and Other Stories (1893), Pomona's Travels (1894), The Adventures of Captain Horn (1895), with its sequel, Mrs Cliff's Yacht (1866), The Great Stone of Sardis (1866), Kate Bonnel (1902), and The Captain's Toll-Gate (with a memoir by Mrs Stockton, and a bibliography, 1903).

STOCKTON, a city and the county seat of San Joaquin county in central California, U.S.A., at the head of the Stockton channel of the San Joaquin river. San Joaquin river (18,500, of whom 4057 were foreign-born; 1910 census 23,432). It is served by the Atchison, Topeka & Santa Fe, the Western Pacific and the Southern Pacific railways, and has also a considerable river trade with San Francisco. It is at the head of regular navigation on the river; at high water boats occasionally go to Hilla Ferry, 150 m. beyond Stockton. The channel has been much improved by the Federal government since 1877. Stockton has a perfectly level site, broad streets and a regular plan. In the city are a good public library, the San Joaquin county law library, St Agnes academy, St Mary's college, a children's home (1866; under the Ladies' Aid Society), St. Joseph's hospital (1899) for the aged, and St Joseph's hospital (1890), both under the Sisters of St Dominic, the Pacific hospital, a county hospital and a state hospital for the insane (1851). Situated in the great valley of the San Joaquin, in the midst of a
rich agricultural region, it is one of the largest grain, vegetable and fruit markets of the West. It manufactures flour, lumber, agricultural machinery and implements, &c. Its factory product in 1905 was valued at $8,035,490, or 45.5% more than in 1903.

Stockton rose into prominence in the early mining days. A settlement named Tuleberg, later called New Albany, stood on the city site in 1847; its future was precarious when the discovery of gold insured its prosperity. In the spring of 1849 a town was laid out and the present name adopted in honour of Colonel John C. Fremont and General Stephen W. Kearny who had possession of California for the United States during the war with Mexico. In 1850 Stockton became the county-seat and was chartered as a city.

Stockton is a market town, market, municipal and parliamentary borough, and port of Durham, England, on the N. bank of the Tees, 58 m. above its mouth, and on the North Eastern railway, 236 m. N. by W. from London. Pop. (1901), 51,478. The parliamentary borough extends across the river into Yorkshire, to include the municipal borough of Thornaby-on-Tees. At Norton, 1 m. north, the church of St Mary, formerly collegiate, shows fine Norman work. The chief buildings are a town hall, with clock-tower and spire, borough-hall, exchange and public library. The quays are accessible to vessels drawing 20 ft. at high water spring tides. There are extensive steel works, blast-furneries and iron foundries, and iron shipbuilding is an important industry. There are also sailcloth works, potteries, breweries and brick and tile works. Exports (iron manufactures, coal and agricultural produce) were valued at £435,439 in 1900; imports (timber, iron, grain, &c.) at £280,371; trade being chiefly with Holland and the Baltic ports, and coastal. The parliamentary borough returns one member. The municipal borough is under a mayor, 10 aldermen and 30 councillors, and has an area of 2933 acres.

It would seem that Stockton (Stotkton) grew up round the castle of the bishops of Durham, to whom the town belonged even before their purchase of the earldom of Sadberge. In 1183 the Boldon Book records that the whole town rendered one milch cow and the ferry twenty pence to the bishop. The castle was probably built between 1183 and 1214. King John visited Bishop Philip of Poitou (d. 1208) there and is said to have granted the place a charter similar to that of Hartlepool in 1214. Of this, however, no traces remain, the rights of the borough, which must have come into existence during the 13th century, being purely prescriptive. Stockton was divided into two parts: the "town," governed by the bailiff of the bishop and afterwards by the vicar and vestrymen, and the borough and siding men. The bishop's bailiff was also the keeper of the castle, though in the 17th century the office belonged to the borough-bailiff. The borough is first mentioned in 1283, when the king took tollage from it during the vacancy of the see. It occurs again in a record of 1328, and in 1344 the mayor and bailiffs entered into an agreement with the mayor and bailiffs of Newcasle for the regulation of trade between the two places. Bishop Hatfield's survey (1377-1382) gives a list of tenants within the borough: 22 burgages and 15 half-burgages are mentioned, the rent of which varies from twenty-two pence to a penny halfpenny. In 1444 the parliamentary troops besieged and burnt the castle, which was dismantled in 1652. In 1666 the population was only 544, for Stockton was an isolated place with little trade. It became a parliamentary borough, returning one member, in 1687. In 1310 the bishop gave the town a market and a fair during the octave of the translation of St Thomas the Martyr, reserving to himself the tolls; Bishop Horton revived the market, which had lapsed at the beginning of the 17th century. Camden speaks of Stockton as a neat, well-built corporation town and especially commends the ale brewed there and sent to various parts of the country. The importance of Stockton as a port dates from the end of the 18th century, when there was a considerable trade in lead, dairy produce and timber.

STODDARD, RICHARD HENRY (1825-1903), American author, was born in Hingham, Massachusetts, on the 2nd of July 1825. He spent most of his boyhood in New York City, where he became a blacksmith and later an iron moulder, but in 1849 he gave up his trade and began to write for a living. He contributed to the Union Magazine, the Knickerbocker Magazine, Painim's Monthly Magazine and the New York Evening Post. In 1853 Nathaniel Hawthorne helped him to secure the appointment of inspector of customs of the Port of New York. He was confidential clerk to George B. McClellan in the New York dock department in 1870-1872, and city librarian of New York in 1874-1875; literary reviewer for the New York World (1860-1870); one of the editors of Vanity Fair; editor of the Aldine (1860-1874), and literary editor of the Mail and Express (1880-1903). He died in New York on the 12th of May 1903. Among the numerous books that he published were: "The Life and Adventures of the Poet" (1886); Melodies and Madrigals, Mostly from the old English Poets (1865); The Late English Poets (1865), selections; Griswold's Poets and Poetry of America (1872), and Female Poets of America (1874); The Bric-a-brac Brac, in 10 vols. (1874-1876); English Verse, in 5 vols. edited with W. J. Linton (1883); and four editions of Poe's works, with a memoir (1872-1894). His original poetry includes Footprints (1849), privately printed and afterwards suppressed; Poems (1852); the juveniles, Adventures in Fairyland (1853); Town and Country (1857), and The Story of Little Red Riding Hood (1864); Songs of Summer (1857); The King's Bid (1862), one of his most popular narrative poems; Abraham Lincoln: A Horatian Ode (1863), The Book of the East (1867), Poems (1888), a collective edition; and The Lion's Cub, with Other Verse (1890). He also wrote Life, Travels and Books of Alexander von Humboldt (1866); Under the Evening Lamp (1893), essays dealing mainly with the modern English poets; and Recollections Personal and Literary (1903), edited by Ripley Hitchcock. More important than his critical was his poetical work, which at its best is sincere, original and marked by delicate fancy, and felicity of form; and his songs have given him a high and permanent place among American lyric poets.

His wife ELIZABETH DREW (Barstow) Stoddard (1825-1902), poet and novelist, was born in Mattapoisett, Massachusetts, on the 6th of May 1823. She studied at Wheaton Seminary, Norton, Mass. After her marriage in 1852 she assisted her husband in his literary work, and contributed stories, poems and essays to the periodicals. She wrote three novels—The Margesons (1862), Two Men (1865) and Temple House (1867), and a volume of poems (1895). A new edition of her novels was issued in 1901. She died in New York on the 1st of August 1902.

STOICHIOMETRY

Gr. στόιχεια, fundamental parts, or elements, μέτρων, measure), in chemistry, a term introduced by
Benjamin Richter to denote the determination of the relative amounts in which acids and bases neutralize one another; but this definition may be extended to include the determination of the masses participating in any chemical reaction. The work of Richter and others who explored this field is treated under Element; here we discuss a particular branch of the subject, viz. the determination of equivalent and atomic weights of elements, and the molecular weights of elements and compounds. Reference to Chemistry, Atom and Element will explain the principles involved. Every element has an “equivalent weight” which can be expressed in terms of the weight of a compound which combines with or replaces unit weight of hydrogen; the “atomic weight” may be regarded as the smallest weight of an element which can be present in a chemical compound, and the “molecular weight” is the weight of the least part of an element or compound which can exist alone. The atomic weight is therefore some multiple of the equivalent weight, and the determining factor is termed the valency (q.v.) of the element.

We have mentioned hydrogen as our standard element, which was originally chosen as being the lightest known substance; but Berzelius, who first performed certain experiments which pointed out that few elements formed stable compounds with hydrogen, and even these presented difficulties to exact analysis, proposed to take oxygen as the standard. This suggestion has been adopted by the International Committee of Atomic Weights, who take the atomic weight of oxygen as 16.000, hydrogen being 1.008.\(^1\)

Deferring the discussion of gaseous elements and compounds we will consider the modus operandi of determining, first, the equivalent weight of an element which forms solid compounds, and, secondly, its atomic weight. Suppose we can cause our element to combine with oxygen to form a definite compound, which can be accurately weighed or, conversely, decompose a known weight of the oxide into its constituents, of which the element can be weighed, then the equivalent weight of the element may be exactly determined.

For if \(x\) grams of the element yield \(y\) grams of the oxide, and if \(W\) be the equivalent of the element, we have \(x\) grams of the element equivalent to \(y-x\) grams of oxygen, and hence the equivalent weight \(W\), which corresponds to 8 grams of oxygen, is given by the proportion \(y-x \cdot x = 8 \cdot W\), i.e., \(W = 8y/(y-x)\). For example, L. L. Stokes found that silver forms silver oxide, \(Ag_2O\), by the interaction of silver and sulphur and hydrogen; these ratios on combination gave the third ratio \(Ag_2O\): these experiments besides giving values for \(Ag_2O\), yielded also the atomic weight of silver, which, however, was not considered accurate enough to be useful in scientific work, but it is sufficient to say that the general routine which he employed has been adopted in all chemical determinations of equivalent weights.

The derivation of the atomic weight from the equivalent weight may be effected in several ways. The simplest are perhaps by means of Dulong and Petit’s law of atomic heats (and by Stas’s law) and by the atomic weight of hydrogen. There is, however, a separate consideration involved, i.e., the doctrine of isomorphism. Dulong and Petit’s law may be stated in the form that the product of the specific heat and atomic weight is approximately 6.4, or that an approximate value of the atomic weight is 6.4 divided by the specific heat. This application may be illustrated in the case of mercury. We have seen above that the red oxide yields a value of about 95 for the equivalent; but a green oxide is known which contains twice as much metal for each part of oxygen, and therefore in this compound the equivalent is about 100. The specific heat of mercury, however, is 0.953, and this number divided into the green oxide value gives an approximate atomic weight of 104. More accurate analyses show that mercury has an equivalent of 100 in the red oxide and 200 in the green; Dulong and Petit’s law shows us that the atomic weight is 200, and that the element is divalent in the red oxide and monovalent in the green. For exceptions to this law see Chemistry: Physical.

The application of isomorphism follows from the fact that chemically similar substances crystallize in practically identical forms, and, more important, form mixed crystals. If two salts yield mixed crystals it may be assumed that they are similarly combined. The atomic weight of a mixed crystal may be determined by converting the substance into a single oxide. General chemical resemblances yield valuable information in fixing the atomic weight after the equivalent weight has been exactly determined.

Gases.—The generalization due to Avogadro—that equal volumes of gases under the same conditions of temperature and pressure contain equal numbers of molecules—may be stated in the form that the densities of gases are proportional to their molecular weights. It therefore follows that a comparison of the density of any gas with that of hydrogen gives the ratio of the molecular weights of the two gases, and if the molecular contents of the gases be known then the atomic weight is determinable. Gas reactions are available in many cases for solving the question whether a molecule is monatomic, diatomic, &c. Thus from the combination of equal volumes of hydrogen and chlorine to form twice the volume of hydrochloric acid, it may

---

1 We may here state that the equivalent weight of oxygen on this basis is 8.000, i.e. one half of its atomic weight. This matter is considered below.

2 The formulae used in the following paragraph were established before Stas began his work; and as oxygen is taken as 16, the results are atomic and not equivalent weights.

3 To 30, and hence if \(z\) grams of chloride bears \(y\) grams of chloride, then the ratio \(KCl:O\) is \(y/(x-y)\). Taking \(O\) as 16 and the experimental value of \(x\) and \(y\), Stas obtained \(KCI:O=74.9502\). To obtain the ratio of AgCl to KC1, known weight of silver monatomic, it can be written as AgNO\(_3\)+KCI=AgCl+KNO\(_3\) which shows that one Ag is equivalent to one KCl. The value found was AgKCI=1477.16. The ratio Ag:O is found by combining these values, for Ag:O=KCI:OXAg:KCI=74.9502 x1.477.16=107.9401. In the second series of experiments \(KCI\) and AgKCIAg were obtained the first by decomposing the chlorides, the second by synthesizing the chloride by burning a known weight of the metal in chlorine gas and weighing the resulting chloride, and the third by dissolving the metal in nitric acid and precipitating it with hydrochloric acid and ammonium chloride. These two sets yield the ratio Ag:O, and also the ratio Cl:O, which, combined with the ratio KCl:O obtained in the first series, gave the atomic weight of potassium.

4 The third and fourth series resembled the second, only the bromate and iodide, and iodate and iodide were worked with. The experiments gave additional values for AgNO\(_3\) and also the atomic weights of bromine and iodine.

5 The fifth series was concerned with the ratios \(AgNO_3\): Ag: Ag\(_2\)O: Ag and Ag\(_2\):O. The first was obtained by reducing silver sulphate to the metal by hydrogen at high temperatures; Ag gives an approximate atomic weight of 104. Sulfur compounds of silver were formed by the interaction of silver and sulphurated hydrogen; these ratios on combination gave the third ratio Ag\(_2\):O: These experiments besides giving values for Ag\(_2\):O, yielded also the atomic weight of Ag, i.e., 107.9401, the value previously obtained by the red oxide method. There is, however, a separate consideration involved, i.e., the doctrine of isomorphism. Dulong and Petit’s law may be stated in the form that the product of the specific heat and atomic weight is approximately 6.4, or that an approximate value of the atomic weight is 6.4 divided by the specific heat. This application may be illustrated in the case of mercury. We have seen above that the red oxide yields a value of about 95 for the equivalent; but a green oxide is known which contains twice as much metal for each part of oxygen, and therefore in this compound the equivalent is about 100. The specific heat of mercury, however, is 0.953, and this number divided into the green oxide value gives an approximate atomic weight of 104. More accurate analyses show that mercury has an equivalent of 100 in the red oxide and 200 in the green; Dulong and Petit’s law shows us that the atomic weight is 200, and that the element is divalent in the red oxide and monovalent in the green. For exceptions to this law see Chemistry: Physical.

6 The application of isomorphism follows from the fact that chemically similar substances crystallize in practically identical forms, and, more important, form mixed crystals. If two salts yield mixed crystals it may be assumed that they are similarly combined. The atomic weight of a mixed crystal may be determined by converting the substance into a single oxide. General chemical resemblances yield valuable information in fixing the atomic weight after the equivalent weight has been exactly determined.

Gases.—The generalization due to Avogadro—that equal volumes of gases under the same conditions of temperature and pressure contain equal numbers of molecules—may be stated in the form that the densities of gases are proportional to their molecular weights. It therefore follows that a comparison of the density of any gas with that of hydrogen gives the ratio of the molecular weights of the two gases, and if the molecular contents of the gases be known then the atomic weight is determinable. Gas reactions are available in many cases for solving the question whether a molecule is monatomic, diatomic, &c. Thus from the combination of equal volumes of hydrogen and chlorine to form twice the volume of hydrochloric acid, it may
be deduced that the molecule of hydrogen and of chlorine contains two atoms (see Atoms); and similar considerations show that oxygen, nitrogen, fluorine, &c., are also diatomic. Physical methods may also be employed. For instance, in monatomic gases the ratio of the specific heat at constant pressure to the specific heat at constant volume is 1.6; in diatomic gases 1.42; with other values for more complex molecules (see Molecule). This ratio may be determined directly by finding the velocity of sound in the gas (Kundt) or by other methods, or indirectly by finding the specific heats separately and then taking the ratio. It is found that the gases just mentioned are diatomic, whereas argon, helium, neon and the related gases, and also mercury and some other metals when in the gaseous condition, are monatomic. A knowledge of the atomicity of a gas combined with its density (compared with oxygen and hydrogen) would therefore give its atomic weight if Avogadro's law were rigorously true. But this is not so, except under extremely low pressures, and it is necessary to correct the observed densities. The correction involves a detailed study of the behaviour of the gas over a large range of pressure (presuming the densities are already corrected to 0°), and may be conveniently written in the form \[ \rho = \frac{1}{\varepsilon d(p)} \] Thus if \( D \) be the observed relative densities of a gas to hydrogen at 0° and under normal atmospheric pressure, \( \varepsilon \) and \( \alpha \) the coefficients of the gas and hydrogen, then the true density, or ratio of molecular weights, is \( \frac{\alpha}{\varepsilon} (1 + \alpha) \). Lord Rayleigh and D. Berthelot have corrected several molecular weights in this fashion. The importance is well shown in the modification of Morley's observed density of oxygen viz. 15.924, which, with Rayleigh's values of \( \alpha = -0.00004 \) and \( \varepsilon = 1.00053 \), gives the corrected density as 15.88. And this is the atomic weight, for both hydrogen and oxygen molecules contain two atoms. Compound gases can also be experimented with. For example Gray (Journ. Chem. Soc., 1905, 87, p. 1601) found that it was easier to prepare perfectly pure nitric oxide than to obtain pure nitrogen, and he therefore determined the density of this gas from which the atomic weight of 14.012, or, corrected for deviations from Avogadro's law, 14.006, was deduced.

The principle indicated here is applicable to the determination of the molecular weight of any vaporizable substance by the so-called method of vapour-density (see Densitry).

Solutes.—The theory of solution permits the investigation of the molecular weights of substances which dissolve in water or some other solvent. It is shown in Solution that a solute lowers the freezing point and raises the boiling point of the solvent in a regular manner as long as dilute solutions are dealt with. It has been shown that if one gram molecule of a solute be dissolved in 100 grams of solvent then the boiling point is raised by \( 0.02 \, T/\lambda \), (say D) degrees, where \( T \) is the absolute boiling point and \( \lambda \) the latent heat of vaporization of the solvent; this constant is known as the molecular rise of the boiling point, and varies from solvent to solvent. If we dissolve say \( m \) grams of a substance of molecular weight \( M \) in 100 grams of the solvent and observe the elevation in the boiling point of the mixture, then it is given by \( M = mD/\lambda \). Similar considerations apply to the freezing points of solutions. In this case \( D = 0.02 \, T/\lambda \), where \( T \) is the absolute freezing point of the pure solvent and \( \lambda \) the latent heat of solidification. To apply these principles it is only necessary therefore to determine the freezing (or boiling) point of the solution (of which a known weight is taken), add a known weight of the solute, allow it to dissolve and then notice the fall (or rise) in the freezing (or boiling point), from which weights, if the molecular depression (or elevation) be known, the molecular weight of the dissolved substance is readily calculated.

The following are the molecular depressions and elevations (with the freezing and boiling points in brackets) of the common solvents.

Molecular depressions: aniline (6°), 58.7; benzene (5.4°), 50-0; acetic acid (17°c), 30-0; nitrobenzene (5-3°), 70-0; phenol (40°), 73; water (c°), 18.5.

Molecular elevations: acetic acid (118-4°), 25.3; acetone (56°), 17 1; alcohol (58°), 11.7; ether (35°), 21.7; benzene (79°), 26.7; chloroform (61°), 35.9; pyridine (115°), 29.5; water (100°), 5.1.

The apparatus used in cryoscopic measurements is usually devised by Beckmann (Zent. phys. Chem. ii, 307). The working part consists of a tube 2-3 cms. in diameter, bearing a side tube near the top; the tube is fitted with a cork through which pass a different thermometer of a range of about \( 0^\circ \) and graduated in \( 0^\circ \) or 100ths, and also a stout platinum wire to serve as a stirrer. The lower part of the tube is enclosed in a wider tube to serve as an air tight cover for the solution; this outer tube is so placed that the thermometer is adjusted so that the freezing point of the pure solvent comes near the top of the scale. A weighed quantity of the solute is placed in the inner tube, and the beaker is filled with a freezing mixture at a temperature a few degrees below the freezing point of the solvent. The thermometer is inserted and both solvent and freezing mixture are stirred. When the temperature is about \( 0^\circ \) below the correct freezing point the tube is removed from the diatherm, and the stirring continued. There ensues a further fall in the thermometer's reading until ice separates, whereupon the temperature rises to the correct freezing point. The ice is then removed, and the operation repeated so as to obtain a mean value. A known weight of the substance is introduced through the side tube, and the freezing point determined as with the pure solvent. The difference of the readings gives the depression; and from this the molecular weight of the solute is obtained. As for the molecular depression, the molecular weight can be calculated from the formula given above.

In the boiling point apparatus of Beckmann the solvent is contained in a tube fitted with side tube to which spiral condensers can be attached; the neck of the tube carries a stopper through which passes a delicate differential thermometer, whilst the bottom is perforated by a small cork and container of glass beads, garnets, etc., which, when heated, the boiling point is reached. The temperature having been read, the apparatus is allowed to cool slightly, and the observation repeated. A known weight of the substance is now introduced, and the solution so obtained treated in the same fashion as the original solvent.

A different procedure wherein in the boiling tube is heated, not directly by a spirit lamp, but by a current of hot air or steam, as proposed by Sakurai (Journ. Chem. Soc., 1892, 61, p. 994). Sakurai's apparatus has been considerably modified, and the form now principally used is essentially due to Landsberger (Ber., 1898, 31, p. 401). The glass vessel is made of lead free glass, and the thermometer is connected by a rubber tube, which is connected with the measuring tube. This consists of a graduated tube fitted with a stopper through which passes a thermometer and an inlet tube, and with the bottom there is a second stopper, which is surrounded by an outer tube which has an exit to a condenser at the side or bottom, communication being made between the measuring tube and jacket by a small hole near the top of the former. In outline the operation consists in placing some solvent in the measuring tube and passing in vapour until the condensed liquid falls at the rate of one drop per second or two seconds. The temperature is then read off. A known weight of the substance is introduced and the boiling point determined as before; but immediately the temperature is read the tube must be disconnected, so that no more vapour passes over and so alters the concentration of the solution. Two methods may be used for obtaining the quality of the solvent. Landsberger weighed the tube; Walker and Lumsden (Journ. Chem. Soc., 1898, 73, p. 502) graduated the tube and thus measured the volume of the solvent; and W. E. S. Turner's apparatus (Journ. Chem. Soc., 1910, 97, p. 1184) both the weight and volume can be determined. Whilst the calculations in both the Beckmann and Sakurai-Landsberger methods are essentially the same the "molecular elevations," differ according to the manner in which the solute is introduced, and in the methods it is necessary to carefully choose the solute in order to avoid dissociation or association. For example, most salts are dissociated in aqueous solution; and acids are bi-molecular in benzene but monomolecular in acetone.

Other methods are available for dissolved substances such as the measurements of the osmotic pressure, lowering of the vapour pressure, etc. Other methods of the same kind are available. Mention may also be made of Ramsay and Shield's method of finding the molecular weights of liquids from surface tension measurements. (See Chemistry: Physical.)
STOICS, a school of philosophers founded at the close of the 4th century B.C. by Zeno of Citium, and so called from the Stoa or painted corridor (στάδον παυνογλα) on the north side of the market-place at Athens, which, after its restoration by Cleon, the celebrated painter Polygnotus had adorned with frescoes representing scenes from the Trojan War. But, though it around on Hellenic soil, from lectures delivered in public place at Athens, the school is scarcely to be considered; a product of purely Greek intellect, but rather as the firstfruits of that interaction between West and East which followed the conquests of Alexander. Hardy a single Stoic of eminence was a citizen of any city in the heart of Greece, unless we make Aristotle of Chios, Cleanthes of Assos and Panaelus of Rhodes exceptions. Such lands as Cyprus, Cilicia and Syria, such cities as Citium, Soli, Hecalea in Pontus, Sidon, Carthage, Seleucia on the Tigris, Apamea by the Orontes, furnished the school with its scholars and presidents; Taras, Hyparchus and Alexander became name as its university towns. As the first founder was of Phoenician descent, so he drew most of his adherents from the countries which were the seat of Hellenistic (as distinct from Hellenic) civilization; nor did Stoicism achieve its crowning triumph until it was brought to Rome, where the grave earnestness of the national character could appreciate its doctrine, and where for two centuries or more it was the creed, if not the philosophy, of all the best of the Romans. Properly therefore it stands in marked antithesis to that fairest growth of old Hellas, the Academy, which saw the Stoa rise and fall—the one the typical school of Greek intellect, the other of the Hellenized East, and, under the early Roman Empire, of the whole civilized world. The transcendent genius of its author, the vitality and romantic fortunes of his doctrine, claim our warmest sympathies for Platonism. But it should not be forgotten that for more than four centuries the tide ran all the other way. It was Stoicism, not Platonism, that filled men's imaginations and exerted the wider and more active influence upon the ancient world at some of the busiest and most important times in all history. And this was chiefly because before all things it was a practical philosophy, a rallying point for those who longed for noble spirits contending against odds. Nevertheless, in some departments of theory, too, and notably in ethics and jurisprudence, Stoicism has dominated the thought of after ages to a degree not easy to exaggerate.

The history of the Stoic school may conveniently be divided in the usual threefold manner: the old Stoa, the middle or transition period (Diogenes of Seleucia, Boethus of Sidon, Panaelus, Posidonius), and the later Stoicism of Roman times. By the old Stoa is meant the period (c. 304–205 B.C.) down to the death of Chrysippus, the second founder; then was laid the foundation of those views to which hardly anything of importance was afterwards added. Confined almost to Athens, the school made its way slowly among many rivals. Aristotle of Chios and Herilus of Carthage, Zeno's heterodox pupils, Persaeus, his favourite disciple and housemate, the poet Aratus, and Sphaerus, the adviser of the Spartan king Cleomenes, are noteworthy minor names; but the chief interest centres about Zeno, Cleantnes, Chrysippus, who in succession built up the wondrous system. What originality it had—at first sight it would seem not much—belongs to these thinkers; but the loss of all their works except the work of Chrysippus, and the impossibility for us of formulating such a system of practical philosophy as can be gleaned from unintelligent witnesses, for the most part of many centuries later, have rendered it a peculiarly difficult task to distinguish with certainty the work of each of the three. The common standpoint, the relation to contemporary or earlier systems, with all that goes to make up the character and spirit of Stoicism, can, fortunately, be more certainly established, and may with reason be attributed to the founder.

Zeno's residence at Athens fell at a time when the great movement which Socrates originated had spent itself in the second generation of his spiritual descendants. Zeno, Neither Theophrastus at the Lyceum, nor Xenocrates and Polemo at the Academy, nor Stilpo, who was drawing crowds to hear him at Megara, could be said to have inherited much of the great reformer's intellectual vigour, to say nothing of his moral earnestness. Zeno visited all the schools in turn, but seems to have attached himself definitely to the Cynics; as a Cynic he composed at least one of his more important works, the much admired Republic, which we know to have been later on stimulated blood to the school. In the Cynic school he found the practical spirit which he desired to be the great need of that stirring troublous age. For a while his motto must have been "back to Socrates," or at least "back to Antisthenes." The Stoics always counted themselves amongst the Socratic schools, and canonized Antisthenes and Diogenes; while reverence for Socrates was the tie which united to them such an accomplished writer upon lighter ethical topics as the variété Persaeus, who, at the capital of Antigonus Gonatas, with hardly anything of the professional philosopher in him, reminded us of Xenophon, or even Prodicus. Zeno commended, then, as a Cynic; and in the developed system we can point to a kernel of Cynic doctrine to which various philosophers of other thinkers (more especially Heraclitus and Aristotle, but also Diogenes of Apollonia, the Pythagoreans, and the medical school of Hippocrates in a lesser degree) were added. Thus, quite apart from the general similarity of their ethical doctrine, the Cynics were materialists; they were also nominalists, and combated the Platonic ideas; in their theory of knowledge they made use of the reminiscence of Parmenides, which was also one of their leading ethical conceptions. In all these particulars Zeno followed them, and the last of the more important, because Chrysippus having adopted a new criterion of truth—a clear and distinct perception of sense—it is only from casual notices we learn that the elder Stoics had approximated to Cynicism in making right reason the standard. At the same time, it is certain that the main outlines of the characteristic physical doctrine, which is after all the foundation of their ethics and logic, were the work of Zeno. The Logos, which had been an ethical or psychological principle to the Cynics, received at hands an extension throughout the natural world, in which Heracleitus's Demokrates is unmistakable of. Reading the Ephesian doctrine with the eyes of a Cynic and the Cynic ethics in the light of Heracliteanism, he came to formulate his distinctive theory of the universe far in advance of either. In taking this immense stride and identifying the Cynic "reason," which is a law for man, with the "reason" which is the law of the universe, Zeno has been compared with Plato, who similarly extended the Socratic "general notion" from the region of morals—of justice, temperance, virtue—to embrace all objects of all thought, the verity of all things that are.

If the recognition of physics and logic as two studies co-operating with each other to form a greater whole that the mature Zeno from the Cynic author of the Republic, no less than from his own heterodox disciple Aristo, the elaboration on all sides of Stoic natural philosophy belongs to Cleantnes, who certainly was not the merely docile and receptive intelligence he is sometimes represented as being. He carried on and completed the assimilation of Heraclitean doctrine; but his own contributions were more distinctive and original than those of any other Stoic. Zeno's seeming dualism of God (or force) and formless matter he was able to transform into the lofty pantheism which breathes in every line of the famous hymn to Zeus. Heracliteus had indeed declared all to be in flux, but we ask in vain what is the cause for the unceasing process of his ever-living fire. It was left for Cleantnes to discover this motive cause in a conception familiar to Zeno, as to the Cynics before him, but restricted to the region of ethics—the conception of tension or effort. The soul of the sage, thought the Cynics, should be strained and braced for judgment and action; his first need is firmness (εθροδη) and Socratic strength. But the mind is a corporeal thing. Then followed the flash of genius: this varying tension of the one substance everywhere present, a purely physical fact, accounts for the diverse destinies of all innumerable particular things; it is the veritable cause of the flux and process of the universe.
Herein lies the entire system of the Stoics, as Cleanthe's epoch-making discovery continually received fresh applications to physics, ethics and epistemology. Other of his innovations, the outcome of his crude materialism, found less favour with his successor, who decided to follow him in denominating the primary substance with fire, or in tracing all vitality to its ultimate source in the sun, the "ruling power" of the world—a curious anticipation of scientific truth. Yet under this poetic Heraclitean mystic the school was far from flourishing. The eminent teachers of the time are said to have been Aristo, Zeno's heterodox pupil, and Arcesilas, who in Plato's name brought Megarian subtleties and Pyrrhonian agnosticism to bear upon the intruding doctrine; and after a vigorous upgrowth it seemed not unlikely to die out. From all danger of such a fate it was rescued by its third great teacher, Chrysippus; "but for Chrysippus there had been no Psychology." Chrysippus had caught the practical spirit of his age—the desire for a popular philosophy to meet individual needs. But there was another tendency in post-Aristotelian thought—to lean upon authority and substitute learning for independent research—which grew stronger just in proportion as the fresh interest in the problems of the universe and the zeal for discovery declined—a shadow, we may call it, of the coming Scholasticism thrown a thousand years in advance. The representative of this tendency, Chrysippus, addressed himself to the ceaseless task of systematizing the doctrines bequeathed to him, and, above all, securing them in their stereotyped and final form, not simply from the assaults of the past, but, as after a long and successful career of controversy and polemical authorship he fondly hoped, from all possible attack in the future. To his personal characteristics can be traced the hair-splitting and formal pedantry which ever afterwards marked the activity of the school, the dry repellent technical procedure of the Dialecticians par excellence, as they were called. He created their formal logic and contributed much that was of value to the psychology and epistemology; but in the main his work was to new-label and new-arrange in every department, and to lavish most care and attention on the least important parts—the logical terminology and the refutation of fallacies, or, as his opponents declared, the exorcization of fallacies which even he could not refute. In his Republic Zeno had gone so far as to declare the routine education of the day (e.g. mathematics, grammar, &c.) to be of no use. Such Cynic crudity Chrysippus rightly judged to be out of keeping with the requirements of a great dogmatic school, and he laboured on all sides after thorough, deliberate and scientific completeness. In short, Chrysippus made the Stoic system what it was, and as he left it we proceed to describe it.

And first we will inquire, What is philosophy? No idle gratification of curiosity, as Aristotle fabled of his life intellectual (which would be but a disguise for refined pleasure), no theory divorced from practice, no pursuit of science for its own sake, but knowledge so far forth as it can be realized in virtuous action, the learning of virtue by exercise and effort and training. So absolutely is the "rare and priceless wisdom" for which we strive identical with virtue itself that the three main divisions of philosophy current at the time and accepted by Zeno—logic, physics and ethics—are defined as the most generic or comprehensive virtues. How otherwise could they claim our attention? According Aristo, holding to Cynicism when Zeno himself had got beyond it, rejected two of these parts of philosophy as useless and out of reach—a divergence which excluded him from the school, but strictly consistent with his view that ethics alone is scientific knowledge. Of the three divisions logic is the least important; ethics is the outcome of the whole, and historically the all-important vital element; but the foundations of the whole system are best discerned in the nature, which deals pre-eminently with the macrocosm and the microcosm, the universe and man, including natural theology and an anthropology or psychology, the latter forming the direct introduction to ethics.

The Stoic system is in brief: (a) materialism, (b) dynamic materialism, lastly (c) monism or pantheism. (a) The first of these characters is described by anticipation in Plato's _Sophist_ (446 C seqq.), where, arguing with those who "who drag everything down to the corporeal" (σῶμα), the Eleatic stranger would fain prove to them the existence of something incorporeal, as follows. "They admit the existence of an animate body. Is soul then something existent (οὐσία)? Yes. And the qualities of soul, as justice and wisdom—are they visible and tangible? No. Do they then exist? They are in a dilemma." Now, however effective against Plato's contemporary Cynics or Atomists, the reasoning is thrown away upon the Stoics, who take boldly the one horn of this dilemma. That qualities of body a (and those which passed from corporeal soul) exist they do not deny; but they assert most uncompromisingly that they are one and all (wisdom, justice, &c.) corporeal. And they strengthen their position by taking Plato's own definition (247 D), namely "being is that which has the power to act or be acted upon," and turning it against him. For this is only true of Body; action, except by contact, is inconceivable; and they reduce every form of causation to the efficient cause, which implies the communication of motion from one body to another. Again and again, therefore, only Body exists. The most real realities to Plato and Aristotle had been thought and the objects of thought, ρύς and ἐργα, whether abstracted from sensibles or inherent in "matter," as the inconceivable basis of all concrete existence. But this was too great an effort to last long. Such spiritualistic theories were nowhere really maintained after Aristotle and outside the circle of his immediate followers. The reaction came and left nothing of it all; for five centuries the dominant tone of the older and the newer schools alike was frankly materialistic. "If," says Aristotle, "there is no other substance but the organic substances of nature, physics is the highest branch of the sciences," and the science of thought, λογικη and νοητικη, whether abstracted from sensibles or inherent in "matter," as the inconceivable basis of all concrete existence. The analogues therefore of metaphysical problems must be sought in physics; particularly that problem of the causes of things for which the Platonic idea and the Peripatetic "constitutive form" had been, each in its turn, received solutions. (b) Tension. But the doctrine that all existence is confined within the limits of the sensible universe—that there is no being save corporeal being or body—does not suffice to characterize the Stoic system; it is no less a doctrine of the Epicureans. It is the idea of tension or toxicity as the essential attribute of body, in contradistinction to passive inert matter, which is distinguished as spirit. The Epicureans leave unexplained the primary constitution and first movements of their atoms or elemental solids; chance or destiny may account for them. Now, to the Stoics nothing passes unexplained; there is a reason (νόημα) for everything in nature. Everything which exists is at once capable of acting and being acted upon. In everything that exists, therefore, even the smallest particle, there are these two principles. By virtue of the passive principle the thing is susceptible of motion and modification; it is matter which determines substance (οὐσία). The active principle _makes_ the matter a given determinate thing, characterizing and qualifying it, whence it is termed quality (προυπηρη). For all that is or happens there is an immediate cause or antecedent; and as "cause" means "cause of motion," and only body can act upon body, it follows that this antecedent cause is itself truly corporeal as the matter upon which it acts. Thus we are led to regard the active principle "force" as everywhere co-extensive with "matter," as pervading and permeating it, and together with it occupying and filling space. This is that famous doctrine of universal pervasion (σαρκον καὶ δαίμονα), by which the axioms that two bodies cannot occupy the same space are derived. Thus that harmony of separate doctrines which contributes to the impressive simplicity of the Stoic physics is only attained at the cost of offending healthy common
sense, for Body itself is robbed of a characteristic attribute. A thing is no longer, as Plato once thought, hot or hard or bright by partaking in abstract heat or hardness or brightness, but by containing within its own substance the material of these qualities, concurred as air-currents in various degrees of tension. We hear, too, of corporeal days and years, corporeal virtues, and actions (like walking) which are bodies (δώματα). Obviously, again, the Stoic quality corresponds to Aristotle's essential form; in both systems the active principle, "the cause of all that matter becomes," is a medium for discerning for the existence of a given concrete thing (Λέγων τις ωσίας). Only, instead of assuming something immaterial (and therefore un-verifyable), we fall back upon a current of air or gas (στρεμμα); the essential reason of the thing is itself material, standing to it in the relation of a gaseous to a solid body. Here, too, the reason of things—that which accounts for them—is no longer some external end to which they are tending; it is something acting within them, "a spirit deeply interwoven," germinating and developing as from a seed in the heart of each separate thing that exists (Λέγων σύστεραμάνος). By its prompting the thing grows, to Apollonia, to a legacy from the 'dualist' doctrines. For the element of quality in the thing, remains constant through all its changes. (c) What then, we ask, is the relation between the active and the passive principles? Is there, or is there not, an essential distinction between substance or matter and pervading force or cause or quality? Here the Stoics show signs of a development of doctrine. Zeno began, perhaps, by adopting the formulas of the Peripatetics, though no doubt with a conscious difference, postulating that form was always attached to matter, no less than matter, as is known to us, is everywhere shaped or informed. Whether he ever overcame the dualism—which the sources, such as they are, unanimously ascribe to him is not clearly ascertained. It seems probable that he did not. But we can answer authoritatively that to Cleantus and Chrysippus, if not to Zeno, there was no real difference between matter and its cause, which is always a corporeal current, and therefore matter, although the finest and subllest matter. In fact they have reached the final result of unveiled hylozoism, from which the distinction of the active and passive principles is discerned to be a merely formal concession, and the Stoic air-current is retained as the universal animating principle within and upon which all things depend. The technical term Form (δῶς) they never use, but always Reason or God. This was not the first time that approaches had been made to such a doctrine, and Diogenes of Apollonia in particular was led to oppose Anaxagoras, who distinguished Nous or Thought from every other agent within the cosmos which is its work by postulating as his first principle something which should be at once physical substratum and thinking being. But until dualism had been thought out, as in the Peripatetic school, it was impossible that monism (or at any rate materialistic monism) should be definitely and consciously maintained. One thing is certain: the Stoics provided no loophole of escape by entrenching upon the "purely material" nature of matter; they laid down with rigid accuracy its two chief properties—extension in three dimensions, and resistance, both being traced back to force. There were, it is true, 'certain inconsistent conceptions, of thought to which nothing real and external corresponded, namely, time, space, void, and the idea expressed in language (διακετω). But this inconsistency was covered by another: though each of these might be said to be something, they could not be said to exist.

The distinction of force and matter is then something transitory and relative to itself as far as the identity of the two elements of the Stoics, for they too, like earlier philosophers, have their "fairy tales of science." Before there was heaven or earth, there was primitive substance or Pneuma, the everlasting presupposition of particular things. This is the totality of all existence; out of it the whole visible universe proceeds, hereafter to be again resolved into it. Not the less is it the creation of a process, which distinguishes this universe from the hierarchical order or cosmos. To the question, What is God? Stoicism replies, What is God not? In this original state of Pneuma God and the world are absolutely identical. But even then tension, the essential attribute of matter, is at work. Though the force working everywhere is one, there are diversities of its operation, corresponding to various degrees of tension. In this primitive Pneuma there must have been a sort of resistance, or at least an effect which makes single bodies expand when heated, whence we infer that there is a pressure in heat, an expansive and dispersive tendency. The Pneuma cannot long withstand this intense pressure. Motion is then realized, and forward and backward, upward and downward, in fiery vapour and to weaken the tension. Hereupon follows the first differentiation of primitive substance—the separation of force from matter, the emanation of the air, and the creation of the germinal world of things (σύστεραμάνος λέγων), which, in virtue of its tension, slumbered in Pneuma, now proceed upon their creative task. The primitive substance, be it remembered, is not Heraclitus' fire which consumes and is consumed, but the air of all the ethereal substances and the fiery principle. It is the air or "breath" of Anaximenes or Diogenes of Apollonia. Chrysippus determined it, following Zeno, to be fiery breath or ether, a spiritualized sublimated intermediate element. The cycle of generations and transformation of matter is a compensation of the life of the universe, the mode of existence proper to finite and particular being. For the universe and all its parts are only different embodiments and stages in the metamorphosis of primi-
tive being which Heraclus had called a progress up and down (ἀφθινον ἀναζωον). Out of it is separated, first, elemental fire, the fire which we know, which burns and destroys; and this, again, condenses this primitive vapour, and the air once more, though not wholly, pervades the elements. Thus we have that principle of unceasing circulation which never diminished is the ether in the highest sphere of the visible heavens, encircling the world of which it is lord and head. From the elements the one substance is transformed into the multitude of individual things in the orderliness which is the sketch of the cosmos, and the Pneuma pervading it, and conditioning life and growth everywhere, is its soul. But this process of differentiation is not eternal; it continues only until the times of the restoration of Pneuma, for the world has grown up in turn and decay. The tension which has been relaxed will again be tightened; there will be a gradual resolution of things into elements, and of elements into the primary substance. The primary substance is divine and geometric; once more Pneuma will be the world to be assimilated to God. Then in due order a new cycle of development begins, reproducing the last in every minutest detail, and so on for ever.

The doctrine of Pneuma, vital breath or 'spirit,' arose in the medical schools. The simplest reflection on pangs and half

civilized men connects vitality with the air inhaled in 
Pneuma, respiration; the disciples of Hippocrates, without much 
doubt, believed in the existence of a vital breath, or pneuma, 
which had its seat in the heart and lungs. But previously to this, 
respiration was considered a mechanical function of the 
organism. But in the time of Alexander the Great 
Praxagoras discovered the distinction between the 
arteries and the veins. Now in the corpse the former 
side to which he referred, to these posterior, was 
declared to be vessels for conveying Pneuma to the 
different parts of the body. A generation afterwards 
Erasistratus made this the basis of a new theory of diseases and their treatment. Vital spirit, 
which was considered to circulate the currents of the 
blood which reach the various centres, especially the brain and the heart, and there causes thought and organic movement. But long before this, the peculiar character of air had been recognized as something 
intermediate to the corporeal and the incorporeal; when Diogenes 
of Apollonia revived the old Ionian hylozoism in opposition to the dualism of Anaxagoras, he made this, the typical example of matter in the gaseous state, his one element. In Stoicism, for the moment, the two concepts are united, soon, however, to diverge—the 
medical conception to receive its final development under Galen, 
while the philosophical conception, passing over to Philo and others, 
and modified by Spinoza, became the foundation of the 
Judaism, whence it played a great part in the developments 
Jewish and Christian thought.

The influence upon Stoicism of Heraclitus has been differently 
considered by different critics. No one will deny that the 
contrast of Heraclitus and his disciple, Zeno, has been 
inspiration to the Stoics; but this is not borne out by the 
concise history found at 

Contrast to Heraclitus. 
They substituted primitive Pneuma for his primitive fire. 

To Zeno (who seems to have been a student of Pythagoras) the 
meteoric fire which the Chaldean (and possibly the 
Lambic), which we may call the archaic fire, the concept 
of fire, was the same as the divine, the principle of all 
light and life. But Heraclitus, with whom they

elements which Chrysippus stated as a simple proposition of physics. Aristotle's view is that there is a system of four basic elements as different grades of tension; to the conception of fire and air as the "form," in Aristotelian terminology, of particulars; nor to the function of organizing fire which works by methodic plan to give the world its "shape" (προσωπωσις ψυχικῆς τῷ κόσμῳ). Nor, again, is there any analogy to the peculiar Stoic doctrine of universal intermingling (κραταῖον & ἄλοιπον). The two active elements interpenetrate the two passive or inertial, with which equal quantities of matter and so pervading the greater masses that there is no mechanical mixture, nor yet a chemical combination, since both "force" and "matter" retain their relative characters as the distinction between "fire" and "water" also alien to the spirit of Heracleitus—is seen to be a necessary consequence. Once assume that every character and property of a particular thing is determined solely by the tension in that thing, then whatever is in the tension, and not capable of change, which cannot be Absolute the same with the thing itself, Pneuma, though present in all things, must be asserted to vary indefinitely in quantity and intensity. So condensed and coarsened is the indwelling air-inorganic bodies that no trace of elasticity or life remains; it cannot even afford them the power of motion; all it can do is to hold them together (σωματικὸς βίος); and, in technical language, Pneuma is present in stone as a retaining principle (φράσις ἀρχιτεκτονικής), explaining the attributes of continuity and numerical identity (συνοχὴ καὶ ποιμανία) which even these natural substances possess. In plants again and all the things capable of change and growth, the third and fourth are possessed of greater tension, called a "nature," or principle of growth (φύσος). Further, a distinction was drawn between irrational animals, or the brute creation, and the rational, i.e. gods and men, lesser in number, more self-conscious, and less in the development of opinion. The older authorities conceded a vital principle, but denied, a soul, to the brutes: animals, they say, are ζώα but not ψυχή. Later on much evidence goes to prove that a soul is the immortality of the body. The motion of the soul is, perhaps (due to Platonistic influence) it was a Stoic tenet to concede a soul, though not a rational soul, throughout the animal kingdom. To this higher manifestation of Pneuma can be reduced the physiognomy of the animal world, as it is divided and analyzed by Galen and Epiphanes, as it is defined by Plato and Aristotle, and, as the whole to which the soul is a heavenly part as the light is to the body, as the universe is to the soul. The universal presence of Pneuma was confirmed by observation. A certain warmth, akin to the vital heat of organic beings, seems to be found in the stone, even in non-living things: from the earth, the stones, the earth for the flint, were claimed as the last remnant of Pneuma not yet utterly slackened and cold. They appealed also to the velocity and dilatation of aeriform bodies, to whirlwinds and inflated balloons. The Lothian mist was judged to be a two-edged sword, piercing even to the dividing asunder of the joints and marrow. Tension itself Chrysippus defined as a fiery stroke (ἀλυκὴ ψυχῆς); in his hymn to Zeus lightning is the symbol of divine activity. Take the fundamental properties of body—extension and resistance. The former results from distance; but distances, or dimensions, are straight lines, i.e. lines of greatest tension (οἱ δὲ διοικτάτα). Tension again, as is explained by Chrysippus, is of considerable importance, again, is explained by cohesion, which implies binding force. Again, the primary substance has rectilinear motion in two directions, backwards and forwards, at once a condensation, which produces cohesion and a stop (κινούμενο ψυχεῖν τὸν σύνθεταν), which we have just mentioned. The interpenetration of the element of fire, which was seen to be the reason for the dissolution of the world; after death the disembodied soul can only maintain its separate existence, even for a limited time, by maintaining that relation to the universe, which is a metaphysical nature. When the soul is subordinated to any object, be it a point, an idea, an object, a purpose, a thought, or the souls of the wise and good alone, which was the opinion of Chrysippus; in any case, sooner or later individual souls are merged in the soul of the universe, from which they proceed. The relation of the soul of the universe to God is quite clear: it is an inherent property, a mode of His activity, an effluence or emanation from the fiery ether which surrounds the universe, penetrating and permeating it. A Stoic might consequently maintain that World-Soul, Providence, Destiny and Germainal Reason are mere names, for they express different aspects of God's relations of God to things. We find ourselves on the verge of a system of abstractions, or "attributes turned into entities," as barren as any excogitated in medieval times. In a certain sense, Scholasticism began with Chrysippus. To postulate different sub-universes as underlying the universe, and to claim that we have already been to the fundamental thought of the system. What really is—the Pneuma—neither increases nor diminishes; but its modes of working, its different currents, can be conveniently considered and enumerated as evidence of any distinct attributes.

If, however, in the science of nature the Stoics can lay claim to no striking originality, the case is different when we consider the science of man. In the rational creatures—man and the gods—Pneuma is manifested in a high degree of purity and intensity as an emanation from the world-soul, itself an emanation from the primary substance of purest ether—a spark of the celestial fire, or, more accurately, fiery breath, which is a mean between fire and air, characterized by vital warmth more than by dryness. The physical basis of Stoic psychology deserves the closest attention. On the one hand, soul is corporeal, else it would have no real existence, would be incapable of extension in three dimensions (and therefore of equable diffusion all over the body), incapable of holding the body together, as the Stoics contended that it does, herein presenting a sharp contrast to the Epicurean tenet that it is the body which confines and shields the light vengeat atoms of soul. On the other hand, this corporeal thing is vitally and identically reason, mind, and ruling principle (θυγατρός, ραίσις, ψυχικός) in virtue of its divine origin Chrethinotes. In fact, "We too can scarcely help but firmly and calmly insist that, if man and God are not on perfect equality, the superiority rests rather on the side. What God is for the world that the soul is for man. The Cosmos must be conceived as a whole, its variety being referred to varying stages of condensation in Pneuma. So, too, the human soul must possess absolute simplicity, its varying functions being conditioned by the degrees or species of its tension. It follows that of parts of the soul, as previous thinkers imagined, there can be no question; all that can consistently be maintained is that from the centre of the body—the heart—seven distinct air-currents are discharged to various organs, which are so many modes of the one soul's activity.1 The ethical consequences of this position will be seen at a later stage. With this psychology is intimately connected the Stoic theory of knowledge. From the unity of soul it follows that all psychical processes—sensation, assent, impulse—proceed from reason, the ruling part; that is to say, there is no strife or division: the one rational soul alone has sensations, assents to judgments, is impelled towards objects of desire just as much as it thinks or reasons. Not that all these powers at once reach full maturity. The soul is in fact a void of consciousness, a vast air-space beyond the nutritive principle of a plant (φυτή): at birth the ruling part is a blank tablet, although ready prepared to receive writing. This excludes all possibility of innate ideas or any faculty akin to intuitive reason. The source of all our knowledge is experience and discursive thought, which manipulates the materials of sense. Our ideas are copied from stored-up sensations. No other theory was possible on the foundation of the Stoic physics.

Note the parallel between the macrocosm and the microcosm. The soul of the world fills and penetrates it: in like manner the human soul pervades and breathes through all the body, informing and guiding it, stamping the man with his essential character of rational. There is in both alike a ruling part, though this is situate in the human heart at the centre—not in the brain, as the analogy of the celestial ether would suggest. Finally, the same cause, a relative of tension, or, in other words, a density, a deepening, an intensification, is at the bottom of both for the dissolution of the world; after death the disembodied soul can only maintain its separate existence, even for a limited time, by maintaining that relation to the universe, which is a metaphysical nature. Whether all souls do survive, as Cleaneaus thought, or the souls of the wise and good alone, which was the opinion of Chrysippus; in any case, sooner or later individual souls are merged in the soul of the universe, from which they proceed. The relation of the soul of the universe to God is quite clear: it is an inherent property, a mode of His activity, an effluence or emanation from the fiery ether which surrounds the universe, penetrating and permeating it. A Stoic might consequently maintain that World-Soul, Providence, Destiny and Germainal Reason are mere names, for they express different aspects of God, different relations of God to things. We find ourselves on the verge of a system of abstractions, or "attributes turned into entities," as barren as any excogitated in medieval times. In a certain sense, Scholasticism began with Chrysippus. To postulate different sub-universes as underlying the universe, and to claim that we have already been to the fundamental thought of the system. What really is—the Pneuma—neither increases nor diminishes; but its modes of working, its different currents, can be conveniently considered and enumerated as evidence of any distinct attributes.

One inevitable consequence of materialism is that subject and object can no longer be regarded as one in the act of perception, as Aristotle assume, the perception of an object consists in the assumption of some purely external connexion, as between any other two corporeal things, is alone adsmissible and some form of the

---

1 These derivatives provide the key senses, speech and the reproductive faculty, and they are the source of our "passions." In the ingenious essay of Mr R D. Archer Hind on the Platonic psychology (Journ. of Phil. x. 120) aims at establishing a parallel unification on the spiritualistic side; cf. Rep. 6.12 A.
representative hypothesis is most easily called in to account for perception. The Stoics explained it as a transmission of the perfected quality of the object, by means of the sense organ, into the perceiver’s mind, the quality transmitted appearing as a disturbance in the sensory organ, which is the "recipient of the corporeal thing," the soul. Sight is taken as the typical sense. A conical pencil of rays diverges from the pupil of the eye, so that its base covers a small area in the sense organ. Perception is the effect of a zone created by an air-current, from the sense organ, here the eye, to the mind, i.e., the soul’s "ruling part" in the breast; the presentation, besides attesting its own existence, gives further information of its object—vision is a test of it wherever it may lie in the plane of the soul.

That Zeno and Cleaneus crudely compared this presentation to the impression which a seal bears upon wax, with protuberances and indentations, while Chrysippus more prudently determined it vaguest of the presentation or sensation, as a reflex of an impression, but not intrinsically important detail. But the mind is no mere passive recipient of impressions from without, in the view of the Stoics. Perception is not a mere relative presentation; it takes a variation in tension, against the current from the sense-organ; and this is the mind’s assent or dissent, which is inseparable from the sense presentation. The contents of experience are not all alike true or valid; hallucination is possible; here the Stoics, in issue with Epicurus. It is necessary, therefore, that assent should not be given indiscriminately; we must determine a criterion of truth, a special formal test whereby reason may recognize the mere impression. Therefore the Stoics thought it must be the case that an inquiry would have seemed superfluous. To Plato and Aristotle the nature and operation of thought and reason constitute a sufficient criterion of truth, irrespective of day not a day of the universe. In comparison sense and reason broken down, but the reasoned scepticism of Pyrrho and Arcesilas had made the impossibly of attaining truth the primary condition of well-believing. Yet the standard which ultimately enabled the Stoics to attack in the third part of Plato’s Theaetetus (201 C seq.)—that simple ideas are given by sense, whereas "opinion," which is a complex of simple ideas, only becomes knowledge when joined, is a necessity.

We may further suppose that the more obvious of Plato’s objections had led to the correction of "reason" into "right reason." However that may be, it is certain from Aristotle (Nic. Eth. vi. 13, 1144b. 17) that virtue was a matter of "opinion" in accordance with this right reason. From Diog. Lec. vii. 54 that the earlier Stoics made right reason the standard of truth. The law which regulates our action is thus the ultimate criterion of what we know—practical knowledge being understood to be of paramount importance. But this criterion was open to the persistent attacks of Epicureans and Academics, who made clear (1) that reason is dependent upon, if not derived from, sense, and (2) that the utterances of reason lack consistency. Chrysippus, therefore, conceded something to his opponents which he substituted for the Logos the new standards of sensation (αἰσθήσεως and general conception (πράγματος, or the generic type (καθ’ ἑαυτόν) of the contemplative mind. At the same time he was more clearly defining and safeguarding his predecessors’ position. For reason is consistent in the general conceptions wherein all men agree, because in all alike they are of spontaneous growth, in the general forms of the universe and the individual forms Chrysippus fixed upon a certain characteristic of true presentations, which he denoted by the much disputed term "apprehensive" (καθαρτική φαντασία). Provided the sense organ and the mind be healthy, provided an external object be really seen or heard, the presentation, in virtue of its clearness and distinctness, has the power to extort the assent which it always lies in our power to give or to withhold.

Formerly this technical phrase was explained to mean "the perception which irresistibly compels the subject to assent to it as true." But this, though apparently supported by Sextus Empiricus (Non. Schol. p. 139) is quite inadequate for the purpose. It is called καθαρτικός, as well as καθαρτική φαντασία, so that beyond all doubt it is something which the percipient subject grasps, and not that which grows or is held of "true" or "essential." Nor, again, is it wholly satisfactory to explain καθαρτική φαντασία as a passive, "apprehensible," like its opposite διέλευθες; for we find διέλεψε τὸν εὐκρίνειον used as an alternative phrase (Diog. Laert. ix. 88). The most satisfactory substitute of the standard of truth is one which, by producing a mental counterpart of a really existent external thing, enables the percipient, in the very act of sense, to "lay hold of" or apprehend an object in the same way as the sense organ or sensation is apprehended in its own mind. The reality of the external object is a necessary condition, to exclude hallucinations of the senses; the exact correspondence between the external object and the internal percept is also necessary, but no greater degree of correspondence is required.

The external object is known only in perception. However, the younger Stoics endeavoured to meet the assaults of their persistent critic Carneades by suggesting various modes of testing a single presentation, to see whether it was consistent with others, especially such as occurred in groups, &c.; indeed, some went so far as to add to the definitiön "coming from a real object and exactly corresponding with it" the clause "provided it encountered no obstacle." Degrees of "knowledge (εἰσοδία) and thinking when it is of the latter kind includes memory (though this is, upon a strict analysis, something intermediate), and conceptions or general ideas (πράγματα), which are purely intellectual; the latter presents itself without the presence of the imaginative faculty. The work of the mind is seen first in "assent"; if to a true presentation the result is "simple apprehension (ἐπιστήμη); this stands in close relation to the καθαρτική φαντασία, as it were, the modification of unapprehensive presentation, the result is "opinion" (μόνος), always deprecated as akin to error and ignorance, unworthy of a wise man.

These processes are conceivable only as "modes" of mind, changes in the soul’s substance, and the same is true of the higher conception of the products of generalization. But the Stoics were not slow to extalt the part of reason, which seizes upon the generic qualities, dialectic, including grammar, in addition to sensory conflict; it is the latter that must decide. One isolated "apprehension," however firm its grasp, does not constitute knowledge or science (εἰσοδία); it must be of the firmest, such as reason cannot shake, and yet, how necessary it is, nothing which can only be by the mind’s exercising the "habit" (μόρια) of attaining truth by continuous tense. Here the work of reason is opposed to the force which binds together the parts of an inorganic unity and reduces them to a system, which can be in the order of the universe than extended mobile bodies and forces in tension in those bodies. So too, in the order of knowledge there is a certain type of relationship and mutual assistance in the works of all the parts. This is an additional reason for looking at experience and connecting sensations and ideas in their proper sequence. Zeno compared sensation to the outstretched hand, flat and open; bending the fingers was assent; the clenched fist was' simple apprehension, the clenched fist was only tied and resolute, but tightly held in the other hand. The illustration is valuable for the light it throws on the essential unity of diverse intellectual operations of enforcing once more the Stoic doctrine that different grades of knowledge and matter; (2) essential quality, i.e., good, evil, virtues and vices, remarks Plutarch, are all capable of being "apprehended"; sense, this common basis of all mental activity, is a soul's own substance, of which the highest is the one which is the soul’s substance recognizes and measures tension.

With this exposition we have already invaded the province of logic. To this the Stoics assigned a miscellaneous of studies—rhetoric, dialectic, including grammar, in addition to sensory logic—to all of which their industry made contributions.

Some of their innovations in grammatical terminology have lasted until now; we still speak of oblique cases, genitive, dative, accusative, and the other active, with their corresponding passive, and the names they gave. Their corrections and fancied improvements of the Aristotelian logic are mostly useless and pedantic. Judgment was used to allude to the force which binds together the parts of an inorganic unity and reduces them to a system, which can be in the order of the universe than extended mobile bodies and forces in tension in those bodies. So too, in the order of knowledge there is a certain type of relationship and mutual assistance in the works of all the parts.

The ethical theory of the Stoics stands in the closest connexion with their metaphysics, and the contents of it will be found in the article Ethics. It may be briefly summarized here. Socrates had rightly said that Virtue is Knowledge, but he had not definitely shown in what way the two are to be connected, or, at least, Socrates, Cynics, made any serious attempt to solve the difficulty. The Stoics not only drew up an elaborate scheme of duties, but also crystallized their theory in a general law, namely that true goodness
lies in the knowledge of nature and is obtained by the exercise of Reason. The most elementary part of nature is pure ether, which is possessed of divine reason. This Reason even non-rational man unconsciously manifests in his mechanical instinctive actions which tend to the preservation of himself. The truth of the matter will therefore live as much as possible in conformity with nature, (i.e. nature uncorrupted by the errors of society), and, though, as an individual, the man is wholly absorbed in the pursuit of his ends, he still retains self-control even in the midst of misfortune and pain. All evil passion is due to erroneous judgment and morbid conditions of mind which may be divided into chronic ailments (συσταθέρα) and infirmities (διάπορα), i.e., into permanent or temporary disorders. In contrast to the Cynics and the Epicureans, the Stoics denied that pleasure is actually or ought to be the object of human activity. The non-rational man aims at self-preservation: he will imitate the, but only imitatively, and when he fails he will suffer with equanimity. To him the so-called "goods" (e.g. health, wealth, &c.) are "indifferent" (διάπορα); since he must live, he will exercise his reasoning faculty upon them, and will regard some as "preferred" (ἐπιποργυροί) and others as "rejected" (ἀποποργυροί), but he will not regard either class as possessed of an intrinsic value. The end of action is, therefore, a harmonious consistent life "according to nature" and (cf. Heraclitus) an ordered unity of action. Virtue is its own good; the highest exercise of reason is its own perfection. It follows (1) that pleasure, being quite outside the pale is not the object but merely an ἐπικύρωσις (accessory) to it, which is only the result that there is no circle of virtue, no degree. An action is simply virtuous or not; it cannot be more or less virtuous. The result of this theory of ethics is of great value as emphasizing the importance of reason. But it has the objection of the fact that the great Socratic paradox that evil is the result of ignorance. For even though they attempt to substantiate the idea of responsibility by maintaining that the whole of our life is voluntary, they cannot find any mode of expression which answers to the question whether some men may not be without the capacity to choose learning (but see ETHICS: History, § STOICS).

In their view of man's social relations the Stoics are greatly in advance of preceding schools. We saw that virtue is a law within and around the universe that Reason and God ordain must be accepted as binding upon all. The particle of reason which is in each one of us. Human law comes into existence when men recognize this obligation; justice is therefore natural and not something merely conventional. The opposite tendencies, to allow the individual responsibility and freedom, and to demand of him obedience to law, are both features of the system; but in virtue even of the freedom which belongs to him qua rational, he must recognize the society of rational beings of which he is a member, and subordinate his own ends to the ends and needs of the community, the two own laws are: one, the city of Zeus, in which men and gods have their dwelling. In that city all is ordained by reason working intelligently, and the members exist for the sake of one another; there is an intimate connexion (συμμετέχει) between them which makes all the wise and virtuous friends, even if personally unknown, and leads them to contribute to one another's good. Their intercourse should find expression in justice, in friendship, in family and political life. But practically the Stoic philosopher always had some good excuse for withdrawing from the narrow political life of the city in which he found himself. The circumstances of the case, such as the decay of Greek city-life, the foundation of large territorial states under absolute Greek rulers which followed upon Alexander's conquests, and afterwards the rise of the world-empires of Rome, aided to develop the leading idea of Zeno's Republic. There he had anticipated a state without family life, without law courts or coins, without schools or temples, in which all differences of nationality would be merged in the common brotherhood of man. This cosmopolitan citizenship remained all through a distinctive Stoic dogma; when first announced it must have had a powerful influence, and contributed to many, divesting them from the distractions of almost parochial politics to a boundless view. There was, then, no longer any difference between Greek and barbarian, between male and female, bond and free. All are members of one body as partaking in reason, all are equally men. Not that this led to any movement for the abolition of slavery. For the Stoics attached but slight importance to external circumstances, since only the wise man is really free, and all the unwise are slaves. Yet, while they accepted slavery as a permanent institution, philosophers as wide apart as Chrysippus and Seneca sought to mitigate its evils in practice, and urged upon masters humanity in the treatment of their slaves.

The religious problem had peculiar interest for the school which discerned God everywhere as the ruler and Upholder, and at the same time the law, of the world that He had evolved from Himself. The physical groundwork lends a religious sanction to all moral duties, and Cleanthes's noble hymn is evidence how far a system of natural religion could go in providing satisfaction for the cravings of the religious temper:

"Most glorious of immortals, O Zeus of many names, almighty and everlasting, sovereign of nature, directing all in accordance with law, it is fitting that all mortals should address... Thou art the charter of the world as it is, as it was, as it shall be ever. The world is all this universe, as it rolls circling round the earth, obeys wherefore ever thou dost guide, and gladly owns thy sway. Such a minister thou holdest in thy invincible hands—the two-edged, fiery, ever-living thunderbolt, under whose stroke all nature shudders. No work upon earth is wrought apart from thee, lord, nor through the divine ethereal sphere, nor upon the sea; save only whatsoever deeds wicked men do in their own foolishness. Nay, thou knowest how to make even the rough smooth, and to bring order out of disorder; and things not friendly are friendly in thy sight. For so fast thou hast fitted all things together, the good with the evil, that there can be one evil, except that over all there is self ignorance. Banish it, father, from their soul, and grant them to obtain wisdom, whereon relying thou rulest all things with justice."

To the orthodox theology of Greece and Rome the system stood in a twofold relation, as criticism and rationalism. That the popular religion contained gross errors hardly needed to be pointed out. The forms of worship were known to be trivial or mischievous, the myths unworthy or immoral. But Zeno declared images, images, temples, sacrifices, prayers and worship to be of no avail. A really acceptable prayer, he taught, can only have reference to a virtuous and devout mind: God is best worshipped in the shrine of the heart by the desire to know and obey Him. At the same time the Stoics felt at liberty to defend and uphold the truth in polytheism. Not only is the primitive substance God, the one supreme being, but divinity must be ascribed to His manifestations— to the heavenly bodies, which are conceived, like Plato's created gods, as the highest of rational beings, to the forces of nature, even to deified men; and thus the world was populated with divinities. Moreover, the myths were not regarded as literal, or allegorized, which was not in either case an original procedure. The search for a deeper hidden meaning beside the literal one had been begun by Democritus, Empedocles, the Sophists and the Cynics. It remained for Zeno to carry this to a much greater extent and to seek out or invent "natural principles" (λάτως φυσικά) and moral ideas in all the legends and in the poetry of Homer and Hesiod. In this sense he was the pattern if not the "father" of all such as allegorize and reconcile. Etymology was pressed into the service, and the wildest conjectures as to the meaning of names did duty as a basis of mythological explanations. The two favourites of the Stoic heroes were Hercules and Ulysses, and nearly every scene in their adventures was made to disclose some moral significance. Lastly, the practice of divination and the consultation of oracles afforded a means of communication between God and man—a concession to popular beliefs which may be explained when we reflect that to the faithful divination was something as essential as confession and spiritual direction to a devout Catholic now, or the study and interpretation of Scripture texts to a Protestant. Chrysippus did his best to reconcile the superstition with his own rational doctrine of strict causation. Omens and portents he explained, are the natural symptoms of certain occurrences. There must be countless indications of the course of Providence, for the most part unobserved, the meaning of only a few having become known to men. His opponents argued, "if all events are foreordained, divination is superfluous"; he replied that both divination and our behaviour under the warnings which
it affords are included in the chain of causation. Even here, however, the bent of the system is apparent. They were at pains to insist upon purity of heart and life as an indispensable condition for success in prophecying and to enlist piety in the service of morality.

When Chrysippus died (Ol. 143 = 208-204 B.C.) the structure of Stoic doctrine was complete. With the Middle Stoae we enter upon a period at first of comparative inaction, a period of Internal History. Hereward as mediate successors were Zeno of Tarsus, Diogenes of Seleucia (often called the Babylonian) and Antipater of Tarsus, men of no originality, though not without ability; the two last-named, however, had all their energies taxed to sustain the conflict with Carneades (q.v.). This was the most formidable assault the school ever encountered; that it survived was due more to the foresight and elaborate precautions of Chrysippus than to any efforts of that "pen-doughty" pamphleteer, Antipater (αὐλαμοῦξαρ), who shrank from opposing himself in person to the eloquence of Carneades. The subsequent events testified to the importance of this controversy. The special objects of attack were the Stoical theory of knowledge, their theology and their ethics. The physical basis of the system remained unchanged but neglected; all creative force or even original research in the departments of physics and metaphysics vanished. Yet problems of interest bearing upon psychology and natural theology continued to be discussed. Thus the cycles of the world's existence, and the universal conflagration which terminates each of them, excited some doubt. Diogenes of Seleucia is said to have wavered in his belief at last; Boethus, one of his pupils, flatly denied the doctrine, and himself the guide and upholder of the world, watching over it from the outside, not as the immanent soul within it, for according to him the world was as soulless as a plant. We have here a compromise between Zeno's and Aristotle's doctrines. But in the end the universal conflagration was handed down without question as an article of belief. It is clear that the activity of these teachers was chiefly directed to ethics: they elaborated fresh definitions of the chief good, designed either to make yet clearer the sense of the formulas of Chrysippus or else to meet the more urgent objections of the New Academy. Carneades had emphasized one striking apparent inconsistency: it had been laid down that to choose what is natural is man's highest good, and yet the things chosen, the "first objects according to nature," had no place amongst goods. Antipater may have met this by distinguishing "the attainment" of primary natural ends from the activity directed to their attainment (Plut. De Comm. Not. 27, 14, p. 1972 F); but, earlier still, Diogenes had put forward his gloss, viz. "The end is to calculate rightly in the selection and rejection of things according to nature." Archedemus, a contemporary of Diogenes, put this in plainer terms still: "The end is to live in the performance of all fitting actions" (πάντα τὰ καθήκοντα ἐπιστευόντας ἢμεῖς). Now it is highly improbable that the earlier Stoics would have sanctioned such interpretations of their dogmas. The mere performance of relative or imperfect duties, they would have said, is something neither good nor evil; the essential constituents of human good is ignored. And similar criticism is actually passed by Posidonius: "This is not the end, but only its necessary concomitant; such a mode of expression may be useful for the refutation of objections put forward by the Sophists" (Carneades and the New Academy?); "but it contains nothing of morality or well-being" (Galen, De Ploc. Hipp. et Plut. p. 470 K). There is everywhere ground, then, for concluding that we have here one concession extorted by the assaults of Carneades. For a similar compromise there is express testimony: "good repute" (εὐόνεια) had been regarded as a thing wholly indifferent in the school down to and including Diogenes. Antipater was forced to assign to it "positive value," and to give it a place amongst "things preferred" (Cic. De fn. iii. 57). These modifications were retained by Antipater's successors. Hence come the increased importance and fuller treatment with which this time forward fall to the lot of the "external duties" (καθήκοντα). The rigour and consistency of the older system became sensibly modified.

This result another important factor contributed. In all that the older Stoics taught there breathed that enthusiasm for righteousness in which has been traced the earnestness of the Semitic spirit; but nothing presents more forcibly the pitch of their moral idealism than the doctrine of the Wise Man. All mankind fall into two classes—the wise and virtuous, the unwise or vicious—the distinction being absolute. He who possesses virtue possesses it whole and entire; he who lacks it lacks it altogether. To be but a hand's-breadth below the surface of the sea ensures drowning as infallibly as to be five hundred fathoms deep. Now the wise man is drawn as perfect. All he does is right, all his opinions are true; he alone is free, rich, beautiful, skilled to govern, capable of giving or receiving a benefit. And his happiness, since length of time cannot increase it, falls in nothing short of that of Zeus. In contrast with all this, we have a picture of the most depraved man. Now, who could claim to have attained to the sage's wisdom? Doubtless, at the first founding of the school Zeno himself and Zeno's pupils were inspired with this hope; they emulated the Cynics Antisthenes and Diogenes, who never shrank out of modesty from the name and its responsibilities. But the development of the system led them gradually and reluctantly to renounce this hope as they came to realize the arduous conditions involved. Zeno indeed could hardly have been denied the title conferred upon Epicurus. Cleanthes, the "second Hercules," held it possible for man to attain to virtue. From anecdotes recorded of the tricks played upon Aristo and his fellows—the water virtuous, the wax impervious—it may be inferred that the former deemed himself infallible in his opinions, i.e. set up for a sage; Perseus himself, who had exposed the pretensions of Aristo, is twitted with having failed to conform with the perfect generalship which was one trait of the wise man when he allowed the citadel of Corinth to be taken by Aratus (Athen. iv. 102 D). The trait of infallibility especially proved hard to establish when successive heads of the school seriously differed in their doctrine. The prospect became daily more distant, and at length faded away. Chrysippus declined to call himself or any of his contemporaries a sage. One or two such manifestations there may have been—Socrates and Diogenes—but the wise man was rarer, he thought, than the phoebus. If his successors allowed one or two more exceptions, to Diogenes of Seleucia at any rate the sage was an unrealized ideal, as we learn from Plutarch (De comm. not. 33, 1076 B), who does not fail to seize upon this extreme view. Posidonius left even Socrates, Diogenes and Antisthenes in the state of progress towards virtue. Although there was in the end a reaction from this extreme, yet it is impossible to mistake the bearing of all this upon a practical system of morals. So long as dialectic subtleties and exciting polemics afforded food for the intellect, the gulf between theory and practice might be ignored. But once let this system be presented to men in earnest about right living, and eager to profit by what they are taught, and an ethical reform is inevitable. Conduct for us will be separated from conduct for the sage. We shall be told not always to imitate him. There will be a new law, dwelling specially upon the "external duties" required of all men, wise or unwise; and even the sufficiency of virtue for our happiness may be questioned. The introducer and expositor of such twofold morality was a remarkable man. Born at Rhodes c. 185 B.C., a citizen of the most flourishing of Greek states and almost the only one which yet retained vigour and freedom, Panaetius lived for years in the house of Scipio Africanus the younger at Rome, accompanied him on embassies and campaigns, and was perhaps the first Greek who in a private capacity had any insight into the working of the Roman state or the character of its citizens. Later in life, as head of the Stoic school at Athens, he achieved a reputation second only to that of Chrysippus. He is the earliest Stoic author from whom we have, even indirectly, any considerable piece of work, as books i. and ii. of the De officiis are a réchaffé, in Cicero's
fashion, of Panaetius "Upon External Duty" (προς τοῦ καθαροῦ).

The introduction of Stoicism at Rome was the most momentous of the many changes that it saw. After the first sharp collision with the jealousy of the national authorities it found a ready acceptance, and made rapid progress among the noblest families. It has been well said that the old heroes of the republic were unconscious Stoics, fitted by their narrowness, their stern simplicity and devotion to duty for the almost Semitic earnestness of the new doctrine. In Greece its insensibility to art and the cultivation of life was a fatal defect; not so with the shrewd men of the world, desirous of quality as of quantity. It supplied them with an incentive to scientific research in archaeology and grammar; it penetrated jurisprudence until the belief in the ultimate identity of the *juris gentium* with the law of nature modified the praetor’s edicts for centuries. Even to the prossic religion of old Rome, with its narrow original conception and multitude of burdensome rites, it became in some sort a concept. Scaevola, following Panaetius, explained that the prudence of statesmen had established this public institution in the service of order midway between the errors of popular superstition and the barren truths of the *principia naturæ*. Soon the influence of this doctrine reacted upon the doctrines taught. Of speculative interest the ordinary Roman had as little as may be; for abstract discussion and controversy he cared nothing. Indifferent to the scientific basis or logical development of doctrines, he selected from various writers and from different schools what he found most serviceable. All had to be simplified and disengaged from technical subtleties. To attract his Roman pupils Panaetius would naturally choose simple topics susceptible of rhetorical treatment or of application to individual details. He was the representative, not merely of Stoicism, but of Greek and Greek literature, and would feel pride in introducing its greatest masterpieces: amongst all that he studied, he valued most the writings of Plato. He admired the classic style, the exquisite purity of language, the flights of imagination, but he admired above all the philosophy. He marks a reaction of the genuine Hellenic spirit against the narrow austerity of the first Stoics. Zeno and Chrysippus had introduced a repellent technical terminology; their writings lacked every grace of style. With Panaetius the Stoae became eloquent: he did his best to improve upon the uncouth words in vogue, even at some slight cost, e.g. to discard προτύπων προς ἀναγνώσιν or else designate it "so-called good," or even simply "good," if the context allowed.

The part Panaetius took in philosophical and historical studies is characteristic of the man. We know little about him save what his contemporaries tell us. He was a profoundly religious man: his life, his influence upon the doctrines taught. Yet then there had been a movement towards a wider and more liberal education, by which even contemporary Epicureans were affected. Diogenes Laërtius had written De vita et moribus Zenonis and De vita et moribus Chryssippon, along with grammar, which had been a prominent branch of study under Chrysippon, philosophy, history, geography, chronology and kindred subjects came to be recognized as fields of activity no less than philosophy proper. It has been recently established that Polybius the historian was a Stoic, and it is clear that he was greatly influenced by the form of the system which he learned to know, in the society of Scipio and his school. Polybius1 is not it is possible to say that the latter served Cicero as the originals of his De republica and De legibus.2 Thus the gulf between Stoicism and the later Cynics, who were persistently hostile to culture, could not fail to be widened.

1 Hirzel, Untersuch. ii. 841 seq. Polybius’s rejection of divinization is decisive. See, e.g. his explanation upon natural causes of Scipio the Elder’s excuse for Carthage, "by the aid of Neptune;"

2 De leg. viii. 1. Voltz holds that in vi. 3, 1, τοὺς κρίτους τῶν φιλόσωσον is an allusion to Panaetius.

3 This at least, is maintained by Schnekel.

A wave of eclecticism passed over all the Greek schools in the 1st century B.C. Platonism and scepticism had left unwanted traces upon the doctrine of such a reformer as Panaetius. His philosophy was, according to a general admission, "eclectic, rhetorical in accordance with the *scientific* and "accordance with the *true*.

The Stoics in Rome.

In the last century B.C. Hippocrates, the philosophical reformer of the *science* of nature, had summed up the principal errors of the *spartaic* school in a treatise entitled *The Laws*. According to the *rhetorical* and *scientific* on the other hand, the *true* was a thing indifferent: there is a natural as well as an unnatural pleasure. But, if so, it would follow that, since pleasure is an emotion, a pensive or erudition of all emotions cannot be unjustified. It would in its turn affect the definition; for in the end was "a life in accordance with the presentations given us by nature"; the terms are all used by older Stoics, but the individual nature (φύσις) seems to be emphasized. From Posidonius, the last philosopher of the Stoics, and Galen, there comes a comprehensive study of natural philosophy, and a subtle erudition, it is not surprising that we get the following definition: the end is to live in contemplation of the unconditioned, and for the strengthening of the natural and the irrational part in man, which Christsippus had strove to subdue.3 Yet in the general approximation and fusion of opposing views which had set in, the Stoics fared far better than rival schools. It would become once more a natural and popular philosophy. All the assaults of the sceptic school had failed, and within fifty years of the death of Carneades his degenerate successors, unable to hold their ground on the question of the criterion, had capitulated to the enemy. Antius of Antioch, the apostle of the apostle, taught a medley of Stoic and Peripatetic dogmas, which he boldly asserted Zeno had first formulated in his school, and which the Stoic and Peripatetic modes of thought may be seen on all hands—in the language of the New Testament writers, in the compendious "histories of philosophy," industriously circulated by a host of writers about this time (cf. H. Diels, *Die Griechische Philosophie*).

The writings of the later Stoics have come down to us, if not entire, in great part, so that Seneca, Cornutus, Persius, Lucan, Epictetus, Marcus Aurelius are known at first hand. They do not profess to give a scientific treatment of doctrine, and may therefore be dismissed somewhat briefly (see Epictetus and Marcus Aurelius). We learn much more about the Stoic system from the scanty fragments of the first founders,4 or even from the epitomes of Diogenes Laërtius and Stobaeus, than from these writers. They testify to the restriction of philosophy to the practical side, and to the increasing tendency, ever since Panaetius, towards a relaxation of the rigorous ethical doctrine and its approximation to the form of religious conviction. This finds most marked expression in the doctrines of submission to Providence and universal philanthropy. But in ethics his innovations were more negative: they either rejected or condemned it (or at least the latter served Cicero as the originals of his De republica and De legibus.2 Thus the gulf between Stoicism and the later Cynics, who were persistently hostile to culture, could not fail to be widened.

1 Works of Posidonius and Hecato seem to have been written before the death of Panaetius, as seems also to be the case with the *De sermone philosophorum* of Posidonius. See P. D. Maass, *Stoicorum Fragmenta* (Berlin, 1882); cf. C. Wachsmuth, *Commentationes II. de Zuneo Ctesiuni et Cleante Assio* (Gottingen, 1874). Baguet’s *Chrysippus* (Louvain, 1822) is unfortunately very incomplete.
released so much intellectual activity from civic duties. The life and death of Cato fired the imagination of a degenerate age in which he stood out both as a Roman and a Stoic. To a long line of illustrious successors, men like Thrasea Paeus and Helvidius Priscus, Cato bequeathed his resolute opposition to the dominant power of the times; unsympathetic, impracticable, but fearless in demeanour, they were a standing reproach to the corruption and tyranny of their age. But when at first, under Augustus, they were prosecuted by the same holder, and his case was followed, he was a man who had the ambition to found a sect, though in ethics he was mainly followed Stoicism. His contemporary Papirius Fabianus was the popular lecturer of that day, producing a powerful effect by his denunciations of the manners of the time. Under Tiberius, Sotion and Attalus were attended by crowds of hearers. In Seneca’s time there was a professor, with few hearers it is true, even in a provincial town like Naples. At the same time the antiquarian study of Stoic writings went on apace, especially those of the earliest teachers—Zeno and Aristo and Cleanthes.

Seneca is the most prominent leader in the direction which Roman Stoicism now took. His penetrating intellect had mastered the subtleties of the system of Chrysippus, but they seldom appear in his works, at least without apology. Incidentally we meet there with the doctrines of Pnumea and of tension, of the corporeal nature of the virtues and the affections, and much more to the same effect. But his attention is claimed for physics chiefly, as a means of training the mind, and as making known the wisdom of Providence and the moral government of the world. To reconcile the ways of God to man had been the ambition of Chrysippus, as we know from Plutarch’s criticisms. He argued plausibly that natural evil was a thing indifferent—that even moral evil was required in the divine economy as a foil to set off good. The really difficult problem why the prosperity of the wicked and the calamity of the just were permitted under the divine government he met in various ways: sometimes he alleged the forgetfulness of higher powers; sometimes he fell back upon the necessity of these contrasts and grotesque passages in the comedy of human life. Seneca gives the true Stoic answer in his treatise On Providence: the wise man cannot really meet with misfortune; all outward calamity is a divine instrument of training, designed to exercise his powers and teach the world the indifference of external conditions. In the soul Seneca recognizes an effluence of the divine spirit, a god in the human frame; in virtue of this he maintains the essential dignity and internal freedom of man in every human being. Yet, in striking contrast to this orthodox tenet is his vivid conception of the weakness and misery of men, the helplessness of the struggle with evil, whether in society or in the individual. Thus he describes the body (which, after Epicurus, he calls the flesh) as a mere husk or litter or prison of the soul; with its departure begins the soul’s true life. Sometimes, too, he writes as if he accepted an irrational as well as a rational part of the soul. In ethics, if there is no novelty of doctrine, there is a surprising change in the mode of its application. The ideal sage has receded; philosophy comes as a physician, not to the whole but to the sick. We learn that there are various classes of patients in “progress” (πρόοδος), i.e. on their way to virtue, making painful efforts towards it. The first stage is the eradication of vicious habits; deficiencies are to be corrected, and a guard kept on the corrupt propensities of the reason. Suppose this achieved, we have yet to struggle with single attacks of the passions; ineradicability may be cured, but we may succumb to a fit of rage. To achieve this second stage the impulses must be trained in such a way that the fitness of things indifferent may be the guide of conduct. Even then it remains to give the will that property of rigid infallibility without which we are always liable to err, and this must be effected by the training of the judgment. Other peculiarities of the later Stoic ethics are due to the condition of the times. In a time of moral corruption and oppressive rule, as the early empire repeatedly became to the privileged classes of Roman society, a general feeling of insecurity led the student of philosophy to seek in it a refuge against the vicissitudes of fortune which he daily beheld. The less any one man could do to interfere in the government, or even to safeguard his own life and property, the more heavily the common fate pressed upon all, levelling the ordinary distinctions of class and rank. To these conditions they employed their energy in severe self-examination, or through a mental resignation to the will of the universe, and towards their fellow men forbearance and forgiveness and humility, the virtues of the philanthropic disposition. With Seneca this resignation took the form of a constant meditation upon death. Timid by nature, aware of his impending doom, and at times justly dissatisfied with himself, he tries all means of reconciling himself to the idea of suicide. The act had always been accounted allowable in the school. If circumstances should call for it: indeed, the first three teachers had found such circumstances in the infirmity of old age. But their attitude towards the “way out” (ἀποπύθων) of incurable discomforts is quite unlike the anxious sentimentalism with which Seneca dwells upon death.

From Seneca we turn, not without satisfaction, to men of sterner mould, such as Musonius Rufus, who certainly deserves a place beside his more illustrious disciple, Epictetus. As a teacher he commanded universal respect, and wherever we catch a glimpse of his activity he appears to advantage. His philosophy, however, is yet more concentrated upon practice than Seneca’s, and in ethics he is almost at the position of Aristeides. Epictetus testifies to the powerful hold he acquired upon his pupils, each of whom felt that Musonius spoke to his heart. The practical conclusion of his philosophy is that he must cheerfully accept the inevitable.

In the life and teaching of Epictetus this thought bore abundant fruit. The beautiful character which rose superior to weakness, poverty and slave’s estate is also presented to us in the Discourses of his disciple Arrian as a model of religious resignation, of forbearance and love towards our brethren, that is, towards all men, since God is our common father. With him even the “physical basis” of ethics takes the form of religious devotion—the providence of God and the perfection of the world. We learn that he regards the θάλαμος or “guardian angel” as the divine part in each man; sometimes it is more nearly conscience, at other times reason. His ethics, too, have a religious character. He begins with human weakness and man’s need of God: whose would become good must first be convinced that he is evil. Submission is enforced by an argument which almost amounts to a retraction of the difference between things natural and things contrary to nature, as understood by Zeno. Would you be cut off from the universe? he asks. Go to, grow healthy and rich. But if not, if you are a part of it, then become resigned to your lot. Towards this goal of approximation to Cynicism the later Stoics had all along been tending. Withdrawal from the active duty of the world must lead to passive endurance, and, ere long, complete indifference. Musonius had recommended marriage and condemned unsparring the exposure of infants. Epictetus, however, would have the sage hold aloof from domestic cares, another Cynic trait. So, too, in his great maxim “bear and forbear,” the last is a command to refrain from the external advantages which nature offers.

Epictetus reigned out amongst Stoics by his renunciation of the world. He is followed by a Stoic emperor, M. Aurelius Antoninus, who, though in the world, was not of it. The Meditations give no systematic exposition of belief, but there are many indications of the religious spirit we have already observed, together with an almost Platonic psychology. Following Epictetus, he speaks of man as a corpse bearing a soul; at another time he has a threefold division—(1) body, (2) soul, the seat of impulse (συνεπεια), and (3) νοῦς or intelligence, the proper ego. In all he writes there is a vein of sadness: the flux of all things, the vanity of
STOKE NEWINGTON—STOKES, SIR G. G.

951

life, are thoughts which perpetually arise, along with resignation to the will of God and forbearance towards others, and the religious longing to be rid of the burden and to depart to God. These peculiarities in M. Antoninus may perhaps be explained in harmony with the older Stoic teaching; but, when taken in connexion with the religious and philosophical influence of the Stoic schools, they are of the greatest significance. None of the ancient systems fell so rapidly as the Stoic. It had just touched the highest point of practical morality, and in a generation after M. Antoninus there is hardly a professor to be named. Its most valuable lessons to the world were preserved in Christianity; but the grand simplicity of its monism slumbered for fifteen centuries before it was revived by Spinoza.

LITERATURE.—The best modern authority is Zeller, Phil. d. Grieche, iii. pt. i. (3rd ed.), Berlin, 1861; and Richter, Geschichte der Ethik by F. A. Allyn (1853). Further may be cited F. Ravaisson, Essais sur le stoicisme (Paris, 1856; M. Heinze, Die Lehre vom Logos (Oldenburg, 1872); H. Siebeck, Untersuchungen zur Phil. d. Griechen (Halle, 1873), and Gesch. d. Psychologie, i. 2 (Gottha, 1884); R. Hirzel, "Die Entwicklung der stoischen Phil.," in Untersuchungen zu Ciceros Schriften, ii. 1–566 (Leipzig, 1882); Ogereau, Essai sur le systeme des Stoiciens (Paris, 1885); L. Stein, Die Psychologie der Stoiber, i. p. ii. (Berlin, 1886–1888); A. C. Pearson, The Fragments of Zeno and Cleanthes (London 1891); A. Schmelle, Die Philosophie der mittleren Stoa (Berlin 1892); A. Bonhoeffer, Epistes und die Stoa (Stuttgart, 1893); A. Schmelle, Die Ethik der alten Stoiber (Berlin, 1897). Indispensable to the student are H. Diels, Doxographi Graeci (Berlin, 1879); J. von Arnim, Stoicorum veterum fragmenta, i–iii. (Leipzig, 1859–1869).

STOKE NEWINGTON, a north-eastern metropolitan borough of London, England, bounded E. by Hackney and W. by Islington, and extending N. to the boundary of the county of London. Pop. (1901), 51,247. It is mainly occupied by small villas. On its western boundary, adjoining Green Lanes, lies Clissold Park (54 acres) and outside the north-western boundary is Finsbury Park (115 acres). In Church Street is the ancient parish church of St Mary, largely restored, but still bearing the stamp of antiquity; opposite to it stands a new church in Decorated style by Sir Gilbert Scott. In the north of the borough are the main waterworks and reservoirs of the L. & H. Water Company, though the waterway continues to a head in Finsbury. Stoke Newington is partly in the north division of the parliamentary borough of Hackney, but the district of South Hornsey, included in the municipal borough, is in the Hornsey division of Middlesex. The borough council consists of a mayor, 5 aldermen and 30 councillors. Area, 863.5 acres.

STOKE-ON-TRENT, a market town and municipal and parliamentary borough of Staffordshire, England, on the upper Trent, in the heart of the Potteries district. Pop. (1901), 30,458. This was the population of Stoke-upon-Trent in 1882, when it was granted borough status. In 1908 arrangements were made whereby Stoke-on-Trent, Burslem, Fenton, Hanley, Longton and Tunstall should be amalgamated as one borough, under the name of Stoke-on-Trent, from the 31st of March 1910. The new corporation consists of a mayor, 26 aldermen and 78 councillors. Stoke is on the North Staffordshire railway, 146 m. north-west from London by the London & North Western railway; and on the Grand Trunk (Trent and Mersey) Canal. The principal public buildings in the old town of Stoke are the town hall, with assembly rooms, law library, and an industrial department; the memorial building, containing a school of art and science; the free library and museum, and the North Staffordshire infirmary, founded in 1815 at Etruria, and removed to its present site in 1868. The head offices of the North Staffordshire Railway Company are here. Four large firms manufacturing every variety of art china and earthenware alone employ over 5000 hands. Coal-mining and iron and machine manufactures are also carried on. A statue commemorates Josiah Wedgwood, born at Burslem in 1730, but other famous names in the pottery trade are more intimately connected with Stoke-on-Trent than Josiah Spode. His second son was born here in 1754, and had a great house at Peakhurst, on the western outskirts of Stoke. He entered into partnership with the Copelands, who continued his business. Herbert Minton (1793–1858) was the founder of another of the large works. The parliamentary borough returns one member.

In the Domesday survey of 1086 half the church of Stoke and landowners in Stoke are said to have belonged to Robert of Stafford. Part of Stoke (Stoche or Stoca) at this time belonged to the Crown, since the royal estate of Penclla (now Penkhill) was included within its bounds. Frequent references to the parish church of Stoke are found during the 14th and 15th centuries. Contemporary writers from 1787 onwards describe Stoke as a market town, but the official evidence states that the market rights were not acquired until 1845. Since then the market days have been Saturday and Monday. Stoke-upon-Trent became the railway centre and head of the parliamentary borough of Stoke-upon-Trent, comprising the whole of the Staffordshire Potteries, which was created by the Reform Bill of 1832. In 1874 it was incorporated as a municipality. From 1833 to 1885 Stoke returned two members to parliament. From the early 17th century, if not earlier, porcelain and earthenware manufactories existed at Stoke-upon-Trent, but they remained unnoticed until in 1686 Dr Plot wrote his survey of Staffordshire. In the middle of the 18th century there was a great industrial development in the Pottery district.

STOKES, SIR G. G.

Clerk Maxwell and Lord Kelvin being the other two, who especially contributed to the fame of the Cambridge school of mathematics in the middle of the 19th century, his work began about 1840, and from that date onwards the great extent of his output was only less remarkable than the brilliance of its quality. The Royal Society's catalogue of scientific papers gives the titles of over a hundred memoirs by him published down to 1883. Some of these are only brief notes, others are short controversial or corrective statements, but many are really long and elaborate treatises. In matter his work is distinguished by a certain definiteness and finality, and even of problems, which when he attacked them were scarcely thought approached. The mathematical analysis of problems which involve solutions which once and for all settle the main principles. This result must be ascribed to his extraordinary combination of mathematical power with experimental skill, for with him, from the time when about 1840 he fitted up some simple physical apparatus in his rooms in Pembroke College, mathematics and experiment ever went hand in hand, aiding and checking each other. In scope his work covered a wide range of physical inquiry, but, as Alfred Cornu remarked in his Rede Lecture of 1889, the greatest part of it was concerned with waves and vibrations, and the problems imposed on these during their passage through various media. His first published paper on hydrodynamics appeared in 1842 and 1843, were on the steady motion of incompressible fluids and some cases of fluid motion; these were followed in 1845 by one on the friction of fluids in motion and the equilibrium and motion of elastic solids, and in 1850 by another on the effects of the internal friction of fluids on the motion of pendulums. To the theory of sound he made several contributions, including a discussion of the effect of wind on the intensity of sound and an explanation of how the intensity is influenced by the nature of the gas in which the sound is produced. These inquiries together put the science of hydrodynamics on a new footing, and provided a key not only to the explanation of many natural phenomena, such as the suspension of clouds in air, and the subsidence of ripples and waves in water, but also to the solution of practical problems, such as the flow of water in rivers and channels, and the skin resistance of ships. But perhaps his best-known researches are those which dealt with the undulatory theory of light. His optical work began at an early period in his scientific career. His first papers on the aberration of light appeared in 1845 and 1846, and were followed in 1851 by one on the refraction of light through the spectrum. In 1849 he published a long paper on the dynamical theory of diffraction, in which he showed that the plane of polarization must be perpendicular to the direction of vibration. Two years later he discussed the colours of thick plates; and in 1852, in his famous paper on the change of refrangibility of light, he described the phenomenon of fluorescence, as exhibited by fluor spar and uranium glass, materials which he viewed as having the power to convert invisible ultra-violet rays into rays of lower periods which are visible. A mechanical model, illustrating the dynamical principle of Stokes's explanation was shown in 1852, during a lecture at the Royal Institution, by Lord Kelvin, who said he had heard an account of it from Stokes many years before, and had repeatedly but vainly begged him to publish it. In the same year, 1852, there appeared the paper on the composition and resolution of streams of polarized light from different sources, and in 1853 an investigation of the metallic reflection exhibited by certain non-metallic substances. About 1860 he was engaged in an inquiry on the intensity of light reflected from, or transmitted through, a pile of plates; and in 1862 he prepared for the British Association a valuable report on double refraction, which marks a period in the history of the subject in England. A paper on the long spectrum of the electric light bears the same date, and was followed by an inquiry into the absorption spectrum of blood. The discrimination of organic bodies by their optical properties was treated in 1864; and later, in conjunction with the Rev. W. Vernon Harcourt, he investigated the relation between the chemical constitution and the optical properties of various glasses, with reference to the conditions of transparency and the improvement of achromatic telescopes. A still later paper connected with the construction of optical instruments discussed the then-advanced ideas in the theory of microscopical objectives. In other departments of physics may be mentioned his paper on the conduction of heat in crystals (1851) and his inquiries in connexion with the radiometer; his explanation of the light border frequently noticed in photographs just outside the outline of a dark body seen against the sky (1883); and, still later, his theory of the Röntgen rays, which he suggested might be transverse waves travelling as immutables solitary waves, not in regular trains. Two long papers published in 1849—one on attractions and Clairaut's theorem, and the other on the period of oscillations of the solar system—gave the definitive notice, as do his mathematical memoirs on the critical values of the sums of periodic series (1847) and on the numerical calculation of a class of definite integrals and infinite series (1856) and his discussion of a differential equation relating to the breaking of railway bridges (1849).

But large as is the tale of Stokes's published work, it by no means represents the whole of his services in the advancement of science. Many of his discoveries were not published, or at least were only touched upon in the course of his oral lectures. An excellent instance is afforded by his work in the theory of viscosity. In his presidential address to the Royal Society in 1851, Lord Kelvin (Sir William Thomson, as he was then) stated his belief that the application of the prismatic analysis of light to solar and stellar chemistry had never been suggested directly or indirectly by any other savant when Stokes taught it to him in Cambridge some time prior to the summer of 1852, and he set forth the conclusions, theoretical and practical, which he derived from Stokes at that time, and which he afterwards gave regularly in his public lectures at Glasgow. These statements, containing as they do the physical basis on which spectrum analysis rests, and the mode in which it is applicable to the identification of substances existing in the sun and stars, make it appear that Stokes anticipated Kirchhoff by at least seven or eight years. Stokes, however, in a letter published some years after the delivery of this address, stated that he had failed to take one essential step in the argument (not perceiving that emission of light of definite refrangibility not merely permitted, but necessitated, absorption of light of the same refrangibility), and modestly disclaimed "any part of Kirchhoff's admirable discovery," adding that he felt some scruples about the correctness of the cause, on the ground that he was not prepared to explain all the phenomena. Sir George Stokes, however, perhaps his most accomplished pupil, seems to have believed that Kirchhoff explained all the phenomena of spectrum analysis. In another way, too, Stokes did much for the progress of mathematical physics. Soon after he was elected to the Lucasian chair he announced that he regarded it as part of his professional duties to help any member of the university in difficulties he might encounter in his mathematical studies, and the assistance rendered was so real that pupils were glad to consult him, even after they had become colleagues, on mathematical and physical problems, in which they found themselves at a loss. Then during the thirty years he acted as secretary of the Royal Society he exercised an enormous if inconspicuous influence on the advancement of mathematical and physical science, not only directly by his own investigations, but indirectly by suggesting problems for inquiry and inviting men to attack them, and by his readiness to give encouragement and help.

Several of the honours enjoyed by Sir George Stokes have already been enumerated. In addition, it may be mentioned that from the Royal Society, of which he became a fellow in 1851, he received the Copley medal in 1857 and, after the recognition of his inquiries into the refrangibility of light, and later, in 1893, the Copley medal. In 1869 he presided over the Exeter meeting of the British Association. From 1838 to 1885 he was Burnett lecturer at Aberdeen, his lectures on Light, which were published in 1884-1887, dealing with its nature, its use as a means of investigation, and its beneficial effects. In 1891, as Gifford lecturer, he published a volume on Natural Theology. His
academic distinctions included honorary degrees from many universities, together with membership of the Prussian Order Pour le Mérite.

Sir George Stokes's mathematical and physical papers were published in a collected form in five volumes; the first three (Cambridge: 1880, 1883, and 1901) under his own editorship, and the two last (1913 and 1915) edited by Sir Joseph Larmor, who also selected and arranged the Memoir and Scientific Correspondence of Stokes published at Cambridge in 1907.

STOKES, WHITLEY (1830–1900), British lawyer and Celtic scholar, was a son of William Stokes (1804–1878), and a grandson of William Whitley Stokes (1763–1845), each of whom was regius professor of physic in the university of Dublin. In his day, William Stokes, who was the author of several books on medical subjects, was regarded by physicians in Europe. Educated at Trinity College, Dublin, young Stokes became an English barrister in 1855, and in 1862 he went to India, where he filled several official positions. In 1877 he was appointed legal member of the viceroy's council, and he drafted the codes of civil and criminal procedure and did much other valuable work of the same nature. In 1879 he was president of the commission on Indian law. He returned to England in 1882. In 1887 he was made a C.S.I., and two years later a C.I.E.; he obtained honorary degrees from many universities, and was a fellow of the British Academy. He died in London on the 13th of April 1909.

Whitley Stokes is perhaps most famous as a Celtic scholar, and in this field he worked both in India and in England. He studied Irish, Breton and Cornish texts, and among his numerous works may be mentioned editions of Three Irish Glossaries (1862); Three Middle-Irish Homilies (1877); and Old Irish Glosses at Würzburg and Carlsruhe (1887). He was one of the editors of the Frische Texte published at Leipzig (1880–1900); and he edited and translated Lives of Saints from the Book of Lismore (1890). With Professor A. Beecroft he wrote Urkundlicher Sprachkurs (1864). His principal legal work was The Anglo-Irish Code (1867).

STOKESLEY, JOHN (c. 1472–1539), English prelate, was born at Colly Weston in Northamptonshire, and became a fellow of Magdalen College, serving also as a lecturer. In 1498 he was made principal of Magdalen Hall, and in 1505 vice-president of Magdalen College. Soon after 1509 he was appointed a member of the royal council and chaplain to Henry VIII. In 1520 he was at the Field of the Cloth of Gold; in 1529 and 1530 he went to France and Italy as ambassador to Francis I. and to gain opinions from foreign universities in favour of the king's divorce from Catherine of Aragon. In 1530 he became bishop of London. In 1533 he christened the princess Elizabeth, and his later years were spent in controversy with Archbishop Cranmer. He opposed all changes in the doctrines of the Church and was very active in persecuting heretics. He was a man of learning, writing in favour of Henry's divorce, and with Cuthbert Tunstall, bishop of Durham, a treatise against Cardinal Pole. He died on the 8th of September, 1539.

STOLBERG, FRIEDRICH LEOPOLD, GRÄF ZU (1750–1819), German poet, the younger son of Count Christian Stolberg, was born at Bramstedt in Holstein on the 7th of November 1750. He studied in Göttingen and was a prominent member of the faculty of the 'Dichterbund'. After leaving the university he made a journey to Switzerland with his brother Christian, in company with Goethe. In 1777 he was appointed envoy of the prince bishop of Lübeck at the court of Copenhagen, but often stayed at Eutin, where he was the intimate associate of his college friend and member of the Dichterbund, Johann Heinrich Voss. In 1782 he married Agnes von Witzleben, whom he celebrated in his poems. After her early death in 1788, he became Danish envoy at the court of Berlin, and contracted a second marriage with the countess Sophie von Redern in 1789. In 1791 he was appointed president of the Lübeck episcopal court at Eutin; he resigned this office in 1800, and retiring to Minden in Westphalia, there joined, with his whole family, the eldest daughter only excepted, the Roman Catholic Church. For this step he was severely attacked by his former friend Voss (Wie ward Fritz Stolberg ein Unfreier? 1819). After living for a while (from 1812) in the neighbourhood of Bielefeld, he removed to his estate of Sondermühlen near Osnabrück, where he died on the 5th of December 1819. He wrote many odes, ballads, satires, and dramas—among the last the tragedy Timoleon (1784), translations of the Iliad (1778), of Plato (1756–1797), Aeschylus (1802), and Ossian (1806); he published in 1815 a Leben Alfreeds des Grossen, and a voluminous Geschichte der Religion Jesu Christi (17 vols., 1806–1818).

Stolberg's brother, CHRISTIAN, GRÄF ZU STOLBERG (1748–1821), was also a poet. Born at Hamburg on the 15th of October 1748, he became a magistrate at Tremsbüttel in Holstein in 1777, and died on the 18th of January 1821. Of the two brothers Friedrich was undoubtedly the more talented, but Christian, though not a poet of high originality, excelled in the utterance of gentle sentiment. They published together a volume of poems, Gedichte (edited by H. C. Boie, 1779); Schauspiele mit Chören (1787), their object in the latter work being to revive a love for the Greek drama; and a collection of patriotic poems Vaterländische Gedichte (1813). Christian von Stolberg was the sole author of Gedichte aus dem Griechischen (1782), a translation of the works of Sophocles (1787), and of a poem in seven ballads, Die weisse Frau (1814), which last attained considerable popularity.

The Collected Works of Christian and Friedrich Leopold zu Stolberg were published in twenty volumes in 1820–1825; 2nd ed. 1827. Friedrich's correspondence with F. H. Jacobi will be found in Jacobi's Briefwechsel (1825–1827); that with Voss has been edited by O. Hellinghaus (1891). Selections from the poetry of the two brothers will be found in A. Sauers Der Göttinger Dichterbund, iii. (Kritik der Deutsch Academical Literatur, vol. 50, 1896). See also T. Mengel, Der Graf F. L. Stolberg und seine Zeitgenossen (2 vols., 1862); J. H. Hennes, Aus F. L. von Stolbergs Jugendjahren (1876); the same, Stolberg in den zwei letzten Jahrzehnten seines Lebens (1873). J. c. und J. W. Graf zu Stolberg (2 vols., 1877), 2nd ed. 1882; W. Keiper, F. L. Stolberg's Jugendpoesie (1893).

STOLBERG, a town of Germany, in the Prussian Rhine Province, situated on the Vichtbach, 7 m. E. of Aix-la-Chapelle, on the main line of railway to Cologne. Pop. (1905), 14,965. It contains two Protestant and two Roman Catholic churches, a castle occupying the site of one said to have been used by Charlemagne as a hunting seat. It is the centre of a very active and varied industry, exporting its produce to all parts of the world. The leading branch is metal-working, which is here carried on in important zinc, brass, and iron foundries, smelting-works of various kinds, puddling and rolling works, and manufactories of needles, pins and other metal goods. The ore is mostly found in the mines around the town, but some is imported from a considerable distance. In or near the town there are also several chemical works, glass-works, a mirror-factory and various minor establishments. Extensive coal-mines in the neighbourhood provide the enormous supply of fuel demanded by the various industries. The industrial prosperity of the town was founded in the middle of the 17th century by French religious refugees, who introduced the art of brass-foundling.

STOLE (Lat. stola and orarium, Fr. stole, It. stola, Sp. estola, Ger. Stola), a liturgical vestment of the Catholic Church, peculiar to the higher orders, i.e. deacons, priests and bishops. It is a strip of stuff, usually silk, some 2½ yards long by 1 yard broad; in the middle and at the ends, which are commonly broadened out, it is ornamented with a cross. Its colour varies with the liturgical colour of the day, or of the function at which it is worn.

There is very little evidence as to the form and character of the stole before the Carolingian age; but from the 9th century onwards representations of the stole show that it varied in no essential particular from that of the present day. In the 11th, 12th and 13th centuries it was remarkably long and narrow. From the 9th to the 13th
century it was mostlly provided with a separate piece by way of finish to the ends, and this in the 12th and 13th centuries was as a rule trapeze-shaped. In the late middle ages the stole was usually of uniform breadth; but from the 16th century onwards the ends again began to be widened, until in the 18th century we have the hideous form with large shovell-shaped ends. Fringes, tassels, little bells and the like were used as decorations of the ends of stoles at least as early as the 9th century; but crosses in the middle and at the ends were rarely added during the middle ages. The usual material of medieval stoles was silk, and the better ones were embroidered with silk, gold thread, pearls, &c.

The stole is worn immediately over the alb; by deacons, scarlet-wise over the left shoulder, across the breast and back to the right side; by priests and bishops, dependent from the neck, the two ends falling over the breast. In the case of bishops, however, the stole always hangs straight down; while priests wear it crossed over the breast when vested in the alb. Essentially, the actual method of wearing the stole conforms to the original practice. During the middle ages there were, however, deviations of custom: e.g. priests, even according to the Roman use, did not wear the stole crossed over the alb, though this had been prescribed for Spain so early as 675 by the 4th canons of the council of Braga. In southern Italy, probably under Greek influence, and in Milan (where the custom still survives) the diaconal stole was put on over the dalmatic. Similarly in Spain and Gaul, anterior to the Carolingian age, the stole was worn by deacons over the alba or outer tunic.

According to the Roman use, the stole is now only worn at mass, in administering the sacraments and sacramentals, when touching the Host, &c., but not e.g. at solemn offices or in processions.

In the middle ages, however, it was the custom to wear it at nearly all liturgical functions. In the 9th and 10th century it was even made obligatory, by the decrees of the synods of Mainz (813) and Tribur (893), on priests throughout the Frank Empire to wear it at all times, especially when travelling. Elsewhere it was the custom to wear it always, at least for a year after ordination.

The custom of giving the stole to priests and deacons at their ordination is of great antiquity. So far as Spain is concerned there is evidence for its use in the decrees of the 4th council of Toledo (633), and for Rome that of the 8th century Ordo of Mabillon.

The present practice—according to which the bishop lays the stole over the left shoulder of the deacon, and crosses it over the breast of the priest—is already found in the pontificial of the 10th century.

There is no evidence to show when the stole was first used in the Western Church. In Gaul and Spain we already find it in the 6th century; our first evidence for its use in Rome is in the 8th century, which is however, of an earlier date and was not in use earlier. The mosaic in the apse of S. Vitale at Ravena, which has been taken to prove the existence of the stole in the first half of the 6th century, has no value as evidence, as the lower part of the figure of Bishop Ecclesius (see Vestments, fig. 2) was renewed in the 12th century. It is noteworthy that at Rome, until the 10th century, the stole was worn by the lower orders of the clergy also.

In the Eastern Church the stole (Gr. ἄφθορον, the diaconal stole, κεντρικήθηκον, the priestly stole; Slav. or, and epitrachil; Arm. or, Sury or; Nest. or; Cap. oration) and pasaškils) makes its appearance very early. The stole of the deacons is mentioned so early as the 4th and 5th centuries, the first instance being in the 22nd canon of the council of Laodicea, where it is mentioned specifically as the insignia of a deacon. Of a priestly stole we hear for the first time in the Theoria mystica (8th century). In the Maronite, Syrian, and Nestorian Churches subdeacons also wear the stole, and among the Maronites the lectors as well. There is very little evidence as to the character of the stole in the ancient Church of the East. The stole of priests and bishops, decorated with crosses, was worn originally in all rites as in the West, i.e. hanging in two loose bands over the breast; at the present day, according to the Greek rite, the two bands are firmly sewn together, while in the Armenian, Syrian and Coptic rites they have even been amalgamated into a single broad strip with an opening at the top for the head. Its ancient form has been retained only by the Nestorians, who wear it crossed over the breast. The diaconal stole was and continues to be worn usually hanging over the left shoulder, the ends falling straight down before and behind. Only the Copts and Armenians wear it scarlet-wise. Originally the diaconal stole would seem to have been made of a strip of folded linen, and it appears in the pictures of the 9th century as a narrow band ornamented with crosses. Later, it was often the habit to embroider on Greek diaconal stoles the words ΑΠΩΣΑΙΟΣ ΑΠΩΣΑΙΟΣ.

The question of the origin of the stole admits of no conclusive answer. It is certainly not derived from the antique stola, called tunica, as was formerly always held, nor yet from the prayer blanket or the Jewish torah. There is no very considerable doubt on the possibility of the derivation of the priest’s stole from the ancient neck-cloth (oratum) and of the diaconal stole from a sash used in the liturgy. A more reasonable theory seems to be that which suggests that, in the East, the stole was originally introduced as that which it was when it first appears in the 22nd canon of Laodicea, viz. a special liturgical mark of distinction for deacons, which in course of time was extended to all the higher orders. In all probability it was introduced straight from the East into Spain and Gaul. Rome also probably imported it from the same quarter, but weakened its significance by merely laying on it a cloth laid right under the shoulders. For St Peter, the bestowal of which at ordination was intended to express the fact that elevation to clerical office in the Roman Church was a sign of the bestowed of beneficence S. Petri and that the ordinands were undertaking with its consecration the duty of serving St Peter, i.e. the Roman Church.

Wherever the Reformation was introduced the stole was done away with, even when chasuble, alb and cope were retained. The reason being that it was the ensign of the major orders, which in the Catholic sense were rejected by the Reformers. 1 (J. B. A.)

STOLEN GOODS. In English law, various points of importance arise in connexion with chattels which have been the subject of larceny and have not been returned to the possession of their owner. The owner of the goods stolen has an action against the thief for the goods or their value. How far he is entitled to pursue his civil right to the exclusion of criminal prosecution does not seem very clear upon the authorities. In Midland Insurance Co. v. Smith (1851, L.R. 6 Q.B.D., 568), Mr Justice Watkin Williams said: "It has been said that the true principle of the common law is that there is neither a merger of the civil right, nor is it a strict condition precedent to such right that there shall have been a prosecution of the felon, but that there is a duty imposed upon the injured person not to resort to the prosecution of his private suit to the neglect and exclusion of the vindication of the public law; in my opinion this view is the correct one.2 Dealing with stolen goods by persons other than the thief, may affect the rights of sue and replevin either criminally or civilly. Two varieties of crime may arise from such dealings. (1) Receiving stolen goods knowing them to have been stolen, a misdemeanour at common law, is by the Larceny Act a felony punishable by penal servitude for fourteen years where the theft amounts to felony, a misdemeanour punishable by penal servitude for seven years where the theft is a

1 The stole was not one of the vestments prescribed by the rubrics of the first Prayer-book of Edward VI. (see Vestments). It is placed in the English Church of Edward VI. to the figure of the Host, and is worn on Fridays, thereby being covered by the scarf, a broad band of black silk, formerly part of the out f a cies of the dignified clergy and without liturgical significance. This vestment has some resemblance to the stole, in that it is worn round the neck and hung straight down in front over each shoulder. This resemblance led, during the 19th century, to a confusion of the two vestments. The scarf was narrowed into the black stole, sometimes ornamented with crosses embroidered in the sides, and the ends, and then worn in front, ornamented by coloured stoles, varying according to the church’s seasons. The stole, either black or coloured, is now almost universally worn by the English clergy, even where the ancient use of the stole has not been adopted. It may be noted that, whatever may be the case with the other reformed churches, it is unsafe to argue from the disuse of the stole in the Church of England that this was intended to some extent to indicate rejection of the Catholic sense, 3 unless this sense be taken to imply a necessary connexion with the doctrine of transubstantiation and the sacrifice of the mass. (W. A. P.)
misdemeanour, as in obtaining goods by false pretences. Recent possession of stolen property may, according to circumstances, support the presumption that the prisoner is a thief or that he is a receiver. The Prevention of Crime Act, 1871, made important changes in the law of evidence in charges of receiving. It allows, under proper safeguards, evidence to be given in the course of the trial of the finding of other stolen property in the possession of the accused, and of a previous conviction for any offence involving fraud and dishonesty. (2) Compounding theft, or thefei(tio (redempitio furti), that is, taking back stolen goods or receiving compensation on condition of not prosecuting, is a misdemeanour at common law. It need not necessarily be committed by the owner of the goods. Under the Larceny Act it is a felony punishable by seven years' penal servitude to take money or reward corruptly for helping to recover stolen goods without using all due diligence to bring the offender to trial. By the same act, to advertise or print or publish any advertisement offering a reward for the return of stolen goods, and using any words purporting that no questions will be asked, &c., renders the offender liable to a penalty of £50. This penalty must, by the Larceny (Advertisements) Act 1870, be sued for within six months, and the assent of the attorney-general is necessary. Various acts provide for the liabilities of pawnbrokers, publicans, marine-store dealers, and others into whose possession stolen goods come. Search for stolen goods can only be undertaken by a police officer under the protection of a search warrant. The law as to stolen goods, as far as it affects the civil rights and liabilities of the owner and third parties, is shortly as follows. As a general rule a purchaser takes goods subject to any infirmities of title. The property in money, bank-notes, and negotiable instruments passes by delivery, and a person taking any of these bona fide and for value is entitled to retain it as against a former owner from whom it may have been stolen. In the case of other goods, a bona fide purchaser of stolen goods in market overt (see Sale of Goods) obtains a good title (except as against the Crown) provided that the thief has not been convicted. After conviction of the thief the property reverts in the owner, and the court before which the thief was convicted may order restitution, except in the cases specially mentioned in the Larceny Act, i.e. the bona fide discharge or transfer of a security for value without notice and the fraudulent dealing by a trustee, banker, &c., with goods and documents of title to goods entrusted to him. After conviction of the thief the goods must be recovered from the person in whose hands they are at the time of the conviction, for any sales and resales, if the first sale was in market overt, are good until conviction of the thief. The protection given by market overt is unknown in Scotland. If the goods were obtained by false pretences and not by larceny, the question then is whether the property in the goods has passed or not, and the answer to this question depends upon the nature of the false pretences employed. If the vendor obtains possession of the goods with the intention by the vendor to transfer both the property and the possession, the property vests in the vendor until the vendor has done some act to discharge the transaction. But if there was never any such intention—if, for instance, the vendor delivers the goods to A.B. under the belief that he is C.D.—the property does not vest in the transferee, and the owner may recover the goods even from a bona fide purchaser.

In the United States the law as to stolen goods is regulated by statute in the various states, but the broad principles are practically in accordance with English law. The doctrine of market overt is not, however, acknowledged by any state. The purchaser from a thief gets no title as against the owner. One who buys goods from a factor who procured them by larceny is not protected by the Factors Act in New York (Soltau v. Gerdau, 119 N.Y. 350). To the same effect (Gentry v. Singleton (1904), 128 Fed. R. 679) is a purchase of cattle from a thief. The U.S. Supreme Court held, in an action of detinue to recover five negro slaves from England, supposed to be sold in market overt, which did not apply in the United States (Ventress v. Smith, 10 Peters 175). In Pennsylvania there is no market overt and a purchaser of personal property cannot get a good title from one without title by paying for it (1907, Heisley v. Economy Tool Co. 33, Pa. Super. Ct. 218). So in Maine (Combs v. Gorden, 59 Me. 111). In Massachusetts a sale of butter in the open market by one who had feloniously acquired possession of it did not transfer the property (Dame v. Baldwin, 8 Mass. 518). So held also in New York where horses stolen from there were sold in Canada, though a purchaser there is entitled to be reimbursed before delivering to the owner (Edgeley v. Bush, 81 N.Y. 193).

See also False Pretences; Larceny.

STOLICZKA, FERDINAND (1836–1874), Austrian palaeontologist, was born at Hochwald, in Moravia, in May 1836. He was educated at Prague and at the university of Vienna where he graduated Ph.D. He was encouraged to work at geology and palaeontology by Professor E. Sues and Dr M. Hoernes; and as early as 1859 he communicated to the Vienna Academy a description of some freshwater mollusca from the Cretaceous rocks of the north-eastern Alps. In 1861 he joined the Austrian Geological Survey, and in the following year he was appointed palaeontologist to the Geological Survey of India. In Calcutta the description of the Cretaceous fossils of Southern India was placed in his hands, and the publication of this great work which formed part of the Palaeontologia indica was commenced with the assistance of H. F. Forbes. In 1864 he died, prematurely, and completed in 1873. During the last ten years of his life he published geological memoirs on the western Himalayas and Tibet, and numerous papers on all branches of Indian zoology, from mammals to insects and corals. In 1873 he was selected as naturalist and geologist to accompany a mission despatched by the Indian government to Yarkand and Kashgar under Mr (afterwards Sir Douglas) Forsey. His health, which had been severely affected by his previous field work in India, proved unequal to the strain, and he died on the 19th of June 1874, at Shyok, in Ladak, while "returning loaded with the spoils and notes of nearly a year's research in one of the least-known parts of Central Asia." Memoir (with bibliography) by V. H. Ball, appended to Scientific Results of the second Yarkand Mission, 1886; Obituary by W. T. Blanford, Nature, July 9, 1874.

STOLP, or STOLPME, a town of Germany, in the Prussian province of Pomerania, on the Stolp, 10 m. from the Baltic Sea and 64 m. W. of Danzig on the railway to Stargard, and with branches to Stolpmünde and Neustettin. Pop. (1905), 31,154. The large church of St Mary, with a lofty tower, dating from the 14th century, the Renaissance castle of the 16th century, now used as a prison, and one of the ancient town-gates restored in 1872 are memorials of the time when Stolp was a prosperous member of the Hanseatic League. It was a Hanseatic church of St. Luka, founded in the 13th century, and now a town hall, and a church of St. Bismark. The manufacture of machinery, amber articles, tobacco and cigars, and bricks, with some iron-founding, linen-weaving, and salmon-fishing in the Stolpe, are the chief industrial occupations of the inhabitants, who also carry on trade in grain, cattle, spirits, timber, fish and geese. Stolpmünde, a fishing-village and summer resort, at the mouth of the river, is the port of Stolp.

Stolp, mentioned in the 11th century, received town rights in 1273. From the 14th to the 16th century it was a member of the Hanseatic League. Until 1637, when it passed to Brandenburg, the town was generally in the possession of the dukes of Pomerania.

STOMACH (Gr. στόμαχος from στόμα, a mouth), the bag-like digestive organ which in man is situated in the upper left part of the abdomen. See, for anatomical details, ALIMENTARY CANAL. For the diseases of the stomach in general see Digestive Organs; and for special forms Gastritis, Gastric Ulcer, Dyspepsia, &c.; also Abdomen (Abdominal Surgery).

Cancer of the Stomach is a common disease. It occurs for the most part in persons at or after middle life, and in both sexes equally. Its favourite situation is the outlet (pyloric cancer), where a hard, fibrous growth forms a contracting ring of the scirrhous variety. But when cancer attacks the inlet of the stomach, the tumour of the bulky epithelomatus variety. It often begins in the tissues of the end of the gullet, spreading downwards to the stomach. Chronic gastric ulcer is not unfrequently the starting point of cancer.
The symptoms of cancer of the stomach are apt to be indefinite (for many weeks or months). There may be long-standing complaints of "indigestion," which is sometimes made better, sometimes worse, by taking food. Then comes a feeling of discomfort, which may be localized by individuals, pointing with his finger to a spot somewhere behind the line of the breastbone. Difficulty and pain in swallowing may be complained of when the cancer is beginning to affect the oesophagus. In the intestinal region, the pyloric obstruction comes on after an hour or two after a meal—at the time that the partially digested food is trying to make its way into the small intestine. Much of the food remains in the stomach and, undergoing fermentation, becomes sour, offensive, and gives rise to unavoidable belching. Later on vomiting occurs. The vomiting may take place every two or three days, enormous quantities of undigested food and mucus vomiting being thrown up. And whilst the stomach is slowly filling up again after one of these uncontrollable emptyings, sudden and violent movements of the individual may cause the fluid to rise to an uncontrolled expel itself even before the vomited material becomes recognizable, though the symptoms are extremely suggestive. But later the vomited matter is blackened by blood which has escaped into the stomach from the ulcerated growth. The patient then rapidly loses flesh and strength, and a hard lump may be felt in the upper part of the abdomen.

A characteristic feature of cancer is the carrying of the epithelial cells (which compose the lining skin of the stomach) from the lining of the pyloric glands and in cancer of the stomach the secondary impalement of the glands may cause the formation of large masses between the stomach and the liver, which may press upon the latter and cause anemia and possibly death. This results in the pyloric obstruction to form also in the liver and they may cause the appearance of a bulging below the ribs on the right side.

Another characteristic of cancer is that it spreads far and wide, destroying itself by causing fibrous bands. These are sometimes erroneously spoken of as the "roots" of cancer, and in the case of cancer of the stomach they may fix it to the pancreas and other organs of the body. The formation of the lymphatic glands and the spreading of the growth into neighbouring organs, render the successful operative treatment of gastric cancer hazardous and disappointing. By the time a tumour has made itself recognizable the probability is that it is too late for the attempt to be made for its removal. But in many cases the patient prefers that the abdomen should be opened for exploration for a possible operation than that he should hopelessly give himself over to a disease which sometimes they are enabled to give great relief, though the removal of the growth itself is impracticable.

When the growth is at the cardiac end of the stomach, blocking the gutter and causing slow starvation, the abdomen may be opened, and, the stomach having been fixed to the surface-wound, a permanent opening may be arranged for the introduction of an adequate amount of food. In certain rare cases the whole of the stomach has been removed, the bowel being brought up and sutured to the end of the gutter.

In the case of pyloric cancer resection of the disease may be performed, the upper end of the intestine being afterwards joined to the middle of the stomach by a kind of short-circuiting operation. In certain rare cases the whole of the stomach has been removed, the bowel being sutured and tied with sutures. The abdominal cavity is then filled with the remaining portions of intestine, so that the food may find its way along the alimentary canal greatly to the relief of the symptoms of gastric dilatation.

In some early cases of pyloric cancer resection of the disease may be performed, the upper end of the intestine being afterwards joined to the middle of the stomach by a kind of short-circuiting operation. In certain rare cases the whole of the stomach has been removed, the bowel being brought up and sutured to the end of the gutter.

In the case of gastric dilatation from pyloric obstruction great relief may be afforded by washing out the viscera by means of a long rubber tube, a funnel, and a jug of hot water, as originally suggested by Adolf Kissenmaul.

Pyloric obstruction is an insidious narrowing of the gateway of the stomach or of the intestine is dealt with by dividing it longitudinally and then suturing the edges of the wound transversely. This ingenious operation widens the track at the expense of an unimportant portion of its length. In cases of great dilatation of the stomach with no obstruction to the outlet the sack of the walls may be gathered up by pleating and so permanently secured by suturing. Loretta’s operation for dilatation of the outlet of the stomach is the same (E. O.).

STONE, CHARLES POMEROY (1824-1887), American soldier, was born in Greenfield, Massachusetts, on the 30th of September 1824. He graduated at West Point in 1845, and in the Mexican War earned two brevets for distinguished conduct. In 1850 he resigned from the army; and in 1857-1861 he led a scientific expedition in the state of Sonora, Mexico. He re-entered the service in 1861, and became a brigadier-general, United States Volunteers, but the defeat of a detachment at Ball’s Bluff (Oct. 21, 1861) was attributed to him, and he was imprisoned for six months, being then released without any charge being brought against him. After serving for short periods in the latter stages of the war, he resigned his commission (Sept. 1864). He was engineer and superintendent of a mining company. In Virginia from 1865 to 1870, when he entered the military service of the khedive of Egypt, whose chief of staff and general aide-de-camp he became, with the rank of lieutenant-general and the title of "Ferik Pasha." He returned to the United States in 1883, and resumed his engineering work. He died in New York City on the 24th of January 1887.

STONE, EDWARD JAMES (1831-1897), British astronomer, was born in London on the 28th of February 1831. Educated at the City of London School, he obtained a studentship at King’s College, London, and in 1856 a scholarship at Queen’s College, Cambridge, graduated as fifth wrangler in 1859, and was immediately elected fellow of his college. The following year he succeeded the Rev. R. Main as chief assistant at the Royal Observatory, Greenwich, and at once undertook the fundamental task of improving astronomical constants. The most important of these, the sun’s mean parallax, was at that time subject to considerable uncertainty. From a discussion of the observations of Mars made in 1860 and 1862 at Greenwich and Williams-town, Melbourne, and Cape Point, he published (Mon. Not. R.A.S. xxii. 153), and in a further investigation in which he included the observations made in 1852, at the Cape of Good Hope, he obtained 8′045″ (Mem. of R.A.S., vol. xxxiii.). Confirmatory results were afforded by his discussion of the observations of the transit of Venus in 1769 which yielded the figure 8′017″ (Mon. Not. R.A.S. xxviii. 235). In 1865 he contributed a memoir to the Royal Astronomical Society on the constant of lunar parallax. He also determined the mass of the moon, and from a discussion of the Greenwich transit circle observations between 1851 and 1865 he deduced 12,441 stars to the 7th magnitude between the South Pole and 25° S. declination, which was practically finished by the end of 1878 and published in 1881. Shortly after the death of Main on the 10th of May 1878, Stone was appointed to succeed him as Radcliffe Observer at Oxford, and he left the Cape on the 27th of May 1879. At Oxford he extended the Cape observations of stars to the 7th magnitude from 25° S. declination to the equator, and collected the results in the Radcliffe Catalogue for 1890, which contains the places of 6424 stars. Stone observed the transit of Venus of 1874 at the Cape, and organized the government expeditions for the corresponding event in 1882. He was elected president of the Royal Astronomical Society (1882-1884), and he was the first to recognize the importance of the old observations accumulated at the Radcliffe Observatory by previous observers, Reber, Radcliffe, and Rigaud (Mon. Not. R.A.S., vol. lv.). He successfully observed the total solar eclipse of the 8th of August 1896 at Novaya Zemlya, and purposed a voyage to India for the eclipse of 1898, but died suddenly at the Radcliffe Observatory on the 9th of May 1897. The number of his astronomical publications exceeds 150, but his reputation depends mainly on his earlier work at Greenwich and his two great star catalogues—the Cape Catalogue for 1880 and the Radcliffe Catalogue for 1890.

STONE, FREDERICK (1798-1859), British painter, was born in Manchester, and was entirely self-taught. He was elected an associate of the Society of Painters in Water Colours in 1833 and member in 1843; and an associate of the Royal Academy in 1847. The works he first exhibited at the Academy were portraits, but
from 1840 onwards he contributed figure pictures, scenes from Shakespeare, scripture and sentimental subjects, many of which were engraved.

STONE, GEORGE (1708–1764), archbishop of Armagh, was the son of Andrew Stone, a London banker, and was educated at Westminster School and Christ Church, Oxford. Having taken holy orders his advancement in the Church was very rapid, mainly through the influence of his brother Andrew. Andrew Stone (1703–1773), who was five years older than George, became private secretary to the duke of Newcastle about 1729, and was for many years on the most intimate and confidential terms both with the duke and with his brother Henry Pelham. In 1734 he was appointed under-secretary of state, and he soon gained a position of great personal influence with George II. by whom he was made tutor to Prince George, afterwards George III. On the accession of the latter to the throne, Andrew Stone was appointed treasurer to Queen Charlotte, and attaching himself to Lord Bute he became an influential member of the party known as the king’s friends,1 whose meetings were frequently held at his house. He was, therefore, well able to promote the preferment of his brother George, who went on to become chaplain to the duke of Dorset when that nobleman became lord-lieutenant in 1731. In 1733 George Stone was made dean of Ferns, and in the following year he exchanged this deanship for that of Derry; in 1740 he became bishop of Ferns, in 1743 bishop of Kildare, in 1745 bishop of Derry, and in 1747 archbishop of Armagh. During the two years that he occupied the see of Kildare he was also dean of Christchurch, Dublin.

From the moment that he became primate of Ireland, Stone proved himself more a politician than an ecclesiastical. “He was said to have been selfish, worldly-minded, ambitious and ostentatious; and he was accused, though very probably falsely, of gross private vice.”1 His aim was to secure political power, a desire which brought him into conflict with Boyle, the Speaker of the Irish House of Commons, who had organized a formidable opposition to the government. The duke of Dorset’s reappointment to the lord-lieutenancy in 1751, with his son Lord George Sackville as secretary of state for Ireland, strengthened the primate’s position and enabled him to triumph over the popular party on the constitutional question as to the right of the Irish House of Commons to dispose of surplus Irish bishops, which then were maintained was the property of the Crown. But when Dorset was replaced by the duke of Devonshire in 1755, Boyle was raised to the peerage as earl of Shannon and received a pension, and other members of the opposition also obtained pensions or places; and the archbishop, finding himself excluded from power, went into opposition to the government in alliance with John Ponsonby. These two, afterwards joined by the primate’s old rival Lord Shannon, and usually supported by the earl of Kildare, regained control of affairs in 1758, during the viceroyalty of the duke of Bedford. In the same year Stone wrote a remarkable letter, preserved in the Bedford Correspondence (ib. 357), in which he speaks very despondingly of the material condition of Ireland and the distress of the people. The archbishop was one of the “undertakers” who controlled the Irish House of Commons, and although he did not regain the almost dictatorial power he had exercised at an earlier period, which had suggested a comparison between him and Cardinal Wolsey, he continued to enjoy a prominent share in the administration of Ireland until his death, which occurred in London on the 10th of December 1764.

Although this much-abused prelate,1 as Lecky calls him, was a firm supporter of the English government in Ireland, he was far from being a man of tyrannical or intolerant disposition. It was due to his influence that in the anti-tithe disturbances in Ulster in 1763 the government acted with conspicuous moderation, and that the movement was suppressed with very little bloodshed; he constantly favoured a policy of conciliation towards the Roman Catholics, whose loyalty he defended at different periods of his career both in his speeches in the Irish House of Lords and in his correspondence with ministers in London. Archbishop Stone, who never married, was a man of remarkably handsome appearance, and his manners were “eminently seductive and insinuating.” Richard Cumberland, who was struck by the “Polish magnificence” of the primate, speaks in the highest terms of his courage, tact, and qualities as a popular leader. Horace Walpole, who gives an unfavourable picture of private character, speaks of his later work on legislations that Stone possessed “abilities seldom to be matched”; and he had the distinction of being mentioned by David Hume as one of the only two men of mark who had perceived merit in that author’s History of England on its first appearance. He was himself the author of several volumes of sermons which were published during his lifetime.

STONE, LUCY [BLACKWELL] (1818–1863), American reformer, anti-slavery and woman’s-rights leader, was born in West Brookfield, Massachusetts, on the 13th of August 1818. Her father refused her the college education that she so eagerly desired, but she earned enough to carry her through Oberlin College, where she graduated in 1847. She immediately went on the lecture platform as an advocate of abolition and of woman’s rights, and her remarkable voice and commanding eloquence often held in check the most disorderly audiences. In 1845 she married Dr. Henry B. Blackwell (1824–1909), a prominent abolitionist and advocate of woman’s rights, who agreed that she should keep her maiden name; after 1870 he assisted her in the management of the Woman’s Journal of Boston, of which she became editor in 1872. She allowed her New Jersey property to be sold for taxes, and then published a pamphlet on “taxation without representation.” She campaigned for woman’s suffrage amendments in Kansas (1867), Vermont (1867), Michigan (1867), Colorado (1872) and Nebraska (1862). She died in Dorchester, Mass., on the 18th of October 1863. Her daughter, ALICE STONE BLACKWELL (b. 1857), carried on with her father’s work in Woman’s Journal after 1893, and in 1895–1905 edited the Woman’s Column.

Her husband’s sisters, ELIZABETH BLACKWELL (1821–1910) and EMILY BLACKWELL (1826–1910), were prominent physicians. The former graduated at the Geneva Medical College, Geneva, New York, in 1849, receiving the first physician’s degree granted to a woman in the United States, and studied in Philadelphia, in Paris and in London, where she began to practise in 1860. She died at Hastings on the 1st of June 1910. Emily Blackwell graduated at the Medical Department of Western Reserve University in 1854; in 1853, with her sister, she founded the New York Infirmary for Women and Children; and she was for many years dean of the Woman’s Medical College of the New York Infirmary which she and her sister established in 1865.

STONE, MARCUS (1840– ), English painter, son of Frank Stone, A.R.A., was trained by his father and began to exhibit at the Academy before he was eighteen; and a few years later he illustrated with much success books by Charles Dickens, Anthony Trollope, and other writers, friends of his family. He was elected an associate of the Royal Academy in 1877, and academician in 1887. In his earlier pictures he dealt with historical incidents, but in his later work he occupied himself chiefly with a particular type of dainty sentiment, treated with much charm, refinement and executive skill. One of his canvases is in the National Gallery of British Art. Most of his works have been engraved, and medals have been awarded to him at exhibitions in all parts of the world.

STONE, NICHOLAS (1586–1647), English sculptor and architect, was the son of a quarryman of Woodbury, near Exeter, and as a boy was apprenticed to Isaac James, a London mason. About 1603 he went to Holland and worked under the sculptor Hendrik de Keyser (1567–1621) and his son Pieter, and married his master’s daughter. Stone is said to have made the portico to the Westerkerk at Amsterdam. Returning to London about 1613 with Bernard Janssens (fl. 1610–1630), a fellow pupil, he settled in Southwark and obtained a large practice; in 1619 he was appointed master-mason to James I, and in 1626 to Charles I, and he died in London on the 4th of August 1647. Stone, whose work is associated with Inigo Jones’s introduction of Renaissance architecture into England, ranks as the great sculptor of his time and the rejuvenator of the art in England. He is best known by his monuments, notably those to Sir Francis Vere, the earl of Middlesex, and Francis Holles in Westminster Abbey; Sir Dudley Digges at Chilham church, Kent; Henry Howard, earl of Northampton, in Dover Castle (removed to Greenwich); Sir Thomas Sutton, at the Charterhouse (with Janssens); Sir Robert Drury at Hawestead church, Suffolk; Sir William Stonehouse at Radley church, Berkshire; Sir Thomas Bodley at Merton College, Oxford; Sir John Pope at Wroxton church, near Banbury; Sir Nicholas Bacon, in Redgrave church, Suffolk (with Janssens); Dr John Donne (winding-sheet), at St Paul’s Cathedral; and Sir Julius Caesar, in St Helen’s, Bishopsgate.

He had three sons: John (d. 1667), a sculptor; Henry (d. 1653)—commonly known as “Old Stone”—a painter, whose copies of Van Dyck were famous, and whose portraits of Charles I and others are in the National Portrait Gallery; and Nicholas (d. 1647), a sculptor, who worked under Bernini at Rome and left a sketch-book, which, with a note-book of his father’s (giving a list of his works between 1614 and 1641), is in the Soane Museum.

STONE, a market town in the western parliamentary division of Staffordshire, England, on the river Trent, 7 m. N. of Stafford by the North Staffordshire railway. Pop. of urban district (1901), 5980. Part of the walls and crypt remain of an abbey which dates from the foundation of a college of canons in 670. The tower of St Michael dates from the 12th, the church having collapsed in the previous year. Alleyne’s grammar school is a foundation of 1558. The chief industry is shoemaking, but matting, brewing and tanning are also carried on. At Bury Bank, on the hills to the north, an earthwork is traditionally considered to be the site of the capital of the Kingdom of Mercia; there are other works in the neighbourhood at Saxton Low.

STONE (O. Eng. ston; the word is common to Teutonic languages, cf. Ger. Stein, Du. steen, Dan. and Swed. sten; the root is also seen in Gr. στένη, pebble), a detached piece or fragment of rock. The word is thus applied to the small fragments scattered in the ground or on roads, to the water-worn pebbles of the seashore or river beds, and to the hewn, dressed or shaped rock used as a building material, with which this article deals. A qualifying word generally accompanies “stone” when the term is applied to pieces of rock cut to a particular size and shape and used for a specific purpose, e.g. “mill-stone,” “hearth-stone,” “grave-stone,” &c. The term “precious stone” is used of those minerals which, from their beauty of colour, &c., their rarity, and sometimes their hardiness, are valued for their suitability for ornaments (see Gems). The word is also often applied to many objects resembling a stone or pebble, such as the hardkerne of certain fruits, as of the cherry, plum, peach, &c., or the calcareous or concretion sometimes formed in the gall or urinary bladder or the kidneys (see Bladder Diseases and Kidney Diseases). The “stone” has been a common measure of weight in north-western Europe. In Germany the “Stein” was of 20 to 22 lb. In the British system of weights the “legal” stone, or “horseman’s” weight is of 14 lb avoirdupois; in weighing wool it was also of 14 lb, but is now usually 16 lb. The “customary” stone for fish or butcher’s meat is of 8 lb.

Building stone.—In selecting a stone for building purposes many important points have to be considered. The stone must be strong enough to bear the load placed upon it; it must be durable and weather well in the atmosphere of the district, and its colour and appearance need to be studied. It must further be ascertained whether a sufficient supply is available, and the price also must be taken into account; some difficulty is often experienced in obtaining a suitable stone at a moderate cost, and considerations of expense frequently have more to do with the choice of a stone than the architect would wish. Where there is risk of fire, as is often the case in business and factory premises, it is necessary to select a stone able to stand the effect of a great heat without damage. Great experience of the strength of stones and of their behaviour under fire is therefore necessary, but even when this knowledge is given and the greatest care is combined with it, some point may be overlooked. For example, the stone facing of the Houses of Parliament at Westminster was chosen on the recommendation of a committee composed of men of eminent scientific and technical skill; yet it has not weathered well because it is not constituted to resist the destroying effects of the London atmosphere.

The prime factor in the choice of a building stone should be the climate to which the material has to be exposed. Stone that in a pure country air will last for ever may quickly decay in an impure city atmosphere, or when subjected to the strong salt winds from the sea. Extreme of temperature, too, are generally speaking prejudicial to the life of stone, the alternations of heat and cold setting up movements in the substances of the stone, which, though slight, will in many cases hasten its disintegration. There are few materials which more quickly decay and fail than stone placed under unsuitable conditions. An analysis, made by E. G. Clayton, of a sample of incrustation found on the Portland stone masonry of St Paul’s Cathedral, London, gave the following result:

The deposit when reduced to a fine grey powder and placed under the microscope did not appear to contain any organic matter. Mr Clayton says that this test points to the fact that the principal constituent of limestones, namely calcium carbonate, has been changed into calcium sulphate by the action of sulphurous and carbonic acids ever present in the smoky London air. Impurities of this nature lodge on the face of the stone and are diluted and driven into the pores by subsequent rain. Having by their chemical action destroyed a portion of the substance of the material, they cause a slight surface to form which is easily washed off. Carbonates of lime and magnesia, the chief constituents of ordinary marbles and limestones, are very susceptible to the solvent action of these acids. Pure water has little or no chemical action upon most building stones, but a danger arises to a porous stone even when situated in pure air. Water will soak into some stones in considerable quantities, and in frosty weather this fact constitutes a serious risk. Clean water when placed in contact with the solid state exerts if checked an enormous pressure, and the face, and sometimes the bulk, of the stone is frequently damaged in this way. One of the best precautions that can be taken by an architect is that on the sills, etc., to examine the condition of the natural situation. This, of course, will give little clue to its behaviour in an impure atmosphere, and therefore, if the particular stone has been previously used in the same district, the buildings in which it has been employed should also be inspected. A hard and lasting stone will show the marks of the tooling, and the arrises of the blocks will be sharp and good, even after many years’ exposure.
The colour has a considerable bearing upon the selection of a stone, but this, although a very important matter, must give way before the question of durability. In large towns and manufacturing districts this is most emphatically the case, for within a few years the exterior of a building in such districts is disguised under a coating of soot and grime.

Should the stone contain iron, especially in the form of pyrites, there is a great likelihood of its being stained more or less deeply according to the acidity of the surrounding atmosphere, and this disfigurement is by no means confined to surfaces. It is also liable to be rusted through at any point, which will weaken and fissure the stone, especially in small particles throughout the mass the rusting may do no more harm than merely deepen the tone of the stone, but if present in large pieces the stain may be carried down to the lower parts of any structure built of such material. It is generally assumed that rusting is caused by an initial trickling of water from above, and that the stone is reconstituted and becomes hard and quite solid. Professor A. H. Church employed this method in arresting the decay of the frescoes in the Houses of Parliament. He used hot Baryta paste or Baryta water, the latter being a more rapid method of treatment by him in the same manner. Baryta is the name given to a siliceous preserving specially recommended for use upon the limestones from the Bath district. It may be applied in either water and to brick, tiles, terraces, etc. It does not materially change the appearance of the stone but enters the pores and prevents decay. Stonewall that is much decayed may be restored by this method. This water gradually evaporates and after some months the stone is so reduced to powder. The stone is restored to its original condition by mixing the powder with an acid which softens and reunites the molecules without decomposition. The invention is of French origin.

Some rusting from the quarry is found to contain a quantity of moisture called "quarry sap," on account of which all stones (even granite) are comparatively soft when first quarried. This water gradually evaporates, and after some months the stone, being exposed to the weather, becomes quite hard.

The hardest, least absorbent, and most compact and uniform stones are of ancient geological formation, and with time and increase in beauty the stone becomes more and more compact. The softer stones are of later formation, and are usually lighter in weight and more porous. A good stone should ring clearly when struck with steel, and a fresh fracture should on examination be found to be clouded with a fine layer of lime. But such material is liable to absorb water and to penetrate through it to the interior of the building in which it is employed.

The microscope is the best means of determining the structure of a stone. A stone consisting entirely of one mineral is the easiest to treat, but it is by no means one of the best stones. A stone consisting of a mixture of various minerals may prove exceedingly troublesome to treat, and to be of no little value in determining the nature of the stone and the best way of carrying out its treatment.

Preservatives.

On the Thames Embankment. This is an Egyptian method of preserving stones. It is the same method of preserving stones for some thousands of years with little deterioration on the spot from which it was removed. But since its erection in London it has been found necessary to coat it periodically with a preservative solution in order to check the rate of deterioration. Among the stones used in the London Embankment are granite, marble, and red sandstone. Similarly the Egyptian obelisk in Central Park, New York, U.S.A., has for some reason been treated with a preparation of paraffin containing creosote dissolved in paraffin oil, and a quantity of paraffin is often seen dripping down from the stone. The obelisk is made of Egyptian granite, but the surface of the stone is very rough and uneven, and the stone is covered with a thick deposit of scale. It is remarkable that the stone has not decayed at all.

The most usual method adopted for preserving stonework is to paint over the exposed surface with ordinary paint or whitewash, but this, though weather-proof, completely hides the natural beauty of the stone. The painting must be redone every four or five years. "Boiled linseed oil is sometimes used as a preservative, one coat being applied at a time in cleaning it. Its use deepens the colour of the stone, and unless very carefully done the work is apt to appear patchy. A large number of processes consist of coating the stonework with a solution of soluble silica. In Kühnmann's process a solution of silicate of potash or soda is brushed into the stone and, aided by the carbonic acid in the air, acts upon some of the constituents of the stone and forms a hard surface which is not liable to decay. In Rouselle's method the stone is heated in a furnace where the carbon dioxide in the atmosphere has been driven off by heat, after which the stone is coated with a solution of lime which fills the pores of the stone and binds its particles, together thereby checking decay. Barita will, when applied to limestone that has decayed owing to the action of sulphuric acid or other valuable preservative, and has a long lifespan, with the result that the stone is reconstituted and becomes hard and quite solid. Professor A. H. Church employed this method in arresting the decay of the frescoes in the Houses of Parliament. He used hot Baryta paste or Baryta water, the latter being a more rapid method of treatment by him in the same manner. Baryta is the name given to a siliceous preserving specially recommended for use upon the limestones from the Bath district. It may be applied in either water and to brick, tiles, terraces, etc. It does not materially change the appearance of the stone but enters the pores and prevents decay. Stonewall that is much decayed may be restored by this method. This water gradually evaporates and after some months the stone, being exposed to the weather, becomes quite hard.

The natural bed of a stone is that surface on which it was originally deposited. But volcanic and other disturbances may have occurred before the bed was laid down, and therefore it frequently happens that a horizontal plane does not coincide with the natural bed of stone as it rests in the ground, and the space which must be filled up to bring the building to the original condition of the ground at the base will have to be provided with a foundation. The method of providing a foundation is to build the floor of the building and to build all stones with their laminae quite level. Exceptions to this rule occur in the projecting stones of cornices and string courses, especially those with undercut members, such as a frieze, in which case the lie of the laminae can be maintained. In these cases the stones should be placed on edge with the laminae vertical, except of course at the angles of the building where the stone must be specially selected and laid on its natural bed. Limestones and sandstones are free from the difficulty of having wide planes of cleavage, giving deep beds which can be quarried in large blocks having no tendency to split in any particular direction, and are thus known as freestone.

Some material like this is found in the quarry to contain a quantity of moisture called "quarry sap," on account of which all stones (even granite) are comparatively soft when first quarried. This water gradually evaporates, and after some months the stone, being exposed to the weather, becomes quite hard.

Limestones consist chiefly of calcium carbonate with small proportions of other substances. They are often classified under four heads: Compact limestones consist of carbonate of lime, either pure or in combination with clay and sand. Granular or oolithic limestones consist of grains of carbonate of lime cemented together by the same substance or mixed with sand and clay. The grains are egg-shaped (hence the name "oolite") and vary in size from small granules to grains of shingle. Oolitic limestones contain almost entirely of small shells, cemented together by carbonate of lime; Magnesian limestones are composed of carbonates of lime and magnesia in varying proportions, and usually also contain small quantities of silicates of lime. "Dolomites" are formed by the decomposition of magnesian limestone. 15% of magnesia are not classed under this head. Dolomites are limestones containing equal proportions of carbonate of lime and carbonate of magnesia. Many of the finest building-stones are limestones containing calcium carbonate and magnesium. In England, the finest building-stones are Bedford stone, Portland stone and Kentish ragstone, and in America those from the states of New York, Indiana (Bedford quarry, light brown stone), Vermont (Vermont green stone, light grey, similar to Portland), Indiana (Indiana limestone, light and dark gray, light grey). Notable French limestones are obtained from the quarries at Peuren (cream), Château-Gaillard (white), Abrots, Normandoux (white), and Villars (grey). Indian stones have been used for a number of years for taking a fine polish. Limestones should be used with care as they are uncertain in their behaviour and usually more difficult to work than sandstones, and as a general rule they do not stand
STONE AGE—STONEHAVEN

action of fire well. On being treated with a dilute acid, limestones will effervescence and by this test they can often be identified. Limestone is usually stony and contains 100 lb and 166 lb per cubic foot. They vary in colour, but most of them are cream or yellowish brown. Marble is a limestone which has been changed by the action of heat and pressure. The crystalline material is replaced by one which is suitable for interior decoration, such as for columns, walls, lining, paving, etc., and in dry sunny climates they may be employed with great effect in external situations. They will take a high polish and are used for the purpose of inlarding and hardening them. The principal supplies of marble are drawn from italy, Belgium and France, but the marbles from Ireland and those from Devonshire and Derbyshire possess the required change of texture and colour, and are much in demand. America has few notable coloured marbles; most of the stones quarried are white or black. The states of Vermont (West Rutland and Sutherland Falls quarries), Tennessee and Alabama are the principal Quarries. (See Plaster.)

Sandstones are composed of grains of sand held together by a cementing substance to form a compact rock. The cementing medium may be silica, alumina, carbonate of lime or an oxide of iron. Those stones that have a siliceous cement are the most durable. Sandstones vary more in colour than limestones, the color being largely due to the presence of iron. Cream, brown, grey, pink, red, light and dark blue, and drab are common colours. Typical British sandstones are Corshill (red) from Dumfriesshire, the Friend (yellow) from Smithfield, Northumberland, and Forestdale (blue and grey) from Gloucestershire. In America sandstones are quarried in many states, principally Connecticut (brown stone), New York (Potsdam red stone), Ohio (Amherst Berea and other quarries), grey stone (Massachusetts), and meadow brown stone). The texture of sandstones varies from a fine, almost microscopical, grain to one composed of large particles of sand. It will generally be found that the heaviest, densest, and least porous stones are the most hard wearing. (See Plasterwork.)

Granites are igneous rocks formed by volcanic action and are of all geological ages. Granite is composed of quartz, felspar and mica intimately compacted in varying proportions to form a hard granular stone. Quartz is the principal constituent and imparts the rock the qualities of durability and strength. Stones containing a large proportion of quartz are hard and difficult to work. Felspar of an earthy nature is opaque in appearance and is liable to decay; it is therefore almost transparent. The characteristic colour of the granite is generally due to this substance, but the stone is often affected by the nature of the mica it contains, whether it be biotite or muscovite. Granite is gray, white, pink, red or drab. Some of the most durable of building-stones, and is difficult and costly to work. When polished, many varieties present a beautiful and lasting surface. By reason of its strength and toughness this stone is often used for foundations, bases, columns, kerbs and paving and in all positions where great strength is required. The granites from the Peterhead and Aberdeen districts of Scotland and from Cornwall and Devonshire in England are much used. In the United States good granites are quarried in Maine, Massachusetts, Minnesota, Canada, especially the eastern provinces, supplies many excellent varieties of granites. Much granite is also exported from Norway and Sweden. The Ragnorit (granites) of Sweden are probably the best varieties. True syenite consists of quartz, felspar and hornblende, the latter taking the place of mica. It obtains its name from a stone found at Syene in Egypt, but it has also been found in many other countries. Syenite is much used for building and in the metallurgical industry as it is thought to contain a higher percentage of mica. It is more hard and is more used for paving and road-metalling than for building purposes.

Stone—The slate used for roofing and other purposes in building is a fine-grained and compact rock composed of sandy clay which has been more or less metamorphosed by the action of heat and tremendous pressure. Such rocks were originally deposited in the form of sand, the sandstones afterwards being compacted by the continual heating up of superincumbent material. Owing no doubt to some sliding motion having at some time taken place, slaty rocks are capable of being split into thin slabs which are trimmed to the various marketable sizes. A good slate is hard, tough, and non-absorbing, will give out a metallic ring if struck, and when trimmed it will not splinter nor will the edges become ragged. Slaty range in colour from pink to grey. The best-known British slates are those of the Welsh and Westmorland quarries. In America good slate is found in the states of New York, Pennsylvania and Maine. (See also Roof.)

The principal varieties of artificial stone are those of the market, consisting of fine cement concrete placed to set in wooden or iron moulds. Artificial Stone—Although from an artistic point of view its use is not desirable, it is prepared with such care that its cheapness and durability have made it a useful addition to building materials. One of the best-known varieties is Victoria stone which is composed of finely crushed Mount Sorrel (Leicestershire) granite and Portland cement, carefully mixed by machinery in the proportions of three to one, and filled into moulds of the required shape. When the blocks are set hard the moulds are loosened and the blocks placed in solution of soluble soda for about two weeks for the purpose of inlarding and hardening them. Many manufacturers turn out a material that is practically non-porous and is able effectively to resist the corroding influence of sea air or the leaching action of rain and various solutions in the atmosphere.

(1.5 Bt.)

STONE AGE, the term employed by anthropologists to describe the earliest stage of human civilization when man had gained no knowledge of metals, and his weapons and utensils were formed of stone, horn or bone. The term has no chronological value, as the Stone Age was earlier in some parts of the world than in others, and even to-day races exist who are still in their Stone Age. This first period of human culture has been subdivided by Lord Avebury into Palaeolithic and Neolithic, words which have been generally accepted as expressing the two stages of the rough, unfinished and polished stone implements. (See Archaeology.)

STONE-FLY, the name given to medium-sized, neuropteron insects of the family Perlidae with long flexile antennae, wide thoracic sterna and with the wings resembling, as regards size, shape and the fan-like folding of the posterior pair, those typical of the Orthoptera except that the anterior pair is membranous and not coriaceous. The immature forms, which are aquatic, carnivorous, and unlike most other insects spend their larval life in the absence of wings and in their method of respiration, which is either cutaneous or effected by means of variously placed integumental tufts richly supplied with tracheae. By some authors the Perlidae are regarded as a special order, Plecoptera; by others as a sub-order of an order Platyptera, which contains the Termitidae and some other insects as well.

STONEHAVEN, a township of Middlesex county, Massachusetts, U.S.A. Pop. (1890), 6,155; (1900), 6,107; (1910, U.S. census), 7,090. Area, 66 sq. m. In the township is Spot Pond, a large lake with islets, so named in 1632 by Governor John Winthrop and a small town which was first discovered it; it is a storage basin for the Metropolitan Water District, and supplies Medford, Melrose and Stoneham. A large part (730 acres) of the Middlesex Falls Reservation of the Metropolitan Park System is in Stoneham. The village of Stoneham, with the only post office in the township, is about 9 m. north by east of Boston, and is served by the Boston & Maine railway and by inter-urban electric lines; it has a public library. Steam power was first used in the manufacture of shoes in Stoneham by John Hill & Co., who introduced many labour-saving devices, notably the heeling machine (1863). Stoneham, long a popular resort of solution of silicate of soda for about two weeks during the making of net, rope and twine and woolen manufactures. The harbour, a natural basin, is protected on the south-east by cliffs and has a quay. The trade is mostly in coal and lime and the exports are chiefly agricultural. The town is an important centre of the fishing industry, and has become a favourite watering-place. On the decay of Kincardine, the original capital, Stonehaven became the county town in 1600, and suffered heavily during the covenanating troubles, Montrose setting it on fire in 1645. The Sluag Road to Banchory-Ternan, or Upper Banchory (pop. 1473), 15 m. distant, is an attractive resort of solution of silicate of soda to Stonehaven. It pursues mainly a north-western direction, at one point being carried over the shoulder of Cairn mon-earn (1245 ft).
STONEHENGE (Sax. Stanhengist, hanging stones), a circular group of huge standing stones (see STONE MONUMENTS), situated on Salisbury Plain, Wiltshire, England, about 7 m. N. of Salisbury. Until comparatively recent times the surrounding district was in a state of nature with merely a thin coating of turf interspersed with tufts of heath and dwarf thistles, but bare of trees and shrubs and altogether devoid of the works of man, with the exception of a series of prehistoric barrows of the Bronze Age which, singly and in groups, stud the landscape. It is safe to say that no prehistoric monument in Great Britain has given rise to more speculation as to its origin, date and purpose; and although the few hoary stones still extant are but a small portion of the original structure they are still sufficiently imposing to excite the wonder of the passing traveller, and mysteriously enough to puzzle the antiquary.

Stonehenge was first mentioned by Nennius in the 9th century, who asserts that it was erected in commemoration of the 400 nobles who were treacherously slain near the spot by Hengist in 472. A similar account of its origin is given in the triads of the Welsh bards, where its erection is attributed to Aurelius Ambrosius, the successor of Vortigern. This was regarded as a miraculous feat brought about by the incantations of the magician Merlin, who caused a great stone circle in Ireland (said to have been previously carried thither out of Africa by giants) to be transported to Salisbury Plain, where, at Merlin’s "word of power," all the stones moved into their proper places. On the other hand, the Welsh bard Aneurin states that Stonehenge existed before the time of Aurelius, whose title of Ambrosius may, as suggested by Davies, have been derived from Stonehenge. Geoffrey of Monmouth, in recording the death of Constantine, which took place about the middle of the 6th century (Historia Briotum), states that he was buried "close by Uther Pendragon, within the structure of stones which was set up with wonderful art not far from Salisbury, and called in the English tongue, Stonehenge." Inigo Jones, in his work on Stonehenge, published in 1655, endeavours to prove that it was a "Roman temple, inscribed to Coelus, the senior of the heathen gods, and built after the Tuscan order." This theory was attacked by Dr. Charleton (1729), one of the physicians of Charles II., who maintained that it was erected by the Danes, and consequently after the departure of the Romans from Britain. The next Controversialist who appeared on the scene was the famous Dr. Stukely (1740) who propounded the theory that Stonehenge, the stone circle at Avebury (Abury), &c., were temples for serpent worship, "Dracoitia" as he called them, the serpent worshippers being the Druids. Subsequent writers dropped the opiate portion of this theory, but still continued to regard Stonehenge as a temple or observatory of the Druids. Lord Avebury regards it as a temple of the Bronze Age (1500–1000 B.C.), though apparently it was not all erected at one time, the inner circle of small unwrought, blue stones being probably older than the rest (Prehistoric Times). On the other hand James Ferguson (1875) contended that it was a sepulchral monument of the Saxon period.

The original number and position of the stones have suffered in the course of time from wind and weather, in days when archaeological interest was not alive to the importance of preserving so ancient a monument. That, however, these natural causes of its dilapidation were assisted by the sacrilegious hand of man there is no lack of documentary evidence. Thus Inigo Jones laments the disappearance of stones that were standing when he measured it; and both Stukely and Aubrey deplore the loss of fallen stones that were removed to make bridges, mill-dams and the like. On the evening of the 31st of December 1900, one of the outer trilithons (22 on plan), with its lintel, was blown down in the course of a severe storm, this being the first collapse since the 3rd of January 1797, when one of the fine trilithons (57, 58) of the horseshoe fell. This catastrophe attracted renewed attention to the state of Stonehenge, and much discussion took place as to the taking of precautions against further decay.

The annexed plan, which is that of Professor Flinders Petrie, shows the state of Stonehenge at the moment preceding the fall of the trilithon on the 31st of December 1900. Within a circular earthwork, 300 ft. in diameter and approached from the north-east by a road or avenue which can still be traced by banks of earth, is an outer circle of trilithons (100 ft. in diameter) formed by great monoliths (sarsens), originally thirty in number, with large lintel stones. About 9 ft. within this circle and concentric with it is another, formed of smaller "blue stones," originally forty in number, but only a few of which now remain in situ; within that was a horseshoe of five huge trilithons formed by ten monoliths with their imposts (all sarsens); and within the horse-shoe was an inner horseshoe of "blue stones," originally nineteen in number. The open part of the horseshoe exactly faces the sunrise at the summer solstice. Beyond the outer circle (not shown on plan) a great monolith—the sun stone, or so-called "Friar’s Heel"—standing on the axis of the horseshoe, marks the point where a spectator, centrally placed within the horse-shoe, would see the sun rise on the horizon at the solstice. On the circumference of the earthen circle or surrounding rampart (not shown on plan), which is here intentionally broken, a great recumbent stone—the slaughter stone—lies along the axis; and across the axis, near the central curve of the inner horse-shoe, lies a fine recumbent stone—the altar stone—15 ft. long.

Only half the outer circle (sarsens) now remained upright, three on the west, thirteen on the east; and this indicated the effect of the prevalent west wind. The fall of trilithon 22 and its lintel opened a larger path to the wind, and added to the danger of further destruction. Moreover, the narrow passages between the eastern monoliths had become worn by use into hollows which threatened their foundations. The acquisition of Salisbury Plain by the war office for military purposes seemed likely, again, to add to the risk of harm from thoughtless visitors. For all reasons an attempt to preserve Stonehenge was desirable; and the owner, Sir Edmund Antrobus, was willing, on certain conditions, as to limitations of access, to co-operate with the Society of Antiquaries, Wiltshire Archaeological Society and Society for the Preservation of Ancient Monuments in taking such steps as might be necessary to prevent more stones from falling, and even (if possible) to set up some which had fallen.

1 The ownership of Stonehenge having been questioned, Sir E. Antrobus’s legal title to it was confirmed by a lawsuit in 1905.
The societies advised that trilithon 6, 7, with linteled—whch had swayed round—and trilithon 56, which was leaning at a dangerous angle, should be examined with a view to replacement as little excavation as possible; that the monolith and lintel 22 be replaced, and its companion sarsen (21) secured; and that trilithon 57, 58, should be re-erected in its place, which was exactly known. Steps were taken to place the matter in the hands of engineering experts. On the 19th of September 1901 trilithon 56 was successfully raised to a perpendicular position. It then presented an imposing appearance, standing 21 ft. above ground; its total length was found to be 29 ft. 6 in., and its weight about 30 tons. The excavations were carried to a depth of 8 ft. 3 in. below surface, and many and varied objects were found, including chippings and lumps of the stones, stone tools, bones, and (in the upper strata) coins and fragments of pottery. Nearly 100 stone implements were excavated—axes, hammer axes, stone hammers and mauls—which, according to Dr Gowland, who superintended the work, had been used not only for breaking the rude blocks into regular forms, but also for working down their faces to a level or curved surface. No light was thrown, however, on the transport of the blocks.

Notwithstanding the many attempts, both by excavations and speculation, to elucidate the history of this unique monument, the archaeological data available are insufficient to decide definitely between the conflicting opinions held with regard to the date of its construction and the purpose for which it was originally intended. The finding of chips of "sarsens" and "blue stones" together "down to the bed of the rock" would seem to disprove the theory that the inner circle and inner horseshoe were built earlier than the rest of the monument. Dr Gowland at a meeting of the Society of Antiquaries (Dec. 19, 1901), read a paper on his recent excavations on the site of Stonehenge, in which he came to the conclusion that the structure was a temple dedicated to the worship of the sun, and he assigns its erection to the end of the Neolithic period (2000 to 1800 B.C.), on the ground that no bronze implements or relics were found during his explorations. It does not follow, however, from the fact that only stone tools were found at the bottom of the trenches that the monument was constructed when metal tools were unknown, because none of the Stonehenge tools have the characteristic forms of Neolithic implements, so that they might have been specially improvised for the purpose of roughly hewing these huge stones, for which, indeed, they were really better adapted and more easily procured than the early and very slightly metal tools of the Bronze Age. On the other hand, the recorded discovery of iron armour, Roman and British pottery and coins, together with the bones and horns of deer and other animals, is of little evidential value without a precise record of the circumstances in which they were found. Only one object, viz., an incense burner, seems to the present writer to have any chronological value, as it is an undoubted sepulchral relic of the Bronze Age.

That the sun on midsummer day rises nearly, but not quite, in line with the "avenue" from the Friar's Heel, has long been advanced as the chief argument in support of the theory that Stonehenge was a temple for sun-worship. On the supposition that this stone was raised to mark exactly the line of sunrise on midsummer's day when the structure was erected, it would naturally follow, owing to well-known astronomical causes, that in the course of time the direction of this line would slowly undergo a change, and that, at any subsequent date since, the amount of deviation would be commensurate with the lapse of time, thus supplying chronological data to astronomers for determining the age of the building. This is the explanation of the problem, has recently been attempted by Sir Norman Lockyer (Stonehenge, and other British Stone Monuments), who calculates that on midsummer day, 1680 B.C., the sun would rise exactly over the Friar's Heel, and in a direct line with the axis of the temple and "avenue." The above date he therefore considers to be the date of the erection of this great national monument, within a margin of possible error, on either side, of 200 years.

Looking at Stonehenge from the architectural standpoint, there can be no hesitancy in regarding it as an advanced representative of the ordinary stone circles, some hundred of which, great and small, are known within the British Isles. It is, however, differentiated from them all by having hewn stones, capstones, tenons and sockets. That its analogues were chiefly used as sepulchres has been fully established, and this is presumptive evidence that the sepulchral element was, at least, one of the objects for which Stonehenge was constructed: and it was probably for this reason that it was erected on Salisbury Plain, where there already existed an extensive necropolis of the Bronze Age. Nor would this by any means militate against its use as a temple for consecrating the dead, or for some other religious purpose.

Authorities.—Among numerous writings on Stonehenge may be mentioned Stonehenge and Abury, by Dr William Stukeley (1749; reprinted in 1840); Davies, Celtic Researches (1804), and Mythology of the Druids (1809); Hoare, Ancient Wiltshire (1812), vol. I.; Browne, An Illustration of Stonehenge and Abury (1823); Ferguson, Rude Stone Monuments (1872); Long, Stonehenge and its Barrows (1760); Gidley, Stonehenge viewed in the Light of Ancient History and Modern Observation (1877); W. M. Finders Petrie, Stonehenge: Plans, Descriptions and Theories (1886); E. T. Stevens, Jottings on Stonehenge (1882); Edgar Barclay, Stonehenge and its Earth Works (1895); Lockyer, Stonehenge and other British Stone Monuments, Astro- nomical Considerations on Prehistoric Time (1894). For a complete bibliography of Stonehenge see The Wiltsire Archaeological and Natural History Magazine (Dec. 1901), by W. Jerome Harrison.

STONEHENGEB, GEORGE (1822-1894), American soldier, was born at Busti, in Chautauqua county, New York, on the 8th of August 1822. He graduated at West Point in 1846, served as second lieutenant with the Mormon battalion in California during the Mexican War, and became a captain in 1855. In February 1861, while in command of Point Brown, Texas, he disregarded the orders of his superior officer, Major-General D. E. Twiggs, to surrender to the Confederate forces, and escaped with the garrison. He served on McClellan's staff during the West Virginia campaign, and was commissioned brigadier-general of volunteers and appointed chief of cavalry of the Army of the Potomac in August 1861, in which capacity he took part in the Peninsula campaign and the Seven Days' Battle. He commanded the III. corps in the Fredericksburg campaign; and was promoted, in November 1862, to be major-general of volunteers. During the Chancellorville campaign he made an unsuccessful cavalry raid toward Richmond. In the early months of 1864 he commanded the XXII. corps, and then, as commander of the cavalry of the department of the Ohio, took part in the Atlanta campaign. While attempting to seize the Confederate prison at Andersonville (July 31, 1864), he was captured at Clinton, Georgia. After his release in October he commanded cavalry in East Tennessee, making successful raids into Virginia and North Carolina, and on the 12th of April 1865 defeated a Confederate force near Salisbury, North Carolina, and captured a large number of prisoners. Afterward he held command in Tennessee and Virginia until 1868. He was mustered out of the volunteer service in September 1866, but served in the regular army as colonel and brevet-major-general till 1871. He then removed to California, was elected governor by the Democrats, and served from 1883 to 1887. In February 1891 he was made a colonel on the retired list, U.S. Army; and on the 5th of September 1894 died at Buffalo, New York.

STONE MONUMENTS, PRIMITIVE.—The raising of commemorative monuments of such enduring material as stone is a practice that may be traced in all countries to the remotest antiquity. By the Acts of Stonehenge and Nineveh, and the monumental erections of modern civilization are but the linear representatives of the unhewn monoliths, dolmens, cromlechs, &c., of prehistoric times. Judging from the large number of the latter that have still survived the destructive agencies (notably those of man himself) to which they have been exposed during so many ages, it would seem that the motives which led to their erection had as great a hold on humanity in its earlier stages of development as at the present time. In giving some
ide of the characteristics of these rude and primitive monuments in Britain and elsewhere it will be convenient to classify them as follows: 1) Isolated pillars, or monoliths (pierres, solitary, and â步入s, stone) of unhewn stones raised on end, are called menhirs (Cornish, monenhir, and Welsh maen, a stone, and hir, long). 2) When these monoliths are arranged in lines they become Stâges, or dolmen, (col, and Fr. ligne, a line), as at Ménec, Carnac (see Plate, fig. 5). 3) But if their linear arrangement be such as to form an enclosure (encontre), whether circular, oval or irregular, the group is designated by the name of cromlech (Gaëlic, crom, crooked, and leac, Welsh leekh, a flagstone), as at Carrowmore, Ireland (see Plate, fig. 4). 4) When the monoliths, instead of standing apart as in the previous structures, are placed close to each other and enclose an area sufficiently small and narrow to be roofed over by one or more capstones so as to form a rude chamber, the monument is called a dolmen (Breton, dalmen, from dol, a table, and men, Welsh maen, a stone). For illustrations of the dolmens at Keriaval and Kit’s Coty House (see Plate, figs. 1 and 2). This megalithic chamber is sometimes wholly embedded in a mound of earth or stones so as to present to outward appearance the form of a tumulus or cairn. As, however, there are many tumuli and cairns which do not contain megalithic chambers, it is only partially that these prehistoric remains come under the category of primitive stone monuments. In the rare instances of a dolmen being constructed of two single standing stones supporting a third, like the lintel of a door, as may be seen at Sceat-Comeg (Breton, Sceat-Kinmig), when the monument is called a trilithon (tripes, three, and â步入s, stone).

Menhirs.—Rude monoliths set on end appear to have been erected in all ages for a variety of commemorative purposes, such as on the accession of kings and chiefs, or to mark the site of a battle, a grave, or a boundary line, &c. Throughout the British Isles such standing stones are widely interspersed, especially in the less cultivated districts. In Scotland, when stones were used ceremonially in the act of crowning a king, they were called tanist stones, the most celebrated of which was the Lia Fail, formerly at Scone (now at Westminster Abbey), on which the kings of Scotland used to be crowned. We read also of haw or hoer stones, cambus or camus stones (cam, crooked), cat (caith), battle stones, witch stones, Druid stones, &c. The Hawk stane, or Saxum Falconis, at St Madoes, Perthshire, was erected in memory of the defeat of the Danes at Luncarty, and a monolith now standing on the field of Flodden is said to mark the place where King James fell. When menhirs were grouped together their number was often significant, e.g. twelve (Joshua iv. 5) or seven (Herod. iii. 8). Some standing stones are found to have been artificially perforated, and with these supernumerary holes associated are small sculptured stones of early Christian times so largely found in that locality. In England monoliths are often associated with the cromlechs or stone circles, as the King’s Stone at Stanton Drew, Long Meg at Little Salkeld, the Ring Stone at Avebury, &c. One of the finest British monoliths stands in the churchyard of Rudston, Yorkshire.

Menhirs are found in all countries which abound in megalithic structures. In France over 1600 isolated examples have been recorded, of which about the half, and by far the most remarkable, are within the five departments which constitute Brittany. Over the rest of France monoliths are generally smaller and not to be compared in size to those of Brittany. At Locmariquer, Morbihan, is the largest menhir in the world. It was in the form of a smooth-sided obelisk, but now lies on the ground broken into four fragments, the aggregate length of which amounts to 20-30 metres (about 67 ft.). It was made of granite foreign to the neighbourhood, and its weight, according to the most recent calculations, amounted to 347,531 kilogrammes, or 342 tons (L’Homme, 1885, p. 193). The next largest menhir is at Pôlisy (Côtes-du-Nord), measuring about 37 ft. in height. Then follows a list of sixty-seven gradually diminishing to 16 ft. in height of which the first ten (all above 26 ft.) are in Brittany. As regards form these menhirs vary greatly. Some are cylindrical, as the well-known pierre de champ-Dolent at Dol (height 30 ft.), and that of Cadifou in Finistère (28 ft.); while that of Penmarch (26 ft.) takes the shape of a partially expanded fan. A menhir of quartz at Mèdric (Ile-et-Vilaine) stands 165 ft. high in the form of a rectangular pillar indubitablet end. On the introduction of Christianity into France its adherents appear to have made use of these menhirs at an early period; many of them at present support a cross, and some a Madonna. While the scattered positions of some monoliths suggest that they were sometimes used as landmarks, or perhaps as places of rendezvous for hunters, the singular grouping of others shows that these were only secondary or subsidiary functions. So far as the Ogam inscriptions, found on some of the standing stones in Scotland, Ireland and Wales, have thrown light on the subject they appear to have been the headstones of graves. It is not uncommon to find a monolith overtopping a tumulus, thus simulating the bauta (grave or battle) stones of Scandinavia. Menhirs of all sizes are also met with in Algeria, Morocco, India, Central Asia, &c.

Alignments.—The most celebrated monuments of this class are to be seen in the vicinity of Carnac in Brittany. They are situated in groups at Ménec (see Plate, fig. 5), Kermario, Kerliscant, Erdeven and Ste Barbe—all within a few miles of each other, and in the centre of a district containing the most remarkable megalithic remains in the world. The first three groups are supposed by some archaeologists to be merely portions of one original and continuous series of alignments, which extended nearly 2 m. in length in a uniform direction from south-west to north-east. Commencing at the village of Ménec the menhirs extend in eleven rows. At first they stand from 10 to 13 ft. above ground, but as we advance they become gradually smaller till they attain only 3 or 4 ft. in height, and then cease altogether. After a vacant space of about 350 yards we come to the Kermario group, which contains only ten lines, but the menhirs are nearly of the same magnitude as those at the beginning of the former group. After a still greater interval we find a monolith apparently at the village of Kerliscant, having a similar position for some three centuries in time in thirteen rows. In 1881 M. Felix Gaillard, Ploumarmel, made a plan of the alignments at Erdeven, from which it appears that, out of a total of 1120 menhirs which originally constituted the group, 290 are still standing, 740 fallen, and 90 removed. The menhirs here may be traced for nearly a mile, but their linear arrangement is not so distinct, nor are the stones so large as those at Carnac. About 50 alignments are known in France. At Penmarch there is one containing over 200 stones arranged in four rows. However, others, are formed of only a single row of stones, as at Kerzdoudec, Leuré and Camaret. The width is 650 metres in length, and terminates in a southeasterly extremity in a kind of croix gammée. At Leuré three short lines meet at right angles. The third is situated on the rising ground between the town of Camaret and the point of Toulinguet. It consists of a base line, some 600 yards long, with 41 stones (others had apparently been removed), and two rectangular lines as short offsets. Close to it were a dolmen and a prostrate menhir. All these monoliths consist of a coarse quartz and are of small dimensions, only one, at Leuré, reaching a height of 0 ft. Alignments are also found in the regions flanking the Pyrenees, but here they are generally in single file—closely straight, but not perfectly parallel. The pyrene valley (Béhère) runs in a straight line from north to south for nearly
STONE MONUMENTS

300 yds. and contains 93 stones, some of which are of great size. At St Columb, in Cornwall, there is one called the Nine Maidens, which consists of eight quartz stones extending in a perfectly straight line for 262 ft. In Britain, however, the alignments are more frequently arranged in a double file, or in avenues leading to, or from, other megalithic monuments, such as still exist, or formerly existed, in connexion with the cromlechs or circles at Avebury, Stonehenge, Dartmoor, Shap, Callernish, &c. The stone circle at Callernish, on the island of Lewis, shows an unusually elaborate design with two parallel rows of upright stones running northwards and a single line across, thus presenting a cruciform appearance. A very tall menhir (17 ft. long) occupies the centre of the circle (42 ft. in diameter). The peat which in the course of ages had accumulated to a depth of 5 ft. was removed in 1858, and hence the characteristic features of this remarkable monument are well seen in the Plate, fig. 3. The only example in England comparable to the great alignments of Carnac is in the vale of the White Horse, in Berkshire. Here the stones, numbering about 800, are grouped in three divisions, and extend over an irregular parallelogram measuring from 500 to 600 yds. in length and from 250 to 300 yds. in breadth. Sir Henry Dryden describes several groups of alignments in Caithness, as at Garry- 

whin, Camster, Yarhouse, and the “Many Stones” at Clyth (Fergusson, Rude Stone Monuments, p. 326). Alignments in single and multiple rows have also been observed in Shetland, India, Algeria, &c.

Cromlechs.—In Britain the use of the word cromlech is vir-
tually synonymous with that of dolmen. In France, however, and especially in Ireland, a cromlech is applied to that class of monument for which in this country only the descrip-
tive name of “stone circles,” or “circles of standing stones,” is used. This application of the term in various countries to different classes of monuments has given rise to some confusion. The earliest known use of the word occurs in Bishop Morgan’s translation of the Bible into Welsh (1588), where “the clefts of the rocks” is rendered by cromlechyd y creigiau. Its earliest occurrence in the special sense in which it has continued to be used by British antiquaries is in a description of some ancient remains by the Rev. John Griffith of Llandyfain (1659), in which he says—“There is a crooked little cell of stone not far from Alaw, where according to tradition Bronwen Leir was buried; such little houses, which are common in this country, are called by the apposite name cromlechosa.” In this article the word cromlech retains its continental meaning and is exclusively used to indicate enclosures (encinctes) formed of rude monoliths placed at intervals of a few yards; and as such enclosures generally assume a circular, or oval, shape they are not infrequently described as stone circles. Rectangular enclosures are, however, not unknown, examples of which may be seen at Curcunno (Mornihan), near the well-known dolmen of that name, and at Saint Just (Ille-et-Vilaine). The former measures 32 by 27 yds., and is now composed of 22 menhirs, all of which are standing (some fallen ones having been restored by the government), while about a dozen appear to be wanting. A “donkey-shoe-shaped” enclosure has been described by Sir Henry Dryden in the parish of Latheron, Caithness, measuring 226 ft. long, 170 ft. wide in the middle, and 85 ft. wide at the two extremities. Stone circles are frequently arranged concentrically, as may be seen in the circles at Kenmore, near Aberfeldy, Porthkerris, as well as in many other Scottish, Irish and Scandinavian examples. More rarely one large circle surrounds inner groups without having a common centre, as at Avebury where the outer circle (1200 ft. in diameter) sur-
rounded two others each of which contained an inner con-
centric circle. The stone circle of Ballynoe, Co. Down, Ireland, consists of inner and outer (eccentric) circles; the former measures about 57 ft. in diameter with 22 stones, and the latter 105 ft. in diameter with 45 stones. At Boscanwen, in Cornwall, there is a group of circles confusedly attached and partially overlapping. Also, on the small island of Er-kanic (near the famous tumulus of Oarvinis), there is a double

cromlech (now partially submerged), the circles of which intersect each other. Cromlechs may also be connected by alignments or avenues, as already explained; and they are often associated with other megalithic monuments. Thus, at the end of the great Carnac alignments are the remains of a large circle which can be readily traced, notwithstanding that some houses are constructed within its area. In the British Isles and in the north of Europe they frequently surround dolmens (as at Carnac, Avebury, Ireland, and Brogar, near Penrith). Examples of a dolmen being surrounded by one or more circles have been recorded by M. Cartailhac from the department of Aveyron, in France. Outside the stone circle there is also frequently to be found a circular ditch as at Avebury, Stone-
henge, Arbor Low, Ring of Brogar, &c. The most remark-
able megalithic monument of this class now extant is Stone-
henge, which differs, however, from its congeners in having the stones of its outer circle partially hewn and attached by trans-
verse lintels. The largest cromlech in France was situated at the bottom of a hill near Kenmore, on 300 ft. in diameter, about the half of it being now destroyed by the encroachment of the houses. The remaining semi-circumference contains 36 menhirs, from 6 to 10 ft. high, and its diameter is about 328 ft. This cromlech, like so many English “circles,” was not circular but slightly elliptical. Only a few of the British cromlechs exceed these dimensions, among which may be mentioned Avebury (1280 by 1170 ft.), Stonehenge (outer circle 300 ft., inner 105 ft.), Stanton Drew (360 ft.), Brogar (345 ft.), Long Meg and her Daughters (350 ft.). One near Dunfries has 11 stones and 591 ft. in diameter, called the “Penrith Stone-circle.” However, more closely approaches what Fergusson calls the 100-metre size; but, generally speaking, the Scottish and Irish examples are of smaller proportions, rarely exceeding 300 ft. in diameter. That most of the smaller circles have been used as sepulchres has been repeatedly proved by actual excavations which showed that interments had taken place within their areas. It is difficult, however, to believe that this could have been the main object of the larger ones. At Mayborough, near Penrith, there is a circular mound entirely composed of an immense aggregation of small stones in the form of a gigantic ring and enclosing a flat area, on about 300 ft. in diameter. This space is entered by a wide aperture in the ring, and near the centre there is a fine monolith, one of several known to have formerly stood there. Of the same type is the Giant’s Ring, near Bel-

faston; but the ring in this instance is made of earth and it is considerably larger in diameter (580 ft.), while the central object is a fine dolmen. It is more probable that such enclosures were used, like many of our modern churches, for the double purpose of burying the dead and addressing the living.

Dolmens.—In its simplest form a dolmen consists of three, four, or five stone supports, covered with a stone cap, or capstone, or table. A well-known example of this kind in England is Kit’s Coty House (see Plate), situated between Rochester and Maidstone, which is formed of three large supports with a capstone measuring 11 by 8 ft. From this simple form there is an endless variety of structures till we reach the so-called Giant Graves and Grotes de Fés, which consist of numerous supports and several capstones. The dolmen of Bagneux, situated in the corner of a plantation on the outskirts of the town of Saumur, measures 18 metres in length, 6.50 in breadth and 3 in height. It is constructed of huge flagstones, 4 on each side, and 4 capstones—the largest capstone measuring 7.50 metres in length, 7 in breadth and 1 in thickness. Another near Essé (Ille-et-Vilaine) called La Roche aux Fés, is con-

structed of 30 supports and 8 capstones, including the vesti-

tule. Dolmens of this kind are extremely rare in the British 

Isles, the only one comparable to them in form being Calliag 

Birra’s House near Monasterboice, Ireland, which consists of 4 capstones supported by 4 or 5 thin stones on edge to form each side, and one stone closing one end. Owing to its small size (12 ft. long by 4 wide) this monument is disappointing in appearance. These free standing megalithic chambers, generally known as allées couvertes, as well as many other examples of the

simple dolmens, show no evidence of having been covered over with a mound. When there was a mound, it necessitated in the larger ones an entrance passage which, like the chamber, was constructed of a series of side stones and capstones. Some archaeologists maintain that all dolmens were formerly covered with a cairn or tumulus—a theory which undoubtedly derives some support from the condition of many examples still extant, especially in France, where they may be seen as it were, in its original state of denudation. Were the soil and stones which compose the tumulus of New Grange, Ireland, removed, leaving only the large stones which form its entrance passage and central chambers, there would be exposed to view a very imposing megalithic structure, not unlike the group of monoliths at Callernish in the Lewis (see Plate, fig. 3). The allées couvertes of France, Germany and the Channel Islands had their entrance at the end; but, on the other hand, those of the Drente, in Holland (Hunebedden), had both ends closed and the entrance was on the side facing the sun. The covered dolmens are extensively variable in shape—circular, oval, quadrangular and irregular being forms commonly met with; and as to size they range from that of an ordinary barrow up to that of New Grange, which rises in the form of a truncated cone to a height of 70 ft. with a diameter of 315 ft. at the base and 120 ft. at the top. Around its base was a circle of some thirty rude monoliths, placed about 10 yds. apart, and forming a circumference of 1000 ft.—only a few of these mounds are now in situ. The entrance passage to the interior of this huge tumulus measures about 63 ft. long, 4 ft. 9 in. high, and 3 ft. 6 in. wide, and discloses some large blocks of stone in the construction of chambers, a measure 26 ft. long, 21 ft. broad and 13 ft. high in the middle. The entrance gallery may be attached to the end of the chamber, as in the Grotte de Gavrinis, or to the side, as in the Giant’s Grave at Oem near Roskilde. In other instances there is no distinct chamber, but a long passage gradually widening from the entrance; and this may be bent at an angle, as in the dolmen du Rocher (Morbihan). Again, there may be several chambers communicating with one entrance passage; or, two or three chambers, having separate entrances, may be imbedded in the same tumulus. A curious specimen of the former may be seen in a ruined tumulus near St Heller, Jersey; and an excellent example of the latter is the partially destroyed tumulus of Rondosee, near Plouharrel railway station, which contains three separate dolmens. That such variations are not due to altered customs, in consequence of wideness of geographical range, is shown by de Mortillet, who gives plans of no less than 16 differently shaped dolmens (Musée préhistorique, pl. 58), all within a confined district in Morbihan.

Ruined dolmens are abundantly met with in the provinces of Hanover, Oldenburg and Mecklenburg. At Riestedt, near Uelsen in Hanover, there is, on the summit of a tumulus, a measures 40 ft. long and 6 ft. wide. Another at Naschendorf, near Weimar, consists of a mound surrounded by a large circle of stones and a covered chamber on its summit. Remains of a megalithic structure at Rudenbeck, in Mecklenburg, though now very imperfect, show that originally it had been constructed like an allée couverte. It had four supports on each side, two at one end (the other end being open and forming the entrance), and two large capstones. The length in its completed state was about 20 ft., breadth 7 1/2 ft., and height from the floor to 3 1/2 under surface, that of the wall 1 1/2 ft. According to Bonstetten, no less than 200 of these megalithic monuments are distributed over the three provinces Lüneburg, Osnabrück and Stade; and the most gigantic examples in Germany are in the duchy of Oldenburg. In Holland, with one or two exceptions, they are confined to the province of Drente, where between 50 and 60 still exist, under the name of Hunebedden (Huns’ beds). The Borger Hunebed, the largest of the group, is 70 ft. long and 14 ft. wide. In its original condition it contained 45 stones, ten of which were capstones. All the Drente monuments are now denuded, but a few show evidences which suggest that they had formerly been surrounded by a mound containing an entrance passage. Only one dolmen has been recorded in Belgium; but in France their number amounts to 3000-4000. They are irregularly distributed over 78 departments, no less than 618 being in Brittany. In the centre of the country they are also numerous, some 435 having been recorded in Aveyron; but here they are of much smaller dimensions than in Brittany. From the Pyrenees these rude stone monuments are sparsely traced along the north coast of Spain and through Portugal to the Atlantic, and the Pyrenees, in considerable numbers, but of their precise numbers and distribution we have no trustworthy accounts. According to Cartailhac (Âges préhistoriques de l’Espagne et du Portugal, p. 152) 118 were recorded up to 1870 under the name of antas. Many of them are in the form of free standing dolmens and allées couvertes. The most remarkable monument of this kind in Spain, and certainly one of the finest in Europe, is that near the village of Antequera, some distance north of Malaga. The chamber, slightly oval in shape, measures 24 metres long, 6-75 metres broad, and from 2-70 metres to 3 metres high. The entire structure comprises 37 monoliths—ten on each side, one at the end and five on the roof. Moreover, the roof is strengthened by three pillars placed along the middle line at the widest part of the chamber. The huge stones are made of the Jurassic limestone of the district and, like those of Stonehenge, appear to have been partly dressed. The entire structure was originally, and still is partially covered by earth, which formed a mound about 100 ft. in diameter. In Africa dolmens are found in large groups in Morocco, Algeria and Tunis. General Faidherbe writes of having examined five or six thousand in the cemeteries of Tesson, Mezzouq, l’Oued Berda, Tébessa, Gastal, &c. (Congrès international d’anth. et d’arch. préhist., 1872, p. 408). In the Channel Islands every kind of megalithic monument is met with. At Mont Cochon, near St Heller, there was lately discovered in a mound of blown sand an allée couverte and, close to it, a stone circle surrounding a small dolmen. In the British Isles dolmens are common in many localities, particularly in the west of England, Anglesey, the Isle of Man, Ireland and Scotland. In the last named country they are not, however, the most numerous and striking remains among its rude stone monuments—the stone circles and cistred cairns having largely superseded them. No dolmens exist in eastern Europe beyond Saxony. They reappear, however, in the Crimea and Circassia, whence they have been traced through Central Asia to India where they are widely distributed. Similar structures have also been recognized by travellers in Palestine, Arabia, Persia, Australia, Madagascar, Peru, &c. The irregular manner in which these megalithic monuments are distributed along the western parts of Europe bordering on the seashore has led to the theory that they were erected by a special people, but as to the when, whence and whither of this megalithic race we have no knowledge whatever. Although the European dolmens, however widely apart they may be situated, have a strong family likeness, yet they present some striking differences in certain localities. In Scandinavia they are confined to Danish lands and a few provinces in the south of Sweden. In the former country the exposed dolmens are often placed on artificial mounds and surrounded by cromlechs which are either circular (runddysser), or oval (langdysser). In Sweden the soppulcre à galerie is very rarely entirely covered up as in the Giant graves of Denmark.

In the absence of historical records and scientific investigations it was formerly the custom to group all these different varieties of primitive stone monuments as of Celtic origin. By some they were supposed to have been constructed by the Druids, the so-called priests of the Celts; and hence they have been described, especially since the time of Aubrey and Stukeley, under the name of Celtic or Druidical monuments. But from more recent researches there can be no doubt that the primary object of this class of remains was sepulchral, and that the megalithic chambers with entrance passages were used as family vaults. Against the theory that any of them were ever used as altars, there is prima facie evidence in the care taken to have
the smoothest and flattest surface of the stones composing the chambers always turned inwards. Moreover, cup marks and other primitive markings, when found on capstones, are almost invariably on their underside, as at the dolmens of Kerival, Keravo and Dol ar Marchant. Also, all the six stones forming the three-sided chamber of the great tumulus of Gavr'în (Morbihan) and most of those in the sides of its long entrance passage (44 ft.), are elaborately sculptured with primitive incised patterns, perfectly analogous to those on the walls of the chamber of New Grange (Ireland). From its position in the centre of a large circular enclosure, as uniformly even as a garden lawn, no dolmen could be more suggestive as a place of great magnificence. Within the tumulus itself, yet nothing could be more inappropriate for such a purpose that its capstone, which, in fact, is nothing more than a large granite boulder presenting on its upper side an unusually rounded surface.

No chronological sequence has been detected in the construction and evolution of these primitive stone monuments; nor can their existence and special forms in different countries be said to indicate contemporaneity. The dolmens of Africa are often found to contain objects peculiar to the Iron Age, and it is possible that in some parts of India the people are still in the habit of erecting ménhirs, cromlechs, dolmens and other megalithic monuments. Scandinavian archaeologists assign their dolmens exclusively to the Stone Age. It would appear that, subsequent to the great chambered cairns of the Stone Age, a period of degradation in this kind of architecture occurred in Britain when the Bronze Age barrows replaced the dolmens, and these again gave way to simple burial in the earth. In Scandinavia the megalithic chamber seems to have been discarded in the Iron Age for burials, either by cremation or inhumation under huge tumuli, as may be seen in the three great mounds of Thor, Odin and Freya at Garla Uppeberg and the ship-barrow at Gokstad on the Sandeford, the scene of the discovery of the Viking ship now exhibited in the museum at Christiania.

Just on the borderland between the works of nature and art comes the so-called Rocking-Stone (Logan, or Loggan, stone, French, Pierre branlante), which usually is nothing more than an erratic, ice-transported boulder, poised so nicely over a rocky bed that gentle pressure with the hand may cause it to rock or oscillate. Such stones appear to be sparsely distributed over the island, often found in areas occupied by the artificial grave monuments, and, being very large, they were pre-eminently calculated to awaken astonishment in the minds of the worshippers of the mysterious works of nature. Hence the important position assigned to them in the Druidical worship invented by Stucly and other antiquaries of the 18th century. Some rocking-stones are evidently artificial, having had the rock cut underneath them, leaving in each a pivot-like prominence on which the block rests; but, on the other hand, natural causes can produce similar results, the stone itself acting like an umbrella to protect the central portion of the bed while weathering outside is going on all around. The same process is often well illustrated on moraine-bearing glaciers where a huge stone may be seen resting on a pillar of ice several feet in height. That man sometimes imitated such striking natural phenomena is quite probable, and to this extent rocking-stones come within the category of primitive stone monuments.

STONE RIVER, BATTLE OF, a battle of the American Civil War, called the battle of Murfreesboro by the Confederates, fought on the 31st of December 1862 and the 2nd of January 1863. After his appointment in October to command the Army of the Cumberland, General W. S. Rosecrans with Chattanooga as his objective moved from Nashville upon General Braxton Bragg, who left the winter quarters he had established at Murfreesboro and met the Union army on Stone river immediately north of Murfreesboro, on the last day of December. The plan of attack on each side was to crush the enemy's right. Bragg's left, commanded by Lieut.-General W. J. Hardee, overlocked and bore back the Union right under Major-General A. McD. McCook, and Major-General T. L. Crittenden commanding the Union left was hurriedly called back from his attack on the Confederate right to support McCook. The Union right was crumpled up on the centre, where Major-General G. H. Thomas's division recovered the lost ground with the loss of 8540, General Bragg's right attempting in vain to displace Crittenden's division on high ground above the river. On the night of the 3rd Bragg withdrew and the Union army occupied Murfreesboro. Tactically a drawn battle, Stone River was strategically a Union victory. The losses on both sides were heavy: of 37,712 Confederates present for duty, 1294 were killed, 7945 were wounded, and about 2500 were missing; and of 44,860 Union forces present for duty, 1677 were killed, 7543 were wounded and 3680 were missing.

STONINGTON, a township of New London county, Connecticut, U.S.A., in the S.E. corner of the state, on Long Island Sound. Pop. of the township (1800), 8340 (of whom 1668 were foreign-born), (1910), 9154, including that of the borough of Stonington, 2083. Stonington is served by the New York, New Haven & Hartford railway, which has repair shops here, by an electric line connecting with New London, Conn., and Westerly, Rhode Island, and, in summer, by steamer to Watch Hill and Block Island. Its harbour is excellent, and it is a port of entry, but its foreign trade is unimportant. On the north is a large island, which, with the town covered with woods, covers an area of about 45 sq. m., and includes besides the borough of Stonington, the villages of Mystic, Old Mystic and Pawcatuck (which is closely allied with Westerly, Rhode Island). Among the manufactures of the township are foundry and machine-shop products, printing presses, silk machinery, fertilizers, spools, thread and cotton, and woollen, silk and velvet goods. Ship building and fishing are among the industries. After its settlement in 1649 and the years immediately succeeding by English planters from Rehoboth in Plymouth Colony (to whom a monument was erected in 1886 in Weathersfield, Connecticut), the town covers an area of about 45 sq. m., and includes, besides the borough of Stonington, the villages of Mystic, Old Mystic and Pawcatuck (which is closely allied with Westerly, Rhode Island). Among the manufactures of the township are foundry and machine-shop products, printing presses, silk machinery, fertilizers, spools, thread and cotton, and woollen, silk and velvet goods. Ontario, and Western railways. Other villages in the township are Grassy Point, where, as in Stony Point, brick-making is the principal industry; Tomkins Cove, where there are stone crushing works; and Jones Point, which has a trade in gravel, building sand and crushed stone. The surface of the township is rough—Dunderberg (1000 ft.) and Bear Mountain (1350 ft.) are the principal eminences, and there is good farming land only at the margin of the river. The township was named from a rocky promontory which juts into the river in the north-east part of the township and rises precipitously on all sides to a height of about 140 ft. above the river. A small part of the promontory is under the jurisdiction of the United States Government which has erected a lighthouse here, and the remaining portion was bought by the state in 1897 for a state battlefield reservation, and has been laid out as a public park. At the entrance to the park is a Memorial Arch (1900), designed by H. K. Bush-Brown and presented to the state by the Daughters of the American Revolution. On Iona Island in the north part of the township is a United States naval magazine. The promontory guards the lower passage to the Highlands of the Hudson, and during the War of Independence, as when the King's Ferry between it and Verplanck's Point was taken, the battle of the “Block House” was an important line of communication between the New England and the Middle States, it was of considerable strategic importance. The Americans occupied it in November 1776, and about two years later erected a blockhouse upon it. The garrison, however, was very small, and on the 31st of May 1779, it was taken by the British, who immediately erected much stronger fortifications. On the night of the 15th/16th of July it was recovered by General Anthony Wayne, in command of about 1350 picked American troops, the garrison (under Lieut.-Colonel Henry Johnson) losing 63 in killed, 70 in wounded, and 543 in captured. The American loss was only 15 killed and 83 wounded. The Americans, however, had no thought from the first of holding the place, and evacuated it on the 18th of July. The British immediately recaptured it, and erected stronger fortifications, but late in October they, too, abandoned it. In the “old Treason House” in the township General Benedict Arnold and Major John André met before daylight on the 22nd of September 1780, to set up plans for the surrender of West Point by Arnold to the British.

STOOL, a low seat without back or arms. The stool is an ancient piece of furniture which came into use when the need began to be felt for a seat more easily portable than heavy settles and benches—the chair was an appanage of rank and dignity to which no ordinary person dreamed of aspiring. Since it could also be used as a small table, it quickly became common. In the First Book of The Task William Cowper gives a sketch of the evolution of the stool which, for all its simplicity, is reasonably exact:

“Joint stools were then created, on three legs
Upbore they stood. Three legs upholding firm
A cassock-thigh, in fashion square round.

*  *  *  *  *  *  *

At length a generation more refined
Improved the simple plan; made three legs four,
Gave them a twisted form vermicular.
And o'er the seat, with plenteous wadding stuff'd,
Induced a sort of cover, green and blue.
And yellow and, of tap'stry richly wrought,
And woven close, or needle-work sublime.”

ii Joint” or “joyned-stool” simply meant that the parts were joined or framed together with mortise and tenon. The wooden four-legged, square or oblong variety is often called a “coffin-stool.” It may be perfectly true that it was once supposed a coffin, but the author thinks it a very occasional one—of many uses, and the name is an entire misnomer. The round three-legged stool was a primitive construction, destined of ornament and rudely, as well as heavily, made. By the middle of the 16th century stools had acquired four legs, braced together by stretchers, and the frame was often well carved. As the Renaissance impulse waned, forms relapsed into cumbrous and unadorned, and, so far as the oak stool of the yeoman and the farmer was concerned, little ornamentation was attempted after the middle of the 17th century. These seats continued to be made until about the end of that period—until, indeed, the increasing cheapness of the chair and the growth of habits of comfort caused it to fall into disuse. Towards the end of the Stuart period the upholstered stool reached England from France. It was not entirely unknown at an earlier date, but what had been an occasional luxury then became a common plenishing of the houses of the rich. The legs and stretchers took the “twisted form vermicular” of which the poet speaks—so far as their underframing was concerned these stools were, to all intents and purposes, chairs. Thenceforward, indeed, they followed very closely the fashions in seats with backs, acquiring the cabriole leg, the claw and ball or pad feet, the carved knees and other characteristics of chairs. The footstool is probably more ancient than the stool itself. The ducking-stool was a contributory result of the wife's sciences, and the chair in a pond without danger. The stool of repentance was reserved, chiefly in Scotland, for the public penance of persons who had offended against morality. The “cutty-stool,” which Jenny Geddes threw—or, according to Dr Hill Burton, did not throw—at the beginning of the riotous protests against Laud's Liturgy in St Giles's Church, Edinburgh, in 1637, was of the fauld-stool variety. “Cutty” simply means short. A fauld-stool was originally a folding stool used chiefly for ecclesiastical purposes. Eventually, while retaining the old name, it became rigid, and the designation has now been extended to a litany-desk. The camp-stool is immediately derived from the original form of the fauld-stool. In France under the ancien régime, a tabouret, or tabouret, acquired a social and courtly significance of the first importance. The wives of princes, dukes, and a few of the highest dignitaries of the realm alone had the right to occupy a tabouret in the presence of the king, and ladies who became widows used every expedient of intrigue to retain a privilege which they regarded as the summit of earthly felicity. La prise du tabouret, when a lady first took possession of her seat, was an occasion of considerable ceremony.

STOOL-BALL, a game formerly very popular in England, and commonly considered as the ancestor of cricket. Joseph Strutt, writing in 1801, says in his Booke of Stool:—”I have been informed, that a called stool-ball is practised to this day in the northern parts of England, which consists simply in setting a stool upon the ground, and one of the players takes his place before it, while his antagonist, standing at a distance, tosses a ball with the intention of striking the stool, and this it is the business of the former to prevent by beating it away with the hand, reckoning one to the game for every stroke of the ball; if, on the contrary, it should be missed by the hand and touch the stool, the players change places; the conqueror in this game is he who strikes the ball most times before it touches the stool. I believe the game also happens if any person who throws the ball can catch and retain it when driven back, before it touches the ground.” Some variety of the game, with modifications due to the development of cricket, has probably been played even since these days.

STOPPANI, ANTONIO (1824-1891), Italian geologist and paleontologist, was born at Lecco on the 24th of August 1824. He became professor of geology in the Royal Technical Institute of Milan, and was distinguished for his researches on the Triassic and Liassic formations of northern Italy. Among his works were Paléontologie Lombarde (1858-1861); Les pétrophîcques d'Ésinne (1858-1862); Géologie et paléontologie des conches à Articul Comitora en Lombardie (1860-1863); Corso di geologia, (3 vols., 1871-1873); and Il faunismo nell'Alto Piemonte. He wore the author discussed the glaciation of the Italian Alps and the history of Italy during the Pleistocene age. He died at Milan on the 1st of January, 1891.
STORAGE, STEPHEN (1763-1796), English musical composer, was born in London in 1763. His father, Stefano Storace, an Italian contrabassist, taught him the violin so well that at ten years old he played successfully the most difficult music of the day. After completing his education at the Conservatorio di Sant’ Onofrio, at Naples, he produced his first opera, Gli Sposi malcontenti, at Vienna, in 1785. There he met the acquaintance of Mozart, in whose Nozze di Figaro his sister, Anna Selina Storace, first sang the part of Susanna. Here also he produced a second opera, Gli Equivoci, founded on Shakespeare’s Comedy of Errors, and a “Singspiel” entitled Der Doctor und der Apotheker, which met with marked success in England, whither he returned in 1787. After creating a favourable impression by bringing out his “Singspiel” at Drury Lane, under the title of The Doctor and the Apothecary, Storace attained his first great success in 1789, in The Haunted Tower, an opera which ran for fifty nights in succession. No Song, No Supper was equally successful in 1790; and The Siege of Belgrade scarcely less so in 1791. The music of The Pirates, produced in 1792, was partly adapted from Gli Equivoci, and is remarkable as affording one of the earliest instances of the introduction of a grand finale in an English opera. These works were followed by some less successful productions; but The CHEROKEE (1794) and The Three and the Devce (1795) were very favourably received, and the music to Colman’s play, The Iron Chest, first performed on the 12th of March 1796, created even a greater sensation than The Haunted Tower. This was Storace’s last work. He caught cold at the rehearsal, and died on the 19th of March 1796.

The character of Storace’s music is pre-eminently English; but his early intercourse with Mozart gave him an immense advantage over his contemporaries in his management of the orchestra, while for the excellence of his vocal writing for the voice he was no doubt indebted to the vocalization of his sister Anna. This lady was born in London in 1766, completed her education at Venice under Sacchi, sang for Mozart at Vienna, and first appeared at the King’s Theatre in London in 1787. After contributing greatly to the success of The Haunted Tower and her brother’s later operas, she crowned a long and brilliant career by winning great laurels at the Handel Commemoration at Westminster Abbey in 1791, retired from public life in 1808, and died on the 24th of August 1817. During her stay in Vienna she married John Abraham Flis, who was employed to keep her so fully occupied that she refused to bear his name, and in her will—bequeathing property to the amount of £5,000—styled herself “spinster.”

STORE (from O. Fr. estor or estoire, Late Lat. staurus or instaurum, stock, provisions, supply, from the late use of instaurare, to provide, properly to construct, renew, restore), a stock or supply of provisions, goods or other necessaries kept for future daily or recurrent use or for a specific purpose; thus the term applies equally to the domestic supply of provisions, &c., and to the accumulated stock of arms, ammunition, clothing, food, &c., kept for the general use of a navy or army. A common secondary meaning is that of the place where a supply or stock is kept, a storehouse, and thus the term is used particularly in the country districts of America for the general shop where goods of all kinds are sold by retail. In English the term “stores” has come into use for large general shops with many departments selling all kinds of goods.

STOREY (equivalents are Fr. étage, Ital. piano, Ger. Stock), the term in architecture given to the floor of a building, and employed generally when referring to a number of floors one above the other; thus a building may be of two, three or more storeys high. It is used to be applied to a series of apartments on one floor, which are now generally known as a flat. “Storey” or “story” is from O. Fr. estoire, building, estoire, to build, equip, furnish, store, from Lat. staurus, only seen in compound instaurare, to repair, restore, ultimately from root sta, to stand. “Story,” a tale or narrative, is a shortened form of “history.”

STORK (A. S. storc, Ger. Storch), the Ciconia alba of ornithology, a well-known bird, which, however, though often visiting Britain, has never been a native or even inhabitant of that country. It is a summer visitor to most parts of the European continent—the chief exceptions being France (where the native race has been destroyed), Italy and Russia—breeding from southern Sweden to Spain and Greece, and being especially common in Poland. It reappears again in Asia Minor, the Caucasus, Persia and Turkestan, but farther to the eastward it is replaced by an allied species, C. boyciana, which reaches Japan. Though occasionally using trees (as was most likely its original habitat) for the purpose, the stork most generally places its nest on buildings, a fact familiar to travellers in Denmark, Holland and Germany, and its brimming with a cherished guest, public belief ascribing good luck to the house to which it attaches itself. Its food, consisting mainly of frogs and insects, is gathered in the neighbouring pastures, across which it may be seen stalking with an air of quiet dignity; but in the season of love it indulges in gestures which can only be called grotesque—leaping from the ground with extended wings in a kind of dance, and, absolutely voiceless as it is, making a loud noise by the clattering of its mandibles. At other times it may be seen gravely resting on one leg on an elevated place, thence to sweep aloft and circle with a slow and majestic flight. Apart from its considerable size—and a stork stands more than three feet in height—its contrasted plumage of pure white and deep black, with its bright red bill and legs, makes it a conspicuous and beautiful object, especially when seen against the fresh green grass of a luxuriant meadow. In winter the storks of Europe retire to Africa—some of them, it would seem, reaching Cape Colony—while those of Asia visit India. A second species, with much the same range, but with none of its relative’s domestic disposition, is the black stork, C. nigra, of which the upper parts are black, brilliantly glossed with purple, copper and greenish-blue. It is white beneath—the bill and legs, with a patch of bare skin round the eyes, being red. The bird breeds in lofty trees, generally those growing in a large forest. Two other dark-coloured, but somewhat abnormal, species are the purely African C. abdimii and the C. episcopus, which has a wider range, being found not only in Africa but in India, Java and Sumatra. The New World has only one true stork, Diusula maguari, which inhabits South America, and resembles not a little the C. boyciana above mentioned, differing therefrom in its greenish-white bill and black tail. Both these species are very like C. alba, but are larger and have a bare patch of red skin above the eyes.

The storks form the family Ciconiidae, and together with the ibises (Ibidiiidae) are now ranked as a sub-order of Ciconiform birds (see Bird). There is no doubt that they include the jabiru (q.v.) and its allies, as well as the curious genus Anastomus (known in India as the "open-bill," because its lower mandible is hollowed out so as only to meet the maxilla at the base and the tip), of which there are an African and an Asiatic species. In all the storks the eggs are white and pitted with granular depressions.

STORWELL, THEODOR WOLSELEN (1817-1888), German poet and novelist, was born at Husum, in Schleswig, on the 14th of September 1817. Having studied jurisprudence at Kiel and Berlin, where he formed a close friendship with the brothers Theodor and Tycho Mommssen, he settled in his native town as advocate; but, owing to his German sympathies, lost his post in 1853. Entering the Prussian service as assistant at Potsdam, he was appointed district judge at Hellenstäd. After the

1 In that country its numbers are said to have greatly diminished since about 1858, when a disastrous spring storm overturned the homeward-bound birds. The like is to be said of Holland since about 1860.

2 To consult its convenience a stage of some kind, often a cartwheel, is in many places set up and generally occupied by successive generations of the young birds, which are fed on fish, worms, and other animal substances.

3 Its common Dutch name is Oostevaar, which can be traced through many forms (Koolmann, Wörterb. d. ostfries. Sprache, 1, 8, 1886, s.v. Aebbe, Aebbe, Aebbe, Aebbe) to one (good). In countries where the stork is abundant it enters largely into popular tales, songs and proverbs, and from the days of Aesop has been a favourite in fable.
Danish War of 1864 Storm returned to Husum, and after filling various judicial appointments in the district, retired on a pension and died at Hademarschen on the 4th of July 1888. Storm is hardly less remarkable as a lyric poet than as a novelist. As the former, he made his début, with the two Mommens, with Liederbuch dreier Freunde (1843); but his Gedichte (1852; 12th edition, 1900) first obtained for him general recognition. As a novelist he gained his highest success with Immensee (1852; 51st edition, 1901); and this was followed by numerous other short stories. He was never weary of painting the scenes of rural and village life, and the quiet life of his native district is at its best when dealing retrospectively with episodes and incidents from his own earlier life. Later he passed to psychological problems with Aquis submersus (1877) and Zur Chronik von Grischnau (1884), and made a deep impression with his fantastic Schimmelreiter (1888).

Storm's Gesammelte Schriften appeared in 10 vols. between 1868 and 1893; new edition in 8 vols. (1898). His correspondence with E. Mörike was published in 1891, with L. Keller in 1904. See E. Schmidt, Charakteristen, i. (1886); also P. Schütz, Theodor Storm, sein Leben und seine Dichtung (1887); F. Wehl, Theodor Storm, ein Bild seines Lebens und Schaffens (1888); A. Biese, Th. Storm und der moderne Stil (1888); and F. Remer, Theodor Storm als norddeutscher Dichter (1897).

STORM (in O. Eng. storm, and so in Du. and Low Ger.; in O. H. Ger. and mod. Ger. Sturm; the root is probably that seen in "stir," to rouse, move, disturb, cf. Ger. stören), a disturbance of the atmosphere, accompanied by high winds or by heavy falls of rain, hail or snow, together with thunder and lightning. The word is not a part of scientific terminology, such terms as "area of low pressure" and "cyclone" being used. In the Beaufort scale (g.a.) the wind-force of a storm is estimated at 10-11 and the limit of velocity at from 56 to 75 m. per hour. (See Meteorology, and for magnetic storms Magnetism, Terrestrial.)

STORNOWAY (Norse, Stiavnar vagr, "Stiavnar's Bay"), the chief and largest town in the western islands and also the principal town of the county of Ross and Cromarty. Pop. (1901), 3832. It is situated on the east coast of Lewis, at the head of a capacious harbour with ample quays and wharves, accessible at all tides and available for steamers of 3000 tons burden. The harbour is protected by two headlands, on the south shore of which is a mound of rock, called Aran Mor—stands a lighthouse. From the end of this point there juts out a line of rocks on the extremity of which a beacon, 32 ft. high, has been erected, which is illuminated by means of a light thrown on to a prism in the lantern from the light in the lighthouse. Stornoway was made a burgh of barony by James VI., and is also a police burgh. It is the centre of the Outer Hebrides fishing district, and during the herring season the population is trebled. Among the public buildings are Lewis Hospital, Mossend Hospital, the Court House, the Drill Hall, the Masonic Hall, a commodious structure in which the public library is housed, and the fish market. Stornoway Castle, overlooking the town from a height on the west side, is a handsome castellated mansion in the Tudor style, built as the residence of Sir James Matheson.

STORRS, RICHARD SALTER (1821-1900), American Congregational clergyman, was born in Braintree, Massachusetts, on the 21st of August 1821. He bore the same name as his grandfather (1763-1819), pastor at Long Meadow, Massachusetts, from 1785 to 1819, and his father (1787-1873), pastor at Braintree, Massachusetts, from 1811 to 1873 (except the years 1831-1836), both prominent Congregational ministers, who were descendants of Richard Mathesone. He graduated at Amherst in 1839, studied law in Boston under Rufus Choate, graduated at Andover theological seminary in 1845, and was pastor of the Harvard Congregational church of Brookline, Massachusetts, in 1845-1846, and of the Church of the Pilgrims in Brooklyn, New York, from 1846 until shortly before his death in Brooklyn on the 5th of June 1900. He was a conservative in theology, and an historical writer of considerable ability. From 1848 to 1861 he was associate editor of the New York Independent, which he had helped to establish; from 1867 to 1897 he was president of the American board of commissioners for foreign missions, and he was prominent in the Long Island Historical Society. His great-grandfather, John Storrs (1735-1799), a chaplain in the Continental Army, had been pastor of the Southold Church in 1763-1776 and in 1782-1787. Dr Storrs's more important published works were: John Wyldlife and the First English Bible (1885), The Recognition of the Supernatural in Letters and in Life (1881), Bernard of Clairvaux (1892), and Foundation Truths of American Missions (1897).

STORY, JOHN (c. 1510-1571), English martyr, was educated at Oxford, where he became lecturer on civil law in 1535, being made later principal of Broadgates Hall, afterwards Pembroke College. He appears to have disavowed his Roman Catholic opinions just after the accession of Edward VI., but having been chosen a member of parliament in 1547 he gained notoriety by his opposition to the act of uniformity in 1548. For crying out "Woe unto thee, O land, when thy king is a child," he was imprisoned by the House of Commons, but he was soon released on parole. He was a member of the Demo-cratic party, and his position at Oxford, which was now that of regius professor of civil law, was made chancellor of the dioceses of London and of Oxford and dean of arches. Queen Mary being now on the throne, Story was one of her most active agents in prosecuting heretics, and was one of her protors at the trial of Cranmer at Oxford in 1555. Under Elizabeth he was again returned to parliament, but in 1560 he underwent a short imprisonment for boasting about his work in the former reign. In 1563 he was again arrested, but managed to escape to Flanders, where he became a pensioner of Philip II. of Spain. The duke of Alva authorized him to exclude certain classes of books from the Netherlands and, in 1570, while engaged in this work, he was decoyed on to a ship at Antwerp and conveyed to Yarmouth. In spite of his claim that he was a Spanish subject, he was tried for high treason, and executed at Tyburn on the 1st of June 1571. In 1886 Story was beatiied by papal decree.

STORY, JOSEPH (1779-1845), American jurist, was born at Marblehead, Massachusetts, on the 18th of September 1779. He graduated at Harvard in 1798, was admitted to the bar at Salem, Mass., in 1801, and soon attained eminence in his profession. He was a member of the Democratic party, and served in the Massachusetts House of Representatives in 1805-1808, and in 1810-1812 for two terms as speaker, and was a representative in Congress from December 1808 to March 1809. In November 1811, at the age of thirty-two, he became, by President Madison's appointment, an associate justice of the United States Supreme Court. This position he retained until his death. Here he found his true sphere of work. The traditions of the American people, their strong prejudice for the local supremacy of the states and against a centralized government, had yielded reluctantly to the establishment of the Federal legislative and executive in 1789. The Federal judiciary had been organized at the same time, but had never grasped the full measure of its powers. Soon after Story's appointment the Supreme Court began to bring out into plain view the powers which the constitution had given it over state courts and state legislation. The leading place in this work belongs to Chief Justice John Marshall, but Story has a very large share in that remarkable series of decisions and opinions, from 1812 until 1832, by which the work was accomplished. In addition to this he built up the department of admiralty law in the United States courts; he devoted much attention to equity jurisprudence, and rendered invaluable services to the department of patent law. In 1819 he attracted much attention by his vigorous charges to grand juries, denouncing the slave trade, and in 1820 he was a prominent member of the Massachusetts Convention called to revise the state constitution. In 1829 he became the first Dane Professor of Law at Harvard University, and continued until his death to hold this position, meeting with remarkable success as a teacher and winning the affection of his students, whom he imbued with much of his own enthusiasm. He died at
Cambridge, Mass., on the 10th of September 1845. His industry was unremitting, and, besides attending to his duties as an associate justice and a professor of law, he wrote many reviews and magazine articles, delivered various orations on public occasions, and published a large number of works on legal subjects, which won high praise on both sides of the Atlantic.

Among his publications are: *Commentaries on the Law of Damages* (1832); *Commentaries on the Constitution of the United States* (3 vols., 1834); a work of profound learning which is still the standard treatise on the subject; *Commentaries on the Conflict of Laws* (1834), by many regarded as his ablest work; *Commentaries on Equity Jurisprudence* (2 vols., 1835-1836); *Equity Pleasings* (1838); *Law of Agency* (1839); *Law of Partnership* (1841); *Law of Bills of Exchange* (1843); and *Law of Promissory Notes* (1845). He also edited several standard legal works. His Supreme Court decisions may be found in *Crandall's* *History of the United States* (1866), *Federal Cases* (in the United States Courts, 1873), *Mason's*, *Sumner's* and *Story's Reports*. His *Miscellaneous Writings*, first published in 1835, appeared in an enlarged edition (2 vols. in 1851).

**STORY, ROBERT HERBERT** (1835-1907), Scottish divine, principal of Glasgow University, was born on the 28th of January 1835 at Rosneath, Dunbartonshire. He was educated at the universities of Edinburgh, St Andrews and Heidelberg. In 1859 he was assistant minister at St Andrew's Church, Montreal, and in February 1860 was inducted as minister of Rosneath in succession to his father. In 1864 he removed to Glasgow as professor of church history; he had also been appointed in 1866 to a chaplaincy at Queen Victoria. In 1868 he became principal of the university, and subsequently of the University of Saint Andrews and moderator of the General Assembly in 1894, and its principal clerk from that year till his death on the 13th of January 1907. Story was a staunch supporter of his Church, and had little sympathy for schemes of reunion with the other Presbyterian communities. He vigorously opposed the action of Bishop Welldon, then metropolitan of Calcutta, in excluding Scottish chaplains and troops from the use of garrison churches in India because these had received episcopal consecration. He was characterized by an absolutely fearless honesty, which sometimes gave offence, but at the basis of his nature there was a warm, tender and sympathetic heart, incapable of meanness or intrigue.

In addition to lives of his father (1862), Professor Robert Lee (1870) and William Carstairs (1876), he published a devotional book *Christ the Consooler*; a volume of sermons, *Credo and Conduct* (1878); *The Apostolic Ministry in the Scottish Church* (Baird Lecture, 1867), and several pamphlets on church questions.

See *Principal Story, a Memoir by his Daughters* (1899).

**STORY, WILLIAM WETMORE** (1810-1895), American sculptor and poet, son of the jurist, Joseph Story, was born at Salem, Massachusetts, on the 12th of February 1810. He graduated at Harvard College in 1833 and at the Harvard Law School in 1840, continued his law studies under his father, but was admitted to the Massachusetts bar, and prepared two legal treatises of value—*Treatise on the Law of Contracts not under Seal* (2 vols., 1844) and *Treatise on the Law of Sales of Personal Property* (1847). Abandoning the law, he devoted himself to sculpture, and after 1850 lived in Rome, whither he had first gone in 1848, and where he was intimate with the Brownings and with Landor. He died at Vallombrosa, Italy, on the 7th of October 1865. He was a man of rare social cultivation and charm of manner, and his studio in Rome was a centre for the gathering of distinguished English and American literary, musical and artistic people. During the American Civil War his letters to the *Daily News* in December 1861 (afterwards published as a pamphlet, *"The American Question,"* i.e. of neutrality), and his articles in *Blackwood's*, had considerable influence on English opinion.

One of his earliest works in sculpture was a statue of his father, now in the memorial chapel of Mount Auburn Cemetery, Cambridge, Mass.; others are "Cleopatra" (of which there is an enthusiastic description in Hawthorne's *Marble Faun") and "Semiramis" in the Metropolitan Museum of Art, New York; the "Jabyn Sibb," "Saul," "Sardanapalus," "Judith," "Delilah," "Jerusalem Desolate," "Alestine," "Medea," "Electra," "Nemesis," "Sappho" and other ideal figures; and portraits of George Peabody, erected in 1869 in London (a replica in bronze being in Baltimore, Maryland); President Quincy of Harvard, at Cambridge, Mass.; Colonel Prescott, at Bunker Hill; Edward Everett, Public Gardens, Boston, Mass.; Chief Justice Marshall, on the west terrace of the Capitol, and Professor Henry for the Smithsonian Institution, Washington; and Francis Scott Key, San Francisco. Among his writings, in addition to the legal treatises mentioned above, are *Life and Letters of Joseph Story* (1851), *Roba di Roma* (1862), *Proportions of the Human Figure* (1863), *Boummet* (1885), a novel, *Conversation in a Studio* (1890), *Excursions in Art and Letters* (1891), and several volumes of poems of considerable merit. His poems were collected in two volumes in 1858. Among the longer are "A Roman Lawyer in Jerusalem" (a rehabilitation of Judas Iscariot), "A Jewish Rabbi in Rome," "The Tragedy of Nero" and "Ginevra di Siena." The last named, with "Cleopatra," was included in his *Grafitti d'Italia*, a collection published in 1868.

His son, JULIAN STORY (1857-1930), the portrait painter, was a pupil of Frank Duveneck, and of Schwalb and Lefebvre of Paris, and became a well-known member of the Society of American Artists, 1892, a chevalier of the Legion of Honour, Paris, 1901, and an associate of the National Academy of Design. He married in 1891 Emma Eames (b. 1867), the operatic prima donna, who secured a divorce in 1907.

See also Henry James, *William Wetmore Story and his Friends* (2 vols., Boston, 1892).

**STOSS, VEIT** (1458 or 1440-1533), German sculptor and wood carver, was born in Nuremberg. In 1477 he went to Cracow, where he was actively engaged until 1499. It was here that he carved the high altar for the Marienkirche, between 1477 and 1484. On the death of King Kasimir IV. in 1492 Stoss carved his tomb in red marble for the cathedral in Cracow. To the same date is ascribed the marble tombstone of the archbishop Zbigniew Oliinnicki in the cathedral at Gnesen; and soon after this he executed the Stanslaus altar for the Marienkirche at Cracow. In 1496 he returned to Nuremberg, where he did a great deal of work in completing altars. His main works are: a relief with the Coronation of the Blessed Virgin in the Germanic museum at Nuremberg, a statue of the Blessed Virgin in the Frauenkirche, the Annunciation in the Lorenzkirche and the circular rosary in the Germanic museum.

**STOTHARD, CHARLES ALFRED** (1786-1821), antiquarian draughtsman, son of Thomas Stothard (q.v.), was born in London on the 5th of July 1786. After studying in the schools of the Royal Academy, he began, in 1810, his first historical piece, the Death of Richard II. In Pomeire Castle. He published in 1811 the first part of his valuable work, *The Monumental Antiquities of Great Britain*. He was appointed historical draughtsman to the Society of Antiquaries, and was deputed by that body to visit Bayeux to make drawings of the tapestry. He was made a fellow of the society in 1816, and subsequently engaged in numerous journeys with the view of illustrating the works of D. Lysons. While engaged in tracing a portrait from one of the windows of the church of Beer Ferrers, Devonshire, he fell and was killed on the spot (May 27, 1821). His widow (afterwards Mrs Bray), with her brother, completed his *Monumental Antiquities*, left unfinished at his death.

A biography, by his widow, was published in 1823.

**STOTHARD, THOMAS** (1755-1834), English subject painter, was born in London on the 17th of August 1755, the son of a well-to-do innkeeper in Long Acre. Being a delicate child, he was sent at the age of five to a relative in Yorkshire, and attended school at Acomb, and afterwards at Tadcaster and at Ilford in Essex. Showing a turn for drawing he was apprenticed to a draughtsman of patterns for brocaded silks in Spitalfields, and during his leisure hours he attempted illustrations to the works of his favourite poets. Some of these drawings were praised by Harrison, the editor of the *Novelist's Magazine*, and, Stothard's master having died, he resolved to devote himself to art.
STOUGHTON—STOURPORT

In 1778 he became a student of the Royal Academy, of which he was elected associate in 1792 and full academician in 1794. In 1812 he was appointed librarian, having served as assistant for two years. He died in London on the 27th of April 1834. Among his earliest book illustrations are plates engraved for Orris1 and for Bell's Poets and Painters. In 1792 he became a regular contributor to the Nooket's Magazine, for which he executed one hundred and forty-eight designs, including his eleven admirable illustrations to Peregrine Pickle and his graceful subjects from Clarissa and Sir Charles Grandison. He contentedly designed plates for pocket-books, tickets for concerts, illustrations to almanacs, portraits of popular players—and into even the slightest and most trivial sketches he infused a grace and distinction which render them of value to the collectors of the present time. Among his more important series are the two sets of illustrations to Robinson Crusoe, one for the New Magazine and one for Stockdale's edition, and the plates to The Pilgrim's Progress (1798), to Harding's edition of Goldsmith's Vicar of Wakefield (1792), to The Rape of the Lock (1798), to the works of Gessner (1802), to Cowper's Poems (1825), and to The Decameron; and while his figures-subjects in the superb editions of Roger's Italy (1839) and Poems (1834) prove that even in latest age his fancy was still unexhausted, and his hand hardly at all enfeebled. He is at his best in subjects of a domestic or a gracefully ideal sort; the heroic and the tragic were beyond his powers. The designs by Stothard were estimated by R. N. Wornum to number five thousand, and of these about three thousand have been engraved; with these and pictures are usually small in size, and rather sketchy in handling. Their colouring is often rich and glowing, being founded upon the practice of Rubens, of whom Stothard was a great admirer. The "Pilgrim's Progress," perhaps his most important oil painting, is in the National Gallery. He was a contributor to Boydell's Shakespeare Gallery, but his best-known painting is the "Procession of the Canterbury Pilgrims," also in the National Gallery, the engraving from which, begun by Luigi and continued by Niccolo Schiavonetti and finished by James Heath, attained an immense popularity. The commission for this picture was given to Stothard by R. H. Cromek, and was the cause of a quarrel with his friend William Blake. It was followed by a companion work, the "Flitch of Bacon," which was drawn in sepia for the engraver but was never carried out in colour.

In addition to his easel pictures, Stothard adorned the grand staircase of Burghley House, near Stamford, with subjects of War, Intemperance, and the Descent of Orpheus in Heli (1799-1803); the mansion of Hafod, North Wales, with a series of scenes from Froissart and Monsirelet (1810); the cupola of the upper hall of the Advocates' Library, Edinburgh (now occupied by the Bank of Scotland); with Apollo and the Nine Muses, with figures of poets, orators, &c. (1822); and he prepared designs for a frieze and other decorations for Buckingham Palace, which were not executed, owing to the death of George IV. He also designed the magnificent shield presented to the duke of Wellington by the merchants of London, and executed with his own hand a series of eight etchings from the various subjects which adorned it. In the British Museum is a collection, in four volumes, of engravings of Stothard's works, made by Robert Balmano.

An interesting but most indiscriminately culligotic biography of Stothard, by his daughter-in-law, Mrs Bray, was published in 1851. A. C. Coxhead's Thomas Stothard, R.A., an Illustrated Monograph (1906), contains a short biographical chapter, and an accurately dated summary of the various books and periodicals illustrated by Stothard; see also Austin Dobson, Eighteenth Century Vignettes, 1st series (1892).

STOUGHTON, JOHN (1807-1897), English Nonconformist divine, was born at Norwich on the 18th of November 1807. His father was an Episcopalian, his mother a member of the Society of Friends. Stoughton was educated at Norwich Grammar School, and, after an interval of legal study, at Highbury Congregational College. In 1833 he became minister at London, in 1843 at Kensington; in 1856 he was elected chair-
in 1846, and with illustrations in 1876. Through the patronage of Archbishop Parker, Stow was enabled to print the Flores historiarum of Matthew of Westminster in 1567, the Chronicle of Matthew Paris in 1571, and the Historia brevis of Thomas Walsingham in 1574. At the request of Parker he had himself compiled a "farre larger volume," *An history of this island*, but circumstances were unfavourable to its publication and the manuscript is now lost. Additions to the previously published works of Chaucer were twice made through Stow's "own painful labours" in the edition of 1561, referred to above, and also in 1597. A number of Stow's manuscripts are in the Harleian collection in the British Museum. Some are in the Lambeth library (No. 306); and from the volume which includes them were published by the Camden Society, edited by James Gairdner, *Three Fifteenth-Century Chronicles*, with Historical Memoranda by John Stowe the Antiquary, and Contemporary Notes of Occurrences written by him (1880). Stow's literary labours did not prove very remunerative, but he accepted poverty in a cheerful spirit.

Ben Jonson relates that once when walking with him Stow jocularly asked two mendicant cripples "what they would have to take him to their order." In March 1604 James I. authorized him and his deputies to collect "amongst our loving subjects their voluntary contributions and kind gratuities," and himself began "the largesse for the example of others." If the royal appeal was successful Stow did not live long to enjoy the increased comfort resulting from it, as he died on the 6th of April 1605. He was buried in the London church of St Andrew Undershaft, where the monument erected by his will, exhibiting a likeness of him, still remains.

Stow's *Survey of London* has been edited with notes by C. L. Kingsford (Oxford, 1908).

**STOWE, HARRIET ELIZABETH** [BEECHER] (1811-1866), American writer and philanthropist, seventh child of Lyman and Roxana (Foote) Beecher, was born at Litchfield, Connecticut, U.S.A., on the 14th of June 1811. Her father (the Congregational minister of the town) and her mother were both descended from members of the company that, under John Davenport, founded New Haven in 1638; and the community in which she spent her childhood was one of the most intellectual in New England.

At her mother's death in 1815 she sank most directly under the influence of her eldest sister Catherine, eleven years her senior, a woman of keen intellect, who a few years later set up a school in Hartford to which Harriet went, first as a pupil, afterwards as teacher.

In 1832 her father, who had for six years been the pastor of a church in Boston, accepted the presidency of the newly founded Lane Theological Seminary at Cincinnati. Catherine Beecher, who was eager to establish what should be in effect a pioneer college for women, accompanied him; and with her went Harriet as an assistant, taking an active part in the literary and school life, contributing stories and sketches to the journals and compiling a school geography. She was married on the 6th of January 1836 to one of the professors in the seminary, Calvin Ellis Stowe. In the midst of privation and anxiety, due largely to her husband's precarious health, she wrote continually, and in 1843 published *The Mayflower*, a collection of tales and sketches. Mrs Stowe passed eighteen years in Cincinnati under conditions which constantly thrust the problem of human slavery upon her attention. A river only separated Ohio from a slave-holding community. Slaves were continually escaping from their masters, and Harriet, included on their way to Canada, by the circle in which Mrs Stowe lived. In the practical questions which arose, and in the great debate which was political, economical and moral, she took a very active part. When, therefore, in 1850, Mr Stowe was elected to a professorship in Bowdoin College, Brunswick, Maine, and removed his family thither, Mrs Stowe was prepared for the great work which came to her, bit by bit, as a religious message which she must deliver. In the quiet of town, far removed from actual contact with painful scenes, but on the edge of the whirlwind raised by the Fugitive Slave Bill, memory and imagination had full scope, and she wrote for serial publication in *The National Era*, an anti-slavery paper of Washington, D.C.
LORD STOWELL'S judgments are models alike of literary execution and of judicial reasoning. After his death, his style in writing, in the study of "Uncle Tom's Cabin; or, Life among the Lowly." The publication in book form (March 20, 1852) was a factor which must be reckoned in summing up the moving causes of the war for the Union. The book sprang into an unprecedented popularity, and was translated into at least twenty-three tongues. Mr. Stowe used the reputation thus won in promoting moral and religious enmity to slavery. She reinforced her story with "A Key to Uncle Tom's Cabin," in which she accumulated a large number of documents and testimonies against the great evil; and in 1853 she made a journey to Europe, devoting herself especially to creating an entente cordiale between Englishwomen and Americans on the question of the day. In 1856 she published "Dred: a Tale of the Dismal Swamp," in which she threw the weight of her argument on the deterioration of a society resting on a slave basis. The establishment of The Atlantic Monthly in 1857 gave her a constant vehicle for her writings, as did also The Independent of New York, and later The Christian Union, of each of which papers successively her brother, Henry Ward Beecher, was one of the editors. From this time forth she led the life of a woman of letters, writing novels, of which The Minister's Wooing (1859) is best known, and many studies of social life in the form both of fiction and essay. She published also a small volume of religious poems, and towards the end of her career gave some public readings from her writings. In 1852 Professor Stowe accepted a professorship in the Theological Seminary at Andover, Massachusetts, and the family made its home there till 1863, when he returned wholly from professional life and removed to Hartford. After the close of the war for the Union Mrs. Stowe bought an estate in Florida, chiefly in hope of restoring the health of her son, Captain Frederick Beecher Stowe, who had been wounded in the war, and in this southern home she spent many winters. After the death of her husband in 1886 she passed the rest of her life in the seclusion of her Hartford home, where she died on the 1st of July 1896. She is buried by the side of her husband at Andover. 

STOWELL, WILLIAM SCOTT, BARON (1745-1836), English judge and jurist, was born at Heworth, a village about 4 m. from Newcastle, on the 7th of October 1745, the son of a "coalitioner" (or tradesman engaged in the transport of coal). His younger brother John became the famous Lord Chancellor Eldon. Scott was educated at the Newcastle grammar school and Corpus Christi College, Oxford, where he gained a Durham scholarship in 1761. In 1764 he graduated and became first a probationary fellow and then—as successor to William (afterwards the well-known Sir William)—a tutor of University College. As Camden reader of ancient history (1774) he rivalled the reputation of Blackstone. Although he had joined the Middle Temple in 1762, it was not till 1776 that Scott devoted himself to a systematic study of law. In 1779 he graduated as doctor of civil law, and, after the customary "year of silence," commenced practice in the ecclesiastical courts. His professional success was rapid. In 1783 he became registrar of the court of faculties, and in 1788 judge of the consistory court and advocate-general, in that year too receiving the honour of knighthood; and in 1798 he was made judge of the high court of admiralty. Sir William Scott twice contested the representation of Oxford University— in 1780 without success, but successfully in 1801. He also sat for Downton in 1790. Upon the coronation of George IV. (1821) he was raised to the peerage as Baron Stowell. After a life of distinguished judicial service Lord Stowell retired from the bench—from the consistory court in August 1821, and from the high court of admiralty in December 1827. His mental faculties became gradually feebler in his old age, and he died on the 28th of January 1836. Lord Stowell was twice married—in 1781 to Anna Maria, eldest daughter and heiress of John Bagwell of Early Court, Berks., by whom he had four children, of whom the eldest daughter, Maria, survived him; and in 1813 to the dowager marchioness of Sligo.
indication in his work it seems to have been about 63 B.C. He studied at Nysa under the grammarian Aristodemus, under Tyrannio the grammarian at Rome, under the philosopher Xenarchus either at Rome or at Alexandria, and he had studied Aristotle along with Boethus (possibly at Rome under Tyrannio, who had access to the Arvitoitdan writings in Sulla's library). He states that he saw P. Servilius Isauricus, who died at Rome in advanced years in 44 B.C., from which it has been inferred that he was still alive at the time of the Cataplin. He had visited the Etruscan, the Greek, and the Egyptian Pyramids (one of the Cyclopes) when Augustus was at Corinth on his return to Rome from the East in 29 B.C., and that he accompanied the prefect of Egypt, Aelius Gallus, on his expedition to Upper Egypt, which seems to have taken place in 25-24 B.C. These are the only dates in his life which can be accurately fixed.

The latest event mentioned in his work is the death of Juba, king of Mauretania, which took place in A.D. 21.

Although he had seen a comparatively small portion of the regions which he describes, he had travelled much. As he states himself: "Westward I have journeyed to the parts of Etruria opposite Sardinia; towards the south from the Euxine to the borders of Ethiopia; and perhaps not one of those who have written geographies has visited more places than I have between those limits." He tells us that he had seen Egypt as far south as Syene and Philae, Comana in Cappadocia, Ephesus, Mylasa, Nysa and Hierapolis in Phrygia, Gyarus and Populonia. Of Greece proper he saw but little; it is by no means certain that he even visited Athens, and though he describes Corinth as an eye-witness, it is clear that he was never at Delphi, and was not aware that the ruins of Mycenae still existed. He had seen Tyre, Cyrene from Tripoli, and the river Euphrates, but not the Nile. He travelled into Asia Minor, where he remained a long time, probably amassing materials, and studying astronomy and mathematics. For nowhere could he have had a better means of consulting the works of historians, geographers and astronomers, such as Eratosthenes, Posidonius, Hipparchus and Appollodorus. We cannot tell where his geography was written, but it was at last finally revised between A.D. 17 and 23, since we have historical allusions which can be dated to that time. Probably Strabo was then in Rome; the fact that his work passed unnoticed by Roman writers such as the elder Pliny does not prove the contrary.

Works.—His earliest writing was an historical work now lost, which he himself describes as his Historical Memoirs. He tells us (xi, 9, 3) that the sixth book of his memoirs was identical with the second of the Continuation of Polybius; probably, therefore, books i–iv, formed an introduction to the main work. This accounts for the fact that he speaks (ii, 70) of having treated of the exploits of Alexander in his Memoirs, a topic which could not have found a place in a work which began where that of Polybius ended (146 B.C.). According to Suilias, the continuation of Polybius was in forty-three books. Plutarch, who calls him "the Philosopher," quotes Strabo's Memoirs (Lec. 28), and cites him as an historian (Sulla, 26). Josephus, who constantly calls him "the Cappadocian," often quotes from him, but does not mention the title of the work.

The Geography is the most important work on that science which antiquity has left us. It was, as far as we know, the first attempt to provide a map of the world, the time attainable, and to compose a general treatise on geography. It is not merely a new edition of Eratosthenes. In general outline it follows necessarily the work of the last-named geographer, who had first laid down a scientific basis for geography. Strabo made considerable alterations, but not always for the better. The three books of the older work formed a strictly technical geographical treatise; its small size prevented it from containing any such general description of separate countries as Strabo rightly conceived to fall within the scope of the geographer. Strabo indeed appears to be the first who conceived a complete geographical treatise as comprising the following divisions: the geographical, the physical, the political, the historical, the geographical, and he endeavoured, however imperfectly, to keep all these objects in view." The incidental historical notices, which are often of great value and interest, are all his own. These digressions at times interrupt the symmetry of his plan; but Strabo had all the Greek love of legendary lore, and he discusses the journeyings of Heracles as earnestly as if they were events within recent history. He regarded Homer as the source of all wisdom and knowledge—indeed, his description of Greece is largely drawn from Apollodorus's commentary on the Homeric "Catalogue of Ships"—and treated his own history, when necessary, with the same spirit.

The principal advantage of Strabo's work is the vast amount of material which he has preserved. He was more interested in the "marvel-mongers." Yet in some respects Herodotus had better information (e.g., in regard to the Caspian) than Strabo himself. Again, Strabo may be censured for disregarding the statements of his predecessors, and for having no regard for the materials which he had been given by Eratosthenes. But in this he relied on Polybius, whom he might justly consider as having from his position at Rome far better means of gaining accurate information. It must be remembered, however, that Strabo, in the process of setting down his material, employed the best authorities of the time; the theory of Strabo just in those very points where he was at variance with Eratosthenes. He showed likewise an unwarranted scepticism in respect to the materials he had been given by Polybius, which without doubt the Carthaginians had long used as an emporium.

Strabo chiefly employed Greek authorities (the Alexandrian geographers Polybius, Posidonius and Theophrastes of Mytilene, the topographical writings of Posidonius of Puteoli, the Rhetoric of Plutarch, and the works of Roman authorities. Although he refers to Caesar's Commentaries once by name, and evidently made use of them in other passages, he but imperfectly availed himself of that work, which he designed his geography as a sequel to his historical writings, and it had as it were grown out of his historical materials, which were chiefly Greek. Moreover Strabo probably amassed his material in the library of Alexandria, so that Greek authorities would naturally furnish the great bulk of his collections. Doubtless, however, he returned to Rome after a long sojourn in Alexandria, a fact which explains the definiteness of his information about the countries to the east of the Caspian Sea, and the possible information derived from the use of the "chorography" of Agrippa, a map of the Roman Empire and adjacent countries set up by order of Augustus in the Porticus Vipsania at Rome. Even in this work he designed the geography for the statesman rather than for the student. He therefore endeavours to give a general sketch of the character, physical peculiarities and natural productions of each country, and his attention is consequently directed rather to the moral curiosity than to geographical accuracy. He limits the work of describing the "chorography", or the morphology of the earth, to its physical aspect; but he is careful to make his work a grand advance on preceding ones. Judged by modern standards, his description of the direction of rivers and mountain-chains seems defective, but allowance must be made for difficulties in procuring information, and for want of suitable instruments. In respect of determining latitudes and longitudes, his lack of scientific training was no great hindrance. He had before him the results of Eratosthenes, Hipparchus and Posidonius. The chief conclusions of astronomers concerning the spherical figure and dimensions of the earth, its relation to the heavenly bodies, and the great circles of the globe—the equator, the ecliptic and the tropics—were considered as well established. He accepted them without a question. The book devoted to geography begins with a general account of the countries of the earth, and then proceeds to the countries of Europe, divided into five zones; he closes the geographical section with the description of the islands of the southern ocean. Each zone is described in detail, with due regard to the natural and political features of the country and the history of the inhabitants. The book concludes with geographical remarks on the countries of the southern ocean.

Editions.—The Aldine (Venice, 1516) was unfortunately based on a very corrupt MS. The first substantial improvements in the text were due to Casaubon (Geneva, 1587; Paris, 1620), whose text remained the basis of subsequent editions till that of Corvis (Paris, 1815-1816), who removed many corruptions. The MSS. were first scientifically collated by Kramer (Berlin, 1844-1892), who demonstrated that Par. 1399 was the best authority for the first nine books (it contains no more errors) and Var. 1329 for the remainder. Of later editions the most important are those of C. Müller (Paris, 1853) and Meinecke (Leipzig, 1866-1877). H. F. Tozer's volume of selections of geographical extracts (1878) is useful. F. L. Thompson's (1880) is a French translation of the Geography to be made by Coraës, Letronne and others (Paris 1805-1819); Grosskurd's German translation (Berlin, 1831-1854), with notes, is a monumental work. The fragments of Strabo's "Historical Memoirs" (Lec. 28), "Historical Life," and "Table of Countries" (Studien xi, 1891) are collated and edited by Müller's Fragmenta historicae geogra- corum, iii. 490 sqq. Burgh's "History of Ancient Geography", vol. ii, chs. 21, 22; and F. Dubois' "Examens de la géographie de Strabon" (Paris, 1891) should also be consulted. (H. S. J.)

STRACHAN, JOHN (1778-1867), first bishop of Toronto, son of John Strachan and Elizabeth Finlayson his wife, was born at Aberdeen, Scotland, on the 12th of April 1778. His father died in 1792 from an accident in the granite quarries of which he was an overseer. Thus from an early age young Strachan had to depend upon his own resources and even to assist his mother,
whom he loyally aided till her death in 1822. He managed, by undertaking private teaching and with the aid of a bursary, to go to the university of Aberdeen, where he took his M.A. degree. He attended some of the divinity classes at the university, where also he formed a lasting friendship with two of his fellow students, well known afterwards as Professor Duncan and Dr Chalmers. In 1790 he emigrated to Canada, having been recommended to the Rev. Dr Wright, and on 3rd March 1793 was admitted as a candidate suitable for tutorial work. Strachan went to Canada a Presbyterian. His associations there, however, were almost exclusively with Episcopalians, including Mr Cartwright and the Rev. Dr. Stuart, for a time the only clergyman in the district. Moreover, special provision had been made in the Constitutional Act of 1791 for the liberal endowment of the Protestant religion, then identified in the official mind with the Church of England, through what were afterwards known as the Clergy Reserves, being one-seventh of the lands of the new townships opened for settlement. Having decided to enter the Episcopal Church, Strachan was ordained on the 22nd of May 1803, and was immediately afterwards appointed to the parish of Cornwall. Thither he removed his school, which soon became the most noted educational institution in the country. There many future leaders of public and professional life in Canada came under the influence of Strachan's vigorous personality. In 1807 he married the youthful widow of Andrew McGill, a wealthy merchant of Montreal, and brother of the founder of McGill University. In 1812 he received the honorary degree of D.D. from his alma mater, Aberdeen University. During the same year Dr Stuart of Kingston died and was succeeded by his son George O'Kill Stuart, incumbent at York, the capital of the province. Through the influence of Lieut.-Governor Gore, supplemented by that of Sir Isaac Brock, Strachan was prevailed upon in 1812 to transfer himself to York, where he was soon deeply involved in civil and ecclesiastical politics.

During the War of 1812 he was of special service to the executive government and the citizens of the town when the American troops captured York and burned the public buildings. He was chiefly instrumental also in founding the Loyal and Patriotic Society of Upper Canada, which raised funds for the relief of the wounded and the assistance of the widows and orphans of the slain. On the urgent recommendation of Lieut.-Governor Gore he was appointed to the executive council of Upper Canada in 1815. A man of great force of character and much ability, of keen ambitions and unusual shrewdness, though not remarkable for breadth of mind, he attained to great influence in the executive government and was soon the leading spirit in that dominant group known in Upper Canadian history as the Family Compact. In 1820 he was appointed by Sir Peregrine Maitland a member of the legislative council in order that the governor might have a confidential medium through whom to make communication to the council. At the instance of the lieutenant-governor he went to England in 1824, to discuss various colonial questions with the earl of Bathurst, then colonial secretary. Strachan had no difficulty in convincing Lord Bathurst of the justice of his claims on all essential matters, the most important of which was the exclusive right of the Church of England in Canada to the Clergy Reserves. Though in favour of selling a portion of these lands to provide a fund for the existing needs of the Church, he secured the defeat of the proposal then before the government to dispose of the Clergy Reserves to the Canada Company. He took much interest in the educational affairs of the province, and in 1807 was instrumental in having provision made for the establishment of the first grammar schools. In 1824 he secured the passing of an act providing assistance for the public schools of each district. During his second visit to England in 1826-1827 he obtained a royal charter for the university of King's College, with provision for its endowment out of the crown lands. It was, however, to be entirely under the control of the Church of England. In 1827 Strachan became archdeacon of York.

The break-up of the Liverpool ministry in 1827 interrupted the successful development of Strachan's plans for placing virtually the whole of the government endowments for religion and education under the control of the Episcopal Church. The storm of protest of the other religious denominations caused the colonial office to undertake an investigation of the whole question, the result of which was presented in the report of 1828. After a long silence in the face of severe and persistent criticism, Strachan made a general reply in a very able speech in the legislative council, which he delivered on 16th March 1832. When the storm had subsided the Clergy Reserves and university questions remained dormant until 1836, when the attempt to apply the Reserves to the endowment of rectories renewed the trouble and contributed largely to the crisis of 1837. Adverse criticism and a suggestion from the colonial office that he should cease from active participation in political affairs led to his resignation from the executive council, but he declined to give up his seat in the legislative council.

On the death of Bishop Stewart of Quebec the Canadian see was divided, and Strachan was made bishop of Toronto in August 1839. He energetically opposed the act of 1840, which sought to settle the Clergy Reserves question by dividing the proceeds among the different religious denominations, the larger share still remaining with the Church of England. The university of King's College was finally established, with certain modifications of its charter, in 1843, Bishop Strachan being the first president. The renewed agitation finally resulted in the elimination of all religious tests by the act of 1849, which also changed the name to that of the university of Toronto. Strachan at once took steps to found another university which should be completely under the control of the Episcopal Church, hence the establishment of Trinity University, which was opened in 1852. Bishop Strachan also raised once more the question of the disposal of the Clergy Reserves. After several strong appeals and counter-appeals to the British government, the Canadian parliament was allowed to deal as it pleased with the question, with the result that the Reserves were completely secularized in 1854, provision being made for the life-interest of the beneficiaries at the time. Bishop Strachan devoted the latter years of his long life entirely to his episcopal duties, and by introducing the diocesan synod he furnished the Episcopal Church in Canada with a more democratic organ of government. He died in November 1867.

STRACHEY, SIR JOHN (1823-1907), British Indian civilian, fifth son of Edward Strachey, was born in London on the 5th of June 1823. After passing through Harleybury, Strachey entered the Bengal civil service in 1842, and served in the North-Western Provinces, occupying many important positions. In 1861 Lord Canning appointed him president of a commission to investigate the great cholera epidemic of that year. In 1862 he became judicial commissioner in the Central Provinces. In 1864, after the report of the royal commission on the sanitary condition of the army, a permanent sanitary commission was established in India, with Strachey as president. In 1866 he became chief commissioner of Oudh, having been chosen by Lord Lawrence to remedy as far as possible the injustice done after the Mutiny by the confiscation of the rights of tenants and small proprietors of land, maintaining at the same time the privileges of the Talukdars of great landholders. As member of the legislative council he introduced several bills for that purpose, which, with the full approval of the Talukdars, passed into law. In 1868 he became member of the governor-general's council, and on the assassination of Lord Mayo in 1872 he acted temporarily as viceroy. In 1874 he was appointed lieutenant-governor of the North-Western Provinces. In 1876, by request of Lord Lytton and the secretary of state, he consented to relinquish that office, and returned to the governor-general's council as financial minister, which post he retained until 1880. During this time, while Lord Lytton was viceroy, important reforms were carried out. The measures for decentralizing financial administration, initiated under Lord Mayo, were practically completed. The salt duties were reduced, and the system under which they were levied was altered, and that opprobrium of our administration, the inland customs line, was abolished. The removal of all
import duties, including those on English cotton goods, and the establishment of complete free trade, was declared to be the fixed policy of the government, and this was in great measure carried into effect before 1880, when Strachey left India. The defective system on which the military accounts were kept occasioned a very erroneous estimate of the cost of the Afghan War of 1878–80. For this error Strachey was technically responsible, and it was made the occasion of a violent party attack which resulted in his resignation. The fact that almost the entire cost of the war was paid for out of revenue is a conclusive proof of the state of finances to which India attainted at the result of his administration. From 1885 to 1895 Strachey was a member of the council of the secretary of state for India. He was joint author with Sir Richard Strachey of The Finances and Public Works of India (1883), besides writing India (3rd ed., 1903), and Hastings and the Rohilla War (1892). He died on the 19th of December 1907.

STRACHEY, SIR RICHARD (1817–1908), British soldier and Indian administrator, third son of Edward Strachey, was born on the 24th of July 1817, at Sutton Court, Somersetshire. From government on the purchase of the Egal Indian railway, £6, was employed for some years on irrigation works in the North-Western Provinces. He served in the Sutlej campaign of 1845–46, and was at the battles of Aliwal and Sobraon, was mentioned in despatches, and received a brevet-majority. From 1858 to 1865 he was chiefly employed in the public works department, either as acting or permanent secretary to the government of India, and from 1867 to 1871 he filled the post of director-general of irrigation, then specially created. During this period the entire administration of public works was reorganized to adapt it to the increasing magnitude of the interests with which this department had had to deal since its establishment by Lord Dalhousie in 1854. For this reorganization, under which the accounts were placed on a proper footing and the forest administration greatly developed, Strachey was chiefly responsible. His work in connexion with Indian finance was important. In 1867 he prepared a scheme in considerable detail for decentralizing the financial administration of India, which formed the basis of the policy afterwards carried into effect by his brother Sir John Strachey under Lord Mayo and Lord Lytton. He left India in 1871, but in 1877 he was sent there to confer with the government on the purchase of the Egal Indian railway, £6, was then selected as president of the commission of inquiry into Indian famines. In 1878 he was appointed to act for six months as financial member of the governor-general's council, when he made proposals for meeting the difficulties arising from the depreciation of the rupee, then just beginning to be serious. These proposals did not meet with the support of the secretary of state. From that time he continued to take an active part in the efforts made to bring the currencies of India and England into harmony, until in 1892 he was appointed a member of Lord Herschell's committee, which arrived at conclusions in accordance with the views put forward by him in 1878. He attended in 1892 the International Monetary Conference at Brussels as delegate for British India. Strachey was a member of the council of the secretary of state for India from 1875 to 1889, when he resigned his seat in order to accept the post of chairman of the East Indian Railway Company. Strachey's scientific labours in connexion with the geology, botany and physical geography of the Himalaya were considerable. He devoted much time to meteorological research, was largely instrumental in the formation of the Indian meteorological department, and became chairman of the purchasing commission of the Royal Geographical Society in 1883. From 1888 to 1890 he was president of the Royal Geographical Society. In 1897 he was awarded one of the royal medals of the Royal Society, of which he became a fellow in 1854; and in the same year he was created G.C.S.I. He died on the 12th of February 1908. His widow, Lady Strachey, whom he married in 1880, became well-known as an authoress and a supporter of women's suffrage.

STRACHEWITZ, MORITZ KARL WILHELM ANTON, GRAF VON (1822–1847), German poet, was born on the 13th of March 1822 at Peterwitz near Frankenstein in Silesia. After studying in Breslau and Berlin he settled on his estate in Moravia, where he devoted himself to literary pursuits. When travelling in Italy in 1847 he was taken ill at Venice, and died on the 11th of December at Vienna. Although he had thus only reached his twenty-fifth year, he revealed a lyric genius of remarkable force and originality. His first collection of poems, Lieder eines Erwachsenen, appeared in 1842 and went through several editions. Neue Gedichte were published after his death in 1848. These poems are characteristic of the transition through which the German lyric was passing between 1840 and 1848; the old Romantic strain is still dominant, especially in his ballads, which are unquestionably his finest productions; but, side by side with it, there is to be seen the influence of Platen, to whose warmest admirers Strachewitz belonged, as well as echoes of the restless political spirit of those eventful years. His political lyric was, however, tempered by an aristocratic restraint which was absent from the writings of men like Herwegh and Freiligrath. Strachewitz's early death was a great loss to German letters; for he was by far the most promising of the younger generation.

Strachewitz's collected Gedichte appeared first in 1850 (9th ed., 1891); a convenient reprint will be found in Reclam's Universalbibliothek. See A. K. T. Tielo, Die Dichtung des Grafen Moritz von Strachewitz (1902).

STRADELLA, ALESSANDRO (1764–1808), Italian composer, was one of the most accomplished musicians of the 18th century. The hitherto generally accepted story of his life was first circumstantially narrated in Bonnet-Bourdol's Histoire de la musique et de ses effets (Paris, 1715). According to this account, Stradella was not only the most successful operatic composer in Venice, but also attained so great a reputation by the beauty of his voice that a Venetian nobleman engaged him to instruct his mistress, Ortensia, in singing. Stradella, the narrative goes on to say, shamefully betrayed his trust, and eloped with Ortensia to Rome, whither the outraged Venetian sent two paid bravò to put him to death. On their arrival in Rome the assassins learned that Stradella had just completed a new oratorio, over the performance of which he was to preside on the following day at S. Giovanni in Laterano. Taking advantage of this circumstance, they determined to kill him as he left the church; but the beauty of the music affected them so deeply that their hearts failed them at the critical moment, and, confessing their treachery, they entreated the composer to ensure his safety by quitting Rome immediately. Thereupon Stradella fled with Ortensia to Turin, where, notwithstanding the favour shown to him by the regent of Savoy, he was attacked one night by another band of assassins, who, headed by Ortensia's father, left him on the ramparts for dead. Through the connivance of the French ambassador the ruffians succeeded in making their escape; and in the meantime Stradella, recovering from his wounds, married Ortensia, by consent of the regent, and removed with her to Genoa. Here he believed himself safe; but a year later he and Ortensia were murdered in their house by a third party of assassins in the pay of the implacable Venetian. Recent research has shown that Stradella was the son of a Cavaliere Marc'antonio Stradella of Ficarazzu, who in 1642–1643 was vice-marchese and governor of Vignola for Prince Boncompagni, who did not wish to live in the dominions from which he took the title of marchese di Vignola. He was deprived of his office in 1643 for having surrendered the castle to the papal troops, although it might have sustained a siege of several days and the help of the duke of Modena was expected. An elder relative of Alessandro Stradella by name, in the service of the Augustinian order, and seems to have enjoyed the protection of the house of Este. Alessandro is supposed to have been born about 1645 or earlier, probably at Vignola, or Monfwestino, a town on the road from Modena to Fristoja, to which his father retired after his dismissal; but no records of his birth have come to light in either of these places. The first certain date in his life is 1672, in which year he composed a prologue for the performance of Cesti's opera La Dori at Rome; and we may conclude that he spent a considerable time at Rome about this period, since his
cantatas and other compositions contain frequent allusions to Rome and noble Roman families. There is, however, no proof that he ever performed the oratorio S. Giovanni Battista in the Lateran. Documents in the archives at Turin relate that in 1677 he arrived there with the mistress of Alvise Contarini, with whom he had eloped from Venice. Contarini desired Stradella both to compose an oratorio and to instruct his sons in music. We hear that Stradella should not be allowed to exercise his profession until the lady had been either placed in a convent or made his legitimate wife. Stradella was protected by the regent of Savoy, the duchess Giovanni Battista de Nemours, and the Contarini family, indignant at his audacity, sent two hired assassins to Turin, by whom Stradella was wounded but not murdered. We hear of Stradella last at Genoa. An opera by him, La Forza dell’amor paterno, was given there in 1678, and his last composition, Il Barcheggio (i.e. a “Water-Music”), was performed on the 16th of June 1681 in honour of the marriage of Carlo Spinola and Paola Brignole, which was solemnized on the 6th of July of the same year. Documents in the archives at Modena inform us that in February 1682 Stradella was murdered at Genoa by three brothers of the name of Lonellini, whose sister he had seduced. It is extremely improbable that Stradella had any great reputation as a singer, since the great Italian singers of the 17th century were almost exclusively castrati; but he may well have been a teacher of singing, and he appears to have instructed his lady pupils in Genoa on the harpsichord. He is principally important as a composer of operas and chamber-cantatas, although compositions like his duets and sonatas have been written with the same care as is often shown in his stock-in-trade. The Stradivari method of violin-making created a standard for subsequent times; but what is regarded as Antonio’s special advantage, now irrecoverable, was his varnish, soft in texture, shading from orange to red, the composition of which has been much debated. (See also VIOLIN.)

STRAFFORD, EARLS OF. The first earl of Strafford was Charles I’s friend and adviser, Thomas Wentworth (see below). When he was attainted and executed in May 1641 his honours were forfeited, but later in the year his only son, William (1626-1688), was created earl of Strafford. His wife being reverseed by act of parliament in 1662, William died without issue on the 16th of October 1695, when all his titles, except the barony of Raby, became extinct. His estates passed to a kinsman, Thomas Watson, afterwards Watson-Wentworth (d. 1723), a son of Anne (1629-1693), daughter of the 1st earl, and his husband Edward Watson, 2nd Baron Rockingham. In 1746 Watson-Wentworth’s son, Thomas Watson-Wentworth (c. 1690-1759), was created marquess of Rockingham, and when his son Charles, the 2nd marquess, died in 1782, the estates passed to his maternal nephew, William Fitzwilliam, 2nd Earl Fitzwilliam. His son, the 3rd earl, Fitzwilliam, was created earl Fitzwilliam, the owner of Wentworth Woodhouse, near Rotherham, and the representative of the Wentworth family. The barony of Raby passed to the 2nd earl’s cousin, Thomas Wentworth (1672-1739), son and heir of Sir William Wentworth of Northgate Head, Wakefield. In early life he saw much service as a soldier in the Low Countries, and was occasionally employed on diplomatic errands. From 1717 to 1714 he was British ambassador at the Hague, and in 1717 he was created earl of Strafford. The earl was one of the British representatives at the congress. In 1717 he was impeached for his share in concluding this treaty, but the charges against him were not pressed to a conclusion. He died on the 15th of November 1729. The earldom became extinct when Frederick Thomas, the 5th earl, died in August 1799. William, the 4th earl (1722-1791), had a sister Anne, who married William Conolly; and one of their daughters, Anne, married George Byng (d. 1759) of Wrotham Park, Middlesex. Their son, Sir John Byng (1772-1869), a distinguished soldier, was created earl of Strafford and Viscount Enfield in 1847. Having entered the army in 1793, Byng served in Flanders and commanded a brigade during the Peninsular War. He was present at Waterloo and field marshal in 1852. The earldom of Strafford is still held by his descendants.
STRAFFORD, THOMAS WENTHURST, EARL OF (1593-1641),
English statesman, son of Sir William Wentworth, of Wentworth Woodhouse, near Rotherham, a member of an ancient family long established there, and of Anne, daughter of Sir Robert Atkins of Stowell, Gloucestershire, was born on the 13th of April 1593, in London. He was educated at St John's College, Cambridge, was admitted a student of the Inner Temple in 1607, and in 1611 was knighted and married Margaret, daughter of Francis Clifford, 4th earl of Cumberland. In 1614 he represented Yorkshire in the Added Parliament, but, so far as is now known, it was not till the parliament of 1621, in which he sat for the same constituency, that he took part in the debates. His position towards the popular party was peculiar. He did not sympathize with their zeal for war with Spain, but James's denial of the rights and privileges of the lower house seems to have caused him no shake in the vindication of the claims of the House of which he was a member, and he was a warm supporter of the protestation which drew down a sentence of dissolution upon the third parliament of James. In 1622 Wentworth's wife died, and in February 1623 he married Arabella Holles, daughter of the earl of Clare. He was returned for Pontefract to the parliament of 1624, but appears to have taken no part in the proceedings. He had no sympathy with the popular outcry against Spain nor for wars undertaken for religious considerations to the neglect of the practical interests of the country. He desired also to avoid foreign complications and "do first the business of the commonwealth." To the advances of Buckingham he replied coldly that "he was ready to serve him as an honest man and a gentleman." In the first parliament of Charles I., June 1625, he again represented Yorkshire, and at once marked his hostility to the proposed war with Spain by supporting a motion for an adjournment before the house proceeded to business. He took part in the opposition to the demand made under the influence of Buckingham for war subsidies, and was consequently, after the dissolution in November, made sheriff of Yorkshire, in order to exclude him from the parlament. In 1626, when Elizabeth, daughter of Sir Geoffrey Rhodes, was brought to the bar, he was present taking part in the attitude of antagonism to the king. His position was very different from that of the regular opposition. He was anxious to serve the Crown, but he disapproved of the king's policy. In January 1626 he had asked for the presidency of the council of the North, and had visited and been favourably received by Buckingham. But after the dissolution of the parliament he was dismissed from the justiceship of the peace and the office of custos rotulorum of Yorkshire, to which he had been appointed in 1615, as the result probably of his resolution not to support the court in its design to force the country to contribute money without a parliamentary grant. At the exorbitant rate of 1627 to contribute to the forced loan, and was imprisoned in consequence.

Wentworth's position in the parliament of 1628 was a striking one. He joined the popular leaders in resistance to arbitrary taxation and imprisonment, but he tried to obtain his end with the least possible infringement of the prerogative of the Crown, to which he looked as a reserve force in times of crisis. With the approbation of the House he led the movement for a bill which would have secured the liberties of the subject as completely as the commonwealth could have done. Afterward a number of them were impeached in the same year and taken to the bar of the House to act unchecked in special emergencies.

On the 22d of July 1628, not long after the prorogation, Wentworth was created Baron Wentworth, and received a promise of the presidencShip of the Council of the North at the next vacancy. This implied no change of principle whatever. He was now at variance with the parliamentary party on two great subjects of policy, disapproving both of the intention of parliament to seize the powers of the executive and also its inclination towards puritanism. When once the breach was made it naturally grew wider, partly from the engrossing energy which each party put into its work, and partly from the personal animosities which of necessity arose. Such and no other was the nature of Wentworth's so-called "apostacy."

As yet Wentworth took no part in the general government of the country. In December he became Viscount Wentworth and president of the Council of the North. In the speech delivered at York on his taking office he announced his intention, almost in the words of Bacon, of doing his utmost to bind up the prerogative of the Crown and the liberties of the subject in indistinguishable unions. "Whoever," he said, "ravels forth into questions the right of a king and of a people shall never be able to wrap them up again into the comeliness and order he found them." His government here was characterized by the same feature which afterwards marked his administration in Ireland and which it was the gravest charge in his impeachment that he intended to introduce into the whole English administration, namely the attempt to centralize all power with the executive at the expense of the individual in defiance of those constitutional liberties which ran counter to and impeded this policy. The session of 1629 ended in a breach between the king and the parliament which made the task of a moderator hopeless. Wentworth had to choose between helping a Puritan House of Commons to dominate the king and helping the king to dominate a Puritan House of Commons. He instinctively chose the latter course, and he threw himself into the work of repression with characteristic energy, as if the establishment of the royal power was the one thing needful. Yet even when he was most resolute in crushing resistance he held that he and his antagonists were maintaining the old constitution, which they had attempted to alter by claiming supremacy for parliament.

In November 1629 Wentworth became a privy councillor. In October 1631 he lost his second wife, and in October 1632 he married Arabella, daughter of Sir Godfrey Rhodes. In January 1632 he had been named lord-deputy of Ireland, and arrived in Dublin in July 1633.

Here he had to deal with a people who had not arrived at national cohesion, and amongst whom English colonists had been from time to time introduced, some of them, like the early Norman settlers, being Roman Catholics, whilst the later importations stood aloof and preserved their Protestantism. In his government here he showed the most remarkable abilities as a ruler. "The lord deputy of Ireland," wrote Sir Thomas Roe to the queen of Bohemia, "doth great wonders and governs with singular skilfulness. He is a man of great courage and some espedience, and is capable to do much service if the king would use him. He swept the pirates from the seas. He reformed and instilled life into the Church and rescued church property. His strong and even administration broke down the tyranny of the great men over the poor. Such was the government of "Thorough," as Strafford expresses it. Yet these good measures were all carried out by arbitrary methods which diminished their usefulness and their stability. Their aim moreover was not the prosperity of the Irish community but the benefit to the English exchequer, and Strafford suppressed the trade in cloth lest it should be a means to prejudice that staple commodity of England. Extraordinary acts of despotism took place, as in the case of Esmond, Lord Chancellor Loftus and Lord Mountnorris, the last of whom Strafford caused to be sentenced to death

in order to obtain the resignation of his office, and then par- 
doned. Promises of legislation such as the concessions known as the "graces" were not kept. In particular Strafford set 
at naught Charles's promise that no colonists should be forced 
into Connaught, and in 1635 he proceeded to that province, 
where, raking up an obsolete title—the grant in the 14th century 
of Connaught to Lord Leitrim, duke of Clarence, whose heir Charles 
was—he insisted upon the grand juries in all the counties 
finding verdicts for the king. One only, that of Galway, re- 
sisted, and the confiscation of Galway was effected by the 
court of exchequer, while he fined the sheriff £1,000 for sum- 
moming such a jury, and cited the jurymen to the castle chamber 
to answer for their offence. In Ulster the arbitrary con- 
fiscation of the property of the city companies aroused dangerous 
animosity against the government. Towards the native Irish 
Wentworth's bearing was benevolent but thoroughly un-
sympathetic. Having no notion of developing their qualities 
by a process of natural growth, he only hoped for them to 
lay in converting them into Englishmen as soon as possible. They 
must be made English in their habits, in their laws and in their 
religion. "I see plainly," he once wrote, "that, so long as this 
kingdom continues popish, they are not a people for the Crown 
of England to be confidant of." High-handed as Wentworth 
was by nature, his rule in Ireland made him more high-handed 
than ever. As yet he had never been consulted on English 
affairs, and it was only in February 1637 that Charles asked his 
opinion on a proposed interference in the affairs of the Con- 
tinental cabinet, which pointed for an immediate renewal of 
the war. In reply he assured Charles that it would be unwise 
to undertake even naval operations till he had secured absolute 
power at home. He wished that Hampden and his followers 
"were well whipped into their right senses." The opinion 
of the judges had given the king the right to levy ship-money, 
but, unless his majesty had the "like power declared to raise 
a land army, the Crown" seemed "to stand upon one leg at 
home, to be considerable by halves to foreign princes 
abroad." When the Scottish Puritans rebelled he advocated 
the most decided measures of repression, in February 1639 send- 
ing the king £20,000 as his contribution to the expenses of the 
coming war, at the same time deploiring an invasion of Scot-
land before the English army was trained, and advising certain 
concessions in religion.

Wentworth arrived in England in September 1639, after 
Cibber's failure in the first Bishops' War, and from that moment 
he became Charles's principal adviser. Ignorant of the extent 
to which opposition had developed in England during his absence, 
he recommended the calling of a parliament to support 
a renewal of the war, hoping that by the offer of a loan from the 
privy councillors, to which he himself contributed £30,000, 
he would place Charles above the necessity of submitting to the 
new parliament if it should prove peaceable. In the summer of 1640, 
he was created earl of Strafford, and in March he went to Ireland 
to hold a parliament, where the Catholic vote secured a grant 
of subsidies to be used against the Presbyterian Scots. An Irish 
army was to be levied to assist in the coming war. When 
in April Strafford returned to England he found the Commons 
holding back from a grant of supply, and tried to enlist the peers 
on the side of the king. On the other hand he induced Charles 
to be content with a smaller grant than he had originally asked for. 
The Commons, however, insisted on peace with the Scots. Charles, 
on the advice, or perhaps by the treachery of Vane, returned to his larger demand of twelve subsidies; and on 
the 9th of May, at the privy council, Strafford, though 
reluctantly, voted for a dissolution. The same morning the 
Committee of Eight of the privy council met again. Vane and 
others were for a mere defence against invasion. Strafford's 
advice was the contrary. "Go on vigorously or let them alone 
. . . go on with a vigorous war as you first designed, loose and 
absolved from all rules of government, being reduced to extreme 
necessity, everything is to be done that power might admit.

You have an army in Ireland you may employ here to reduce this kingdom . . . . He proposed to force the citizens of London to lend money. He supported a project for debasing 
the coinage and for seizing bullion in the Tower, the property 
of foreign merchants. He also advocated the purchase of a loan 
from Spain by the offer of a future alliance. He was ultimately 
appointed to command the English army, and was made a 
knighthood of the Garter, but he was seized with illness, and the 
rout of Newburn made the position hopeless. "Pity me," he wrote to his friend Sir George Radcliffe, "for never 
any man to so lost a business . . . . In one word here alone 
to fight with all these evils, without any one to help." In 
the great council of peers, which assembled on the 24th of September 
at York, the struggle was given up, and Charles announced that 
he had issued writs for another parliament.

The Long Parliament assembled on the 3rd of November 
1640, and Charles immediately summoned Strafford to London, 
proposing that he "should not suffer in his person, honour or 
fortune." He arrived on the 9th and on the 10th proposed to 
the king to forestall his impeachment, now being prepared by 
the parliament, by accusing the leaders of the popular 
party of treasonable communications with the Scots. 
The plan however having been betrayed, Pym immediately took 
up the impeachment to the Lords on the 11th. Strafford came 
to the house to confront his accusers, but was ordered to 
withdraw and committed into custody. On the 25th of November 
the preliminary charge was brought up, whereupon he was 
sent to the Tower, and, on the 31st of January 1641, the accusa-
ations in detail were presented. These were, in sum, that 
Strafford had endeavoured to subvert the fundamental laws 
of the kingdom, and that the scheme was high treason. Much 
stress was laid on Strafford's reported words already cited—
"You have an army in Ireland you may employ here to reduce 
this kingdom," England, it being contended, and not Scotland 
being here meant. It is clear nevertheless that however tyrannical 
and mischievous Strafford's conduct may have been, his 
offense was not one which could by any straining of language 
be included in the limits of high treason; while the copy of a 
copy of rough notes of Strafford's speech in the committee 
of the council, the genuineness of which was asserted only by 
the defendant's accusers or personal enemies and not supported 
by other counselors who had also been present on the occasion, 
could not be evidence which would convict in a court of law.

In addition, the words had to be arbitrarily interpreted as 
referring to the subjection of England and not of Scotland, 
and were also spoken on a privileged occasion. Advantage 
was freely taken by Strafford of the weak points in the attack, 
and the lords, his judges, were considerably influenced in his favour. 
But behind the legal aspect of the case lay the great constitu-
tional question of the responsibility to the nation of the 
leader of its administration, a principle which was now to be 
revived after many centuries of neglect, and, in the circumstances 
then prevailing, could only be enforced by the destruction 
of the offender. The Commons therefore, feeling their victim 
slipping from their grasp, dropped the impeachment, and 
bring in and passed a bill of attainder, though owing to the 
opposition of the Lords, and Pym's own preference for the more 
judicial method, the procedure of an impeachment was prac-
tically adhered to. Strafford might still have been saved 
but for the king's ill-advised conduct. A scheme to gain over 
the leaders of the parliament, and a scheme to seize the Tower 
and to liberate Strafford by force, were entertained concurrently 
and were mutually destructive; and the revelation of the army 
plot on the 6th of May caused the Lords to pass the attainder. 
Nothing now remained but the king's signature. Charles had, 
after the passing of the attainder by the Commons, for the 
time secured Strafford "upon the word of a king, you 
shall not suffer in life, honour or fortune." Strafford now wrote 
releasing the king from his engagements and declaring his 
willingsness to die in order to reconcile Charles to his subjects.

"I do most humbly beseech you, for the preventing of such 
masacres as may happen by your refusal, to pass the bill; 
by this means to remove . . . . the unfortunate thing forth of 
the way towards that blessed agreement, which God, I trust, 
shall for ever establish between you and your subjects;"
STRAIN

Finally Charles yielded, giving his fatal assent on the roth of May. Strafford met his fate on the 12th of May on Tower Hill, receiving Laud's blessing, who was then also imprisoned in the Tower, on his way to execution.

Thus passed into history "the great person," as Clarendon well calls him, without doubt one of the most striking figures in the annals of England. Strafford's patriotism and ideas were fully as noble as those of his antagonists. Like Pym, a student of Bacon's wisdom, he believed in the progress of England along the line of natural development, but that development, in opposition to Pym, he was convinced could only proceed with the increase of the power of the executive, not of the parliament, with a government controlled by the king and not by the people. He was equally an upholder of the union of interests and affection between the sovereign and his subjects, but believed this could only exist when the king's will, and not that of the parliament, was paramount. The development of the constitution, in his opinion, either in the direction of a democracy or an aristocracy, was equally fatal and could only lead to anarchy, to the waste of national resources and in degeneration. As a result, he developed and unarmmed executive directed by a single will, wise reforms could be carried out, the weak defended against the strong, the resources of the country developed to its full extent, the hesitations, delays and contradictions caused by barren discussions avoided, and the national forces concentrated on objects worth the aim. For one brief moment it was given to Strafford to carry out his ideals, and the final failure of his Irish administration, and especially its inability to endure in spite of its undoubted successes, has afforded an object-lesson in one-man government for all time. If such events in Ireland, where political ideas were still rude and elementary, still less could success be expected from the attempt to introduce the centralization and absolute power of the executive into England, where principles of government had been highly developed both in theory and practice, and a contrary tendency had long been established towards the increase of the rights of the individual and the power of parliament.

While arousing in the course of his career the most bitter enmities—and no man's death was ever received with more public rejoicing—Strafford was capable of inspiring strong friendships in private life. Sir Thomas Roe speaks of him as "Severe abroad and in business, and sweet in private conversation; retired in his friendships but very firm; a terrible judge and a strong enemy." His appearance is described by Sir Philip Warwick: "In his person he was of a tall stature, but stooped much in the neck. His countenance was cloudy whilst he moved or sat thinking, but when he spake, either seriously or facetiously, he had a lightsome and a very pleasant air; and indeed whatever he then did he performed very gracefully." He himself jests on his own "bent and ill-favoured brow," Lord Exeter replying that had he been "cursed with a meek brow and an arch of white hair upon it," he would never "have governed Ireland nor Yorkshire.”

Strafford was married three times: (1) in 1611 to Lady Margaret Clifford, daughter of Francis, 4th earl of Cumberland; (2) in 1625 to Lady Arabella Holles, daughter of John, 1st earl of Clare; (3) in 1632 to Elizabeth, daughter of Sir Godfrey Rhodes. He left three daughters and one son, William, 2nd earl of Strafford.

See the article on Strafford in the *Dict. Nat. Biog.* by S. R. Gardiner; Strafford's Letters, ed. by W. Knowler (1739); R. Browning’s *Life of Strafford*, with introduction by C. H. Firth (1892); *Papers relating to Thos. Wentworth*, ed. by C. H. Firth for the Camden Society (1889); Camden Miscellanies, vol. ix., *Private Letters from the Earl of Strafford to his third Wife* (Philobiblon Soc. Blog. & Hist., Misc. 1854, vol. i.); Lives by H. D. Traill (1889) in *English Men of Action Series,* and by Elizabeth Cooper (1886); *Hist. of State Papers, Domestic and Irish, exp. 1623-1647*, Introduction; *Hist. MSS. Comm. MSS. of Earl Cowper; Strafford’s Correspondence,* of which the volumes published by Knowler represent probably only a small selection, remains still in MS. in the collection of Earl Fitzwilliam at Wentworth Woodhouse.

**STRAIN** (through O. Fr. *straindre, estraindre,* mod. *drentre,* from Lat. *stringere,* to draw tight, related to stress, stretch, string, &c.), to draw out, extend, stretch, especially with the idea of great effort or beyond measure or limit; hence, from the idea of pressure or constriction, to separate coarser matter or light solids from a liquid by pressure through a "strainer," which may be either a sieve or a colander (*Lat. colare,* to strain), a metal vessel with perforations in the bottom. Another type is the filter (q.v.). Straining can also be effected by means of cloths, and the name strainer is used of a coarse open cloth usually of flax; a coarser cloth of a more open texture is technically known as "screw." For "strains" and "stresses" in physics see *Mechanics; Elasticity and Strength of Materials.*

**STRAITS SETTLEMENTS,** the collective name given to the crown colony formed by the British possessions on or adjacent to the mainland of the Malay Peninsula, as opposed to the Federated Malay States, the British protectories in the same region. The Straits Settlements consist of the island of Singapore with about a score of islets of insignificant size lying in its immediate vicinity, of the town and territory of Malacca, the islands and territory of the Dindings, the island of Penang, sometimes officially called Prince of Wales Island, and Province Wellesley.

The colony of the Straits Settlements is administered by the governor with the aid of an executive council, composed wholly of official members, and there is a legislative council, composed partly of official and partly of nominated members, of which the former have a narrow permanent majority. The governor of the Straits Settlements is also high commissioner for the Federated Malay States of the peninsula, for British North Borneo, Brunei and Sarawak in Borneo, and since the administration of the colony of Labuan, which for a period was vested in a British North Borneo Company, has been resumed by the British government he is also governor of Labuan. The Cocos Keeling Islands (which were settled and are still owned by a Scottish family named Ross) and Christmas Island were formerly attached to Ceylon, but in 1886 the care of these islands was transferred to the government of the Straits Settlements. Penang and Malacca are administered, under the governor, by resident councillors. British residents control the native states of Perak, Selangor, Negri Sembilan and Pahang, but since the 1st of July 1896, when the federation of these states was effected, a resident-general, responsible to the high commissioner, has been placed in supreme charge of all the protectorates in the peninsula. The work of administration, both in the colony and in the Federated Malay States, is carried on by means of a civil service whose members are recruited by competitive examination held annually in London.

*Population.—* The following are the area and population, with details of race distribution, of the colony of the Straits Settlements, the figures being those of the census of 1901:

The population, which was 306,732 in 1871 and 423,384 in 1881, had increased more than a third, to 572,225. As the rate of natural increase is solely due to immigration, more especially of Chinese, though a considerable number of Tamils and other natives of India annually settle in the Straits Settlements. The total number of births in 1898 was 8,248, and the deaths 5,285, giving a ratio per 1,000 of the population during 1896, 1897 and 1898 respectively was 22-18, 20-52 and 21-57; while the number of registered marriages during 1898 was 4,221, 36-90, 30-43, 31-66 and 36-25 respectively, the number of deaths registered during 1900 being 23,385. The ratio to which the excess of deaths over births is to be attributed is to be found in the effect of the Custom and Importation, with which 339,083, or over 59% of the whole, is composed of 261,412 males and only 77,671 females, and a comparatively small number of the latter are married women and mothers of families. The male Europeans in 1898 numbered about two thousand, among the Malays and Eurasians, who alone have a fair proportion of both sexes, the infant mortality is always excessive, this being due to early marriages and other well-known causes. The number of immigrants landed in the various settlements during 1898 was:

The total number of immigrants for 1900 was therefore 285,560, as against 391,366 emigrants, mostly Chinese returning to China. In 1867, the date of the transfer of the colony from the East India Company to the Crown, the total population was estimated at 283,384.

The account is for 1896 only amounted to $1,301,843. That for 1888 was $6,512,132. During 1898, $4,106,180 was received on account of land sales. Of this sum, $6,660,558 was derived from opium, wines and spirits, and licences to deal in these articles, $777,976 from land revenue, $1,666,002 from postal and telegraphic revenue, and $276,078 from port and harbour duties. The expenditure, which in 1868 amounted to $5,111,511, was reduced to $3,656,000 in 1896. The total $2,546,000 of administrative establishments amounted to $4,450,791, of which $2,586,195 was on account of personal emoluments and $1,864,596 was on account of other charges. The military expenditure (the colour pay on the Coast 20% of its gross revenue to the Imperial government by way of military contribution) amounted to 1896 in $1,702,438. A sum of $2,578,052 was expended on upkeep and maintenance of existing public works, and $710,939 on new roads, streets, gardens and buildings.

**The Dingdings and Province Wellesley.**—The various settlements of which the colony of the Straits Settlements is composed, and the protectorates named in this article, are all dealt with separately, except the Dingdings and Province Wellesley.

The former, which consists of some islands near the mouth of the Pétrak River and a small piece of territory on the adjoining mainland, belonged originally to Pétrak, and was ceded to the British government under the treaty of Pangkor in 1874. Hopes were entertained that its excellent natural harbour would prove to be a first-rate naval base; but it has proved a disappointment, and the islands, which are sparsely inhabited, are unimportant both politically and financially, are now administered by the government of Pétrak.

Province Wellesley, which is situated on the mainland opposite to the island of Penang, was ceded to Great Britain by the sultan of Kedah in 1798. It marches with Pétrak on the south, but on the north and east with Kedah. The boundary with Kedah was rectified by treaty with Siam in 1867. It is administered by a district officer, with some assistants, who is responsible to the resident counciller of Penang. The country consists, for the most part, of fertile plains, thickly populated by Malays, and occupied in some parts by sugar-planters and others engaged in similar agricultural industries and employing Chinese and Tamil labour. About a tenth of the whole area is covered by low hills with thick jungle. Large quantities of rice are grown by the Malay inhabitants, and between October and February there is excellent snipe-shooting to be had in the paddy-fields. A railway from Bâtu Kawan, opposite to Penang, runs through Province Wellesley into Pétrak, and thence via Selângor and the Negri Sembilan to Malacca. There is also an extension via Mâar, which is under the rule of the sultan of Johor, and through the改制ated state to Johor Bharu, opposite the island of Singapore.

See Straits Settlements Blue Book, 1896 (Singapore, 1907); Straits Directory, 1908 (Singapore, 1908); Journal of the Straits branch of the Royal Asiatic Society (Singapore); Sir Frederick Weld and Sir William Maxwell, severally, on the Straits Settlements in the Journal of the Royal Colonial Institute (London, 1884 and 1892).

**STRAWSUND**

**STRAWSUND,** a seaport of Germany, in the Prussian province of Pomerania, on the west side of the Stralsund, an arm of the Baltic, 13 m. wide, which separates the island of Rügen from the mainland, 135 m. by rail from Berlin and 45 m. N.W. of Ros- tock. Pop. (1905), 31,813, of whom more than a fourth reside in the Knieper, Tribseeseer, Franken and other suburbs on the mainland. A steam railway ferry connects it with the island railway on Rügen, and so with Sassnitz, whence a regular steamboat service connects it with Trellingen in Sweden.

The situation of the town proper, on a small triangular islet only connected with the mainland by three miles and bridges at the angles, has always rendered its fortification comparatively easy, and, down to 1875, it was a fortress of the first rank. Since that year the ramparts have been levelled and their site occupied by public promenades and gardens. The defences of the place are now solely confined to the island of Dänholm, known down to the 17th century as Strelha or Strehlo, lying in the Sound.

The quaint architecture of the houses, many of which present their curious and handsome gables to the street, gives Stralsund a unique charm and old-fashioned appearance. The four Gothic churches of St Nicholas, St Mary, with a lofty steeple, St James and The Holy Ghost, and the fine medieval town hall, dating in its oldest part from 1306 and restored in 1882, are among the more striking buildings. The last houses the provincial antiquarium museum and the municipal library of 70,000 volumes. There is a fine monument commemorating the war of 1870-71, one (1859) to the local patriot Ferdinand von Schill, and another (1900) to the poet and patriot E. M. Arndt. Among the educational establishments of the place must be mentioned the classical school (Gymnasium), founded in 1560, and a school of navigation. The manufactures of Stralsund are more miscellaneous than extensive; they include machinery, playing cards, sugar, soap, cigars, gloves, furniture, paper, oil and beer. The trade is chiefly confined to the shipping of grain, fish, coal, malt and timber, with some cattle and wool, and to the import of coal and tar, but of late years it has declined, despite excellent wharf accommodation and a considerable depth of water (12-15 ft.). Stralsund entertains passenger-boat communications with Barth, Stettin, Rostock and Lübeck as well as with various small ports on the isle of Rügen.

The town was founded in 1234, and, though several times destroyed, steadily prospered. It was one of the Wendish towns whose alliance extorted from King Eric of Norway a favourable commercial treaty in 1284-1285; and in the 14th century it was second only to Lübeck in the Hanseatic League. Although under the sway of the dukes of Pomerania, the city was able to maintain a marked degree of independence, which is still apparent in its municipal privileges. Its early Protestant sympathies placed it on the side of Sweden during the Thirty Years' War, and in 1625 it successfully resisted a siege of eleven weeks by Wallenstein, who had sworn to take it "though it were chained to heaven." He was forced to retire with the loss of 12,000 men, and a yearly festival of the town still celebrates the occasion. After the peace of Westphalia Stralsund was ceded with the rest of Western Pomerania to Sweden; and for more than a century and a half it was exposed to attack and capture as the étoile-de-point of the Swedes in continental Europe. It was taken by France in 1807, and in 1815 it passed to Prussia. In 1809 it was the scene of the death of Ferdinand von Schill, in his gallant though ineffectual attempt to rouse his countrymen against the French invaders.

See Möhlnke and Zober, *Sachsische Chroniken* (Stralsund, 1833-1854); Israël, *Die Stadt Stralsund* (Leipzig, 1895); Bauer, *Sachsische Geschichte* (Stralsund, 1902); and T. Reisahn, *Wallenstein und die Belagerung Stralsunds* (Stralsund, 1887).

1 A remarkable series of 14th-century frescoes, in perfect condition, were disclosed in 1909 by the removal of the whitewash which had for centuries covered the interior of this fine church.
STRAMONIUM, in medicine, a drug obtained from the leaves and seeds of the Datura stramonium. Both contain an alkaloid known as daturine. From the seeds is made extreomum stramonii. The tiucura stramonii is made from the leaves. The physiological action of stramonium resembles that of belladonna, except that stramonium relaxes to a greater extent the unstripped muscle of the bronchial tubes; for this reason it is used in asthma to relieve the bronchial spasm. Cigarettes made of stramonium leaves may be smoked or the tincture may be taken internally. Frequently the leaves powdered together with equal quantities of the powdered leaves of the Cannabis Indica and lobelia mixed with potassium nitrate are burned in an atmosphere of nitrogen in the preparation of certain dense funereal wax, and afford great relief to the asthmatic paroxysm. Numerous patent "cures" for asthma contain these ingredients in varying proportions. Daturine is used as daturinae sulphas. In acute mania it acts like hyoscyamine in producing sleep. In large doses stramonium is a narcotic poison producing the well-marked stages of exaltation of function, diminution of functional activity, and later loss of function, sinking into coma and paralysis.

STRANGE, WILLIAM (1590–1643), English painter and engraver, was born at Dumbarton, N.B.; on the 13th of February 1599, the son of Peter Strange, builder. He was educated at the Dumbarton Academy, and worked for fifteen months in the counting-house of a firm of shipbuilders. He went to London in 1675 when he was sixteen, and studied his art under Alphonse Legros at the Slade School for six years. Strange became assistant master in the etching class, and himself followed this art with great success. He was one of the original members of the Royal Society of Painter-Etchers, and exhibited at their first exhibition in 1881. Some of his early plates were published in the Portfolio and other art magazines. He worked in many manners, etching, dry point, mezzotint, sand-ground mezzotint, and burin engraving, and invented a draw-burin of his own. Lithography and wood-cutting were also used by him to reproduce his abundant imaginations. He cut a large wood-engraving of a man ploughing, that has been published by the Art for Schools Association. A privately produced catalogue of his engraved work contains more than three hundred items. Amongst his earlier works "Tinkers," "St Jerome," "A Woman washing her Feet," an "Old Book-stall with a man fighting his pipe from a flare," and "The head of a Peasant Woman," on a sand-ground mezzotint, may be remembered. Later plates such as "Hunger," "The Bachelor's End," "The Salvation Army," and "Home," cannot be forgotten. Some of his best etchings have been in series; one of the earliest, illustrating William Nicholson's ballad of "Aken Drum," is remarkable for delicate and clear workmanship in the shadow tones, showing great skill and power over his materials, and for strong drawing. Another good series was the "Pilgrim's Progress," revealing austere sympathy with Bunyan's teaching. Coleridge's "Ancient Mariner" and Strange's own "Allegory of Death" and the "Plowman's Wife," have served him with suitable imaginations. Some of Rudyard Kipling's stories have been illustrated by him, too, and Strange's portrait of Kipling has been one of his most successful portrait plates. Other good etched portraits are of Mr Ernest Sibley, fine as a Vandyck, and of Mr J. B. Clark, with whom Strange collaborated in illustrating Baron Munchausen and Sindbad the Sailor and Ali Baba, published in 1893 and 1896. Thomas Hardy, Henry Newbolt and many other distinguished men also sat to him. Proofs from these plates have been much valued; in fact, Strange's portrait etchings have inaugurated a new form of reproductive portraiture. A portrait which is a work of art and can be reproduced a number of times without losing any of its art qualities is one ideal way of recording appearances, as such prints can be treasured by many owners. Strange produced a number of good paintings, portraits, nude figures in landscapes, and groups of peasant families, which have been exhibited in the Royal Academy, the International Society, and several German exhibitions. He painted a decorative series of scenes from the story of Adam and Eve for the library of Mr Hudson of Wolverhampton; they were exhibited at the Whitechapel exhibition in 1910. Some of his drawings from the nude model in silver point and red and black chalk are very beautiful as well as powerful and true. He also painted a number of landscapes, mostly of a small size. In later years he developed a style of drawing in red and black chalk, with the whites and high lights rubbed out, on paper stained with water colour. This method gives qualities of delicate modelling and refined form and gradations akin to the drawings of Holbein. He drew portraits in this manner of many members of the Order of Merit for the royal library at Windsor Castle. In an etching of the Royal Society of Painting in Water-colors, as a protest against the inclusion in its exhibitions of etched or engraved reproductions of pictures. His work was subsequently seen principally in the exhibitions of the Society of Twelve, of the International Society, to which body he was elected in 1905, and of the Royal Academy. Strange was elected an associate engraver of the Royal Academy when that degree was wisely revived in 1906. (C. H.)

STRANGE, SIR ROBERT (1721–1792), Scottish line engraver, descended from the Scottish family of Strange, or Strang, of Balcaskye, Fife, was born in the mainland of Orkney on the 14th of July 1721. In his youth he spent some time in an attorney's office; but, having manifested a taste for drawing, he was apprenticed, in 1735, to Richard Cooper, an engraver in Edinburgh. After leaving Cooper in 1741 he started on his own account as an engraver, and had attained a fair position when, in 1745, he joined the Jacobite army as a member of the corps of life-guards. He engraved a half-length of the Young Pretender, and also etched plates for a bank-note designed for the payment of the troops. He was present at the battle of Culloden, and after the defeat remained in hiding in the Highlands, but ultimately returned to Edinburgh, where, in 1747, he married Isabella, only daughter of William Lumisden, son of a bishop of Edinburgh. In the following year he proceeded to Rouen, and there studied drawing under J. B. Descamps, carrying off the first prize in the Academy of Design. In 1749 he removed to Paris, and placed himself under the celebrated Le Bas. It was from this master that he learned the use of the dry point, an instrument which he greatly improved and employed with excellent effect in his own engravings. In 1750 Strange returned to England. Presently he settled in London along with his wife and daughter, and superintended the illustrations of Dr William Hunter's great work on the Grand Uterus, published in 1774. The plates were engraved from red chalk drawings by Van Rymsdyk, now preserved in the Hunterian Museum, Glasgow, and two of them were executed with great skill by Strange's own hand. By his plates of the "Magdalen" and "Cleopatra," engraved after Guido in 1753, he at once established his professional reputation. He was invited in 1759 to engrave the portraits of the prince of Wales and Lord Bute, by Allen Ramsay, but declined, on the ground of the insufficient remuneration offered and of the pressure of more congenial work after the productions of the Italian masters. His refusal was attributed to his wholesome dislike of Isaac, and the latter's furious correspondence with Ramsay, and to the loss, for the time, of royal patronage. In 1760 Strange started on a long-mediated tour in Italy. He studied in Florence, Naples, Parma, Bologna, and Rome, executing innumerable drawings, of which many—the "Day" of Correggio, the "Danae" and the "Venus and Adonis" of Titian, the "St Cecilia" of Raphael, and the Barberini "Magdalen" of Guido, &c.—were afterwards reproduced by his burin. On the Continent he was received with great distinction, and he was elected a member of the academies of Rome, Florence, Parma and Paris. He left Italy in 1764, and, having engraved in the French capital the "Justice" and the "Meckness" of Raphael, from the Vatican, he carried them with him to London in the following year. The rest of his life was spent mainly in these two cities, in the diligent prosecution of his art. In 1766 he was elected a member of the Incorporated Society of Artists, and in 1775, piqued by
the exclusion of engravers from the Royal Academy, he published an attack on that body, entitled An Enquiry into the Rise and Progress of the Royal Academy of Arts at London, and prefaced by a long letter to Lord Bute. In 1787 he engraven West's "Apotheosis of the Princes Octavius and Alfred," and was rewarded with the honour of knighthood. He died in London on the 5th of July 1792.

After his death a splendid edition of reserved proofs of his engraving was issued; and a catalogue of his works, by Charles Blanc, was published in 1864 by Randolph Weigel of Leipzic, forming part of Les Gravure en taille douce.

STRANGFORD, VISCOUNT, an Irish title held by the family of Smythe, from 1625, when it was conferred upon Sir Thomas Smythe (d. 1635) of Ostenhanger and Ashford, Kent, until 1869, when it became extinct. From Sir Thomas the title passed down to his descendant, Percy Clinto Sydney Smythe (1780-1853), who succeeded his father, Lionel, as 6th viscount in 1801. Entering the diplomatic service in 1802, Smythe represented his country at Lisbon, in Brazil, at Stockholm, Constantinople and St Petersburg, and in 1825 he was created a peer of the United Kingdom as Baron Penshurst. He had literary tastes, and in 1803 published Poems from the Portuguese of Camoens, with Remarks and Notes, Byron at this time describing him as "Hibernian Strangford"); he died on the 29th of May 1855.

His eldest son George Augustus Frederick Percy Sydney Smythe (1818-1857), who now became the 7th viscount, was associated with Disraeli and Lord John Manners in the conduct of the "Young England" party. He entered parliament in 1841, and was under-secretary for foreign affairs in 1845-1846, losing his seat at Canterbury in 1852. In 1852 he fought a duel at Weybridge with Colonel Frederick Romilly (1810-1882), the last encounter of this kind in England. Like his father, Smythe had literary tastes, and he is thought to be the original of Disraeli's Coningsby. In 1844 he wrote Historic Fancies, a collection of poems and essays, and his novel Angelo Pisani was published posthumously, with a memoir of the author in 1875. As a journalist he wrote in the Morning Chronicle. He died on the 23rd of November 1857, and was succeeded by his brother Percy Ellen Frederick William Sydney Smythe (1826-1866) as 8th viscount.

Born at St Petersburg on the 26th of November 1826, during all his earlier years Percy Smythe was nearly blind, in consequence, it was believed, of his mother having suffered very great hardships on a journey up the Baltic in wintry weather shortly before his birth. His health through life was very delicate, but did not prevent his showing quite early most remarkable powers of mind. His education was begun at Harrow, whence he went to Meriton College, Oxford. From the very first he gave proofs of extraordinary ability as a linguist, and was nominated in 1845 as student-attached at Constantinople. A very interesting account of his colleagues, more especially of Mr Almeric Wood, who was a man of phenomenal capacity, was written by him later in life, and is to be found in the two volumes of his collected essays published by his widow. While at Constantinople, where he served under Lord Stratford de Redcliffe, Percy Smythe gained a mastery not only of Turkish and its dialects, but of almost every form of modern Greek, from the language of the literati of Athens to the least Hellenized Romaina. Before he went to the East he had a large knowledge both of Persian and Arabic, and the necessities of his business led him to study the past, present and future of the sultan's empire he had given no attention to the tongues which he well described as those of the international rabble in and around the Balkan peninsula. He made, while in the East, a careful study of these, and was the first Englishman to see that the Bulgarians were much more likely than the Servians to come to the front as the Ottoman power declined. He avowed himself a Liberal in English politics, and those with whom he chiefly lived were Liberals; but he was not an anti-Turk, as so many Liberais afterwards became. On succeeding to the peerage in 1857 he did not abandon the East, but lived on at Constantinople for several years, immersed in Oriental studies. At length, however, he returned to England and began to write a great deal, sometimes in the Saturday Review, sometimes in the Quarterly, and much in the Pall Mall Gazette. A rather severe review in the first of these organs of the Egyptian Sepulchres and Syrian Shrines of Emily Anne Beaumont (on an event to a royal and very much the marriage of the reviewer and of the authoress. One of the most interesting papers Lord Strangford ever wrote was the last chapter in his wife's book on the Eastern Shores of the Adriatic. That chapter was entitled "Chaos," and was the first of his writings which made him widely known amongst careful students of foreign politics. From that time forward everything that he wrote was watched with intense interest, and even when it was anonymous there was not the slightest difficulty in recognizing his style, for it was unlike any other. He died in London on the 9th of January 1869, when his titles became extinct. A Selection from the Writings of Viscount Strangford on Political, Geographical and Social Subjects was edited by his widow and published in 1869. His Original Letters and Papers upon Philology and Kindred Subjects were also edited by Lady Strangford (1878).

See E. B. de Fonblanque, Lives of the Lords Strangford through Ten Generations (1877).

STRANRAER, a royal and police burgh and seaport of Wigtownshire, Scotland. Pop. (1901), 6036. It is situated at the head of Loch Ryan, an arm of the North Channel (Irish Sea), 50 m. S.S.W. of Ayr by the Glasgow & South-Western railway, with a station in the town and at the harbours. Depths 39 m. E. by N. of Larne in Co. Antrim, Ireland, with which there is daily communication by mail steamer. Stranraer, originally called St John's Chapel, became a burgh of barony in 1596, and a royal burgh in 1617. In the centre of the town are the ruins of the castle of the 15th century, occupied for a time by John Graham of Claverhouse, Viscount Dundee, when he held the office of sheriff of Galloway (1682). The principal buildings within the parish are the old town hall, now used as a volunteer drill hall and armoury; the county buildings, containing the town hall and court-house; the academy; reformatory and the Wigtownshire combination poor-house. Dairy utensils and implements are made; there are several nurseries; brewing and milling are carried on, but the bulk of the trade is in farm and dairy produce. Pier and harbour accommodation has been extended and the shipping is brisk. The oyster beds, for which Loch Ryan was once noted, are not cultivated, but the fisheries (white fish and herrings) are still of some consequence. Three miles east of Stranraer is Lochinch, the residence of the earl of Stair, a modern structure in the Scots Baronial style. It stands in grounds 4000 acres in extent, which include the White and Black Lochs and the ruins of Castle Kennedy, thinly situated on the isthmus between the lakes. This castle was erected in the reign of James VI. for the earls of Cassils, and passed into the hands of the Stair family in the 17th century. It was struck by lightning in 1716 and burned down and never rebuilt. The estate is famous for its plantations and Dutch gardens, the pinetum containing the most representative collection of araucarias, deodars and other conifers in Europe. A mile south are the green mounds marking the site of the abbey of Saulset, founded for Premonstratensian monks by Fergus, "king" of Galloway, early in the 12th century. It stood on the banks of a small loch and was known as the ancient boundaries of the mass of confervae with which the water was continually covered.

Four miles west by north of Stranraer is situated Lochmaw Castle, the ancient seat of the Agnew, who were hereditary sheriffs of Galloway till 1747, when hereditable jurisdictions were abolished. The five-storied embattled tower in the centre dates from 1426, and the modern mansions from 1820. On the coast, 7½ m. south-west of Stranraer by rail, lies Portpatrick, formerly called Port Montgomerie. Owing to its proximity to Ireland (21½ m. to Donaghadee), it was for more than 200 years a starting-point.
of the mail service between Great Britain and Ireland. In consequence, however, of the frequent violence of the south-westerly gales and other causes, the communication ceased in the middle of the 17th century, and the artificial harbour designed by John Rennie has gradually fallen into decay. The town is in repute as a holiday resort for its healthy climate and beautiful situation.

**STRASSBURG**, or STRASBURG (French Strasbourg), a town of Germany, the capital of the imperial province of Alsace-Lorraine and a fortress of the first rank, is situated in a fertile plain at the junction of the Ill and the Breusch, 2 m. W. of the Rhine, 88 m. by rail N. from Basel, 370 m. S.W. from Berlin, 30 m. E. of the French frontier. Pop. (1890), 123,501; (1900), 130,688; (1910), 144,957. Since 1871 it has been the seat of government for the German territory of Alsace-Lorraine, and it is also the see of a Roman Catholic bishop and the headquarters of the XV. Corps of the German army. It is surrounded by outlying fortifications and strategic works and contains a garrison of 16,000 men of all arms.

The town proper is divided by the arms of the Ill into three parts, of which the central is the largest and most important. Most of the streets in the heart of the city are narrow and irregular, and the quaint aspect of a free medieval town has to a considerable extent been maintained. The quarters which suffered most in the bombardment of 1870 have, however, been rebuilt in more modern fashion, and the recent widening of the circle of fortifications, with the destruction of the old walls, has given the city opportunity of expansion in all directions; thus, with the exception of Berlin and Leipzig, there is perhaps no town in Germany which can show so many handsome new public buildings as Strassburg. Of its older edifices by far the most interesting and prominent is the cathedral, or Münster, which in its present form represents the activity of four centuries. Part of the crypt dates from 1015; the apse showing a reconstruction from the Romanesque; and the nave, finished in 1275, is a fine specimen of pure Gothic. Of the elaborate west façade, with its screen of double tracery and its numerous sculptures, the original design was finished by Erwin von Steinbach (d. 1318). The upper part of the façade and the towers were afterwards completed in accordance with a different plan, and the spire on the north tower was added in 1435. This tower is 465 ft. high, being thus one of the highest buildings in Europe, and it commands a fine view. The cathedral has some fine stained glass, a sculptured pulpit and the famous astronomical clock in the south transept; this contains some fragments of the clock built by the mathematician, Conrad Dasypodius, in 1574. The Protestant church of St Thomas, a Gothic building of the 13th and 14th centuries, contains a fine monument of Marshal Saxe, considered the chef d'œuvre of the sculptor, Jean Baptiste Pigalle. Other notable churches are the Protestant Temple Neuf, or Neue Kirche, rebuilt since 1870, and the Roman Catholic church of the Sacred Heart, erected in 1889-1893.

The old episcopal palace, built in 1731-1741, was used for university purposes from 1872 to 1893; it is now the municipal museum of art. Other notable buildings are the Frauenhaus, with some interesting sculptures, and the Hôtel du Commerce, the finest Renaissance building in the town. The imperial palace, designed by H. Eggert in the Florentine Renaissance style, was built in 1889-1893; it is crowned by a cupola 115 ft. high and is richly ornamented. The provincial and university library, with over 800,000 volumes, and the hall of the provincial Diet (Landesausschuss), built in 1888-1892, both in the Italian Renaissance style, occupy the opposite side of the Kaiserplatz, and behind the latter is the large new post office. Between the university and the library is the Evangelical garrison church (1892-1897), built of reddish sandstone in the early Gothic style. The principal squares of the town are the Kaiserplatz, the Brogileplatz, the Schlossplatz and the Kleberplatz. Still to be mentioned are the Grosse Metzg, containing the Hohenlohe museum, the theatre, the town hall, and the so-called Aubette, with a conservatory of music. A new synagogue was completed in 1868, and the viceregal palace was entirely rebuilt in 1872-1874. The town has new law courts, a Roman Catholic garrison church, an iron bridge across the Rhine to Kehl and statues of General Kléber and of the printer Gutenberg.

The university of Strassburg, founded in 1567 and suppressed during the French Revolution as a stronghold of German sentiment, was reopened in 1872; it now occupies a site in the new town and is housed in a handsome building erected for it in 1877-1894. This is adorned with statues and frescoes by modern German artists, and has near it the chemical, physical, botanical, geological, seismological and zoological institutes, also the observatory, all designed by Eggert and built between 1877 and 1888. On the south of the old town are the various schools, libraries and museums of a similar nature, and the Strassburg Academy since 1877. The university, which has six faculties, is attended by about 1400 students and has 330 professors. Other educational establishments are the Protestant gymnasium, founded in 1538, various seminaries for teachers and theological students and numerous schools.

The chief industries of Strassburg are tanning, brewing, printing and the manufacture of steel goods, musical instruments, paper, soap, furniture, gloves and tobacco. To these must be added the fattening of geese for Strassburg's celebrated "foie gras" which forms a useful item of income to the poorer classes. There is also a brisk trade in agricultural produce, hams, sausages, coal, wine, leather goods and hops. The development of this trade is favoured by the canals which connect the Rhine with the Rhone and the Marne, and by a new port of 250 acres in extent with quays and wharves on the Rhine, which has been constructed since 1891.

Strassburg has always been a place of great strategic importance, and as such has been strongly fortified. The pentagonal citadel constructed by Vauban in 1682-1684 was destroyed during the siege of 1870. The modern German system of fortifications consists of a network of fortresses and fortresses of the forthwith divided, forming a protective barrier for the Rhine from the S.W. to the S.E. The chief of the fortresses is the Kaiserpfalz, 3.5 miles from the centre of the town. Kehl, the tête-de-pont of Strassburg, and several villages are included within this enceinte, and three of the outworks lie on the right bank of the Rhine, in the territory of Baden. In case of need the garrison can lay a great part of the environs under water.

The site of Strassburg was originally occupied as a Celtic settlement, which was captured by the Romans, who replaced it by the fortified station of Argentoratum, afterwards the headquarters of the eighth legion. In the year 357 the emperor Julian saved the frontier of the Rhine by a decisive victory gained here over the Alamanni, but about fifty years later the whole of the district now called Alsace fell into the hands of that people. Towards the end of the 5th century the town passed to the Franks, who gave it its present name. The famous "Strassburg oaths" between Charles the Bold and Louis the German were taken here in 842, and in 923, through the homage paid by the duke of Lorraine to the German king Henry I., began the connexion of the town with the German kingdom which was to last for over seven centuries. The early history of Strassburg consists mainly of struggles between the bishop and the citizens, the latter as they grew in wealth and power feeling that the fetters of ecclesiastical rule were inconsistent with their full development. This conflict was finally decided in favour of the citizens by the battle of Oberhausbergen in 1362, and the position of a free imperial city which had been conferred upon Strassburg by the German king, Philip of Swabia, was not again disputed. This casting off of the episcopal yoke was followed in 1332 by an internal revolution, which admitted the gilds to a share in the government of the city and impressed upon it the democratic character which it bore down to the French Revolution. Strassburg soon became one of the most flourishing of the imperial towns, and the names of natives or residents like Sebastian Brant, Johann Tauler and Gellert von Kaisersberg show that its eminence was intellectual as well as material.

In 1349 two thousand Jews were burned at Strassburg on a charge of causing a pestilence by poisoning the wells. In 1381
the city joined the Städtebund, or league of Swabian towns, and about a century later it rendered efficient aid to the Swiss confederates at Grazano and Nancy. The reformed doctrines were readily accepted in Strassburg about 1533, its foremost champion here being Martin Bucer, and the city was skillfully piloted through the ensuing period of religious dissensions by Jacob Sturm von Sturmeck, who secured for it very favourable terms at the end of the war of the league of Schmallkalden.

In the Thirty Years' War Strassburg escaped without molestation by observing a prudent neutrality. In 1681, during a time of peace, it was suddenly seized by Louis XIV., and this unjustifiable action received formal recognition at the peace of Ryswick in 1697. The immediate effect of this change was a partial reaction in favour of Roman Catholicism, but the city remained essentially German until the French Revolution, when it was deprived of its privileges as a free town and sank to the level of a French provincial capital. In the War of 1870-71 Strassburg, with its garrison of 17,000 men, surrendered to the Germans on the 28th of September 1871 after a siege of seven weeks. The city and the cathedral suffered considerably from the bombardment, but all traces of the havoc have now disappeared. Before the war more than half of the inhabitants spoke German, and this proportion has increased greatly of recent years, owing to the large influx of pure German elements into the city and the almost complete reconciliation of the older inhabitants to the rule of Germany.

The bishopric of Strassburg existed in the days of the Merovingian kings, being probably founded in the 4th century, and embanked by the archbishops on both banks of the Rhine, which was afterwards diminished by the creation of the bishoprics of Spires and Basel. The bishopric was in the archdiocese of Mainz and the bishop was a prince of the empire. The episcopal lands were annexed by France in 1789 and the subsequent Roman Catholic bishops of Strassburg discharged spiritual duties only.

For the history of the bishopric see Granddier, Histoire de l'église et de l'Université de Strasbourg (Strassburg, 1775-1778); C. Meyer, Geschichte des Bistums Strassburg (Strassburg, 1879-1886); and J. Fritz, Das Territorium des Bistums Strassburg (Strassburg, 1885).

For the city see the Strassburger Chroniken, edited by Hegel (Leipzig, 1870-1871); the Urgenben und Akten der Stadt Strassburg (Strassburg, 1879 seq.); G. Schmoller, Strassburgs Blätter im 13. Jahrhundert (Strassburg, 1873); Schricker, Zur Geschichte der Universität Strassburg (Strassburg, 1872); J. K. K. de la Reuss, Deutsch in Strassburg (Strassburg, 1886); H. Ludwig, Deutsche Lieder und Könige in Strassburg (Strassburg, 1889); A. Seyboth, Strassburgs historique (Strassburg, 1894); and C. Stahling, Histoire contemporaine de Strasbourg (Nice, 1884 seq.).

STRATA-FLORIDA—STRAEGUS

the ruins of a celebrated Cisterian abbey of Cardiganshire, Wales, situated amidst wild and beautiful scenery near the source of the river Teifi. The abbey is a m. distant from the village of Whitland. The bridge of the blessed lord) on the Teifi, and about 4 m. from the station of Strata-Florida on the so-called Manchester and Milford branch line of the Great Western railway. The existing remains are not extensive, but the dimensions of the church, 213 ft. long by 61 ft. broad, are easily traceable, and excavations made at different times during recent years have brought to light encaustic tiles and other objects of interest. The most prominent feature of the ruined abbey is the elaborate western portal of the church, which is regarded as a unique specimen of the transitional Norman-English architecture of the 12th century. A fine silver seal of the abbey is preserved in the British Museum.

Founded and generously endowed in 1164 by Rhys ap Griffith, prince of South Wales, the Cistercian abbey of St Mary at Strata-Florida (which was probably a revival of an older monastic house on or near the same site) continued for over a century to be reckoned one of the wealthiest and most influential of the Welsh religious houses. It was much favoured by Welsh bards, nobles and princes, several of whom were buried in the adjoining cemetery; and in its library were deposited many official documents and records of the native princes. In 1158 Llewelyn ap Iorwerth, "the Great," summoned all his vassals to this spot to do homage to his heir, afterwards Prince David II. The abbey suffered severely during the Edwardian wars, and in or about 1294 a large portion of its buildings was destroyed by fire, though whether as the result of accident or design remains unknown; in any case Edward I. gave a donation of £15 towards the restoration of the fabric. During Owen Glendower's rebellion in Henry IV.'s reign, the abbey was pillaged for some months by Harry of Monmouth (Henry V.) with a body of troopers. With the extinction of Welsh independence the abbey lost much of its wealth and influence, and at the dissolution of the monasteries its gross revenue was returned at only £122, 6s. 8d. a year, one Richard Talley being its last abbot. The fabric of the abbey and its surrounding lands came into the possession of the Stedman family, whose 17th-century mansion, built out of materials from the monastic buildings, has long been used as a farmhouse. By marriage the abbey and the estate of the Stedmans passed into the possession of the family of Powell of Nanteos.

STRAEGUS (στραγηγός), strictly the Greek word for a general, or officer in command of an army, but frequently the name of a state officer with much wider functions. Such an officer is found in many Greek states, the best known being the Athenian strategus, originally a military official, whose functions gradually developed until, in the latter half of the 5th century B.C., he became the most important magistrate in the state. According to Aristotle's Constitution of Athens iv., the office existed in the time of Draco and the qualification was property (G. 5.). The value of 100 minae made up the stipend (the high water mark at which the archonship was obtained); but it is certain that until the end of the 6th century the archon (g.r.) was the most important state official. If, as is probable, the chapter in the Constitution is a forgery (see DRAKO), we may conclude that the Strategen (board of ten generals) was a result of the tribal system of Cleisthenes, and that the college is to be ascribed to the year 501 B.C. Some maintain that Cleisthenes himself created it, but the evidence (Ath. Pol. xxii.) is against this. It all events, as late as the battle of Marathon the head of the army was the Polemarch (see ACHERON). It follows that the strategus was, until 487 B.C., subordinate to the Polemarch. The tribal unit was represented in the army by the taxis, and each taxis was led by a strategus. After the Persian Wars the command of the taxis passed to officers called taxiarchoi, who acted as colonels under the strategus. If Herodotus may be trusted, the command of the army, at the time of the battle of Marathon, passed to the strategi in turn from day to day. No trace of this system, however, is to be found in the subsequent history. It was the customary practice in the 5th century to appoint a certain number of the generals, usually three or five, for a particular field of operations, and to assign the chief command to one of them. Exceptions to this rule are found in the well-known instances of the Sicilian expedition (when the three commanders, Nicias, Alciabides and Lamachus were given co-ordinate powers), and of the battle of Arginiaeus, when the command was divided among the whole board. In crises such as the Samian revolt, the outbreak of the Peloponnesian War or that which led to the recall of Alciabides, we find the whole board subordinated to a single member (e.g. Pericles or Alciabides). Originally each strategus was elected by and out of the tribe he commanded (Ath. Pol. lxi.), and it may probably be inferred from Plutarch (Cimon, viii.) that the system prevailed as late as the archonship of Aephephon (469 B.C.). In the 4th century, however, the strategi were elected out of all the citizen body irrespective of tribes; the change must have occurred between 470 and 440 B.C., because in the latter year, and again in 433, one of Pericles' colleagues was Dionitus, a member of his own tribe (cf. Alciabides and Adeimantus in 408 B.C.). But from Xenophon (Memorab. iii. 4) we learn that one strategus was still elected by each tribe, i.e. each strategus represented a tribe, though he might not be a member of it. Though the strategi were the nominal heads of the army, it is important to notice that they had no power to choose their taxiarchoi, who, like the strategi, were elected by the tribes they were to command. It was only
as low as the lochogi (commanders of ὥγοι, companies) that the Ecclesia allowed them to select. From the Constitution (ki. 3), however, it appears that in the 4th century, at any rate, the lochogi were appointed by the taxiarques, not the strategi. By a gradual process in the course of the 5th century, the regimental command was transferred to the taxiarques, the strategi thus becoming general officers in command, while they at the same time acquired important political functions (see below). On the other hand the strategi commanded by both land and sea, and thus held the power divided at Sparta between the king and the strategos (admiral). In the 4th century, when the ascendancy of the taxiarques was, as Beloch, Meyer, and Moltke's works show, about to become connected with the word, and the essential quality in the general's personality which alone rendered ruses practicable, or guaranteed success in their execution, passed out of men's minds, until the gradual disappearance of these methods in the Napoleonic period focused attention again on its essential meaning, i.e. the art of the leader. Then the term "strategy" became limited as a technical term to the "practice of the art of war by an executive agent of a supreme government," or in Moltke's words, "the practical adaptation of the means placed at a general's disposal to the end contemplated by the object in view." This definition fixes the responsibility of a commander-in-chief to the government he serves. He cannot be held answerable for the "means," not even for the training of the "means" for a particular operation, unless he be appointed to his task in adequate time. He is charged with their employment within the limits of the theatre of operations assigned to him. If he considers the means placed at his disposal inadequate he need not accept the position offered him, but he steps beyond his province as a strategist if he attempts to dictate to the government what, in the widest sense, the means supplied to him should be.

Since, however, the "means," i.e. the conditions of the problems presented by war, are subject to infinite variation (climate, topography, equipment, men, all being liable to collective or independent change) it is clear that their employment can never be reduced to a "science" but must retain to the full the characteristics of an "art." This distinction is essential, and must be borne in mind, for no soldier can expect to become a Napoleon merely by the study of that great strategist's campaigns. But if he lack practice and experience, and at a general's disposal to the end of such teachings as the contemplation of the works of his predecessors can only do so at his own peril; and when, as in the case of the soldier, the whole destiny of an empire may depend on his action, he must be held indeed who would neglect all possible precautions. The cases for study, however, rest on yet broader foundations, for, though theory deduced from history can never, from the nature of things, formulate positive prescriptions, it can at any rate enable the student to throw off the chains of convention and prepare his mind to balance the conflicting claims of the many factors which at every moment clamour for special recognition.

To understand the subject thoroughly it is necessary to follow in some detail the successive stages of human evolution. From the earliest times the defeat of the fighting men of a race has been the most certain road to the acquisition of its wealth, or the trade conditions on which that wealth was based.

To defeat an enemy it was first necessary to march to meet him, and during that march the invaders must either live on the country or carry their own food. If the defender drove off the cattle and burnt the crops, the latter alternative was forced upon them. Thus, since the supplies which could be carried were of necessity small, the defenders had only to create or utilize some passive obstacle for defence which the invaders could not traverse or destroy in the limit of time (fixed by the provisions they carried) at their disposal, to compel the latter to retire to their own country. Every sedentary nation, therefore, had a fixed striking radius which could only be extended by the exercise of ingenuity in the improvement of means of transport, i.e. carts and roads. The existence of roads, however, limited the march of an invader to certain directions, and hence it became possible for the defender to concentrate his efforts for their
defence on certain points, in fact, to create fortresses, greater or less in proportion to his fear of the enemy and his intelligent appreciation of the degree of sacrifice it was worth while to make to obtain security. A barbarian horde could be stopped by any barrier which could not be set on fire or escaded without ladders or appliances. Ruses, such as the wooden image of Troy, then became the fashion, and the land had to be met by the cultivation of a higher order of intelligence, which naturally thrived best in a crowded community, where each felt his dependence on his neighbour. Thus, for ages, the fort or fortress limited barbarian encroachments, and made possible the growth of civilization in the plains. Ultimately, when the civilized communities grew into contact with one another, developed antagonistic interests, and fell out with one another, intelligence was brought to bear on both sides, and the assailant met fortification with siege-craft. Then the whole cycle worked itself out again. To carry out a siege, men in numbers had to be concentrated and fed whilst concentrated. The stores for attack were also heavy and difficult to convey, hence roads developed increased importance, and troops had to be abstracted from the fighting force to protect them. Thus again a limit of striking radius was fixed for the invader, and in proportion as the dimensions of the invaded country exceeded this radius, and its people made the requisite sacrifices to maintain their fortifications in order, the continued existence and growth of the smaller country was assured. Broadly, this equilibrium of forces remained for generations; the smallest states were eaten up, the larger ones continued to exist side by side with far more powerful enemies, or else, but only on condition of their readiness to make the requisite sacrifice of their personal liberty and the property of their constituent units.

Then came the introduction of gunpowder and of siege artillery, and a fresh readaptation of conditions, which culminated in the Netherlands during the 17th century and forms the starting-point of all modern practice.

Essentially the change consisted in this, viz. that in spite of the superiority of the cannon-ball to the battering-ram, yet to attack a wall effectively many guns had to be employed, and while the duration of the siege was enormously shortened, a far greater strain was thrown on the line of supply, for not only did guns weigh as much as their predecessors but they could expend their own weight of ammunition in a day. Hence the importance of good roads became enhanced and correspondingly the incentive to attack the fortresses which guarded them. In comparison to the money devoted to modern armies, the sums sunk on passive defences during the 16th and 17th centuries were colossal, but they could not keep pace with the progress of the attack, and once more fresh readjustment of means to end became necessary. The obvious course was to carry the war into the enemy's country from the outset, but since this transferred the burden of the siege upon the aggressor, the latter was compelled to develop the standing mercenary army, as feudal levies could not keep the field long enough to reduce a fortress. Mercenary armies, however, were difficult to keep together. They had to be tactfully commanded to ensure contentment, and allowed to maintain social order amongst themselves, and the prospect of loot while on active service had to be held out to them. The sack of a city became thus the absolute and undeniable right of the soldiers. If in this or any other way their employer broke his contract, individual property was deserted to the other side. But this right of sack led to a recrudescence of the spirit of resistance in the fortresses (War of Dutch Independence and Thirty Years' War), and hence to a reaction in favour of greater humanity in warfare. But this was only obtained by the concession of a higher scale of pay and comfort to the men, which again threw an increased strain upon the communications, and also upon the treasure chest of their employer.

The growth of the mercenary system, and the facility with which such men could and did change their allegiance, led very rapidly to almost complete uniformity in the composition, training and tactical methods of all armies. Every one of them in advance the degree of effort his adversary had to put forward in the next campaign, and made corresponding preparations to meet him. Practically the king desiring to make war submitted his idea to the best-known generals of his day and asked them to tender for its execution. The king, on his side, generally agreed to find the bulk of the labour—his standing army, reenforcement of auxiliaries to any desired extent—and as in the case of a modern government contract, the lowest tender was almost invariably accepted, with a pious exhortation to the successful competitor to spare his employer's troops to the best of his ability. Thus the opposing generals took the field, each equally fettered by the conditions of his tender. But two such armies, alike in almost every respect, were far too closely matched to be able easily to gain a decision in the open field. Once they were committed to a battle it was impossible to separate them until sheer physical exhaustion put a stop to the slaughter, and these highly trained men were difficult and expensive to replace. Naturally, then, the generals sought to destroy the existing equilibrium by other means. Primarily they took to strong entrenchments, but the building of these being a matter of time, the communications grew in importance and attempts against them became more serious. One side or the other, consequently, to cover its communications, so extended its front that at length lines stretched right across whole frontiers till their flanks rested on the sea, or on some great fortress or neutral territory. The two armies would then face one another for months, each exhausting every device to induce the other to concentrate on one part of his front whilst an attempt was made by a rapid move to seize a relatively unguarded point elsewhere, e.g. Marlborough's surprise of the Ne plus ultra lines (see Spanish Succession). During such periods of immobility the wars grew to the solility of permanent fortifications, with wide and deep ditches, and with every obstacle known to engineers, whilst to render them defensible by the minimum number of muskets, they were laid out so as to cross their fire over and over again opposite every weak point in their tracing. No amount of battering could alter their general trace, and so they remained defensible as long as their garrisons could be trusted to line the parapets at all. This state of things might have continued, but the invention of a weapon with sufficient accuracy and shell power to drive the defenders from their parapets and keep them away till the last moment preceding assault, had not fresh factors evolved themselves from causes at work under totally different topographical limitations and conditions.

First amongst these comes the accession to the throne of Prussia of a king who was commander-in-chief of his own army, and as such responsible to no one for the use he chose to make of it. This would really remove him at once from the category of strategists in the restricted sense in which the term is now employed, but since the whole power of a state in the action of a ruler playing the double part of soldier and governor, it is convenient both in his case and in that of Napoleon to use the expression to cover the wider sphere. The permanence of the association between king and army enabled Frederick the Great to train his men specifically for the work he intended them to perform. Realizing to the full the value of the foundation laid by his father in developing to its utmost the fire power of the infantry, he devoted special attention to imparting to them a skill and rapidity in manoeuvre which ensured that in the open field his generals would always be able to place their artillery to best advantage and they trained in the highest tactics relatively to the enemy; and his cavalry were trained to such a pitch of mobility and precision in drill that they could be relied on to arrive at the appointed time and place to reap the fruits which the infantry fire had sown. To these startling innovations the Austrians had no new ideas to oppose. The old school, the survival of the fittest in the special theatre of its growth, i.e. the Netherlands and the Rhine, could not deal with the complete change in topographic surroundings—the far wider area of operations, the comparative scarcity of fortresses and the general practicability of the country for the movement of troops—not trains—off the roads. Frederick, relying absolutely on the intrinsic superiority of his army, knew that if he could catch his enemy in the open victory
was a foregone conclusion. If the enemy, in accordance with precedent, fortified a position, a threat to his communications would force him to come out on pain of being surrounded (Pirmas 1756, Prague 1737). He followed this principle (see Seven Years' War) until the accession, first of France and the South German states, and afterwards of Russia, to the list of his enemies compelled him to give one enemy time to prepare a position whilst he was engaged against another. Before directing his preparations he had to consider that if he could bring thousands, as they would have been in the Netherlands, and at length he was compelled, for want of an adequate artillery, to adopt the same procedure as his adversary. Thus the war ultimately came to an end by a process of mutual exhaustion. But it had brought out conspicuously the value of highly disciplined soldiery, and a fresh fetter was prepared for those on whom, after Frederick's death, the responsibility of command was to fall, and practically all Europe went back to the warfare by contract of the previous generation.

Meanwhile in France events were at work preparing the instrument Napoleon was destined to wield. Contrary to the prevailing opinion amongst modern historians, it is the fact that at no time in history was the art of war, and of all things appertaining to it, more closely studied than during the last years of the old royal army of France. Gibbon paved the way for the creation of the artillery destined to win for Napoleon his greatest victories, and authors and generals such as the prince de Ligne (q.v.), the Duc de Broglio, Guibert (q.v.), Bosroger, du Teil and many others pointed out clearly the line of reform must take if the existing deadlock between attack and defence was to be removed; but none could suggest the first practical steps to apply, because the existing conditions were too closely interwoven and consolidated. In fact reform was impossible until the dissolution of society itself gave its ultimate particles freedom to combine in more suitable formations. Broadly, however, all were agreed that the protracted and indecisive operations of former wars were economically disastrous. A crushing and decisive victory was the aim for which all should strive; as a first step towards this object decentralization of command was essential, for freedom of manoeuvre, the only answer to the French methods, was impossible but without it. This led to the idea of the permanently organized division of all arms; and events had reached this point when the deluge of the French Revolution overwhelmed them, and in face of a coalition of all Europe it became necessary to build up a new army from the very foundations. The steps by which it was sought to provide the men are dealt with in the article Constitution; it is only necessary to point out here that it was not till 1799 that the laws became sufficiently defined to ensure a regular annual increment of recruits, and it was this regularity of supply, and not the fact that compulsion was needed to enforce it, which rendered expedient the complete revolution in warfare which Napoleon was destined to effect.

Until this reform was complete the revolutionary commanders were compelled to make war as best they could under pressure of the law of self-preservation, with the consequence that the whole army became habituated to the fact that orders in the field had to be obeyed at any sacrifice of life and comfort, and that neither hunger nor want of shoes, even of muskets, could be accepted as an excuse for hesitation to advance and to fight. Threatened on all sides, France was at first compelled to guard every avenue of approach by small separate forces taking their instructions only from a central authority in Paris, and thus the "division," a mobile force of all arms, which the earlier reformers had demanded, came spontaneously into existence to meet the requirements of the moment, and, thrown on its own resources, developed the brain and nervous system, i.e., the staff, necessary to co-ordinate the action of its limbs.

The next step in evolution came from the obvious advantage which must arise if these units, though starting from different bases, operated towards the attainment of a common purpose. The realization of this ideal, the starting-point of modern strategy, was the creation of Carnot, whose ideas, though far in advance both of contemporary opinion and of the technical means of execution then available (especially in the matter of imperfect means of telegraphy), formed a necessary step in the preparation of the machinery Napoleon was to inherit.

These, therefore, were the materials placed at his disposal when he began to practise the art of the leader: (1) a practically inexhaustible supply of men (the law in fact was not passed till two years later, but the idea was sufficiently evident); (2) recruitment units and commanders, trained to absolute obedience to field orders, and accustomed to solve the problems presented to them in their own way, without guidance from superior authority; (3) the idea of co-operation between separate columns for a common purpose; and (4) a tradition that the word "impossible" did not exist for French soldiers.

The equipment of the allies started from very different foundations. To them the individual soldier was a valuable possession, representing an investment of capital generally estimated at £300 (as great a strain on the exchequer then as £4,000 now); and not only was he exposed to the risk of death in action, but he might die of disease or exhaustion on the march, and could always desert if he felt discontented. Moreover, the last campaigns of the Seven Years' War seemed altogether to justify methods of evasion and "strong positions." Frederick the Great, beginning with the most audacious offensive, had ended by copying the caution of his antagonists, and each side had learnt to gauge the fighting value of a single battalion so accurately that to move a force, recognized by both as adequate for its purpose, into a threatening position, sufficed of itself to induce the adversary to accept the situation thus created. Since the battlefields were level, and the land occupied on the ground, the cult of topography became a mania, and (as Clausewitz puts it) the world lost itself in debating whether "the battalion defended the mountain or the mountain defended the battalion." The care for the comfort of the private soldier was pushed to such a degree that commanders would not report their units fit for action until complete to the last garter button and provided in advance with the regulation scale of rations for a fixed number of days. Over-centralization continued; though the expressions "divisions" and "corps" were already known, the idea that these words now convey had not yet even come into existence. Though a certain number of units might be assigned to a subordinate commander, they still received all orders, except on the battlefield, from the central authority, and were, moreover, considered interchangeable. There was no personal bond between them and their general. To what lengths this system was pushed, and the consequences which flowed from it, may best be gauged from the fact that in 1805 Mack, when writing his defence for his failure at Ulm (see Napoleonic Campaigns), thought it quite natural to explain the delay in his movements on the day of Elchingen by the fact that when news of the French attack was received he was busy writing out the orders for the following day, which occupied fourteen pages of foolscap and "did not contain one superfluous word." Further, the idea prevailed in middle Europe that war was a matter concerning the contend ing governments in which the ordinary citizen had no interest whatever. It was true that the result of a war might transfer his allegiance from one crown to another, but this was scarcely more to the people than a change of landlords. Consequently they took little if any interest in the progress of a war, and on the whole were most inclined to help the army which most respected their private property and was willing to pay highest for its accommodation while billeted in their towns and villages. Since the goodwill of inhabitants is always valuable, commanders vied with one another in their efforts to purchase it, and respect for private property and rights reached an unprecedented level. Thus, during the whole of the campaign of the Netherlands in 1793 the Austrians paid hire to the owners of the fields in which they camped; and when on one occasion payment for lodgings hired for the wounded was in arrear, the wretched men were flung out on the streets. Yet another, and in a way more remarkable, illustration of this tendency occurred at the capture
of Mainz by the French (1794). A strong armed party of
Austrians, endeavouring to escape across the Rhine to Kastel,
were refused the use of the ferry boats until the regular payment
was made, and actually laid down their arms to the enemy rather
than break the law and seize the boats.

The cumulative influence of all these forces of retardation
is easily followed. To avoid the cost of innumerable petty cash
transactions with the inhabitants the troops were compelled
to have recourse to the magazine system, which in turn tied
them absolutely to the main roads; and the roads being numerous
the army had to be broken up into small detachments to guard
them. Thus the so-called "cordon" system grew out of its
surroundings in a perfectly natural way, and was not due to the
imbecility of the generals who employed it, but to the restraints
placed upon them by the necessity of preserving the feeling of
the more fortunate for the French could be imagined. Destitute
of all the paraphernalia hitherto considered necessary, and com-
pelled to fight at any cost in order to live, they found in these
accumulated magazines and moving convoys the best possible
bait to attract their starving men; relieved of all impediments,
they could move freely through forests and marshes generally
considered impracticable; and since from the magnitude of front
covered, and the relatively small number of troops available, the
allies could not oppose an unbroken front to their raids, they
could swarm around the flanks of the positions and thus compel their
enemies to maintain more troops on the flanks of positions led, as before in Marlborough's time and in our own
day in Manchuria and South Africa, to a competition in
extension, and at Napoleon's advent it was common to find
armies of 20,000 to 30,000 men fighting desultory actions over a
front of 20 to 30 m. This over-extension gave him his first
opportunity, when the fire and energy he threw into his work,
and the reckless disregard of human life he immediately displayed,
stamped him at once as a born leader of men, and laid the
foundation of that confidence in his guidance on the part of his
troops which to a certain extent compensated the limitations of
his personality. Whether Napoleon's evolution the reader is referred to
the articles FRENCH REVOLUTIONARY WARS and NAPOLEONIC CAMPAIGNS, and here it will suffice to point out the leading
characteristics of those campaigns. Having swept the Austrians
out of Sardinia, he turned against them in eastern Lombardy,
and by a series of outflanking attacks threw them back into the
Alps, defeating all their attempts to break out again by
what is now known as a "series of operations on interior lines."
All these were successful, not because of the form the operations
took, but because the enormous increment of mobility he managed
to impart to his men deprived his adversary of all possible
data by which to time his own combinations. It cannot with
justice be said that the French won because they fought harder;
but the rapid sequence of success confirmed both leader and
men in a conviction of their combined superiority which led
Napoleon in 1800 to the very brink of disaster. In 1796 through-
out he was acting fairly in accordance with the teaching he had
imbibed from his studies; in 1800 he appears as if seeking to
determine how many of the established rules he could afford
to neglect. We find him advancing to meet his adversary on
a widely extended front, without waiting for the victory,
to learn where or in what strength that adversary stood.
In 1805 this mistake is not repeated; a cavalry screen covers his
advance, and his orders are based on the intelligence it transmits.
But this precaution also proves insufficient. Cavalry can only
see, they cannot hold; and only a combination of circumstances
which he could not by any possibility have foreseen prevents his
ever from evading the blow at the last moment. What
the position of the French would have been had Mack carried
out his intention of leaving Ulm and destroying all his accumu-
lalion of supplies can only be imagined. But contemporary
evidence proves beyond doubt that Napoleon had already tried
the endurance of his men to the utmost.
In 1806 the mistake of sole reliance on a cavalry screen is
no longer repeated. The cavalry now is backed by a strong
advanced guard, one quarter of the whole army, following
behind it at short distance; and the whole command is now
disposed in such a manner that no matter in what direction the
enemy may appear it can concentrate in forty-eight hours to meet
him. It is another form of the idea, prominent in British
campaigns in the Sudan, of the advance in squares through the
desert against a mobile enemy, the difference being that
Napoleon's great "bataillon carré" has the advantage of
mobility over its adversary. Concentration within forty-
hours, however, would in itself be worse than useless
unless the enemy stood fast to receive the Intended shock;
and it was the special object of the strong advanced guards or
flank detachments to force him to do so. This could
only be attained by a resolute offensive; no mere feeling
the enemy's position would suffice to compel him to stand,
and in the end prove more costly to him. However the task devolved
upon the troops thus selected was essentially different from that
usually connected with the idea of an advanced or flank guard,
and involved the conception of purchasing with their lives and by
the vigour of their action the time necessary for the rest of
the army to deliver a decisive blow.

This is the true meaning of Napoleon's maxim: On ne
manoeuvre qu'autour d'un point fixe, a phrase which has
been much misunderstood. The troops first engaged fix the
enemy by the vigour of their attack, and thus constitute a pivot
about which the rest of the manoeuvre revolves.

Hitherto, however, the French armies had been operating in a
country in which roughly one square mile of area would feed
one thousand men for two days. Their freedom from convoys
and other impediments enabled them to sweep out an area
sufficient for their needs from day to day. But events now led
them into a region in which this relation between the day's
march and their subsistence no longer obtained. The emperor
in fact had formed no conception of the roadlessness and poverty
of Poland and East Prussia. His men, no longer able to pick
up their day's food by a day's march, rapidly fell off in condition
and discipline (for short commons with the French always en-
tailed marauding). As men and horses lost in condition the day's
march dwindled further, with the result that heavier demands
were made on the supply columns; and these being improvised
and entrusted to an untrained personnel, the sufferings of the
troops became unendurable, while the mobility of the French
army sank below that of the enemy. Under these conditions
the system of the advanced guard could no longer be trusted to
work. Moreover the Russians, though deficient in the dash
necessary to win victories in attack, have always taken longer
to defeat than any other continental troops, and in the short
days of the first half of the Polish campaign the emperor had no
longer time to beat them into dissolution. The Russians
would fight all day and retreat at night. As they fell back
along their communications their feeding was easy. The
exhausted French could never overtake them, and the emperor
was at length compelled to adopt an expectant attitude. Not
before Friedland (June 14, 1807), when the days were long and
the country dry and everywhere passable, did his calculations
of time and space prove realized and the system justified by
the results.

In 1812 he again attempted to apply it at Vilna and
Smolensk the Russians successfully repeated their tactics of
vaison on every occasion, until, when they had fallen back to
Borodino, their enemy had so far diminished that a battle in a
selected position promised reasonable chances of success.

Meanwhile a fresh development in the tactics of the three
arms added a new weapon to Napoleon's armoury, rendering
the application of his system or any variant of it markedly
more certain and efficacious. Whilst the infantry which fought
under Napoleon's eagles had been steadily deteriorating, owing
to the exorbitant demands his ceaseless marching campaigns
had made upon them, the quality of his enemies had been as
steadily improving. The growth of the sentiment of nationality
had rendered it possible to throw aside the rigidity and imped-
iments of the old conditions. There was no longer any fear that
men would desert if called on to hivouac or if rations failed to
come up to the accepted standard, and the essential points of the French infantry tactics having been assimilated they developed a relatively higher standard of endurance as measured by time. Meads had to be discovered to ensure their destruction before nightfall gave them the opportunity of withdrawal; and the evolution of the artillery arm (see Artillery) at last gave Napoleon the weapon required to realize the ideal implanted in his mind by his teacher de Teul, viz. concentration of the destructive elements on the decisive point, which was derived originally from the analogy between the attack on a fortress and the conduct of a battle. A battle is but an abbreviated siege, or a siege a prolonged battle. In the former the object is to purchase time at the cost of men's lives, in the latter to economize men by expenditure of time; but in both the final step is the same, viz. the creation of a breach of continuity in the enemy's defence through which the assaulting columns can penetrate to the heart of his position. Thanks to the increased mobility in the field artillery and skill in handling it (the result of years of experience), it was now possible, once the aim of the enemy's infantry had been unsteadied, to bring up masses of guns to case-shot range and to break the living rampart of the defence; and through the gap thus created, infantry or cavalry, or both combined, poured to overwhelm the last reserves beyond. This step completed Napoleon's means of destroying that "independent will power" of his adversary which is after all the greatest variable in the whole problem of war. His advanced guard engaged and fixed his adversary's infantry, while he brought his own artillery to bear and compelled him to use all his reserves, and when the battle was "ripe," to use his own expression, the great blow was delivered with overwhelming suddenness by the balance of fresh troops which he had in hand. But the whole of his action depended essentially on an exact appreciation of the endurance of his own troops first engaged, at the cost of whom the reserves were saved up. It was the possession of this method which rendered Napoleon supreme upon the battlefield and fully justified the reluctance which his enemies showed to hazard its issue; but in the end it also proved the cause of his downfall, for in its very peculiar economy of force to action in 1813 he so completely wore out his troops that it became physically impossible for them to meet his demands. The campaign of 1813 deserves attentive study, for in it Napoleon was both at his best and worst, acting as strategist pure and simple, applying the means at hand to the attainment of the object in view almost without a second thought for the diplomatic relations which so often hampered his military action, notably in 1814. In the famous "defensive campaign" of the latter year, which is usually held up as a model for imitation, he can hardly be said to have acted as a strategist at all; his movements were essentially directed to the destruction of the personal relations existing between the three allied monarchs, not to the annihilation of their respective armies, a task for which from the first he knew his resources to be entirely inadequate. The Waterloo campaign (q.v.) again reveals the application of this system in its most finished form. That it failed ultimately was due primarily to atmospheric influences beyond the emperor's control, and in the second place to the introduction of a new tactical method by the British army for which his previous experience had in no way prepared him. The Aftermath. Napoleon had to have some means to justify himself further proof of the essential duality of his nature, which only rose to intuitive genius in war under the pressure of visible and tangible realities. Relaxed from excitement, he was the creature of his surroundings, controlled by contemporary thought like everyone else; and it is to failure to recognize this duality in his mind that all subsequent confusion in strategical thought owes its origin. It was clear that the career of such a genius could not pass unnoticed by military critics, hence, even while it was still in the making, every student of the military art felt compelled to pass judgment upon its incidents merely to show that he was abreast of the times. More or less, each one tried to show that Napoleon's victories were due to the observance of the critic's own hobbies. These men, brought up on the old military classics, and unaware of the ceaseless current of social changes which was seething around them, instinctively distorted facts to fit in with their preconceived theories. This is always inevitable with regard to contemporary criticism, since distance of time is always needed to bring facts down to their true perspective. It is quite clear from his innumerable reported conversations, and it is quite natural when heard once or twice, how Napoleon, in the back of his mind he stood rather in awe of these older and often far more deeply-read men. In any case it was quite obvious to him that his military reputation would stand or fall by their collective judgment. Hence, as soon as he had leisure, he set himself to explain his exploits in terms which they could understand. That he would be criticized for his frequent departure from established practice (for instance, in neglecting his communications, and again and again accepting or forcing on a battle in situations in which defeat must have spelt utter ruin) he was well aware. Hence, while such criticism in itself he went out of his way to accentuate the care he had devoted to his communications, as in the Marengo campaign, at Ulm, at Austerlitz, and again and again in the campaigns of Wagram and of Dresden. But the truth really is that as long as he adhered to his "bataillon carré" formation, and the country in which he was operating was fertile enough to support his men, his communications mattered little to him. His certainty of victory, if only the enemy could be induced to stand, was so great that he could fight his way through to where his reinforcements were prepared for him, in whatever direction suited his purpose, and the longer the enemy continued in his attempt to prevent him, the more he economized his forces. He was aware, but the criticism of whose minds he was quite familiar, Marmont, Rogniat, Soulé and St Cyr were men for whose intellect he had the highest esteem, and all wrote at length on the subject of his campaigns, yet not an expression in their works, not a manoeuvre in their independent commands, can be held to betray a knowledge of what was really the secret of the emperor's successes. For instance, by the year 1812 Marmont may fairly be assumed to have learnt all he ever could learn from Napoleon's example; yet at Salamanca we find him manoeuvring quite like one of Frederick's generals. Napoleon would have attacked Wellington's entrenchments at Welling- ton, and the ground would have been strewn with English dead at the least, and whilst the latter was busied in wading off his assailant's successive blows the emperor would have swung the remainder round upon his enemies' flank, and, with a three-to-one superiority at the decisive point, have driven him off the road back to Salamanca. This idea never even entered Marmont's head. Watching Wellington with a screen of vedettes only, he set his whole army in motion to march round his flank, like Frederick at Leuthen. An Austrian army in the old days would usually stand to be surrounded, but Wellington, instead, set his whole force in motion, i.e. marched through. Again in 1813 (just after frequent conversations with the emperor, in one of which the latter stated his opinion that war was a "science" like any other, and that some day he would write a book out of which one could learn it,) Marmont, in command of the VI. corps, found himself opposed to the Silesian army under Blücher, and immediately took up a defensive position, which he occupied by two lines of brigades deployed in line and echeloned from left to right. No one who had entered into the spirit of the emperor's method could have adopted such a formation. Instances of a similar nature might be multiplied, and their multiplicity need surprise no one who has studied the psychology of action taken under circumstances of intense excitement or imminent danger. Most of us know rules for
conduct in all kinds of emergencies, but how often afterwards could anyone describe with accuracy the mental process by which his action in such crises was dictated? Probably never. Intuitively the mind recognizes the right course and fixes upon it, and with the cessation of the emergency finds it impossible to recall the order in which the facts presented themselves to his consciousness. In war these emergencies are constantly arising, so that by degrees the recollection of them becomes blurred, and the chief actor's presentation of them is often the least trustworthy testimony we possess. The act speaks for itself. But where hundreds of thousands of acts are crowded into the short compass of a campaign, a true view of their whole can only be obtained when all have become accessible and time emancipates criticism from partiality. But nations cannot afford to wait until lapse of time renders it safe to publish all diplomatic and other secrets; and many were ready to attempt the solution of the problems of Napoleon's career.

The most prominent were Jomini (q.v.), speaking for the French army, and Clausewitz (q.v.), for the Prussian. The former, a native of Switzerland, had attracted the attention of Napoleon by the insight his criticisms revealed, and had been attached by him to the staff, where he served under Ney almost continuously from 1806 to 1815. In the latter year there is no doubt that he contributed valuable service in the operations culminating with the battle of Bautzen; but, receiving no adequate recognition for them, he deserted to the allies, and was attached by the emperor Alexander, where again he rendered conspicuous service, notably at Leipzig; but his desertion caused him to be viewed with such marked disfavour by all honourable men that he speedily sank into social oblivion, although he remained in the Russian service until his death in 1869. Nevertheless, though he had deserted his cause, he still retained unbounded admiration for the genius of his great master, whose reputation certainly does not suffer at his hands, except for the excess of adulation and bombast with which his historical writings are disfigured. But his social isolation cut him off from authentic eyewitness sources, and he was by nature an inventor of systems. The secret of Napoleon's success he found in the system of "interior lines"—a phrase he invented to designate a method which was almost as old as war itself; and from this system he deduced its opposite, "exterior lines," and a whole sequence of others, which in the end all resolve themselves into the same idea. A diagram will make the matter clearer than many words. If an army A stands in a central position relatively to two other armies B, C, converging upon it, then, if it moves against each in succession and beats them both, it is said to act on "interior lines"; whilst B and C act on "exterior lines." What it is said to do when at the first shock B beats it out of existence the books fail to inform us. From this theorem are deduced in succession the advantages and disadvantages of salient and re-entering angles, &c., with which, as a rule, military historians so freely befog their pages.

Since the object of all strategy is to bring the greatest possible force to bear against the decisive point, it is obvious to ask why armies should not always be concentrated, and why they should ever divide. The answer is that a given district and a single road will only subsist a certain number of men, a number which in practice is found to be about 60,000 with their requisite guns and train. Hence an army, say of 120,000 men, not only cannot subsist on a single line or road, but when divided into two equal parts, and separated only by a short day's march, is really more ready for instant action than an army of 60,000 on one road. Separation, therefore, when large numbers are in question, is a necessity of existence, not a matter of free choice; but when it is thus forced upon a commander he regulates the rate of his march so that his separate columns cannot be attacked singly before the heads of both are within supporting distance of one another; the jaws of the crackers then close on the nut, and unless the nut proves harder than the crackers the nut is crushed. But this calculation reposes on an accurate knowledge of the marching powers of the adversary, and it was in this that Napoleon's enemies failed. Accustomed only to their own deliberate methods, they were quite unable to imagine Napoleon's lightning-like rapidity. Marching twenty-five miles in a day, his whole army would hurl itself on one of the columns whilst the other was still too far off to convey to its aide-de-camp their already approached so close that mutual co-operation was imminent, he would send a detachment against one to purchase time by the sacrifice of its men's lives, and would then strike at the other with the bulk of his forces united. How the detachment executed its task depended chiefly on the nature of the ground. It might fight a series of rear-guard actions if a succession of readily defensible sections favoured such action, or it might conceal its weakness and impose caution and respect on its opponent by the vigour of its attacks; for that there could be no rule, and circumstances alone could decide. In this form Napoleon won most of his earlier successes, but a little reflection will show that the method depended essentially upon his superior mobility and the willingness of his enemy to fight or the reverse. In time this dawned upon his opponents also, and when in 1813 around Dresden he tried to put this plan into force the allied column immediately threatened retreated before him, whilst the other continued its advance, thus compelling him to return to succour his retreating detachment, which, of course, could not struggle on indefinitely against a marked superiority of numbers. He himself confessed during the September days in Dresden that this jeu de va-et-vient, as he described it, had completely broken down his system. If, on the other hand, the commander of the central army underestimates his opponent's marching powers its doom is sealed, for both his flanks are turned in advance and he comes under a concentrated fire to which it can only oppose a divergent one. This difference is more marked now than formerly; and stated in its extreme form, for rifle fire only, it really means that every bullet fired from the circumference stands a tenfold better chance of hitting something vulnerable than those directed from the centre towards the circumference. The only salvation of an army thus threatened is to move by a lateral march outside the jaws of the circle, and fall on one limb only; if it is tactically formidable, it stands a good chance of overwhelming the force immediately opposed to it before the others can arrive. For instance, at Königgrätz, if the Austrian main army, pivoting on the fixed point made by their 2nd and 4th corps engaged with Prince Frederick Charles's army, had swung round the remaining six corps upon that of the crown prince by a short march of from six to eight miles, the Elbe army would have struck a blow in the air, and the situation
would have been rescued in spite of the slowness and indecision of previous movements. An army standing on interior lines, therefore, occupies a position of advantage or the reverse according to the skill of its leader and its own inherent fighting capacity, and this whether its position arises from operations during the actual course of hostilities, or from circumstances already pre-existent in peace time, as for instance, the configuration of frontiers. The phrase, therefore, "the use of interior lines," though convenient to those who are thoroughly agreed as to its limitations, of itself explains nothing, and is a pitfall for the inexperienced.

A, however, in moving as suggested against his enemy's outer flank, exposes at the same time his own communications with any place lying directly behind his point of departure. If his army suffers only from slowness, but is really superior in fighting power, this risk may be lightly taken—victory settles all things. In proportion, however, as the result of collision is doubtful, alternative lines of retreat or supply will be advantageous. Hence a broad, if possible a concave or re-entering, base or starting-line is of great importance, and, since as an invader penetrates into his enemy's country his base becomes salient, whilst that of the defender becomes re-entrant, we have here a compensating arrangement which, under given conditions of country, equipment and the like, fixes the striking radius of an aggressor precisely as was the case in former times. The case of the French invasion of Russia in 1812 is an illustration. The Russian base at any moment may be considered as formed by lines traced just outside the striking radius of small bands of French marauders; the French base as including all the territory in their occupation, for within that area they were free to fortify or protect any accumulations of stores and supplies they chose to make. By the time the French reached Moscow the Russians could afford to attack them from any direction, for, whatever happened, retreat into their own undevastated country was always open. The South African war affords a modern example of the same thing.

These ideas are, after all, elementary, and readily grasped even by the average intellect, though many volumes have been devoted to proving them, and yet they are all that Jomini and his followers have to offer us—a fact that both explains and justifies the contempt with which military study was so long regarded by practical soldiers in England.

Clasuewitz, however, approached his subject from a higher standpoint. Gifted with a mind of exceptional power, which he had trained to the utmost in the school of German philosophy, and having seen war from the beaten side, he knew well that something more than phrase-making was needed to force a great nation to the final subjugation of its independent will. He stood throughout in the closest connexion with the directing wills which guided the German nation to achieve the final downfall of Napoleon; and he knew that these men were neither bunglers nor fools, but men whose experience well entitled them to the authority they exercised. Hence he reasoned that the catastrophes they had shared in common needed deeper analysis than they had as yet received. First of all he sought a satisfactory definition of what war really meant, and he found the closest analogy to it in the "unrestricted competition of the business world." Had he written in modern times he would doubtless have cast it in the Darwinian mould, viz. "war is the struggle for existence transferred to the national plane," and this is a far more important contribution to sociology and the welfare of humanity, and will certainly exercise much greater influence on the evolution of the nations (on which, after all, the fate of the individual depends) than all the works of Darwin and Herbert Spencer combined. This transference of the question to the national plane is in fact their very antithesis, for whereas the survival of the fittest threatens the stability of society on the principle of the Kilkenny cats, the survival of the race necessitates its coherence. Next, Clausewitz analysed his subject into its constituent factors. In this process he investigates all the theories of bases and geometrical relations, only to discard them as quite inadequate solutions of war's many phenomena; and finally, as between equally armed opponents, he shows that essentially success in war depends on the moral factors only. First is "courage." in all its forms, from its lowest manifestation in the excitement of a charge, to its highest in the fearless acceptance of supreme responsibility in face of the most imminent personal danger. Next comes "duty," again in its widest sense, from the uncompelling endurance of the humblest musketeer in the ranks, to the readiness of the whole nation to submit to the sacrifice of, and the restraint on, personal liberty that readiness for war entails. This "readiness," moreover, he shows to be cardinal (for nations with land frontiers), for indubitably, under the conditions then prevailing, the surest guarantee of victory in the field was the concentration of every man, horse and gun in the shortest time on the decisive point. Thus only could the advantages of greater wealth, larger population and so forth be neutralised, and the growth of modern means of communication, railways, telegraphs, &c., have only confirmed his position. It has been the gradual appreciation of portions of Clausewitz's teaching, enforced by the drastic lessons of 1866 and 1870, which has turned all Europe into an armed camp, and this fact must, for generations, stultify all ideas of European disarmament. For since everything depends on instantaneous readiness for action, it is absurd to expect that any nation will voluntarily consent to throw away the advantages these sacrifices have obtained by agreeing to delay at the very moment when its existence is most gravely threatened. An unready nation has obviously everything to gain from delay.

All this portion of Clausewitz's work is fundamental, and no changes in armament or other conditions can ever affect it; it applies as much to land as to sea power, and essentially was the doctrine of Nelson and St Vincent. Indeed, at sea Nelson was in advance of Napoleon, for he quite understood the advantage to be gained in paralysing the independent will-power of his opponent by a vigorous attack, and was willing to stake his existence upon this principle, notwithstanding the infinitely more uncertain elements of wind and weather which conditioned his movements. But the rest of Clausewitz's teaching is too deeply coloured by his personal experiences, and he stood in too close a relation to the events of his time to be able to focus the details of the whole subject. Although he was the first to seize the meaning of Napoleon's case-shot attack (the description occurs for the first time in his Campaign of 1812), he did not realise how this might be applied to the destruction of what he himself formulated as the most serious of all the many indeterminate factors with which a commander is called upon to deal, viz. "the independent will-power of his opponent." He saw clearly enough that time and space were the underlying conditions of all stratagical calculation, and that time could be
bought at the cost of men's lives; but he did not take the next step forward and show how these calculations must inevitably be upset if the enemy possessed the power of destroying men faster than experience led one to expect. He formulates from his experience that a force of the magnitude of a division, say, 10,000 men, can hold an overpowering enemy at bay for about six hours, and an army corps can hardly be destroyed in less than a day; on these data he bases his estimates of the marching area which an army may safely cover. But what if a new and unexpected method of applying "the means at hand to the attainment of the object in view" suddenly wipes out the division in two hours, or the army corps in six? In that case, surely, the independent will-power of the adversary would receive a most unwelcome check. Nor did he ever cleanly formulate as a principle the importance of combinations. Every one of course had in a general way understood the advantages of "getting there first," and all of us have for years been familiar with the importance which Napoleon attached to rapid marching. But the tendency has always been to consider the rate of marching in itself as an invariable factor, and to calculate every operation or disposition from the time a column normally takes to deploy into position from a road or defile. But no systematic attempt to determine the advantages which might on occasion be obtained by sacrificing comfort and convenience to the acceleration of a march has ever been undertaken. Yet Napoleon saw and appreciated the point, and it must remain a riddle for all time how such a mind as Clausewitz's, which again and again had seen at first hand the consequences which followed from Napoleon's marche de manoeuvre—guns and trains upon the roads, infantry and cavalry moving in mass across country—could have failed to place on record the enormous advantages which might follow its adoption. The book as it stood, however, became the bible of the Prussian army, and its comprehension is an indispensable preliminary to all useful study of contemporary practice in war. Moltke's mind, and that of his whole generation, was formed upon it. To its strength the Germans owed all their successes, and in its weaknesses certain grave errors that were almost disasters.

Meanwhile the progress of invention suddenly destroyed the governing condition of all previous experience. The Napoleonic strategy, as we have shown, depended primarily on the certainty of decision conferred on him by his "case-shot attack"; but the introduction of the long-range infantry rifle (muzzle-loader) rendered it practically impossible to bring the masses of artillery to the close ranges required by the Napoleonic method. In the 1859 campaign (see ITALIAN WAR) between France and Austria both sides were disposed to use muskets and rifles. The absence of intelligence, and the marksmanship of the Austrians in particular was so very inferior, that neither side derived advantage from the change. But when, in 1861-65 (see AMERICAN CIVIL WAR), the theatre of interest was transferred across the Atlantic, the other causes united to give it immense importance. America in the sixties was almost as roadless as East Prussia and Silesia in Frederick the Great's time, and its forests, rivers and marshes were far more impenetrable. Both the Southern and Northern armies, moreover, were entirely new to their work, and consequently their operations became exceedingly slow. As far as roads and railways had been studied war at all they had been brought up to the Napoleonic tradition as handed down by Jomini and his school; and failing as a body to appreciate the intimate interdependence of the three arms, they believed that a resolute crowding on of masses (whether in line or column does not signify) upon the decisive point must suffice to overrun all opposition. But the slowness of operations gave time for entrenchments, and consequently scope for the powers of the new rifle. Whereas against the old musket one rush sufficed to cover the danger zone, the rifle widened this zone about threefold, so that human lungs and limbs could no longer accomplish the distance without pause, during which pauses, since guns could no longer assist effectively, the attacking infantry had to protect itself by its own fire, standing in the open within point-blank range of the rifles of the cool, skilful and well-covered defenders. Thus when similar experiences had established uniformity of practice in the two contending forces the result was a deadlock, which was ended only by enormous numerical superiority and the "policy of attrition."

The lesson, however, passed unnoticed in Europe except in so far as popular attention was caught by the deadliness of the rifle fire, which was attributed, not as it should have been to the peculiar conditions under which it was employed, but to the nature of the weapon itself; and from this conclusion it was a short step to the inference that the breech-loader, firing five rounds to one of the muzzle-loader, must prove a terrible instrument of destruction. Actually this inference has hampered strategic progress ever since.

The campaigns of 1866 in Bohemia, and of 1870 in France, furnish positive proof that Clausewitz did not appreciate the Napoleonic teaching to its full extent, for though the conditions again and again were ideal for its application, no trace of his fundamental principle is distinguishable in Moltke's orders. In the former it would seem from the maps that the Austrians actually possessed the form, though they had forgotten the spirit, as the detached group in Bohemia (see SEVEN WEEKS' War) might well be considered as an avant-garde générale, and on the three days preceding Königgrätz, the distribution of the Austrian main army was such that the application of Napoleon's method must have followed had the idea been present. That it was not there is shown by the employment of Clausewitz's army in a situation promising certain victory. It is true that he had, wherein the whole Prussian army was to march across the front of the Austrians in position, precisely as Frederick had done with disastrous results at Kolin a century before.

No campaign, however, demonstrates in more striking manner the fatal consequences of ignoring Napoleon's saying, On ne manoeuvre qu'autour d'une pointe fixe than 1870. Here was an army enormously superior in numbers and organization, disposing of an admirable cavalry and far superior artillery, repeatedly on the edge of disaster, not because of the superior cunning of its adversary, but precisely because of his own errors, and a reasonable man proved quite incapable of conceiving the blunders that his adversary perpetrated. Moltke always preserved himself in his enemy's position and decided on what would be the rational course for him to pursue. He gave him the recognized three courses, but it happened that it was always the fourth (the unexpected, because from Moltke's standpoint so hopelessly irrational) that he took. The situations of the 8th, 11th and 16th of August are all instances in point. On the last of these dates (see FRANCO-GERMAN WAR) the French commander-in-chief was standing still through irresolution found himself in a situation promising certain victory. It is true that he had no advantage of it, and nothing can detract from the magnificent resolution of von Alvensleben, commander of the III. Corps, and the gallantry with which his troops and his comrades supported him. But, equally, nothing can alter the fact that in spite of all Bazaine's mistakes the dawn of the 17th of August found the German headquarters with only the débris of two corps on the ground face to face with the whole French army, of which only one-third had been seriously engaged. Sedan nearly ended in the same way. The Germans had, with the greatest care, fixed that part of the position of their armies but no troops were told off to hold them, and all throughout the afternoon of the 31st and morning of the 1st the French army was free to issue from the bridge-head of Torcy on a broad front in masse de manoeuvre and separate the wings of the Prussian army. Judging by the way they actually fought in the hopeless position in which they elected to remain, their prospects of success in the suggested manœuvre were not small. After the war it was easy and natural to place the blame for the situations in the early days on the shoulders of the German cavalry, but closer study of the facts has shown that in spite of all their shortcomings this arm did not deserve it; for they actually found the enemy and reported his positions, while nothing could be urged against them in respect to Sedan, for by that time they had established a relative superiority over their enemy which
was absolutely crushing. The truth is that the Prussian staff had not realized that cavalry reports alone, even if they arrive in time (which in fact very few ever did), do not afford a su
...
But the less time the defender has been allowed in which to improve his position, the more rapidly will a given number of guns achieve the required result; and though we must admit the many difficulties of execution which prevent complete realization of the ideal in practice, yet it is clear that the more closely one can approximate to this ideal, the less the demands which will be made upon the infantry when its turn comes to go forward. This matter is of such importance to the whole subject that we will put it forward in another form. Let us assume that the shells on bursting create only smoke and disturb the dust, delivering no man-killing fragments at all. Still it is clear that, say, 1,000 shells a minute bursting over a front of some 600 yards would shatter that front so completely with this dust that its occupants would be quite unable to direct their aim upon the approaching assailants, and under cover of this smoke and dust cloud the latter would be free to carry out what dispositions they might please with the minimum of loss. When finally the shell fire had to be stopped and the smoke lifted, the two infantries would be in presence of one another under conditions which have always been held to offer the maximum guarantee possible to the assailant, viz. an assured numerical superiority disposed in relatively the best positions for the use of their weapons, i.e., their fire converging on the point of attack.

This from the consequent assault only entrenchments and physically insuperable obstacles (a deep ditch for example) or wire entanglements which require machinery to tear away, can save the defenders. But such obstacles require time for their creation, hence the supreme importance of the utmost possible mobility. Now though in practice every great commander has utilized to the utmost such mobility as he might find in his troops (and by its use he has often, in countries well supplied with roads, succeeded in rendering the erection of entrenchments practically impossible, or in forcing an entrenched enemy to come out and fight in an unprepared position), yet no scientific attitude of the modern kind has ever been made to defend the importance of mobility, notwithstanding the fact that the Boer War of 1900-02 proved its importance up to the very hilt. The Boers were wanting in every quality which renders an enemy really formidable except mobility, but because of that supreme qualification and the fact that the enormous area of their country and their exact knowledge of its topography gave them every facility to employ it to the utmost, about nine times their numbers were required to subdue them; and the method ultimately adopted, though freely criticized, was in fact the only feasible under the circumstances to bring them to a final surrender.

Actually, all systems, the Napoleonic as well as the others, can be defeated finally by an excess of mobility, the exact proportion depending on the topographical nature of the country fought over, the roads available and its extent. So great is its influence that it overrides all changes in armament or in tactics, as was shown in Manchuria in 1904-05, where in spite of both armies, or perhaps better because both armies were trained on western European lines, the actual form which the war assumed was that of Marlborough’s times. It is sufficient to imagine the Japanese supplied with sufficient pioneer battalions, of the type employed on the Indian frontier, and a first-rate transportation (which would have doubled their average rate of daily progress), to see how completely the situation would have been altered. They could have reached Mukden in half the time actually required, and would then have possessed a numerical superiority sufficient to ensure for them a second Metz or even a Sodon. It is in this direction that all great progress is to be looked for, but it involves experiment and organization beyond the capacity of any single student. We may, however, indicate the general outline such a development would require. Primarily time is chiefly lost in the hesitation of leaders and in the preparation and circulation of orders. A clear apprehension of the powers which modern weapons confer on the attack will lead to the elimination of the first, and a higher intellectual training of the whole army will materially reduce the second, for the limit to the brevity of orders is fixed by the trained intelligence of the recipients. Napoleon’s marshals could move effectively in response to an order of a couple of sentences; Mack’s generals needed fourteen sheets of foolscap.

Next comes the rapidity of movement of the troops themselves when on the road. They cannot march for longer hours than already at times they are called upon to do; but by a better distribution of the weights carried between the men and their transport, they might well cover much more ground in the same time. Here again determination to take the offensive, and to keep it, largely governs the situation. An army determined to attack needs no entrenching gear, certainly not on its men. Its fire is its best protection, and when as in recent campaigns in Bulgaria and the Far East the need for entrenchment has only occurred because the whole weapon of attack, viz., that combination of the three arms which we call an army, was not properly balanced in its parts at those particular moments so as to enable it to maintain its forward impulse. Either, as in Bulgaria, the staff was not up to its duties, or, as in the case of the Japanese, the artillery arm was too slow, or was locally outclassed by the artillery power of its adversary. But in all countries, roadless ones in particular, the progress of the front is conditioned by the efficiency of the transport services in rear, and only because this branch of the army has never received all the attention it deserves. Besides, it has only been necessary to overload the men and horses at the front in the prepromis manera manner which custom has everywhere sanctioned, which for the most part has been inherited from the time of Marlborough.

Over and over again in the past two centuries men have shown that literally only muskets and ammunition are required to win battles, and that a great victory won by rapid marching is by far the most economical use that can be made of human powers. But again and again the pendulum has swung back, and the soldier, in order to be prepared for emergencies which only defeat can bring about, has been burdened down by a weight which has brought him on the field too late and too weary to win it, but in ample time to incur all the penalties of disaster.

In the future in western Europe that army whose transport service, based on motor vehicles and a good road maintenance corps of real working men, will relieve the soldier and his horse (where he has one) of every ounce of superfluous weight, including even in that expression greatcoats and all rounds of ammunition in excess of 120 apiece, and whose men are uniformly trained to the Bersaglieri march (7 m. in one hour or 15 m. in three consecutive hours), will possess a superiority over its adversary which he will require twofold odds to counteract. The suggestion that the ammunition supply should be limited may create sur- prise, but is a logical consequence, and precisely one of those points on which the strategist of the future will require a firm conviction. The fundamental fact on which all tactical practice is based is this, that a relatively small loss suddenly inflicted exercises a far greater demoralizing effect upon its recipient than a much heavier punishment extended over a longer period. First-rate troops have often broken back in disorder under a sudden hail of bullets which has swept away not more than 2 to 3% of their strength, whilst exactly similar battalions in the same action have held out all day and remained an efficient fighting body after even 30% had fallen. But, armament being equal, this sudden loss can only be inflicted by placing the troops on the field in the best position possible, relatively to their enemy to derive the full benefit of their fire-power; and mobility is the chief factor in attaining this end. The point is most clearly seen in the case of the action of a well-mounted force against a slow-moving convoy; the convoy forms a target which men can hardly miss; the assailants are a number of dots it is scarcely possible to hit. Two thousand rounds per man of the escort would scarcely suffice to obtain the same results as twenty rounds a man on the side of the assailants. This is a clear illustration of the principle involved, which should always be kept in mind.

Lastly the student should master the elementary principles of railway transportation. The progress since railways were last used in warfare in western Europe has been so enormous that the data supplied therefrom are entirely antiquated, and
there is no indication that any general staff in Europe is alive to the possibilities they present in defence. As already pointed out, it is not enough to count on their aid once he has penetrated within the enemy's country, and the farther he advances the worse matters become for him. It is enough to consider an invading force based on the east coast of Yorkshire with its head about Leeds; the technical excellence of English railways is so great that 120,000 men with all their share of guns and necessary equipment could be easily transferred say from Glasgow and Edinburgh round to Sheffield in twenty-four hours for a flank attack. Even double that number, from the south of England to the north of Yorkshire, could be moved in the same time. It is certainly inferred that such movements might be in the power of the enemy, in their command the spirit of blind trust and confidence that placed men like Cromwell, Marlborough, Frederick and Napoleon almost beyond reproach. By the side of this power the technical knowledge and ingenuity displayed in their several undertakings appear quite trivial; probably the same ideas have occurred to thousands of quite mediocre men, but were never put into execution, because they could not count on the whole-souled devotion of their men to execute them. This power is born in a man, not acquired, but even those who possess it in embryo can increase and develop it enormously by a systematic study of the laws which govern the action of humanity in the mass.

From the above we arrive at the following definitions for the term most generally employed by writers on military history and strategy.

Base.—The point, or line joining a series of points, from whence military operations originate. Ultimately military operations have their inception in an area, i.e. a whole country from which organization draws men, arms, food and material of all descriptions, forwarding them through a network of communications—roads, railways, canals, rivers, &c., and delivering them at points as near to the general enemy as circumstances render expedient. As an army never has too many men, and normal civil transport is cheaper in every way than military, the tendency is always to maintain the collection of men and materials under civil arrangements as much as possible. Thus as the country advances forward, settling the district behind it as it advances, the civil administration follows after it, only ceasing to exercise its functions when these can be no longer performed without military assistance. Right from the beginning there is a zone in which civil transport and supply exist side by side with military precautions greater or less, but for all practical purposes each column, whatever its strength, has its "base" at that point where the existing magazines are filled by civilian contractors in the ordinary course of trade, and with no extra charge for war risks.

Line of Communication.—The line of communication is the greatest main road, trunk railway, canal or river, or any combination of these means, for the transport of stores leading from the base to the army at the front. Along these arteries of communication depends the military success of armies on land and sea. Any arrangement is made that foresees can suggest to meet the abnormal demands that a condition of war naturally gives rise to. Napoleon always used the words route de l'armée, which conveyed perhaps a different idea of the whole of military communications than the term now in use. He had to comply with than the current term. In proportion to the numbers which have to be supplied by this line of communication its importance naturally increases. Thus when in 1870 the Germans made the choice of their main roads, even of canals and railroads, and if one were temporarily interrupted could switch off the current of supply to another without great difficulty, the numbers of troops British armies are to a single railway, any interruption of which must have paralleled altogether their vast army which ultimately numbered 400,000 mouths to be fed. It is clear, therefore, that the importance attaching to the preservation of the communications is in direct accordance with the nature of the country in which war is carried on, the state of its communications of all sorts, the facility for establishing new ones, and the number of men depending for subsistence on any single road, railway, river or canal.

Line of Operations is a term applied to an imaginary line drawn from the centre of gravity of the army at the front to the country from which it originates. Whereas lines of communication, being dependent on the topographical conformation of the district may be very circuitous; these lines of operations are always in a direct direction more convenient to keep in mind than the more complex idea embodied in the former word. Since practically all supply flow to an army along its line or lines of communication, and without it the army can carry on its operations only in so far as supplies that can arise in war can be referred to their possible consequences in endangering more or less either one's own communications or the enemy's. A "flank" when its communications run parallel to the direction it assumes when facing the enemy (see diagram). It is clear that in case of a defeat at or near A the communications are most gravely endangered, or the enemy may force a lodgment, which in the construction unless he is absolutely confident in the power of his troops to beat the enemy and by so doing places his antagonist in even a worse position in case of defeat. This he can only do by placing himself more or less astride his adversaries' communications. But the latter if beaten is ruined beyond retrieval. Thus in the Marengo campaign, in 1800, Napoleon, in placing himself astride the Austrian line of communications, made himself the base of operations to form front to a flank, but this was only possible because the geographical relation of the French and Italian frontiers enabled him from the outset of the campaign to aim a blow in the rear of his opponents' actual front. Conversely, when their situation permits, he can reach the enemy by a move in a flank." Thus the advantages gained by defeating an army when forming front to a flank is equally great, if not so great as to equal it. Consequently the advantages of a flank position are in fact transferred more from the point of view of strategy to the point of view of tactics.
STRATFORD, J. DE—STRATFORD DE REDCLIFFE

side which has to traverse the mountains (marsh or forest) will always be at a disadvantage for the actual attack, but at an advantage in regard to the secrecy with which it can fall upon the point of his own choice, and the more secure his telegraph lines, the greater will this advantage be.

STRATFORD, JOHN DE (d. 1348), archbishop of Canterbury, was born at Epping-on-Avon and educated at Merton College, Oxford, afterwards entering the service of Edward III. He served as archdeacon of Lincoln, canon of York and dean of the court of arches before 1323, when he became bishop of Winchester, an appointment which was made during his visit to Pope John XXII. at Avignon and which was very much disliked by Edward II. In 1327 the bishop joined Queen Isabella's partisans; he drew up the six articles against Edward II., and was one of those who visited the captive king at Kenilworth to urge him to abdicate in favour of his son. Under Edward III., he became the virtual head of the Lancastrian party, and as such acted in the high political importance dates from the autumn of 1330, the time when Roger Mortimer lost his power. In November of this year Stratford became chancellor, and for the next ten years he was actively engaged in public business, being the king's most prominent adviser and being politically, says Stubbs, the "head of the Lancastrian or constitutional party." In 1333 he was appointed archbishop of Canterbury and he resigned the chancellorship in the following year; however, he held this office again from 1335 to 1337 and for about two months in 1340. In November 1340 Edward III., humiliated, indulgent and ailing, was borne at Stratford-on-Avon from Flambards and vended his wrath upon the archbishop's brother, the chancellor, Robert de Stratford. Fearing arrest John de Stratford fled to Canterbury, and entered upon a violent war of words with the king, and by his firm conduct led to the establishment of the principle that peers were only to be tried in full parliament before their own order (en pleyn parlement et devant les piers). But good relations were soon restored between the two, and the archbishop acted as president of the council during Edward's absence from England in 1345 and 1346, although he never regained his former position of influence. His concluding years were marked by changes in the discharge of his spiritual duties, and he died at Mayfield in Sussex on the 23rd of August 1348.

John's brother, Robert de Stratford, was also one of Edward III.'s principal ministers. He served for a time as deputy to his brother, and in 1337 became chancellor and bishop of Chichester; he lost the former office in 1340 and died on the 9th of April 1362.

Ralph de Stratford, bishop of London from 1340 until his death at Stepney on the 7th of April 1354, was a member of the same family. All three brothers were benefactors to Stratford-on-Avon.

STRATFORD, a city and port of entry of Ontario, Canada, and capital of Perth county, situated 83 m. W.S.W. of Toronto by the Grand Trunk railway, on the Avon river. Pop. (1901), 9059. The repair and engineering shops of the Avon river, flour-, saw- and woollen-mills, engine and agricultural implement works are the principal industries. A large export trade in cheese and other dairy and farm produce is carried on.

STRATFORD DE REDCLIFFE, STRATFORD CANNING,Viscount (1786-1889), British diplomatist, was born in Clement's Lane in the city of London, on the 4th of November 1786. His father, P. Canning, M.P. for Wanstead, had been disinherited for his marriage with Mehetabel Patrick. He settled in London as a merchant. On his death, six months after the birth of his son, his widow took a house at Wanstead near Epping Forest. Stratford Canning was educated first at a dame's school at Wanstead, then at Hackney, and after 1794 at Eton. In 1803 he was elected a scholar of King's College, Cambridge, but he only kept two terms, and in 1807 was appointed private writer to the foreign office by his cousin George Canning. He received his degree in 1812, residence having been dispensed with on the ground that he was absent on the king's service. In 1807 he went as secretary to Mr Merriy on a diplomatic mission to Copenhagen. In 1808 he was appointed first secretary to Mr (afterwards Sir Robert) Adair, who was sent as ambassador to Constantinople. When Mr Adair was transferred to Vienna in 1810, Canning remained at Constantinople as chargé d'affaires. The British government was then in the very crisis of its struggle with Napoleon, and it left Canning entirely to his own discretion. His principal task was to persuade the Turkish government not to show undue favor to the French privateers which were operating in the Levant. In May 1812 he was able to play the part of "honest broker" in arranging the peace of Bucharest between Turkey and Russia, which left a powerful Russian army free to take part in repelling Napoleon's invasion. Canning was able to hasten the decision of the Turks, by making judicious use of Napoleon's plan for the partition of their empire. A copy of it had been left in his hands by Mr Adair to be used at the proper moment. In July he left Constantinople with the sincere desire never to return, for he was tired of the corrupt and stiff-necked Turkish officials. His ambition was to lead an active career at home, but his success in the diplomatic service which he had marked him out for diplomatic employment. His absence from home in early youth and the independent position he had held much before the usual age, had in fact disqualified him for the career of a parliamentary party man. By the friendly intervention of Castlereagh, his cousin's old opponent, he received a pension, or rather a retaining fee, of £1200 a year, on the "usual conditions"—which were that he should bind himself to accept the next diplomatic post offered, and should not attempt to enter parliament. Canning spent his leisure in traveling about England, and he also spent much of his time in the presence of Byron, whom he had known in boyhood and had met in Constantinople. In 1814 he was appointed minister plenipotentiary to Switzerland. In this capacity he had a share in reorganizing the confederation after the fall of the Napoleonic settlement, and he attended the congress at Vienna. He was an eye-witness of the dramatic change produced at Vienna by Napoleon's return from Elba. Canning retained his post in Switzerland till 1818. In 1816 he married Miss Harriet Raikes, daughter of a governor of the Bank of England. Her death in childbirth in 1818, had a strong influence in inducing him to resign his post, of which he was again offered, but he felt the British govern- ment had merely formal duties to perform in normal times, and the place was unsuitable for a man of Canning's capacity and desire for work. In 1819 he was appointed minister at Washing- ton, a station of great difficulty owing to the ill-feeling created by the war of 1812 and the many delicate questions outstanding between the British and the American governments. Canning, whose naturally quick temper had been developed by early independence, came into occasional collision with John Quincy Adams, the American secretary of state, who was, on his own showing, by no means of a patient disposition. Yet the American statesmanrecognized that the "arrogance" of the British minister was combined with absolute candour and that he was above all petty diplomatic trickery. They parted with mutual respect. Canning returned to England in 1823 on leave and did not go back to Washington. The general treaty he had arranged with Mr Adams was rejected by the United States Senate. In 1824 Canning was selected as ambassador to Turkey, and proceeded to Constantinople after a preliminary visit to Vienna and St Petersburg. In the Russian capital he was engaged in discussing the arrangement of the Alaska boundary, and partly in sounding the Russian government as to the course to be taken with the Greek revolt against Turkey. He left for Constantinople in October 1825, accompanied by his second wife, the daughter of Mr Alexander of Somerhill near Tonbridge. At Constantinople he was engaged with the ambassadors of France and Russia in an enterprise which he afterwards recognized as having been hopeless from the beginning—namely in endeavouring to induce Sultan Mahmud II. to make concessions to the Greeks, without applying to him the pressure of armed force. After the battle of Navarino (9 Oct.) on the 29th of October 1827, the ambassadors were compelled to retire to Corfu. Here Canning learned that his conduct so far had been approved, but as he desired to know what view was taken of the final rupture with the Porte he came home. He was sent out again on the 8th of July 1828. Canning did not agree on all points with his superior, Lord Aberdeen, and in 1829 he, for the time being, turned from diplomatic to
parliamentary life. He sat for Old Sarum, for Stockbridge (rotten
boroughs) and for Southampton, but did not make much mark
in parliament. He was twice absent on diplomatic missions.
At the end of 1831 he went to Constantinople to attend the
conferences on the delimitation of the Greek frontier, arriving
immediately after the receipt of the news of Mehemet Ali's
invasion of Syria (see MEMEHET ALI). Sultan Mahmud now
proposed to Canning an alliance between Great Britain and Tur-
key, and Canning strongly urged this upon Palmerston, pointing
out the advisability of helping the sultan against Mehemet Ali
in order to forestall Russia, and of at the same time placating
Mehemet Ali by guaranteeing him certain advantages.
This advice, which largely anticipated the settlement of 1841, was
not followed; but Canning himself was in high favour with the sultan,
from whom he received the unique distinction of the sovereign's
portrait set in diamonds. In 1833 he was selected as the special
envoy to Russia, but the tsar Nicholas I. refused to receive him.
The story that the tsar was influenced by merely personal
animosity seems to be unfounded. Nicholas was no doubt
sufficiently informed as to the peremptory character of Sir
Stratford Canning (he had been made G.C.B. in 1838) to see
his unfitness to represent Great Britain at a really independent
court.
After Canning had declined the treasurership of the Household
and the governor-generalship of Canada, he was again named
ambassador at Constantinople. He reached his post in January
1839 and retained it till his resignation in February 1839. His
tenure of office in these years was made remarkable—first by his
constant efforts to induce the Turkish government to accept
reform and to conduct itself with humanity and decency;
then by the Crimean War (q.v.). Canning had no original liking
for the Turks. He was the first to express an ardent hope
that they would be expelled from Europe with "bag and
baggage"—a phrase made popular in after times by Gladstone.
But he had persuaded himself that under the new Sultan Abd-ul-
Mefid they might be reformed, and he was willing to play the
part of guiding providence. He certainly impressed himself on
the Turks, and on all other witnesses, as a strong personality.
In particular he struck the imagination of Kinglake, the author
of the Invasion of the Crimea. In that book he appears as a kind
of magician who is always mentioned as the "great Elchi" and
who influences the fate of nations by mystic spells cast on pallid
sultans. Great Elchi is the Turkish title for an ambassador,
and Elchi for a minister plenipotentiary. The use made of the
exotic title in Kinglake's book is only one of the Corinthian
ornaments of his style. In sober fact Canning's exertions on
behalf of reform in Turkey affected little below the surface. His
stint in the Crimean War cannot be told here. On the fall of
Palmerston's ministry in February 1839 he resigned, and though
he paid a complimentary farewell visit to Constantinople, he had
no further share in public life than the occasional speeches he
delivered from his place in the House of Lords. He had been
raised to the peerage in 1852. During his later years he wrote
several essays collected under the title of The Eastern Question
(London, 1881). In 1873 he published his treatise, Why I am a
Christian, and in 1876 his play, Alfred the Great at Athelney.
The only son of his second marriage died before him. His wife
and two daughters survived him. Lord Stratford died on
the 5th of August 1880, and was buried at Frant in Sussex. A
monument to him was erected in Westminster Abbey in
1884.
See Life of Lord Stratford de Redcliffe, by S. Lane Poole (London,
1888).

STRATFORD-ON-AVON, a market town and municipal borough
in the Stratford-on-Avon parliamentary division of Warwick-
shire, England; on a branch line of the Great Western railway
and on the East & West Junction railway, in connexion with
which it is served by London by the Great Central (923 m.)
and the London & North-Western railways. Pop. (1901), 3910.
The town is situated on the river Avon in the rich valley of the Avon.
The neighbourhood, comprised in the rich valley of the Avon,
is beautiful though of no considerable elevation. The river
flows in exquisite wooded reaches, navigable only for small
boats. The Stratford-on-Avon canal communicates with the
Warwick and Birmingham canal. The river is crossed at
Stratford by a stone bridge of 14 arches, built by Sir Hugh
Clapton in the reign of Henry VII. The church of the Holy
name occupies the site of a Saxon monstery, which existed
before 691, when the bishop of Worcester received it in exchange
from Ethelred, king of Mercia. It is beautifully placed near the
river, and is a fine cruciform structure, partly Early English and
partly Perpendicular, with a central tower and lofty octagonal
spire. It was greatly improved in the reign of Edward III.
by John de Stratford, who rebuilt the south aisle. He also in 1352
founded a chantry for priests, and in 1354 Ralph de Stratford
built for John's chantry priests a "house of square stone,"
which came to be known as the college, and in connexion with which
the church became collegiate. The present beautiful choir was built
by Dean Basha (1465-1491), and in the reign of Henry VII.
the north and south transepts were erected. A window commemo-
rates the Shakespearian scholar J. O. Halliwell-Phillips.
The foundation of the chapel of the gild of the Holy Cross was laid
by Robert de Stratford. The gild, to which both sexes were
admitted, was in existence early in the 13th century, and it was
incorporated by a charter from Edward III. in 1322. It was
dissolved in 1547. The gildhall is a picturesque half-timbered
building. A beautiful house of the 16th century belonged to one
Thomas Rogers, whose daughter was mother of John Harvard,
the founder of Harvard College, U.S.A. Among the building
are the town hall, originally dated 1633, rebuilt 1766, and altered
1863; market house, corn exchange and three hospitals. There
are recreation grounds. Brewing is carried on, but the trade
is principally agricultural. Area, 4013 acres.

Shakespearian Connexion.—To no town has the memory
of one famous son brought wider notoriety than that which
the memory of William Shakespeare has brought to Stratford;
yet this notoriety sprang into strong growth only towards the end
of the 18th century. The task of preserving for modern eyes
the buildings which Shakespeare himself saw was not entered
upon until much of the visible connexion with Shakespeare had
been destroyed. Yet the town is under no great industrial or other
modernizing influence, and therefore stands in the position of an
ancient shrine, drawing a pilgrimage of modern origin. The
plan of Shakespeare's Stratford at least is preserved, for the road
crossing Clapton's bridge is an ancient highway, and forks in
the midst of the town into three great branches, about which
the village grew up. The high cross no longer stands at the market-
place where these roads converged. But the open space where is
now a memorial fountain was the Rother market, and Rother
Street preserves that name. The word signifies horned cattle,
and the name of Shakespeare may have descended from one
"It is the pasture lards the rother's sides" (Timon of Athens),
where "brother's" was originally the accredited reading.
In Henley Street, close by, is the house in which the poet was born,
greatly altered in external appearance, being actually two half-
timbered cottages connected. A small apartment is by imme-
 morial tradition shown as his birth-room, bearing on its white-
washed walls and its windows innumerable signatures of visitors,
among which such names as Walter Scott, Dickens and Thack-
ray may be deciphered. Part of the building, used by the poet's
father as a wool-shed, is fitted as a museum with Shakespearean
beauties. It has attended the grammar school attached to the old gildhall
in Church Street. This was a foundation in connexion with the
gild of the Holy Cross, but was refounded after the dissolution
by King Edward VI. in 1553, and bears his name. The site of
Shakespeare's house, New Place, bought by him in 1597, was
acquired by public subscription, chiefly through the exertions
of J. O. Halliwell-Phillips, and was handed over to the trustees
of the birthplace in 1876. The house was built by Sir Hugh
Clapton. Shakespeare acquired a considerable property adja-
cent to it, retired here after his active life in London, and here
in 1613 died (John Shakespeare, his father, appearing in 1571, having
been exonerated from the charge of traitor to his family), and the mansion he built was in turn
destroyed by Sir Francis Castell in 1579. The site, which is

998 STRATFORD-ON-AVON
traceable, is surrounded by gardens. Shakespeare is buried in the chancel of Holy Trinity church, his wife lying next to him. The slab over the poet’s grave bears the lines beginning

“Good friend, for Jesus’ sake forbear
To dig the dust enclosed here”;

while the effigy on the mural monument above may well be an authentic representation, though somewhat altered and damaged by time and restoration (see Shakespeare: Portraits).

Apart from the interest attaching to the pleasant country town and its pastoral environment, through their influence traceable in Shakespeare’s writings, there are further connexions with himself and his family to be found. The house adjacent to New Place known as Nash’s house was that of Thomas Nash, who married Shakespeare’s granddaughter Elizabeth Hall; it is used as a museum. At Shottery, 1 m. west of Stratford, is the picturesque thatched cottage in which Shakespeare’s wife, Anne Hathaway, was born. It was purchased for the nation in 1892. The maiden name of the poet’s mother was Mary Arden, and this name, that of an ancient county family (see Arden), is the most north-west of Stratford, the Forest of Arden, though the true forest character is long lost. At Snitterfield to the north, where the low wooded hills begin to rise from the valley, lived Shakespeare’s grandfather and uncle.

The principal modern monument to the poet’s memory in Stratford is the Shakespeare Memorial, a semi-Gothic building of brick, stone and timber, erected in 1877 to contain a theatre, picture gallery and library. A performance of one of the plays is given annually. The memorial stands by the river above the site of the ancient town in the site of what were once timber gardens where, in 1769, a celebration in honour of the poet was organized by David Garrick. Evidence of the intense interest taken by American visitors in Stratford is seen in the memorial fountain and clock-tower presented in 1887, and in a window in the church illustrating scenes from the Incarnation and containing figures from English and American history.

History.—Stratford-on-Avon (Stratford, Stratford, Stratford-on-Avon) is a place of great antiquity. A Roman road may have run past the site; coins, &c., have been found, and the district at any rate was inhabited in Roman times. The manor was granted by King Æthelred to the bishopric of Winchcombe and it was under the protection of the bishops of Worcester, who were granting privileges as early as the reign of Richard I., that the inhabitants of the town assumed borough rights at an early date. The Gild of the Holy Cross, founded in the 11th century for the support of poor priests and others, exercised great authority over the town for many years. Its dissolution was the cause of the incorporation charter of Edward VI. in 1553, by which the town was incorporated under the title of the bailiff and burgesses, who were to bear the name of aldermen. Another charter, containing former liberties but altering the constitution of the corporation, was granted in 1671. By the charters of 1604 and 1674 the corporation was given the title of mayor, aldermen and burgesses. The governing body now consists of a mayor, 6 aldermen and 18 councillors. A market, formerly held on Thursdays by a grant of 1300, is now held on Fridays. The various trades of weaving, saddlery, glove-making, collar-making, candle-making, soap-making were carried on during the 16th, 17th and 18th centuries, but have lost their importance.

STRATHAVEN (locally pronounced Strighn), a manufacturing and market town of Lanarkshire, Scotland. Pop. (1901), 2076. It lies on the Avon, 16 m. S.S.E. of Glasgow by road, and is the terminus of the Caledonian Railway Company’s branch line from Hamilton. It has manufactures of silk, cotton and hosiery and is a market for cheese and grain. The picturesque ruins of Avondale Castle are situated on Powmilion Burn, a stream that runs through Strathaven to join the Avon, a mile below the town. Remains of a Roman road are traceable for several miles immediately to the south of the Avon. Stonehouse (pop. 2961), a mining and weaving town about 4 m. north-west, is claimed as the birthplace of the Scottish martyr, Patrick Hamilton (1504-1528). Six miles south-west of Strathaven, on the moor of Drumclog, the Covenanters defeated John Graham of Claverhouse, Viscount Dundee, on the 1st of June 1679. A granite obelisk commemorates the battle, but the religious meetings that used to take place on the anniversary are no longer held.

STRATHCLYDE, the name given in the 9th and 10th centuries to the British (Welsh) kingdom, which from the 7th century onwards was probably confined to the basin of the Clyde, together with the adjacent coast districts, Ayrshire, &c., and the western part of Scotland. Its capital was Dunbarton (fortress of the Britons), then known as Alclyde. On the south this kingdom bordered on the territories of the Niduari Picts of Galloway, including the modern counties of Wigtown and Kirkcudbright, a region which from the middle of the 7th century seems to have been in the possession of the Northumbrians. Strathclyde is also sometimes called Cumbria, or Cumberland, and the survival of the latter name on the English side of the border preserves the memory of a period when the territories of the northern Welsh were of much greater extent. Such notions, though it is perhaps not certain that the race possessed political unity at that time. Of the origin of the kingdom of the North Britons we have no information, but there seems little reason to doubt that they were the dominant people in southern Scotland before the Roman invasion.

After the withdrawal of the Romans in the 5th century the northern Britons seem to have shown greater determination in maintaining their independence than any of the southern kingdoms and, according to Welsh tradition, Cunedda, the ancestor of the kings of Gwynedd, had himself come from the north. The Historia Brittonum we read of several princes of the northern Britons. The chief of these appears to have been Urien, who is said to have fought against the Northumbrian king Theoderic, and Rhysderch Hen who is mentioned also in Adamnan’s Life of S. Columba. Rhysderch Hen appears to have secured the supremacy amongst these Welsh princes after the great battle of Ardderyd fought about the year 573, to which frequent reference is made in early Welsh poetry. His death seems to have taken place in 603. A late authority states that he was succeeded by his son Constantine, but the subsequent kings were descended from another branch of the same family. Such notion that the chief of the history of Strathclyde in the 7th and 8th centuries are preserved only in the chronicles of the surrounding nations and even these supply us with little more than an incomplete record of wars with the neighbouring Scots, Picts and Northumbrians. It is probable that the Britons were allied with the Scots when Aidan, the king of the latter, invaded Northumbria in A.D. 597. In 642, however, we find the two Celtic peoples at war with one another, for in that year the Britons under their king Owen defeated and slew the Scottish king Domnall Breac. In the same year they came into conflict with the Northumbrian king Oswi. In 649 there appears to have been a battle between the Britons and the Picts, but about this time the former must have become subject to the Northumbrian kingdom. They recovered their independence, however, after the defeat of Ecfrith by the Picts in 685. In 711 and again in 717 we hear of further wars between the Britons and the Scots of Dalriada, the former being defeated in both years. Towards the middle of the 8th century Strathclyde was again threatened by an alliance between the Northumbrians and Picts, and in 750 the Northumbrian king Eadbereht wrested from them a considerable part of their territories in the west including Kyle in Ayrshire. In 756 the North Britons are said to have been forced into submission and from this time we have very little of their history, though occasional references to the deaths of their kings show that the kingdom still continued to exist.

In 870 Dumbarton was attacked and destroyed after four months’ siege by the Scandinavian king Ivarr, and for some time after this the country was exposed to ravages by the Norsemen. It is believed that the native dynasty came to an end early in the 10th century and that the subsequent kings belonged to a branch of the Scottish royal family. At the end of the reign of Edward the Elder (925) the Britons of Strathclyde submitted to that king together with all the other princes of the north.
IN the reign of his successor Ethelstan, however, they joined with the Scots and Norwegians in attempts to overthrow the English supremacy, attempts which were ended by their defeat at the battle of Brunanburh in 937. In 945-46 Strathclyde was ravaged by King Edmund and given over to the Scottish king Malcolm I. The fall of the kingdom was only temporary, for we hear of a defeat of the Scottish king Cuilean by the Britons in 971. In the 11th century Strathclyde appears to have been finally incorporated in the Scottish kingdom, and the last time we hear of one of its kings is at the battle of Carham in 1018 when the British king Owen fought in alliance with Malcolm II.

The following is a list of kings whose names are mentioned in the chronicles:

Rhyderych Hen d. 603
Constantine son of Rhyderych (?) . . .
Iudruis (?). 633
Owain (Eugein) d. 642
Gward (Gureit) 658
Dyfnwal (Dommhnall), son of Owain . . . .
Beli, son of Eolphin . . .
Tewdwr (Teudubr), son of Beli . . .
Dyfnwal (Dannagual), son of Tewdwr . . .
Cyman, son of Ruedrach . . .
Artgbe . .
Run, son of Artgbe . .
Dyfnwal (Dowrivaclus) . .
Dyfnwal (Dowrivaclus), son of Ede (Arth) Owain . .
Dyfnwal (Dommhnall), son of Eoghain (on pilgrimage) . .
Malcolm, son of Dyfnwal . .
Owain (Enguicus) 1018

STRATHCONA AND MOUNT ROYAL, DONALD ALEXANDER SMITH, BARON (1820—), Canadian statesman and financier, was born at Forres, Scotland, on the 6th of August 1820, the second son of Alexander Smith (d. 1850), a Highland merchant. His mother, Barbara Stewart, of Abernethy, was the sister of John Stewart (d. 1847), a famous fur trader in the Canadian North-West, who gave his name to Stewart Lake and Stewart river. Through him Donald Smith was appointed in 1838 a junior clerk in the Hudson's Bay Company, which at that time controlled the greater part of what is now the Dominion of Canada. Smith was sent to Labrador, and stationed at Hamilton Inlet. For thirteen years he roved it there, mastering the work of the fur trade, introducing various improvements into the conditions of life, being the first to prove that potatoes and other vegetables could be grown with success on that bleak coast, and varying his business routine with much reading and letter-writing. Then he was for ten years on Hudson Bay, rising in the company's service to be a chief trader and then a chief factor. In 1868 he was appointed to the post of resident governor, with headquarters at Montreal. In the next year Louis Riel's (g.v.) rebellion broke out on the Red River, caused chiefly by the transfer of territorial rights from the company to the Dominion of Canada, and in December Smith was sent by the Canadian government with wide powers as special commissioner to endeavour to check the rebellion, and to report on 'the best mode of quieting and accommodating the discontented and dissatisfied.' On arriving at Fort Garry (now Winnipeg) he advised the government that it would be necessary to send troops; in the meanwhile he kept cool in face of a very ugly situation, and it was largely owing to his tact and diplomacy that the lives of the numerous prisoners were saved, that Riel's position was gradually undermined and that the relief expedition under Colonel (afterwards Lord) Wolseley had no fighting to do. Apart from the rebellion, there was difficulty with the company's traders. The company's control over the North-West was to be surrendered to Canada for £300,000, certain grants of lands and certain trading privileges, and the traders on the spot feared that in the distribution of the money their rights might not be guarded, but Smith succeeded in persuading them to trust him to secure their share, and asserted their claims so effectually that £107,000 was paid to them. During these complications in the North-West he occupied for a time the position of acting governor: in December 1870, on the first election to the legislative assembly of the new province of Manitoba, he was returned for Winnipeg, and in March 1871, after a very bitter contest, he was elected as one of the four Manitoba representatives to the Dominion House of Commons, as member for Selkirk. The reorganization of the Hudson's Bay Company in 1871— involving the loss of its administrative functions and its restriction to questions of trade only— made it necessary to appoint a chief commissioner for the North-West, and in 1873 Smith received the appointment when in London, after his championship of the claims of the local traders. At Ottawa he at once became the spokesman of the new territories, though for a time subject to the suspicion of those who thought the company had abandoned any hint of a Canadian government against Riel, and he was frequently involved in parliament and out of it on various charges. In 1872 he became one of the original members of the first North-West council under the act providing for the government of the territories by the lieutenant-governor of Manitoba and a council of eleven.

It was at this time that the construction of the Canadian Pacific railway became a practical question. The terms of the entrance of British Columbia into the Dominion in 1871 included a stipulation for the immediate beginning of a railway from the Pacific towards the Rockies, with a point to be selected east of the Rockies towards the Pacific; this line, connecting the Pacific seaboard with eastern Canada, was to be completed within ten years from the date of union. After a controversy on the merits of private or government construction, in 1872 a charter was given by Sir John MacDonald's government to a company, with Sir Hugh Allan at its head, for the construction of the line, with a subsidy in land grants and money, but in 1873 disclosures of corrupt practices in relation to this charter (the so-called Pacific Scandal) led to the fall of the government, and the company was soon afterwards dissolved. In the great debate which ended in the resignation of the government, one of the chief causes of its downfall was a moderate but powerful speech by Smith, which led to a temporary estrangement between him and MacDonald. The Liberal government which came into power early in 1874 reverted, though timidly, to the policy of government ownership.

Meanwhile Donald Smith, together with his cousin Mr George Stephen (afterwards Lord Mount Stephen), and other Canadian and American financiers, had bought out the Dutch bondholders of the insolvent St Paul & Pacific railway, an American line, which by 1873 had been completed from St Paul to Breckenridge, but which lacked funds to proceed farther. After long negotiations the new owners persuaded the government of Manitoba to build a line from Winnipeg to Pembina on the American frontier. This done, in 1879 the partners formed the St Paul, Minneapolis & Manitoba Railway Company, and by continuing the line from Breckenridge to Pembina united Manitoba with the south and west.

In 1878 the Liberal party was defeated, and Sir John Macdonald returned to office with the support of Smith, who had been driven to rejoin the Conservatives by the over-cautious railway policy of the Liberals. In 1880 the new government made a contract for the construction of a transcontinental railway. In 1882 he left parliament, but returned to it in 1885, and represented Montreal West till 1886, when he was appointed to succeed Sir Charles Tupper in London as high commissioner for Canada. In that year he was made G.C.M.G.; in 1897 he was raised to the peerage and in 1900 made G.C.V.O. In 1889 he became governor of the Hudson's Bay
Company. On the 21st of March 1806 he was appointed government commissioner to Manitoba and the Territories to endeavour to lessen the bitterness in the discussion as to Roman Catholic rights in the public schools, and the compromise of 1807 followed the lines which he suggested (see CANADA).

In January 1800, during the war in South Africa, he raised, equipped and presented to the British government a regiment of irregular cavalry, 600 strong. Strathcona’s Horse, as it was called, was recruited in the Canadian West, and did good service during the war. Though this was perhaps the most striking of the many services which his great wealth enabled him to do for Canada and the British Empire, he left no side of Canadian life untouched. With his counsel, Lord Mountstuart, he founded and endowed the Royal Victoria Hospital in Montreal, and both in Canada and in Scotland gave largely and wisely to university work. He was the backbone of the emigration policy which from 1806 on did much to increase the population and the prosperity of Canada. He helped in the improvement of the waterways of the Canadian West, and in placing steamers on them, and gave much assistance to the proposed All Red Route of British-owned steamers, encircling the world. From the first he was a member of the Pacific Cable Board, controlling the cable laid in 1902 by the combined governments of Great Britain, Canada, and Australia. No man did more to tighten the ties which bind Canada to the British Empire.

The Life by Beckles Willson contains some useful information. The Histories of the Hudson’s Bay Company by Beckles Willson, Rev. George Bryce and Miss Agnes C. Laut tell his early struggles. Sir Wilfrid Laurier (2 vols.), by J. Willson, describes the financial dealings between the Canadian government and the Canadian Pacific railway. His parliamentary speeches are in the Canadian Hansard.

Strathnairn, Hugh Henry Rose, 1st Baron (1801–1885), British field-marshall, third son of the Right Hon. Sir George Henry Rose of Sandhills, Christchurch, Hampshire (minister plenipotentiary at the Prussian court), was born at Berlin on the 6th of April 1801. He was educated at Berlin, and received military instruction at the cadet school. He entered the 93rd Sutherland Highlanders as an ensign on the 8th of June 1820, but was transferred to the 19th Foot, then quartered in Ireland, and took part in preserving order during the “Ribbon” outrages. He was promoted rapidly, to a lieutenancy in 1821, a captaincy in 1824, and an unattached major at the end of 1826. He was brought into the 92nd Highlanders as a regimental major in 1829, and the following year was appointed equerry to H.R.H. the duke of Cambridge. The 92nd Highlanders were in Ireland, and Rose again found himself employed in maintaining law and order. He rendered important services in suppressing disaffected meetings, but his conduct was so courteous to the ringleaders that he incurred no personal hostility. In 1833 he accompanied his regiment to Gibraltar, and three years later to Malta, where he exerted himself with so much zeal during a serious outbreak of cholera in attending to the sick soldiers that his conduct elicited an official approval from the governor and commander-in-chief. In 1839 he was promoted, by purchase, to an unattached lieutenant-colonel. In the following year Rose was selected, with other officers and detachments of Royal Artillery and Royal Engineers, for special service in Syria under the orders of the foreign office. They were to co-operate on shore, under Brigadier-General Michell, R.A.—in conjunction with the Turk units on the coast, for the expulsion of Mehmet Ali’s Egyptian army from Syria. Sir Stratford Canning sent Rose from Constantinople on a diplomatic mission to Ibrahim Pasha, commanding the Egyptian army in Syria, and after its execution he was attached, as deputy adjutant-general, to the staff of Omar Pasha, who landed at Jaffa with a large Turkish force from the British fleet. Rose distinguished himself in several engagements, and was twice wounded at El Muden in January 1841. He was mentioned in despatches, and received from the sultan the order of Nishan Iftihar in diamonds, the war medal and a salute of honour. The king of Prussia sent him the order of St. John, and expressed his pleasure that “an early acquaintance” had so gallantly distinguished himself. Shortly after he succeeded to the command of the British detachment in Syria with the local rank of colonel, and in April 1841 he was appointed British consul-general for Syria. For seven years, amidst political complications and intrigues, Rose, by his energy and force of character, did much to arrest the horrors of civil war, to prevent the feuds between the Maronites and Druses coming to a head, and to administer justice impartially. On one occasion in 1841, when he found the Maronites and Druses drawn up in two lines and firing at each other, he rode between them at imminent risk to his life, and by the sheer force of a stronger will stopped the conflict. In the first year of his appointment his action saved the lives of several hundred Christians at Deir el Khama, in the Lebanon, and his services were warmly recognized by Lord Aberdeen in the House of Lords, and he was made C.B. In 1845, by his promptness and energy, at great personal risk, he rescued 600 Christians belonging to the American mission at Absy, in the Lebanon, from the hands of the Druses, and brought them to Beirut. In 1848, during the outbreak of cholera at Beirut, he was most devoted in his attention to the sick and dying.

At the end of this year he left Syria on leave of absence, and did not return, as Lord Palmerston appointed him secretary of embassy to Constantinople in January 1851. In the following year he was charged d’affaires in the absence of Sir Stratford Canning during the crisis of the question of the “holy places,” and he so strengthened the hands of the Porte by his determined action that the Russian attempt to force a secret treaty upon Turkey was foiled. During the war with Russia in 1854–56 he was the British commissioner at the headquarters of the French army, with the local rank of brigadier-general. At Varna he succeeded in quenching a fire which threatened the French small-arm ammunition stores, and received the thanks of Marshal St Arnaud, who recommended him for the Legion of Honour. He was present at the battle of the Alma, and was wounded on the following day. At Inkerman he reconnoitred the ground between the British and French armies with great sang-froid under a withering fire from the Russian pickets, and his horse was shot under him. He distinguished himself on several other occasions by maintaining verbal communication between the allied forces, and by his tact and judgment contributed to the good feeling that existed between the two armies. His services were brought to notice by the commanders-in-chief of both armies, and he received the medal with three clasps and the thanks of parliament, was promoted to major-general, and was made K.C.B. and commander of the Legion of Honour. On the outbreak of the Indian Mutiny in 1857 Rose was given command of the Poona division. He arrived in September, and shortly after took command of the Central India force. In January 1858 he marched from Bhow, captured Rathgarh after a short siege, and defeated the raja of Bhopur near Baroda in the same month. He then relieved Saipur, captured Gathakota and the fort of Barodia, and early in March defeated the rebels in the Madanpur Pass and captured Madanpur and Chanderi. He arrived before Jhansi on the 20th of March, and during its investment defeated a relieving force under Tantia Topi at the Betwa on the 1st of April. Most of Rose’s force was locked up in the investment, and to Tantia Topi’s army of 20,000 he could only oppose 1500 men; yet with this small force he routed the enemy with a loss of 1500 men and all their stores. Jhansi was stormed and the greater part of the city taken on the 3rd, and the rest the following day, and the fort occupied on the 5th. Kunch was captured, after severe fighting in a temperature of 116° in the shade, on the 7th of May. Rose himself was only able to hold out by medical treatment, and many casualties occurred from the great heat. Under the same conditions the march was made on Kalpi. The rebels came out in multitudes on the 22nd of May to attack his small force, exhausted by hard marching and weakened by sickness, but after a severe fight under a burning sun, and in a suffocating hot wind, were utterly routed and Kalpi occupied the following day. Having completed his programme, Rose obtained sick leave, and Sir Robert Napier (g.v.) was appointed to succeed him, when news came of the defection of Sindhi’s troops and the
occupation of Gwalior by Tanjia Topi. Rose at once assumed command and marched into Gwalior by forced marches, and on the 16th of June won the battle of Mehtar. Leaving Napier there, he attacked Gwalior on the 19th, when the city was captured. The fortress was stormed and won the following day, and Napier gained a signal victory over the flying enemy at Jaora-Alipur on the 22nd. Rose then made over the command to Napier and returned to Poona. It was to Rose's military genius that the suppression of the Indian Mutiny was largely due; but owing to official jealousy his outstanding merit was not fully recognized at the time.

For his services he received the medal with clasp, the thanks of both houses of parliament, the regimental colonelcy of the 2nd foot, and was created G.C.B. By a legal quibble the Central India force, after protracted litigation, was not allowed its share of prize-money, a loss to Rose of £20,000. Rose was promoted lieutenant-general for his "eminence services" in February 1860, and the next month was appointed commander-in-chief of the Bombay army, and on the departure of Lord Clyde from India in the following June he succeeded him as commander-in-chief in India. During his tenure of the command-in-chief Rose improved the discipline of the army, while his powerful assistance enabled the changes consequent upon the amalgamation of the Indian army with the British army to be carried out without friction. He was created K.C.S.I. in 1861 and G.C.S.I. on the enlargement of the order. On his return home he was made an honorary D.C.L. of Oxford University.

Rose held the Irish command from 1865 until 1870, was raised to the peerage in 1866 as Baron Strathnairn of Strathnairn and Jhansi, transferred to the colonelcy of the 92nd Foot, and appointed president of the army transport committee. By a good organization and disposition of the troops under his command in 1866 and 1867 he enabled the Irish government to deal successfully with the Fenian conspiracy. He was transferred the general in 1867. On relinquishing the Irish command he was made an honorary LL.D. of Trinity College, Dublin. For the rest of his days he lived generally in London. He was gazetted to the colonelcy of the Royal Horse Guards in 1869, and promoted to field marshal in June 1877. He died in Paris on the 16th of October 1885, and was buried with military honours in the graveyard of the Priory Church, Christchurch, Hampshire. An equestrian bronze statue, by E. Onslow Ford, R.A., was erected to his memory at Knightsbridge, London. He was never married.

R. H. V.

**STRATHEFFER**, a village and spa of the county of Ross and Cromarty, Scotland, 5 m. W. of Dingwall by a branch of the Highland railway. Pop. (1901), 354. It lies in a valley of varying elevation (200 to 400 ft. above the sea), but is sheltered on the west and north and has a comparatively dry and warm climate. There are several sulphurous springs—one saline, another strongly impregnated with sulphurised hydrogen—in great repute for gout, rheumatism, skin diseases and affections of the liver and kidneys. The well of effervescent chalybeate water is largely resorted to for anaemia and as a tonic. A peat bath, similar to those at Franzenbad in Bohemia, has also been established. The season runs from May to October, and during the past few years Strathpeffer has become a very popular resort. The pump-room (1829) and pavilion (1881) are situated in the middle of the village. Castle Leod (pron. Loud), a seat of the countess of Cromartie, upon whose property Strathpeffer is built, lies a mile to the north and is an example of the Scots Baronial style dating from 1600. The village was the scene of the fight between the Mackenzies and Macdonalds in 1478, and later between the Mackenzies and the Munros. The Mackenzies prevailed in both encounters. The ascent of Ben Wyvis (3420 ft.) is commonly made from Strathpeffer.

**STRAUBING**, a town of Germany, in the kingdom of Bavaria, pleasantly situated in a fertile plain, on the right bank of the Danube, here crossed by two bridges, 25 m. S.E. of Regensburg, on the railway to Passau. Pop. (1905), 20,856, nearly all of whom are Roman Catholics. Its oldest and most characteristic building is the tall square tower with its five-pointed turrets, dating from 1268. It has eight Roman Catholic churches.

Among them being the church of St. James, a handsome Late Gothic edifice, with some paintings ascribed to Wohlgemuth; the old Carmelite church containing a monument to Duke Albert II. of Bavaria; and that of St. Peter with the tomb of Agnes Bernauer. It has also a Gothic town-hall, a castle, now used as barracks, and two fine squares. The numerous educational establishments include a gymnasium, an episcopal seminary for boys and a normal school. The industries of Straubing are tobacco-making, metal-working, and brewing, freed of foreign influence, and trade in grain and cattle.Straubing is a town of remote origin, believed to be identical with the Roman station of Sorbiodurum. In definite history, however, it is known only as a Bavarian town, and from 1353 to 1425 it was the seat of the ducal line of Bavaria-Straubing. Its chief historical interest attaches to its connexion with the unfortunate Agnes Bernauer (q.v.), who lived at the chateau here with her husband Duke Albert III.

**STRAUS, LUDWIG** (1835–1890), Austrian violinist, was born at Pressburg on the 28th of March 1835. He studied at the Viennese Conservatorium from 1843 to 1848, as a pupil of Böm; made his first appearance in 1850, and five years afterwards made a tour in Italy; in 1857 he became acquainted with his lifelong friend, the 'cellist Piaotti, and toured with him in Germany and Sweden. From 1860 to 1866 he was concert-meister at Frankfort, and during these years he visited England frequently, in the year 1864 taking up his residence there. He was for many years leader of Hallé's orchestra in Manchester, and a familiar figure at the Popular Concerts in London. He was first violin in the Queen's Band. He retired, owing to ill health, in 1893, and from that time till his death, on the 23rd of October 1899, lived at Cambridge. His playing, whether of violin or viola, had very great qualities; he was perfect in ensemble, and his power of self-effacement was of a piece with his gentle disposition and with the pure love of art which distinguished him through his life. A more lovable nature never existed, and his quiet influence on the art of his time was very great.

**STRAUS, DAVID FRIEDRICH** (1801–1874), German theologian and man of letters, was born at Hildesbourg, near Stuttgart, on the 27th of January 1808. In his thirteenth year he was sent to the evangelical seminary at Blaubeuren, near Ulm, to be prepared for the study of theology. Amongst the principal masters in the school were Professors Kern and F. C. Baur, who infused into their pupils above all a deep love of the ancient classics. In 1825 Strauss passed from school to the university of Tübingen. The professors of philosophy there failed to interest him, but he was strongly attracted by the writings of Schleiermacher, which aroused his keen dialectical faculty and delivered him from the vagueness and exaggerations of romantic and somnambulistic mysticism. In 1830 he became assistant to a country clergyman, and nine months later accepted the post of professor in the high school at Maulbronn, having to teach Latin, history and Hebrew. In October 1831 he resigned his office in order to study under Schleiermacher and Hegel in Berlin. Hegel died just as he arrived, and, though he regularly attended Schleiermacher's lectures, it was only those on the life of Jesus which exercised a very powerful influence upon him. It was amongst the followers of Hegel that he found kindred spirits. Under the leading of Hegel's distinction, "Vorstellung" and "Begriff," he had already conceived the idea of his two principal theological works—the Leben Jesus and the Christliche Dogmatik. In 1832 he returned to Tübingen and became repetent in the university, lecturing on logic, history of philosophy, Plato, and history of ethics, with great success. But in the autumn of 1832 he resigned this position in order to devote all his time to the completion of his projected...
Leben Jesu (1835). The work produced an immense sensation and created a new epoch in the treatment of the rise of Christianity. In 1837 Strauss replied to his critics (Briefe an meinen Leuten. Der alte Leben Jesu, Zweite Ausgabe, 1839), and in Zweie friedliche Blätter, he made important concessions to his critics, which he withdrew, however, in the fourth edition (1840; translated into English by George Eliot, with Latin preface by Strauss, 1846). In 1840 and the following year he published his Christliche Glaubenslehre (2 vols.), the principle of which is that the history of Christian doctrines is their disintegration. Between the publication of this work and that of the Friedliche Blätter he had been elected to a chair of theology in the university of Zurich. But the appointment provoked such a storm of popular ill will that he withdrew the application for his pension before he entered upon his duties, although this concession came too late to save the government. With his Glaubenslehre he took leave of theology for upwards of twenty years. In August 1841 he married Agnes Schebest, a cultivated and beautiful opera singer of high repute, but not adapted to be the wife of a scholar and literary man like Strauss. Five years afterwards, when two children had been born, a separation by arrangement was made. Strauss resumed his literary activity by the publication of Der Romanztier an dem Thron der Clären, in which he drew a satirical parallel between the Apostles and the members of the Prussian IV. of Prussia (1847). In 1848 he was nominated a member of the Frankfort parliament, but was defeated. He was elected for the Württemberg chamber, but his action was so conservative that his constituents requested him to resign his seat. He forgot his political disappointments in the production of a series of biographical works, which secured for him a permanent place in German literature (Schubarts Leben, 2 vols., 1849; Christian Möcklin, 1853; Nikodemus Frischlin, 1855; Ulrich von Hutten, 3 vols., 1858-1860, 5th ed. 1865; H. S. Reimarus, 1862). With this last-named work he returned to theology, and two years afterwards (1864) he published his Leben Jesu für das deutsche Volk (15th ed., 1904). It failed to produce an effect comparable with that of the first Life, but the replies to it were many, and Strauss answered them in his pamphlet Die Halben und die Ganzon (1862), directed specially against Schenkel and Hengstenberg. His Christus des Glaubens und der Jesus der Geschichte (1867) is a severe criticism of Schleiermacher's lectures on the life of Jesus, which were then first published. From 1865 to 1872 Strauss resided in Darmstadt, and in 1872 published his lectures on Voltaire (9th ed., 1902). His second work on the Apostles and der ruhige Baldachin (1871), English translation by M. Blind, 1873), produced almost as great a sensation as his Life of Jesus, and not least amongst Strauss's own friends, who wondered at his one-sided view of Christianity and his professed abandonment of spiritual philosophy for the materialism of modern science. To the fourth edition of the book he added a Nachwort als Vorwort (1873). The same year symptoms of a fatal malady appeared, and death followed on the 8th of February 1874.

Strauss's mind was almost exclusively analytical and critical, without depth of religious feeling or philosophical penetration, or historical sympathy; his work was accordingly rarely constructive. His Life of Jesus was directed against not only the traditional orthodoxy view of the Gospel narratives, but likewise the rationalistic treatment of them, whether after the manner of Reimarus or that of Paulus. The mythical theory that the Christ of the Gospels, excepting the meager outline of personal history, was the unintentional creation of the early Christian Messianic expectation, he applied with merciless rigour to the narratives. But his operations were based upon fatal defects, positive and negative. He held a narrow theory as to the miraculous, a still narrower as to the historical; and he had a defect in the nature of historical tradition, while, as F. C. Baur complained, his critique of the Gospel history had not been preceded by the essential preliminary critique of the Gospels themselves. Authorities.—Strauss's works were published in a collected edition in 12 vols., by E. Zeller (1876-1878), without his Christliche Dogmatik. His Ausgewählte Briefe appeared in 1895. On his life and works, see E. Zeller, David Friedrich Strauss in seinen Schriften (1874); A. Haussath, D. F. Strauss und die Theologie seiner Zeit (2 vols., 1896-1898); F. J. Vischer, Kritische Gänge (1844), vol. 1, and by the same writer, Altes und Neues (1883), vol. iii.; R. Gottschall, Literarische Charakteristiken (1896), vol. iv.; S. Eck, D. F. Strauss (1899); K. Harraeus, D. F. Strauss, sein Leben seiner Schriften (1901); and T. Zieger, D. F. Strauss (2 vols., 1908-1909).
1885 Strauss succeeded Bölow as conductor of the Meiningen orchestra, but the appointment was held only for a few months, since in April of this year Strauss resigned his post in order to travel in Italy, and on his return in the early autumn he became 3rd conductor of the Munich Opera under Hermann Levi. Four years later he was installed in Weimar as Hofkapellmeister, but once again he held his post only for a brief period, for in 1894, the year of his marriage to Pauline de Ahna, the eminent singer, he was promoted to 1st conductor at Munich. Between these various appointments and that of Hofkapellmeister in Berlin (1899) Strauss travelled considerably in the usual musical direction, not only as conductor, anon in propagandism. His first professional visit to London was in 1897, and laid the foundation of a local English cult that culminated six years later in a Strauss festival. From that time Strauss's path lay in pleasant places. He frequently returned to London, notably to conduct a performance of Elektra, in Beecham's season at Covent Garden in the spring of 1910, and a part of a concert at Queen's Hall, when he achieved a genuine triumph by his conducting of Mozart's music.

Of the early period of Strauss the composer there is little of importance to be said. His early works were neither better nor worse than those of scores of talented students of an advanced skill in matters of technique. Indeed it has often been said, with some show of authority, that the ultimate development of Strauss is seen to any appreciable extent first in the symphonic poem Macbeth (op. 23). Here, in spite of the earlier Don Juan (op. 20), Strauss is himself, thematically and orchestrally, for the first time, for Aus Italien (op. 16) is a comparatively poor and quite unrepresentative effusion apart altogether from the faux pas contained in it by the mistake of a popular song composed in St John's Wood, London, for a Neapolitan folk-song. A year only divides Macbeth (1887) from Don Juan (1888)—"To tow und Worte," as they have been called. But there is an age between them and Tod und Verklärung (1886)—the bridge from one part to the other and the opening of the second section of which are amongst Strauss's most glorious inspirations. Between the last-named work and Till Eulenspiegel's lustigen Streiche (1894), Strauss's first opera, Guntram finds place (first performance, Weimar, 1894), the latter a work that in spite of much reclamation for the composer failed to maintain a position upon the stage. In Till Eulenspiegel is to be found a sense of the domain of note (as of emulation), and it is perhaps worth recording that no more noteworthy example of Rondo form exists in modern music, while its approximate successor, Don Quixote (1897), is an absolutely outstanding example of the Variation form. Further, Strauss reached in Don Quixote his zenith as a musical realist. In between there occurred the Nietzschean poem Also sprach Zarathustra (1895), which stirred up more temporary strife than any of its predecessors, if not so much perhaps as was engineered later on by the production of Ein Heldenleben (1898), or by the comparatively ingenious Symphony domestica (1904). For various reasons these compositions roused the somewhat sleepy academies of musical Europe from their lethargy. They revived, with the usual negative results, the ancient fight as to the legitimacy or otherwise of programme music. But though performances were comparatively rare in England up to the middle of 1910, those that had occurred proved undoubtedly attractive, while their rareness might quite reasonably be attributed to the very large fees demanded for their performance.

Up to 1910 Strauss had composed four operas. Of these, Guntram was on frankly Wagnerian lines. Feuersnot, on the other hand, a satirical, purely Munich work—a page out of the Munich annals, as it were, so closely is it identified with the Bavarian capital in its musical and personal reference, though produced at Dresden in 1901, remained sufficiently alive to have merited performance at His Majesty's theatre, London, again under Thomas Beecham's direction in July 1910. The same enthusiastic musician had previously produced Elektra with immense yet equal success in London (Covent Garden) in the early spring of 1910. Perhaps none of these operas enjoyed the réclame of Salome (Dresden 1905), which in England was originally barred by the censor of plays, but was performed several times at Covent Garden under Thomas Beecham in the autumn of 1910.

As a composer of songs Strauss enjoys the widest popularity in the conventional sense of the word. Many an example could be given from the hundred and more of his "Lieder" of Strauss's lawful right to be considered a lineal descendant of the royal line of German song writers. Some are transcendentally beautiful. But this very fact has been thought to militate against his supreme greatness as a composer in the widest sense. The proof, indeed, which is the true Richard Strauss, the composer of the cacophonous Ein Heldenleben or of the exquisite Morgen or Traum durch die Dämmerung? But by 1910 he had at any rate won his place in the musical Walhalla. Whether the composer's name will survive by means of his many exquisite "Lieder," by means of his satire and grim humour, by means of his realism or his original classicism, remains to be seen. That his position is assured among the immortals is clear if only on account of his absolute independence of thought and of expression, of his breadth of artistic vision and of his capacity to say his say in the musical language of his own day. His heartiest detractors admit that Strauss has enlarged the means of musical expression even if they cavil at his somewhat realistic utterance on occasion. To put it no higher, he must rank as a 20th-century Berlioz with a vastly wider musical knowledge and equipment. (R. H. L.)

STRAW AND STRAW MANUFACTURES. Straw (from straw, as being used for strewing), is the general term applied to the stalky residue of grain-plants (especially wheat, rye, oats, barley). It forms the raw material of some important industries. It serves for the thatching of roofs, for a paper-making material, for ornamenting small surfaces as a "straw-mosaic," for plaiting into door and table mats, mattresses, &c., and for weaving and plaiting into light baskets, artificial flowers, &c. These applications, however, are insignificant in comparison with the place occupied by straw as a raw material for the straw bonnets and hats worn by both sexes. Of the various materials which go to the fabrication of plaited head-gear the most important is wheaten straw. It is only in certain areas that straw suitable for making plait is produced. The straw must have a certain "length of pipe " between which is to possess a clear delicate, golden color and must not be brittle. The most valuable straw for plaiting is grown in Tuscany, and from it the well-known Tuscan plait is made and Leghorn hats are made. The straw of Tuscany, specially grown for plaiting, is distinguished into three qualities—Ponterdas Senone being the finest, Mazzuolo the second quality, from which the bulk of the plait is made, while from the third quality, Santa Fioro, only "Tuscan pedals" and braids are plaited. The wheat-seed for these straws is sown very thickly on comparatively elevated and arid land, and it sends up long attenuated stalks. When the grain in the ear is about half developed the straw is pulled up by the roots, dried in the sun, and subsequently spread out for several successive days to be bleached under the influence of alternate sunlight and night-dews. The pipe of the upper joint alone is selected for plaiting, the remainder of the straw being used for other purposes. These pipes are made up in small bundles, bleached in sulphur fumes in a closed closet, assorted into sizes, and so prepared for the plaiters. Straw-plaiting is a domestic industry among the women and young children of Tuscany and some parts of Emilia. Tuscan plait and hats vary enormously in quality and value; the plait of a hat of good quality may represent the work of four or five days, while hats of the highest quality may each occupy six to nine months in making. The finest work is excessively trying to the eyes of the plaiters, who can at most give to it two or three hours' labour daily.

The districts around Luton in Bedfordshire and the neighbouring counties have, since the beginning of the 17th century, been the British home of the straw-plait industry. The straw
of certain varieties of wheat cultivated in that region is, in
favourable seasons, possessed of a fine bright colour and due
tenacity and strength. The straw is cut as in ordinary har-
vesting, but is allowed to dry in the sun before binding.
Subsequently straws are selected from the sheaves, and of these
the pipes of the two upper joints are taken for plaiting. The
pipes are assorted into sizes by passing them through graduated
openings in a grilled wire frame, and those of good colour are
bleached by the fumes of sulphur. Spotted and discoloured straws
are dyed either in pipe or in plant. The plaiters work up
the material in a damp state, either into whole straw or
split straw plaits. Split straws are prepared with the aid of a
small instrument having a projecting point which enters the
straw pipe, and from which radiate the number of knife-edged
cutters into which the straw is to be split. The plaiting of
straw in the counties of Bucks., Beds., Berks. and Herts. formerly
gave employment to many thousands of women and young
children; but now vast quantities of plait are imported at a
very cheap rate from Italy, China and Japan. The result is
that, while the Luton trade in the manufacture of straw and
fancy hats of every description has largely extended, the number of
plaiters, all told, was not more than a few hundreds
in 1907, as compared with 30,000 in 1871. The plaits are sewed
partly by hand and in a special sewing-machine, and the hats or
bonnets are finished by stiffening with gelatin size and
blocking into shape with the aid of heat and powerful pressure,
according to the dictates of fashion.

In the United States straw-plait work is principally centred
in the state of Massachusetts.

Many substances besides straw are worked into plaited and braids
for both material and in the fronds of numerous palms. "Brazilian " hats
made from the fronds of the palmetto palm, Sabal palmetto and
S. mexicana, are now largely made at St Albans. The famous
Panama hats, fine qualities of which were at one time worth £20 to
£30 each, are made from the leaves of the screw pine, Carludovica
palmata. They are now manufactured at Dresden, Strasburg and
Nancy, and can be purchased at 30s. or £2.

STRAWBERRY (Fragaria).—Apart from its interest as a
dessert fruit, the strawberry has claims to attention by reason of
the peculiarity of its structure and the excellent illustrations
it offers of the inherent power of variation possessed by the
plant and of the success of the gardener in availing himself of
this tendency. The genus Fragaria consists of about eight
species, native of the north temperate regions of both hemi-
spheres, as well as of mountain districts in warmer climes; one
species is found in Chili. The tufted character of the plant, and
its habit of sending out long slender branches (runners) which
produce a new bud at the extremity, are well known. The
leaves have usually three leaflets palmately arranged, but
the number of leaflets may be increased to five or reduced to
one. While the flower has the typical Rosaceous structure, the
so-called flower is very peculiar, but it may be understood by the
contrast it presents with the "hip" of the rose. In the last-
named plant the top of the flower-stalk expands as it grows
into a vase-shaped cavity, the "hip," within which are concealed
the true fruits or seed-vessels. In the rose the extremity of
the floral axis is concave and bears the carpels in its interior.
In the strawberry the floral axis, instead of becoming concave,
swells out into a fleshy, dome-shaped or flattened mass in
which the carpels or true fruits, commonly called pips or seeds,
are more or less embedded but never wholly concealed. A
ripe strawberry in fact may be aptly compared to the "fruit"
or organ turned inside out.

The common wild strawberry of Great Britain (fig. 1), which
indeed is found throughout Europe and great part of temperate
Asia and North America, is Fragaria vesca, and this was the
first species brought under cultivation in the early part of the
17th century. Later on other species were introduced, such as
F. elatior, a European species, the parent stock of the hawthorns
strawberries, and especially F. virginiana from the United States
and F. chiloensis from Chile. From these species, crossed and
recessed in various manners, have sprung the vast number

of different varieties now enumerated in catalogues, whose
characteristics are so inextricably blended that the attempt to
trace their exact parentage or to follow out their lineage has
become impossible. The varieties at present cultivated vary
in the most remarkable degree in size, colour, flavour, shape,
degree of fertility, season of ripening, liability to disease and
constitution of plant. Some, as previously stated, vary in foliage,
others produce no runners, and some vary materially in the
relative development of their sexual organs, for, while in most
cases the flowers are in appearance hermaphrodite, at least
in structure, there is a very general tendency towards a separa-
tion of the sexes, so that the flowers are males or females only

as to function, even although they may be perfect in construc-
tion. This tendency to dioecism is a common characteristic
among Rosaceae, and sometimes proves a source of disappoint-
ment to the cultivator, who finds his plants barren where he had
hoped to gather a crop. This happens in the United States
more frequently than in Britain, but when recognized can readily
be obviated by planting male varieties in the vicinity of the
barren kinds. Darwin, in alluding to the vast amount of
variability in the so-called "fruit"—a change effected by the
art of the horticulturist in less than three centuries—contrasts
with, this variability the fixity and permanence of character
presented by the true fruits, or pips, which are distributed over
the surface of the swollen axis. The will and art of the gardener
have been directed to the improvement of the one organ,
while he has devoted no attention to the other, which conse-
quently remains in the same condition as in the wild plant.
Too much stress is not, however, to be laid on this point, for
it must be remembered that the foliage, which is not specially
an object of the gardener's "selection," nevertheless varies
considerably.

The larger-fruited sorts are obtained by crossing from F.
chiloensis and F. virginiana, and the smaller alpines from F.
vesca. The alpine varieties should be raised from seeds;
while the other sorts are continued true to their kinds by
runners. If new varieties are desired, these are obtained by
judicious crossing and seeding.

The seeds of the alpines should be saved from the finest fruit
ripened early in the summer. They may at once be sown, either in a
sheltered border outdoors or in pots, or better in March under glass,
when they will produce fruit in June of the same year. The soil
should be rich and light, and the seeds very slightly covered by
sifting over them some leaf-mould or old decomposed cow dung.
When the plants appear and have made five or six leaves, they are

![Fig. 1.—Wild Strawberry (Fragaria vesca), § nat. size. In flower
and fruit, and bearing a runner.](image-url)
transplanted to where they are to remain for bearing. The seeds sown in pots may be helped on by gentle heat, and when the plants are large enough they are pricked out in fine rich soil, and in June transferred to the open ground for bearing; they will produce a partial crop in the autumn, and a full one in the following season. The same treatment may be applied to the choicer seedlings of the larger-fruited sorts from which new varieties are expected. Amongst the best is a rose strawberry, to which the name of "perpetual" has been given, are those known as St. Joseph and St. Anthony of Padua.

The runners of established sorts should be allowed to root in the soil adjoining the plants, which should, therefore, be kept light and fine, or layered into small pots as for forcing. As soon as small leaves are produced on each of the secondary runners should be stopped. When the plants have become well-rooted they should at once be planted out. They do best in a rather strong loam, and should be kept tolerably moist. The scarlet section prefers a rich sandy loam. The ground should be trenched 2 or 3 ft. deep, and supplied with plenty of manure, a good proportion of which should lie just below the surface, 10 to 12 in. from the surface. The plants may be put in on an average about 2 ft. apart.

A mulching of strawy manure put between the rows in spring serves to keep the ground moist and the fruit clean, as well as to afford nourishment to the plants. Unless required, the runners are cut off early, in order to promote the swelling of the fruit. The plants are watered during dry weather after the fruit is set, and occasionally till it begins to colour. As soon as the fruit season is over, the runners are again removed, and the ground hoed and raked.

The plantation should be renewed every second or third year, or less frequently if kept free of runners, if the old leaves are cut away. If the fruit has been cut away and if a good mulch or of rotten dung or leaf-mould is applied. A top-dressing of loam is beneficial if applied before the plants begin to grow in spring, but after that period they should not be disturbed during the summer either at root or top. If the plants produce a large number of flower-scales, each should, if large fruit is desired, have them reduced to about four of the strongest. The lowest blossoms on the scapes will be found to produce the largest, earliest and best fruits. The fruit should not be gathered till it is quite ripe, and then, if possible, it should be quite dry, but not heated by the sun. Those intended for preserving are best taken without the stalk and the calyx.

Forcing.—The runners propagated for forcing are layered into 3-in. pots, filled with rich soil, and held firm by a piece of raffia, a peg or stone. If kept duly watered they will soon form independent plants. The earlier they are secured the better. When firmly rooted they are removed and transferred into well-drained 6-in. pots, of strong well-enriched loam, the soil being rammed firmly into the pots, which are to be set in an open airy place. In severe frosts they should be covered with dry litter or bracken, but do not necessarily require to be placed under glass. They are moved into the forcing houses as required. The main points to be kept in view in forcing strawberries are, first, to have strong stocky plants, the leaves of which have grown sturdy from being well exposed to light, and secondly, to grow them on slowly till fruit is set. When they are first introduced into heat, the temperature should not exceed 45° or 50° by fire heat, and air must be freely admitted; should the leaves appear to grow up thin and delicate, less fire heat and more air must be given, but an average temperature of 55° by day may be allowed and continued while the plants are in flower. When the fruit is seen to be heavy, it may be gradually increased, till at the ripening period it stands at 65°, and occasionally at 75° by sun heat. While the fruit is swelling the plants should never be allowed to get dry. A good moderating temperature and moisture should be given than is absolutely requisite to keep the leaves from flagging. The plants should be removed from the house as soon as the crop is gathered. The forced plants properly hardened make first-rate outdoor plantations, and if put out early in summer, in good ground, will often produce a useful autumnal crop.

Diseases.—The most troublesome fungoid attacks to which the strawberry is subject are mildew and leaf-spot. The former, like all mildews, attacks the leaves and spreads to the fruit, these being covered with the white mycelium. The fungus is identical with that causing mildew in hops (Sphaerotheca humuli), and its development is greatly furthered by exposure of its host to cold drafts or low night temperatures. Spraying the foliage with potassium sulphide (1 oz. to the gallon of water) should be tried, but the plants should not be sprayed when the fruit is developing. The "leaf-spot" is caused by the fungus Sphaerella fragariae. The first symptom of this attack is the appearance of small, circular, white spots on the leaves, having a brown, definite, dark reddish margin.

(From George Mann's Textbook of Plant Diseases, by permission of Duckworth & Co.)

**Fig. 3.** _Sphaerella fragariae._

1. Strawberry leaf showing diseased spots.
2. Ascon with eight spores from a perithecium. (× 300.)
3. Spores or conidia of the _Ramularia_ stage. (× 300.)

On these spots a whitish mould (formerly considered to be a distinct species under the name _Ramularia tilasmel_) develops, and this is followed later by the perfect form of the fungus, the fruits of which appear to the naked eye as small black spots seated on the white dead spot on the leaf. Potassium sulphide may be used as for the mildew, or, perhaps better, Bordeaux mixture. It has been recommended to cut off the leaves after fruiting and burn the beds over so as to destroy the fungus in the leaves.

The grubs of the cockchafer (_Melolontha vulgaris_) and the rose-chafer (_Cetonia aurata_) frequently feed upon the roots of the strawberry and do considerable damage, while the larvae of the garden swift moth (_Hepialus_) behave in a similar way. The imago of _Cetonia aurata_ also frequently damages the flowers of the strawberry by devouring their centres, and is often troublesome in this way in forcing-houses, particularly. The carnivorous ground beetles, particularly _Pterostichus nigra_ and _Harpalus rufimanus_, when the fruit is ripe attack it at night, returning to the soil in the daytime. They are to be caught by placing jars containing some attractive matter, such as meat and water, at intervals about the beds with their mouths sunk level with the surface of the soil. Millepedes also are often found in the ripe fruit, but occur mostly where the soil is very rich in organic matter and poor in lime.

**STREATHAM**, a large residential district in the south of London, England, within the municipal borough of Wandsworth. The name appears to indicate its position on an ancient "street" or highway. According to Domedez, Streatham included several manors, two of which, Tooting and Balham (to follow the modern nomenclature), belonged to the abbots of St Mary de Bec in Normandy. One of several public grounds on the approach road to Streatham is called Tooting Bec Common. The parish church of St. Leonard, Streatham, contains among its memorials that of Henry Thrale (d. 1781), with an inscription by Samuel Johnson, who was a constant visitor at Thrale's house, Streatham Park, which is no longer standing.

**STREATOR**, a city of La Salle county, Illinois, U.S.A., on the Vermillion river, in the N. part of the state, about 95 m. S.W. of Chicago. Pop. (1890), 11,414; (1900), 14,070, of whom 3749 were foreign-born; (1910 census) 12,735; land area,
297 sq. m. It is served by the Atchison, Topeka & Santa Fé, the Chicago, Burlington & Quincy, the Chicago & Alton, the Chicago, Indiana & Southern and the Wabash railways. Streator has a public library and a Chautauqua auditorium. It is in the Vermilion coal region, and clay for brick and tile is abundant in its vicinity. The city's manufactures include glass, brick, tile, foundry and machine-shop products, &c. In 1905 the factory product was valued at $1,888,894, being 51.4% greater than in 1900. Streator was laid out in 1868, was chartered as a village in 1870 and was chartered as a city in 1882.

**STREET, GEORGE EDMUND** (1824–1881), English architect, was born at Woodford in Essex on the 20th of June 1824. He was the third son of Thomas Street, solicitor, by his second wife, Mary Anne Millington. George went to school at Mitcham in about 1830, and later to the Camberwell collegiate school, which he left in 1839. For a few months he was in his father's business in Philpot Lane, but on his father's death he went to live with his mother and sister at Exeter. There his thoughts first turned to architecture, and in 1841 his mother obtained a place in the office of Mr. Owen Carter at Winchester. Afterwards he worked for five years as an "improver" with Sir George Gilbert Scott in London. At an early age Street became deeply interested in the principles of Gothic architecture, and devoted an unsparing amount of time and labour to studying and sketching the finest examples of medieval buildings in England and on the Continent. His first commission was for the designing of Biscory Church, Cornwall. In 1849 he took an office of his own. He was a draughtsman of a very high order; his sketches are masterpieces of spirit and brilliant touch. In 1857 he published a very careful and well-illustrated work on *The Brick and Marble Architecture of Northern Italy*, and in 1865 a book on *The Gothic Architecture of Spain*, with very beautiful drawings by his own hand. Street's personal taste led him in most cases to select for his design the 13th-century Gothic of England or France, his knowledge of which was very great, especially in the skillful use of rich moldings. By far the majority of the buildings erected by him were for ecclesiastical uses, the chief being the convent of East Grinstead, the theological college at Cuddesdon and a very large number of churches, such as St. Philip and St. James's at Oxford, St. John's at Torquay, All Saints' in the office of S. J. G. Gordon, St. Margaret's at Liverpool and St. Mary Magdalene, Paddington. His largest works were the nave of Bristol Cathedral, the choir of the cathedral of Christ Church in Dublin, and, above all, the new courts of justice in London. The competition for this was prolonged and much diversity of opinion was expressed. Thus, the judges wanted Street to make the exterior arrangements and Barry the interior, while a special committee of lawyers recommended the designs of Alfred Waterhouse. In June 1868, however, Street was appointed sole architect; but the building was not complete at the time of his death in December 1881. Street was elected an associate of the Royal Academy in 1866, and R.A. in 1871; at the time of his death he was professor of architecture to the Royal Academy, where he had delivered a very interesting course of lectures on the development of medieval architecture. He was also president of the Royal Institute of British Architects. He was a member of the Royal Academy of Vienna, and in 1878, in reward for drawings sent to the Paris Exhibition, he was made a knight of the Legion of Honour. Street was twice married, first on the 17th of June 1852 to Mariquita, second daughter of Robert Proctor, who died in 1880; on the 16th of January 1881, second daughter of William Holland, who died in the same year. The architect's own death, on the 18th of December 1881, was hastened by overwork and professional worries connected with the erection of the law courts. He was buried on the 20th of December in the nave of Westminster Abbey.

**STRELITZ (Strēlētsi),** a body of Russian household troops originally raised by the tsar Ivan the Terrible in the middle of the 16th century. They numbered 40,000 to 50,000 infantry, and formed the greater part of the Russian armies in the wars of the 16th and 17th centuries. They were a fierce and ill-disciplined force, individually brave and cruel in war, and almost ungovernable in peace. Their mutinies were frequent and dangerous, and at last, in 1682, an unusually serious outbreak led Peter the Great to compass the abolition of the force. The Strelitz were gradually drawn to the western frontier of Russia, and in 1685 they rose in mutiny for the last time. Crushed in battle by Peter's general, Patrick Gordon, they ceased to exist as a military force, and about 2000 of them who were not killed fought to the last. The hands of the tsar were barbarously tortured and put to death.

**STRENGTH OF MATERIALS**, that part of the theory of engineering which deals with the nature and effects of stresses in the parts of engineering structures. Its principal object is to determine the proper size and form of pieces which have to bear given loads, or, conversely, to determine the loads which can be safely applied to pieces whose dimensions and arrangement are already given. It also treats of the relations between the applied loads and the changes of form which they cause. The subject comprises experimental investigation of the properties of materials as to strength and elasticity, and mathematical discussion of the stresses in ties, struts, beams, shafts and other elements of structures and machines.

**Stress** is the mutual action between two bodies, or between two parts of a body, whereby each of the two exerts a force upon the other. Thus, when a stone lies on the ground there is at the surface of contact a stress, one aspect of which is the force directed downwards with which the stone pushes the ground, and the other aspect is the equal force directed upwards with which the ground pushes the stone. A body is said to be in a state of stress when there is a stress between the two parts which lie on opposite sides of an imaginary surface of section. A pillar or block supporting a weight is in a state of stress because at any cross section the part above the section pushes down against the part below, and the part below pushes up against the part above. A stretched rope is in a state of stress, because at any cross section the part on each side is pulling the part on the other side with a force in the direction of the rope's length. A plate of metal that is being cut in a shearing machine is in a state of stress, because at the place where it is about to give way the portion of metal on either side of the plane of shear is tending to drag the portion on the other side with a force in that plane.

**Normal and Tangential Stress.**—In a solid body which is in a state of stress the direction of stress at any imaginary surface of division may be normal, oblique or tangential to the surface. If oblique it is conveniently treated as consisting of a normal and a tangential component. Normal stress may be either push (compression) or pull (tension); while the stress component parallel to the surface is called shearing stress. Oblique stress may be regarded as so much push or pull along with so much shearing stress. The amount of stress per unit of surface is called the intensity of stress. Stress is said to be uniformly distributed over a surface when each fraction of the area of surface bears a corresponding fraction of the whole stress. If a stress P is uniformly distributed over a plane surface of area S, the intensity is P/S. If the stress is not uniformly distributed, the intensity at any point is dP/dS, where dP is the amount of stress on an indefinitely small area dS at the point considered. For practical purposes intensity of stress is usually expressed in pounds per square inch, pounds weight per square inch, or kilogrammes weight per square millimetre or per square centimetre.

**Simple Longitudinal Stress.**—The simplest possible state of stress is that of a short pillar or block compressed by opposite forces applied at its ends, or that of a stretched rope or other tie. In these cases the stress is wholly in one direction, that of the length. These states may be distinguished as simple longitudinal push and simple longitudinal pull. In them there is no stress on planes parallel to the direction of the applied forces.

**Compound Stress.**—A more complex state of stress occurs if the block is compressed by forces applied to opposite sides, as well as by forces applied to its ends—that is to say, if two simple longitudinal stresses in different directions act together. A still more complex state occurs if a third stress be applied to the block, causing the hair of sides to be bent in two different ways. Then any state of stress which can possibly exist at any point of a body may be produced by the joint action of three simple push or pull stresses in three suitably chosen directions at right angles to each
other. These three are called principal stresses, and their directions are called the axes of principal stress. These axes have the important property that the intensity of stress along one of them is greater, and along another it is less, than in any other direction. These are called respectively the axes of greatest and least principal stress.

Resolution of Stress.—Returning now to the case of a single simple longitudinal stress, let AB (fig. 1) be a portion of a rod or a strut, which is being pulled or pushed in the direction of the axis AB with a total stress P. On any plane CD taken at right angles to the axis we have a normal pull or push of intensity \( p = P/S \), S being the area of the normal cross-section. On a plane EF whose normal is inclined to the axis at an angle \( \theta \) we have a stress still in the direction of the axis, and therefore oblique to the plane EF, of intensity \( P/S', \) where \( S' \) is the area of the surface EF, or \( S' = S/\cos \theta \). The whole stress P on EF may be resolved into two components, one normal to EF, and the other a shearing stress tangential to EF. The normal component \( (P\cos \theta) \) is \( P\cos \theta \), the tangential component \( (P\sin \theta) \) is \( P\sin \theta \). Hence the intensity of normal pull or push on EF, or \( p_n \), is \( P\cos \theta \), and the intensity of a shearing stress EF, or \( p_s \), is \( P\sin \theta \). This expression makes \( p_s \) a maximum when \( \theta = 45^\circ \): surfaces inclined at \( 45^\circ \) to the axis are called surfaces of maximum shearing stress; the intensity of shearing stress on the plane \( \theta = 45^\circ \).

Combination of Two Simple Pull or Push Stresses at Right Angles to One Another.—Suppose next that there are two principal stresses: it can be shown that in addition to the simple pull or push stress of fig. 1 there is a second pull or push stress acting at right angles to it as shown in fig. 2. Call these \( P_x \) and \( P_y \) respectively. On any inclined surface EF there will be an intensity of stress whose normal component \( p_n \) and tangential component \( p_t \) are found by summing up the effects due to \( P_x \) and \( P_y \) separately. Let \( P_x \) and \( P_y \) be the intensities of stress produced by \( P_x \) and \( P_y \) respectively on planes perpendicular to their own directions. Then

\[
\begin{align*}
p_n &= (P_x \cos \theta + P_y \sin \theta) \\
p_t &= (P_x \sin \theta - P_y \cos \theta)
\end{align*}
\]

\( \theta \) being the angle which the normal \( \theta \) is inclined to the surface that makes with the direction of \( P_x \).

The tangential stress \( p_t \) becomes a maximum when \( \theta = 45^\circ \), and its value then is

\[ \text{Max. } p_t = (P_x - P_y) \]

If in addition there is a third principal stress \( P_z \), it will not produce any tangential component on planes perpendicular to the plane of the figure. Hence the above expression for the maximum tangential stress will still apply, and it is easy to extend this result so as to reach the important general proposition that in any condition of stress whatever the maximum intensity of shearing stress is equal to one-half the difference between the greatest and least principal stresses and occurs on surfaces inclined at \( 45^\circ \) to them.

State of Simple Shear.—A special case of great importance occurs when there are two principal stresses only, equal in magnitude and opposite in sign; in other words, when one is a simple push and the other a simple pull. Then on surfaces inclined at \( 45^\circ \) to the axes of pull and push there is nothing but tangential stress, for \( p_n = 0 \); and this intensity of tangential stress is numerically equal to \( p_t \) or \( p_s \). This condition of stress is called a state of simple shear.

The state of simple shear may also be developed in another way. Let an elementary cubical part of any solid body (fig. 4) have tangential stresses \( QQ \) applied to one pair of opposite faces, A and B, and equal tangential stresses applied to a second pair of faces C and D.

Figs. 3, 4, 5, 6, 15, 16, 17, 18, 19, 20, 23, 24, and 25 are from Ewing's "Strength of Materials," by permission of the Cambridge University Press.

As in the figure. The effect is to set up a state of simple shear. On all planes parallel to A and B there is nothing but tangential stress, and the summation of all planes parallel to C and D. The intensity of the stress on both systems of planes is equal throughout to the intensity of the stress which was applied to the face of the block.

To see the connexion between these two ways of specifying a state of simple shear consider the equilibrium of the parts into which the block may be divided by ideal diagonal planes of section. To balance the forces \( QQ \) (fig. 3), there must be normal pull on the diagonal plane, the amount of which is \( P = Q/2 \). But the area of the surface over which \( P \) acts is greater than that of the surface over which \( Q \) acts in the proportion which \( P \) bears to \( Q \), and hence the intensity of \( P \) is the same as the intensity of \( Q \).

Again, taking the other diagonal plane (fig. 6), the same argument applies except that here the normal force \( P \) required for equilibrium is a push instead of a pull. Thus the state of stress represented in fig. 4 admits of analysis into two equal principal stresses, one of push and one of pull, acting in directions at right angles to one another and inclined at \( 45^\circ \) to the planes of shear stress.

Equality of Shearing Stress in Two Directions.—No tangential stress can exist in one direction without an equal intensity of tangential stress existing in another direction at right angles to the first. To prove this it is sufficient to consider the equilibrium of the elementary cube of fig. 4. The tangential forces acting on two sides A and B produce a couple which tends to rotate the cube. No arrangement of normal stresses on any of the three pairs of sides of the cube can balance this couple; that can be done only by equal tangential forces on C and D.

Fluid Stress.—Another important case occurs when there are three principal stresses all of the same sign and of equal intensity \( \rho \). The tangential components on any planes cancel each other: the stress on every plane is wholly normal and its intensity is \( \rho \). This is the only state of stress that can exist in a fluid at rest because a fluid exerts no statical resistance to shear. For this reason the state is often spoken of as a fluid stress.

Strain is the change of shape produced by stress. If the stress is a simple longitudinal pull, the strain consists of lengthening in the direction of the pull, accompanied by contraction in both directions at right angles to the pull. If the stress is a simple push, the strain consists of shortening in the direction of the push and expansion in both directions at right angles to that; the stress and the strain are then exactly the reverse of what they are in the case of simple pull. If the stress is one of simple shearing, the strain consists of a distortion such as would be produced by the sliding of layers in the direction of the shearing stresses.

A material is elastic with regard to any applied stress if the strain disappears when the stress is removed. Strain which persists after the stress that produced it is removed is called permanent set. For brevity, it is convenient to speak of strain which disappears when the stress is removed as elastic strain.

Limits of Elasticity.—Actual materials are generally very perfectly elastic with regard to small stresses, and very imperfectly elastic with regard to great stresses. If the applied stress is less than a certain limit, the strain is in general small in amount, and disappears wholly, or almost wholly, when the stress is removed. If the applied stress exceeds this limit, the strain is, in general, much greater than before, and most of it is found, when the stress is removed, to consist of permanent set. The
limits of stress within which strain is wholly or almost wholly elastic are called limits of elasticity.

For any particular mode of stress the limit of elasticity is much more sharply defined in some materials than in others. When well defined it may readily be recognized in the testing of a sample from the fact that after the stress exceeds the limit of elasticity the strain begins to increase in a much more rapid ratio to the stress than before. This characteristic goes along with the one already mentioned, that up to the limit the strain is wholly or almost wholly elastic.

Hooke's Law.—Within the limits of elasticity the strain produced by a stress of any one kind is proportional to the stress producing it. This is Hooke's law, enunciated by him in 1676. In the case of stress to the uniform elongation the longitudinal stress—such as the case of a bar stretched by simple longitudinal pull—may be measured by the change of length per unit original length which the bar undergoes when stressed. Let the original length be \( l \), and let the whole change of length be \( \Delta l \) when a stress is applied whose intensity \( p \) is within the elastic limit. Then the strain is measured by \( \Delta l/l \), and this by Hooke's law is proportional to \( p \). This may be written

\[
\text{\( \Delta l = \frac{p}{E} \text{l} \)},
\]

where \( E \) is a constant for the particular material considered. The same value of \( E \) applies to push and to pull; these modes of stress being essentially continuous, and differing only in sign.

Young's Modulus.—This constant \( E \) is called the modulus of elasticity of the material. It is also denoted by \( Y \), but in the present work is always expressed in the same units as are used to express intensity of stress, may be measured directly by exposing a sample of the material to longitudinal pull and noting the extension, or indirectly by measuring the change of length of the material by means of a vibratory beam, and computing the frequency of vibrations. It is frequently spoken of by engineers simply as the modulus of elasticity, but this name is too general, as there are other moduli applicable to other modes of stress. Since \( E = p/\Delta l \), the modulus may be defined as the ratio of the intensity of stress \( p \) to the longitudinal strain \( \Delta l/\text{l} \).

Modulus of Rigidity.—In the case of simple shearing stress, the strain may be measured by the angle through which each of the originally right angles in the square prism of fig. 3 is altered by the distortion of the prism. Let this angle be \( \phi \) in radians; then by Hooke's law \( p=\phi c \), where \( p \) is the intensity of shearing stress and \( c \) is a constant which measures the rigidity of the material. It is called the modulus of rigidity, and is usually determined by experiments on torsion.

Modulus of Cubic Compressibility.—When three simple stresses of equal intensity \( p \) and of the same sign (all pulls or all pushes) are applied in three directions, the material (provided it is isotropic, that is to say, provided its properties are the same in all directions) suffers change of volume only, without distortion of form. If the volume is \( V \) and the change of volume \( \Delta V \), the ratio of the stress \( p \) to the strain \( \Delta V/V \) is called the modulus of cubic compressibility, and will be denoted by \( K \).

Of these three moduli the one of most importance in engineering applications is Young's modulus \( E \). When a simple longitudinal pull or push of intensity \( p \) is applied to a piece, the longitudinal extension \( \Delta l \) is proportional to \( p/l \). This is accompanied by a lateral contraction or expansion, in a transverse direction, whose amount may be written \( p/E \), where \( \sigma \) is the ratio of longitudinal to lateral strain. It is shown in the article Elasticity, that for an isotropic material:

\[
E = \frac{9CK}{3K+C} \text{ and } \sigma = \frac{2(3K+C)-3K\text{c}}{3K-2C}.
\]

Plastic Strain.—Beyond the limits of elasticity the relation of strain to stress becomes very indefinite. Materials then exhibit, to a greater or less degree, the property of plasticity. The strain is much affected by the length of time during which the stress has been in operation. A material may assume a permanent strain only after a long (perhaps an indefinitely long) time. Finally, when the stress is sufficiently increased, the ratio of the increment of strain to the total strain may become indefinitely great if time is given for the stress to take effect. In other words, the substance then assumes what may be called a completely plastic state; it flows under the applied stress like a viscous liquid.

Ultimate Strength.—The ultimate elongation of a material with regard to any stated mode of stress is the stress required to produce rupture. In reckoning ultimate strength, however, engineers take, not the actual intensity of stress at which rupture occurs, but the value which the intensity would have reached had rupture ensued without previous alteration of shape. Thus, if a bar whose original cross-section is 2 sq. in. breaks under a uniformly distributed pull of 60 tons, the ultimate tensile strength of the material is reckoned to be 30 tons per sq. in., though the actual intensity of stress at the time of production may have been much greater than this, owing to the contraction of the section previous to fracture. The convenience of this usage will be obvious from an example. Suppose that a piece of material of the same quality be used in a structure under conditions which cause it to bear a simple pull of 6 tons per sq. in. It will conclude at once that the actual load is one-fifth of that which would cause rupture, provided of course the material might contract in section if overstrained. The stresses which occur in engineering practice are, or ought to be, in all cases far below the limits of elasticity; hence, with these limits the change of cross-section caused by longitudinal pull or of the kind is so small that it may be neglected in reckoning the intensity of stress.

Ultimate tensile strength and ultimate shearing strength are well defined, since these modes of stress (simple pull and simple shearing stress) lead to distinct fracture if the stress is sufficiently increased. Under compression some materials yield so continuously that their ultimate strength to resist compression can scarcely be specified; others show so distinct a fracture by crushing that their compressive strength may be determined with some precision.

Some of the materials used in engineering, notably timber and wrought iron, are so far from being isotropic that their strength is widely different for stresses in different directions. In the case of wrought iron the process of rolling develops a fibrous structure on account of the presence of streaks of slag which become interspersed with the metal in puddling; and the ultimate strength of a rolled plate is found to be considerably greater in the direction of rolling than across the plate. Steel plates, being rolled from a nearly homogeneous ingot, have nearly the same strength in both directions; but they have provided the process of rolling is carried out at a temperature high enough to allow recrystallization to take place in cooling. Cold-rolled or cold-drawn metal is not isotropic because the crystals of which it is made up have been elongated in one direction by pressure and reformed by heating the stress to re-form.

Permissible Working Stress.—In applying a knowledge of the strength of materials to determine the proper sizes of parts in an engineering structure we have to estimate a permissible working stress. This is based partly on special tests and partly on experience of the behaviour of the material when worked into the structures. The working stress is rarely so much as one-third of the ultimate strength; it is more commonly one-fourth or one-fifth and in some cases, especially where the loads to be borne are liable to reversal or to much change, it may be prudent to make the working stress even less than this.

Factor of Safety.—The ratio of the ultimate strength to the working stress is called the factor of safety. The factor should in general be such as to bring the working stress within the limit of elasticity and even to leave within that limit a margin which will be ample enough to cover such contingencies as imperfections or less than perfect theory. The margin is generally larger when the metal is in the cold-drawn or cold-rolled condition; it is also larger when the metal is in the hot state, in which it is more ductile, less liable to work-hardening, and less liable to fatigue or disintegration of workmanship which may cause the actual dimensions to fall short of those that have been specified, alterations arising from wear, rust and so forth. An important distinction has to be drawn in this connexion between steady or "dead" loads and loads which are subject to variation and especially to reversal. With the former the working stress may reach or pass the elastic limit without destroying the structure; but in a piece subject to reversals a stress of the same magnitude would lead inevitably to rupture, and hence a larger margin should be left to ensure that in the latter case the elastic limit shall not even be approached.

It is in fact the elastic limit rather than the ultimate strength of the material on which the question mainly depends of how high the working stress may safely be allowed to rise in any particular conditions as to mode of loading, and accordingly it becomes a matter of much practical importance to determine by tests the amount of stress which can be borne without permanent strain. From an engineering point of view the structural merit of a material, especially when variable loads and possible shocks have to be sustained, depends not only on the strength but also on the ductility, or capacity of the material to deform without rupture. This characteristic is shown in tests made to determine tensile strength by the amount of ultimate elongation, and also by the contraction of the cross-section which occurs through the flow of the metal before rupture. It is often, tested in other ways, such as by bending and unbending bars in a circle of specified radius, or by examining the effect of repeated blows. Tests by impact are generally
made by causing a weight to fall through a regulated distance on a piece of the material supported as a beam.

Tests of Strength.—Ordinary tests of strength are made by submitting the piece to direct pull, direct compression, bending or torsion. Testing machines are frequently arranged so that they may apply any of these four modes of stress; tests by direct tension are the most common, and next to them come tests by bending. When the samples to be tested for tensile strength are mere wires, the stress may be applied directly by weights; for pieces of larger section some mechanical multiplication of force becomes necessary. Owing to the plasticity of the materials to be tested, the applied loads must be able to follow considerable change of form in the test-piece: thus in testing the tensile strength of wrought iron or steel provision must be made for taking up the large extension of length which occurs before fracture. In most modern forms of large testing machines the loads are applied by means of hydraulic pressure acting on a piston or plunger to which one end of the specimen is secured, and the stress is measured by connecting the other end to a lever or system of levers provided with adjustable weights. In small machines, and also in some large ones, the stress is applied by screw gearing instead of by hydraulic pressure. Springs are sometimes used instead of weights to measure the stress, and another plan is to make one end of the specimen act on a diaphragm forming part of a hydrostatic pressure gauge.

Single-lever Testing Machine.—Figs. 7 and 8 show an excellent form of single-lever testing machine designed by J. H. Wicksteed (Proc. Inst. Mech. Eng., August 1882) in which the stress is applied by an hydraulic plunger and is measured by a lever or steel-yard and a movable weight. The illustration shows a 30-ton machine, but machines of similar design are in common use which exert a force of 100 tons or more. AA is the lever, on which there is a graduated scale. The stress on the test-piece T is measured by a weight W of 1 ton (with an attached vernier scale), which is moved along the lever by a screw-shaft S; this screw-shaft is driven by a belt from a parallel shaft R, which takes its motion, through bevel-wheels and a Hooke's joint in the axis of the fulcrum, from the hand-wheel H. (The Hooke's joint in the shaft R is shown in a separate sketch above the lever in fig. 8.) The holder for the upper end of the sample hangs from a knife-edge 3 in. from the fulcrum of the lever. The lower holder is jointed to a cross-head C, which is connected by two vertical screws to a lower cross-head B, upon which the hydraulic plunger shown in section in fig. 7 exerts its thrust. G is a counterpoise which pushes up the plunger when the water is allowed to escape. Hydraulic pressure may be applied to the plunger by pumps or by an accumulator. In the present instance it is applied by means of an auxiliary plunger Q, which is pressed by screw gearing into an auxiliary cylinder. Q is driven by a belt on the pulley D. This puts stress on the specimen, and the weight W is then run out along the lever so that the lever is just kept floating between the stops E, E. Before the test-piece is put in the distance between the holders is regulated by means of the screws connecting the upper and lower cross-heads C and B, these screws being turned by a handle applied at F. The knife edges are made long enough to prevent the load on them from ever exceeding 5 tons to the linear inch. To adapt a machine of this class for tests in compression, a small platform is suspended like a stirrup by four rods from the weigh-beam, and hangs below the cross-head, which is pulled down when the hydraulic cylinder is put in action. The arrangement is that of two stirrups linked with one another, so that when the two pull against each other a block of material placed between them becomes compressed. For tests in bending one of the stirrups, namely, the platform which hangs from the weigh-beam, is made some 4 or 5 ft. long, and carries two knife-edge supports at its ends on which the ends of the piece that is to be bent rest, while the cross-head presses down upon the middle of the piece. In both cases the force which is exerted is measured by means of the weigh-beam and travelling weight, just as in the tension tests. To apply the force continuously, without shock, and either quickly or slowly at will, a very convenient plan is to use an hydraulic intensifier, consisting of a large hydraulic piston operating a much smaller one. By gradually admitting water to the large piston from any convenient source under moderate pressure, such as the town water mains, a progressively increased pressure is produced in the fluid on which the small piston acts, and this fluid is admitted to the straining cylinder of the machine. One of the advantages of the vertical type of machine, with its single horizontal lever, is the facility with which the correctness of its readings may be verified. The two things to be tested are (i) the distance between the knife-edges, one of which forms the fulcrum of the
weigh-beam and from the other of which the shackle holding the upper end of the specimen is hung, and (2) the weight of the travelling poise. The weight of the poise is readily ascertained by using a supplementary known weight to apply a known moment to the beam, and measuring how far the poise has to be moved to restore equilibrium. The distance between the knife-edges is then found by hanging a known heavy weight from the shackle, and again observing how far the poise has to be moved. Another example of the single-lever type is the Werder testing machine, much used on the continent of Europe. In it the specimen is horizontal; one end is fixed, the other is attached to the short vertical arm of a bell-crank lever, whose fulcrum is pushed out horizontally by an hydraulic ram.

Multiple-lever Testing Machines.—In many other testing machines a system of two, three or more levers is employed to reduce the force between the specimen and the measuring weight. In most cases the fulcra are fixed, and the stress is applied to one end of the specimen by hydraulic power or by screw gearing, which takes up the stretch, as in the single-lever machines already described. David Kirkaldy, who was one of the earliest as well as one of the most assiduous workers in this field, applied in his 1,000,000 lb machine a horizontal hydraulic press directly to one end of the horizontal test-piece. The other end of the piece was connected to the short vertical arm of a bell-crank lever; the long arm of this lever was horizontal, and was connected to a second lever to which weights were applied.

Machines have been employed in which one end of the specimen is held in a fixed support; an hydraulic press acts on the other end, and the stress is calculated from the pressure of fluid in the press, this being observed by a pressure-gauge. Machines of this class are open to the obvious objection that the friction of the hydraulic plunger causes a large and very uncertain difference between the force exerted by the fluid on the plunger and the force exerted by the plunger on the specimen. It appears, however, that in the ordinary conditions of packing the friction is very nearly proportional to the fluid pressure, and its effect may therefore be allowed for with some exactness. The method is not to be recommended for work requiring precision, unless the plunger be kept in constant rotation on its own axis during the test, in which case the effects of friction are almost entirely eliminated.

Diaphragm Testing Machines.—In another class of testing machines the stress (applied as before to one end of the piece, by gearing or by hydraulic pressure) is measured by connecting the other end to a flexible diaphragm, on which a liquid acts whose pressure is determined by a gauge. Fig. 9 shows the Thomasset’s testing machine, in which one end of the specimen is pulled by an hydraulic press A. The other end acts through a bell-crank lever B on a horizontal diaphragm C, consisting of a metallic plate and a flexible ring of india-rubber. The pressure on the diaphragm causes a column of mercury to rise in the gauge-tube D. The same principle is applied in the remarkable testing machine of Watertown arsenal, built in 1879 by the U.S. government to the designs of A. H. Emery. This is a horizontal machine, taking specimens of any length up to 30 ft., and exerting a pull of 360 tons or a push of 480 tons by an hydraulic press at one end. The stress is taken at the other end by a group of four large vertical diaphragm presses, which communicate by small tubes with four similar small diaphragm presses in the scale case. The pressure of these acts on a system of levers which terminates in the scale beam. The joints and bearings of all the levers are made frictionless by using flexible steel connecting-plates instead of knife-edges. The total multiplication at the end of the scale beam is 420,000.

Stress-strain Diagrams.—The results of tests are very commonly exhibited by means of stress-strain diagrams, or diagrams showing the relation of strain to stress. A few typical diagrams for wrought iron and steel in tension are given in fig. 10, the data for which are taken from tests of long rods by Kirkaldy. Up to the elastic limit these diagrams show sensibly the same rate of extension for all the materials to which they refer. Soon after the limit of elasticity is passed, a point, which has been called by Sir A. B. W. Kennedy the yield-point, is reached, which is marked by a very sudden extension of the specimen. After this the extension becomes less rapid; then it continues at a fairly regular and gradually increasing rate; near the point of rupture the metal again begins to draw out rapidly. When this stage is reached rupture will occur through the flow of the metal, even if the load be somewhat decreased. The diagram may in this way be made to come back towards the line of no load, by withdrawing a part of the load as the end of the test is approached.

Fig. 11 is a stress-strain diagram for cast iron in extension and compression, taken from Eaton Hodgkinson’s experiments. The extension was measured on a rod 50 ft. long; the compression was also measured on a long rod, which

---

3 Experiments on the Mechanical Properties of Steel by a Committee of Civil Engineers (London, 1868 and 1870).

was prevented from buckling by being supported in a trough with partitions. The full line gives the strain produced by loading; it is continuous through the origin, showing that Young's modulus is the same for pull and push. (Similar experiments on wrought iron and steel in extension and compression have given the same result.) The broken line shows the set produced by each load. Hodgkinson found that some set could be detected after even the smallest loads had been applied. This is probably due to the existence of initial internal stress in the metal, produced by unequally rapid cooling in different portions of the cast bar. A second loading of the same piece shows a much closer approach to perfect elasticity. The elastic limit is, at the best, ill defined; but by the time the ultimate load is reached the set has become a more considerable part of the whole strain. The pull curves in the diagram extend to the point of rupture; the compression curves are drawn only up to a stage at which the bar buckled (between the partitions) so much as to affect the results.

*Autographic Recorders.*—Testing machines are sometimes fitted with autographic appliances for drawing strain diagrams.

When the load is measured by a weight travelling on a scale, a distance may be determined by allowing the weight with a drum by means of a wire or cord, so that the drum is made to revolve through angles proportional to the travel of the weight. At the same time another wire, fastened to a clip near one end of the specimen, and passing over a pulley near the other end, draws a pencil through distances proportional to the strain, and so traces a diagram of stress and strain on a sheet of paper stretched round the drum.1

In Wicksteed's autographic recorder the stress is determined by reference, not to the load on the lever, but to the pressure in the hydraulic cylinder by which stress is applied. The main cylinder is in communication with a small auxiliary hydraulic cylinder, the plunger of which is kept rotating to avoid friction at its packing. This plunger abuts against a spring, so that the distance through which it is pushed out varies with the pressure in the main cylinder. A drum covered with paper moves with the plunger under a fixed pencil, and is also caused to rotate by a wire from the specimen through distances proportional to the strain. The scale of loads is calibrated by occasional reference to the weighted lever.2

In Kennedy's apparatus autographic diagrams are drawn by applying to the test-piece through an elastic master-bar of larger section. The master-bar is never strained beyond its elastic limit, and within that limit its extension furnishes an accurate measure of the stress; this gives motion to a pencil, which writes on a paper moved by the extension of the test-piece.3

Strain beyond the Elastic Limit: Influence of Time.—In testing a plastic material such as wrought-iron or mild steel it is found that the behaviour of the metal depends very materially on the time rate at which stress is applied. When once the elastic limit is passed the full strain corresponding to a given load is reached only after a perceptible time, sometimes even a long time. If the load be increased to a value exceeding the elastic limit, and then kept constant, the metal will be seen to draw out (if the stress be one of pull), at first rapidly and then more slowly. When the applied load is considerably less than the ultimate strength of the piece (as tested in the ordinary way by steady increment of load) it appears that this process of slow extension comes at last to an end. On the other hand, when the applied load is nearly equal to the ultimate strength, the flow of the metal continues until rupture occurs. Then, as in the former case, extension goes on at first quickly, then slowly, but finally, instead of approaching an asymptotic limit, it quickens again as the piece approaches rupture. The same phenomena are observed in the bending of timber and other materials when in the form of beams. If, instead of being subjected to a constant load, a test-piece is set in a constant condition of strain, it is found that the stress required to maintain this constant strain gradually decreases.

The gradual flow which goes on under constant stress—approaching a limit if the stress is moderate in amount, and continuing without limit if the stress is sufficiently great—will still go on at a diminished rate if the amount of stress be reduced. Thus, in the testing of soft iron or mild steel, the strain in which the stress is applied by hydraulic power, a stage is reached soon after the limit of elasticity is passed at which the metal begins to flow with great rapidity. The pumps often do not keep pace with this, and the result is that, if the lever is to be kept floating, the weight on it must be run back. Under this reduced stress the flow continues, more slowly than before, until presently the pumps recover their lost ground and the increase of stress is resumed. Again, near the point of rupture, the flow again becomes specially rapid; the weight on the lever has again to be run back, and the specimen finally breaks under a diminished load. These features are well shown by fig. 12, which is copied from the autographic diagram of a test of mild steel.

*Hardening Effect of Permanent Set.*—But it is not only through what we may call the viscosity of materials that the time rate of loading affects their behaviour under test. In iron and steel, and probably in some other metals, time has another effect of a very remarkable kind. Let the test be carried to any point a (fig. 13) past the original limit of elasticity. Let the load then be removed; during the first stages of this removal the material continues to stretch slightly, as has been explained above. Let the load then be at once replaced and loading continued. It will then be found that there is a new yield-point b at or near the value of the load formerly reached. The full line bc in fig. 13 shows the subsequent behaviour of the piece. But now let the experiment be repeated on another sample, with this difference, that an interval of time, of a few hours or more, is allowed to elapse after the load is removed and before it is replaced. It will then be found that a process of hardening has been going on during this interval of rest; for when the loading is continued the new yield-point appears, not at b as formerly, but at a higher load d. Other evidence that a change has taken place is afforded by the fact that the ultimate extension is reduced and the ultimate strength is increased (e, fig. 13).

A similar and even more marked hardening occurs when a load (exceeding the original elastic limit), instead of being removed and replaced, is kept on for a sufficient length of time without change. When loading is resumed a new yield-point
is found only after a considerable addition has been made to the load. The result is, as in the former case, to give greater ultimate strength and less ultimate elongation. Fig. 14 exhibits two experiments of this kind, made with annealed iron wire. A

load of 23.5 tons per square inch was reached in both cases; abc shows the result of continuing to load after an interval of five minutes, and acd after an interval of 43.5 hours, the stress of 23.5 tons being maintained during the interval in both cases. It may be concluded that, when a piece of metal has in any way been overstressed by strain exceeding its limits of elasticity, it is hardened, and (in some cases at least) its physical properties go on slowly changing for days or even months. Instances of the hardening effect of permanent set occur when plates or bars are rolled cold, hammered cold, or bent cold, or when wire is drawn. When a hole is punched in a plate the material contiguous to the hole is severely distorted by shear, and is so much hardened in consequence that when a strip containing the punched hole is broken by tensile stress the hardened portion, being unable to extend so much as the rest, receives an undue proportion of the stress, and the strip breaks with a smaller load than it would have borne had the stress been uniformly distributed. This bad effect of punching is especially noticeable in thick plates of mild steel. It disappears when a narrow ring of material surrounding the hole is removed by means of a rimer, so that the material that is left is homogeneous. Another remarkable instance of the same kind of action is seen when a mild-steel plate which is to be tested by bending has a piece cut from its edge by a shearing machine. The result of the shear is that the metal close to the edge is hardened, and, when the plate is bent, this part being unable to stretch like the rest starts a crack or tear which quickly spreads across the plate on account of the fact that in the metal at the end of the crack there is an enormously high local intensity of stress. By the simple expedient of planing off the hardened edge before bending the plate homogeneity is restored, and the plate will then bend without damage.

Annealing.—The hardening effect of overstrain is removed by the process of annealing, that is, by heating to redness and cooling slowly. In the ordinary process of rolling plates or bars of iron or mild steel the metal leaves the rolls at so high a temperature that it is virtually annealed, or pretty nearly so. The case is different with plates and bars that are rolled cold: they, like wire supplied in the hard-drawn state (that is, without being annealed after it leaves the draw-plate), exhibit the higher strength and greatly reduced plasticity which result from permanent set.

Extensometers.—Much attention has been paid to the design of extensometers, or apparatus for observing the small deformation which a test-piece in tension or compression undergoes before its limit of elasticity is reached. Such observations afford the most direct means of measuring the modulus of longitudinal elasticity of the material, and they serve also to determine the limits within which the material is elastic. In such a material

as wrought iron the elastic extension is only about \( \frac{1}{2} \) th of the length for each ton per square inch of load, and the whole amount up to the elastic limit is perhaps \( \frac{1}{2} \) th of the length; with a length of 8 in., which is usual in tensile tests, it is desirable to read the extension to, say, \( \frac{1}{2} \) th in. If the modulus of elasticity is to be found with fair accuracy, or if the limits of proportionality between strain to stress are under examination, measurements taken between marks on one side of the bar only are liable to be affected by bending of the piece, and it is essential either to make independent measurements on both sides or to measure the displacement between two pieces which are attached to the bar in such a manner as to share equally the strain on both sides.

In experiments carried out by Baenschinger, independent measurements of the strains on the opposite faces of the bar were made by using mirror micrometers of the type illustrated diagrammatically in fig. 15. Two clips a and b clasp the test-piece at the place between

which the extension is to be measured. The clip c carries two small rollers \( d_1, d_2 \) which are free to rotate on centres fixed in the clip. These rollers press on two plane strips \( e_1, e_2 \) attached to the other clip. When the specimen is stretched the rollers consequently turn through angles proportional to the strain, and the amount of turning is read by means of small mirrors \( g_1 \) and \( g_2 \) fixed to the rollers, which reflect the divisions of a fixed scale \( f \) into the reading telescopes \( e_1, e_2 \). In Martens's extensometer each of the rollers is replaced by a rhombic piece of steel with sharp edges, one of which bears against the test-piece, while the other rests in a groove formed in the spring projecting parallel to the test-piece from the distant clip.

Much excellent work has been done by extensometers of this class, but in point of convenience of manipulation it is of great advantage to have the apparatus self-contained. J. A. Ewing has introduced a microscope extensometer of the self-contained type which is shown in fig. 16; its action will be seen by reference to the diagram fig. 17. Two clips B and C are secured on the bar, each by means of a pair of opposed set-screws. Between the two is a rod \( B' \) which is hinged to B and has a blunt pointed upper end which makes a ball-and-socket joint with C at P. Another bar R hangs from C, and carries a mark which is read by a microscope attached to B. Hence, when the specimen stretches, the length of \( B'B \) increases, the bar R is pulled up relatively to the microscope, and the amount of the movement measured by a micrometer scale in the eyepiece. A screw at P serves to bring the mark on R into

\[ \text{Fig. 15.} \]
\[ \text{Fig. 16.} \]
\[ \text{Fig. 17.} \]
the field of view, and also to calibrate the readings of the micro-
meter scale. The scale allows readings to be taken to 0.001 in.,
by estimating tenths of the actual divisions. The arms CP and CQ
are equal, and hence the movement of Q represents twice the
extension of the bar under test. In another form of the instru-
ment adapted to measure the elastic compression of short blocks
the arm CQ is four times the length of CP, and consequently there
is a mechanical magnification of five besides the magnification
afforded by the microscope.

When the behaviour of specimens of iron, steel, or other
materials possessing plasticity, is watched by means of a sensitive
extensometer during the progress of a tensile test, it is in general
observed that a very close proportionality between the load
and the extension holds during the first stages of the loading,
and that during these stages there is little or no "creeping" or
supplementary extension when any particular load is left
in action for a long time. The strain is a linear function of
the stress, almost exactly, and disappears when the stress
is removed. In other words, the material obeys Hooke's law.
This is the stage of approximately perfect elasticity, and
the elastic limit is the point rather vaguely defined by
observations of the strain, at which a tendency to creep
is first seen, or a want of proportionality between strain
and stress. "Creeping" is usually the first indication that
it has been reached. As the load is further augmented,
there is in general a clearly marked yield-point, at which a
sudden large extension ensues. In metals which have been
annealed or in any way brought into a condition which is
independent of the effects of earlier applications of stress, this
elastic stage is well marked, and the limit of elasticity is as a
rule sharply defined. But if the metal has been previously
overstrained, without having had its elasticity restored by
annealing or other appropriate treatment, a very different

J. Muir 1 that the rate at which this recovery of elasticity occurs
depends on the temperature at which the piece is kept, and that
complete recovery may be produced in iron or steel by exposure
of the overstrained specimen for a few minutes to the tempera-
ture of boiling water. Figs. 18 and 19 illustrate interesting points
in Muir's experiments. In these figures the geometrical device
is adopted of shearing back the curves which show extension
in relation to load by reducing each of the observed extensions
by an amount proportional to the load, namely, by one unit of
extension for each 19 tons per square inch of load. The effect is
to contract the width of the diagrams, and to make any want of
straightness in the curves more evident than it would otherwise
be. To escape confusion, curves showing successive operations
are drawn from separate origins. In the experiment of figs. 18
and 19 the material under test was a medium steel, containing
about 0.4% of carbon, which when tested in the usual way
showed a breaking strength of 39 tons per square inch with
a well-marked elastic limit at about 22 tons. In fig. 18
the line A relates to a test of this material in its primitive
condition; the loading was raised to 35 tons so as to produce
a condition of severe overstrain. The load was then removed,
and in a few minutes it was reapplied. The line B exhibits
the effect of this application. Its curved form shows plainly
that all approach to perfect elasticity has disappeared, as
a consequence of the overstraining. There is now no elastic
limit, no range of stress within which Hooke's law applies.
With the lapse of time the curve gradually recovers its straight-
ness, and the material, if kept at ordinary atmospheric tempera-
ture, would show almost complete recovery in a month or two.
But in this instance the recovery was hastened by immersing
the piece for four minutes in boiling water, and line C shows that
this treatment restored practically perfect elasticity up to a limit
as high as the load by which the previous overstraining had been
effected. The loading in C was continued past a new yield-point;
this made the elasticity again disappear, but it was restored
in the same way as before, namely, by a few minutes' exposure
to 105° C., and the line D shows the final test, in which the elastic
limit has been raised in this manner to 45 tons. Other tests have
shown that a temperature of even 50° C. has a considerable influ-
ence in hastening the recovery of elasticity after overstrain.

In the non-elastic condition which follows immediately on
overstrain the metal shows much hysteresis in the relation of

1 See experiments by Johann Bauschingher, Mitt. aus dem mech-tech.
Lab. in München (1886), and by the writer, Proc. Roy. Soc., vol.
xxxviii. (1892). A summary of Bauschingher's conclusions will be
found in Martens's book, cited above, and in Unwin's Testing of
Materials.
be expected, no approach to conformity with Hooke's law until recovery has been brought about either by prolonged rest at ordinary temperature or by exposure for a short time to some higher temperature. After recovery has taken place the elastic limit in compression is found to have been lowered; that is to say, it occurs at a lower load than in a normal piece of the same metal. But it appears from Muir's experiments that the amount of this lowering is not at all equal to the amount by which the elastic limit has been raised in tension. In other words, the general effect of hardening by overstrain, followed by recovery of elasticity, is to widen the range within which a practically complete proportionality between strain and stress holds good.

**Conclusion of Section at Rupture.**—The extension which occurs when a bar of uniform section is pulled is at first general, and is distributed with some approach to uniformity over the length of the bar. Before the bar breaks, however, a large additional amount of local extension occurs at and near the place of rupture. The material flows in that neighbourhood much more than in other parts of the bar, and the section is much more contracted there than elsewhere. The contraction of area at fracture is frequently stated as one of the results of a test, and is a useful index to the quality of materials. If a flaw is present sufficient to determine the section at which rupture shall occur the contraction of area will in general be distinctly diminished as compared with the contraction in a specimen free from flaws, although little reduction may be noted in the total extension of the piece. Local extension and contraction of area are almost absent in cast iron and hard steel; on the other hand, they are specially prominent in wrought iron, mild steel and other metals that combine plasticity with high tensile strength. An example is shown in fig. 20, which is copied from a photograph of a broken test-piece of Whitworth mild fluid-compressed steel. The piece was of uniform diameter before the test. Experiments with long rods show that the general extension which occurs in parts of the bar not near the break is somewhat irregular; it exhibits here and there incipient local stretching, which has stopped without leading to rupture. This is, of course, due in the first instance to want of homogeneity. It may be supposed that when local stretching begins at any point in the earlier stages of the test it is checked by the hardening effect of the strain, until, finally, under greater load, a stage is reached in which the extension at one place goes on so fast that the hardening effect cannot keep pace with the increase in intensity of stress which results from diminution of area; the local extension is then unstable, and rupture ensues. Even at this stage a pause in the loading, and an interval of relief from stress, may harden the locally stretched part enough to make rupture occur somewhere else when the loading is continued.

**Influence of Local Stretching on Total Elongation.**—Local stretching causes the percentage of elongation which a test-piece exhibits before rupture (an important quantity in engineers' specifications) to vary greatly with the length and section of the piece tested. It is very usual to specify the length which is to exhibit an assigned percentage of elongation. This, however, is not enough; the percentage obviously depends on the relation of the transverse dimensions to the length. A fine wire 8 ft. long will stretch little more in proportion to its length than a very long wire of the same quality. An 8-in. bar, say 1 in. in diameter, will show something like twice as much the percentage of elongation as a very long rod. The experiments of Barba show that, in material of uniform quality, the percentage of elongation is constant for test-pieces of similar form, that is to say, for pieces of various size in which the transverse dimensions are varied in the same proportion as the length. It is to be regretted that in ordinary testing it is not practicable to reduce the pieces to a standard form with one proportion of transverse dimensions to length, since tests in which the relation of length to cross-section differ give results which are incapable of direct comparison with one another.

**Influence on Strength.**—The form chosen for test-pieces in tension tests affects not only the extension but also the ultimate strength. In the first place, if there is a sudden or rapid change in the area of cross-section at any part of the length under tension (as at AB, fig. 21), the stress will not be uniformly distributed there. The intensity will be greatest at the edges A and B, and the piece will, in consequence, pass its elastic limit at a less value of the total load than would be the case if the change from the larger to the smaller section were gradual. In a non-ductile material rupture will for the same reason take place at AB, with a less total load than would otherwise be borne. On the other hand, with a sufficiently ductile material, although the section AB is the first to be permanently deformed, rupture will preferably take place at some section not near AB, because at and near AB the contraction of sectional area which precedes rupture is partly prevented by the presence of the projecting portions C and D. Hence, too, with a ductile material samples such as those of fig. 22, in which the part of smallest section between the shoulders or enlarged ends of the piece is short, will break with a greater load than could be borne by long uniform rods of the same section. In good wrought iron and mild steel the flow of metal preceding rupture and causing local contraction of section extends over a length six or eight times the width of the piece; and, if the length throughout which the section is uniform be materially less than this, the process of flow will be rendered more difficult and the breaking load of the sample will be raised.

These considerations have, of course, a wider application than to the mere interpretation of special tests. An important practical case is that of riveted joints, in which the metal left between the rivet holes is subjected to tensile stress. It is found to bear, per square inch, a greater pull than would be borne by a strip of the same plate if the strip were tested in the usual way with uniform section throughout a length great enough to allow complete freedom of local flow.

**Fracture by Tension.**—In tension tests rupture may occur by direct separation over a surface which is nearly plane and normal to the line of stress. This is not uncommon in hard steel and other comparatively non-ductile materials. But in ductile materials under tension the piece generally gives way by shearing on an inclined surface. Very often the effect is a more or less perfect ring-shaped crater on one side of the break and a truncated cone on the other.

---

1. See Kirkaldy's Experiments on Fagersta Steel (London, 1874).
3. The greater strength of nicked or grooved specimens seems to have been first remarked by Kirkaldy (Experiments on Wrought Iron and Steel, p. 74, also Experiments on Fagersta Steel, p. 27). See also a paper by E. Richards, on tests of mild steel, Journ. Iron and Steel Inst. (1882).
4. See Kennedy's "Reports on Riveted Joints," Proc. Inst. Mech. Eng. (1881-1885). In the case of mild-steel plates a drilled strip may have as much as 12% more tensile strength per square inch than an undrilled strip. With punched holes, on the other hand, the remaining metal is much weakened, for the reason referred to in the text.
Fracture by Compression.—In compression tests of a plastic material, such as mild steel, a process of flow may go on without limit; the piece (which must of course be short, to avoid buckling) shortens and bulges out in the form of a cask. This is illustrated by fig. 23 (from one of Sir W. Fairbairn’s experiments), which shows the compression of a round block of steel (the original height and diameter of which are shown by the dotted lines) by a load equal to 100 tons per sq. in. of original sectional area. The surface over which the stress is distributed becomes enlarged, and the total load must be increased in a corresponding degree to maintain the process of flow. The bulging often produces longitudinal cracks, as in the figure, especially when the material is fibrous as well as plastic (as in the case of wrought iron). A brittle material, such as cast iron, brick or stone, yields by shearing on inclined planes as in figs. 24 and 25, which are taken from Hodgkinson’s experiments on cast iron. The simplest fracture of this kind is exemplified by fig. 24, where a single surface (approximately a plane) of shear divides the compressed block into two wedges. With cast iron the slope of the plane is such that this simplest mode of fracture can take place only if the height of the block is less than about \( \frac{1}{4} \) the width of the base. When the height is less the action is more complex. Shearing must then take place over more than one plane, as in fig. 25, so that cones or wedges are formed by which the surrounding portions of the block are split off. The stress required to crush the block is consequently greater than if the height were sufficient for shearing in a single plane.

Plane of Shear.—The inclination of the surfaces of shear, when fracture takes place by shearing under a simple stress of pull or push, is a matter of much interest, throwing some light on the question of how the resistance which a material exerts to stress of one kind is affected by the presence of stress of another kind—a question scarcely touched by direct experiment. At the shorn surface there is, in the case of tension tests, a normal pull as well as a shearing stress, and in the case of compression tests a normal push as well as shearing stress. If this normal component were absent the material (assuming it to be isotropic) would shear in the surface of greatest shearing stress, which, as has already been shown, is a surface inclined at \( 45^\circ \) to the axis. In fact, however, it does not shear on this surface. Hodgkinson’s experiments on the compression of cast iron give surfaces of shear whose normal is inclined at about \( 55^\circ \) to the axis of stress, and Kirkaldy’s, on the tension of steel, show that when rupture of a rod under tension takes place by shear the normal to the surface is inclined at about \( 25^\circ \) to the axis. These results show that normal pull diminishes resistance to shearing and normal push increases resistance to shearing. In the case of cast iron under compression, the material prefers to shear on a section where the intensity of shearing stress is only 0.94 of its value on the surface of maximum shearing stress (inclined at \( 45^\circ \)), but where the normal push is reduced to 0.66 of the value which it has on the surface of maximum shearing stress.

Lüders’s Lines.—It is interesting to refer in this connexion to the phenomenon observed in 1859 by W. Lüders of Magdeburg and afterwards studied more fully by L. Hartmann. When a bar of plastic metal such as mild steel, preferably flat and with a polished surface, is extended a little beyond its elastic limit, markings appear on the surface in the form of narrow bands running transversely across it. These bands are regions within which a shearing deformation has taken place, resulting from the tension, as has been explained with reference to fig. 1, and they are distinguished from the remainder of the bar because in the early stages of plastic strain the yielding is local. For the reason that has just been explained in speaking of surfaces of rupture, Lüders’s lines in a rod strained by direct pull are found to be inclined, not at \( 45^\circ \), but at an angle more nearly normal to the axis of pull (making about 65° with it). Their inclination shows that the metal prefers to elongate by shearing on a section where \( \sigma \), the shearing stress is not at its maximum, because \( \sigma \), the normal component—which is a pull—is greater there, and this can only mean that the presence of a normal component of the nature of a pull at any section reduces the resistance to yielding under the shearing stress which acts at that section, while similarly the presence of a normal component of the nature of a push increases the resistance to shear.

Yielding under Compression.—The question of much theoretical interest and also of some practical importance is, what determines the yielding of a piece when it is subjected not to a simple pull or push alone but to a stress combined of two or of three principal stresses? According to one view, which in the absence of experimental data appears to have been taken by W. J. M. Rankine, the material yields when the greatest principal stress reaches a certain limit, irrespective of the existence of the other principal stresses. According to another view (Barré de Saint-Venant), it yields when the maximum strain reaches a certain value, and in the strain depends, in part on each of the three principal stresses this gives a different criterion. Neither the maximum stress theory nor the maximum strain theory can be regarded as satisfactory, and probably a much sounder view is that the material yields when the greatest shearing stress reaches a certain limit. Even this, however, requires some qualification in the light of what has just been said about the inclination of surfaces of shear and Lüders’s lines, for it is clear from these experimental indications that resistance to shear is affected by the presence of normal stress on the plane of shear, and consequently a theory which takes account of shearing stress only as the criterion of yielding cannot be completely correct. According to the greatest shearing stress theory the yielding under compound stress depends directly on the difference between the greatest and least principal stress. In such cases of compound stress as have to be dealt with in engineering design this furnishes a criterion which though imperfect is certainly to be preferred to the criterion furnished by calculating the greatest principal stress.

Experiments on Compound Stress.—In experiments carried out by J. J. Guesdi (Phil. Mag., 1900, vol. 50) the action of combined stresses was investigated by subjecting thin tubes to (1) tension alone, (2) tension and torque, (3) tension and internal (fluid) pressure, and (4) torque and internal pressure, while measurements were made of the axial strain and the twist so as to detect the first failure of elasticity. The general result of the experiments, so far as they went, was to support the view that yielding depends primarily on the greatest shearing stress, that is to say, on the difference between the greatest and least principal stresses.

Fatigue of Metals.—A matter of great practical as well as scientific interest is the destructive action which materials
may suffer through repeated changes in their state of stress. It appears that in some if not in all materials a limited amount of stress-variation may be repeated time after time without appreciable deterioration in the strength of the piece; in the balance-spring of a watch, for instance, tension and compression succeed each other some 150 millions of times in a year, and the spring works for years without apparent injury. In such cases the stresses lie well within the elastic limits. On the other hand, the toughest bar breaks after a small number of bendings to and fro, when these pass the elastic limits, although the stress may have a value greatly short of the normal ultimate strength. A laborious research by A. Wöhler, extending over twelve years, gave much important information regarding the effects on iron and steel of very numerous repeated alternations of stress from positive to negative, or between a higher and a lower value without change of sign. By means of ingeniously-contrived machines he submitted test-pieces to direct pull, alternated with complete or partial relaxation from pull, to repeated bending in one direction and also in opposite directions, and to repeated twisting towards one side and towards opposite sides. The results show that a stress greatly less than the ultimate strength (as tested in the usual way by a single application of load continued to rupture) is sufficient to break a piece if it be often enough removed and restored, or even alternated with a less stress of the same kind. In such a case, the variation of stress being less, the number of repetitions required to produce rupture is greater. In general, the number of repetitions required to produce rupture is increased by reducing the range through which the stress is varied, or by lowering the upper limit of that range. It may be reduced, removed, or even reversed many million times without destroying the piece. Wöhler's results are best shown by quoting a few figures selected from his experiments. The stresses are stated in centners per square zoll; in the case of bars subjected to bending they refer to the top and bottom sides, which are the most stressed parts of the bar.

Hence it appears that the actual strength of this material varies in a ratio which may be roughly given as 3:2:1 in the three cases of (a) steady pull, (b) pull alternating with no stress, very many times repeated, and (c) pull alternating with push, very many times repeated. For steel Wöhler obtained results of a generally similar kind. His experiments were repeated by L. Spanenberg, who extended the inquiry to the effect of repeated stress on phosphor-bronze. A considerable amount of light has been thrown on the nature of fatigue in metals by microscopic investigations, which will be referred to presently.

### Resilience.

A useful application of diagrams showing the relation of strain to stress is to determine the amount of work done in straining a piece in any assigned way. The term "resilience" is conveniently used to specify the amount of work done when the strain just reaches the corresponding elastic limit. Thus a rod in simple tension or simple compression has a resilience per unit of volume = $f/2E$, where $f$ is the greatest elastic pull or push. A blow whose energy exceeds the resilience (reckoned for the kind of stress to which the blow gives rise) must in the most favourable case produce a permanent set; in less favourable cases local permanent set will be produced although the energy of the blow is less than the resilience, in consequence of the strain being unequally distributed. In a plastic material a strain exceeding the limit of elasticity absorbs a relatively large amount of energy, and generally increases the resilience for subsequent strains. Fracture under successive blows, as in the testing of rails by placing them as beams on two supports, and allowing a weight to fall in the middle from a given height, results in the piece, the weight of which is brought about by the energy of each blow exceeding the resilience.

### Internal Stress.

Professor James Thomson pointed out that the effect of any externally applied load depends, to a very material extent, on whether there is or is not initial internal stress, or, in other words, whether the loaded piece is initially in what Professor Karl Pearson has called a state of ease. Internal stress existing without the application of force from without the piece must satisfy the condition that its resultant vanishes over any complete cross-section. It may exist in consequence of set caused by previously applied forces (a case of which instances are given below), or in consequence of previous temperature changes, as in cast iron, which is thrown into a state of internal stress by unequally rapid cooling of the mass. Thus in (say) a spherical casting an outside shell solidifies first, and has become partially contracted by cooling by the time the inside has become solid. The inside then contracts, and its contraction is resisted by the shell, which is thereby compressed in a tangential direction, while the metal in the interior is pulled in the direction of the radius. Allusion has already been made to the fact, pointed out by J. Thomson, that the defect of elasticity under small loads which Hodgkinson discovered in cast iron is probably due to initial stress. In plastic metals a nearly complete state of ease is brought about by annealing; even annealed pieces, however, sometimes show, in the first loading, small defects of elasticity, which are probably due to initial stress, as they disappear when the load is reapplied.

### Microscopic Examination.

Of all recent aids to a knowledge of the structure of metals, of their behaviour under stress, and of the nature of plastic strain, perhaps the most important is microscopic examination. The microscopic study of metals was initiated by H. C. Sorby as early as 1864 (see Brit. Assoc. Rep. 1864). 1 Über das Verhalten der Metalle bei wiederholten Anstrengungen (Berlin, 1872). For interesting notices of the fatigue of metals in railway axles, bridge tresses, &c., and results of experiments showing reduced plasticity in fatigued metal, see Sir B. Baker's address to the Mechanical Section of the British Association (1883). In many of the cases where pieces of metal in a fatigue state have been examined the phenomenon is occasioned by the occurrence of blows or shocks whose energy is absorbed in producing strains often exceeding the elastic limits, sometimes of a very local character, in phosphor-bronze. However, on the other hand, such shocks may cause an accumulation of set which finally leads to rupture in a way that is not to be confused with ordinary fatigue of strength. The effects of the accumulation may be removed by annealing.

---

1 Die Festigkeits-Versuche mit Eisen und Stahl! (Berlin, 1870), or Zeitschr. für Bauwesen (1860-1870); see also Engineering (1871), vol. I. For early experiments by Fairbairn on the same subject, see Phil. Trans. (1864).

2 According to Bauschinger the center per square zoll in which Wöhler gives his results is equivalent to 6,837 kislos per sq. cm., or 0.0454 ton per sq. in.
for that year). After a period of neglect, it has been pursued with much energy by a large number of observers, and has yielded results which are of fundamental importance in relation to the strength of materials. For the purpose of microscopic examination it is usually necessary to bring a small piece of the metal to a state of high surface polish, the final stage of which is performed by rubbing on a surface treated with a thin paste of rouge and water (see also Metallography). The specimen is then lightly etched in dilute acid or treated with a staining medium, such as liquorice or cocoa, to make the structure visible. When the surface is examined under a lens of suitable power it is seen to be made up of irregular areas with well-defined boundaries. The areas into which the surface is divided differ in apparent texture, and when illuminated obliquely it is found that some of them shine out brightly while others are dark; by changing the direction of the incident light other areas become bright and those previously bright become dark. These areas are the sections of crystalline grains which constitute the mass of the metal. Each grain is a crystal, the elementary portions of which are all oriented in one way, but the orientation changes as we pass from grain to grain. The irregular boundaries are the chance surfaces in which one grain meets another during the progress of its crystalline growth. Etching a polished surface develops a multitude of facets which have the same orientation over any one grain, and therefore give it a uniform texture and a uniform brightness in reflecting light of any particular incidence. The size of the grains depends very much upon the previous thermal treatment to which the metal has been subjected. Sudden cooling from a high temperature tends to make the grains small, slow cooling tends to keep them large; and protracted exposure to moderately high temperature has been observed in some cases to favour the growth of very large grains.

When the metal is strained in any manner beyond its limit of elasticity the grains are found to have altered their shape, becoming lengthened in the direction in which stretch has occurred. Subsequent exposure to a temperature which is high enough to remove the mechanical hardnes produced by overstraining is found to bring about a reconstruction of the grains; the original pattern is not reproduced, but the reformed grains show no direction of predominating length. Researches by J. A. Ewing and W. Rosenhain ("The Crystalline Structure of Metals," Phil. Trans., 1900) showed that metals retain their crystalline character even when so severely strained as to exhibit qualities of plasticity which are at first sight inconsistent with the idea of crystalline structure. The manner in which a metal yields when the strain exceeds the elastic limit is by slips which occur in the cleavage or "sliding" planes of the individual crystals. These slips are seen under the microscope as sharply defined lines which appear on the polished surface of each grain as soon as the yield-point in any process of straining has been reached. Seen under normal illumination the lines are dark; seen under oblique illumination they may be made to appear as bright lines on a dark ground. The appearance of each line shows that it is a narrow step produced by the slipping of one part of the crystalline grain over another part. The diagram Fig. 26 represents a section between two contiguous surface grains, having cleavage or gliding planes as indicated by the dotted lines, AB being a part of the polished surface. When straining beyond the elastic limit takes place, as by a pull in the direction of the arrows, yielding occurs by finite amounts of slip at a limited number of places, as at a, b, c, d, e. This exposes short steps, which are portions of cleavage surfaces, and which, when viewed under normally incident light, appear black because they return no light to the microscope. They consequently appear as dark lines or narrow bands extending over the polished surface in directions which depend on the intersection of that surface with the planes of slip. Many such lines appear as the process of straining goes on; they are spaced at more or less regular intervals, and in general three systems of them may be observed intersecting one another. With three independent systems of slips it is clear that the grain may take any shape in the process of straining; in many cases four systems of slips are seen. In this way severe deformations occur without affecting the crystalline character of the structure, although the shape of each crystal undergoes much change. A bar of iron which has been rolled cold from a large to a small section shows, when it is polished and etched, a structure in which each grain has all the characteristics of a crystal, although the grains have been distorted into forms very different from those which are found in bars which are rolled at a red heat or are annealed after rolling. It appears that the process of straining has occurred through movements which preserve the parallelism of all the portions of each individual grain so long as continuity of the parts of the grain is preserved. In many metals, however, a further effect of severe strain is to develop twin striations and this implies a rotation of one group of elements through a definite angle with respect to the other elements of the same grain. Excessively severe straining, as, for instance, the squeezing of a block of lead into a thin flat plate, is found to produce a crystalline structure in which the grains have a greatly reduced size; the slips have in that case gone so far as to cause divisions and interpenetrations of the crystals.

Growth of Crystals.—Microscopic examination further shows that after severe straining the structure of a metal is far from stable, a fact which connects itself with what is observed in respect to mechanical quality. Thus, when an iron bar has been rolled, and notably in lead, severe straining is followed, even at atmospheric temperatures, by a protracted crystalline growth which results in the formation of crystals which are relatively very large. A piece of ordinary sheet lead shows the effects of this growth well; it will be found, when etched, to consist in general of crystals enormously larger than any that could have survived the process of manufacture by rolling. A similar growth may readily be traced from day to day or week to week in a piece of lead which is kept under observation after being severely strained. The process is not one of "grain growth" in the ordinary sense, but is the result of the grains spreading out, and thus some grains being more or less analogous to this goes on in iron and steel during the change which occurs when elastic recovery takes place after overstraining may be conjectured, though there is as yet no direct evidence on the point. The growth of large crystals which is seen to occur in lead at very moderate temperatures has perhaps a more direct relation to the changes which occur in iron or steel at temperatures high enough to produce annealing. The structure of steel as exhibited by the microscope has received much attention, notably at the hands of F. Osmond and J. O. Arnold. Microscopic examination of the low or medium carbon steel used for structural purposes shows it to consist of grains of iron (ferrite), interspersed with grains which have in general a laminated structure and are composed of alternate bands of two constituents, namely, iron and carbide of iron (Fe₃C). To these laminated grains the name of pearlite has been given. In steel such as is used for rails, containing about 0.4 or 0.5% of carbon, the grains of pearlite occupy about large a volume of the specimen as the grains of unalloyed ferrite; but when the proportion of carbon is increased to about 0.9% the whole is a mass of pearlite having an exceedingly intimate mixture of the two constituents. This appears to be a eutectic alloy, and the same intimately blended structure is characteristic of eutectic alloys generally. Important variations in the visible structure result from quenching, annealing, and
other varieties of thermal treatment, as well as from the presence of other constituents in the steel, but to discuss these would be beyond the scope of the present article.

In experiments by Ewing and J. C. W. Humphrey ("The Fracture of Metals under repeated Alternations of Stress," Phil. Trans., 1903) the microscope was employed to examine the process by which metals break through "fatigue" when subjected to repeated reversals of stress. The test-pieces were short rods overhanging from a revolving mandrel and loaded at the end so as to produce a bending movement. A part near the support, where the stresses due to bending were greatest, was polished beforehand for observation in the microscope. After a certain number of reversals the surface was examined, and the examination was repeated at intervals as the process continued.

The material was Swedish iron following Hooke's law (in tension) up to 13 tons per sq. in. and having a well-marked yield-point at 17 tons per sq. in. It was found that the material suffered no damage from repeated reversals of a stress of 5 tons per sq. in., but that when the greatest stress was raised to 7 tons per sq. in. incipient signs of fatigue began to be apparent, after 1500 reversals, though the piece was still intact after the number of reversals had reached three millions. With a stress of 9 tons per sq. in., or more, repeated reversals brought about fracture. The first sign of fatigue as detected in the microscope was that slip lines began to appear on one or more of the crystals in the region of greatest stress: as the process went on these became more distinct and tended to broaden, and at length some of them developed into cracks which were identified as such because they did not disappear when the surface was repolished. Once a crack had formed it quickly spread, and finally the piece broke at a sharp fracture, showing practically no plastic change of form before rupture.

It may be concluded that under repeated alternations of stress fatigue, leading to fracture, is liable to occur if, and only if, the stress is such as to produce slips in some of the crystals: in other words if, and only if, the limit of elasticity is locally exceeded; but the limit for particular crystals may be considerably lower than what is usually taken as the limit for the metal as a whole. The resistance to slip in any one crystal depends on three things: (1) the inherent strength of its own substance, (2) the amount of support it receives from its neighbours, and (3) the orientation of the crystal with respect to the surfaces of maximum shearing stress. It may be inferred that even in the most homogeneous metal some crystals have a liability to develop slips more readily than others, and that it is with them we are concerned in dealing with the safe limits of alternating stress.

The same considerations have a bearing on certain effects of heat treatment. It is well known that in steel which has been overheated (by unnecessarily prolonged exposure to a high temperature) a somewhat gross crystalline structure is developed, showing large ferrite areas not broken up by interwoven pearlite. The resistance to slip in the large ferrite crystals is comparatively small, and hence the overheated metal has a low elastic limit and shows but little power of resisting alternating stress. By suitable heat treatment, on the other hand, it is possible to bring the metal into a state in which the crystals are small and the ferrite and pearlite are so intimately blended that there is much mutual support: the elastic limit is high and the metal is well adapted to endure stresses which would otherwise cause fatigue.

It may be asked, How is the crystal constituted to admit of elastic and plastic strain? How can slip take place without destroying the adhesion between the faces until that is destroyed by many back and forth rubbings at the surface of slip? J. A. Ewing has endeavoured to picture a molecular constitution in which the molecules are assumed to possess polar quality along three axes, and to be free to turn except in so far as they are constrained by the mutual forces between the pole of each molecule and those of its neighbours. This theory, which was developed by its author in his presidential address to the engineering section of the British Association in 1906, accords well with many of the obscure phenomena of elastic and plastic strain, with what is known of fatigue, and with the loss of elasticity after overstrain and its subsequent recovery.

Influence of Foreign Matter.—It is a well-known characteristic of metals that small quantities of foreign matter may produce an altogether disproportionately large influence on their mechanical and other properties. The effect of small quantities of carbon in iron, of nickel in iron, of aluminium in copper, are important practical instances. These high beneficial effects, in respect of strength and ductility, is produced. The introduction of the qualities possessed in steel from pure iron at one end to tool steel at the other is due to quantities of carbon which lie, for the most part, under 1%. The addition of about 0.5 to 4% of nickel to mild steel has given an important new structural material possessing increased strength and a high elastic limit, and retaining ample capacity for plastic strain. The presence of manganese in small quantities is known to be an essential condition of strength in mild steel. The addition of from 1½ to 3% of chromium enables steel to acquire, under suitable heat treatment, that degree of hardness desirable in armour plate and armour-piercing shell. Small quantities of vanadium added to steel improve it sufficiently to be advantageous in certain applications where saving of weight is important, notably in steel for motor carriage engines, notwithstanding the extra cost.

Data as to Strength of Steel.—A few figures may be quoted as for the strength and plasticity of steel, some of which are taken from the reports of the Engineering Standards Committee (1906-1907) special tests to which no reference has been made herein.Ordinary plates and bars of mild steel for structural purposes (bridges, ships, &c.), containing as a rule not more than 2% of carbon, have a tensile strength of 28 to 32 tons per sq. in., and an 8-in. specimen with a cross-section of from 1½ to 1⅞ sq. in. should stretch at least 20%. They should stand being bent cold through 180° on a radius 1½ times the thickness of the specimen, the test-piece, at a bending being lower than 1500. When to a bath of somewhat softer steel, have a tensile strength of 20 to 30 tons, with 25% of elongation on 8 in. Steel rails, containing 0.4 to 0.5% of carbon, have a tensile strength of 38 to 48 tons and stretch 15% of its length, the area of section of the test-piece being 1¼ sq. in. Steel for axles has a tensile strength of 35 to 40 tons and stretches 25 to 30% on the 2-in. length. The elastic limit should be at least 50% of the breaking load. Steel for tires may in some cases require a tensile strength as high as 60 tons with 10% extension in 1 in. Steel castings commonly range in tensile strength from 20 to 35 tons, with about 15% elongation on 2 in. In the case of steel of a tensile stress higher than that of bar or plates: 70 to 100 tons per sq. in. is not unusual, and in steel piano-forte wire it may be as high as 150 tons per sq. in.

Steel guns, containing generally 0.3 to 0.4% of carbon, has a tensile strength of 33 to 44 tons per sq. in., with at least 17% extension in 2 in., the test-piece having the usual cross-section of 1¼ sq. in. Nickel steel for guns, containing 0.4% of carbon and 4% nickel and 1% carbon, has a tensile strength of 45 and 50 tons and an elongation of 16% in 2 in. Much the same figures apply to nickel-chrome steel for the same purpose, with 1% of chromium, 4% of nickel and 0.3% of carbon. Flat specimens of gun steel 3/16 in. wide and 0.075 in. thick stand bending cold through 180° on a radius of 3½ in. All these tests of gun steel are made after forging and after the normal heat treatment, which consists first of oil-hardening by plunging the steel at a temperature not lower than 1500° F into a bath of water and then tempering, by reheating to a temperature generally about 900° to 1000° F. This heat treatment brings the metal into a condition in which the granular structure is minute and the constituents are very thoroughly intermixed, with the result of giving a high elastic limit. Tests made on gun steel containing about 0.35% of carbon show that the yield-point occurred at 13 tons per sq. in. before the heat treatment, and at 25 tons after it, the extension remaining practically unchanged at 30% in 2 in. In nickel steel the yield-point is initially higher, but in it too the heat treatment effects a considerable improvement in this respect without reducing the elastic limit. It is remarkable that though the strength of wrought iron and steel may range from 20 tons per sq. in., or even less, up to 150 tons per sq. in., the modulus of rigidity of the former is nearly the same in all gauges. The modulus of rigidity of steel is from 10,000 to 14,000 tons per sq. in., and the modulus of rigidity C from 30,000 to 5700 tons per sq. in.
The stress which acts on any plane surface AB (fig. 27), such as an imaginary cross-section of a strained piece, may be represented by a figure formed by setting up ordinates $A_0, B_0, \&c.$, from points on the surface, the length of these being made proportional to the intensity of stress at each point. This gives an ideal solid, which may be called the stress figure, whose height shows the distribution of stress over the surface which forms its base. A line drawn from the centre of gravity of the stress figure, parallel to the ordinates $A_0, B_0, \&c.$, determines the point $c$, which is called the centre of stress, and is the point through which the resultant of the distributed stress acts. In the case of a uniformly distributed stress, $a$ is a plane surface parallel to $AB$, and $c$ is the centre of gravity of the surface $AB$. When a bar is subjected to simple pull applied axially—that is to say, so that the resultant stress passes through the centre of gravity of every cross-section—the stress may be taken as (sensibly) uniformly distributed over any section near a place where the form of the cross-section changes, provided the bar is homogeneous in respect of elastic quality and is initially in a state of ease and the stress is within the limits of elasticity.

**Uniformly Varying Stress.**—Uniformly varying stress is illustrated by fig. 28. It occurs (in each case for stresses within the elastic limit) in a bent beam, in a tie subjected to non-axial pull, and in a long strut or column where buckling makes the stress become non-axial. In the case of a column, the intensity $p$ at any point $P$ is proportional to the distance of $P$ from MN, called the neutral axis, which lies in the plane of the stressed surface and at right angles to the direction $AB$, which is assumed to be that in which the intensity of stress varies most rapidly. There is no variation of stress along lines parallel to $AB$. If $MN$ passes through C, the centre of gravity of the surface, as in fig. 28, it may easily be shown that the total pull stress on one side of the neutral axis is equal to the total push stress on the other side, whatever be the form of the surface $AB$. The resultant of the whole stress on $AB$ is in that case a couple, whose moment may be found as follows. Let $dS$ be an indefinitely small part of the surface at a distance $x$ from the neutral axis through $C$, and let $p$ be the intensity of stress on $dS$. The moment of the stress on $dS$ is $xpdS$. But $p = px/xi = px/i$, (see fig. 29). The whole moment of the stress on $AB$ is $\int px/dS = \int pxi/dS$, where $I$ is the moment of inertia of the surface $AB$ about the neutral axis through $C$.

A stress such as that shown in fig. 28 or fig. 30 may be regarded as a uniformly distributed stress of intensity $\rho_0$ (which is the intensity at the centre of gravity of the surface) and a stress of the kind shown in fig. 29. The resultants $p_0dS$ is $\int pxi/dS$, which is the whole area of the surface, and it acts at a distance $CD$ from $C$ such that the moment $p_0CD = \rho_0/\int x/dS$. Hence $p_0 = p_0(1 + \xi_0CD/\int x/dS)$.

Simple bending occurs when a beam is in equilibrium under equal and opposite couples in the plane of the beam. Thus if a beam (fig. 31) supported at its ends, be loaded at two points so that $W_1 = W_2$, the portion of the beam lying between $W_1$ and $W_2$ is subjected to a simple bending stress. On any section $AB$ the only stress consists of pull and push, and has for its resultant a couple whose moment $M = W_1d_1 = W_2d_2$. This is called the bending moment at the section. If $H$ is the distribution of stress will be changed in consequence of the fact that the outer layers of the beam are taking set while the inner layers are still following Hooke’s law. As a simple instance we may consider the case of a material strain of a bar parallel to a certain stress, and then so plastic that a relatively very large amount of strain is produced without further change of stress, as not very far from being realized by soft wrought iron and mild steel. The diagram of stress will now take the form sketched in fig. 33. If the elastic limit is (say) less for compression than for tension, the diagram will be as in fig. 34, with the neutral axis shifted towards the tension side. When the beam is relieved from external loading it will be left in a state of internal stress, represented for the case of fig. 33, by the dotted lines in that figure.

In consequence of the action which has been shown in the figures, the moment required to break the beam cannot be calculated by taking for $f$ the value of the ultimate tensile or compressive strength of the material in the formula $M = fJ$, because the distribution of stress which is assumed to exist in finding this relation ceases as soon as overstraining begins.

**Strain produced by Bending.**—The strain produced by bending stress in a bar or beam is, as regards any imaginary filament taken along the length of the piece, sensibly the same as if that filament were directly pulled or compressed by itself. The resulting deformation of the piece consists, in the first place and chiefly, of curvature in the direction of the length, due to the longitudinal extension and compression of the filaments, and, in the second place, of transverse flexure, due to the lateral compression and tension by which the beam becomes the change of $l$ by extension or compression at a distance $y$ from the neutral axis. But if $l = l/E$, and $p_0 = M_0/I$. Hence $R = EI/M$. The transverse flexure is not, in general, of practical importance. The centre of curvature for it is on the opposite side from the centre for longitudinal flexure, and the radius is $R_0$, where $\varepsilon$ is the ratio of longitudinal extension to lateral contraction under simple pull.

**Ordinary Bending of Beams.**—Bending combined with shearing is the mode of stress to which beams are ordinarily subject, the loads, or externally applied forces, being applied at right angles to the section of the beam. Let $H$ (fig. 36) be any cross-section of a beam in equilibrium. The portion $B$ of the beam, which lies on one side of $HK$, is in equilibrium under the joint action of the external forces $F_1, F_2, F_3, \&c.$, and the forces which the other portion $A$ exerts on $B$ in consequence of the state of stress at $HK$. The forces...
The stress due to the bending moment, consisting of longitudinal push in filaments above the neutral axis and longitudinal pull in filaments below the neutral axis, is the thing chiefly to be considered in practical problems relating to the strength of beams. The general formula for bending stress is $\sigma = \frac{My}{I}$, where $M$ is the bending moment, $y$ is the distance from the neutral axis, and $I$ is the area moment of inertia of the cross-section. The bending stress is equal to the sum of the forces about one side of the section $2F_2$ and a shearing force equal to the sum of the forces on the other side of the section $2F_1$. The shearing force causes a shearing stress in the plane of shearing, the magnitude of which will be investigated later. This shearing stress in the plane of the section is necessarily accompanied by an equal and opposite shearing stress in horizontal planes parallel to the length of the beam.

The shearing stress at any point in a beam is equal to the force of shearing at the point divided by the width of the beam at that point. The shearing stress at any point is the resultant of all the forces acting at the point in a direction perpendicular to the axis of the beam.

Principles of Shearing Stress and Bending Moments:—The bending moment is defined as the moment about the neutral axis of the shearing force at any section. The bending moment is equal to the sum of the products of the shear forces and the distances from the neutral axis. The bending moment is a measure of the tendency of the beam to bend. The bending moment is also equal to the integral of the shear force along the length of the beam.

The shearing stress is defined as the force per unit area acting on a plane parallel to the axis of the beam. The shearing stress is equal to the shear force divided by the width of the beam at that section.

The deflection of a beam is defined as the displacement of a point on the beam from its original position. The deflection of a beam is equal to the integral of the bending moment along the length of the beam. The deflection of a beam is a measure of the deformation of the beam. The deflection of a beam is also equal to the integral of the shear force along the length of the beam.
elasticity, a radius CD turns round to CD', and a line AD drawn at any distance r from the axis, and originally straight, changes into the helix AD'. Let $\theta$ be the angle which this helix makes with lines parallel to the axis, or in other words the angle of shear at the distance $r$ from the axis, and let $t$ be the angle of twist DCD'. Taking two sections at a distance $dx$ from one another, we have the arc $6dx=\tau dx$. Hence $t$, the intensity of shearing stress in a plane of cross-section, varies as $r$, since $CQ=Cr\,dt/dx$.

The resultant moment of the whole shearing stress on each plane of cross-section is equal to the twisting moment $M$. Thus

$$\int 2\pi r\tau rdr = M.$$ 

Calling $r_1$ the outside radius (where the shearing stress is greatest) and $g_1$ its intensity there, we have $qg_1=\tau r_1$, and hence, for a solid shaft, $q = 2M/r_1^2$. For a hollow shaft with a central hole of radius $r_2$, the same reasoning applies: the limits of integration are now $r_1$ and $r_2$, and

$$\int 2\pi r\tau rdr = M.$$ 

The lines of principal stress are obviously helices inclined at 45° to the axis.

If the shaft has any other form of section than a solid or symmetrical hollow circle, an originally straight radial line becomes warped when the shaft is twisted, and the shearing stress is no longer proportional to the distance from the axis. The twisting of shafts of square, triangular and other sections has been investigated by Saint-Venant. In a square shaft (side = $h$) the stress is greatest at the middle of each side, and its intensity there is $q = M/2h^2$. For round sections the angle of twist per unit of length is

$$\frac{\tau}{C} = \frac{2M}{\pi Cr^3}$$

in solid and

$$\frac{\tau}{C} = \frac{2M}{\pi Cr'^3}$$

in hollow shafts.

It has been said above that it is assumed that the stress is within the limit of elasticity. When the twisting couple is increased so that this limit is passed, plastic yielding begins in the outermost layer, and a larger proportion of the whole stress falls to be borne by layers nearer the centre. The case is similar to that of a beam bent beyond the elastic limit, described above. If we suppose the process of twisting to be continued, and that after passing the limit of elasticity the material is capable of much distortion without further increase of shearing stress, the distribution of stress on any cross section will finally have an approximately uniform value $q'$, and the moment of torsion will be

$$\int 2\pi r^2q'dr = 2g'(r'^2-r_2^2).$$ 

In the case of a solid shaft this gives for $M$ a value greater than it has when the shear in the outermost layer only reaches the intensity $q'$, in the ratio of 4 to 3. It is obvious from this consideration that the ultimate strength of a shaft to resist torsion is no more deducible from a knowledge of the ultimate shearing strength of the material than the ultimate strength of a beam to resist bending is deducible from a knowledge of the tensile and crushing strength. It should be noticed also that as regards ultimate strength a solid shaft has an important advantage over a hollow shaft of the same elastic strength, or a hollow shaft so proportioned that the greatest intensity of stress is the same as in the solid shaft.

Twisting Combined with Bending.—This important practical case is realized in a crank-shaft (fig. 40). Let a force $P$ be applied at the crank-pin at right angles to the plane of the crank. At any section of the shaft $C$ (between the crank and the bearing) there is a twisting moment $M_1 = P\,AB$ and a bending moment $M_2 = P\,BC$. There is also a direct shearing stress $	au$ due to the force $P$, but this does not require to be taken into account in calculating the stress at the top or bottom of the circumference (where the intensity is greatest), since the direct shearing stress is distributed so that its intensity is zero at these points. The stress at the top and bottom of the circumference is consequently made up of longitudinal normal stress (due to bending), $P = M_2/r_1^2$, and shearing stress (due to torsion), $q = 2M_1/r_1^2$, the whole amounting to $q + \tau = 2M_1/r_1^2$.

The greatest shearing stress is $\tau = r_2M_2 = \sqrt{(M_1+M_2)^2} = r_2M_2$, or $r_2 = 2P(BC/AC)^{1/2}$.

The theory of moments in problems of bending and torsion is described on p. 151 of this book.
are $P$, the total pressure from without and a force $T$ at each side due to the circumferential stress at the plate of fig. 42. $P = T$. Hence $P = \alpha R$. The ends of the cylinder may or may not be held together by longitudinal stress in the cylinder sides; if they are, then, whatever be the form of the ends, a transverse section, the area of which is $2\pi R$, has to bear a total force $pR^2$. Hence, if $p'$ be the intensity of longitudinal stress, $P = pR^2 = \frac{1}{2}(T + p')/E$. A thin hollow sphere under internal pressure has equal circumferential pull in all directions. To find its value, consider the plate of fig. 42. There are now four equal forces $T$, on each of the four sides, to equilibrate the radial force $P$. Hence $P = 2T$ and $p = \frac{1}{2}R$. Thick Cylinder.—When the thickness is not small compared with the radius, the radial pressure is transmitted from layer to layer with relatively little distortion of the cylindrical shell. The thickness therefore diminishes towards the outside. In the case of a thick cylinder with free ends we have to deal at any point with two principal stresses, radial and circumferential, which may be denoted by $p$ and $p'$ respectively. Supposing (as we may properly do in dealing with a cylinder which is not very short) that a transverse section originally plane remains plane, the longitudinal strain is uniform. Since there is no longitudinal stress this strain is due entirely to the lateral action of the stresses $p$ and $p'$, and its amount is $(p + p')/E$. Hence at all points $p + p' = \text{constant}$. Further, by considering the equilibrium of any thin layer, as we have already considered that of a thin cylinder, we have $\frac{1}{p} = \frac{1}{p'}$. These two equations give by integration $p = C + C'/r^2$, and $p' = C - C'/r^2$.

If $r_1$ be the external and $r_2$ the internal radius, and $p_0$ the pressure on the inner surface, the condition at $r_2$ is $p_0 + p_0 = C - C'/r_2^2$, or $C = p_0(2r_2^2 - 1)$. At the outside, where this is greatest, its value is $-p_0(2r_1^2 - 1)$, but this is a quantity always greater than $p_0$, however thick the cylinder is.

In the construction of guns various devices have been used to equalise the circumferential tension. With cast gun, a charged core has been employed to make the inner layers solidify and cool first, so that they are afterwards compressed by the later contraction of the outer layers. In guns built up of wrought-iron or steel hollow hoops, small wrought-iron hoops are arranged around an iron tube and shrunk on over the barrel or over the inner hoops. In J. A. Longridge's system, largely used for heavy ordnance, the gun is made by winding steel wire or ribbon, with suitable initial tension, on a central steel tube.

The circumferential stress at any point of a thick hollow sphere exposed to internal fluid pressure is found, by a process like that of the last paragraph, to be $-p_0(2r_1^2 - 1)/2(r_1^2 - r_2^2)$, which gives, for the greatest tension, the value $-p_0(2r_1^2 - 1)$.

STRESA, a village of Piedmont, Italy, in the province of Novara, situated on the west side of Lago Maggiore, on the Simplon railway, 10 m. N. of Arona, 673 ft. above sea-level. Pop. (1901), 1477. It is remarkable for the beauty of its scenery and for its fine villas, and is a favourite resort in spring, summer and autumn.

STOCKLAND, AGNES (1860-1874), English historical writer, was born in 1860, the third daughter of Thomas Strickland, of Reaydon Hall, Suffolk. Her first literary efforts were historical romances in verse in the style of Walter Scott—"Worcester Field" (published without date), "Demetrius" and other Poems (1833). From this she passed to prose histories, written in a simple style for the young. A picturesque sketch of the Pilgrims of Walsingham appeared in 1835, two volumes of Tales and Stories from History in the following year. Then, with the assistance of her sister, she projected a more ambitious work, The Lives of the Queens of England, from Matilda of Flanders to Queen Anne. The first volume appeared in 1840, the twelfth and last in 1849. Miss Strickland was a warm partisan on the side of royalty and the church, but she made industrious study of "official records and other public documents," gave copious extracts from them, and drew interesting pictures of manners and customs. While engaged on this task she found time in 1843 to edit the British Society's "Memoirs of Queen of Scots," where innocence she championed with enthusiasm.

In 1850 she followed up her Queens of England with the Lives of the Queens of Scotland, completing the series in eight volumes in 1859. Unresting in her industry, she turned next to the Bachelor Kings of England, about whom she published a volume in 1861. The Lives of the Seven Bishops followed in 1866.—after a longer interval, part of which was employed in producing an abridged version of her Queens of England. Her last work was the Lives of the Last Four Stuart Princesses, published in 1872. In 1871 she obtained a civil-list pension of £100 in recognition of her merits. She died on the 8th of July 1884.

A Life by her sister, Jane Margaret Strickland, appeared in 1887.

HUGG EDWIN (1811-1853), English naturalist and geologist, was born at Brighton, in the East Riding of Yorkshire, on the 2nd of March 1811, and was grandson of Sir George Strickland, Bart. As a lad he acquired a taste for natural history which dominated his life. He received his early education from private tutors and in 1820 entered Oriel College, Oxford. He attended the anatomical lectures of Dr John Kidd and the geological lectures of Dr W. Buckland and he became greatly interested both in zoology and geology. He graduated B.A. in 1831, and proceeded to M.A. in the following year. Returning to his home at Harecombe House, near Tewkesbury, he began to study the geology of the Vale of Evesham, communicating papers to the Geological Society of London (1833-1834). He also gave much attention to ornithology. Becoming acquainted with Murchison he was introduced to William John Hamilton (1805-1867) and accompanied him in 1835 in a journey through Asia Minor, the Thracian Bosporus and the Island of Zante. Mr Hamilton afterwards published the results of this journey and of a subsequent excursion by himself to Armenia in Researches in Asia Minor, Pontus and Armenia (1838). After his return in 1836 Strickland brought before the Geological Society several papers on the geology of the districts he had visited in southern Europe and Asia. He also described in detail the drift deposits in the counties of Worcestershire and Warwick, drawing particular attention to the fluvial deposits of Croftpurde in which remains of hippopotamus, &c., were found. With Murchison he read before the Geological Society an important paper "On the Upper Formations of the New Red Sandstone System in Gloucestershire, Worcestershire and Warwickshire" (Trans. Geol. Soc., 1840). In other papers he described the Bristol Bone-bed near Tewkesbury and the Ludlow Bone-bed of Woolhope. He was author likewise of ornithological memoirs and "Bibliography of the British Society, the Annals and Magazine of Natural History and the British Association. He also drew up the report, in 1842, of a committee appointed by the British Association to consider the rules of zoological nomenclature. He was one of the founders of the Ray Society suggested in 1843 and established in 1844, the object being the publication of works on natural history which could not be undertaken by scientific societies or by publishers. For this society Strickland corrected, enlarged and edited the MS. of Agassiz for the Bibliographia Zoologica et Geologica (1848). In 1845 he edited with J. Buckman a second and enlarged edition of Mary Queen of Scots' Outline of the Geography of the Neighbourhood of Cheltenham. In 1846 he settled at Oxford, and two years later he issued in conjunction with Dr A. G. Melville a work on The Dodo and its kindred. In 1850 he was appointed deputy reader in geology at Oxford during the illness of Buckland, and in 1852 he was elected F.R.S. In the following year, after attending the meeting of the British Association at Hull, he went to examine the cuttings on the Manchester, Sheffield & Lincolnshire railway near Retford, and he was there knocked down and killed by a train on the 14th of September 1853. He was buried at Deerhurst church near Tewkesbury, where a memorial window was erected.

STRIEGAU is a town of Germany, in the Prussian province of Silesia, on the Striegau Water (Striegauer Wasser), 30 m. by rail S.W. of Breslau. Pop. (1905), 13,427. It contains four Roman Catholic churches, among which is that of St Peter and St Paul, with a vaulted roof 100 ft. in height, the highest in Silesia; a Protestant church and numerous educational and charitable institutions. The chief industries of the place are the making of cigars, malt and machinery; also of albums, portfolios and other articles in leather. Granite is quarried in the neighbourhood and there is an extensive trade in grain. It was near Striegau the present great gained the important victory usually named after the village of Hohenfriedberg, on the 4th of June 1745. The town rights of Striegau date from 1242.

STRIKES AND LOCK-OUTS. A strike, in the labour sense, is a stoppage of work by common agreement on the part of a body of work-people for the purpose of obtaining or resisting a change in the conditions of employment. The body of work-people may be large or small, and the cessation of work may be simultaneous or gradual; e.g. if the notices to cease work happen to expire at different dates, the cessation may nevertheless be a strike, provided it takes place at the result of a common agreement. It will be seen from the above definition that a strike, though the immediate result of an agreement, formal or tacit, on the part of work-people to withhold their labour, may originate in a demand on the part of the employer as well as on the part of the employers. In the former case the stoppage is often (though loosely) termed a "lock-out." It is obvious, however, that to distinguish stoppages as strikes or lock-outs according to the source of the original demand for a change of conditions would lead to a very arbitrary and misleading classification. Frequently it is not easy to say whether the original demand to which the dispute is to be attributed, and frequently a stoppage is the result of a break-down of negotiations in the course of which demands have been made by both sides. Moreover, in so far as the distinction can be drawn, it would lead to the result that in almost all cases a dispute in times of improving trade would be termed a strike, and in times of declining trade a lock-out. It is not possible to frame an entirely satisfactory definition of a lock-out which shall enable it always to be discriminated from a strike. It may be noticed that the attempt to make this distinction has been abandoned in the board of trade statistics, since 1894, both in regard of strikes and lock-outs, now included under the comprehensive title of "trade disputes."

The only basis of distinction between a "strike" and a "lock-out," which is sufficiently definite for precise or statistical purposes, is the source from which the actual notice to cease work emanates, cessations resulting from notices given by the employers being termed "lock-outs," while those which either result from notices given by the men, or from their withdrawal from work without notice, would be termed "strikes." But whether the term "lock-out" be restricted as above, or applied, as in the popular use of the term, to any dispute in which the employers appear to be the aggressors, the distinction does not afford a sound basis for the statistical classification of disputes. The source of the actual notices to leave work is often quite an unimportant matter; while, on the other hand, if the ordinary current use of the terms be followed, there will be many disputes which, according to the workmen's view, should be termed lock-outs, and, according to the employers, should be termed strikes—a difficulty which was well illustrated in the controversy as to whether the "strike clauses" in admiralty contracts could be invoked in the case of work stopped through the engineering dispute of 1897. In the present instance, therefore, no distinction is drawn for statistical purposes between a strike and a lock-out.

Another distinction, perhaps of greater importance than the above, but which in practice it is sometimes difficult to draw, is between a stoppage in pursuance of a trade dispute and a stoppage due to a bona-fide dismissal or change of employment arising from the intention of an employer to cease to employ a particular set of men, or of a group of workmen to cease to work for a particular employer. Generally speaking, a stoppage may rightly be termed a trade dispute if there be an intention on the part of both parties (at least at the beginning) to resume the relations of employer and employed on the satisfaction of certain specified conditions. Where the willingness to resume this relation exists on one side only the question is more difficult, and accordingly it is not uncommon for an employer to deny the existence of a trade dispute, although the men formerly in his employ may be actually drawing "strike pay" from their unions and "picketing" his works to prevent their places being filled. Such cases sometimes arise when the workmen consider that the dismissal of some of their colleagues is due not to personal faults or slackness of employment, but to some collective action which they have taken, or to their membership of some organization. Broadly speaking, however, the distinction is that a trade dispute is a temporary stoppage entered into to obtain or to resist a change of conditions of employment.

The essence of a strike or lock-out is a refusal on the part of a number of workmen collectively or of an employer to renew contracts of employment except on certain changed conditions. This simple situation may be complicated by actual breaches of contract, as when a body of work-people leave work without notice, or by attempts on their part to prevent other persons from entering into contracts of service, or to persuade other persons to terminate or break their contracts. But such features as these, though common to many strikes, are not essential. The question of the legal position of strikes, and of the methods adopted for the conduct of strikes, is discussed below. Here it is only necessary to point out that strikes, as such, are incidents arising out of the modern relationship of free contract as between employers and workmen, and have little real analogy with the revolts of serf or semi-serf labour in ancient or medieval times.

Trade Disputes in the United Kingdom.

Since 1888 the board of trade have kept a record of strikes and lock-outs in the United Kingdom. The following table, based on the official returns published by that department, shows the number and importance of these stoppages in the United Kingdom from 1893 to 1907:

<table>
<thead>
<tr>
<th>Year</th>

It should be noted that by "indirectly affected" are meant the work-people employed in the same establishments as those on strike, who are thrown out of employment owing to the strike, but are not themselves engaged in it. The board of trade statistics do not take into account the persons employed in kindred trades who are indirectly affected. An important feature of the above statistics is that in many years they are dominated by a few large disputes. Some of the larger cases are shown on the following page.

In 1907 487 of the recorded disputes (or about four-fifths of the whole number) accounted for less than one-third of the total time lost, and this, it is to be remembered, is after the very small disputes have been excluded.

By "aggregate duration" or "time lost" is meant the product of the number affected multiplied by the duration of the dispute in working days, with some allowance for those
who have found work elsewhere or been replaced by others. Though this figure is the best general index of the importance of the disputes of each year, it is but a rough approximation to the time actually lost through disputes.

For example, if a strike causes a postponement or accumulation of work, the extra demand for labour, and the overtime worked after its conclusion, may partially compensate for the stoppage. On the other hand, if a dispute should drive away trade or cause the closing of works, it may lessen the field of employment for a long period after its termination, and such lost time cannot be taken into account in the estimates of "aggregate duration."

For these reasons all estimates of wages lost through disputes are somewhat fallacious. The real importance of strikes lies less in the value of the actual time consumed by their duration, than in their indirect effects on the organization and effectiveness of the industry, and on the relations of employer to employed, and also in their reaction on the conditions of allied trades. The comparative insignificance of the actual loss to production owing to the mere loss of time caused by strikes will be seen from the fact that the total duration of strikes during the seven years 1901-1907, if spread over the entire adult male working population, would be equivalent to less than the loss of one-third of a day per head per annum. As a matter of fact, however, the loss owing to strikes is very unequally distributed over the industrial population. In large groups of industries, e.g. agriculture, strikes are of rare occurrence. In others, such as the building trades, they are frequent, but mostly small and local; while in mining they are not only frequent and often prolonged, but in many cases they involve large numbers of persons and extend over wide areas. Thus on an average of the seven years 1901-1907 there were 43 disputes annually in the building trades, and 133 in mining and quarrying, but the latter disputes have involved nearly seventeen times as many persons and had an aggregate duration nearly six times as great. Intermediate between these groups of trades is the metal, engineering and shipbuilding group, in which, more perhaps than in any other group, the importance of disputes varies according to the state of trade.

The principal facts relating to the distribution of trade disputes among the more important groups of trades are given in the above table for the mean of the seven years 1901-1907.

It would be natural to expect that trade disputes would be most prevalent at or just after a turn in the tide of employment, when there is most room for bona-fide disagreement as to the conditions of the labour market. These are undoubtedly the most critical times in the relations of employers and employed, but the disturbing influence of accidental causes is too great to enable any regular law of variations in disputes to be established by statistical evidence. It is to be remembered that in recent years there has been a great development in the means available for avoiding stoppages by conciliatory action (see ARBITRATION AND CONCILLLATION), and this of itself would greatly complicate the task of tracing any correspondence between the prevalence of actual stoppages and the state of employment. Broadly it may be said that the great majority of upward and downward changes of wages are settled nowadays without strikes, and in many trades actual stoppages, instead of being a normal feature in the relations between employer and employed, are rather to be looked on as cases of accidental breakdown of the recognized machinery of negotiation.

The causes of disputes are of course very varied, embracing all the matters relating to conditions of employment on which differences may arise between employers and employed. Experience shows, however, that the great bulk of disputes relate to questions of wages, a much smaller proportion to hours of labour, and the balance to a large number of miscellaneous questions, such as the employment of persons or classes obnoxious to the strikers on the ground that they do not belong to their union, or have worked against its interests, or because they are held to have no "right" to the particular occupation on which they are employed, either on account of not having gone through the recognized training or of belonging to another trade. Among this class of strikes are to be included the so-called "demarcation" disputes between two bodies of workmen as to the limits of their trades, which frequently cause suspension of work by both groups, to the great inconvenience of the employer. Strikes are also not uncommon on the question of trade unionism pure and simple—i.e. to obtain or defend freedom to belong to a union, or to act through its agency in negotiations with employers. This question enters more or less as a factor into a large number of disputes, most usually, however, as a secondary cause or object, so that it does not appear prominently in the tabulation of causes in the board of trade statistics, which is based on principal causes only. Thus the formulated demands of the strikers are usually for improved conditions of work, the question of "recognition" of the trade union only arising incidentally when the parties attempt to negotiate as to these demands. The following table, showing the principal causes of disputes for the seven years 1901-1907, is based on the official statistics:

XXV. 33
The results of trade disputes are nearly as varied as their causes. Sometimes a strike goes on until the employer is ruined or retires from business, and is only ended by
the permanent closing of the works; sometimes, especially when trade is slack and the dispute
not large, the places of the men are almost immedi-
dately filled, and the only economic result of the strike is
to replace one body of men by another without perceptible inter-
ruption of business. There have been frequent cases of this
kind in strikes of unskilled labourers. Sometimes, on the other
hand, the demand for labour is so active that the whole of the
strikers immediately find work elsewhere, and the only eco-
monic result is to transfer a body of men from one set of employers
to another with little or no interruption of their employment.

In years of active employment the building trades have afforded
many examples of this issue of a trade dispute. In other cases, after a more or less prolonged stoppage, the disputes end by the
permanent "blocking" of an employer's establishment by a
union, or the permanent refusal of the employer to take back
any of his former employees. All these, however, are extreme,
and on the whole exceptional cases. The vast majority of
trade disputes are settled by mutual arrangement, and whether
such arrangement is wholly in the nature of a compromise or
involves a compromise, its terms provide that the whole or part
of the body of work-people whose labour was withheld or
excluded shall return on agreed conditions to their former
employment.

During the period 1901 to 1907 there were on an average 405
disputes settled annually, affecting directly and indirectly
156,800 work-people, and of these only 44 disputes, involving
15,700 work-people, were ended by the return to work of the
strikers on their employers' terms without negotiation of any
kind, and 69 disputes involving 5500 persons by replacement
of the work-people or by the closing of works. All the remain-
ing disputes, 1532 in number, involving 135,600 persons, were con-
cluded by negotiation between the parties either with, or more
usually without, the aid of an outside mediator or arbitrator.

The following figures for 1901-1907 (which practically coincide
with those of the previous decennial average) show the compara-
tive results of trade disputes. The percentages refer to the
proportion of work-people directly involved in disputes which
resulted in the manner indicated:

It is, of course, to be understood that the figures in the above
table only relate to the immediate results, as determined by the
relative extent or weight of the parties, or in enforcing their
requests. The question of the ultimate effect of the stoppages on the welfare of the parties or of the
community generally is an entirely different question.

Organisation of Strikes and Lock-outs.

In the great majority of cases strikes are organized and controlled
by trade unions. It does not, however, follow from this that the growth of trade unionism has always
fostered and encouraged strikes, there being evidence
that in many trades the strengthening of organization
has had the effect, not only of restraining ill-considered
partial stoppages, but also of preventing more serious dislo-
cations of industry by providing a channel for the expression
of grievances and a recognized means of negotiating with
employers. Much of the evidence given before the Royal
Commission on Labour (1897-1899) tended to show that the
growth of trade unions has the effect of the whole of lessening
the frequency, though of widening the area, of disputes. The
commission, moreover, laid down that the stage of industry
in which disputes are likely to be most frequent and bitter is
that in which it is emerging from the "patriarchal" condition, in
which each employer governs his establishment and deals
with his own men with no outside interference, but has not
fully entered into that other condition in which transactions
take place between strong associations fully recognizing each
other. In this state of industrial organization bitterness is often
caused by the insistence of the work-people on the " recognition "
involving the terms of employment, or by the employment of
employers as outside parties interfering and causing estrangement
between them and the work-people actually in their employ.

Probably next to the patriarchal stage, in which each factory is
a happy family, the industrial conditions most favourable
to peace are when a powerful trade union is face to face with
a representative employers' association, both under the guidance
of strong but moderate leaders and neither feeling it beneath
its dignity to treat on equal terms with the other. When, on
the other hand, some or all of these conditions are absent, the
greater the conflict of interest or combination of the parties
or the greater the trade union's activity, the more likely are
strikes to be more frequent and violent.

Whether, however, trade unionism tends generally to encourage
or to restrain strikes, the organization and policy of all trade-unions, as at present constituted, are based on
the possibility of a collective withdrawal from work in the last
resort. Dispute pay is consequently the one universal form of
trade-union benefit. Though, however, in most of the
disputes recorded the strikers are financially supported by some
trade union, this is by no means always the case. Many strikes
have been entirely carried out without the instrumentality of a
permanent combination, the work-people affected belonging
to no union and merely improvising a more or less representa-
tive strike committee to control the movement. It is not
uncommon, however, for a permanent union to originate in a
strike of non-unionists. In other cases (e.g. in the London
lock strike of 1886) an insignificant trade union may initiate a
strike movement involving several thousands of labourers out-
side its membership. In the case quoted the membership of the
Dockers' Union rose during the few weeks of strike from
800 to over 20,000. A conspicuous case of a widespread strike
of workmen not belonging to a trade union was the South Wales
coal miners' dispute of 1902. Of the total amount of this strike
probably not more than 12,000 belonged at the time to any
trade union, but the workmen's representatives on the committee
of the sliding scale (against which the movement was directed)
formed the nucleus of a strike committee, and one result of the
strike was the formation of the "South Wales Miners' Federation," affiliated to the Miners' Federation. In the case
of strikes of non-unionists, the strikers, of course, have to depend
for their maintenance on their own resources or on the proceeds
of public subscriptions. Frequently grants are made in their aid
by sympathetic trade unions, and in the case of the South Wales
strike above referred to, several boards of guardians gave out-
door relief illegally to strikers who had exhausted their resources.

The majority of strikers, however, belong to trade unions and receive "dispute benefit," which usually consists of a
weekly payment of from 10s. to 15s. In 1906 the sum expended by
100 of the principal trade unions in support of men engaged
in disputes was £212,000. In years of big disputes this sum has
been largely exceeded.

Although most strikes are controlled by trade unions, cases
are comparatively rare in this country in which the central
committee of a trade union takes the initiative and directs its
members to cease work. More usually a local strike movement
is initiated by the local workmen, and the central committee
is generally empowered by the rules to refuse its sanction to a
strike and to close it at its discretion, but has no authority to
order it. In many unions a ballot is taken of the members of the
districts affected before a strike is authorized, and a
two-thirds (or even greater) majority, either of members or of
branches, in favour of a stoppage may be required before the sanction of the central executive is granted. Some unions in their rules draw a distinction between strikes to enforce new conditions (e.g. a rise of wages, a restriction of hours or of overtime) and strikes to oppose the introduction of new conditions by the employers, greater freedom being allowed to the local members in the case of "defensive" than of "offensive" strikes.

Sometimes also the executive committee, before refusing their consent to go on strike, and declining to allow the funds of the society to be used to support the strikers, may tacitly permit a local committee to take what action it pleases and to collect funds for the purpose. Some strong unions, however, especially those which have entered into general agreements with employers' associations, not only refuse financial support to an unauthorized strike, but even expel from their society strikers who refuse to obey their order to return to work. The Boiler-makers' and Iron Shipbuilders' Union has more than once taken drastic action of this kind, even to the extent of fining or superseding recalcitrant members and officials. In 1890 the National Union of Boot and Shoe Operatives, which is a party to an agreement with the Employers' Federation (known as the "Terms of Settlement") was fined £300 by the umpire under that agreement for failing to pay or to induce to return to work certain of their members who took part in a strike contrary to the provisions of the agreement. It sometimes happens, however, that the central committee of a trade union is not strong enough to withhold financial support even from an unauthorized strike.1

When a strike has been authorized by the executive, the conduct of it is frequently entrusted to a "strike committee," appointed ad hoc, one reason being that a strike of any considerable dimensions often affects members of several unions, so that the common action necessary in a conflict with employers can only be attained by a committee representing all the societies involved. A strike committee has often no power to draw on the funds of the unions represented, each of which pays dispute pay in accordance with its rules to its own members, the financial power of the strike committee being limited to the support of non-unionists out of any funds available for the purpose, or the collection and administration of funds in connection with the exhaustion of the resources of any of the unions represented.

The financial support of a local or sectional strike imposes but little strain on the resources of a large society, but where a considerable proportion of the members are affected it is usual for a union to replenish its funds by imposing a "levy" or special contribution on members remaining at work. During the engineering dispute of 1897-1898 the levies imposed by the Amalgamated Society of Engineers rose to 2s. 6d. per week, and one of the main objects of the federated employers was to diminish the revenue obtained from this source by enlarging the area of the dispute.

When there is no regular provision for the financial support of strikers, or when this provision is exhausted, the strike leaders have a much more difficult task in preventing the return to work of some of their followers; and it is in these cases that intimidation and violence are most to be apprehended. In all strikes, however, except in the few cases in which the whole of the workmen in the trade are in the union, and the skill required is such that no new labour can enter the trade during the dispute, there is the possibility of the strikers being replaced by other labour, and the efforts of the strike organizers are largely directed to the prevention of this by all means in their power. The chief method employed has generally been that known as "picketing," viz. the placing of members of the union to watch the approaches to the works or factories affected, to give information as to the strike to any workmen who attempt to enter, and to endeavour to dissuade them from accepting employment. Other methods of preventing workmen from taking the place of strikers may also be adopted or attempted, ranging from the publication of information in leaflets or otherwise as to the existence of a dispute, or appeals to workmen to avoid the works affected, to systematic annoyance or intimidation of workmen who take or retain employment during a stoppage by threats or by actual violence and outrage.

The methods adopted by strikers and strike organizers naturally suggest the counter measures adopted by employers. To break down the resistance of a body of workpeople supplied with a weekly strike allowance, or with some other supply of funds, or with a powerful trade union employers sometimes have recourse to some method of mutual indemnification by which the financially weaker of their number are temporarily subsidized by the stronger, whether through the machinery of a permanent employers' association or of an emergency committee. Employers' associations being usually composed of much smaller numbers than trade unions, are, as a rule, able to act in concert with greater secrecy and less formality than is possible in a workmen's union. Apart from any financial support which employers may guarantee their colleagues when attacked by a trade union, they have in forms cases formed or aided organizations for the systematic provision of a reserve of "free labourers" available to replace men on strike. By "free labourers" is meant not necessarily non-unionist, but labourers pledged to work amicably with others whether members of a union or not. The Shipping Federation, an organization of shipowners and shipowners' associations which was formed in 1890 to combat the strikes then prevalent among seamen, arranged a system of shipping offices at which seamen could be engaged who were prepared to give a pledge that they would work amicably with non-unionists. They also opened similar offices for shore labourers in some ports. Other independent agencies exist for supplying employers with labour during a dispute. It is not uncommon, in disputes in which there is any apprehension of intimidation or violence, for employers to board and lodge the imported work-people. Another method on which employers in recent years showed an increased tendency to rely was the institution of legal proceedings to restrain individual strikers or the union to which they belong from taking wrongful action injurious to their business. This led to the passage of the Trade Disputes Act of 1906 legalizing several forms of action by strikers which the courts had declared illegal (see below). There has been no attempt in England to induce the courts to restrain bodies of workpeople from striking by injunction, as has been frequently done in American strikes affecting inter-state commerce. In many disputes the attitude of public opinion is of some importance in determining the results, and accordingly both sides frequently issue statements or manifestoes giving their versions of the difference, and in other ways (e.g. by an offer of arbitration) one party or the other endeavours to enlist public opinion on its side.

Public Action with regard to Strikes and Lock-outs.

Though the majority of labour disputes have little importance for third parties, stoppages of this kind sometimes acquire a special interest for the general public either by reason of the large number of workpeople whose livelihood is affected, or of their indirect effects on employment in kindred trades, or of the danger and inconvenience that may be caused to the public, or of the fear that industry may be diverted abroad, or that a breach of the peace may be caused by attempts on the part of the strikers to coerce persons outside their combinations. In other cases the strikes and other remedies used by employers are usually regarded as a class of disputes in which legislative interference has more justification than in the case of other kinds of industrial and commercial differences.

Legislative action, with the view of providing alternative methods of adjusting labour difficulties, is discussed in the article ARBITRATION AND CONCILIATION. It is there shown that in New Zealand, New South Wales, Western Australia, the commonwealth of Australia and Canada (for certain industries) alternative methods have been made compulsory, but there are indications that the great majority of employers

1 Noteworthy in this respect was the strike of boilermakers on the Tyne in 1910, in defiance of their executive.
and workmen in Great Britain would not be prepared for such measures, involving as they would the surrender by those directly concerned of their freedom to arrange these matters by voluntary agreement or by a trial of strength. Without the provision of some alternative by the state, it would be impossible in a free country to prohibit altogether the termination of labour contracts by collective agreement among workpeople or employers.

The law, however, may and does restrict or prohibit the use of some of the methods of promoting or carrying on strikes which interfere with the liberty of other labourers, or inflict a wrong on employers, or injuriously affect the public interest.

The relation of the law in the United Kingdom to strikes and lock-outs is defined by the law relating to the employment of children. Since the decision of 1875, there has been no question of the legality of a strike as such, viz. of a combined abstention from work in order to influence the conditions of employment, but the method in which the strike is carried out may subject the strikers either to criminal or civil liabilities. In this connection the chief questions of interest relate to the limits within which strikers may lawfully act for the purpose of inducing other persons not to take their places, and for the purpose of bringing indirect pressure to bear upon the employer by influencing others not to work for or deal with him; and, on the other hand, what may act inducing other employers to abstain from employing workmen or members of a trade union with whom they have a dispute.

Strikers are necessarily liable to the general criminal law, but the doctrine of the exception of force contained in 1875 affecting strikes, as an agreement or combination by two or more persons to do, or procure to be done, any act in contemplation or furtherance of a trade dispute between employers and workmen shall not be indictable as a conspiracy if such act or combination was committed by one person would not be punishable as a crime, namely, on indictment or on summary conviction with the statutory liability of imprisonment either absolutely or alternatively for some other punishment.

The Trade Disputes Act 1906 extended the exemption to civil liability providing that an act done in pursuance of an agreement or combination in contemplation or furtherance of a trade dispute shall not render an act or person liable to action for such agreement or combination would be actionable. This act also extended the definition of trade dispute so as to include disputes between workmen and workmen, and also to make it clear that the workmen referred to need not necessarily be in the employment of the employer with whom a trade dispute arises.

The act of 1875 does not affect any conspiracy punishable by statute nor the law relating to riot, unlawful assembly, breach of the peace or sedition, or any offence against the state or sovereign. The act also does not apply to seamen, or to apprentices to the sea service.

Sudden breach of contract of service in gas and water undertakings has resulted in damage liable to cause serious bodily injury, or expose valuable property to destruction or serious injury, are made punishable offences by special sections, but the miscellaneous provisions of the act are the most important. The trade dispute, as amended by the act of 1906, subject to a penalty of fine or imprisonment every person who, with a view to compel any other person to abstain from doing, or doing, or failing to do any act which such other person has a legal right to do or abstain from doing, wrongfully and without legal authority.

1. Uses violence to or intimidates such other person, or his wife or children, or injures his property;
2. Persistently follows such other person about from place to place;
3. Hides any tools, clothes or other property owned or used by such other person, or deprives him of or hinders him in the use thereof;
4. Watches or besets the house or other place where such person resides, or works, or carries on business, or happens to be, or the approaches to such place;
5. Follows such other person with two or more other persons in a disorderly manner in or through any street or road.

It has, however, expressly provided by § 2 of the act of 1906 that the right of workmen or employers, or of any person on his own behalf or on behalf of a trade union or of an individual employer or firm in contemplation or furtherance of a trade dispute, to attend at or near a house or place where a person resides or works or carries on business shall not be, if the person so attended, whether by undue pressure of peacefully obtaining or communicating information, or of peacefully persuading any person to work or abstain from working, or

statement was intended to nullify the effect of the earlier of recent decisions (of which Lyons v. Wilkins, 1896 and 1899, was the most important), which interpreted the act of 1875 to mean that all picketing was illegal and that the purpose only of communicating information. Until recently it was supposed that for wrongs committed in strikes only the individual wrong-doers could be made responsible. But the decision of the House of Lords in the Taff Vale railway case (1901) showed that a trade union could be sued in tort for acts done by its agents within the scope of their authority and might suffer the loss in its collective capacity, and execution of any damages recovered could be enforced against its general funds. The effect of this decision was nullified by § 4 (1) of the Trade Disputes Act of 1906, which expressly forbids the union to commit any criminal or civil act in contemplation or furtherance on behalf of all the members of the union in respect of any tortious act alleged to have been committed by or on behalf of the union.

**Economic Effects.**

The question of the effectiveness or otherwise of strikes and lock-outs for the purpose of influencing the conditions of employment is part of the wider question of the economic effect of combinations, the strike or lock-out being only one of many methods adopted by combinations of workmen or employers to enforce their demands. (This matter is discussed in the article TRADE UNIONS.) Apart, however, from the question of the extent of the immediate advantage, if any, which one party or the other is able to obtain from a stoppage, we have to consider generally the economic effects of strikes and lock-outs to the community as a whole. Stoppages of work are against their nature wasteful, time, which might be employed in work yielding wages to the workpeople and profits to the employers, is lost never to be recovered, while many forms of fixed capital deteriorate during idleness. In attempting, however, to estimate the utility or disadvantage of strikes and lock-outs, whether to the parties themselves or to the industrial community as a whole, it is insufficient to take into account the value of the wages and profits foregone during the stoppage, and to balance these against the gains made by one party or the other. Attempts have often been made to measure the loss or gain due to strikes in this way, but even as applied to particular disputes, looked at purely from the point of view of one or other of the parties involved, the method is unsatisfactory. On the one hand, the time and work apparently lost may be afterwards partially recouped by overtime, or some of the strikers may be replaced by others, or may themselves find work elsewhere, so that the actual interruption of production may be less than would appear from the magnitude of the dispute. On the other hand, the total loss due to the stoppage may be augmented by the diversion of trade for a longer or shorter period after the resumption of work. Again, the ultimate effect of the forever-conceivable stoppage may be the abandonment of a method of labour by the workers or the employers, by the employers by the workers, or may be advantageous to the nominal victors, by contracting the field of employment or by lowering the efficiency of the service. If, however, the arithmetic computation of the value of the time lost compared with the value of the terms gained is an unsatisfactory test of the benefit or disadvantage of a particular strike to the parties concerned, it is wholly fallacious as a method of estimating the social utility or otherwise of strikes and lock-outs as instruments for effecting changes in the condition of employment. For any satisfactory consideration of this wider question we must look not merely to the actual strike, but to the whole process of free bargaining between employers and organized bodies of workpeople, of which, as already shown, the strike may be regarded as merely an untoward incident. The actual cessation of work is a symptom that for the time there is a deadlock, and frequency of such cessations in any trade is a sign of the imperfection of means of negotiation. In many trades in which both employers and workmen are strongly organized various forms of machinery have been brought into existence for the purpose of minimizing the chance of stoppages (see ARBITRATION AND CONCILIATION). But wherever there is free combined negotiation there is always in the background the possibility of combined stoppage. This being understood, the question of the utility of strikes as an industrial method resolves itself into the questions: (1) Whether the process of settling the terms of employment by agreements affecting considerable bodies of workpeople and employers is superior to the method of individual settlements of labour contracts, or, at least, whether its advantages are sufficient to outweigh the cost of strikes
and lock-outs; (2) whether free collective negotiation could be replaced with advantage by any other method of settling the conditions of employment of bodies of work people, which would dispense with the necessity of testing the labour market by a suspension of work.

1. The first of these questions is virtually the question of the advantages and disadvantages to the community of combinations of workmen and employers, which is discussed in the first of these paragraphs. As regards the question of the direct cost of strikes and lock-outs, it is proper to remember that individual bargaining does not do away with stoppages; in fact, the aggregate amount of time lost in the process of adjusting ten thousand separate labour contracts may be considerable—possibly not less than that consumed on an average in effecting a single agreement involving the whole body, even if the chance of a collective stoppage of work occurring during the process of combined bargaining be taken into account.

While, then, the strikes and lock-outs which accompany the system of combined bargaining are rightly to be described as wasteful, this is not so much because of the excessive amount of working time which they consume, as because of the disturbance and damage done to industry by the violent breach of continuity—a breach which may dislocate trade to an extent quite disproportionate to the actual loss of time involved, and the fear of which undoubtedly affects the minds of possible customers and hampers enterprise on the part of employers. The extent of the injury directly inflicted on the consuming public by a strike varies greatly in different cases, being at its maximum in the case of industries having the total or partial monopoly of supplying some commodity or service of prime necessity, e.g., gas-works, water-works, railway or tramway service; and least in the case of a local stoppage in some widely-spread manufacturing or constructive industry open to active competition from other districts.

In speaking above of the loss occasioned by strikes and lock-outs attention has only been paid to the effects of the actual stoppage as such, and not to the particular methods adopted by the strikers to make the stoppage effective. The evils arising from the practice of intimidation or violence towards workmen, or from the increase of class-hatred and bitterness engendered by the strike between employer and employed, are patent to all, though they cannot be estimated from an economic point of view.

2. As to the second question, viz. the possibility of maintaining combined negotiation, but of substituting some better method than strikes of resolving a deadlock, it is hardly necessary to say that so far as such substitution can be voluntarily carried out with the consent of both parties, whether by the establishment of wages boards or joint-committees, or by agreements to refer differences to third parties, the result is an economic as well as a moral advantage.

But the increasing adoption of these voluntary expedients for diminishing the chance of industrial friction lends no countenance to the expectation that a satisfactory universal substitute for strikes and lock-outs can be devised except at the price of economic liberty. Compulsory reference of disputes to a state tribunal cannot be reconciled with freedom of voluntary negotiations.

Unless, then, we are prepared for a scheme of compulsory regulation of industry by the state, strikes and lock-outs must be accepted as necessary evils, but their frequency may be greatly diminished with the improvement of means of information as to the true condition of the labour market, and the influences by which it is determined. Many disputes arising purely from mismanagement and misunderstanding are wholly avoidable. While there is no warrant for expecting the total abolition of strikes and lock-outs, it is not unreasonable to hope that the spread of education and the means of rapidly obtaining information, the improvement of class relations, and the adoption, where practicable, of conciliatory methods, may gradually tend to confine actual stoppages to the comparatively few cases in which there is a genuine and serious difference of principle between the parties.

Important British Strikes and Lock-outs.

Some of the more important labour disputes which have occurred in various groups of trades in the United Kingdom are noted below. With regard to the statistics given, it may here be noted that whilst the same year serves to the same ends, and whilst it is possible that certain numbers were idle for a specified number of days, it must not be supposed that in all cases the whole number affected were idle for the whole number of days.

The following is a list of strikes which has always been more convulsed by labour disputes than any other, probably owing to the violent oscillations of prices and wages, and to the varied and ever-changing conditions under which work is carried on. Several of the receipts recorded are the result of prolonged contests, but are attributed to the term of engagement rather than the rate of wages. In 1765 the Northumberland miners struck for several weeks unsuccessfully for the suspension of the system of quarterly hold of service, which was then prevalent. In 1810 a strike of seven weeks in the same district against a variation of the yearly bond ended in a compromise. Turbulent strikes in Northumberland and Durham are also giving half the reduction claimed by the coal-owners. The introduction, for a general removal of grievances, and the latter, in which they were defeated, for the maintenance of the union. These strikes were attended with violence and destruction of property. In 1873 another prolonged strike took place in the north of England to enforce alterations in the terms of the yearly bond. From 30,000 to 40,000 men were out for 18 weeks. New men, however, the strike was ended, and the agreement renewed. A widespread strike took place in South Yorkshire and South Staffordshire, the one for an advance and the other against a reduction of wages. The Yorkshire strike is said to have affected 37,000 men, and the Staffordshire strike 20,000. The latter lasted over four months.

The rapid fall in the price of coal after the abnormal inflation in 1871-1872 produced a series of obstinate strikes and lock-outs arising out of reductions of wages, in which the men were usually defeated. The South Wales miners, to the number of 70,000, were out for 11 weeks in 1873 and for 10 weeks in 1875, the latter dispute being ended by a compromise. After several years' experience the formation of the first of the series of sliding scales under which the industry in South Wales was regulated until the end of the year 1902. In 1877 the West Lancashire miners (30,000) were out for 6 weeks, the dispute being terminated by an arbitration award which last-mentioned dispute was terminated by an arbitration award in the miner's favour. In 1879, 70,000 Durham men were out for 6 weeks, the dispute being terminated by an arbitration award which, however, did not affect the scale of wages. The introduction of sliding scales in Durham and Northumberland in 1877 and 1879 did something to preserve peace in those districts, though the Durham scale did not prevent the dispute of 1879 mentioned above. Both scales, however, were terminated in 1883 and in 1885 respectively. In 1880-1881 the Lancashire coal-mining industry was stopped for 7 weeks by a strike of 50,000 to gain a footing in the dispute against 'contracting out' of the Employers' Liability Act of 1880.

The fall of prices from 1879 led to a renewal of disputes. In 1892 there was a prolonged stoppage in the Durham coalfield, 75,000 men being out for 12 weeks.

In 1893 the greatest dispute took place that has ever been recorded in the coal-mining industry, affecting the whole area covered by the Miners' Federation, viz. Yorkshire, Lancashire and Cheshire, and the Midlands. During the years 1891 and 1892 most of the districts covered by the Miners' Federation submitted to reductions of wages varying from 15% off the standard in Durham to 42½% in South Wales and 50% in Scotland, where the previous rise had been greatest. The Miners' Federation, however, refused to recognize the principle that wages should follow prices, and put forward instead the theory that a minimum or 6-living-wage' should be paid and should itself be increased at this rate. They declared altogether to agree to any reduction, and so strong was their combination that the coal-owners deferred any definite action until the middle of 1893, when they considered the time had arrived for some reduction, though it was not necessary to go so far as to be carried on. On the 30th of June they passed a resolution after a conference with the men, demanding a reduction of 25% of the standard rate of wages (the sliding scale rates of wages then in force were 6s. per week for the 12 months of the year, and prices being at the then current rates of wages), and offered arbitration as an alternative; but the federation absolutely refused any reduction, and the contest began. Shortly before the beginning of the dispute Northumberland and Durham had become largely affiliated to the federation, and the miners were not threatened by a reduction, and they seceded from the federation sooner than strike, as demanded by that body to obtain the return of the reductions sustained since 1891. These districts remained in the federation, and the agitation there spread through Scotland and (except for a part of August and September) South Wales, reaping the advantage of the increased prices and wages resulting from the restriction of production due to the stoppage.
Within the federation districts proper there were some localities in which no notices of reduction were posted, but the policy of the Miners’ Federation was to make the stoppage as universal as possible, and the whole movement required the concurrence of the other miners, however, though members of the federation, were for special reasons permitted to continue at work. By the middle of November the proportion of the union miners occupying the hours of the stoppage was not far from 75,000, and in some districts, noticeable, the number of coal-miners in the United Kingdom. The early stages of the dispute were uneventful, but as the funds of the unions affiliated to the federation became exhausted, and the pinch of distress grew heavier, the number of disaffected, and in some districts, deplorable acts of violence were committed. At Featherstone, in Yorkshire, an attack was made on a colliery, in the course of which the military fired on the rioters, two of whom were killed.

After the Federation met on 10th December and called on all its members to leave work, whether under notice of reduction or not, had from the beginning met with considerable opposition in certain districts, and the attempt to prevent persons going on strike was made by the stoppage increased. At the end of August a ballot on the question showed a small majority still in favour of a universal stoppage, but the experience of another month led to a formal reversal of policy in this respect, a meeting of the federation at Chesterfield on the 29th of September deciding to allow all men to return to work who could do so at the old rates of pay, such men to pay a levy of is. a day in aid of those still on strike. Up to October no step was taken towards a settlement beyond an offer on the part of the miners on the 22nd of August to pledge themselves not to ask for an advance until prices reached the 1890 level, and also to resist any cuts in other wages, and this offer was rejected by the coal-owners. On the 9th of October a meeting of the representatives of the parties was held at Sheffield, at the invitation of the mayors of six important towns affected, but without definite result. The deadening of interest, and the virtual suspension of the stoppage, was mainly on account of the coal-owners for an immediate 15% reduction, and the regulation of future changes in wages by a conciliation board. The men, however, still refused all reduction, and during October a number of coal-owners, especially in the Midlands, threw open their pits at the old rate of wages.

A further advance towards a compromise was made by the Federation on 25th October, when it was urged that the 15% reduction should be returned to the men in the event of the conciliation board (with an independent chairman) deciding in their favour. In consequence of this offer a meeting was held between the representatives of the parties on the 3rd and 4th of November, but without arriving at a settlement. Matters had now reached a deadlock, and, accordingly, on the 13th of November, the government addressed an invitation to both parties to be represented at a conference under the presidency (without a casting vote) of Lord Rosebery, who was then foreign secretary. The conference took place at the foreign office on the 17th of November, and resulted in a settlement, the men to resume work at once at the old rate of wages, to be continued until the 1st of February 1894, from which date wages were to be regulated by a conciliation board, consisting of fourteen representatives of the coal-owners, and twenty-one representatives of the miners, to be mutually elected, or in default nominated by the Speaker of the House of Commons, the chairman to have a casting vote.

This agreement terminated the dispute. The Speaker appointed Lord Selborne to chair the board of the following year, by mutual arrangement, the constitution of the conciliation board was modified so as to provide for limits below and above which wages could not fall, and these limits were fixed by the board in most of the other important centres of the mining industry.

During the summer of 1893 there was also a strike of about 90,000 men in South Wales, which lasted about 5 weeks. 1894 saw several disputes in the Scotland, but the miners there, men vainly attempting to resist the fall of wages which followed the fall of coal prices from the abnormal level to which they had risen during the English strike of the previous year, were out from 15 to 16 weeks. In 1898 there was an unsuccessful stoppage lasting 25 weeks in South Wales and Monmouth affecting 100,000 men, for the abolition of the amendment of the sliding scale agreement which had been made by the miners at the stoppage in 1891 in which they had secured a 15% reduction of wages awarded by the conciliation board threw a large body of miners idle for some time in various parts of the federation.

In 1906 a series of local strikes occurred in South Wales in which miners sought a reduction of the wages of coal-owners who were locked out of the north of England and the miners decided to lock out the coal-owners. The immediate occasion of the stoppage was a demand on the part of the miners for a special day of work, to be held on the next day, and the whole day was spent in working machines. The men ceased working overtime, and were locked out for over three months, during which time several strikes occurred in South Wales, but with little success. In 1897-1898 there was a widespread and prolonged dispute in the engineering industry in England, which lasted about 6 months. The dispute arose out of the depression resulting from the drop in the price of iron and steel, and the reduction in the demand for engineering products. The immediate cause of the stoppage was the failure of the manufacturers to agree to a reduction of wages.

In 1897-1898 a number of strikes occurred in the engineering industry in England, which lasted about 6 months. The dispute arose out of the depression resulting from the drop in the price of iron and steel, and the reduction in the demand for engineering products. The immediate cause of the stoppage was the failure of the manufacturers to agree to a reduction of wages. The men were locked out by the employers and the employers were successful. The strike lasted about 6 months, during which time the miners were locked out of work and the employers had to bring their whole force to bear on employers in particular localities.
with the result that the stringency of the conditions and restrictions enforced varied very greatly in different districts, according to the comparative strength of the unions in those districts. Employers complained bitterly about their increased operating costs on their competitors, and they declared that they were severely handicapped as compared with America and other countries, where engineering employers had much more complete control over the wages of their workmen. The clash of interests between the Federation of Engineering Employers by the coalition of the local associations on the Clyde and in Belfast, and this federation gradually spread to other districts until it finally covered the United Kingdom generally.

The policy of the federation was to defeat the attempts of the unions to put pressure on particular individuals or localities by the counter-threat of a general lock-out of trade unions over all districts. The lock-out notices were framed in such a way that 25% of the trade unionsists employed were to be dischaged at the end of each week until the whole were locked out. Lock-out notices of this kind were always made a month in advance of the split-up of the trade unions before the general dispute, but in each case the dispute was averted before the notices took effect. But the conferences which took place in April 1897 between the representatives of employers and unions led to no agreement or commitment on any important points.

When, therefore, in June 1897 the London employers, threatened with a strike for an eight-hour day, put their case in the hands of the employers to the Federation for a settlement, it was determined to attempt the financial support received from the Australian trade unions and from the general public. It began on the 13th of August with a small local dispute at the West India Docks about the wages earned by the shipwrights. These were increased by 6d. per day, or 2s. per week, by the employers, and the dock labourers in the port, who took the opportunity of demanding an increase in the rate of pay for time work from 5d. to 6d., the abolition of contract and piece work, and the removal of the lockout. They were joined by the employers and the shipwrights, who came out "in sympathy," though the latter class of men soon formulated a set of demands of their own. Employment was blocked, and the threat of a sympathetic strike was given. In a few days not less than 16,000 men were idle. For the most part they were unconnected with trade unions which could give them strike pay, but during the month that the strike lasted the public at home and abroad took up the cause of the strikers, and the employers were forced to put pressure on the dock companies to allow them to employ labour direct within the docks. The apprehensions of the public led to the formation of a conciliation committee at the Mansion House, including Lord Arthur Hardinge, Lord Shaftesbury, Sir John Lubbock (Lord Avebury), and others, who mediated between the strikers and the dock directors, with the result that after one abortive attempt, that at about 4 on the 23rd of August, which was rejected by the men, an agreement was arrived at on the 14th of September, under which the dock labourers obtained the greater part of their demands. From the 4th of November the rate of hourly wages for time work was raised to 7s. 6d., a week, by a centenary effect born through the board of trade. The issues of this dispute were of ironworkers in Staffordshire for 4 weeks in 1883 against a reduction of wages, attended by rioting and destruction of plant.

The nailmakers in the Dudley district engaged in widespread disputes. The 1885 and 1886 disputes were failures, but the reduction of wages was unsuccessful. Those of 1885 and 1887 were for advance of wages; the former was wholly successful. The workers of Clapton Heath successfully struck in 1910 for an increase of wages.

Other Trades.—Among other noteworthy disputes are to be mentioned:

1. A successful strike of 14,000 persons in the Leicester hosiery trade in 1891 for an advance in wages.

2. An unsuccessful strike of 13,000 or more tailors in London for a rise of wages and reduction of hours, lasting several months.

3. A number of disputes among agricultural labourers resulting against the terms of yearly hiring, leading to a general lock-out of over 15,000 men for 10 weeks, which ended in the defeat of the men.

4. A series of disputes among agricultural labourers in 1872-1874 for increases of wages and other improvements in the conditions of employment, in which the men were mostly successful. These, which are almost the only unionised disputes recorded in agriculture, evoked much public interest.

5. In 1889 there was a prolonged strike of dock and waterside labourers in London for a rise in wages and other alterations in the conditions of employment, and the employers attempted to gain the financial support received from the Australian trade unions and from the general public. It began on the 13th of August with a small local dispute at the West India Docks about the wages earned by the shipwrights. These were increased by 6d. per day, or 2s. per week, by the employers, and the dock labourers in the port, who took the opportunity of demanding an increase in the rate of pay for time work from 5d. to 6d., the abolition of contract and piece work, and the removal of the lockout. They were joined by the employers and the shipwrights, who came out "in sympathy," though the latter class of men soon formulated a set of demands of their own. Employment was blocked, and the threat of a sympathetic strike was given. In a few days not less than 16,000 men were idle. For the most part they were unconnected with trade unions which could give them strike pay, but during the month that the strike lasted the public at home and abroad took up the cause of the strikers, and the employers were forced to put pressure on the dock companies to allow them to employ labour direct within the docks. The apprehensions of the public led to the formation of a conciliation committee at the Mansion House, including Lord Arthur Hardinge, Lord Shaftesbury, Sir John Lubbock (Lord Avebury), and others, who mediated between the strikers and the dock directors, with the result that after one abortive attempt, that at about 4 on the 23rd of August, which was rejected by the men, an agreement was arrived at on the 14th of September, under which the dock labourers obtained the greater part of their demands. From the 4th of November the rate of hourly wages for time work was raised to 7s. 6d., a week, by a centenary effect born through the board of trade. The issues of this dispute were of
STRIKES AND LOCK-OUTS

interest as involving the scope and limits of the functions of trade union action and of arbitration in relation to the management of business. The terms of settlement, which were of an elaborate character, are still in operation.

8. Two prolonged disputes at Lord Penrhyn's slate quarries in North Wales in 1896 and 1900 attracted public notice from the obstinacy with which the contests were conducted on both sides. About 2500 workmen were affected, and the questions at issue were the recognition of the men's combination and the remedy of a number of alleged grievances, including the abolition of the contract system. After 48 weeks' stoppage, during which the board of trade vainly tried to mediate, the first dispute was ended by a compromise; but in 1900 another struggle began which was persisted in by many of the men until November 1903, but without success.

Foreign Countries.

Below is given a brief account of the most recent strike statistics in the principal countries other than the United Kingdom, except those of the United States, which are dealt with in a separate section.

France.—Detailed statistics of strikes and lock-outs in France have been published annually since 1890 by the French office du travail. The following are the figures for 1900-1906:

<table>
<thead>
<tr>
<th>Year</th>
<th>Number of Disputes</th>
<th>Number of Workpeople directly affected</th>
<th>Aggregate Duration in Working Days</th>
</tr>
</thead>
<tbody>
<tr>
<td>1900</td>

The principal groups of industries affected by disputes were in 1900 and 1901 the transport, involving 47,125 and 36,636 workpeople respectively; in 1902 the mining and quarrying, involving 119,181 workpeople; in 1903 the textile manufacturing industry, involving 76,376 workpeople; in 1904 the textile manufacturing industry, involving 75,293 workpeople; the transport, involving 69,203 workpeople, and the agricultural, forestry and fishing group, involving 52,333 workpeople; in 1905 the building and metal trade groups of industries, involving about 32,000 workpeople in each; and in 1906 the building, metal and mining quarrying groups of industries, involving about 90,000 workpeople each.

In the French statistics of causes of disputes a dispute due to several causes is entered as many times as there are causes, not merely under its principal cause, as in the United Kingdom statistics. It would be possible to summarize the relative prevalence of different groups of causes of trade disputes by the numbers involved, but it is sufficient to say that the results during the period 1900 to 1906 were as follows: 15% in favour of the workpeople, 25% in favour of the employers, and 63% compromised. A general strike of railway employees all over France in 1910 threatened to spread to other industries and caused an acute political crisis, but the energetic measures taken by M. Briand's government, especially the issue of mobilization orders to all the reservists on the affected lines, brought about its collapse in little more than a week.

Germany.—Before 1890 there were no official statistics of strikes and lock-outs throughout the German Empire, but certain figures were collected and published by the committee of the " Gewerkschaften," or Social Democratic trade unions, in their Correspondenzblatt. These figures, however, were admittedly incomplete. From 1899, however, statistics have been published by the German imperial statistical office for strikes and lock-outs other than in agriculture.

The figures from 1901 are summarized below:

<table>
<thead>
<tr>
<th>Year</th>
<th>Number of Disputes terminating in the year</th>
<th>Number of Workpeople directly and indirectly affected</th>
</tr>
</thead>
<tbody>
<tr>
<td>1901</td>
<td>1091</td>

<td>286,016</td>
</tr>
</tbody>
</table>

In 1905, 323,425 workpeople employed in the mining and smelting group were involved in disputes, and in 1906 and 1907, 102,880 and 90,896 workpeople employed in the building group of trades were so involved.

In the German statistics disputes are counted more than once if due to more than one separate cause. Of the total number of disputes tabulated in this way during the period 1900-1906, 56% were on questions of wages, 15% on questions of hours, 10% on questions of the employment of particular classes of persons and the balance on questions of working rules and other causes.

During the same period 20% of the disputes were settled in favour of the workpeople, 45% in favour of the employers, and 35% were compromised.

Belgium.—The following figures are based on reports published by the Belgian labour department.

The table given below shows the number of strikes and the number of workpeople directly affected by strikes in each of the years 1901 to 1907:

<table>
<thead>
<tr>
<th>Year</th>
<th>Number of strikes</th>
<th>Number of workpeople directly affected</th>
</tr>
</thead>
<tbody>

</table>

In 1906 five lock-outs were recorded, all in the textile industry, affecting 23,621 workpeople, and in 1907 four lock-outs were recorded affecting 16,714 workpeople (one of these lock-outs affecting 16,000 workpeople employed in the transport trade).

The number of workpeople indirectly affected by strikes was 11,468 in 1906 and 16,248 in 1907.

Sweden.—The Swedish labour department has published statistics of strikes since 1903. There were in 1903 142 disputes directly affecting 22,568 workpeople, in 1904 215 disputes directly affecting 11,485 workpeople, in 1905 175 disputes directly affecting 32,368 workpeople, in 1906 277 disputes directly affecting 18,012 workpeople, and in 1907 288 disputes directly affecting 21,732 workpeople. Of the 1107 disputes recorded in the five years 691 were caused by questions of wages. Of the 1107 disputes 362 ended in favour of the workpeople, 272 in favour of the employers, and 39 in a compromise. In 1909 there was a great national strike involving almost every industry, and lasting some six months.

Denmark.—The statistics of disputes in Denmark are published by the Danish statistical bureau. During the period 1900 to 1906 the number of disputes varied from 37 in 1901.
to 89 in 1906, and the number of work-people directly affected, from 7666 (involved in 68 disputes) in 1900 to 1148 (involved in 43 disputes) in 1903. The number of work-people shown is the maximum number affected at any one time, but the number involved is not obtained for all disputes. Of the total number of disputes which took place during the seven years’ period 1900-1906, viz. 518, 53% were caused by questions of wages, 5% by hours of labour, 7% by working arrangements, rules, &c., 6% by questions of trade unionism, and 31% by other causes or causes unknown.

Holland.—Statistics of disputes in Holland are published by the central statistical bureau. During the three years 1904, 1905 and 1906 the number of disputes recorded were 102, 132 and 181 respectively, and the number of work-people directly affected 11,186, 7364 and 18,858 respectively, but the number of work-people affected was not ascertained in every dispute. The causes of disputes are measured by the number of days lost by the work-people directly affected (though these particulars were not obtained for all disputes), and the days lost by disputes which had more than one cause are included under each cause or object. In 1904 25%, in 1905 53% and in 1906 51% of the time lost was caused by questions of wages. The results of disputes in the three years are shown in the following table:

The figure for 1906 does not include 8 “sympathetic” disputes which came to an end when the original dispute terminated in connexion with which they occurred.

Australia and New Zealand.—Four of the Australian states (Victoria, New South Wales, South Australia and Western Australia) and the Commonwealth as a whole have enacted laws with a view to the peaceable settlement of disputes between employers and work-people, but the laws of Victoria and South Australia are inoperative though unrepealed. These two states and Queensland have, however, established wages boards which tend to prevent disputes on the question most frequently the cause of disputes or lock-outs. The original inspiration of the conciliation and arbitration laws arose from the great strikes of 1899 and 1902, which led to the creation of industrial boards in the attempt of labour unions to secure a monopoly of employment. They all ended in the defeat of the work-people and in a great weakening of trade unionism in the colony.

In New Zealand a law has also been in force since 1894 for the encouragement of the formation of industrial unions and associations, and to facilitate the settlement of industrial disputes. Strikes and lock-outs are now illegal in New Zealand.

In the tabulation of causes or objects of disputes the work-people are entered as many times as there are causes. During the period 1900 to 1906 questions of wages were the pre-dominating cause of dispute.

Twenty-five % of the work-people were involved in disputes during 1900 to 1906 which resulted in favour of the employers, 13% in disputes which resulted in favour of the work-people, and 62% in disputes which were compromised.

The British Colonies.

Canada.—Statistics of disputes are published by the department of labour. During the seven years 1901 to 1907 the total number of disputes recorded was 859, the number each year being as follows:

<table>
<thead>
<tr>
<th>1901.</th>
<th>1902.</th>
<th>1903.</th>
<th>1904.</th>
<th>1905.</th>
<th>1906.</th>
<th>1907.</th>

<td>104</td>
<td>123</td>
<td>160</td>
<td>103</td>
<td>87</td>
<td>138</td>
<td>144</td>
</tr>
</tbody>
</table>

In 1904 the number of work-people involved was 15,665; in 1905, 16,127; in 1906, 26,014 and in 1907, 34,972. The number of working days lost during the same four years were 278,956, 284,146, 489,775 and 613,986 respectively. Of the total number of disputes in the seven years (859), 282 occurred in the building trades, 150 in the metal trades, 79 in the clothing trades, 62 in the mining industry, 60 in the transport trades and 48 in the food and tobacco preparation industry. Of the 740 disputes occurring in the same period for which a cause could be tabulated, 245 were for an increase in wages, 94 against the employment of particular persons, 64 were for both an increase in wages and a decrease in hours of labour, and 45 against a reduction in wages; and of the 841 disputes for which the result could be tabulated, 293 were in favour of the employers, 250 were in favour of the work-people, 200 were settled by compromise, and the balance (8) were indefinite in their settlement. Four of the Canadian provinces, Ontario, Nova Scotia, British Columbia and Quebec, and the Dominion government have enacted laws with a view to the peaceful settlement of industrial disputes. Under the Industrial Disputes Investigation Act of 1907 strikes and lock-outs are unlawful in industries termed public utilities prior to or during a reference of such dispute to a board of conciliation, a provision which is enforced by heavy penalties. Thirty days’ notice of intended changes in wages or hours have to be given under the act.

Authorities.—The following are among the more important official publications on strikes and lock-outs: Reports of the Chief Labour Correspondent of the Board of Trade (1875-1888); Labour Gazette (Board of Trade), were published monthly from May 1893; Reports of Royal Commission on Labour (1891-1894); Report of the Royal Commission on Trade Disputes and Trade Combinations (1906); Third Abstract of Foreign Labour Statistics (Board of Trade, 1896—Section on Trade Disputes), and the publication of the offices given as the authorities for the strike statistics of the various foreign countries and colonies. (See also list of authorities on TRADE UNIONS AND ARBITRATION AND CONCILIATION.)

United States.—The first recourse to a strike in the United States occurred in 1740 or 1741, when a combined strike of journeymen bakers occurred in New York City. An information was filed in 1741 against the strikers for conspiracy not to bake until their wages were raised. On this they were tried and convicted, but it does not appear that any sentence was ever passed. In May 1796 an association of journeymen shoemakers in Philadelphia ordered a "turn-out" or strike to secure an increase of wages, and again in 1798, for the same purpose, both strikes being
successful. In 1799 the shoemakers of Philadelphia struck against a reduction of wages, the strike lasting about ten weeks, and being only partially successful. These four are the only strikes to which any reference can be found that occurred in the United States prior to the 19th century. The conditions of industry generally during the colonial days was not conducive to strikes. The factory system had not taken deep root, masters and men worked together, and so there was no opportunity for concerted action.

The first notable American strike occurred in November 1803, in the city of New York, and is commonly known as the “sailors’ strike.” The sailors in New York had been receiving $10 per month. They demanded an increase to $14. In carrying out their purpose they formed in a body, marched through the city, and compelled other seamen who were employed at the old rates to leave their ships and join the strike. The strikers were pursued and dispersed by the constables, who arrested their leader and lodged him in gaol, the strike thus terminating unsuccessfully. In 1805 the Journeymen Shoemakers’ Association of Philadelphia again turned out for an increase of wages. The demands ranged from 25 to 75 cents per pair increase. This strike lasted six or seven weeks and was unsuccessful. The strikers were tried for conspiracy, the result of the trial being published in a pamphlet which appeared in 1806. An account of this trial may be found in the United States Supreme Court library. In November 1809 a strike among the cordwainers occurred in New York. The employers quietly took their work to other shops, and by this stratagem defeated the strikers; but the action being discovered, a general turn-out was ordered by the Journeymen Cordwainers’ Association against all the master workmen of the city, nearly two hundred men being engaged in the strike. At that time a stoppage of work in one shop by the journeymen was called a “strike”; a general stoppage in all shops in a trade was known as a “general turn-out.” A member of a journeymen’s association who did not keep his obligations to the organization was denounced as a “scab.”

In 1815 and 1817 the journeymen cordwainers of Pittsburgh, Pennsylvania, were tried for conspiracy on account of their connexion with a strike, and were convicted. In 1817 a peculiar labour difficulty occurred at Medford, Massachusetts. Thacher Magoun, a ship-builder of that town, determined to abolish the grog privilege customarily paid at that time. Mr. Magoun gave notice to his people that no liquor should be used in his shipyard, and the words “No rum!” “No rum!” were written on the clapboards of the workshop and on the timbers in the yard. Some of Mr. Magoun’s men refused to work; but they finally surrendered, and a ship was built without the use of liquor in any form.

The period from 1821 to 1834 witnessed several strikes, but rarely more than one or two in each year. These strikes occurred among the compositors, hatters, ship carpenters and caulkers, journeymen tailors, labourers on the Chesapeake & Ohio Canal, the building trades, factory workers, shoemakers and others. One of the most notable of these, for its influence upon succeeding labour movements, occurred in 1834, in the city of Lynn, Massachusetts. During the latter part of the preceding year the female shoebinders of that town began to agitate the question of an increase of wages. The women engaged in this work usually took the materials to their homes. The manufacturers were unwilling to increase the prices paid, so a meeting for consultation was held by more than one thousand binders. This was on the 1st of January 1834. The binders resolved to take out no more work unless the increase was granted. The employers, however, steadily refused to accede to the demands, as they found no difficulty in having their work done in neighbouring towns at their own prices. The strike, after three or four weeks, came to an unsuccessful termination. In February of the same year a disturbance of short duration occurred at Lowell, Mass., among the female factory operatives. Their strike was to prevent a reduction of wages. During the year 1835 there was a large number of strikes throughout the country, instigated by both men and women. The number of strikes by dissatisfied employees had at this time become so numerous as to call forth protests from the public press, the New York Daily Advertiser of the 6th of June 1835 declaring that “strikes are all the fashion,” and suggesting that it was “an excellent time for the journeymen to come from the country to the city.”

The United States government, through the census office and the department (now bureau) of labour, has investigated the question of strikes, the result being a fairly continuous record from 1880 to the 31st of December inclusive. In 1880, according to the tenth census, there were 616 strikes, but the number of establishments involved in them was not reported; the record must therefore commence with 1881, and since then the facts have been continuously and uniformly reported by the department (now bureau) of labour. This record, so far as numbers are concerned, is shown in the following table:

Total 36,757 181,407 3,803,824 18,547 825,610

Statistics of Strikes.—Out of the total of 181,407 establishments at which strikes took place during the period named, 60,899 were in building trades, 17,925 in coal and coke, 1,751 in tobacco, 20,914 in clothing, 4,500 in stone-quarrying and cutting, 1,555 in boots and shoes, 1,551 in furniture, 1,476 in brick-making, 2,990 in printing and publishing, and 1,086 in cooperage. These ten industries supplied 128,336, or 70.74% of the whole number of establishments in which strikes occurred during the twenty-five years. In the lock-outs occurring during the same time five industries bore a very large proportion of the burden, involving 13,716, or 73.93% of the whole number of establishments, which was 18,437. The industries affected were: building trades, 10,142; clothing, 1,493; stone-quarrying and cutting, 901; boots and shoes, 327; tobacco 393. The whole number of persons thrown out of employment by strikes was 8,793,824, of whom 55-57% were males and 43-43% were females; and the total number thrown out of employment by lock-outs during the same period was 825,610, of whom 84-18% were males and 15-82% were females. About 70% of the whole number of strikes were ordered by labour organizations; and of the number so ordered (25,533) 49.48% succeeded, 15.87% succeeded partly, and 34.65% failed. Of the whole number of strikes, 47.94% succeeded, 15.28% succeeded partly and 36.78% failed. Of the lock-outs, 50.79% succeeded, 10.71% succeeded partly and 39.09% failed. The average duration
of the strikes for the whole period was 254 days, and of the lock-outs 84-6 days.

More strikes were occasioned by demands for increase of wages than for any other one cause, 32-24% of all strikes being for this cause, but this in combination with other causes attributable in whole or in part to demands for increase of wages brings the demands up to 40-72%.

The next most fruitful cause of strikes is disagreement concerning the recognition of the union and union rules. For this 18-84% of strikes were declared, and both alone and combined with other causes produced 32-35% Object the reduction of wages caused 11-96% while demands for reduction of hours alone and combined with other causes produced 9-78% of strikes.

Of the total number of establishments involved in strikes 57-91% were involved for causes either in whole or in part due to demands for increase of wages. The most important cause of lock-outs during the twenty-five years was disputes concerning the recognition of the union and union rules and employees' organizations, which alone and combined with various causes, produced nearly one-half of all lock-outs and more than one-half of all establishments involved in lock-outs. The United States government's account of losses from strikes is for the period from January 1881 to the 31st of December 1900, the five years from 1901 to 1905 inclusive not being included in that account. It is difficult to ascertain the exact losses of employees and employers resulting from strikes and lock-outs. Differences may balance each other; so that the results given below for the period named may be considered as fairly accurate.

The total loss to employees and employers alike in the establishments in which strikes and lock-outs occurred, for the period of twenty years, was thus $4,68,968,581. The number of establishments involved in strikes during this period was 117,509, making an average wage loss of $2194 to employees in each establishment in which strikes occurred. The number of persons thrown out of employment by reason of strikes was 6,105,694, making an average wage loss of $42 to each person involved. The number of establishments involved in lock-outs was 9,933, making an average loss of $49 to employees in each establishment in which lock-outs occurred.

</table>

The figures given relate to all strikes, of whatever magnitude, occurring in the United States from 1881 to the 31st of December 1900 inclusive. Among them are not included what may be called historic strikes, the first of which was in 1877, though of course many very severe strikes had taken place prior to that year. The great railway strikes of 1877 began on the Baltimore and Ohio Railroad at Martinsburg, West Virginia, the immediate cause of the first strike being a 10% reduction of wages of all employees. This, however, was but one of many grievances that had been present prior to that year. There was no general employment. Men with families were permitted to work only two, three, or four days a week, the remainder of the time being forced to spend away from home at their own expense, living on whatever little money for domestic use. Wages, payable on demand and often retained several months. The tonnage of trains was increased, and the men were paid only for the number of miles run, irrespective of the time consumed. So there were many alleged causes for the great strikes of 1877. Riot, destruction of property and loss of life occurred at Martinsburg, Baltimore and various places in Pennsylvania. The state militia at Martinsburg and Pittsburg sympathized with the strikers.
affiliated with them and refused to fire upon them. United States troops were ordered from Eastern garrisons, and they dispersed the strikers. On October 20, 1884, the Toledo anatomy and the mills tramps collected, and succeeded in closing most of the shops, factories and rolling-mills in those cities. There were also formidable demonstrations in Chicago, as well as in Syracuse, Binghamton and elsewhere. New York State, which was dispersed by the state militia without violence or destruction of property.

The Pennsylvania Railroad also had a memorable strike, accompanied by riots and much violence and destruction of property, during the same year, the strike being ordered on account of a general reduction in wages and some other causes which came in to create a movement. With the completion of this strike it was to terminate here; but from the beginning the strikers had the active sympathy of a large proportion of the people of Pittsburgh, where the chief movements occurred. The actual loss to the Pennsylvania Company was not great, but the loss of property and loss of business at Pittsburgh amounted to over $5,000,000. Claims were presented before the courts in Allegheny County to the amount of over $3,500,000, while the actual amount paid by compromise and judgments was over $2,750,000.

The next great strike was that of the telegraphists, which occurred in the year 1889. The telegraphists of the American Bell Company had been notified that on the first of January, 1889, their present wages would be increased by twenty-five cents a day. They declined to accept the increase, and on the 4th of January the mails were stopped.

Another historic strike, only partially successful, was that on the South-Western or Goulstream system of railways in the years 1888-1889, but the strike of the labourers at Homestead was a complete failure. The Homestead Works, near Pittsburgh, growing out of a disagreement in the previous month in regard to wages.

The parties were unable to come to an agreement, and the company closed its works on the 30th of June and discharged its men. Only a small portion of the men were affected by the proposed adjustment of wages. The larger portion of them, who were members of the Amalgamated Association of Iron and Steel Workers, were not employed in the Homestead Works, but were the employees of other companies. At the Homestead Works, there were some thirty thousand, in number, who were not members of that association. The company refused to recognize the union, and struck the employees against its representatives. Upon the failure to arrive at an adjustment of the wage difficulty the company proposed to operate its works by the employment of non-union men. The men, who could not secure work, took to the streets, and discharged and also came to the determination that they would resist the company in every attempt to secure non-union workers.

The history of the events at Homestead shows that the lodges composing the Amalgamated Association proceeded to organize what was styled an "advisory committee" to take charge of affairs for the strikers. All employees of the company were directed to break their contracts to refuse to work, and the Amalgamated Association was recognized and its terms agreed to. The works were shut down two days prior to the time provided by the contract under which the men were working and, as a result, the works began to hang the premises of the company.

On the 4th of July the officers of the company asked the sheriff of the county to appoint deputies to protect the works while they carried out their intention of making repairs. The employees, on their part, petitioned the sheriff to declare any illegal or unfair evictions, or the calling or eviction of strike-breakers or demands to enter; in fact, they took possession of the Homestead Works. When the sheriff's men appeared, they refused them entry into the works, and threatened them to leave the place, as they did not intend to create any disorder, and would not allow any damages to be done to the property of the company. They further offered to act as deputies, an offer which was accepted.

The immediate cause of the fighting which subsequently took place at Homestead was the apprehension of a body of Pinkerton's detectives, who were gathered in two barges on the Ohio river, some miles below the works. When the Pinkertons arrived the workmen broke through the mill fence, entrencing themselves, and were joined by a mob of some 5000. The Pinkertons made their way to the settlement, with the approach of the Pinkerton barges; and they resisted all attempts to land, the result being a fierce battle, brought on by a heavy volley of shots from the strikers. The Pinkertons were armed with revolvers and shotguns; and their barges were the approach of the embankment single file, and so were soon driven back to the boats, suffering severely from the fire of the strikers. Many efforts were made to prevent the landing of the Pinkertons and to stop the way during the day. It was renewed the following day. A brass ten-pound cannon had been secured by the strikers, and planted so as to command the barges moored at the banks of the river. Another cannon was obtained and placed on the opposite side of the river, where they protected themselves and a cannon which they had obtained by a breechwork of railway ties. Before nine o'clock a bombardment commenced, the cannon being turned on the boats, and the firing was kept up for several hours.

The boats were protected by heavy steel plates inside, so efforts were made to fire them. Hose was procured and oil was carried in barrels of oil was emptied into the river above the mooring place, the purpose being to ignite it and then allow it to float against the boats. Under these combined movements the Pinkertons were obliged to leave the barges and take to the boats. The latter was not a safe place, however, since the former had been hoisted out of the terms. Seven had been killed and twenty three wounded. On the 10th of July, after several days' correspondence with the sheriff, the latter removed the embankment of the village from the state to Homestead. On the 12th the troops arrived, the town was placed under martial law, and order was restored. There had been much looting, clubbing and stoning, and the detectives, the sheriff's officers, and the strikers were mixed in every crime, and were treated with great abuse. Eleven workmen and spectators were killed in the fights.

Congress made an investigation of this strike, but no legislative action was ever taken. Some indictments were made and lawsuits followed, so many suit were brought before the courts, the strike was not declared off until the 20th of November 1892. The Homestead strike must be considered as the bittest labour war in the United States prior to the Chicago strike in 1894. It was unsuccessful.

The Chicago and Pullman Strike

The Chicago and Pullman Strike, a strike of Pullman's Palace Car Company employees against their employer in 1894, was one of the most famous labor disputes in American history. The strike began when the company announced it would end its practice of paying workers a salary and instead pay them a percentage of the price of the ticket each time they sold a ticket. The workers, members of the Amalgamated Association of Street Railway Employees of America, went on strike in response to the new wage system. The strike was centered in Chicago, and the company was operating a large number of electric streetcars, which were essential for the transportation of goods and people in the city. The company's failure to come to an agreement with the workers ultimately led to a violent confrontation at the Pullman Palace Car Company's plant in Chicago, known as the "Great Pullman Strike."
Another force was soon involved in the strike, which was, very naturally, an ally of the Pullman Company. This was the General Managers' Association, a body of railway men representing all the roads in the country. A strike demand for reduction in the wage of the railroad employees in the United States. These three great forces, therefore, were engaged in a battle for supremacy, and that rivalry alone, without reference to the conditions and circumstances accompanying it, makes this one of the historic strikes of the period.

According to the testimony of the officials of the railways involved and the statements of the Pullman strikers, the cost of the strike, including the salaries of the deputy marshals and other incidental expenses, at least $685,000. The loss of earnings of these roads on account of the strike is estimated at nearly $5,000,000. About 3,000 employees at Pullman lost $1,000,000. The Pullman strikers, on the other hand, claimed as wages the twenty-four railroads radiating from Chicago, all of which were more or less involved in the strike, lost in wages, as estimated, nearly $1,000,000. Beyond these amounts very great losses, widely distributed, were suffered incidentally throughout the country. The suspension of transportation at Chicago paralysed a vast distributive centre, and imposed many hardships and much loss upon the great and busy community. Employment, travel and necessary supplies depend upon and demand regular transportation, to and through Chicago. The loss to the country at large are estimated by the Pullman strikers at $100,000,000, or ten times the wages. They are, whether more or less, they teach the necessity of preventing such disasters, and the strike illustrates how a small local disturbance, arising from the complaints of a few people, can affect a whole country. The centripetal force of the Pullman strikers and the centripetal force of the railway companies are in this case the centripetal force of the railway companies are in this case the center of disturbance. The railway authorities therefor the Pullman strikers and declared their boycott against Pullman cars, and the General Managers' Association took every means to protect their interests and prevent obstructions to the free carrying of the mails, to prevent interference with interstate commerce, and to enforce the decrees and mandates of the Federal courts. They took no part in any attempt to suppress the strike, nor could they, as a matter of policy, bring the city and state authorities. The police of the city were used to suppress riots and protect the property of citizens, and the state militia was called in for the same service. The total of these forces employed during the strike was estimated at 125,000.

Many indictments and law-suits originated in the difficulties occurring in Chicago. But all the remaining circumstances of the strike point to one conclusion—that the strike was the result of a combination of forces, the purpose of which was to suppress the strike, not to suppress the strikers. The strike generated a vast deal of bitter feeling—so bitter that neither party was ready to consider the rights of the other. The attacking parties claimed that their grievances were inculcated in them adopting any means in their power to force concessions. This is the attitude of all strikers. The other parties, on the other hand, claimed that they were justified in adopting any means in their power to resist the demands of the attacking party. The probability is that neither recognized the rights of the public to such an extent as to induce them to forbear bringing inconvenience and disturbance to the inhabitants of the city. The general strike and the invasion of the states by the United States, and if it only proves a lesson sufficiently severe to teach the public its rights in such matters, and to teach it to adopt measures to preserve these rights, it will be worth the cost. The strike, it is said, has cost the taxpayers the money it was likely to make. The strike has cost the taxpayers the money it was likely to make. The strike, it is said, has cost the taxpayers the money it was likely to make. The strike, it is said, has cost the taxpayers the money it was likely to make. The strike, it is said, has cost the taxpayers the money it was likely to make. The strike, it is said, has cost the taxpayers the money it was likely to make. The strike, it is said, has cost the taxpayers the money it was likely to make.
STRINDBERG—STRINGED INSTRUMENTS

C. D. W.

STRINDBERG, AUGUST (1849—1912), Swedish author, was born at Stockholm on the 22nd of January 1849. He entered the University of Upsala in 1867, but was compelled by poverty to interrupt his studies, which he resumed in 1870. His gloomy experiences of student life are reflected in a series of sketches named after two districts of Upsala, Från Fjärdering och Svarthäcken (1877), which aroused great indignation at the time. After various experiments as schoolmaster, private tutor and actor, he turned to journalism, and afterwards more than avenged himself for the triviality and narrowness of his new surroundings in his famous Sena, under which title he published some of which are still used in the sub-title of "A Soul's Development." The revelations of this book explain much of the bitterness of his work, and it was followed in 1883 by a fourth part in German, Die Beichte eines Thäufers ("A Fool's Confession"), followed by a volume in Swedish. With this he should be classed his Inferno (1897) and Sömmersgårdförni ("The Nights of a Somnambulist," 1900). Strindberg's first marriage was an unfortunate one, and was dissolved in 1893. He then married an Austrian lady, from whom he was separated in 1896. In 1907 he married the Swedish actress Harriet Bosse, from whom he was amicably separated soon afterwards. He suffered at different times from mental attacks, of which he gave analytic accounts on his recovery.

A number of criticisms on Strindberg from eminent hands are collected in En bok om Strindberg (Karljus, 1894).

STRING, a general term for the cord, or stout thread, a line or rod which holds a musical instrument. The O. Eng. word is strong, cf. Dan. strong, Ger. Steng, and meant that which is strongly or tightly twisted; it is related to "strang," and is to be referred to the root seen also in Lat. stringere, to draw tight, whence "stringent" and "strict," and in Gr. στραγγίζω, a halter, whence comes "strangle," to choke, throttle. The word is particularly used of the cord of a bow, and of the stretched cords of gut and wire upon a musical instrument, the vibration of which produces the tones (see STRINGED INSTRUMENTS below). In architecture the term "string-course" is applied to the projecting course or moulding running horizontally along the face of the building.

STRINGED INSTRUMENTS (Fr. instruments à cordes; Ger. Saiteinstrumente; Ital. strumenti a corde), a large and important section of musical instruments comprising subdivisions classified (A) according to the method in which the strings are set in vibration (B) according to certain structural characteristics of the instruments themselves.

Section A.—This includes instruments with strings (i) plucked by fingers or plectrum; (ii) struck by hammers or tangents; set in vibration (3) by friction of the bow, (4) by friction of a wheel or (5) by the wind. In all these classes we are also acquainted with the fact that the strings are stretched in order to ensure resonance, and with the measures taken to obtain more than one sound from each string.

1. Strings plucked by Fingers or Plectrum.—Twanging the strings by the fingers is the most primitive method, probably suggested by the fl eeble note given out by the tense string of the hunters' bow, which was the prototype of the harp. In this ancient instrument, popular in all ages and lands, the strings are stretched à vide between two supports of a frame, the lower of which acts as a soundboard from which the strings rise perpendicularly. The scale of all harp-like instruments is produced by means of one string for each note, difference in pitch being obtained by varying the length of the strings. In the modern pedal harp with double action the strings can be shortened sufficiently to raise the tone of a semitone or a tone, by means of a foot pedal. In the chromatic harp (Playford Woff & Co.) the same object has been obtained without violating the principle by ingeniously increasing the number of strings. The range of the ancient Egyptian hars, instruments in which the strings are produced in the British Museum, an instrument having a boat-shaped body with a long curved neck from which the strings stretch at right angles to the soundboard, is the usual link as yet discovered between harp and violin. In the device of stretching the strings partly over a soundboard and partly à vide, as in the cithara, the lyre, the lute, the mandolin, the guitar, &c., the building lying parallel with the soundboard are slightly raised over a bridge, by means of which the vibrations are communicated to the belly of the instrument. Between the soundboard and the
cross-bar, upheld by two arms springing from the body of the instrument, the strings at first bridged an open space, greater convenience, and then the string was held there without the aid of stopping, or a third string at the other end. The principal closing up of this open space marks the various steps in the transition from cithara to fiddle. In the Egyptian cithara the harp-like appearance was more pronounced, and the fiddle was only an oblique. In the Assyrian and later in the Greek and Roman citharas and lutes all the strings were of the same length, difference in pitch being secured by varying the thickness of the strings. A classification of the new instruments was based on the disposition of the strings space altogether, whereby the third method of stringing the strings was evolved. In these new instruments the strings lay over the sound-chest, raised on bridges which determined their vibrating length. The musical instrument, by the addition of the bow, divided the strings into separate units. As examples of this type may be cited the psaltery or psaltery, and in the middle ages the zither.

The term stringed instrument, as a means of increasing its scope, created a new class of instruments in which the principal of the principal members were the clavicymbalum, the virginal, spinet, and the harpsichord. In these the principle of plucking the strings was determined by a plectrum. The strings were fixed in the pivoted tongue of a piece of wood, known as a “jack”, which rested on the end of a balanced key. The jack worked easy through a rectangular hole in the soundboard, and when the key was pressed down the jack was thrown up, the quilt catching the string and plucking it. The string thus plucked vibrated over the whole length from hitch-pin to belly-brIDGE (cf. the effect of the bow in the violin). The strings were stretched over the fretted finger-board, for which the pegs were placed half-way up the neck, a complement of a finger-strings stretched a note from the bridge tail-piece to the end of the neck, where a second peg was fixed. The strings were divided in the class of lute instruments, for which the order which produced but one note, were about 5 ft. long; the education of similar construction was in size between the former and the latter.

The spectrum was used to pluck the strings in classic Greece and Rome, in order to provide an additional effect of brilliancy for joyous or martial themes. If the music gained in brilliancy, the instrument lost the power of expressing the performer’s emotions. During the middle ages the use of wire and spun strings in some instruments, such as the mandola, rendered the use of the spectrum a necessity. 2. Stripes struck by Hammers or Tongues.—The earliest known instrument thus played was the Assyrian dulcimer, or psaltery, recognized during the historical period by Layard from the mound of Kuyunjik, and preserved at the British Museum among scenes from the history of Sardanapalus; it is the instrument erroneously rendered psaltery in Dan. iii. 5, while the instrument mentioned in the Authorized Version of the Bible should be bugabbe.

In the dulcimer the strings, as in the psaltery, were stretched over a rectangular or trapzezoid sound-chest, the vibrating length being determined by means of two bridges. The strings were struck by means of two curved sticks, or by hammers, with an elastic wrist action, which produced clear, bell-like tones. The dulcimer has survived in the kombos or cimbal of the Hungarian gypsy. The application of the keyboard to the dulcimer produced the clavichord and the piano-forte. In the earliest clavichords, known as frettet (Ger. gebunden), one string was made to vibrate by the throw of a key. The strings were divided into notes, the notes being produced by a key with a brass tapering towards the bottom, where it was fastened into the end of the key, replaced the hammer of the dulcimer, for which it was hardly a substitute for the following reason. The function of the hammer on the strings of the dulcimer, the tangent remained on the tangent in the clavichord. When the key was pressed down, and as it rose cloth dampers stopped the vibration. It is usual to compare the tangent of the clavichord to the hammer of the dulcimer, but the action of the tangent more nearly resembles the pressure of the fingers on the violin string. The finger in the dulcimer is a fixed point of the vibrating length of the violin string from the bridge, so the tangent sets the strings vibrating from the point of impact to the belly-brIDGE. By twisting the key levers, the tangents belonging to the subsequent notes were brought to bear on the string or group of unisons at different points, all the strings being of the same length. It was not until the 18th century that fret-free or hand-strung clavichords were invented; they had throughout the compass a key and a tangent to each pair of unisons. The action of the hammer of the dulcimer reappeared in the pianoforte. Owing to this similarity of action it was possible to produce on the clavichord the vibrato effect (Bebang) of the violin, a result which is impracticable on any other keyboard instrument. 3. Strings set in Vibration by Friction of the Bow.—Although used with various other instruments such as the viol in the eighteenth century and by the German predecessor the rebec, with the oval vielle, the guitar, or troubadour-fiddle and the viols, it is with the bow on the perfecrioned type represented by the violin family that we are dealing here. Speaking of the bow, the capacity of bringing the bow to the strings, difference in pitch being secured by thickness and tension. The fingers, by pressing the strings, produce a variety of notes from each string at a moment shortening the vibrating section as the position of the fingers shifts in the direction of the bridge. The friction of the bow on the string induces a twofold vibration, the actual longitudinal vibration of the string and the string, both of which functions are transmitted to the soundboard, whereby they become intensified or reinforced. To this class belong also the Welsh crwth and the tromba marina.

4. Strings set in Vibration by Friction of a Wheel.—This class is small, being represented mainly by the organistrum and the hurdy-gurdy and a few sostenite keyboard instruments. In these instruments the rosin-shoulder performs mechanically the function of the bow, setting the strings in vibration as it revolves. A row of ten or twelve keys controlling wooden tangents performs the function of the fingers in stopping the strings. Two or more strings outside the range of the tangents always sound the same drone bass; the fingers play only on the strings. In the cithara and the organistrum, however, the strings are divided into aliquot parts, thus producing various harmonics.

Section B.—There are, besides, certain structural features in the instruments independent of the strings, which influence the quality of tone to a greater or lesser degree. First, the construction of the sound-chest, the box form consisting of back and belly or soundboard, joined by ribs of equal width, giving the best results in classes 1 and 3. The sound-chest, consisting of a vaulted back to which is glued a flat soundboard, gives very poor results in class 3, but is eminently suitable for class 1. The position and shape of the sound-holes on each side of the strings for bowed instruments, and in the center for plucked, in which the strings are plucked, are not without influence on the tone. STROP, to remove or tear off the outer covering of anything, hence to rob or plunder; also a narrow long piece of stuff or material, or a mark or division narrow in proportion to its length distinguished from its ground or surroundings by colour or other variation of texture, character, &c.; a stripe; this last word is a variant of "strip," a particular meaning, that of a stroke or lash of a whip, is either due to the original meaning of "strip," to fay, or to the long narrow mark or wheel left by a blow. The O. Eng. strapes, to strip, is cognate with Du. streepen. sire. strof, an act of tearing, or a stroke, is possibly seen in "strike," Lat. stringere. "To strip" has many times been used to separate the tobacco leaf from the stems, to remove the overlying soil from a mineral deposit before opening and working it, to turn a gun-barrel in a lathe, &c. In architecture, a "strip-pilaster" is a narrow pilaster such as is found in Saxon work and in the Italian Romanesque churches. "Stripling," a youth, is apparently a diminutive of "strip," in the sense of a young growing lad.

STRODE, RALPH (fl. 1350-1400), English schoolman, was probably a native of the West Midlands. He was a fellow of Merton College, Oxford, before 1360, and famous as a teacher of logic and philosophy and a writer on educational subjects. He belonged, like Thomas Aquinas and Bonaventura, to that "School of the Middle" which meditated between realists and nominalists. Besides his Logica, which has not survived, he wrote Consectuamia, a treatise on the syllogism, and Obliga- tiones or Scholastica milita, a series of formal exercises in scholastic dialectics. He had some not unfriendly controversy with his colleague John Wyclif, against whom he defended the possession of wealth by the clergy, and held that in the Church abuses were better than disturbance. He also attacked Wyclif's doctrine of predestination. His positions are gathered from Wyclif's Responsorum ad Redolphum Strudum (MS. 3926,
STRODE, W.—STRONTIUM

Vienna Imperial Library). Strode is also associated with John Gower in Chaucer's dedication of Troilus and Criseyde, and Strode himself, according to the 15th-century Vetus catalogus of fellows of Merton, was a "poeta nobilis." Leland and Bale confirm this testimony, and Professor I. Gollancz has suggested the identification of the Phantasma Rodulphi attributed to Strode to put the name of the 15th-century elegiac poem The Pearl. If this hold good, Strode wrote also Cleanliness, Patience, and Sir Gawayne and the Green Knight. From 1375 to 1385 this Strode or another of the same name was common sergeant of the city of London; he died in 1387.

See Prantl, Geschicht der Logik: for an attempt to distinguish between Strode the schoolman and Strode the poet, see J. T. T. Brook, in The Scottish Antiquary (1897), vol. xi.

STRODE, WILLIAM (1598–1643), English parliamentarian, second son of Sir William Strode, of Newham, Devon. A policy of (a member of an ancient family long established in that county, which became extinct in 1897), and of Mary, daughter of Thomas Southcote of Bovey Tracey in Devonshire, was born in 1598. He was admitted as a student of the Inner Temple in 1614, matriculated at Exeter College, Oxford, in 1617, and took the degree of B.A. in 1619. He was returned to parliament in 1624 for Brereton, and represented the borough in all succeeding parliaments till his death. He from the first threw himself into opposition to Charles I. and took a leading part in the disorderly scene of the 2nd of March 1629, when the speaker, Sir John Pym, refused to put the resolution of Sir John Eliot, that arbitrary taxation and innovations in religion, was held down in the chair (see Holles, Denzel). Prosecuted before the star chamber, he refused "to answer anything done in the House of Parliament but in that House." On the 7th of May a fresh warrant was issued, and a month later, to prevent his release on bail, he was sent by Charles with two of his fellow members to the Tower. Refusing to give a bond for his good behaviour, he was sentenced to imprisonment during the king's pleasure, and was kept in confinement in various prisons for eleven years. In January 1640, in accordance with the king's new policy of reconciliation, he was liberated, and on the 13th of April took his seat in the Short Parliament, with a mind embittered by the sense of his wrongs.

In the Long Parliament, which met on the 3rd of November 1640, he was the first to propose the control by parliament over ministerial appointments, the militia, and its own duration; supported the Grand Remonstrance of the 7th of November 1641; and displayed a violent zeal in pursuing the prosecution of Strafford, actually proposing that all who appeared as the prisoner's counsel should be "charged as conspirators in the same treason." As a result he was included among the five members, the others being Sir Fabius of Grafton, Sir John Hampden, John; Hesbidge, Sir Arthur; and Charles I. He opposed all suggestions of compromise with Charles, urged on the preparations for war, and on the 23rd of October was present at the battle of Edgehill. In the prosecution of Laud he showed the same relentless zeal as he had in that of Strafford, and it was he who, on the 28th of November 1644, carried up the message from the Commons to the Lords, desiring them to hasten on the ordinance for the archbishop's execution. Strode did not long survive his victim. He is mentioned as having been elected a member of the assembly of divines on the 31st of January 1645. He died on the 9th of September of the same year, and by order of parliament was accorded a public funeral in Westminster Abbey. The body was exhumed after the Restoration. Strode was a man of strong character, but of narrow, though clear and decided judgment, both his good and his bad qualities being exaggerated by the wrongs he had suffered. Clarendon speaks of him as a man "of low account and esteem," who only gained his reputation by his accidental association with those greater than himself; but to his own party his "insuperable constancy" gave him a title to rank with those who had, at the time when the wealth of England hung in the balance, deserved best of their country.

The identity of the W. Strode imprisoned in 1628 and of the W. Strode impeached in 1642 has been questioned, but is now established. See Monist, Mem. Mem. Winnersh, edn. of J. Eliot, ed. 1872, ii. 237, note; J. L. Sanford, Studies, p. 397; Gardiner, Hist. of England, ix. 223). On the other hand he is to be distinguished from Colonel Wm. Strode of Barrington, also parliamentarian and K.I.P., who died in 1661; and from William Strode (1602 or 1603–1645), the orator, poet and dramatist, whose poetical works were edited, with a memoir, by Bertram Dobell in 1907.

STRONTIUM, a police burgh and seaport, in the island of Pomona, county of Orkney, Scotland. Pop. (1901), 2450. It is situated on the side of a well-sheltered bay, 14 m. by steamer west of Kirkwall. Many of the houses are within tidal limits and furnished with quays and jetties. The harbour admits vessels of all sizes and is provided with a pier and slips. The deep-sea fishery attracts hundreds of boats from the north of Scotland and most of the catches are landed at Stornoway, though there are ruins of the palace built by Robert Stewart, earl of Orkney (d. 1592), natural son of James V., the traces of which is believed to have been built by Jarl Thorfinn on his return from Rome, in which the remains of St Magnus reposed until their burial in Kirkwall Cathedral, and, on the Broch of Birsay (5 ft. high), the ruins of St Peter's church.

STRONGYLIUM, a Greek sculptor, the author of a bronze figure of a horse set up on the Acropolis of Athens late in the 5th century B.C., which represented the wooden horse of Troy with the Greek heroes inside it and looking forth. The inscribed basis of this figure has been found. Other works of the sculptor were a figure of Artemis at Megara, a group of the Muse with an Amazon which was greatly admired by the emperor Nero.

STRONTIANITE, a mineral consisting of strontium carbonate, SrCO₃. It takes its name from Strontian in Argyllshire, where it appears to have been known as far back as 1764, but it was not recognized as a distinct mineral until later, when the examination of it led to the discovery of the element strontium. It crystallizes in the orthorhombic system and is isomorphous with aragonite and witherite. Distinctly developed crystals are, however, of rare occurrence; they are usually acicular with acute pyramid-planes and are repeatedly twinned on the prism. Many of the saltier specimens are, however, of a much finer texture.

The colour is white, pale green or yellowish brown. The hardness is 3½ and the specific gravity 3.7. Strontium is sometimes partly replaced by an equivalent amount of calcium. The mineral occurs in metalliferous veins in the lead mines of Strontian in Argyllshire, Pateley Bridge in Yorkshire, Brünsdorf near Freiberg in Saxony; abundantly in veins in calcareous marl near Münster and Hamm in Westphalia; and in limestone at Schoharie in New York. It is used for producing red fire in pyrotechny and for refining sugar.

STRONTIUM [Symbol Sr] is a soft, heavy, white-grey metal weight 87.62 (140) and atomic weight 87.62 (140). It is a metallic chemical element belonging to the alkaline earth group. It is found in small quantities very widely distributed in various rocks and soils, and in mineral waters; its chief sources are the minerals strontianite, celestine and barytocalcine. The metal was detected in the mineral strontianite, found at Strontian in Argyllshire, by Cruikshank in 1877, and by Crawford in 1879; and the discovery was confirmed by Hope in 1872 and by Klaproth in 1793. The metal was isolated in 1807 by Sir H. Davy by electrolysis of the moist hydroxide or chloride, and has been obtained by A. Guntz and Roederer (Comptes rendus, 1890, 145, p. 908) by heating, the hydrate in a vacuum to 100°. By dissolving an aqueous solution of the chloride with a mercury cathode, a liquid and a solid amalgam, SrHg₂, are obtained.
The hydrate, SrH₂O, was obtained by Gunz on heating strontium amalgame in a current of hydrogen. It is a white solid, which readily decomposes in the cold and behaves as a strong reducing agent. It dissociates when heated to a high temperature and produces hydrogen. The hydrate or strontium oxide is formed by strongly heating the nitrate, or commercially by heating the sulphide or carbonate in superheated steam (at about 500–600°C). It is a white amorphous powder which resembles lime gas. It is decomposed by dry ammonia and hydroxide, and is soluble in ammonia and water, and its solution is decomposed by excess of nitric acid. It forms a crystalline precipitate when hydrogen peroxide is added to an aqueous solution of strontium hydroxide.

Strontium fluoride, SrF₂, is obtained by the action of hydrofluoric acid on the carbonate, or by the addition of potassium fluoride to strontium chloride solution. It may be obtained as a yellowish or white solid by heating the anhydrous fluoride or by heating the amorphous variety to redness with an excess of an alcoholic chloride. Strontium chloride, SrCl₂·6H₂O, is obtained by dissolving the carbonate in hydrochloric acid, or by fusing the carbonate with calcium chloride and extracting the melt with water. It crystallizes in small colourless needles and is easily soluble in water; the concentrated aqueous solution dissolves bromine and iodine readily. By concentrating the aqueous solution between 90–150°C, or by passing hydrochloric acid gas into a saturated aqueous solution, a second hydrated form of composition, SrCl₂·2H₂O, is obtained. The anhydrous chloride is formed by heating strontium or its monoxide in chlorine, or by heating the hydrated chloride in a current of hydrochloric acid gas, or by fusing the carbonate with gaseous hydrochloric acid to form SrCl₂·NH₃, and when heated in superheated steam it decomposes with evolution of hydrochloric acid.

Strontium sulphide, SrS, is formed when the carbonate is heated to redness in a stream of nitrogen or by igniting the oxide with magnesium (H. R. Ellis, Chem. News, 1899, 99, p. 4). It is readily decomposed by water, with liberation of ammonia. Strontium nitrate, Sr(NO₃)₂, is formed by dissolving strontium salts in nitric acid. It crystallizes from water (in which it is very soluble) in monoclinic prisms which approximate in composition to Sr(NO₃)₂·4H₂O or Sr(NO₃)₂·5H₂O. When heated it fuses in its own water of crystallization and becomes anhydrous at 110°C. It is used in pyrotechny for the manufacture of red-fire. A strontium boride, SrB₄, was obtained as a black crystalline powder by H. Moissan and P. Williams (Comptes rendus, 1897, 123, p. 633) by reducing the borate with aluminium in the electric furnace.

Strontium carbide, SrC₂, is obtained by heating strontium carbonate with carbon in the electric furnace. It resembles calcium carbide, decomposing rapidly with water, giving acetylene. Strontium oxide, SrO, is formed in the furnace in the case of a solution of a carbonate is added to one of a strontium salt. It is an amorphous solid, insoluble in water, but its solution in hydrochloric acid forms the precipitate of strontium hydroxide.

Strontium salts may be recognized by the characteristic crimson colour they impart to the flame of the Bunsen burner and by the precipitation of the insoluble sulphate. On the preparation of pure strontium salts, see Adrian and Bougarel, Journ. pharm. chim., 1892 (5), p. 345; and S. P. L. Sooreen, Zeit. anorg. chem., 1904, 30, p. 376. Strontium compounds are due to T. W. Richards (Zeit. anorg. Chem., 1905, 47, p. 145), who, by estimating the ratios of strontium bromide and chloride to silver, obtained the values 87 663 and 87 661.

STROPHANTHUS, a genus of plants of the natural order Apocynaceae, deriving its name from the long twisted thread-like segments of the corolla, which in one species attain a length of 12 or 14 inches. The genus comprises about 30 species, mainly tropical African, extending into South Africa, with a few species in Asia, from farther India to the Philippines and China. Several of the African species furnish the natives with the drug from which picrotoxin is derived. It contains poison of the Gouroum, the koubé of equatorial North Africa, the arghas of the banks of the Niger and the Warren and Kanizibar are all derived from members of this genus. The exact species used in each case cannot be said to be accurately known. There is no doubt, however, that S. hispidus and S. kombe are those most frequently employed.

Both S. hispidus and S. kombe have hairy seeds with a slender thread-like appendage, terminating in a feathery tuft of long silky hairs, the seeds of the former being coated with short hairs and those of the latter with the hairs flattened. It is furnished in the species used at Delagoa Bays, and called "uncoiled." The thread-like appendage of the seed is absent. The natives pound the seeds into an oily mass, which assumes a red colour, portions of this mass being smeared on the arrow immediately behind the barb.

Under the name of strophanthi semina, the dried ripe seeds of Strophanthus kombe, freed from awns, are official in the British and many other pharmacopoeias. The seeds must be mature. They are about ⅛ in. long, ⅛ in. broad, greenish fawn, covered with flattened silky hairs, and oval-acuminate in shape. They are almost odourless, but have an intensely bitter taste. The chief constituent is a white microcrystalline glucoside, known as strophanthine, a very slowly soluble crystalline substance, not virtually volatile, or ether, and melting at about 178°C. It constitutes about 50% of the mature cotyledons of the seed, the proportion rising as maturity is reached. It is very similar to, but not identical with, onabain. It is split up by acids into strophanthin and a methyl-ether of a peculiar sugar. The seeds also contain an active principle, inuin, a body known as kobic acid, fat, resin and starch. The resin is contained in the husk, and occurs in the alcoholic tincture of strophanthus, its presence tending to cause digestive disturbance and diarrhea. When the seeds are treated with sulphuric acid and heat is applied, a violet-coloration is produced. A section of the seeds nears a greenish, due to the cold sulphuric acid.

The British Pharmacopoeia contains two preparations of this important and valuable drug, a dry extract and a tincture. The former is hardly ever prescribed. The official tincture is much preferred, in that originally introduced into medical practice, in being much too weak, and in being prepared with alcohol instead of ether, which differs from alcohol in not dissolving the resin contained in the husks. It is therefore advisable to order the tincture of the British Pharmacopoea of 1885, or to prescribe the tincture in double the official dose and combined with cardamoms, ginger or capsicum, in order to counteract the irritating properties of the resin which it contains.

Strophanthin itself may be injected hypodermically in doses of 1/100 to 1/10 grain. Unfortunately the injections usually cause some pain and sometimes produce some local irritation, which is due to the fact that the dose is the only one of any avail when a result is wanted at once or even within several hours. Precisely the same observation applies to digitalis, the other great cardiac tonic.

Pharmacology.—The common action of strophanthin is as follows:—

1. It has a direct peripheral action on the heart muscle; the force of contraction is increased, and the cardiac muscle is more resistant to the action of the artificial irritant. The electric stimulator has no action on the muscle under the influence of strophanthin.

2. It is a positive chronotropic agent, increasing the heart rate, and in this respect resembles digitalis. The rhythm of the heart remains unchanged. This action is produced in the presence of a sufficient quantity of the drug, but, in general, it stimulates the heart before it has become excited, and when the heart is much excited it has little or no effect. It is stronger than digitalis in this respect.

3. It causes a direct peripheral action on the heart muscle; the force of contraction is increased, and the cardiac muscle is more resistant to the action of the artificial irritant. The electric stimulator has no action on the muscle under the influence of strophanthin.

4. It is a positive chronotropic agent, increasing the heart rate, and in this respect resembles digitalis. The rhythm of the heart remains unchanged. This action is produced in the presence of a sufficient quantity of the drug, but, in general, it stimulates the heart before it has become excited, and when the heart is much excited it has little or no effect. It is stronger than digitalis in this respect.

5. It causes a direct peripheral action on the heart muscle; the force of contraction is increased, and the cardiac muscle is more resistant to the action of the artificial irritant. The electric stimulator has no action on the muscle under the influence of strophanthin.

6. It is a positive chronotropic agent, increasing the heart rate, and in this respect resembles digitalis. The rhythm of the heart remains unchanged. This action is produced in the presence of a sufficient quantity of the drug, but, in general, it stimulates the heart before it has become excited, and when the heart is much excited it has little or no effect. It is stronger than digitalis in this respect.
STROPHÉ—STROUD

STROPHÉ (Gr. στροφή, from στρέφειν, to turn), a term in versification which properly means a turn, as from one foot to another, or from one side of a chorus to the other. In its present use the strophe is a collection of various prosodical systems combined into a structural unit. In modern poesy the strophe usually becomes identical with the stanza, and it is the arrangement and the recurrence of the rhymes which give it its character. But the ancient strophe was a combination of verse-periods a system, and gave the name strophe to such a system only when it was repeated once or more in unmodified form. It is said that Archilochus first created the strophe by binding together systems of two or three lines. But it was the Greek ode-writers who introduced the practice of strophe-writing on a large scale, and the art was attributed to Stesichorus, although it is probable that earlier poets were acquainted with it. The arrangement of an ode in a splendid and consistent artificial strophe, antistroph and epode was carried to its height by Pindar (see One). With the development of Greek prosody, various peculiar strophe-forms came into general acceptance, and were made characteristic of poets. For instance, the epode in the Iliad was a strophe in a strophic poem. Among these were the Sapphic, the Eleigic, the Alcaic and the Iildean strophe, all of them prominent in Greek and Latin verse. The briefest and the most ancient strophe is the dactylic distich, which consists of two verses of the same class of rhythm, the second producing a melodic counterpart to the first. The forms in modern English verse which reproduce most exactly the impression aimed at by the ancient ode are the elaborate rhymed stanzas of such poems as the "Nightingale of Keats or the "Scholar-Gypsy" of Matthew Arnold (see Verse).

STROSSMAYER, JOSEPH GEORGE [JOSEF JURAJ ŠTROSMAYER] (1815–1905), Croatian bishop and politician, was born at Esseg in Croatia-Slavia on the 4th of February 1815. Strossmayer was of German descent and his parents had emigrated from Linz in Austria. He was educated at the Roman Catholic seminary of Djakovo, in his native country, and at Budapest, where he studied theology. In 1838 he took holy orders, and during the next ten years became lecturer on theology at the Seminary of St. Stanislaus in Hungarian and Cyrillic, professor, and director of the Augustinian body at Rome. In 1849 he was consecrated bishop of Djakovo, with the official title "Bishop of Bosnia, Slavonia and Sirmium." He fostered the growth of Slavonic nationalism in Croatia-Slavia, in Dalmatia, and among the Slovaks of south Austria, aiding the Ban Jelačić in his campaigns against Hungary (1848–49), and subsequently becoming a recognized leader of the opposition to Hungarian predominance (see CROATIA-SLAVONIA). Besides being foremost among the founders of the South Slavonic Academy in 1867, and of Agram University in 1874, he helped to reorganize the whole educational system of Dalmatia and Croatia-Slavia. He built a palace and cathedral at Djakovo, founded a seminary for the Bosnian Croats, presented the South Slavonic Academy with a gallery of valuable pictures, and published collections of national songs and tales. He also aided Augustin Theiner, then librarian at the Vatican, to compile his VETERA MONUMENTA Slavorum meridionalium historiam illustrantes (Rome, 1863). As a theologian, Strossmayer became prominent by his energetic opposition to the dogma of infallibility at the Vatican council of 1870, and by his denunciation of the Jesuits, while they in return charged him with allowing Communards into the school, and the orthodox Greek confession. For years he refused to accept the doctrine of infallibility, but ultimately he yielded. Despite this attitude, he enjoyed the confidence of PONTIF. XIII. He headed the Slavonic depositions which visited Rome in 1881 and 1888, and won for them the retention of a Slavonic liturgy by the Roman Catholics of Illyria. Strossmayer withdrew from political life in 1888, in consequence of a rebuke administered to him by the emperor for his public expression of sympathy with Russia and his consistent hostility to Hungary. He died in his ninety-first year, on the 19th of April 1905. He was a canon of the Holy Roman Empire, a bishop of the pontifical throne, and a member of the theological faculties of Budapest and Vienna. By Leo XIII. he was decorated with the archiepiscopal pallium.

STROUD, a market town in the Stroud parliamentary division of Gloucestershire, England, 102¼ m. W. by n. of London. Pop. of urban district (1901), 9153. It is served by the Great Western railway and a branch of the west-and-north line of the Midland. It lies on the steep flank of a narrow and picturesque valley and traversed by the Thames and Severn and the Stroudwater canals, which unite at Wallbridge close by. The church of St. Lawrence is modern excepting the tower and spire. The Elizabethan town-hall and the school of science and art, commemorating Queen Victoria, are noteworthy. Stroud is the principal seat of the west of England cloth manufacture, the industry extending to Stonehouse and other places in the vicinity. Stroud has also silk-mills, dyeworks, breweries, foundries, and a manufacture of umbrellas and walking-sticks.

There is no evidence of the existence of Stroud before the Conquest, and in 1067 it was still part of the manor of Bisley, from which it was separated in the reign of Edward II. It became a centre of the cloth trade in the Tudorperiod. In 1607 Henry, Lord Danvers, lord of the manor, obtained a charter from James I., authorizing a weekly market. During the 18th century the commercial importance of the town increased, though, owing to its distance from any of the great highways and to the localization of the clothing trade in scattered factories near water power, it was never a great centre of population. By the Reform Act of 1832 Stroud became a borough and returned two members to parliament until 1885, when it was merged in the Stroud division of Gloucestershire. The manufacture of very fine brocadel and of scarlet-dyed cloth
STROZZI—STRUENSEE

Strozzi, the name of an ancient and noble Florentine family, which was already famous in the 14th century. Palla Strozzi (1372–1462) played an important part in the public life of Florence, and founded the first public library in Florence in the monastery of Santa Trinita. Filippo Strozzi il Vecchio (1426–1491), son of Matteo and of Alessandra Macigni, a famous literary woman, began to build the beautiful Strozzi palace in Florence. More celebrated was another Filippo Strozzi (1488–1538), who, although married to a Medici, opposed the hegemony of that house and was one of the leaders of the rising of 1527. On the final overthrow of the republic in 1530 Alessandro de' Medici attempted to win over Filippo Strozzi, but Strozzi had no faith in the tyrant and retired to Venice. After the murder of Alessandro he undertook the leadership of a band of republican exiles with the object of re-entering the city (1537); but having been defeated and captured and put to the torture, he committed suicide. His son Leone (1535–1554) was a distinguished admiral in the service of France and fought against the Medici; he died of a wound received while attacking Sarzino. Another Filippo (1441–1528) served in the French army, and was captured and killed by the Spaniards. Senator Carlo Strozzi (1587–1671) formed an important library and collected a valuable miscellany known as the *Carlo Strozziiane*, of which the most important part is now in the state archives of Florence; he was the author of a *Storietta della città di Firenze dal 1370 al 1592* (unpublished) and a *Storia della casa Barberini* (Rome, 1649). The Strozzi acquired by marriage the titles of princes of Forano, dukes of Bagnolo, &c. The Strozzi palace, which belonged to the family until 1907, was bequeathed by will to the Italian nation.

See A. Bardi, *Filippo Strozzi* (Florence, 1894); B. Niccolini, *Filippo Strozzi* (Florence); C. Guasti, *Le Carte Strozziiane* (Florence, 1884–1891).

STRUENSEE, JOHAN FREDERICK (1731–1772), Danish political philosopher, was born at Halle in 1731. His father, subsequently superintendent-general of Schleswig-Holstein, was a rigid Pietist; but young Struensee, who set himself down in the 'sixties as a doctor at Altona, where his superior intelligence and elegant manners soon made him fashionable, revolted against the narrowness of his father's creed, became a fanatical propagandist of the atheism associated with the *Encyclopädie*, and scandalized his contemporaries by his frank licentiousness. But he was a clever doctor, and, having somewhat restored the king's health, and gained his affection, was retained as court physician, accompanied Christian VII. on a foreign tour and returned with him to Copenhagen. It had always been Struensee's ambition to play a great part. In 1770 at 25 he expressed his dream of reform. He had gathered from various Danish friends, most of them involuntary exiles of doubtful character, that the crazy, old-fashioned Dano-Norwegian state, misruled by an idiot, was the fittest subject in the world for the experiments of a man of superior ingenuity like himself; and he proceeded to worm his way to power with considerable astuteness.

First he reconciled the king and queen, for he calculated shrewdly enough, that if the king was to be his tool he must needs make the queen his friend. At first Carolina Matilda disliked Struensee, but the unfortunate girl (she was scarce eighteen) could not fail to be deeply impressed by the highly gifted young doctor, who speedily and completely won her heart. By January 1770 she was notoriously her lover; a successful vaccination of the baby crown prince in May still further increased his influence; and when, in the course of the year, the king sank into a condition of mental torpor, Struensee's authority became paramount. Previously to this, the capable minister of foreign affairs, J. H. E. Bernstorff (q.v.), was got rid of by a royal letter of the 13th of September 1770, and Struensee's disreputable friend, the exiled Count Rantzau-Ascheburg, was recalled to court; and with him came another Altona acquaintance of Struensee's, Enevold Brandt, who had also been living abroad under a cloud.

For a time Struensee kept himself discreetly in the background, though from henceforth he was the wirepuller of the whole political machine. But he soon grew impatient of his puppets. In December the council of state was abolished; and Struensee appointed himself *maître de reqüetes*. It was now that he endeavored to bring all the reports from the various departments of state; and, Christian VII. being scarcely responsible for his actions, Struensee dictated whatever answers he pleased. His next proceeding was to dismiss all the heads of departments, and to abolish the Norwegian stadholderships. Henceforth the cabinet, with himself as its motive power, was to be the one supreme authority in the state. Unfortunately, he had made up his mind to regenerate the benighted Danish and Norwegian nations on purely abstract principles, without the slightest regard for native customs and predilections, which in his eyes were prejudices. He was hampered moreover, by not knowing a word of Danish. Many of his reforms, such, for instance, as the establishment of foundling hospitals, the abolition of capital punishment for theft and of the employment of torture in judicial process, the doing away with such demoralizing abuses as perquisites, and of "lackeyism," or the appointment of great men's domestic to lucrative public posts, were distinctly beneficial if not original. Unfortunately reform was not as much a principle as a mania with Struensee. The mere fact that a venerable institution still existed was a sufficient reason, in his eyes, for doing away with it. Central to which a prudent minister might have been expected to have been introduced is in a generation he rushed through in less than a fortnight. Between the 29th of March 1771 and the 16th of January 1772—the ten months during which he held absolute sway—he issued no fewer than 1096 cabinet orders, or more than three a day. In order to be sure of obedience he dismissed wholesale without pension or compensation the staffs of all the public departments, substituting for old and experienced officials nominees of his own, in many cases untired men who knew little or nothing of the country they were supposed to govern.

The dictator's manners were even worse than his morals. He habitually adopted a tone of insulting superiority, all the more irritating as coming from an ill-informed foreigner; and sometimes he seemed deliberately to go out of his way to shock the most sacred feelings of the respectable people. Nor was this all. His system of retrenchment, on which he particularly prided himself, was in the last degree immoral and hypocritical, for while reducing the number of the public officials, or clipping down their salaries to starvation points, he squandered thousands upon balls, masquerades, and other amusements of the court, and induced the imbecile king to present him and his friend Brandt with 600,000 Rigsdaler as a gift.

Still, in spite of all his blunders and brutalities, it is clear that, for a short time at least, middle-class opinion was, on the whole, favourable to him; and, had he been wise, he might perhaps have been able to defy any hostile combination. But such was his contempt for the Danish people that he cared not a jot whether they approved or disapproved of his reforms. What incensed the people most against him was the way in which he put the king completely on one side; and this feeling was all the stronger as, outside a very narrow court circle, nobody seems to have believed that Christian VII. was really mad, but only that his will had been weakened by habitual ill usage; and this opinion was confirmed by the publication of the cabinet order of the 14th of July 1771, appointing Struensee "ghejme kabinetminister," with authority to issue cabinet orders which were to have the force of royal ordinances, even if unprovided with the royal sign-manual.
Nor were Struensee's relations with the queen less offensive to a nation which had a traditional veneration for the royal house of Oldenburg, while Caroline Matilda's shameless conduct in public brought the Crown into contempt. The society which daily gathered round the king and queen excited the derision of the foreign ambassadors. The unhappy king was little more than the butt of his environment, and once, when he threatened his keeper, Brandt, with a flogging for some impertinence, Brandt, encouraged by Struensee and the queen, actually locked him in his room and beat him with his fists till he begged for mercy. Things were at their worst during the winter of 1772; the queen, who had, in the meantime, created himself a count, now gave full rein to his licentiousness and brutality. If, as we are assured, he publicly snubbed the queen, we may readily imagine how he treated common folk. Before long the people had an opportunity of expressing their disgust openly. In the summer of 1772, Caroline Matilda was delivered of a daughter, who was christened Louise Augusta; and a proclamation commanded that it "Te Deum" in honour of the event should be sung in all the churches; but so universal was the belief that the child was Struensee's that, at the end of the ordinary services, the congregation rose and departed en masse.

The general ill will against Struensee, which had been smouldering all through the autumn of 1771, found expression at last in a secret conspiracy against him, headed by Rantzau-Ascheburg and Brandt, in the name of the queen-dowager Juliana Maria. Early in the morning of the 17th of January 1772 Struensee, Brandt and the queen were arrested in their respective bedrooms, and "the liberation of the king," who was driven round Copenhagen by his deliverers in a gold carriage, was received with universal rejoicing. The chief charge against Struensee was that he had usurped the royal authority in contravention of the Kongelov. He defended himself with considerable ability and, at first, confident that the prosecution would not dare to lay hands on the queen, he denied that their liaison had ever been criminal. But, on hearing that she was also a prisoner of state, his courage evaporated, and he was base enough to betray her, though she did all in her power to shield him. On the 25th of April Struensee and Brandt were condemned first to lose their right hands and then to be beheaded; their bodies were afterwards to be drawn and quartered. Sentence of death was the least that Struensee had to expect. He had undoubtedly been guilty of base-motives in the usurpation of the royal authority, both capital offences according to pars. 7 and 26 of the Kongelov. The sentences were carried out on the 28th of April, Brandt suffering first.

STUTT, JEDEDIH (1726-1707), British inventor and manufacturer, was born at South Normanton, Derbyshire, where his father occupied a farm, on the 28th of July 1726. He was educated at a good country school, with a view to becoming a farmer, but, showing great aptitude for mechanical arts, he was in 1740 articled for seven years to a wheelwright at Fidnern, near Derby. Here he lodged with a hosier, Woodall, whose daughter he married in 1755. In the meantime he had inherited, from his uncle, the stock on a farm at Blackwell, near south Normanton, now, and probably then, the property of the duke of Devonshire. While in occupation of this farm his brother-in-law, William Woollatt, brought to his notice the efforts that had been unsuccessfully made to produce ribbed as well as plain goods on the stocking frame, and here he invented Strutt's Derby ribbing machine. Strutt and Woollatt in 1758 and 1759. Strutt went to live at Derby, and with his brother-in-law started a factory, "Derby Patent Ribs," at once becoming popular. In 1762 Strutt and Woollatt joined Samuel Need, a hosier of Nottingham, and carried on there and at Derby a very successful business. In 1768 they were approached by Richard Arkwright (g.v.), who had been recommended by Messrs Wright, bankers of Nottingham, to consult Need as to the possibilities of his cotton-spinning frame. Strutt at once realized its value, and was able to solve one or two minor difficulties which had interrupted the smooth working of the new mechanism. The farm of Arkwright, Strutt & Need started their first cotton mill at Nottingham, for the manufacture of cotton thread. Later works were erected at Cromford and, about 1780, after Strutt dissolved partnership with Arkwright, he built himself the mills at Belper and Milford, the greater part of which are still used. The partnership with Need had terminated in 1773 with the expiration of the patents. Shortly before this Strutt had made the discovery, which revolutionized the manufacture of calico, that cotton could be used throughout in its making. To house the machinery for this new invention the first fire-proof mill in England was built at Derby. In order to be near his work Strutt built, from his own designs, a house near the mill, which he inhabited until 1795, when ill health compelled him to return to Derby. Here he died in 1797. He left three sons and two daughters.

His eldest son, William Strutt (1756-1830), was also of great mechanical ability. It was he who designed the calico factory above mentioned; he applied himself to the house-heating problem and, finally, invented the Belper stove. He also devised a self-acting spinning mule, which had however no great success. He was a fellow of the Royal Society. His son, Edward Strutt (1801-1860), was for some time M.P. for Derby, and in 1856 was raised to the peerage with the title of Baron Belper of Belper.

STRUVE, FRIEDRICH GEORG WILHELM (1793-1864), German astronomer, the son of Jacob Struve (1755-1841), was born at Altona on the 15th of April 1803. In 1808 he entered the university of Dorpat (Yurièv), where he first studied philosophy, but soon turned his attention to astronomy. From 1813 to 1820 he was extraordinary professor of astronomy and mathematics at the new university and observer at the observatory, becoming in 1820 ordinary professor and director. He remained at Dorpat, occupied with researches on double stars and geodesy till 1859, when he removed to St Petersburg, where he occupied a supervisory position at Pulkova near St Petersburg, afterwards becoming director. Here he continued his activity until he was obliged to retire in 1861, owing to failing health. He died at St Petersburg on the 23rd of November 1864.

Struve's name is best known by his observations of double stars, which he carried on for many years. These bodies had first been regularly measured by W. Herschel, who discovered that many of them formed systems of two stars revolving round their common centre of gravity. After him J. Herschel (and for some time Sir James South) had observed them, but their labours were eclipsed by Struve. With the 93-in. refractor at Dorpat he discovered a great number of double stars, and published in 1827 a list of all the known objects of this kind (Catalogus novus stellarum duplicitum). His micrometric measurements of 2714 double stars were made from 1822 to 1837, and are contained in his principal work, Tabulae stellarium duplicitum et multiplicitatum positions mediae, St Petersburg, 1837 seq.; a convenient summary of the results is given in vol. i. of the Duncaitl Observatory Publications, 1876. The places of the objects were at the same time determined with the Dorpat meridian circle (Stellarum fixarum impressis duplicitum et multiplicitiptum positions mediae, St Petersburg, 1852 seq.). At Pulkova he redetermined the "constant of aberration," but was chiefly occupied in working out the results of former years and in the completion of the geodetic operations in which he had been engaged during the greater part of his life. He had commenced with a survey of Livonia (1816-1818), which was followed by the measurement of an arc of meridian on the coast of Norway at Ismail on the Danube (Arc du méridien de 25° 20' entre le Danube et la Mer Glaciale, 2 vols., and 1 vol. plates, 410, St Petersburg, 1857-1860). (See GEODESY; EARTH, Figure of.)
STRYCHNINE.—STUPE

His son OTTO WILHELM STRUVE (b. 1819), having studied at the academy at St. Petersburg, became assistant at Pulkowa, in 1839, and director in 1862 on his father’s resignation. From 1847 to 1862 he was advising astronomer to the headquarters of the army and navy; chairman of the International Astronomical Congress from 1867-1878; acting president of the International Geographic Union in 1872; and president of the International Congress for a Photographic Survey of the Stars in 1887, in which year he was also made a privy councilor. His contributions to astronomy cover a wide field: a list of his publications is given in Poggendorff, Biographisch-Literarische, vol. 2, 3, 4.

Another son, WILHELM STRUVE (b. 1824), studied chemistry, and obtained a public appointment as chemical expert to the administration of the Caucasus.

Two of Otto Wilhelm Struve’s sons have also been prominent in the world of science. KARL HERMANN STRUVE (b. 1834) studied mathematics at Dorpat, and became in 1883 assistant, and in 1890, on his father’s retirement, astronomer at the observatory at Pulkowa. In 1895 he became professor at the Albertus University and director of the observatory at Königsberg; and in 1904 he was called to Berlin as professor and director of the observatory. One of the sons of the latter, Gustav Wilhelm Ludwig Struve (b. 1859), studied at Dorpat, Bonn and Leipzig, and became observer at the Dorpat observatory in 1886. This post he retained until 1894, when he migrated to the university of Cracow as extraordinary professor, becoming in 1897 ordinary professor of astronomy and geodesy.

STRYCHNINE, CaH2N04, an alkaloid discovered in 1818 by Pelletier and Caventou in St. Ignatius’s beans (Strychnos Ignatii); it also occurs in other species of Strychnos, e.g. S. nuxvomica, S. cedreiera, S. Trantil, and is generally accompanied by another alkaloid brucine, CaH2N04.H20, which was isolated by Pelletier and Caventou in 1819. Strychnine crystallizes from alcohol in colourless prisms, which are practically insoluble in water, and with difficulty soluble in the common organic solvents. Its taste is exceptionally bitter. It has an alkaline reaction, and is a tertiary monacid base. It is optically active, the natural form being laevorotatory. Brucine closely resembles strychnine, and is its dimethoxy derivative. The constitution is unknown (see J. Schmidt, Die Alkaloidschemie, 1904, 1909).

Medicine.—The B.P. dose of strychnine is 7/10 to 7/10 gr. in solution or pill form. A preparation is syrupsus farris phosphatus a quinta e strychnina, containing 5/12 gr. of strychnine in each fluid drachm. Strychninae hydrochloridum is also used; it is much more soluble than strychnine. From it is prepared liquor strychninae hydrochloridit, containing 1 gr. of hydrochloride in 110 minims. The United States pharma-coeia also contains strychninae nitris and strychninae sulphas. Strychnine is incompatible with liquor arsenicalis and potassium iodide.

Physiological Action.—Applied externally strychnine is a powerful antiseptic, but its poisonous nature prevents it from being used for this purpose. Brucine is a local anaesthetic. Strychnine enters the blood as such, being freely absorbed from mucous surfaces or when given hypodermically. Internally strychnine acts, as a bitter, increasing the secretion of gastric juice and the intestinal peristalsis, being a direct stimulant to the muscular coat; in this manner it has a purgative action. The specific effects of the drug, however, are upon the central nervous system. It excites the motor area of the spinal cord and increases their reflex irritability. Small doses increase the sensibility of touch, sight and hearing; large doses cause twitching of the muscles and difficulty in swallowing; while in convulsions and in tetanus spasms are produced. The convulsive convulsions remain unaffected, but the important centres of the medulla oblongata are stimulated. Not only is the brain stimulated but the cardiac centre is acted upon both directly by the deafening and indirectly for a time by the increased pressure in blood, causing a temporary arrest of all over the body. Ordinary doses have no effect upon the temperature but in overdosage may cause fever during a convulsion. Strychnine is eliminated by the kidneys as strychnine and strychnic acid. It is excreted very slowly and therefore accumulates in the system. Therapeutics.—Strychnine is chiefly used as a stimulant. It is indicated in paralyses (chiefly functional), and is most valuable in the treatment of post-diphtheretic paralysis. In progressive lead palsy, beri-beri, and the paralyses following acute alcoholism, fairly large doses are used. In syphilis, asthma, and beri-beri, where the patient is liable to sudden collapse, a hypodermic injection of strychnine will often save the patient’s life. In collapse following severe haemorrhage and in sudden and accidental arrest of the heart or respiration, strychnine in doses of 3/100 gr. may be given, or the chloretone which produces muscular injection of 8/100 gr. of the hydrochloride may stimulate the cardiac action. In acute opium poisoning strychnine is very valuable. It is a physiological antagonist of chloral hydrate, morphia, and physostigmine, and may be given by these drugs. In dyspepsia due to emphysema, phthisis and asthma, strychnine is of service, given internally in doses of 1 to 3 minims in syrup or liquor. The syrup of iron, quinine and strychnine is used as a tonic.

Toxicology.—The symptoms of strychnine poisoning usually appear within twenty minutes of the ingestion of a poisonous dose, and may be described as a sudden and intense headache, stiffness of the back, and a feeling of impending suffocation. The patient is then seized with violent convulsions of a tetanic character; the arms are stretched out, respiration impeded, the muscles are usually the body is thrown into opisthotonos, i.e. it rests bow- form on the head and the heels (occasionally the body is flexed forward [emprosthotonos], the eyes remain wide open and fixed, the stomach is not thrown upwards, the body usually relax, and the patient sinks back exhausted, consciousness being preserved throughout. Any noise, a draught of air or a touch may cause a convulsion. If the case is about to terminate fatal, the spasms may occur at intervals for several days, occurring within two hours, either from asphyxia produced by spasm of the respiratory muscles or more rarely from exhaustion. After death the position of the body may or may not be flexed; usually rigidly extended. In cases of tetanus the convulsions diminish in severity, leaving the patient exhausted. Complications are infrequent. The average fatal dose for an adult is 10,000 grains, but death has occurred in twenty minutes from the poison. On the other hand, recovery has taken place after 5 and 10 and even 20 grains have been swallowed, but in the latter case an emetic was at once administered. Idiosyncrasy plays a considerable part in determining the effects, some people being particularly susceptible. Death has occurred in five minutes from the appearance of the first symptoms, but when a narcotic has been administered at the same time as the poison the development is proportionately slow. Tetanus results from strychnine poisoning, but the development of convulsions in tetanus is usually much slower, death rarely occurring within 24 hours. In strychnine poisoning trismus or lockjaw is generally secondary to spasm of the other muscles, while in tetanus it is the first symptom, no relaxation taking place between the spasms.

The treatment of strychnine poisoning is to immediately evacuate the stomach with a stomach-evacuating mercurial, the latter being administered to allay the spasms. If the patient can swallow, draughts of water containing tannic acid may be given. Nitrite of amyl inhalations are useful in the early stages when the respiratory muscles are free. Chloral hydrate may be given. The effect of morphine may be given as physiological antidotes. If death from asphyxia appears imminent artificial respiration may be resorted to.

STREYTENS, or STREYTEK, a Cossack village of Asiatic Russia, in the province of Transbaikalia, 231 m. by rail E. of Chita, and a terminus of the Trans-Siberian railway. It is situated on both banks of the river Shika, and its population of 800 rises to over 10,000 during the season of navigation. Streypesk, has steam flour-mills and soap works.

STRYPY, JOHN (1643-1737), English historian and biographer, was born in Houndsditch, London, on the 1st of November 1643. He was the son of John Strype, or van Strype, a member of a Brabant family who, to escape religious persecution, settled in London, in a place afterwards known as Strype’s Yard in Petticoat Lane, as a merchant and silk thrower. The younger John was educated at St Paul’s School, and on the 5th of July 1662 entered Jesus College, Cambridge; whence he proceeded to Catherine Hall, where he graduated B.A. in 1665 and M.A. in 1669. On the 14th of July of the latter year he became perpetual curate of Beyton and a lecturer at St. Mary’s, Cambridge. He became vicar of Stratford and perpetual curate of Leyton in the same county. He was never instituted or inducted to the living of Leyton, but in 1674 he was licensed by the bishop of London to preach and expound the word of God, and to perform the full office of priest and curate while it was vacant, and until his death he received the profits of it. In 1717 he obtained from Archbishop Tenison the sinecure of West Tarring, Sussex, and he discharged the duties of lecturer at Hackney from 1689 till 1724. At the latter
place he spent his last years with a married granddaughter, the wife of a surgeon, Thomas Harris, dying there on the 11th of December 1757, at the age of ninety-four. He was buried in the church.

Through his friendship with Sir William Hicks Strype obtained access to the papers of Sir Michael Hicks, secretary to Lord Burghley, from which he made extensive transcripts; he also carried on an extensive correspondence with Archbishop Wake and Bishops Burnet, Atterbury, etc. The materials so obtained form the basis of his historical and biographical works, which relate chiefly to the period of the Restoration. The greater portions of his original materials have been preserved, and are included in the Latin manuscripts in the British Museum. His works can scarcely be entitled original compositions, his labour having consisted chiefly in the arrangement of his materials, but on this very account the value of the books produced is much enhanced, as it affords easier access and almost as trustworthy as the original documents.

**STUART, ARABELLA** (1575–1619), daughter of Charles Stuart, earl of Lennox, younger brother of Lord Darnley and Mary Queen of Scots, was born in London on the 25th of May 1575, and was the daughter of Don John of Austria, the son of Emperor Charles V. She was the eldest of the seven children of James, Duke of Richmond, and Mary of Guise, Queen of Scotland. His father's mother was Margaret Douglas, the daughter of Henry VII. Her daughter, Queen Margaret of Scotland, and the earl of Angus. She was born in 1575 and early became the centre of the intrigues of those who in Elizabeth's reign refused to accept James as his successor. Various suitors for her hand were proposed, including Henry IV. of France, the earl of Northumberland, and Esmé Stuart, duke of Lennox. In 1585 a plot was planned by her mother, the Roman Catholics, of marrying her to Raunuccio, eldest son of the duke of Parma, who was descended from John of Gaunt, and of raising her with Spanish support to the throne. She was in consequence regarded with suspicion and disfavour by Elizabeth and closely watched and guarded at Hardwick by the dowager countess of Shrewsbury. In 1602 the queen's suspicions were increased by the discovery of a plot to marry Arabella to Edward, eldest son of Lord Beauchamp, who as grandson of Edward Seymour, earl of Hertford, and of Lady Catherine Grey (younger sister of Elizabeth), was living in the Tower on the crown of himself and his predecessors, according to the will of Henry VIII. According to other accounts the intended husband was Thomas Seymour, a younger son of the earl of Hertford. Arabella entered with ardour into the project, and planned an escape from Hardwick with the aid of her chaplain Starkey, who after its failure committed suicide. In December she wrote secretly to Lord Hertford proposing her marriage with his grandson, but the latter immediately informed the council. In February 1603 another attempt at escape failed, and she was then transferred to the care of the earl of Kent at West House. The anxiety and anger aroused by her conduct was reputed to be the cause of Elizabeth's death the same year. When James I. had gained secure possession of the throne, Arabella was received at court and treated with favour, and she showed her fidelity to James by revealing a communication made to her by the conspirators in the Main and Bye Plots, in which her name had been used without her sanction. Every effort, however, was made to prevent her marriage. She is described at this time by Scaramelli, Venetian secretary in London, as "of great beauty and remarkable qualities, being gifted with many admirable virtues, amongst them being the knowledge of Latin, French, Spanish, Italian, besides her native English"; as having "very exalted ideas, having been brought up in firm belief that she would succeed to the crown," as limited in means, of the Puritan persuasion, and very proud, insisting on a precedence over the princesses, though ordered back by the master of the ceremonies and in consequence being expelled from the court. A little later she is called "a regular termagant" and in 1607 "not very belov'd." In December 1609 she planned an escape with Sir George Douglas to Scotland, apparently with a view of arranging a marriage with Stephen Bogdan, pretender to Moldavia, and on the scheme being discovered she was arrested. She was, however, restored to favour, granted a pension of £1600 a year by James, and given 10,000 crowns to pay her debts. But on the 2nd of February 1610 she became engaged to William Seymour, younger brother of Edward, and grandson of Lord Hertford, a suitor especially forbidden by James. A promise was exacted from them by the privy council that they would not marry without the king's consent, but nevertheless they secretly married on the 22nd of June at Greenwich. Immediately it was known the queen sent Arabella at Lambeth and her husband in the Tower. In 1611 she was placed in charge of the bishop of Durham. Her application for a writ of habeas corpus was refused, and on the 16th of March she left London, progressing however, on account of illness and prostration, only as far as Barnet. She escaped on the 3rd of June 1611 disguised in man's clothing, and succeeded in getting on board a ship bound for Calais. Meanwhile her husband had also effected his escape and was sailing towards the coast. Their two ships were drawing together when "a great wind, which was blowing, did drive them each other ever more." Soon afterwards the unfortunate Arabella was captured and brought back to the Tower, where she spent the rest of her unhappy career. James was dead to all intercession in her favour, and is reported to have answered the queen when pleading for her that "she had eaten of the forbidden fruit." In November 1613 a new plot for her escape failed. Abandoning at last all hope she sank into melancholy, ill health, and, according to some accounts, insanity, and died a victim to state policy on or about the 25th of September 1615. She was buried in the tomb of Mary Queen of Scots in Henry VII. chapel in Westminster Abbey. There appears to be no support for the statement that a child was born to her.

Her husband, after awaiting her in vain at Ostend, went on to Paris. He returned to England in 1616 after his wife's death and was restored to favour. He married in 1618 Frances, daughter of Robert Devereux, earl of Essex, became earl of Hertford by the death of his grandfather in 1621, and marquess in 1624. He took an active part in the civil war in Charles I.'s reign, was governor of the prince of Wales, and at the Restoration the duke of Somerset was revived in his favour. He died 1660 and, though the failure of his male descendants in the person of his son John, 4th duke, the dukedom of Somerset passed to the descendants of his brother, Francis, Baron Seymour of Trowbridge, and, on the extinction of the latter's male line to the eldest branch of the Seymour family, descended from Sir Edward Seymour of Berry Pomeroy, Devon.

See also The Life and Letters of Arabella Stuart, by E. T. Bradley (1869), which supersedes The Life by E. Cooper (1866).

**STUART, GILBERT** (1755–1828), American artist, was born at North Kingstown, Rhode Island, on the 3rd of December 1755. He studied at Newport, Rhode Island, with Cosmo Alexander, and went with him to Scotland, but returned to America after Alexander's death and obtained many portrait

1 Cat. of State Papers, Venetian, ix. 541. x. 42. 514.
commissions. In 1775 he went to England, and became a pupil of Benjamin West in 1778. His work, however, shows none of the influence of West, and after four years Stuart set up a studio for himself in London, meeting with much success. Living beyond his means, he got into financial difficulties, and in 1788 escaped to Dublin. In London he had painted George III. and the future George IV., and in Paris had painted Louis XVI., and his success was no less great in Ireland. After five years he left Ireland for his native land in order to paint General Washington, who was said to be the only person in whose presence Stuart found himself embarrassed, and his first portrait Stuart felt was a failure; but Washington sat to him again, though with some reluctance, and a few days later, in May, a canvas, showing the left side of the face. This remains the accepted likeness of Washington, of whom he also painted a full-length for Lord Lansdowne; of each of these portraits he executed many replicas. Among his portraits are those of Presidents Washington, John Adams, Thomas Jefferson, James Madison, James Monroe and John Quincy Adams, and John Jay, Governor Winthrop, Generals Gates and Knox, Bishop White, Chief Justice Shippen, John Singleton Copley, Sir Joshua Reynolds, Benjamin West, Lords Clinton, Lyndhurst, and Inchiquin, Sir Edward Thornton, Marquis Patterson-Bonaparte and Horace Binney. Stuart's technique, make him not only one of the few great American artists, but one of the greatest portrait painters of his time. He settled at Boston in 1805, and died there on the 27th of July 1828.

See George C. Mason, Life and Works of Gilbert Stuart (New York, 1879).

STUART, JAMES EWELL BROWN (1833-1864), American soldier, was born in Virginia on the 6th of February 1833 and entered West Point military academy in 1850. Commissioned in 1854 second lieutenant of cavalry, he saw considerable service in Indian warfare, and took part also in the repulsion of civil disorder in Kansas. In 1855 he had married a daughter of Colonel Philip St George Cooke, who was regarded as the most capable cavalry officer in the United States service, and gave his son-in-law the benefit of his experience and judgment. In 1859 Stuart, while staying in Washington on official business, was sent to assist Colonel R. E. Lee in the suppression of the John Brown raid on Harper's Ferry. Two years later the Civil War presaged by the Kansas troubles and John Brown's expedition broke out, and when Virginia seceded Stuart resigned his commission in the United States army to share in the defence of his state. He had resigned as a lieutenant—a notification of his promotion to captain had actually crossed his letter of resignation in the post—but trained officers, especially of cavalry, were so scarce that he was at once made a colonel. With very little delay, and with the scantiest of formal training, his regiment was mustered into the Confederate army, and assigned to Joseph Johnston's force in the Shenandoah Valley. His men were mounted on their own horses, knew the country thoroughly, and in his capable hands soon made themselves proficient in outpost duty. In the opening campaign Stuart's command acted as a screen to cover Johnston's movement on Manassas, and at the first battle of Bull Run which followed, Stuart distinguished himself by his personal bravery. During the autumn and winter of 1861 he continued his outpost service and was somewhat severely handled by General Ord's force at the action of Dranesville. He was now promoted brigadier-general and placed in command of the cavalry brigade of the army of Northern Virginia. Just before the Seven Days' Battle (q.v.) he was sent out by Lee to locate the right flank of McClellan's army, and not only successfully achieved his mission, but rode right round McClellan's rear to deliver his report to Lee at Richmond. After the battle of Gaines's Mill on the 27th of June, Stuart's cavalry raided McClellan's abandoned line of communication with White House, and his dismounted riflemen, aided by a light howitzer, successfully engaged a Federal gunboat on the Pamunkey. But such romantic and far-ranging raids on this occasion, as on several others, contributed little or nothing to the success of the army as a whole. In the next campaign, it is true, he had the good fortune, in his raid against General Pope's communications, not only to burn a great quantity of stores, but also, what was far more important, to bring off the headquarters' staff document of the enemy, from which Lee was able to discover the strength and positions of his opponents in detail. Stuart, now a major-general and commander of the cavalry corps, was present at the second battle of Bull Run, and during the Maryland campaign he brilliantly defended one of the passes of South Mountain (Crampton's Gap), thus enabling Lee to concentrate his disseminated army in time to meet McClellan's attack. After this battle the indefatigable troopers embarked upon a fresh raid, which, though without any military object, had the effect of breaking up McClellan's line after the quasi-defeat of Antietam, and in addition wore out the Federal cavalry in vain efforts to pursue them. On this occasion the swift Virginians covered 80 miles in 27 hours and escaped with the loss of but three men. At Fredericksburg Stuart's cavalry were as usual in the flank of the army, and his horse artillery under Major Pelham rendered valuable service in checking Franklin's attack on "Stonewall" Jackson's corps by diverting a whole infantry division that formed part of Franklin's command. At Chancellorsville Stuart was specially appointed to look after the left flank of the army, and when less than a day's march Jackson had been wounded, and though unused to commanding so large a force of all arms he acquitted himself so well in the second day's fighting that many considered that a grave injustice was done to him by the promotion of Major-General Ewell. Jackson's principal lieutenant, to fill the position left vacant by Jackson's death. The next campaign, Gettysburg, was preluded by the cavalry battle of Brandy Station, in which for the first time the Federal cavalry showed themselves worthy opponents for Stuart and his men. The march to the Potomac was screened by the cavalry corps, which held the various approaches on the right flank of the army, but at the crisis of the campaign Stuart was absent on a raid, and although he attempted to rejoin Lee during the battle, he was met and checked some miles from the field by General Gregg, so that the skill and courage which might have turned the scale in favour of Lee on the first and second days of the great battle were employed only in covering his retreat. The cavalry took part in the war of manœuvre between Meade and Lee in the autumn of 1863, and then went into winter quarters. Very shortly after the opening of the campaign of 1864 Stuart's corps was drawn away from Lee's army by the Union cavalry under Sheridan, and part of it, with which was Stuart himself, was defeated at Yellow Tavern on the 14th of May. Stuart himself was killed.

Stuart possessed the ardent and resolute character of the true cavalry leader, and although he was fortunate enough to command brigades and regiments exclusively composed of men who were both born horsemen and natives of Virginia, and to be opposed, for the first two years, by docile but unenterprising squadrons which were recruited in a more ordinary way, yet it was undeniable that he possessed the gift, indeed the genius, of a great leader. That his energy was sometimes squandered on useless raids was but natural, considering the character of his forces, but in regard to his performances in the more exhausting and far more vital service of security and reconnaissance, General Johnston could ask "How can I sleep unless he is on the outpost?" and General Lee could say "He never brought me a false report." Stuart preserved under all circumstances the gaiety of a cavalry subaltern and the personal character of an earnest Christian, and the army regarded his loss as almost as heavy a blow to the Confederate cause as that of Jackson.

See Life by H. B. McClellan (1885).

STUART, SIR JOHN, COUNT OF MAIDA (1759-1813), British lieutenant-general, was born in Georgia. His father, Colonel John Stuart, was superintendent of Indian affairs in the southern district, and a prominent royalist in the War of Independence. Educated at Westminster School, young Stuart entered the 3rd Foot Guards in 1778, and almost immediately went to America with his regiment. He was present at the siege of
Charleston, the battle of Camden and Guildford court-house, and the surrender of Yorktown returning a regimental lieutenent. The banks of York was the usual uniform for Guards.

Ten years later, as captain and lieutenant-colonel, he was present with the Duke of York’s army in the Netherlands and in northern France. He took part in the sieges and battles of the 1703 campaign, Valenciennes, Lincelles, Dunkirk and Lannoy. In the following year, now at the head of his battalion, he was present at Landrecies and at Pont-à-Chin or Tournay, and when the tide turned against the allies, he shared with his guards in the discomforts of the retreat. As a brigadier-general he served in Portugal in 1766, and in Mainz in 1758. In 1801, his handling of his brigade called forth special commendation in general orders, and a year later he became substantive major-general. After two years in command of a brigade in Kent, Stuart went with Sir James Craig to the Mediterranean. The English were employed along with Lacy’s Russians in the defence of the kingdom of Naples, but Austerlitz led to the recall of the Russian contingent, and the British soon afterwards evacuated Italy. Thus exposed, Naples fell to the advanced troops of Masséna, but Gaeta still held out for King Ferdinand, and Masséna’s الصفحه المسدوده في متن النص الذي تم إخراجه

Oxford, where he graduated in 1848, obtaining a first-class in classics and a third in mathematics. He was elected a fellow of Trinity College, and held the college living of Navestock, Essex, from 1850 to 1866. He was librarian at Lambeth, and in 1862 was an unsuccessful candidate for the Chichele professorship of modern history at Oxford. In 1866 he was appointed regius professor of modern history at Oxford, and held the chair until 1884. His lectures were thinly attended, and he found them grievous interruptions to his historical work. Some of his statistical lectures are published in his Lectures on Medieval and Modern History. He was rector of Cholderton, Wiltshire, from 1875 to 1879, when he was appointed a canon of St Paul's.

He served on the ecclesiastical courts commission of 1881-1883, and wrote the weighty appendices to the report. On the 25th of April 1884 he was consecrated bishop of Chester, and in 1889 was translated to the see of Oxford.

Until Bishop Stubbs found it necessary to devote all his time to his episcopal duties, he pursued historical study with unremitting diligence. He rejected the theory of the unity and continuity of history so far as it would obliterate distinctions between ancient and modern history, holding that, though work on modern history is a useful preparation for the study of modern history, either may advantageously be studied apart. He urged that history is not to be treated as an exact science, and that the effects of individual character and the operations of the human will necessarily render generalizations vague and consequently useless. While pointing out that history has a utility as a mental discipline and as a part of a liberal education, he recommended its study chiefly for its own sake, for the truth's sake and for the pleasure which it brings. It was in this spirit that he worked; and his intellectual character was peculiarly fitted for his work, for he was largely endowed with the faculty of judgment and with a genius for acute and critical investigation.

He was eminent alike in ecclesiastical history, as an editor of texts and as the historian of the English constitution. His right to be held as an authority on ecclesiastical history was proved in 1858 by his Registrum sacrum anglicanum, which sets forth episcopal succession in England, by many other later works, and particularly by his share in Councils and Ecclesiastical Documents, edited in co-operation with the Rev. A. W. Haddan, for the third volume of which he was specially responsible. His place as a master in critical scholarship and historical exposition is founded on the work of the nineteen volumes which he contributed for the Rolls series of Chronicles and Memorials. It is, however, by his Constitutional History of England that he is most widely known as a historian. The appearance of this book, which traces the development of the English constitution from the Teutonic invasions of Britain till 1485, marks a distinct step in the advance of English historical learning. Specialists may here and there improve on a statement or a theory, but it will always remain a great authority, a monument of patient and exhaustive research of intellectual power, and of ripe and disciplined judgment.

It's companion volume of Select Charters and other Illustrations of English Constitutional History, admirable in itself, has a special importance in that its plan has been imitated with good results both in England and the United States.

Bishop Stubbs belongs to the front rank of historical scholars both as an author and a critic. Among Englishmen at least he excels all others as a master of every department of the historian's work, from the discovery of materials to the elaboration of well-founded theories and literary production. He was a good palaeographer, and excelled in textual criticism, in examination of authorship, and other such matters, while his vivid imagination and retentive memory made him second to none in interpretation and exposition. His carefulness was exemplary, and his references are always exact. His merits as an author are often judged solely by his Constitutional History. The learning and insight which this book displays are unquestionable: it is well planned, and its contents are well arranged; but constitutional history is not a lively subject, and, in spite of the skill with which Stubbs handled it and the genius displayed in his narrative chapters, the book does not afford an adequate idea of his place as a writer of history. What that is cannot be determined without taking into account the prefaces to some of the volumes which he edited for the Rolls series. Several of them contain monographs on parts, or the whole, of the author's work, written with remarkable literary skill. In these his language is vigorous and dignified; he states the results of his labour and thought with freshness and lucidity; tells numberless stories in a most delightful manner, and exhibits a wonderful talent for the representation of personal character; the many portraits of historic personages which he draws in these prefaces are as brilliant in execution as they are exact and convincing. Among the most notable examples of his work for the Rolls series are the prefaces to Roger of Hoveden, the Gesta regum of William of Malmesbury, the Gesta Henrici II., and the Memorials of St. Dunstan.

Both in England and America Bishop Stubbs was universally acknowledged as the head of all English historical scholars, and no English historian of his time was held in equal honour in European countries. Among his many distinctions he was D.D. and hon. D.C.L. of Oxford, L.L.D. of Cambridge and Edinburgh, Doctor in utroque jure of Heidelberg; an honorary member of the university of Kiev, and of the Prussian, Bavarian and Danish academies; he held the benefice of the order Pour le mérite, and was corresponding member of the Académie des sciences Morales et Politiques of the French Institute.

Stubbs was a High Churchman whose doctrines and practice were grounded on learning and a veneration for antiquity. His opinions were received with marked respect by his brother prelates, and he acted as an assessor to the archbishop in the trial of the bishop of Lincoln. His tastes were those of a student, and he did not disguise his dislike of public functions and the constant little journeys which take up so much of a bishop's time. Nevertheless he fulfilled all his episcopal duties with diligence, and threw all his heart into the performance of those of a specially spiritual nature, such as his addresses at confirmations and to those on whom he conferred orders. As a ruler of the Church he showed wisdom and courage, and disregarded any effort to influence his policy by clamour. In character he was modest, kind and sympathetic, ever ready to help and encourage serious students, generous in his judgment of the works of others, a most courteous companion, full of wit and humour. His wit was often used as a weapon of defence, for he did not suffer fools gladly. An attack of illness in November 1900 seriously impaired his health. He was able, however, to attend the funeral of Queen Victoria on the 2nd of February 1901, and preached a remarkable sermon before the king and the German emperor on the following day. His illness became critical on the 29th of April, and he died on the 22nd. In 1859 he had married Catherine, daughter of John Dollar, of Navestock, and had a numerous family.

**STUCCO** (Ital. stucco, adapted from O.H.G. stucchi, crust, piece, patch, Ger. Stück, piece, allied to stock), a kind of plaster used for the covering of walls, or for decorative or ornamental features such as cornices, mouldings, &c., or for ceilings. The stucco used as an exterior covering for brick or stone work is coarse; a finer kind is used for decorative purposes. (See Plaster-Work.)

**STUCK, FRANZ** (1863— ), German painter, was born at Tettenweis, in Bavaria, and received his artistic training at the Munich Academy. He first made a name with his illustrations for Fliegende Blätter, and vignette designs for programmes and book decoration. He did not devote himself to painting till after 1889, the year in which he achieved a marked success with his first picture, "The Warder of Paradise." His style in painting is based on a thorough mastery of design, and is sculptural rather than pictorial. His favourite subjects are of mythological and allegorical character, but in his treatment of time-worn motifs he is altogether unconventional. A statuette of an athlete, bronze casts of which are at the Berlin and Budapest
national galleries and the Hamburg Museum, affords convincing proof of his talent for plastic art. Among his paintings the best known are "Sin and "War," at the Munich Pinakothek, "The Sphinx," "The Crucifixion," "The Rivals," "Paradise Lost," and "Lucifer." Though Stuck was one of the leaders of the Munich "Sensation," he enjoyed an appointment of professor at the academy.

STUCLEY (or STUKELEY), THOMAS (c. 1525-1578), English adventurer, son of Sir Hugh Stucley, of Attenley, near Ilfracombe, a knight of the body to King Henry VIII., was supposed by some of his contemporaries to have been an illegitimate son of the king. He was a standard-bearer at Boulogne from 1547 to 1550, entered the service of the duke of Somerset, and after his master's arrest in 1551 a warrant was issued against him, but he succeeded in escaping to France, where he was in the service of the French army. His military talents brought him under the notice of Montmorency, and he was sent with a letter of recommendation from Henry II. of France to Edward VI. On his arrival he proceeded on the 16th of September 1552 to reveal the French plans for the capture of Calais and for a descent upon England, the furtherance of which had, according to his account, been the object of his mission to England. Northumberland evaded the payment of any reward to Stucley, and sought to gain the friendship of the French king by pretending to disbelieve Stucley's statements. Stucley, who always well have been the originator of the plans hatched by the French, was imprisoned in the Tower for some months. A prosecution for debt on his release in August 1553 compelled him to become a soldier of fortune once more, but he returned to England in December 1554 in the train of Philip II., duke of Savoy, after obtaining security against his creditors. He temporarily improved his fortunes by marrying an heiress, Anne Curtis, but in a few months had to return to the service of Savoy. As early as 1558 he was summoned before the council on a charge of piracy, but was acquitted on the ground of insufficient evidence. In 1562 he obtained a warrant to bring into England ships which had been taken, although England and France were nominally at peace. With six ships, one of which was supplied by Queen Elizabeth, he started buccaneering against French, Spanish and Portuguese ships, though his commission was concerned with an expedition to Florida. Repeated remonstrances on the part of the offended powers compelled Elizabeth to disavow Stucley, who surrendered in 1565, but his prosecution was merely formal.

He had met Shane O'Neill at the English court in the winter of 1561-1562, and was employed in 1566 by Sir Henry Sidney in a vain effort to induce the Irish chief to come over to the Flemings with the government. Sidney desired to allow Stucley to purchase the estates and office of Sir Nicholas Bagnall, marshal of Ireland, for £3000, but Elizabeth refused to permit the transaction. Undeterred by this failure, Stucley bought lands and the office of seneschal of Wexford from Sir Nicholas Heron, but in June 1568 he was dismissed, and in the next year imprisoned in Dublin Castle on a charge of high treason, but was released in October. He now offered his services to Fendol, the French ambassador in London, and was thenceforward continuously engaged in schemes against Elizabeth. Philip II. invited him to Madrid and loaded him with honours, a testament known at the Spanish court by the curious title of "duke of Ireland," and was established with a handsome allowance in a villa near Madrid. He was knighted in 1571, and prepared to become a member of a religious order of knighthood. His credit with Spain was seriously injured by another Irish malcontent, Maurice Gibbon, archbishop of Cashel; but Stucley, who now desired to leave Spain, only obtained his passports after Elizabeth had demanded his dismissal. He commanded three galleys under Don John of Austria at the battle of Lepanto. His exploits won him to favour at Madrid, and on the 2nd of March 1572 he was at Seville, offering to hold the narrow seas against the English with a fleet of twenty ships. In four years (1570-1574) he is said to have received over 27,000 ducats from Philip II. Weared by the Spanish king's delays he sought more serious assistance from the new pope, Gregory XIII., who aspired to make his illegitimate son, Giacomu Buoncompagno, king of Ireland. He set sail from Civita Vecchia in March 1578, but put into Lisbon, where he was to meet his confederate, James Fitzmaurice Fitzgerald, and to secure better ships before sailing for Ireland; and particularly to seek a species purpose by King Sebastian, with whom he sailed for Morocco. He commanded the centre in the battle of Alcazar on the 4th of August 1578, and was killed, in fair fight apparently, though tradition asserted that he was murdered by his Italian soldiers after the battle.

Stucley's adventurous career made considerable impression on his contemporaries. A play generally assigned to George Peele, The Battle of Alcazar ... with the Death of Captain Stucley, printed by E. Alde in 1591, was probably identical with a popular piece referred to by Henslowe as Muley surnamed Abdelmilch. It deals with Stucley's arrival in Lisbon and his Moorish expedition, but in a long speech before his death he recapitulates the events of his life. A later piece, The Famous History of the Life and Death of Captain Thomas Stucley, printed for Thomas Panyer (1605), which is possibly the Stucley played, according to Henslowe, on the 11th of December 1596, is a biographical piece dealing with successive episodes, and seems to be a patchwork of older plays on Don Antonio and on Stucley. His adventures also form the subject of various ballads.

Stud is a detailed biography of Stuckey, based chiefly on the English, Venetian and Spanish state papers, in R. Simpson's edition of the 1605 play (School of Shakespeare, 1878, vol. 1), where the leisurely and tranquil style of dedication is transferred to a more contemporary poetry are quoted by Dyce in his introduction to the Battle of Alcazar in Peeke's Works.

STUD. (1) A number of horses kept for the purpose of breeding, also the place or establishment where they are kept; similarly, a "stud horse," a stallion, "stud groom," the head groom of a stud, "stud-book," the register containing the pedigree of thoroughbred horses. The word in Old English is stod, and cognate forms are found in Icelandic and Danish, cf. also German Gestiit; sted, now a literary word for horse, meant in Old English (steda) a stud-house, and is the same as stud in origin. The horse of a stud is also called a "cover," and is usually referred to as a "stock," or "stall," of a stud. A stud meant, therefore, an establishment. (2) A word which is used of many different objects, the primary meaning being a "prop" or support. The Old English word is studan, and cognates are found in Danish, Swedish and Icelandic. The ultimate origin is also the root sta-, to stand. The chief applications of the term are as follows: in architecture, to a post; quarter or upright in wooden partitions; to the transverse pieces of iron which strengthen the links of a chain; to a boss or knob inserted on a belt, collar, or piece of armour, often decorated and forming an integral part of the piece, particularly, to a species of button, consisting of a rounded head, neck and flat base, used for fastening a collar, shirt, &c.

STUDER, BERNHARD (1704-1887), Swiss geologist, was born at Buren, near Berne, in August 1704. Although educated as a clergyman, he became so interested in geology at the university of Göttingen that he devoted his life to its pursuit. He subsequently studied at Freiburg, Berlin and Paris, and in 1818 was appointed teacher of mathematics and physics in the Berne Academy. In 1825 he published Beiträge zu einer Monographie der Malasse. Later on he commenced his detailed investigations and published in 1834 his Geologie der westlichen Schweizer-Alpen. In the same year, largely through his influence, the university of Berne was established and he became the first professor of mineralogy. His Geologie der Schweiz in two vols. (1851-1853), and his geological maps of Switzerland prepared with the assistance of Arnold Escher von der Linth, are monuments of his research. In 1859 he organized the geological survey of Switzerland, being appointed president of the commission, and retaining this position until the close of his life. It has been remarked by Marcou that Studer was present at the first meeting of the Société helvétique des sciences naturelles at Geneva on the 6th of October 1815, and remained a member during 72 years. He was awarded the Wollaston medal by the Geological Society of London, 1870. He died at Berne on the 2nd of May 1877. Obituary by Jules Marcou, Ann. rep. amer. acad. sci. for 1888.
STUKELEY—STURE

STUKELEY, WILLIAM (1687–1765), English antiquary, was born at Holbeach, Lincolnshire, on the 7th of November 1687, the son of a lawyer. After taking his M.B. degree at Cambridge, he went to London and studied medicine at St Thomas’s Hospital. In 1710 he started in practice in Lincolnshire, removing in 1717 to London. In the same year he became a fellow of the Royal Society, and, in 1718, joined in the establishment of the Society of Antiquaries, acting for many years as its president. In 1716 he took his M.D. degree, and in 1720 became a fellow of the Royal College of Physicians, publishing in the same year his first contribution to antiquarian literature. His principal work, an elaborate account of Stonehenge, appeared in 1740, and he wrote copiously on other supposed Druid remains, becoming familiarly known as the “Arch-Druid.” In 1720 he took holy orders, and, after holding two livings in Lincolnshire, was appointed rector of a parish in Bloomsbury, London. He died in London on the 3rd of March 1765.

STUMPF, JOHANN (1500–1570), one of the chief writers on Swiss history and topography, was born at Brennwald (near Carlsruhe). He was educated there and at Strassburg and Heidelberg. In 1520 he was received as a cleric or chaplain into the order of the Knights Hospitalers or of St John of Jerusalem, was sent in 1521 to the preceptory of that order at Freiburg in Brisgau, ordained priest in Basel, and in 1522 placed in charge of the preceptory at Bubikon (north of Rapperswil, in the canton of Zürich). But Stumpf soon went over to the Protestants, was present at the great Disputation in Berne (1528), and took part in the first Kappel War (1529). He had carried the banner of the Reformation to the cantons, and was later called to care for, as the Protestant pastor at Bubikon, till 1543, then becoming pastor at Stammbheim (same canton) till 1561, when he retired to Zürich (of which he had been made a burgher in 1548), where he lived in retirement till his death in 1576. In 1530 he married the first of his four wives, a daughter of Heinrich Brenwald (1478–1551), who wrote a work (still in MS.) on Swiss history, and stimulated his son-in-law to undertake historical studies. Stumpf made wide researches, with this object, for many years, and undertook also several journeys, of which that in 1544 to Engellberg and through the Valais seems to be the most important, perhaps because his original Diary has been preserved to us. The fruit of his labours (completed at the end of 1546) was published in 1548 at Zürich in a huge folio of 934 pages (with many fine wood engravings, coats of arms, maps, &c.), under the title of Generis Helvetiorum et Helvetiae Historiae libri quatuor (of which the German translation appeared in several editions). Stumpf left a valuable collection of documents concerning Switzerland in the possession of the city of Zürich, and he was also the first to point out the importance of the medallions and other objects in the possession of the city of Zürich. Stumpf also published a monograph (very remarkable for the date) on the emperor Henry IV. (1556) and a set of laudatory verses (Lobgesänge) for the electors of Hesse-Cassel (1573). (W. A. B. C.)

STURDA, or STURZA, the name of an ancient Rumanian family, of unknown origin, which probably came from Trebișond and settled in Moldavia. The Sturda family has been long and intimately associated with the government first of Moldavia and afterwards of Rumania. Its members belong to two main divisions, which trace their descent respectively from John (Ioan) or from Alexander (Sandu), the sons of Kirak Sturda, who lived in the 17th century, and may be regarded as the founder of the family.

1. To the first division belongs Michael [Michail] Sturda (1705–1884), who was prince of Moldavia from 1834 to 1849. A man of liberal education, he established the first high school, a kind of university, in Jassy. He brought scholars from foreign countries to act as teachers, and gave a very powerful stimulus to the educational development of the country. In 1844 he decreed the emancipation of the gipsies. Until then the gipsies had been treated as slaves and owned by the Church or by private landowners; they had been bought and sold in

the open market. Michael Sturdza also attempted the secularization of monastic establishments, which was carried out by Prince Cuza in 1846, and the utilization of their endowments for national purposes. He quelled the attempted revolution in 1848 without bloodshed by arresting all the conspirators and expelling them from the country. Under his rule the internal development of Moldavia made immense progress; roads were built, industry developed, and Michael is still gratefully remembered by the people.

See Michel Stourdza et son administration (Brussels, 1834); Michel Stourdza, ancien prince regnant de Moldavie (Paris, 1854); A. C. Sturdza, Régne de Michel Stourdza, prince de Moldavie 1834–1849 (Paris, 1897).

2. GREGORY [Grigorie] Sturza (1821–1901), son of the above, was educated in France and Germany, became a general in the Ottoman army under the name of Muklis Pasha, and afterwards attained the same rank in the Moldavian army. He was a candidate for the Moldavian throne in 1859, and was made a prominent member of the Russian party in the Rumanian parliament. He wrote Lois fondamentales de l’univers (Paris 1891).

3. JOHN [Ioan] Sturza, prince of Moldavia (1822–1828), was the most famous descendant of Alexander Sturdza. Immediately after the Greek revolution, Prince John Sturza took an active part in subduing the roving bands of Greek Hetairists in Moldavia; he transformed the Greek elementary schools into Rumanian schools and laid the foundation for that scientific national development which Prince Michael Sturdza continued after his accession to Brăila and which was carried through the country and took Prince John prisoners. He died in exile.

4. ALEXANDER [Alexandru] Sturza (1791–1854), Russian publicist and diplomatist, was a member of the same family, born in Bessarabia and educated in Germany. After entering the Russian diplomatic service, he wrote Betrachtungen über die Lehre und der Geist der orthodoxen Kirche (Leipzig, 1817). His Mémoire sur l'état actuel de l'Allemagne, written at the request of the tsar during the congress of Aix-la-Chapelle, was an attack on the German universities, repeated in Coup d'œil sur les universités de l'Allemagne (Aix, 1818). His other important works are the Histoire de la terre (Leipzig, 1828) and Oeuvres post-humées religieuses, historiques, philosophiques et littéraires (5 vols., Paris, 1858–1861).

5. DEMETRIUS [Dimitrie] Sturza, Rumanian statesman, was born in 1833 at Jassy, and educated there at the Academia Michaeilica. He continued his studies in Germany, took part in the political movements of the time, and was private secretary to Prince Cuza. Demetrios afterwards turned against Cuza, joined John Brătianu, and became a member of the so-called Liberal government. In 1890 he was elected leader of the party after succession to Brătianu and was four times prime minister (see ROMANIA: History). Though a man of great capacity for work, he represented the narrowest nationalism, and through his enmity to all that was “alien” did more than any other man to retard the political and industrial development of the country. He was appointed permanent secretary of the Rumanian Academy, and became a recognized authority on Rumanian numismatics. As secretary of the academy he was instrumental in assisting the publication of the collections of historic documents made by Harmuzaki (30 vols., Bucharest, 1876–1897), and other acts and documents (Bucharest, 1900 sqq.), besides a number of minor political pamphlets of transitory value. (M. G.)

STURE, an ancient patrician family of Sweden, the most notable members of which were the following:

1. STEN GUSTAFSSON, commonly called Sten Sture the Elder (1440–1503). In 1464 he came prominently forward in support of Bishop Kettil Karlsson Vasa in his struggle against Christian I. of Denmark, and showed great ability in winning over the peasants and making soldiers of them. In 1470 we find him in the forefront of the Swedish national leaders and victorious over both Erik Karlsson Vasa and King Christian himself. After the death of Karl Knutsson, commonly called Charles VIII., Sture was elected regent of Sweden, and from 1470 to 1497 displayed some
of the highest qualities of a statesman. In 1471 he again defeated Christian I. at the great battle of Brunkebjörk which materially strengthened his position in Sweden. In 1483 he was obliged to acknowledge Hans of Denmark and Norway as king; but the strife of factions enabled him to hold his own till the arrival of Hans in Sweden in 1497. His position had in the meantime been weakened by a ruinous war with Russia. He succeeded, however, in annexing Öland to Sweden. After the terrible defeat of Hans by the Dithmarschers in 1500 Sture was a second time elected regent, holding that office till his death.

2. STAYNT STURE (d. 1512) is mentioned as a senator in 1482. He was one of the magnates who facilitated King Hans's conquest of Sweden by his opposition to Sten Sture the Elder. Subsequently, however, he was reconciled to the latter and succeeded him as regent. He was by no means so imposing a figure as his predecessor, though, like him, Svante in his later years patriotically resisted the Danish claim of sovereignty. He died suddenly at Vasteras Castle.

3. STEN STURE, commonly called Sten Sture the Younger (1452-1520), the son of Svante. After his father's death he was elected regent by the majority of the lesser gentry to the exclusion of the candidate of the high aristocratic faction, Erik Trolle, whence the inextinguishable hatred of the two families. In 1513 the aged archbishop of Upsala, Jakob Ulfsson, resigned in favour of Gustaf Trolle, son of Erik Trolle, who was elected by the cathedral chapter and recommended to the pope by the regent on condition that the new archbishop should do him homage. Unfortunately these two masterful young men (Trolle was twenty-seven, Sture barely twenty-three), who represented rival lines of descent, ecclesiastical and secular, in the highest civil authority in Sweden, were only too prone to carry on the family feud. On the return of Trolle from Rome he refused to do homage to the regent till all his enemies had been punished, and allied himself with Christian II. of Denmark, who hastened to the archbishop's assistance when Sture besieged Trolle in his stronghold at Stäke (1516). Nevertheless Sture not only defeated Christian II. at Vedla, but took and razed Stäke to the ground, and shut up the archbishop in a monastery at Vesterås. A riksmöte, or national assembly, held at Stockholm in 1517, declared unanimously that Sweden would never recognize Trolle as archbishop because he had defied the regent and brought the enemy into the land. The war with Denmark was then vigorously resumed. On Midsummer Day 1518 Christian II. appeared before Stockholm with his fleet and landed an army, but was again defeated by Sten Sture at Bränkyrka. An attempt of the papal legate Arcimboldus to mediate between the two countries at Arboga (Dec. 1518) failed. In 1520 Christian, with a regular army, and armed with a papal bull excommunicating Sture, again invaded Sweden. The armies clashed near Börgerund on Lake Åarunden (Jan. 19). At the very beginning Sture was hit by a bullet and his peasant levies fled to the wild mountainous regions of Tiveden where they made a last desperate but unsuccessful stand. The mortally-wounded regent took to his sledge and posted towards Stockholm, but expired on the ice of Lake Mälar two days later, in his 27th year.

See Större historia, vol. i. (Stockholm, 1877-1878); K. O. Arnoldson, Nordens Enhet och Kristian II. (Stockholm, 1899). (R. N. B.)

STURGE, JOSEPH (1795-1859), English philanthropist and politician, was the son of a farmer in Gloucestershire. He was a member of the Society of Friends, and refused, in his business as a corn factor, to deal in grain used in the manufacture of spirits. He went to Birmingham in 1822, where he became an alderman in 1835. He was an active member of the Anti-Slavery Society, and made a tour in the West Indies, publishing on his return an account of slavery as he there saw it in The West Indies in 1837 (London, 1837). After the abolition of slavery, to which, as Lord Brougham acknowledged in the House of Lords, he had largely contributed, Sturge started and generously supported schemes for benefiting the liberated negroes. In 1841 he travelled in the United States with the poet Whitter to examine the slavery question there. On his return to England he gave his support to the Chartist movement, and in 1842 was candidate for Nottingham, but was defeated by John Walter, the proprietor of The Times. He then took up the cause of peace and arbitration, to support which he was influential in the founding of the Morning Star in 1835. The extreme narrowness of Sturge's views was shown in his opposition to the building of the Birmingham town-hall on account of his conscientious objection to the performance of sacred oratorio. He died at Birmingham on the 14th of May 1859. He married, first, in 1834, Eliza, daughter of Charles Cropper; and, secondly, in 1846, Hannah, daughter of Barnard Dickinson.

STURGEON (Acipenser), the name given to a small group of fishes, of which some twenty different species are known, from European, Asiatic and North American rivers. The distinguishing characters of this group, as well as its position in the system, are dealt with in the article TELEOSTOMES. They pass a great part of the year in the sea, but periodically ascend large rivers, some in spring to deposit their spawn, others later in the year for some purpose unknown; few of the species are exclusively confined to fresh water. None occur in the tropics or in the southern hemisphere.

Sturgeons are found in the greatest abundance in the rivers of southern Russia, more than ten thousand fish being sometimes caught at a single fishing-station in the fortnight during which the up-stream migration lasts. They occur in less abundance in the fresh waters of North America, where the majority are caught in shallow portions of the shores of the great lakes. In Russia the fisheries are of immense value. Early in summer the fish come into the rivers or towards the shores of freshwater lakes in large shoals for breeding purposes. The ova are very small, and so numerous that one female has been calculated to produce about three millions in one season. The ova of some species have been observed to hatch within a very few days after exclusion. Probably the growth of the young is very rapid, but we do not know how long the fry remain in fresh water before their first migration to the sea. After they have attained maturity their growth appears to be much slower, although continuing for many years. Frederick the Great placed a number of them in the Görland Lake in Pomerania about 1750; which have since increased to such an extent that the fish are so abundant that they are often caught as a sport in open water.

Professor von Baer also states, as the result of direct observations made in Russia, that the Haussen (Acipenser huso) attains to an age of from 200 to 300 years. Sturgeons ranging from 8 to 11 ft. in length are by no means scarce, and some species grow to a much larger size.

Sturgeons are ground-feeders. With their projecting wedge-shaped snout they stir up the soft bottom, and by means of their sensitive barbels detect shells, crustaceans and small fishes, on which they feed. Being destitute of teeth, they are unable to seize larger prey.

In countries like England, where few sturgeons are caught, the fish is consumed fresh, the flesh being firmer than that of ordinary fishes, well flavoured, though somewhat oily. The sturgeon is included as a royal fish in an act of King Edward II., although it probably but rarely graces the royal table of the present period, or even that of the lord mayor of London, who can claim all sturgeons caught in the Thames above London Bridge. Where sturgeons are caught in large quantities, as on the rivers of southern Russia and on the great lakes of North America, their flesh is dried, smoked or salted. The ovaries, which are of large size, are prepared for caviar; for this purpose they are beaten with switches, and then pressed through sieves, leaving the membranous and fibrous tissues in the sieve, whilst the eggs are collected in a tub. The quantity of salt added to them before they are finally packed varies with the season, scarcely any being used at the beginning of winter. Finally, one of the best sorts of isinglass is manufactured from the air-bladder. After it has been carefully removed from the body, it is washed in hot water, and cut open in its whole length, to separate the inner membrane, which has a soft consistency, and contains 70% of glitin.
The twenty species of sturgeons (Acipenser) are nearly equally divided between the Old and New Worlds. The more important are the following:—

1. The common sturgeon of Europe (Acipenser sturio) occurs on all the coasts of Europe, but is absent in the Black Sea. Almost all the British species of sturgeon belong to this species; it crosses the River Thames on its way to the North Sea. When it is fully grown, it reaches a large size (a length of 12 ft.), but is always caught singly or in pairs, so that it cannot be regarded as a fish of commercial importance. The form of its snout varies with age (as in the other species), and is more blunt and abbreviated in old than in young examples. There are 11–13 bony shields along the back and 29–31 along the side of the body.

2. Acipenser gueldenstaedtii is one of the most valuable species of the rivers of Russia, where it is known under the name "Osseť"; it is said to inhabit the Siberian rivers also, and to range eastwards as far as Lake Baikal. It attains to the same large size as the common sturgeon, and is so abundant in the rivers of the Black and Caspian seas that more than one-fourth of the caviare and isinglass manufactured in Russia is derived from this species.

3. Acipenser stellatus, the "Senruga" of the Russians, occurs likewise in great abundance in the rivers of the Black and Caspian seas, and reaches its largest size, averaging 50 lb. each. The sturgeons of the lakes are unable to migrate to the sea, whilst those below the Falls of Niagara are good waders; and it is quite possible that a specimen of this species said to have been obtained from the Firth of Tay was really captured on the coast of Scotland.

4. Acipenser huso, the "Hausen" of Germany, is recognized by the absence of osseous scutes on the snout and by its flattened, tape-like barbels. It is one of the largest species, reaching the enormous length of 24 ft. and a weight of 2000 lb. It inhabits the Caspian and Black seas, and the Sea of Azof, whence in former years large shoals of fish entered the large rivers of Russia and the Danube. But its numbers have been much thinned, and specimens of 1200 lb. in weight have now become scarce. Its flesh, caviare and air-ladder are of less value than those of the smaller species.

5. The stilet (Acipenser ruthenus) is one of the small species, which likewise inhabits both the Black and Caspian seas, and is distinguished from the rest by its shorter barbels and by the fact that it is the only one of the other sturgeons; thus, for instance, it is not uncommon in the Danube at Vienna, but specimens have been caught as high up as Rhadson and Ulm. It is more abundant in the rivers of Russia, where it is seen for miles along the banks contributing also to the best kinds of caviare and isinglass. As early as the 18th century attempts were made to introduce this valuable fish into Prussia and Sweden, but without success. The stilet is distinguished from the other European species by its long and narrow snout and fringed barbels. It rarely exceeds a length of 6 ft.

The family Acipenseridae includes one other genus, Scaphirhynchus, the shovel-head or shovel-nosed sturgeon, distinguished by the long, broad and flat snout, the suppression of the spiracles, and the union of the gills. All American species are confined to fresh water. One of them is common in the Mississippi and other rivers of North America, the other three occur in the larger rivers of eastern Asia.

STURGIS, RUSSELL (1836–1899), American architect and art critic, was born in Baltimore county, Maryland, on the 6th of October 1836. He graduated from the Free Academy in New York (now the College of the City of New York) in 1856, and studied architecture under Leopold Eidlitz and then for two years in Paris. In 1862 he returned to the United States. He designed the Yale University chapel and the Farnham and Durfee dormitories at Yale, the Flower Hospital, the Farmers' and Mechanics' Bank of Albany, and many other buildings, but did comparatively little professional work after 1880. He was in Europe in 1850–1854; and for a short time after his return was secretary of the New York Municipal Civil Service Board. He was president of the Architectural League of New York in 1889–1893, was first president of the Fine Arts Federation in 1895–1897, and was a member of the National Society of Mural Painters, the National Sculpture Society, the National Academy of Design, and the New York chapter of the American Institute of Architects. He lectured on art at Columbia University, the Metropolitan Museum of Art in New York, the Peabody Institute of Baltimore and the Art Institute of Chicago; his lectures in Chicago being published under the title The Interdependence of the Arts of Design (1902). He is best known as a writer on art and architecture. He edited A Dictionary of Architecture and Building (3 vols., 1901–1902) and the English version of Wilhelm Ueckel's Outlines of the History of Art (2 vols., 1904), and he wrote European Architecture and its Influence on Art (1902) and The Appreciation of Sculpture (1904), The Appreciation of Pictures (1905), A Study of the Artist's Way of Working in the Various Handicrafts and Arts of Design (2 vols., 1905), and an unfinished History of Architecture (1906 seq.). During his last years he was nearly blind. He died in New York on the 11th of February 1900.

STURGIS, JACQUES CHARLES FRANÇOIS (1803–1855), French mathematician, of German extraction, was born at Geneva on the 24th of September 1803. Originally tutor to the son of Mme de Staël, he resolved, with his schoolfellow Colladon, to try his fortune in Paris, and obtained employment on the Bulletin universel. In 1826 he discovered the theorem, regarding the determination of the number of real roots of a numerical equation included between given limits, which bears his name (see Equation, V.), and in the following year he was appointed professor of mathematics at the Collège Rollin. He was chosen a member of the Académie des Sciences in 1836, became "répétiteur" in 1838, and in 1849 professor in the École Polytechnique, and finally succeeded S. D. Poisson in the chair of mathematics in the Faculté des Sciences at Paris. His works, Cours d'analyse de l'école polytechnique (1857–1858), and Cours, de mécanique de l'école polytechnique (1861), were published after his death at Paris on the 18th of December 1855.

STURM, JULIUS (1816–1869), German poet, was born at Köstritz in the principality of Reuss on the 21st of July 1816. He studied theology at Jena from 1837 to 1841, and was appointed preceptor to the hereditary prince Henry XIV. of Reuss. In 1851 he became pastor of Göschnitz near Schleiz, and in 1857 at his native village of Köstritz. In 1858 he retired with the title of Geheimrat. He died at Leipzig on the 2nd of May 1869. Sturm was a writer of lyrics and sonnets and of church poetry, breathing a spirit of deep piety and patriotism.

STURM VON STURMECK—STUTTGART

Neue Lieder (1880, 2nd ed., 1888), Neue lyrische Gedichte (Leipzig, 1894) and In Freude und Leid, letzte Lieder (1896).

See A. Hepling, Julius Sturm (Giessen, 1896); F. Hoffmann, Julius Sturm (Hamburg, 1908).

STURM VON STURMECK, JACOB (1489–1553), German statesman and reformer, was born at Strassburg where his father, Martin Sturm, was a person of some importance, on the 10th of August 1489. He was educated at the universities of Heidelberg and Freiburg, and about 1517 he entered the service of Henry, provost of Strassburg (d. 1527), a member of the Wittelsbach family. He soon became an adherent of the reformed doctrines, and leaving the service of the provost became a member of the governing body of his native city in 1524. He was responsible for the policy of Strassburg during the Peasants' War; represented the city at the Diet of Spires in 1526; and at subsequent Diets gained fame by his ardent championing of its interests. As an advocate of union among the Protestants he took part in the conference at Marburg in 1529; but when the attempts to close the breach between Lutherans and Zwinglians failed, he presented the Confessio tetrpolitana, a Zwinglian document, to the Augsburg Diet of 1530. As the representative of Strassburg Sturm signed the "protest" which was presented to the Diet of Spires in 1529, being thus one of the original "Protestants." He was on friendly terms with Philip, landgrave of Hesse. Owing largely to his influence Strassburg joined the league of Schmalkalden in 1531. The troops of Strassburg held when the league attacked Charles V. in 1546; but in February 1547 the citizens were compelled to submit when Sturm succeeded in securing very favourable terms from the emperor. He was also able to obtain for his native city some modification of the Interim issued from Augsburg in May 1548. Sturm is said to have been in the pay of Francis I. of France, but this seems very unlikely. He founded the Bibliothek and a gymnasium in Strassburg, where he died on the 30th of October 1553.

See H. Baumgarten, Jakob Sturm (Strassburg, 1876); A. Baum, Magistral- und Reformation zu Strassburg bis 1526 (Strassburg, 1887); W. Rathsheber, "Strassburg im 10. Jahrhundert" (Stuttgart, 1971); O. Winkelmanna, "Jakob Sturm," in Allgemeine deutsche Biographie, Bd. xxxvii. (Leipzig, 1894); and Johannes Sturm, Conversatio ad senium arginitinensem de morte ... Jacobi Sturmii (Strassburg, 1553).

STURT, CHARLES (d. 1869), English explorer in New South Wales and in South Australia, was born in England, and entered the army, reaching the rank of captain. Having landed in Australia with his regiment (the 30th), he became interested in the geographical problems which were exciting attention. A first expedition (1828) led to the discovery of the Darling river; and a second, from which the explorer returned almost blind, made known the existence of Lake Alexandrina. From his third journey (1844–1849), in which terrible hardships had to be endured, he returned quite blind, and he never altogether recovered his sight. He was appointed surveyor-general of South Australia in 1833, and subsequently chief secretary, which position he held until 1856 when responsible government was introduced, and Captain Sturt retired on a pension and went to live at Cheltenham, England, where he died on the 16th of June 1869, before he could be invested with the dignity of K.C.M.G. to which he had been designated.

STUTTGART, a city of Germany, capital of the kingdom of Württemberg. It lies in a basin watered by the Nesenbach just above its confluence with the Neckar, 115 m. N.W. from Munich, and at the centre of a network of railways placing it in direct communication with all the principal towns of south Germany. Pop. (1905), 249,443, of whom about one-half reside in the suburbs of Cannstatt, Berg, Gaishurst, Gaglenen and others. Charmingly situated among vine-clad and wooded hills, Stuttgart stands at a height of nearly 300 ft. above the sea and enjoys a healthy climate. It is intersected from south-west to north-east by the long and handsome Königsstrasse, dividing it into an upper and a lower town. In all its main features it is essentially a modern town, and few of its principal buildings are older than the 19th century. Many of them, however, are of considerable architectural importance and the revival of the Renaissance style is perhaps illustrated nowhere better than in Stuttgart. The lower, or south-eastern, part contains both the small group of streets belonging to old Stuttgart, and also the most important part of the new town. Of the numerous churches in the city the most interesting are the Stiftskirche, with two towers, a fine specimen of 15th-century Gothic; the Leonhardskirche, also a Gothic building of the 15th century; the Hospitalkirche, restored in 1847, the cloisters of which contain the tomb of Johann Reuchlin; the fine modern Gothic church of St John; the new Roman Catholic church of St Nicholas; the Friedenskirche; and the English church. A large proportion of the most prominent buildings are clustered round the spacious Schlossplatz, with its fine promenades. Among these are the new palace, an imposing structure of the 18th century, finished in 1807; the old palace, a 16th-century building, with a picturesque arcaded court; the Königshaus, a huge modern building with a fine colonnade, containing ball and concert rooms; the so-called Akademie, formerly the seat of the Kunstschule, where Schiller left part of his education, and now containing the royal library; and the court theatre, destroyed by fire in 1902, and subsequently rebuilt. In the centre of the Schlossplatz is the lofty jubilee column, erected in 1847 in memory of the king of Württemberg, William I., and in the courtyard of the old palace is a bronze equestrian statue of Duke Eberhard the Bearded. On or near the Schlossplatz also are the new courts of justice; the Wilhelmspalast and the palace of the crown prince; the large royal stables; the new post office; and the central railway station, one of the handsomest structures of the kind in Germany. The town also contains a fine statue of Schiller, designed by Thorvaldsen; a bronze statue of Christopher, duke of Württemberg; a monument to the emperor William I.; an equestrian statue of King William I. in the court of the museum of the plastic arts; and a large monumental fountain in the Eugenplatz. Other prominent buildings are: the Queen Olga buildings, erected in 1893–1895 in the Renaissance style; the national industrial museum (1890–1896) in the late Renaissance style, flanked by two cupola-crowned towers and decorated with medallions of famous Swabians; the magnificent new town-hall; and the railway viaduct across the valley of the Neckar, 742 yds. long.

The art collections of Stuttgart are numerous and valuable. The museum of art comprises a picture gallery, a collection of casts of Thorvaldsen's works and a cabinet of engravings. The royal library contains about 400,000 printed volumes, including one of the largest collections of Bibles in the world, and also about 20,000 MSS., many of great rarity. To these may be added the industrial museum, the cabinet of coins, the museum of natural history, the collection of majolica vases in the new palace, and the Württemberg museum of antiquities. The city also contains numerous excellent educational establishments, although the state university is not here but at Tübingen, and its conservatorium of music has long been renowned. The technical high school, which since 1809 has possessed the right to confer the degree of doctor of engineering, practically enjoys academic status and so do the veterinary high school and the school of art.

Stuttgart is the centre of the publishing trade of south Germany, and it has busy industries in everything connected with the production of books. Its other manufactures include machinery, pianos and other musical instruments, cotton goods, cigars, furniture, leather, paper, colours and chemicals. Its trade also in books, hops, horses, and cloth is considerable, and a large banking and exchange business is done here. The beauty of its situation and its educational advantages attract numerous foreign residents, especially English and American. Stuttgart is the headquarters of the XIII. corps of the German army, and contains a fairly large garrison for which accommodation is provided in the extensive barracks in and around the city.

To the north-east of the new palace lies the beautiful palace park, embellished with statuary and artificial sheets of water, and extending nearly all the way to Cannstatt, a distance of
over two miles. Cannstatt, which was incorporated with Stuttgart in 1800, attracts numerous visitors owing to its beautiful situation on the Neckar and its saline and chalybeate springs. In the environs of Stuttgart and Cannstatt lie Rosenstein, Wilhelma and other residences of the royal family of Württemberg.

Stuttgart seems to have originated in a stud (Stuten Garten) of the early counts of Württemberg, and is first mentioned in a document of 1229. Its importance, however, is of comparatively modern growth and in the early history of Württemberg it was overshadowed by Cannstatt, the central situation of which on the Neckar seemed to mark it out as the natural capital of the country. After the destruction of the castle of Württemberg early in the 14th century, Count Eberhard transferred his residence to Stuttgart, which about 1500 became the recognized capital of Württemberg. But even as capital its growth was slow. At the beginning of the 19th century it did not contain 20,000 inhabitants, and its real advance began with the reign of Kings Frederick and William I., who exerted themselves in every way to improve and beautify it. In 1849 Stuttgart was the place of the meeting of the assembly called the Rumpfparlament.

STUYVESANT, PETER (1592–1672), Dutch colonial governor, was born in Scherpenzeel, in southern Friesland, in 1592, the son of a minister. He studied at Franeker, entered the military service in the West Indies about 1614, and was sent the following year by the West India Company's colony of Curaçao from 1634 to 1644. In April 1644 he attacked the Portuguese island of Saint Martin and was wounded; he had to return to Holland, and there one of his legs was amputated. Thereafter he wore a wooden leg ornamented with silver bands. In May 1645 he was selected by the West India Company to supersede William Kieft as director of New Netherland. He arrived in New Amsterdam (later New York) on the 11th of May 1647, and was received with great enthusiasm. In response to the demand for self-government, in September 1647 he and the council appointed—after the manner then followed in Holland—and with the consentives chosen by the people a board of nine to confer with him and the council whenever he thought it expedient to ask their advice; three of the nine, selected in rotation, were permitted to sit with the council during the trial of civil cases; and six were to retire each year, their successors to be chosen by the director and council from twelve candidates nominated by the board. The leading burghers were, however, soon alienated by his violent and despotic methods, by his defence of Kieft, and by his devotion to the interests of the company; the nine men's name (as early as 1650, when they sent the famous Van der Steige, or Remonstrance, to the states-general asking for burgher government and other reforms) the centre of municipal discontent; and a bitter quarrel ensued. In 1650 the states-general suggested a representative government to go into effect in 1653, but the company opposed it; in 1653, however, there was established the first municipal government for the city of New Amsterdam modelled after that of the cities of Holland. Stuyvesant also aroused opposition through his efforts to increase the revenues of the company, to improve the system of defence, and to prevent the sale of liquor and firearms to the Indians, and through his persecution of Lutherans and Quakers, to which the company finally put an end. He had a bitter controversy with the patroon of Rensselaerwijk, who claimed to be independent of the West India Company. In 1647 he seized a Dutch ship illegally trading at New Haven and claimed jurisdiction as far as Cape Cod; the New Haven authorities refused to deliver to him fugitives from justice in Manhattan; he retaliated by offering refuge to runaways from New Haven; but finally he offered pardon to the Dutch fugitives and revoked his proclamation. In September 1650 he came to an agreement with the commissioners of the United Colonies of New England at Hartford upon the boundary between New Netherland and Connecticut, involving the sacrifice of a large amount of territory, the new boundary crossing Long Island from the west side of Oyster Bay to the Atlantic Ocean, and on the mainland north from a point west of Greenwich Bay, 4 m. from Stamford. On Long Island, during Stuyvesant's rule, Dutch influence was gradually undermined by John Underhill, Stuyvesant's deputy, and the Swedes were defeated. A few hundred men were bailed into the Delaware in 1655, captured Fort Casimir (Newcastle)—which Stuyvesant had built in 1651—and which the Swedes had taken in 1654—and overthrew the Swedish authority in that region. He also vigorously suppressed Indian uprisings in 1655, 1658 and 1663. In March 1664 Charles II. granted to his brother, the duke of York, the territory between the Connecticut river and Delaware Bay, and Colonel Richard Nicolls with a fleet of four ships and about three or four hundred men was sent out to take possession. Misled by instructions from Holland that the expedition was directed wholly against New England, Stuyvesant made no preparation for defence until just before the fleet arrived. As the burghers refused to support him, Stuyvesant was compelled to surrender the town and fort on the 8th of September. He returned to Holland in 1665, and was made a scapegoat by the West India Company for all its failings in New Amsterdam; he went back to New York again after the treaty of Breda in 1667, having secured the right of free trade between Holland and New York. He spent the remainder of his life on his farm called the Bouwerie, from which the present "Bowery" in New York City takes its name. He died in February 1672, and was buried in a chapel, on the site of St. Mark's Church.

STY, an enclosed place or pen to keep pigs in. The word means properly a pen or enclosure for any domestic animal, as is seen from its occurrence in Scandinavian languages and in German, e.g. Swed. och. pit, pen; dansk, hog-sten, pig-stye; Swed. stige, pig-sty. It is usual to refer the word to stil 건, to clump which would be the direct equivalent of the original meaning to be an enclosure raised on steps, others, in view of the Gr. στιχος, row, would take the basic sense to be a row of pales or stakes forming a pen or enclosure; cf. the use of στυξις for poles supporting nets to catch game in (Xen. Cooke, 6. 10). If the derivation from stil 건 is correct, the word is the same as that meaning a small inflated swelling, tumour or abscess on the eyelid, the Old English word for which was stilgig, i.e. short for stilgig edge, a rising or swelling eye, hence in M. Eng. sting, taken as equivalent to sty on eye. STYL (from Gr. στυλος) was used in architecture, especially for a column or pilaster as a support, and the term was used to differentiate between its characteristics in various countries and at different periods (see Architecture). The derivation of the word suggests that it was at first employed to distinguish the classic styles, in which the column played the chief part, and it would be more appropriate to speak of the Doric and Ionic styles than orders (q.v.). In the Assyrian, Sassanian and perhaps the Byzantine styles, the column was a secondary feature of small importance, whereas the Greek, Doric and Ionic styles are based completely on the column and the weight of the superstructure it was required to carry. In France the term is sometimes employed of the individuality of character which is found in an artist's work. For the use of the term "style" in botany see FLOWER.

STYLE, in literature a term which may be defined as language regarded from the point of view of the characteristics which it
reels; similarly, by analogy, in other arts, a mode or method of work is characterized by distinctive features. The word (which is derived from a term used in architecture, see above) is derived from the instrument stilus (wrongly spoiled stylus), of metal, wood or ivory, by means of which, in classic times, letters and words were imprinted upon waxen tablets. By the transition of thought known as metonymy the word has been transferred from the object which makes the impression to the sentences which are impressed by it, and a mechanical observation has become an intellectual conception. To turn the stylus was to correct what had been written by the sharp end of the tool, by a judicious application of the blade. But is the terminal discipline of which literary excellence depends. The energy of a deliberate writer would make a firm and full impression when he wielded the stylus. A scribble of rapid and fugitive habit would press more irregularly and produce a less consistent text. The varieties of writing induced by these differences of temperament would reveal the nature of the writer, yet they would be attributed, and with justice, to the implement which immediately produced them. Thus it would be natural for any one who examined several tablets of wax to say, "The writers of these pieces possessed the general characteristics of their writer's style;" or "The style of the implement is the medium by which the temperament is transferred to the written speech.

If we follow this analogy, the famous phrase of Buffon becomes at once not merely intelligible but luminous—"the style est l'homme même." This axiom is constantly misquoted ("le style c'est l'homme"), and not infrequently misconstrued. It is usual to interpret it as meaning that the style of a writer is that writer's self, that it reveals the essence of his individuality. That is true, and the statement of it is useful. But it is not probably the meaning, or at least not the original meaning, that Buffon had in mind. It should be recollected that Buffon was a zoologist, and that the phrase occurs in the course of his great Natural History. He was considering man in the abstract, and differentiating him from other genera of the animal kingdom. Hence, no doubt, he remarked that "style was man himself," not as every reviewer repeats the sentence to-day, "the man." He meant that style, in the variety and elaboration of it, distinguished the language of man (Homo sapiens) from the monotonous roar of the lion or the limited gamut of the bird. Buffon was engaged with biological, not with aesthetic ideas. Natural classification given to the phrase "le style est l'homme même" may be accepted as true and valuable. According to an Arab legend King Solomon inquired of a djinn, "What is language?" and received the answer, "a wind that passes." "But bow," continued the wisest of men, "can it be held?" "By one art only," replied the djinn, "by the art of writing." It may be well to follow a little closely the processes of this art of writing. A human being in the artless condition, in whom, that is to say, the conception of personal expression has not been formed, uses written language to state primitive and general matters of fact. He writes, "The sea is rough to-day; the wind is cold." In these statements there is some observation, but as yet no personal note. We read them without being able to form the very smallest conjecture as to the character or condition of the writer. From these bald and plain words we may rise in degree until we reach Victor Hugo's celebrated parallel of the ocean with the genius of Shakespeare, where every phrase is singular and elaborate, and every element of expression redolent of Victor Hugo, but of no other person who ever lived. Another example, in its own way still more striking, is found in comparison of the famous paragraph which occurs in the Cyrus-Garden (1668) of Sir Thomas Browne. A primitive person would say, "But it is time to go to bed;" this statement is drawn out by Browne into the wonderful page beginning: "But the quincunx of Heaven runs low," and collects around it as it proceeds on its volupitous course the five ports of knowledge, cables of cobwebs, the bed of Cleopatra, the ghost of a rose, the huntsmen of Persia, and a dozen other examples of prolific and ornamented style. In its final form it is so fully characteristic of its author that it may be justly said that the passage is Browne himself.

It follows from what has just been said that style appeals exclusively to those who read with attention and for the pleasure of reading. It is not even perceived by those who read primarily for information, and these form the great majority of readers. Even these have a glimmering impression that we must not live by bread alone; that the human heart, with its imagination, its curiosity and sensitiveness, cannot be satisfied by bald statements of fact delivered on the printed page as messages are shouted along the telegraph. This instinct it is which renders the tale fall into those errors of false style to which we shall presently call attention. In the untrained there yet exists a craving for beauty, and the misfortune is that this craving is too easily met by gaudy rhetoric and vain repetitions. The effect on the nature of a human being which is produced by reading or listening to a book, or a passage from a book, which that being greatly admires, is often so violent as to resemble a physical shock to the nerves. It causes a spasm of emotion, which is betrayed by tears or laughter or a heightened pulse. This effect could not be produced by a statement of the fact and is denied in language. It is the result of the liberty which that fact is presented. In other words, it is the style which appeals so vividly to the physical and moral system of the reader—not the fact, but the ornament of the fact. That this emotion may be, and often is, caused by bad style, by the mere tinsel of rhetoric and jangle of alliteration, is not to the point. The important matter is that it is caused by style, whether good or bad. Those juvenile ardours and audacities of expression which so often amuse the wise man and exasperate the pedant are but the effects of style acting on a fervid and unripe imagination. That deep delight with which a grown man of experience reads Milton or Dante is but the same phenomenon produced in different conditions.

It is, however, desirable at the outset of an inquiry into the elements of style to insist on the dangers of a hasty which found audacious expression towards the close of the 19th century, namely, that style is superior to thought and independent of it. Against this may be set at once another of the splendid apotheosis of Buffon, "Les idées seules forment le fond du style." Before there can be style, therefore, there must be thought, clearness of knowledge, precise experience, sanity of reasoning conveyed in language, but as the result of the liberty in which there is no thought, the beauty even of some poems, the sequence of words in which is intentionally devoid of meaning, being preserved by the characteristics of the metre, the rhymes, the assonances, all which are, in their degree, intellectual in character. A confusion between form and matter has often confused this branch of our theme. Even Flaubert, than whom no man ever gave closer attention to the question of style, seems to dissociate them. For him the form was the work itself: "As in living creatures, the blood, nourishing the body, determines its very contour and external aspect, just so, to his mind, the matter, the basis, is a work of art, imposed, necessarily, the unique, the just expression, the measure, the rhythm, the form in all its characteristics." This ingenious definition seems to strain language beyond its natural limits. If the adventures of an ordinary young man in Paris be the matter of L'Éducation sentimentale it is not easy to admit that they "imposed, necessarily," such a "unique" treatment of them as Flaubert so superlatively gave. They might have been recounted with feebler rhythm by an inferior novelist, with bad rhythm by a bad novelist and with no rhythm at all by a police-news reporter. What makes that book a masterpiece is not the basis of adventure, but the superstructure of expression. The expression, however, could not have been built up on no basis at all, and would have fallen short of Flaubert's aim if it had risen on an inadequate basis. The perfect union is that between adequate matter and an adequate form. We will borrow from the history of English literature an example which may serve to illuminate this point. Locke has no appreciable style; he has only thoughts. Berkeley has thoughts which are as valuable as those of Locke, and he
STYLE

has an exquisite style as well. From the artist's point of view, therefore, we are justified in giving the higher place to Berkeley, but in doing this we must not deny the importance of Locke. If we compare him with some pseudo-philosopher, whose style is highly ornamental but whose thoughts are valueless, we see that Locke greatly prevails. Yet we need not pretend that he rises to an equal height with Berkeley, in whom the basis is no less solid, and where the superstructure of style adds an emotional and aesthetic importance to which Locke's plain speech is a stranger. At the same time, an abstract style, such as that of Pascal, may often give extreme pleasure, in spite of its absence of ornament, by its precise and pure definition of ideas and by the just mental impression it supplies of its writer's distinguished vivacity of mind. The abstract or concrete style, moreover, what Rossetti called "fundamental brain-work," must always have a leading place.

When full justice has been done to the necessity of thought as the basis of style, it remains true that what is visible, so to speak, to the naked eye, what can be analysed and described, is an artistic arrangement of words. Language is so used as to awaken impressions of touch, taste, odour and hearing, and those are roused in a way peculiar to the genius of the individual who brings them forth. The personal aspect of style is therefore indispensable, and is not to be ignored even by those who are most rigid in their objection to mere ornament. Ornament in itself is no more style than facts, as such, constitute thought. In an excellent style there is an effect upon our senses of the mental force of the man who employs it. We discover himself in what he writes, as it was excellently said of Chateaubriand that it was into his phrases that he put his heart; again, D'Alembert said of Fontenelle that he had the style of his thought, like all good authors. In the words of Schopenhauer, style is the physiognomy of the soul. All these attempts at epigrammatic definition tend to show the sense that language ought to be, and even unconsciously is, the mental picture of the man who writes.

To attain this, however, the writer must be sincere, original and highly trained. He must be highly trained, because, without the exercise of clearness of knowledge, precise experience and the habit of expression, he will not be able to produce his soul in language. It will, at best, be perceived as through a glass, darkly. Nor can anyone who desires to write consistently and well, afford to neglect the laborious discipline which excellence entails. He must not be satisfied with his first sprightly periods; he must polish them, and then polish them again. He must never rest until he has attained a consummate adaptation of his language to his subject, of his words to his emotion. This is the most difficult aim which the writer can put before him, and it is the light of the man who advances. Perfection is impossible, and yet he must not despair, but seek to pursue perfection. In this connexion the famous tirade of Tammblaine in Marlowe's tragedy cannot be meditated upon too carefully, for it contains the finest definition which has been given in any language of style as the unapproachable fire of the mind:

"If all the pens that poets ever held
Had fed the feeling of their master's thoughts,
And every sweetness that inspired their hearts,
Their minds, and muses, on admired themes—
If all the heavenly quintessence they still
From their immortal flowers of poetry,
Wherein, as in a mirror, the highest reaches of a human wit—
If those had made one poem's period,
And all combined in beauty's worthiness,
Yet should there hover in our restless heads
One thought, one grace, one wonder, at the least.
Which into words no virtue can digest."

Flaubert believed that every thought or grace or wonder had one word or phrase exactly adapted to express it, and could be "digested" by no other without loss of clearness and beauty. It was the passion of his life, and the despair of it, to search for this unique phrase in each individual case. Perhaps in this research after style he went too far, losing something of that simplicity and inevitability which is the charm of natural writing.

It is boasted by the admirers of Flaubert that his style is an enamel, and those who say this perhaps forget that the beauty of an enamel resides wholly in its surface and not at all in the substance below it. This is the danger which lies in wait for those who consider too exquisitely the value and arrangement of their words. Their style becomes too glossey, too highly varnished, and attracts too much attention to itself. The greatest writing is that which in its magnificent spontaneity carries the reader with it in its flight; that which detains him to admire itself can never rise above the second place. Forgetfulness of self, absence of conceit and affectation, simplicity in the sense not of thinness or poorness but of genuineness—these are elements essential to the cultivation of a noble style. Here again, thought must be the basis, not vanity or the desire to astonish. We do not escape by our ingenuities from the firm principle of Horace, "scribendi recti sopore est et principiurn et fons."

In speaking of originality in style it must not be forgotten that memory exercises a strong and often an insidious effect upon writing. That which has been greatly admired will have a tendency to impregnate the mind, and its echo, or, what is worse, its cadence, will be unconsciously repeated. The cliché is the greatest danger which lies in wait for the rapid modern author, who is tempted to adopt, instead of the one fresh form which suits his special thought, a word or even a chain of words, which conventionally represents it. Thus "the devouring element" was once a striking variant for the short word "fire," and a dangerous hindered place was once well described as "a visible shield," but these have long been clichés which can only be used by writers who are insincere or languid. Worse than these are continuous phrases, and even sentences, such as are met with in the leaders of daily newspapers, which might be lifted bodily from their places and inserted elsewhere, so completely have they lost all vitality and reality.

With regard to the training which those who wish to write well should resign themselves to undergo, there is some difference of opinion, based upon difference of temperament. There are those who believe that the gift of style is inborn, and will spend the moment of it the more happily without any external help. There are others who hold that no amount of labour is excessive, if it be directed to a study and an emulation of what are called "the best models." No doubt these theories are both admissible. If a man is not born to write well, no toil in the imitation of Addison or Ruskin will make his style a brilliant one; and a born writer will express himself with exactitude and fire even though he be but an idle student of the classics. Yet, on the other hand, the very large number of persons who have a certain aptitude for writing, yet no strong native gift, will undoubtedly cure themselves of faults and achieve skill and smoothness by the study of those writers who have the most kinship with themselves. To be of any service, however, it seems that those writers must have used the same language as their pupils. Of the imitation of the ancients much has been written, even to the extent of the publication of manuals. But what is that imitation of the verse of Homer which leads to Chapman and to-morrow to Pope? What the effect of the study of the prose of Theophrastus which results in the prose of Addison? The good poet or prose-man, however closely he studies an admirable foreign model, is really anxious to say something which has never before been said in his own language. He is stimulated which he receives from any foreign possession must be in the direction of analogous or parallel effort, not in that of imitation.

The importance of words, indeed, is exemplified, if we regard it closely, in this very question, so constantly mooted, of the imitation of the ancients, by the loss of beauty fatally felt in a bad translation. The vocabulary of a great writer has been, as Pater says, "winnowed"; it is impossible to think of Sophocles or of Horace as using a word which is not the best possible for introduction at that particular point. But the translator has to interpret the ideas of these ancient writers into a vocabulary which is entirely different from their own and yet have almost equal impecableness he will undo the winnowing work.
He will scatter chaff and refuse over the pure grain which the classic poet's genius had so completely fanned and freed. The employment of vague and loose terms where the original author has been eclectic, and of a flood of verbiage where he has been frugal, destroys all semblance of style, although the meaning may be correctly preserved.

The errors principally to be avoided in the cultivation of a pure style are confusion, obscurity, incorrectness and affectation. To take the earliest of these first, no fault is so likely to be made by an impetuous beginner as a mingling together of ideas, images, propositions which are not on the same plane or have no proper relation. This is that mass of "stunning sounds and voices all confused" which Milton depreciates. One of the first lessons to be learned in the art of good writing is to avoid perplexity and fatigue in the mind of the reader by retaining clearness and order in all the segments of a style, as well as propriety of grammar and metaphor in every phrase. Those who have overcome this initial difficulty, and have learned to avoid a jumble of misrelated thoughts and sentences, may nevertheless sin by falling into obscurity, which, indeed, is sometimes a wilful error and arises from a desire to cover poverty of thought by a semblance of profundity. The meaning of "obscurity" is, of course, in the first instance "darkness," but in speaking of literature it is used of a darkness which arises from unintelligibility, not from depth of expression, but from cloudiness and fogginess of idea.

Of the errors of style which are the consequences of bad taste, it is difficult to speak except in an entirely empirical spirit, because of the absence of any absolute standard of beauty by which artistic products can be judged. That kind of writing which in its own age is extravagantly cultivated and admired may, in the next age, be as violently repudiated; this does not preclude the possibility of its recovering critical if not popular favour. Perhaps the most remarkable instance of this is the revolution made against the cold and stately Ciceronian prose of the middle of the 16th century by the so-called Euphuiasts. This occurred almost simultaneously in several nations, and has been more thoroughly studied in the Spanish of Guevara and in his English imitators, North and Pettic, whom Lyly in his turn followed with his celebrated Euphues. Along with these may not unfairly be mentioned Montaigne in France and Castiglione in Italy, for, although these men were not proficients in Guevara's artificial manner, his estilo alto, still, by their easiness and brightness, their use of vivid imagery and their graceful illumination, they marked the universal revulsion against the Ciceronian stiffness.

Each of these new manners of writing fell almost immediately into desuetude, and the precise and classic mode of writing in another form came into vogue (Addison, Bossuet, Vico, Johnson). But what was best in the ornamental writers of the 16th century is now once more fully appreciated, if not indeed admired to excess. A facility in bringing up before the memory incessant analogous metaphors is the property, not merely of certain men, but of certain ages; it flourished in the age of Marino and is welcomed again in that of Meredith. A vivid, concrete style, full of colour and images, is not to be condemned because it is not an abstract style, scholastic and systematic. It is to be judged on its own merits and by its own laws. It may be good or bad; it is not bad merely because it is metaphorical and ornate. The amazing errors which lie strewn along the shores of criticism are evidence to the lack of sympathy which has not perceived this axiom and has wrecked the credit of dogmatists. To De Quincey, a convinced Ciceronian, the style of Keats "belonged essentially to the vilest collections of work filagree or gilt gingerbread"; but to read such a judgment is to encourage a question whether all discussion of style is not futile. Yet that particular species of affectation which encourages untruth, affectation, parade for the mere purpose of producing an effect, must be wrong, even though Cicerio be guilty of it.

The use of the word "style," in the sense of the present remarks, is not entirely modern. For example, the early English critic Puttenham says that "style is a constant and continual phrase or tenour of speaking and writing." (1589). But it was in France and in the great age of Louis XIV, that the art of writing began to be carefully studied and ingeniously described. Mme de Sévigné, herself mistress of a manner exquisitely dis- tinctive, judged "la manière nouvelle de composer les lettres," as the writer, and in the 18th century, is particularly fond of using the word "style" in its modern sense, as the expression of a complete and rich personality. She says, in a phrase which might stand alone as a text on the subject, "Ne quittez jamais le naturel, votre tour s'y est formé, et cela compose un style parfait." Her contemporary, Boileau, contributed much to the study, and spoke with just pride of "mon style, ami de la jumiere." The expression to form one's style, à se faire un style, appears, perhaps for the first time, in the works of the abbe d'Olivet (1668-1768), who was addicted to metaphysical speculation. Two great supporters of the pure art of writing were Swell and Voltaire. The latter is most celebrated for his style in the 18th century. The former declared that "proper words in proper places make the true definition of a style"; the latter, more particularly, that "le style rend singulieres les choses les plus communs, fortifie les plus faibles, donne de la grandeur aux plus simples." Voltaire speaks of "le mélange des styles" as a great fault of the age in which he lived; it has come to be looked upon as a principal merit of that in which we live.

The problem of how to obtain a style has frequently been treated by works of more or less ephemeral character. In France the treatises of M. Albaret have received a certain amount of official recognition, and may be mentioned here as containing a good deal of sound advice mixed with much that is jejune and pedagogic. If M. Albaret distributes a poison, the antidote is supplied by the wit of M. Remy de Gourmont; the one should not be imbibed without the other.

See Walter Pater, An Essay on Style (London, 1880); Walter Raleigh, Style (London, 1897); Antoine Albaret, L'Art d'écrire enseigné en vingt leçons (Paris, 1898); and De la Formation du style (Paris, 1901); Remy de Gourmont, Le Problème du style (Paris, 1902). Also Goyen-Linguet, Le Génie de la langue française (Paris, 1846), and "Loyson-Bridet, (i.e. Marcel Schwob), Moeurs des diurnaires (Paris, 1902), a satire on the principal errors to which modern writers in all languages are liable.

**STYLOBATE** (Gr. στύλός, a column, and βάσις, a base), the architectural term given to the upper step of the Greek temple on which the columns rest, and generally applied to the three steps.

**STYRIA** (German, Steiermark or Steiermark), a duchy and crownland of Austria, bounded E. by Hungary and Croatia, S. by Carniola, W. by Carinthia and Salzburg, and N. by Upper and Lower Austria. It has an area of 3690 sq. m., and is distinguished by the beauty of its scenery and by its mineral wealth. Geographically it is divided into northern or Upper Styria, and southern or Lower Styria, and is traversed by various ramifications of the eastern Alps. To the north of the Enns are ramifications of the Salzkammergut and Enns Alps, which include the Dachstein (9830 ft.), and the Grimming (7713 ft.), and the groups of the Todtes Gebirge (6850 ft.) and of the Pyrgs with the Grozer Pyrgs (7300 ft.). The last two groups are separated by the Pyhrn Pass (3100 ft.), traversed by a road constructed in the Roman period. Then comes the Buchenau group with the Grosser Buchenau (7204 ft.). This group forms the northern flank of the celebrated Gesäuse, a defile 12 m. long, between Admont and Hieflau, through which the Enns forces its course, forming a series of rapids. The southern flank is formed by the massif of the Reichensteiner Gebirge, which culminates in the Hochthor (7780 ft.) and belongs to the north Styrian Alps, also called Eisenzer Alp. This group extends east of the Enns, and contains the Erzberg (9000 ft.) celebrated for its iron ores. Other groups of the northern Styrian Alps are the Hochschwab, with the highest peak the Hochschwab (7482 ft.) and the Hochwelscht with the Hohe Welsch (9550 ft.). Then comes the Lower Austrian Alps, with the groups of the Vorarl (5800 ft.), of the Schneealpe (6254 ft.), and the Kaxalpe, with the Heukuppe (6950 ft.). All
these mountains belong to the northern zone of the eastern Alps. South of the Enns, Styria is traversed by groups of the central zone of the eastern Alps: the Niedere Tauern, the primitive Alps of Carinthia and Styria and the Styrian Nieder Alps. The principal divisions of the Niedere Tauern are: the Radistädter Tauern with the Hochgolling (9300 ft.), the Wölzer Alps with the Pitzgillin (8549 ft.), the Rottenmanner Tauern with the Groser Rösenstein (8032 ft.), and the Seekauer Alpen or Zinken group, which culminates in the Zinkenkogel (7895 ft.). The principal ramifications of the primitive Alps of Carinthia and Styria are: the Stang Alps with the Königstuhl (7646 ft.) and Eisenhut (8007 ft.), the Judenburger or Seetaler Alps with the Zirbitzkogel (7868 ft.), and the Koralpen which culminates in the Grosser Spießkogel (7023 ft.). The Styrian Nieder Alps cover the county north and east of the Mur, and contain the Fischbacher Alps with the Hochlantsch (5946 ft.), the Wchsell group (5700 ft.), and the small Semmerring group with the Stuhleck or Spitaler Alps (5827 ft.), and the Sonnenwendstein (4994 ft.). In this group is the famous Semmerring Pass, which leads from Lower Austria into Styria and is crossed by the Semmerring railway. This railway, which was completed in 1854, is the oldest of the great continental mountain railways, and is remarkable for its numerous and long tunnels, its viaducts and galleries. It has a length of 35 m., beginning at Gloggnitz in Lower Austria and ending at Mürzzuschlag in Styria, and passes through some exceedingly beautiful scenery. The whole region is now a favourite summer resort. South of the Drave Styria is traversed by the following ramifications of the southern zone of the eastern Alps: the Bacher Gebirge with the Cornel Vrch or Schwarzberg (3978 ft.), and the Sannenthal or Steiner Alps with the Ostrizza (7909 ft.) and the highest peak of the group, the Grinotz or Grinoutz (8420 ft.), which is situated on the threefold boundary of Carinthia, Carniola and Styria. Here is also the mountain country of Cilli, with the highest peak, the Wachberg (3364 ft.). The mountains decrease in height from west to east, and the south-east of Styria may be described as hilly rather than mountainous. This part is occupied by the eastern outliers of the Alps, known as the Styrian hill country, and by the Windisch Büheln, which is one of the most renowned vine districts in the whole of Austria. Styria belongs to the watershed of the Danube and its principal rivers are: the Enns with its affluent the Salza, the Raab with the Feistritz, the Mur with the Mürz, the Drau or Drave, and the Sau or Save, which receives the Sann and the Sotla. Styria has numerous small Alpine lakes of which the most important are the Grundl-see, the Töplitz-see, and the Leopoldsteiner-see. There is a mean annual difference of about 0° F. between the north-west and the south-east. The best known mineral springs are the alkaline springs of Rohitsch and Gleichenberg, the brine springs of Aussee, and the thermal springs of Tüffer, Neuhau and Töplitz, which are mentioned above.

In spite of the irregular nature of the surface, but little of the soil can be called unproductive. Of its total area 47-49% is covered with fine forests. About 10% is arable land, 12% pastures, 5-60% meadows, while 10-15% is occupied by gardens and 1-4% by vineyards which produce wine of a good quality. Cattle-rearing has taken a great development and also dairying in the Alpine fashion. A good race of horses is bred in the valley of the Enns, while poultry-rearing and bee-keeping are carried on in the south. Fish and game are also plentiful. The great wealth of Styria, however, lies underground. Its extensive coalfield at Leoben, which is worked during the Roman period, yields nearly half of the total production of iron in Austria. The principal foundries are at Eisenerz, Vordernberg, Trofaiach, Hieflau, Zeltwald and Neuberg. Next in importance comes the mining of brown coal, which has also been carried on for a long time. The richest coalfields are situated near Leoben; near Voitsberg and Köflach, near Elbwald and Wies, and round Triffal, Tüffer and Hrustig. Its other mineral resources include graphite, copper, zinc, lead, salt, alum, potter's clays: marble and good mill and building stones. Iron-foundries, machine-shops and manufactures of various kinds of iron and steel goods are very numerous. A special branch is the making of scythes and sickles which are exported in large quantities. Among its other industrial products are glass, paper, cement, cotton goods, chemicals and gunpowder. Linen-weaving is a household industry.

The population of Styria in 1900 was 1,356,058, which is equivalent to 156 inhabitants per square mile. This proportion is considerably above the rate in the other mountainous regions of Austria. Nearly all (98-74%) profess the Roman Catholic faith and are under the bishops of Seckau and of Laven. The Protestants number only a little over 13,000, while there are about 2500 Jews. Two-thirds of the inhabitants are Germans; the remainder, chiefly found in the valleys of the Drave and Save, are Slavs (Slovenes). At the head of the educational institutions of the province stands the university of Graz. The local Diet, of which the two Roman Catholic bishops and the rector of the university of Graz are members ex officio, is composed of 63 members, while Styria sends 27 deputies to the Reichsrat at Vienna. For administrative purposes, the province is divided into 21 districts and 4 towns with autonomous municipalities, namely Graz (pop. 138,370), the capital, Cilli (6743), Marburg (24,501) and Pettau (4227). Other important places are Leoben (10,204), Bruck on the Mur (7527), Mariazell (1263), Mürzschlag (4856), Eisenerz (6494), Vordernberg (3111), Judenburg (4901), Trifial (10,851), Eggenberg (19570), Donawitz (13,003), Köflach (3345) and Voitsberg (3321).

In the Roman period Styria, which even thus early was famed for its iron and steel, was inhabited by the Celtic Taurisci, and divided geographically between Noricum and Pannonia. Subsequent to these it was successively occupied or traversed by Visigoths, Huns, Ostrogoths, Langobard, Franks and Avars. Towards the end of the 6th century the last-named began to give way to the Slavs, who ultimately made themselves masters of the entire district. Styria was included in the conquests of Charlemagne, and was henceforth comprised in the German marks erected against the Avar and the Slav. At first the identity of Styria is lost in the great duchy of Carinthia, corresponding more or less closely to the Upper Carinthian mark. This duchy, however, afterwards fell to pieces, and a distinct mark of Styria was recognized, taking its name from the margrave Ottocar of Steier (1056). A century or so later it was created a duchy. In 1192 the duchy of Styria came by inheritance to the house of Austria, and from that time it shared the fortunes of Upper and Lower Austria, passing like them to the Halshurschs in 1282. The Protestant Reformation met an early and general welcome in Styria, but the dukes took the most stringent measures to stamp it out, offering their subjects recantation or expatriation as the only alternatives. At least 30,000 Protestants preferred exile, and it was not till the edict of tolerance of 1781 granted by Joseph II. that religious liberty was recognized.

STYROLENE, C₄H₆·CH₂·CH₃, also known as phenylethylene or vinylbenzene, an aromatic hydrocarbon found to the extent of 1 to 4% in storax; it also occurs with crude xylene in coal tar fractions. It may be obtained from storax by distillation with water, and synthetically by heating cyclic acid with lime, by the action of aluminium chloride on a mixture of vinyl bromide and benzene, by removing the elements of hydrobromic acid from bromobenzene benzene by means of alcoholic potash, or, best, by treating β-bromohydrobromic acid with soda, when it yields styrene, carbon dioxide and hydrobromic acid. It also results on condensing acetylene, and on reducing phenylacetylene by zinc dust and acetic acid. It is a clear, strongly refractive liquid, which has a pleasant odour; it boils at 144° and has a specific gravity of 0·925 at 0°. Styrene is oxidized by nitric or chromic acids to benzoic acid; reduction gives ethylbenzene; hydrochloric and hydrobromic acids yield α-haloid ethylbenzenes, e.g. C₆H₅·CHCl·CH₃; whilst chlorine and bromine give α-haloid ethylbenzenes, e.g. C₆H₅·CHCl·CH₂Cl.
Styrene gives origin to three series of derivatives, two of which contain the substituents in the side chain, e.g. C₆H₅-C=CH₂ or C₆H₅-C=C(CH₃)₂). Compounds, e.g. C₆H₅-C=CH₂-C₆H₅, of the third benzene nucleus is substituted. The α-halogen compounds are obtained by heating styrene chloride (or bromide) with lime or alcoholic potash; they are liquids which have a penetrating, comfortable odour, and are used with water. So:C₆H₅-C=CH₂ + HCl → C₆H₅-C=CHCl (Ber., 1866). From this compound on heating with a strongly alkaline solution, e.g. sodium hydroxide, the corresponding dyes are obtained. When heated with water, it yields acetoephene.

Related to styrene is phenylacetylene, C₆H₅-C≡CH, which results when acetylenic compounds are heated with sulphuric acid, sulphur, and potassium chlorate. It forms a white solid and is a valuable source of ethylene.

Stilbene or toluylene, C₆H₅-C=CH₂, is symmetrical diphenylethylene. It may be obtained by distilling benzyl sulphide for disulphonic acid, by the action of sodium on benzaldehyde or benzal chloride, by distilling furanolic and cinnamic phenyl esters: C₆H₅-C=CH₂-C₆H₅-C=CH₂ + 2Na + 2H₂O. From the vapour through red-hot tubes it yields anisochrome and tolulene. Reduction with hydriodic acid gives dibenzyl, and heating with sulphur gives tetraphenylethylene or thio-phenylacetylene, which melts at 151°. On heating, it decomposes at 150° and is oxidized in two structural forms, exhibiting geometrical isomerism after the mode of fumaric and maleic acids. Those substituted in the benzene nucleus are obtained by condensing two molecules of a substituted benzyl or benzylchloride with the dier of chloral, which dinitro compounds result from the action of alcoholic potash on ortho- and para-nitrobenzyl chloride. The latter on reduction yields a diaminocompound, the disulphonic acid of which gives valuable substantive cotton dyes after the type yielded by Benzidine. Stilbene bromide when treated with alcoholic potash gives diphenyl acetylene or tolane, C₆H₅-C=CH₂.

STYX, in Greek mythology, a river which flowed seven times round the world of the dead. In the Iliad it is the only river of the underworld; in the Odyssey it is coupled with Ceyttus and Pythralphoton, which flow into the chief river Acheron. Hesiod says that Styx was a daughter of Ocean, and that, when Zeus summoned the gods to Olympus to help him to fight the Titans, Styx was the first to come and her children with her; hence as a reward Zeus ordained that the most solemn oath of the gods should be by her and that her children (Emulation, Victory, Power and Force) should always live with him. Again, Hesiod tells us that if any god, after pouring a libation of the water of Styx, foreswore himself, he had to lie in a trance for a year without speaking or breathing, and that for nine years afterwards he was excluded from the society of the gods. In historical times it was the name given to an island in the sea, opposite the town of Adras in Arcadia. Pausanias (viii. 17. 6) describes the cliff over which the water falls as the highest he had ever seen, and indeed the fall is the highest in Greece. The ancients regarded the water as poisonous, and thought that it possessed the power of breaking or dissolving vessels of every material, with the exception of the hoof of a horse or a mule. Considering the undoubted importance attached by the ancients to an oath by the water of the Styx (cf. Herodotus vi. 74), and the supposed fatal result of breaking it, it is probable that drinking the water originally formed a necessary part of the oath, and that we have to do with the tradition of an ancient poison ordeal, common amongst barbarous peoples (for the geography and similar ceremonies see Frazer's Pausanias, iv., pp. 250-255). The people in the neighbourhood, who call it Mavro Nerò (the Black Water), still think that it is unwholesome, and that no vessel will hold it.

SUAKIN, or SAWAKIN, a seaport of the Anglo-Egyptian Sudan on the west side of the Red Sea in 10° 7' N., 37° 20' E. Pop. (1905), 10,000. Suakin stands on a coraline islet connected with the suburb of El-Kef on the mainland by a causeway and a viaduct. Access is gained to the harbour through a winding and dangerous passage over 2 m. long, terminating in a deep oval-shaped basin several acres in extent, and completely sheltered from all winds. For centuries the chief port of the eastern Sudan, Suakin has been since 1906 to some extent superseded by Port Sudan (q.v.), a harbour 36 m. to the north. The custom- house and government offices present an imposing frontage to the sea, and the principal houses are of white coral stone three storeys high. The mosques are those who were mother's kin...
Bartolommeo Suardi has been much confused with a certain Bramantino da Milano, of whom Vasari makes frequent and specific mention in his life of Piero della Francesca, his observations on Benvenuto Cellini and Girofallo da Ghedi, and his life of Jacopo Sutrosovo. The Bramantino of Vasari, if he existed at all, worked for Pope Nicholas V. between 1450 and 1455.

**SUAREZ, FRANCISCO** (1548-1617), Spanish theologian and philosopher, was born at Granada on the 5th of January 1548, and educated at Salamanca. Influenced by the Jesuit Juan Ramírez he entered the Society of Jesus in 1564, and after teaching philosophy at Segovia, taught theology at Valladolid, at Alcalá, at Salamanca, and at Rome successively. After taking his doctorate at Evora, he was named by Philip II. principal professor of theology at Comillas. Suarez may be considered the last exponent of the scholasticism. In philosophical doctrine he adhered to a moderate Thomism. On the question of universals he endeavoured to steer a middle course between the pantheistically inclined realism of Duns Scotus and the extreme nominalism of William of Occam. The only veritable and real unity in the world of existence is the individual; to assert that the universal exists separately ex parte rei would be to reduce individuals to mere accidents of one indivisible form, Suarez maintains that, though the humanity of Socrates does not differ from that of Plato, yet they do not constitute reflection one and the same human form; there are many "formal unities" (in this case, humanities) as there are individuals, and these individuals do not constitute a factual, but only an essential or ideal unity ("ita ut plura individua, quae dicuntur esse ejusdem naturae, non sint unum quid verum entitate quae sit in rebus, sed solum fundamentaliter vel per intellectum "). The formal unity, however, is not an arbitrary creation of the mind, but exists "in natura rei ante omnem operationem intellectum." In theology, Suarez attached himself to the doctrine of Luis Molina, the celebrated Jesuit professor of Evora. Molina tried to reconcile the doctrine of predestination with the freedom of human action. The current view is that man's free will is dependent upon God's foreknowledge of the free determination of man's will, which is therefore in no way affected by the fact of such predestination. Suarez endeavoured to reconcile this view with the more orthodox doctrines of the efficacy of grace and special election, maintaining that, though all share in an absolutely sufficient grace, there is granted to the elect a grace which is so adapted to their peculiar dispositions and circumstances that they infallibly, though at the same time quite freely, yield themselves to its influence. This mediating system was known by the name of "congruism." Suarez is probably more important, however, as a philosophical jurist than as a theologian or metaphysician. In his extensive work *Tractatus de legibus ac deo legislatore* (reprinted, London, 1679), he is to some extent the precursor of Grociet and Samuel Pufendorf. Though his method is throughout scholastic, he covers the same ground, and Grotius speaks of him in terms of high respect. The fundamental position of the work is that all legislative as well as all paternal power is derived from God, and that the authority of every law resolves itself into His. Suarez refutes the patriarchal theory of government and the divine right of kings founded upon it—doctrines popular at that time in England and to some extent on the Continent and the power by its very nature belongs to no one man but to a multitude of men; and the reason is obvious, since all men are born equal. It has been pointed out that this accords well with the Jesuit policy of deprecating the royal while exalting the papal prerogative. But Suarez is much more moderate on this point than a writer like Mariana, approximating to the modern view of the rights of ruler and ruled. In 1613, at the instigation of Pope Paul V., Suarez wrote a treatise dedicated to the Christian princes of Europe, entitled *Defensio catholicae fidei contra anglicanae sectae errores.* This was directed against the oath of allegiance which James I. exacted from his subjects. James caused it to be burned by the common hangman, and forbade its perusal under the severest penalties, complaining bitterly at the same time to Philip III. that he should harbour in his dominions a declared enemy of the throne and majesty of kings. Suarez lived a very humble and simple life. He died after a few days' illness on the 23rd of September 1617 at Lisbon.

The collected works of Suarez have been printed at Mainz and Lyons (1630), at Venice (1740-1751), at Besançon (1856-1862) and in the collection of the Abbé Migne. His life has been written by Deschamps (Vita Fr. Suarezis, Perpignan, 1671). The chief modern authority is Are K. Werner, *Francesc Suarez u. die Scholastik der letzten Jahrhunderte* (Regensburg, 1861), and Stocki's Geschichte der Philosophie des Mittelalters, iii. 643 seq.

**SUBIACO** (anc. *Sublacense*), a town of Italy, in the province of Rome, from which it is 47 m. E. by rail, picturesquely situated on the right bank of the Anio, 1330 ft. above sea-level. Pop. (1901), 7076 (town), 8003 (commune). It has ironworks and paper-mill. Sublacuam was so called from its position under the three artificial lakes constructed in the 16th century in connexion with the aqueduct of the Anio Novus, which had its intake at the lower end of the lowest of them (the Simbruina stagia of Tacitus). On the banks of this lake Nero constructed a villa, in the remains of which was found the beautiful headless statue of a youth kneeling, now in the Museo delle Termine at Rome. There is no mention of the villa after Nero's time. The lakes gradually ceased to exist owing to the action of the Anio, the last dam being washed away in 1305. In 494 St Benedict retired to this spot, then already deserted, and took up his abode as a hermit in a cave (Sacro Speco) above the lakes of the Anio. In 565, probably, he founded the first of his twelve monasteries, completing their number between 510 and 529, when he went to Cassino. The chronicles state that the principal monastery was devastated by the Lombards in 601, and rebuilt in 705; but there is little foundation for these statements. The first authentic document that we have is the mention in the *Liber pontificum* of the gift of vestments by Leo IV. (847-855) to the monastery of S. Silvester, S. Benedict and S. Scholastica, and to the church of SS. Cosmas and Damian. The former is probably that at the Sacro Speco. The monastery was confirmed in the possessions by Pope Gregory I. and his successors, and had by the 10th century very considerable landed properties with feudal jurisdiction enumerated in several documents, the first dating from 926, and an inscription of 1052 (cf. *Regesto sublacense*, Rome, 1891). The church dedicated to S. Scholastica, S. Benedict's sister, was erected in 987, according to an inscription belonging to a later date, but carved upon a slab decorated with reliefs of the end of the 8th, or the beginning of the 9th century.

In 1053 the church was restored and a campanile built, which still exists; and in the middle of the 13th century the church was rebuilt in the Gothic style. Other buildings grew up round it till the cloister on the right is a fine Romanesque arcaded court with twisted columns and mosaics, the south side of which was constructed by Lorenzo, the first of the family of the Cosmati, early in the 13th century, while the other three sides are due to his son Jacopo and to Jacopo's sons Luca and Jacopo, who worked here in the time of the abbot Landi (1227-1243). The irregular atrium in front of the church is probably contemporary with its reconstruction in the Gothic style about 1274, while the outer court dates from the end of the 10th century. The church, with the exception of the campanile, was modernized in 1771-1777. The right of the monks to eat their own abbot, who by that time obtained a position of great importance, was cancelled in 1388, and in 1455 the abbot was suspended, and the administration handed over to the Spanish cardinal, Giovanni Torquemada. For the whole of the 16th century it was in the hands of the Colonna family, who were commendatories of it. During the 17th century, the Barberini held it, but in 1753 Benedict XIV. separated the spiritual and temporal dominions, placing the latter under officials directly dependent on the papacy. The commendatories were as a rule cardinals. As regards monastic discipline, the abbey had since 1514 been subject to the rule of Monte Cassino, and it was only in 1872 that it regained from the

The bull of 956 attributed to him is, however, now recognized as apocryphal.
Pius IX. its independence and became an autonomous congre-
gation. Arnold Pannartz and Conrad Schweinheim, two German
eclesiastics, set up here the first printing press in Italy, issuing
an edition of Donatus (1465), followed by one of Cicerio (1465)
and of Lactantius (1465). Copies of the Lactantius, of the Augustus-
tine of 1437, which was probably printed not here but in Rome,
whither the printers migrated in that year, and of other rare incauto-
balla are still preserved here. Still more interesting is the monas-
tery of the Sacro Speco, higher up the hill, dating it seems, from
the 9th century, though little earlier than the 13th remains. The Grotto
del los Pastori contains some frescoes of the 9th century, while the Sacro
Speco, or cave of St Benedict, contains frescoes of the 13th, and so does
the lower church, the latter having been decorated in the first twenty
years of the 14th century, and in part repainted in the latter half of
the same century by an otherwise unknown master Cineolus.
The upper church contains scenes from the life of Christ by an
unknown Siene master of the end of the 14th century, to whom
is also attributable a remarkable fresco of the triumph of death,
the stairs from the tower church to the Cappella dei Pastori,
and some 15th-century work, and in the chapel of St. Gregory a
remarkable portrait of St Francis of Assisi (who was perhaps
here in 1218), probably painted before 1228, as it lacks the halo
and the stigmata. The whole group of buildings is constructed
against the rocky sides of the gorge, part of it on massive sub-
strictures. The town contains various buildings constructed by
Pius VI., who as cardinal was commendatory abbot of Subiaco.
It is crowned by a medieval castle constructed originally by
Gregory VII.
See P. Egidii, G. Giovannoni, F. Hermanin, V. Federici, I Menas-
teri di Subiaco (Rome, 1904); A. Colussanti, L'Aniene (Bergamo,
1906).

SUBINFEUDATION, in English law, the practice by which
tenants, holding land under the king or other superior lord,
carved out in their turn by subletting or alienating a part
of their lands new and distinct tenures. The tenants were termed
"mesne-lords," with regard to those holding from them, the
immediate tenant being tenant in capite. The lowest tenant of
all was the freeholder, or, as he was sometimes termed tenant
paravail. The Crown, who in theory owned all lands, was lord
paramount. The great lords looked with dissatisfaction on the
increase of such subtenures. Accordingly in 1290 a statute was
passed, Quia emptores, which allowed the tenant to alienate
whenever he pleased, but the alienee or person to whom he
granted was to hold the land not of the alienor but of the same
immediate lord, and by the same services as the alienor held it
before. (See further, MANOR.)

SUBJECTIVISM, a philosophical term, applied in general
to all theories which lay stress on the purely mental sides of
experience opposed to objectivism. In the narrowest sense
subjectivism goes to the logical extreme of denying that mind
can know objects at all (cf. SOLIPSISM). The doctrine originates
in the fact that the most elementary psychic phenomena pre-
sume in addition to the data of the senses (which as such are
momentary) a combining action of the mind. (See IDEALISM.)

SUBLEYRAS, PIERRE (1609-1749), French painter, was born
at Uzès (Gard) in 1609. He left France for Italy in 1728, having
carried off the grand prix. He there painted for the Canons of
Asti "Christ's Visit to the House of Simon the Pharisee" (Louvre,
engraved by Subleyras himself), a large work, which made
his reputation and procured his admission into the Academy of
St Luke. Cardinal Valenti Gonzaga next obtained for him
the decoration of the Basilica Valtieri, to which a study
was given (Louvre), which was executed in mosaic for St Pater's,
Benedict XIV, and all the princes of Rome sat to him, and
the pope himself commanded two great paintings—the "Marriage
of St Catherine" and the "Ecstasy of St Camilla"—which he
placed in his private apartments. Subleyras shows greater
individuality in his curious genre pictures, which he produced
in considerable number (Louvre). In his illustrations of La

Fontaine and Boccaccio his true relation to the modern era
comes out; and his drawings from nature are often admirable
(see one of a man draped in a heavy cloak in the British Museum).
Exhausted by overwork, Subleyras tried a change to Naples,
but returned to Rome at the end of a few months to die
(May 28, 1749). His wife, the celebrated miniature painter,
Maria Felice Tibaldi, was sister to the wife of Trémollière.

SUBLIME (Lat. sublimis, exalted), in aesthetics, a term applied
seem, in the sense of an intellectual or artistic. It is specially used for
the sublime with which nothing else can be compared and which is beyond
all possibility of calculation or measurement. Psychologically
the effect of the perception of the sublime is a feeling of awe or
helplessness. The first study of the value of the sublime is
the treatise ascribed to Longinus (q.v.), On the Sublime (strictly
Πεῖρης Ἡγών). Burke and Kant both investigated the subject
(cf. Burke's Essay on the Sublime and Beautiful, 1759) and both
distinguished the sublime from the beautiful. Later writers
tend to include the sublime in the beautiful (see AESTHETICS).

SUBLIMAL SELF. The phrase "subliminal self," which is one
that has figured largely of recent years in discussions of
the problems of "Psychical Research," owes its wide currency
to the writings of F. W. H. Myers, especially to his posthumous
work Human Personality and its survival of Bodily Death.
It is used in a wider, looser sense and a narrower, stricter sense,
which two senses are often confused in a way very detri-
mental to clear thinking. In the stricter usage the phrase implies
the peculiar conception of human personality expounded
at great length and with a wealth of learning and eloquence by
Myers, put forward for an hypothesis which seemed to its author
to bring almost all the strange facts he and his associates observed,
and as many alleged facts whose reality still remains in dis-
pute, under one scheme of explanation and to bring them also
into intelligible relation with the body of generally accepted
scientific principles. But the phrase "Subliminal Self" is now
often used by those who do not fully accept Myers's hypothesis,
as a convenient heading to which to refer all the facts of many
different kinds that seem to imply subconscious or unconscious
mental operations. This article is only concerned to expound
the meaning of the phrase as it was employed by Myers, and
it is much to be wished that it should only be used in this
stricter sense.

In the speculations of Schopenhauer and of Eduard von
Hartmann, the "Unconscious" played a great part as a meta-
physical principle explanatory of the phenomena of the life and
mind of both men and animals. But with these exceptions,
the philosophers and psychologists of the 19th century showed them-
selves in the main reluctant to admit the propriety of any con-
ception of unconscious or subconscious mental states or opera-
tions. The predominant tendency was to regard as the issue of
"automatic" nervous action or of "unconscious cerebration" what-
ever bodily movements seemed to take place independently of
the consciousness and volition of the subject, even if those
movements seemed to be of an intelligent and purposeful
character. This attitude towards the subconscious is still
maintained by some of the more strictly orthodox scientists; but
it is now very widely accepted that we must recognize in
some sense the reality of subconsciousness or of subliminal
psychical process. The conception of a limen (threshold) of
consciousness, separating subconscious or subliminal psychical
process from supraliminal or conscious psychical process,
figured prominently in the works of G. T. Fechner. The latter
Fechner sought to prove that a sensory stimulus too feeble to
affect consciousness produces nevertheless a psychical effect
which remains below the threshold of consciousness, and he tried
to show ground for believing in the existence of a vast realm of
such subliminal psychical processes. But his arguments, founded
though they were on epoch-making experiments, have failed
to carry conviction; and it is in the main on other grounds
than those adduced by Fechner that the reality of modes of
mental operation which may properly be called subconscious or

1 Paramount and paravail are derived from the Latin ad moniem and ad vallem, signifying the highest and lowest, respectively.
SUBLIMINAL SELF

SUBLIMINAL self is now generally admitted. During the last quarter of the 19th and the opening years of the 20th century, there has been accumulated a mass of observations which suffices, in the opinion of many of those best qualified to judge, to establish the reality of processes which express themselves in purposeful actions and which bear all the marks from which we are accustomed to infer conscious cognition and volition, but of which nevertheless the subject or normal personality has no knowledge or awareness other than such as may be shared by any second person observing his actions.

Among the commonest and most striking of such manifestations is the "automatic writing" which a considerable proportion of normal persons are capable of producing. A person who has this power may sit absorbed in reading or in conversation, while his hand produces written words or sentences, of which he knows nothing until he afterwards reads them. The matter so written varies in different cases from illegibly scrawled fragments of words and sentences to long, connected, sometimes eloquent, frequently more or less dramatic, disquisitions. In some cases the "automatically" writing hand can be induced to make intelligible replies to questions whispered or otherwise put to the subject in such a way as not to draw his attention from some other object or topic with which it seems to be fully occupied. In some cases the matter so written states facts previously known to the subject but which he is unable to recollect by any voluntary effort. And in rare cases the matter written seems to imply knowledge or capacities which the subject was not believed to possess either by himself or by his friends. Other actions, including connected speech, may be produced in a similar fashion, and in the last case the subject hears and understands the words uttered from his own mouth in the same way only as those from the mouth of another person. "Table-tilting," "planchette-writing," and the various similar modes of spelling out by the aid of a code intelligible replies to questions, which have long been current in spiritistic circles and which, by those who practise them, are often regarded as the operations of disembodied intelligences, seem to belong to the same class of process. In extreme cases the manifestations of such subconscious or (better) co-conscious operations are so frequent, exhibit so much continuity and express so clearly a train of thought, purpose and memory, that they compel us to infer an organized personality of which they are the expression; such are the cases of double or multiple consciousness or personality. Very similar manifestations of a "co-consciousness" may be produced in a considerable proportion of apparently normal persons by means of post-hypnotic suggestion; as when suggestions are made during hypnosis, which afterwards the subject carries out without being aware of the actions, or of the signals in response to which he acts, and without any awareness or remembrance of the nature of the suggestions made to him. The more sober-minded of the investigators of these phenomena have sought to display all such cases as instances of division of the normal personality, and as explicable by the principle of cerebral dissociation (see HYPNOTISM); the more audacious, concentrating their attention on the more extreme instances, regard all such manifestations as instances of the possession and control (partial or complete) of the organism of one person by the spirit or soul of another, generally a deceased person. Myers's hypothesis of the subliminal self was a brilliant attempt to follow a middle way in the explanation of these strange cases, to reconcile the two kinds of explanation with one another, and at the same time to bring into line with these other alleged facts of perplexing character, especially veridical hallucinations (q.v.), various types of communication at a distance (see TELEPATHY), and all the more striking instances of the operation of suggestion and of hypnosis, including the exaltation of the powers of the senses, of the memory and of control over the organic processes.

Myers conceived the soul of man as capable of existing independently of the body in some super-terrestrial or extraterrene realm. He regarded our normal mental life as only a very partial expression of the capacities of the soul, so much only as can manifest itself through the human brain. He regarded the brain as still at a comparatively early stage of its evolution as an instrument through which the soul operates in the material world. So much of the life of the soul as fails to find expression in our conscious and organic life through its interactions with this very inadequate material mechanism remains beneath the threshold of consciousness and marks to constitute the subliminal self. The subliminal self as thus conceived would be better described as the subliminal part of the self, a part which surpasses the supraliminal or normal conscious self to an indefinitely great degree as regards its range of psychical faculties. It was further conceived as being in touch with a realm of psychical forces from which it is able to draw supplies of energy which it infuses into the organism, normally in limited quantities, but, in exceptionally favourable circumstances, in great floods, which for the time being raise the mental operations and the powers of the mind over the body to an abnormally high level.

It is a leading feature of this protean conception, that many of the abnormal mental manifestations that have commonly been regarded as symptoms of mental or nervous disease or degeneration are by its aid brought into line with mental processes that are by common consent of an unusually high type, the intuitions of genius, the outbursts of inspired poesy, the emotional fervour or the ecstasy that carries the martyr triumphantly through the severest trials, the enthusiasm that enables the human organism to carry through incredible labours. Myers's hypothesis thus boldly inverts the dominant view, which sees in all departures from the normal symptoms of weakness and which seeks to bring genius and ecstasy down to the level of madness and hysteria; the hypothesis of the subliminal self seeks to level up, rather than to level down, and to display many of these departures from normal mental life as being of the same nature as the operations of genius, as being, in common with these, uprushes of the subliminal self, which temporarily acquires a more complete control of the organism and therefore achieves at such times a more complete expression of its powers. And these rare displays of subliminal capacities are held to foreshadow the further course of mental evolution, to afford us a glimpse of the higher plane on which the mind of man may habitually and normally live, if further evolution of the nervous system shall render it a less inadequate medium for the exercise of the spiritual faculties and for the influx of the psychical energies which at present, owing to its imperfections, are for the most part latent or confined to the subliminal self.

This bold and far-reaching hypothesis has not up to the present time been accepted by any considerable number of professional psychologists, though its author's great literary power has secured for him a respectable hearing. The comparative indifference shown to it by the scientific and philosophical world must be ascribed to considerations of two kinds. In the first place, it is rightly felt that a very large proportion of the alleged facts which it is designed to explain are not yet supported by evidence of such a nature as warrants an unreserved acceptance of them. Secondly, even if further investigations of the type of those carried on by the Society for Psychological Research should prove Myers's belief in the reality of all or most of these facts to have been well-founded, there will remain difficulties and weaknesses intrinsic to the hypothesis, which at present seem very serious. In addition to all the great difficulties that must attach to any conception of human personality as a spiritual entity capable of existing independently of the body, Myers's conception raises many difficulties peculiar to itself, the chief of which may be briefly indicated. First, the conception of the relation of the subliminal to the normal or supraliminal self is in Myers's presentation extremely vacillating and uncertain, and it is probably radically incapable of definition and consistency. Secondly, two alleged supernormal phenomena, to the establishment of which "psychical research" has been devoted most energetically and (in the view of many of the workers) with the greatest success, and which from every point of view are the most important and interesting, are supernormal communications
between the living (telepathy) and communication between the
dead and the living. Now, if either or both of these modes of
communication should eventually prove to be facts of nature,
neither will need the hypothesis of the subliminal self for its
explanation. Such evidence as we have of the latter kind of
communication is almost wholly of the form of messages written
or spoken by entranced persons (see Trance) which claim to be
sent by the souls of the dead to friends still living, and these
messages (if they are what they claim to be) imply, and were held
by Myers himself to imply, possession or control of the brain
of the living medium by the soul of the dead who transmits the
message. Both phenomena need, then, for their explanation
only the two great assumptions—first, that the soul is an entity
capable of disembodied existence; second, that in its psycho-
physical interactions any soul is not strictly confined to inter-
action with one particular brain.

The third great difficulty is of an emotional order. All the
laborious research whose results Myers has sought to harmonize
by means of his conception of the "subliminal self" has been
initiated and sustained by the desire of proving the continued
existence of the human personality after the death of the body.
But, if Myers's doctrine is true, that which survives the death of
the body is not the normal self-conscious personality of a man
such as is known and valued by his friends, but a personality of
which this normal personality is but a stunted distorted frag-
ment; and it would therefore seem that according to this doctrine
death must involve so great a transformation that such slight
continuity as obtains must be insufficient to yield the emotional
satisfaction demanded. The hypothesis would thus seem to
destroy in great measure the value of the belief which it seeks to
justify and establish.
