What, then, is the measure of value? What regulates the amount of one thing which will be given for another? Labour, Smith answers, "is the real measure of the exchangeable value of all commodities. It is the worth of the labour by which each commodity is rendered equal to that of another. All commodities, when compared in the market, are of equal value to the labourer." "Labour alone, therefore, never varying in its own value, is alone the ultimate and real standard by which the value of all commodities is estimated, and calculated. It is their real price; money is their nominal price only." Money, however, in men's actual transactions—actions the measure of value, as well as the vehicle of exchange; and these are continually suited for purposes for which money is not in its own value for periods of moderate length; for distant times, corn is a better standard of comparison. In relation to the earliest social stage, we need consider nothing but the amount of labour employed to produce food. There are two kinds of labour: one, the work of the labourer; when the wealth of the nation is progressive, his wages are high; they are low when it is stationary or regressive. The interest of the third order has not the same connexion with the amount of capital as that of the first two orders; it is always in some respects different from and opposite to that of the public.

The second book is "the nature, accumulation and improvement of stock." A man's whole stock consists of two portions—that which is reserved for his immediate consumption, and that which is employed so as to yield a revenue to its owner. The one is called "consumption," and is divided into the" fixed "and "circulating." The first is such as yields a profit without passing into other hands. The second consists of such goods, raised, manufactured or purchased, as are sold for a profit after having been processed by others, and is paid for by wages regularly going from and returning to the hands of its owner. The whole capital of a society falls under the same two heads. Its fixed capital consists chiefly of (1) machines, (2) edifices which are the means of procuring a revenue, (3) agricultural improvements and (4) the acquired and useful abilities of all members of the society (since sometimes known as "personal capital"). Its circulating capital is merely ready set out for the former (1) productive, or provisions in the hands of the dealers, (3) materials and (4) completed work in the hands of the manufacturer or merchant. Next comes the distinction of the gross national revenue from the net or profit of the stock. Here, if the gross profit is the stock, the second what remains after deducting the expense of maintaining the fixed capital of the country and that part of its circulating capital which is altogether different from the goods which are circulared by means of it; it is a costly instrument by means of which all that each individual receives is distributed to him, and the expenditure that is necessary for his maintaining the services of the profit of the workman, the latter in that of the menial servant. A broad line of demarcation is thus drawn between the labour which results in commodities or increased value of commodities, and that which the employment of capital: unproductive labour, as well as those who do not labour at all, are all maintained by revenue. In advanced industrial communities, the productive are the producers of the capital which every addition to the capital of industry, which adds to the value of the annual produce. The annual, is saved is as regularly consumed as what is spent, but by a different set of persons, by productive labourers instead of unproductive labourers; and the former reproduce with a profit the value of their consumption. The prodigal, encroaching on his capital, diminishes, as far as in him lies, the amount of productive labour, and thus the wealth of the country. But this is ameliorated by his expenditure being on home-made, as distinct from foreign commodities. Every prodigal, therefore, is a public enemy; every frugal man a public benefactor. The only mode of increasing the annual product of the land and labour is to increase either the number of productive labourers or the productive powers of those labourers. Either process will in general require additional capital, the former to maintain the new labourers, the latter to improve the means of introducing a more complete division of labour. In what are commonly called loans of money, it is not really the money, but the money's worth, that the borrower has got to pay for. The amount of loans is a portion of the annual produce of the land and labour of the country. As the general capital of a country increases, so also does the particular portion of it from which the possessors wish to derive a revenue, though without benefitting the public in the way that would be provided, and, as the quantity of stock thus available for loans is augmented, the interest diminishes, not merely "from the general causes which make the market price of things contrary, and, as the interest of capital..." it becomes gradually more and more difficult to find within the country a...
SMITH, ADAM

profitable method of employing any new capital—"whence arises a comparative advantage to different capitalists in making the same, which must diminish the price which can be paid for the use of capital, or in other words the rate of interest. It was formerly supposed, and even Locke and Montesquieu did not escape this error. He must, however, be excused, for the value of the land of Great Britain, and the first improvements on the discovery of the American mines was the real cause of the general lowering of the rate of interest in Europe. But this view, although it has been perhaps occasionally entertained, is erroneous. In some countries the interest of money has been prohibited by law as something as everywhere could be made by the use of money, something ought everywhere to be paid for the use of it," and will in far greater degree establish the principle that only by the prevention of usury by increasing the risk to the lender. The legal rate should be a little above the lowest market rate; sober people will then be preferred as borrowers to prodigals and projectors, who at a higher legal rate, they could not advantage over them, being alone willing to offer that rate.

As to the different employments of capital, the quantity of productive labour made by an equal amount varies extremely according to that amount is employed—(1) in the improvement of lands, mines or fisheries, (2) in manufactures, (3) in wholesale or (4) retail trade. In agriculture "Nature labours along with man," not only the capital of the farmer is reproduced with all its profits, but also the rest of the landlord. It is therefore the employment of a given capital which is most advantageous to society. Next in order come manufactures; then wholesale trade—first the home, and then the foreign trade of the domestic capital, is carried on. All these employments of capital, however, are not only advantageous, but necessary, and will introduce themselves in the state of actions in every individual society.

These first two books contain Smith's general economic scheme; and we have stated it as fully as was consistent with the brevity here necessary, because from this formulation of doctrine the Economic classics of mankind, and round which the ideas and sentiments of modern times in different countries have a great measure revolved.

The critical philosophers of the 18th century were often dépeint of the historical spirit, which was no part of the endowment needed for their principal social office. But some of the most eminent of them, especially in Scotland, showed a marked capacity and precision for historical studies. Smith was among the latter; Karl Marx particularly admired "the masterly sketches of this kind which occur in the Wealth of Nations." The critical scholar of the second half of the 18th century was a political economist, who had studied the principles of speech to which he attached his name, and who had been employed by the government of Great Britain to examine the state of agriculture and commerce in some of the colonies. His teaching on the subject is not altogether unqualified; but, on the whole, with respect to the economic theory, where economic motives alone enter, his voice is in favour of freedom. He has regard, however, to political as well as economic interests, and on the ground that "defence is of much more importance than opulence," "he pronounces the Navigation Act to have been "perhaps the wisest of all the commercial regulations of England." While objecting to the prevention of the export of wool, he proposes a tax on that export as somewhat less injurious to the interest of growers than to the interest of manufacturers, and would rather see the domestic over the foreign manufacturer. This is, perhaps, his most marked deviation from the rigour of principle; it was doubtless a concession to popular opinion, and a mark of an improvement in the practice of retaliation in order to procure the repeal of high duties or prohibitions imposed by foreign governments depends, he says, altogether on the likelihood of its success in effecting a particular benefit, but not at all on the contrary, the amount of evil which would be caused by the immediate abolition of the duties is, in his opinion, commonly exaggerated. The case in which no justified protection that, namely, when a country is starved by the acquirement of landlords, with the acquired ascendency of foreign producers—is referred to by Smith; but he is opposed to the admission of this exception for reasons which do not appear to be conclusive. He is perhaps scarcely consistent in appealing the concession of temporary monopolies to joint-stock companies of "of which the public is afterwards to reap the benefit." He is less absolute in his doctrine of governmental non-interference when he comes to consider in his fifth book the "expenses of the government," and to formulate the functions of the state. The erection and maintenance of those public institutions and public works which, though advantageous to the society, could not repay, and therefore must not be thrown upon, the individual members of the state, is a specific case, and it is by historical that the performance of these functions requires very different degrees of expense in the different periods of society. It is in the political economy of government that Smith exhibits a balance of wisdom, which, though he would apparently prefer that it should be met by the voluntary contributions of those who think themselves for such education or instruction.

To sum up, it may be said that The Wealth of Nations certainly operated powerfully through the harmony of its critical side with the tendencies of the half-century which followed its publication to the advantages of "the intellect," which is a word Smith would have used to describe the economic policy of the past, and promoted the overthrow of institutions which had come from earlier times, but were unsuited to modern society. As a theoretic treatment of social economy, or a guide to political practice and policy in the future, it is provisional, not definitive. But when the study of its subject comes to be systematized on the basis of a general social philosophy more complete and durable than Smith's, no contribution has been made that long can be forgotten.

Buckle has the idea that the two principal works of Smith, the Theory of Moral Sentiments and the Wealth of Nations, are mutually complementary parts of one great scheme, in which human nature is intended to be dealt with as a whole—the former exhibiting the operation of the benevolent feelings, the latter of what, by a singular nomenclature, inadmissible since Butler wrote, he calls "the passion of selfishness." In each division the motive contemplated is regarded as acting singly, without any interference of the opposite principle. This appears to be an artificial and misleading notion. Neither in the plan of Smith's university course nor in the well-known passages at the beginning of the Wealth of Nations does he hint at the system of his having conceived such a bipartite scheme. The object of the Wealth of Nations is surely in no sense psychological, as that of the Theory of Moral Sentiments; the whole point of the work is to exhibit social phenomena, not to demonstrate their source in the mental constitution of the individual.

The following may be referred to for biographical details: Dugald Stewart's History of the Reign of Queen Victoria (1864) before the Royal Society of Edinburgh, and afterwards prefixed to Smith's Essays on Philosophical Subjects: J. A. Farring, Adam Smith (1881); R. B. Haldane, Life of Smith (1887), and the very full and excellent Life of Adam Smith by John Runciman (1895). Additional particulars are given in Brougham's Men of Letters and Science, Burton's Life of Hume and Alexander Carlyle's Autobiography; and some characteristic anecdotes of him will be found in Memoirs of the Life and Works of Sir John Sinclair (1837). For comments on his Theory of Moral Sentiments, see, besides Stewart, as cited above, Dr. T. Brown's Philosophy of the Human Mind, lctns. 80 and 81; Sir J. Murray's "Adam Smith and the Theology of the 18th Century" in the Edinburgh Review, and the "Life of Smith" in the Dictionary of National Biography. For Smith's influence on contemporary economic thought, see the "I'Economie Politique" of the Encyclopédie, the "Dictionnaire d'économie politique" of Bagehot's Economic Studies (1880); and Cosse's Guide to the Study of Political Economy (Eng. trans., 1880), chap. v. "Theoretical Principles," (358), and "Theoretical Principles of Political Economy," which is a critical study of the Economics of Imperialism, with special reference to the ideas of Adam Smith; and Professor W. J. Ashley's essay in Comparative Club Lectures (1905) on "Political Economy and the Problem of Economic Progress," and Ashley's Select Chapters and Passages from the "Wealth of Nations" (1895).

1 Professor Bastable calls attention to the interesting fact that the proposal of an export duty on wool and the justification of a temporary monopoly to joint-stock companies both appear for the first time in the edition of 1784.
SMITH, A. R.—SMITH, CHARLOTTE

SMITH, ALBERT RICHARD (1816–1860), English author and public entertainer, was born at Chertsey, Surrey, on the 24th of May 1816. He studied medicine in Paris, and his first literary effort was an account of his life there, which appeared in the *Mirror*. He gradually relinquished his medical work for light literature. Though a journalist rather than a literary figure, he was one of the most popular men of his time, and a favourite humorist in the vein of humour then in vogue. He was one of the early contributors to *Punch* and was also a regular contributor to *Bentley’s Miscellany*, in whose pages his first and best book, *The Adventures of Mr Ledbury*, appeared in 1842. His other books were, *Christopher Tadpole* (1848), issued in monthly parts, *Polettom’s Legacy* (1849), and *Miss Hector’s Alphabet Girl, The Idle upon Town* and *The Fisht*. Albert Smith also wrote extravaganzas and adapted some of Charles Dickens’s stories for the stage. He founded and edited a monthly magazine called *The Man in the Moon*, from 1847 to 1849. In 1851 he ascended Mont Blanc, and the year after produced at the Egyptian Hall the descriptive entertainment, which he called “Mont Blanc,” describing the ascent of the mountain and the Englishman abroad. This success was followed by other entertainments of the kind, among them “China.” Smith married in 1850 a daughter of Robert Keeley, the comedian. He died in Fulham, London, on the 3rd of May 1860. Smith received great help from his brother, Arthur W. W. Smith (1825–1861), who had also been educated for medicine. He managed the entertainments at the Egyptian Hall from 1852 to 1860. He also planned Charles Dickens’s readings in 1858, and made arrangements for a second series, but died before they were completed.

SMITH, ALEXANDER (1830–1867), Scottish poet, son of a lace-designer, was born at Kilmarnock on the 31st of December 1830. His parents being too poor to send him to college, he was placed in a linen factory to follow his father’s trade of a pattern designer. His early poems appeared in the *Glasgow Citizen*. In his pupil-days, James Hedderwick, he found a sympathizing and appreciative friend. *A Life Drama and other Poems* (1853) was a work of promise, ran through several editions, and gained Smith the appointment of secretary to Edinburgh University in 1854. As a poet he was one of the leading representatives of what was called the “Spasmodic” School, now fallen into oblivion. Smith, P. J. Bailey and Sydney Dobell were satirized by W. E. Aytoun in 1854 in *Firmilans a Spasmodic Tragedy*. In the same year Sydney Dobell came to Edinburgh, and an acquaintance was thus sprang up between the two which resulted in their collaboration in the *Book of War Sonnets* (1855), inspired by the Crimean War. After publishing *City Poems* (1857) and *Edwin of Deira* (1861), a Northumbrian epic poem, Smith turned his attention to prose, and published *Dreamthorp: Essays written in the Country* (1863) and *A Summer in Skye*. His last work was an experiment in fiction, *Alfred Hagari’s Household* (1866), which ran first through *Good Words*. He died on the 9th of January 1867.

A memoir of Smith by P. P. Alexander was prefixed to a volume entitled *Last Leaves*.

SMITH, ANDREW JACKSON (1831–1897), American soldier, was born in Bucks county, Pennsylvania, on the 28th of April 1831 and graduated at West Point in 1858. He was engaged on active service on the south-west frontier and in Mexico, and afterwards in Indian warfare in Washington and Oregon territories, becoming first lieutenant in 1845, captain in 1847, and major in 1861. In the latter year, on the outbreak of the Civil War, he became a colonel of volunteer cavalry in the Federal army, rising early in 1862 to the rank of brigadier-general U.S.V., and to the chief command of the cavalry in the Missouri department. Assigned afterwards to the Army of the Tennessee, he took part in the first attack on Vicksburg and the capture of Arkansas Post, and commanded a division of the XIII corps in the final Vicksburg campaign. Later he led a division of the XVI corps in the Red River expedition of Gen. N. P. Banks, and received the brevet of colonel for his services at the action of Pleasant Hill. In May 1864, he became lieutenant-colonel U.S.A. and major-general U.S.V., and during the greater part of the year was employed in Missouri against the Confederate general Sterling Price. Thence he was summoned to join forces with G. H. Thomas at Nashville, then threatened by the advance of Gen. J. B. Hood. He bore a conspicuous share in the crowning victory of Nashville (4th), after which he commanded the XVI corps in the final campaign in the South. Just before the close of the war he was brevetted brigadier-general U.S.A. for his services at the action of Tupelo, Mississippi, and major-general U.S.A. for Nashville. He resigned his volunteer commission in 1866 and became colonel of the 7th U.S. Cavalry. In 1869, however, he resigned in order to become postmaster of St. Louis, where he died in 1874.

SMITH, CHARLES EMORY (1842–1908), American journalist and political leader, was born in Mansfield, Connecticut, on the 18th of February 1842. In 1849 his family removed to Albany, New York, where he attended the public schools and the Albany Academy. He graduated at Union College in 1861, was a recruiting officer on the staff of General John F. Rathbone (1819–1902) in 1861–1862, taught in the Albany Academy in 1862–1865, and was editor of the *Albany Express* in 1865–1870; joined the staff of the *Albany Journal* in 1870, and was editor-in-chief of this paper from 1876 to 1886. In 1876–1880 he was a regent of the University of the State of New York. From 1886 until his death he was editor and part proprietor of the *Philadelphia Press*. He was active as a Republican in state and national politics; was chairman of the Committee on Resolutions of the New York State Republican Conventions from 1874 to 1880 (excepting 1877), and was president of the convention of 1879; and was a delegate to several National Republican Conventions, drafting much of the Republican platforms of 1876 and 1880. In 1890–1892 he was United States minister to Russia, and during that period had charge of distributing among the Russian famine sufferers more than $600,000 in money, and five shipsloads of food. He was postmaster-general in the cabinet of Presidents McKinley and Roosevelt from April 1898 until January 1902, and did much to develop the rural free delivery system. He died in Philadelphia on the 19th of January 1908.

SMITH, CHARLES FERGUSON (1807–1862), American soldier, graduated from West Point Academy in 1825, and a few years later became an instructor there, rising eventually to be commandant. As a battalion commander he distinguished himself at the Mexican War, at Palo Alto, Resaca, Monterey and Churubusco. He commanded the Red River expedition of 1866, and served under Albert Sidney Johnston in Utah (1857–1860). On the outbreak of the Civil War in 1861 he accepted a commission as brigadier-general of Union volunteers, and found himself under the command of Grant, who had been his pupil at West Point. This difficult situation was made easy by Smith’s loyalty to his young chief, and the old soldier led his division of raw volunteers with success at Fort Donelson. His ripe experience, dignity, and unselfish character made him Grant’s mainstay in the early days. He went up the Tennessee with the first expedition, but at Savannah, Tennessee, met with a serious accident. His senior brigadier led his division at the battle of Shiloh and he died on April 25, 1862. The early ups and downs in high command deprived the Union army of one of its best leaders, and his absence was nowhere more felt than on the battlefield of Shiloh, where the Federals paid heavily for the ineffectiveness of their generals. A month before his death he had been made major-general of volunteers.

SMITH, CHARLOTTE (1749–1860), English novelist and poet, eldest daughter of Nicholas Turner of Stoke House, Surrey, was born in London on the 4th of May 1749. She left school when she was twelve years old to enter society. She married in 1765 Benjamin Smith, son of a merchant who was a director of the East India Company. They lived at first with her father-in-law, who thought highly of her business abilities, and wished to keep her with him; but in 1774 Charlotte and her husband went to live in Hampshire. The elder Smith died in 1776, leaving a complicated will, and six years later Benjamin Smith was imprisoned for debt. Charlotte Smith’s first publication was *Elegiac Sonnets*.
and other Essays (1874), dedicated by permission to William Hayley, and printed at her own expense. For some months Mrs Smith and her family lived in a tumble-down château near Dieppe, where she produced a translation of Maison Lescou (1785) and a Romance of Real Life (1786), borrowed from Les Causes Célèbres. On her return to England Mrs Smith carried out a friendly separation between herself and her husband, and thenceforward devoted herself to novel writing. Her chief works are: Emélie de l'Orphelie (1786); Celestina (1792); Desmond (1792); The Old Manor House (1793); The Young Philosopher (1798); and Conversations Introducing Poetry (1804). She died at Tildorf, near Farnham, Surrey, on the 28th of October 1806. She had twelve children, one of whom, Lionel (1778–1842), rose to the rank of lieutenant-general in the army. He became K.C.B. in 1832 and from 1833 to 1839 was governor of the Windward and Leeward Islands.

Charlotte Smith's novels were highly praised by her contemporaries and are still noticeable for their ease and grace of style. Hayley said that Eméline, considering the situation of the author, was the most wonderful production he had ever seen, and not inferior to any book in that fascinating species of composition (Nichols, Illustrations of Literature, viii. 708). The best known of Mrs Smith's portraits is that of Sir Walter Scott, later Sir Walter Scott, painted by Fanny Kemble, as it is based on material supplied by her sister, Mrs Dorset, with a detailed criticism of her work by Scott (Miss. Prose Works, 1841, i. 348–350). Charlotte Smith is best remembered by her charming poems for children.

SMITH, COLVIN (1793–1875), Scottish portrait-painter, was born at Brechin, Scotland, in 1793. He studied in London in the schools of the Royal Academy and worked in Nollekens's studio. He then proceeded to Italy, where he executed some fine copies from Titian; and at Antwerp he made some of the works of Rubens. Returning to Scotland in 1827, he settled in Edinburgh, occupying the house and studio which had formerly belonged to Raeburn. Soon he attained a wide practice as a portrait-painter, and among his sitters were Lord Jeffrey, Henry Mackenzie, author of The Man of Feeling, and many of the most celebrated Scotsmen of the time. His portrait of Sir Walter Scott was so popular that he executed some twenty replicas of it, for seven of which he received fresh sittings. His works are distinguished by excellent draftsmanship, by directness and simplicity of treatment, and by well-marked individuality. He died in Edinburgh on the 21st of July 1875.

SMITH, EDMUND KIRBY (1824–1893), Confederate general in the American Civil War, was the son of Joseph Lee Smith (1776–1846), an American lawyer and soldier, who served with credit in the War of 1812 and rose to the rank of colonel U.S.A. His elder brother, Ephraim Kirby Smith (1807–1847), also a soldier, fell at Molino del Rey; and Joseph Lee Kirby Smith, Ephraim's son, who took the Federal side in the Civil War, was mortally wounded at the battle of Corinth, having at the age of twenty-six attained the rank of brevet-colonel U.S.A. Edmund Kirby Smith was born at St Augustine, Fla., on the 16th of May 1824, and graduated at West Point in 1845, being assigned to the infantry. In the Mexican War he was brevetted first lieutenant, and captain for gallantry at Vera Cruz and Cerro Gordo and at Contreras-Churubusco. He was assistant professor of mathematics at West Point from 1849 to 1852 and was later engaged in Indian warfare on the Texas frontier. In 1861 he attained the rank of major. When Florida seceded he resigned his army commission and entered the Confederate service as a lieutenant-colonel. He was made a brigadier-general on the 17th of June 1861, and was wounded at the battle of Bull Run (q.v.). In command of the Confederate forces in the Cumberland Gap region Kirby Smith detached a part in General Bragg's invasion of Tennessee in the autumn of 1862, and inflicted upon the Federal forces a severe defeat at Richmond, Ky., on the 30th of August; and was present at the battles of Perryville and Murfreesboro (Stone River). From February 1863 to the fall of the Confederacy he was in command of the trans-Mississippi department, and was successful in making this section of the Confederacy (isolated from the rest by the fall of Vicksburg) self-supporting. He instituted a regular system of blockade-running, and met and defeated the Red River expedition under General N. P. Banks in 1864. Kirby Smith and his troops surrendered on the 26th of May 1865, being the last armed forces of the Confederate States to do so. After the war, he was from 1866 to 1868 president of the Atlantic and Pacific Telegraph company, from 1868 to 1870 president of the Western Military Academy, from 1870 to 1875 chancellor of the university of Nashville, and from 1875 to his death professor of mathematics at the university of the South, Sewanee, Tennessee. He died at Sewanee on the 28th of March, 1893.

SMITH, FRANCIS HOPKINSON (1838–1907), American author, artist and engineer, was born in Baltimore, Maryland, on the 23rd of October 1838, a descendant of Francis Hopkinson, one of the signers of the Declaration of Independence. He became a contractor in New York City and did much work for the Federal government, including the stone ice-breaker at Bridgeport, Connecticut, the jetties at the mouth of the Connecticut river, the foundation for the Bartholdi Statue of Liberty in New York harbour, the Race Rock Lighthouse of New London, Conn., and many life-saving stations. His vacations were spent, sketching in the White Mountains, in Cuba, in Mexico, and afterwards in Venice, Constantinople and Holland. He published various volumes of travel, illustrated by himself; they include Old Lines in New Black and White (1883); Well-Worn Roads (1886); A White Umbrella in Mexico (1889); Gondola Days (1897), and The Venice of To-Day (1897). His novels and short stories are especially felicitous in their portrayal of the Old South. Among them are: Col. Carter of Cartersville (1891), which was successfully dramatized; A Day at La Guerre's and other Days (1892); A Gentleman Vagabond (1893); Tom Snaggin's (1900); The Fortune's End (1899); The Fortunes of Oliver Horn (1902), which has reminiscences of his artist friends; Col. Carter's Christmas (1904); At Close Range (1905); The Tides of Barneagi (1906); The Veiled Lady (1907); The Romance of an Old Fashioned Gentleman (1907); Peter (1908); and Forty Minutes Late and Other Stories (1909).

SMITH, GEORGE (1789–1846), British publisher, founder of the firm of Smith, Elder & Co., was born in Scotland in 1789. From Elgin, where he was apprenticed to a bookseller, he migrated to London, where he found employment first with Rivington, and afterwards with John Murray. In 1816 Smith and another Scot, Alexander Elder, began business at 158 Fenchurch Street as booksellers and stationers; and in 1819 they became publishers also. It was here that GEORGE SMITH (2) (1824–1901), the most famous member of the firm, was born on the 19th of March 1824; and in the same year the business was removed to 65 Cornhill. At the age of fourteen George Smith (2) came into the business, and in 1843 he took over the control of the publishing department. On his father's death in 1846 the responsibility of the business devolved principally upon him, and under his management it increased thirteen times in twenty years. A large portion of the business was connected with foreign agencies and banking, especially with India, but this was relinquished in 1868 to his partner Henry S. King, who now separated from the firm, retaining the old premises at Cornhill, while Smith removed the publishing business, now under his sole control, to 15 Waterloo Place. For over thirty years Smith was the friend and publisher of Ruskin, and it was with him that Jane Eyre found a publisher. In 1855 was started the Overland Mail, a weekly periodical for Indian readers, and the Homeward Mail, containing Indian news for English readers. By Smith, Elder & Co. were issued works by Robert and Mrs Browning, Wilkie Collins, Matthew Arnold, Miss Martineau, James Payn and Mrs Humphry Ward. In 1866 was published Trollope's Last Chronicles of Barset, for which £3000 was paid. In January 1860 the first of George Smith's three great undertakings was begun, the Cornhill Magazine being issued in that month under the editorship of Thackeray. The second venture was the founding in 1863 of the Pall Mall Gazette (see Newspapers). The third and most important was the publication of the Dictionary of National Biography, the first volume of which was issued in 1882; it was completed in 1901, in 66 volumes; and this
monumental work was the crowning effort of a successful career. Smith was a rich man, not only from his publishing business, but on account of his large ownership of the Manchester and Salford Docks. His second son, Alexander Murray Smith, joined the firm in 1830, and with him was associated in 1834 his brother-in-law Reginald J. Smith, who in 1839 became acting partner. George Smith himself died at Byfleet, near Weybridge, on the 6th of April 1891. See the memoir (1901) of George Smith (2) prefixed to vol. i. of the supplement to the Dictionary of National Biography; reminiscences of the Cornhill Magazine (Nov. 1900-Feb. 1901) by George Smith; an article by Sir Leslie Stephen in the same magazine (May 1901); and the special number of the Cornhill Magazine in January 1910, published on its 50th anniversary.

SMITH, GEORGE ("George Smith of Coaulville ") (1831-1859), English philanthropist, was born near Tunstall, Staffordshire, on the 16th of February 1831. His father was a brickmaker, and, when nine years old, George Smith was working thirteen hours a day in brickfields. Nevertheless he contrived to obtain some education, so that in time he improved his position, becoming manager of a brick and tile works. In 1857 he discovered, at Coaulville, Leicestershire, valuable seams of clay, and on the strength of this discovery organized a large brick-making business there. He advocated legislation in the interests of brickmakers, and in particular called attention to the cruelty suffered in the brickfields by child-workers, whose claims he pressed at the Social Science congresses. In 1871 he published The Cry of the Children. This was the expression of the interest of the several early canals and the discovery of A. J. Mundella, in the same year, was passed an act providing for the government inspection of brickyards, and the regulation of juvenile and female labour there. Smith's share in this act aroused great antagonism, and at the end of 1872 he was dismissed from his position at Coaulville, and reduced to great poverty. Nevertheless he turned his attention to the conditions of life of the hundred thousand persons living on canals. As the result of his representations on the subject the Canal Boats Bill was introduced by Mr Sclater-Booth (afterwards Lord Basing). This bill, which came into force in 1875, provided for the education of the young and for the sanitary condition of life on board. In 1884 was passed another bill strengthening the provisions of the first. From that date onwards Smith devoted his attention to improving the condition of Gipsy children which he had described in his Gipsy Life (1866). A Moveable Dwellings Bill embodying his views was several times introduced into parliament, but always defeated. In 1885 Smith received a grant from the royal bounty fund. He died at Crick near Rugby on the 21st of June 1895.

SMITH, GEORGE (1840-1876), English Assyriologist, was born on the 26th of March 1840 at Chelsea, London. His father was a working man, and at fourteen the boy was apprenticed to Messrs Bradbury and Evans to learn bank-note engraving. He had already shown a keen interest in the explorations of Layard and Rawlinson, and during the next few years he devoted all his spare time to studying the cuneiform inscriptions at the British Museum. His earnestness attracted the attention of Sir Henry Rawlinson, who permitted him the use of his room at the museum and placed the many casts and photographs of cuneiform inscriptions at his disposal. Smith was thus enabled to make his first discovery (the date of the payment of the tribute by Jehu to Shalmanezer), and Sir Henry suggested to the trustees of the Museum that he should be associated with himself in the preparation of the third volume of Cuneiform Inscriptions of Western Asia. Accordingly, in 1867, Smith was appointed assistant in the Assyriology department, and the earliest of his successes was the discovery of two inscriptions, one fixing the date of the total eclipse of the sun in the month Sivan in May 763 B.C., and the other the date of an invasion of Babylonia by the Elamites in 2580 B.C. In 1871 he published Annals of Assur-bani-pal, transliterated and translated, and communicated to the newly-founded Society of Biblical Archaeology a paper on "The Early History of Babylonia," and an account of his decipherment of the Cypriote inscriptions. In 1872 Smith achieved world-wide fame by his translation of the Chaldæan account of the Deluge, which was read before the Society of Biblical Archaeology on the 3rd of December. In the following January Sir Edwin Arnold, the editor of the Daily Telegraph, arranged with Smith that he should go to Nineveh at the expense of that journal, and carry out excavations with a view to finding the missing fragments of the Deluge story. This journey resulted not only in the discovery of the missing tablets, but of fragments which recorded the succession and duration of the Babylonian dynasties. In 1874 Smith again left England for Nineveh, this time at the expense of the Museum, and continued his excavations at Kouyunjik. An account of his work is given in Assyrian Discoveries, published by the British Museum. The rest of the year was spent in fixing together, and translating the fragments relating to the Creation, the results of which work were embodied in The Chaldæan Account of Genesis. In March 1876 the trustees of the British Museum despatched Smith once more to excavate the rest of Assur-bani-pal's library. At Ikijsi, a small village about 60 m. N.E. of Aleppo, he was prostrated by fever, and finally died at Aleppo on the 10th of August. He left a wife and children, on whose behalf a public subscription was made.

SMITH, GEORGE ADAM (1856— ), Scottish divine, was born in Calcutta on the 19th of October 1856, where his father, George Smith, C.I.E., was then principal of the Doveton College. He was educated at Edinburgh in the Royal High School, the University and New College. After studying at Tübingen and Leipzig and travelling in Egypt and Syria, he entered the ministry of the Free Church of Scotland and was appointed professor of Old Testament subjects in the Free Church College at Glasgow 1892. In 1900 he was appointed principal of the University of Aberdeen.

Among his works are The Book of Issiah (2 vols., 1888-1890); The Book of the Twelve Prophets (2 vols., 1896-1897); Historical Geography of the Holy Land (1894); Jerusalem (2 vols., 1897); The Preaching of the Old Testament to the Age (1893); The Life of Henry Drummond (1898).

SMITH, GERRIT (1797-1874), American reformer and philanthropist, was born in Utica, New York, on the 6th of March 1797. After graduating at Hamilton College in 1818, he assumed the management of the vast estate of his father, Peter Smith (1768-1837), long a partner of John Jacob Astor, and greatly increased the family fortune. About 1828 he became an active worker in the cause of temperance, and in his home village, Peterboro, he built one of the first temperance hotels in the country. He became an abolitionist in 1835, after seeing an anti-slavery meeting at Utica broken up by a mob. In 1840 he took up the work of the Liberty party and in 1848 and 1852 he was nominated for the presidency by the remnant of this organization that had not been absorbed by the Free Soil party. An "Industrial Congress" at Philadelphia also nominated him for the presidency in 1848, and the "Land Reformers" in 1856. In 1840 and in 1858 he was a candidate for the governorship of New York on an anti-slavery platform. In 1853 he was elected to the National House of Representatives as an independent, and issued an address declaring that all men have an equal right to the soil; that wars are brutal and unnecessary; that slavery could be sanctioned by no constitution, state or federal; that free trade is essential to human brotherhood; that women should have full political rights; that the Federal government and the states should prohibit the liquor traffic within their respective jurisdictions; and that government officers, so far as practicable, should be elected by direct vote of the people. At the end of the first session he resigned his seat. After becoming an opponent of land monopoly, he gave numerous farms of fifty acres each to indigent families, and also attempted to colonize tracts in N. New York with free negroes; but this experiment was a failure. Peterboro became a station on the "underground railroad"; and after 1850 Smith furnished money for the legal expenses of persons charged with infractions of the Fugitive Slave Law. With John Brown, to whom he gave a farm in Essex county, New York, he became very intimate, and from time to time supplied him with funds, though it seems
without knowing that any of the money would be employed in an attempt to incite a slave insurrection. Under the excitement following the raid on Harper's Ferry he became temporarily insane, and for several weeks was confined in an asylum in Utica. He favoured a vigorous prosecution of the Civil War, but at its close advocated a mild policy toward the late Confederate states, declaring that part of the guilt of slavery lay upon the North. He even became one of the securities for Jefferson Davis, thereby incurring the resentment of Northern radical leaders.

In religion as in politics Gerrit Smith was a radical. Believing that sectarianism was sinful, he separated from the Presbyterian Church in 1843, and was one of the founders of the Church at Peterboro, a non-sectarian institution open to all Christians of whatever shade of belief. His private benefactions were boundless; of his gifts he kept no record, but their value is said to have exceeded $8,000,000. Though a man of great wealth his life was one of marked simplicity. He died on the 8th of December 1874, while on a visit to relatives in New York City.

SMITH, GOLDWIN (1824-1910), British historian and publicist, was born at Reading on the 20th of August 1824. He was educated at Eton and Magdalen College, Oxford, and after an undergraduate career of exceptional brilliancy was elected to a fellowship at University College. He threw his keen intellect and trenchant style into the cause of university reform, the leading champion of which was another fellow of University College, Arthur Penrhyn Stanley. On the Rückwärts, the reform of the University of which Stanley was secretary, he served as assistant-secretary; and he was secretary to the commissioners appointed by the act of 1854. His position as an authority on educational reform was further recognized by a seat on the Popular Education Commission of 1858. In 1868, when the question of reform at Oxford was again growing acute, he published a brilliant pamphlet, entitled The Reorganization of the University of Oxford. Besides the abolition of tests, effected by the act of 1871, many of the reforms there suggested, such as the revival of the faculties, the reorganization of the professoriate, the abolition of celibacy as a condition of the tenure of fellowships, and the combination of the colleges for lecturing purposes, were incorporated in the act of 1877, or subsequently adopted by the university. He gave the counsel of perfection that “pass” examinations ought to cease; but he recognized that this change “must wait on the reorganization of the educational institutions immediately below the university, at which a passman ought to finish his career.” His aspiration that colonists and Americans should be attracted to Oxford has been realized by Mr Rhodes’s will.

On what is perhaps the vital problem of modern education, the question of ancient versus modern languages, he pronounced that the latter “are indispensable accomplishments, but they do not form a high mental training”—an opinion entitled to peculiar respect as coming from a president of the Modern Language Association. The same conspicuous openness of mind appears in his judgment, delivered after he had held the regius professorship of Modern History at Oxford from 1858 to 1866, that “ancient history, besides the still unequalled excellence of the writers, is the best instrument for cultivating the historical sense.” As a historian, indeed, he left no abiding work; the multiplicity of his interests prevented him from concentration on any one subject. His chief historical writings—The United Kingdom: a Political History (1890), and The United States: an Outline of Political History (1863)—though based on thorough familiarity with their subject, make no claim to original research, but are remarkable examples of terse and brilliant narrative.

The outbreak of the American Civil War proved a turning-point in his life. Unlike most men of the ruling classes in England, he warmly championed the cause of the North, and his pamphlets, especially one entitled Does the Bible sanction American Slavery? (1863), played a prominent part in converting English opinion. Visiting America on a lecture tour in 1864, he received an enthusiastic welcome, and was entertained at a public banquet in New York. In 1868 he threw up his career in England and settled in the United States, where he held the professorship of English and Constitutional History at Cornell University till 1871. In that year he removed to Toronto, where he edited the Canadian Monthly, and subsequently founded the Week and the Bystander. He did not, however, cease to take an active interest in English politics. He had been a strong supporter of Irish Disestablishment, but he refused to follow Gladstone in accepting Home Rule. He expressly stated that “if he ever had a political leader, his leader was John Bright, not Mr Gladstone.” Speaking in 1886, he referred to his “standing by the side of John Bright against the dismemberment of the great Anglo-Saxon community of the West, as I now stand against the dismemberment of the great Anglo-Saxon community of the East.” These words form the key to his views of the future of the British Empire. He always maintained that Canada, separated by great oceans, running north and south, into four zones, each having unimpeached communication with the adjoining portions of the United States, was destined by its natural configuration to enter into a commercial union with them, which would result in her breaking away from the British empire, and in the union of the Anglo-Saxons of the American continent into one great nation. These views are most fully stated in his Canada and the Canadian Question (1891). Though describing himself as “anti-Imperialistic to the core,” he was yet deeply penetrated with a sense of the greatness of the British race. Of the British empire in India he said that “it is the only country in the world which presents an attempt to make conquest the servant of civilization. About keeping India there is no question. England has a real duty there.” His fear was that England would become a nation of factory-workers, thinking more of their trade-union than of their country. These forebodings were intensified in his Commonwealth or Empire? (1902)—a warning to the United States against the assumption of imperial responsibilities. Among other causes that he powerfully attacked were liquor prohibition, female suffrage and State Socialism. All these are discussed in his Essays on Questions of the Day (revised edition, 1894), and also published sympathetic monographs on Cooper and Jane Austen, and attempted verse in Bay Leaves and Specimens of Greek Tragedy. In his Guesses at the Riddle of Existence (1897), he abandons the faith in Christianity expressed in his lecture of 1861 on Historical Progress (where he forecast the speedy reunion of Christendom on the “basis of free conviction”), and writes in a spirit “not of Agnosticism, if Agnosticism imports despair of spiritual truth, but of free and hopeful inquiry, the way for which it is necessary to clear by removing the wreck of that upon which we can find our faith no more.” In his later years he published views in a weekly journal, The Freeman's Sun, and published in 1904 My Memory of Gladstone, while occasional letters to the Spectator showed that he had lost neither his interest in English politics and social questions nor his remarkable gifts of style. He died at his residence, The Grange, Toronto, on the 7th of June 1910.

Goldwin Smith left in manuscript a book of reminiscences, which was edited by Mr Arnold Haulcain, his private secretary.

SMITH, HENRY BOYNTON (1815-1877), American theologian, was born in Portland, Maine, on the 21st of November 1815. He graduated at Bowdoin College in 1834; studied theology at Andover, where his health failed, at Bangor, and after a year (1836-1837) as librarian and tutor in Greek at Bowdoin, in Germany at Halle, where he became personally intimate with Tholuck and Ulrici, and in Berlin, under Neander and Hengstenberg. He returned to America in 1840, was a tutor for a few months (1840-1841) at Bowdoin, and in 1842, shut out from any better place by distrust of his German training and by his frank opposition to Unitarianism, he became pastor of the Congregational Church of West Amesbury (now Merrimac), Massachusetts. In 1847-1850 he was professor of moral philosophy and metaphysics at Amherst, and in 1851-1853 Washburn professor of Church history, and in 1854-1874 Roosevelt professor of systematic theology, at Union Theological
SMITH, SIR H. G. W.—SMITH, H. J. S.

Seminary. His health failed in 1874 and he died in New York City on the 7th of February 1877. Of the old school of the "New England Theology," Smith was one of the foremost leaders of the new school Presbyterians. His theology is most strikingly contained in the Andover address, "Relations of Faith and Philosophy," which was delivered before the Porter Rhetorical Society in 1849. He always made it clear that the ideal philosophy was Christocentric; he said that Reformed theology must "'Christologize' predestination and decrees, regeneration and sanctification, the doctrine of the Church, and the whole of the Eschatology."

Henry Smith (b. 1866) was pastor of the Freehold (New Jersey) Presbyterian Church in 1886-1896, and from 1897 to 1903 was professor of systematic theology in Lane Theological Seminary.

From notes of his lectures, William S. Karr prepared two volumes of Dr. Smith's theological writings, Introduction to Christian Theology (1883) and System of Christian Theology (1884). Dr. Smith contributed articles on Calvin, Kant, Pantheonism, Miracles, Reformed Churches, Schelling and Hegel to the American Cyclopaedia, and contributed to McClintock and Strong's Cyclopaedia; and was editor of the American Theological Review (1859 seq.), both in its original form and after it became the American Presbyterian and Theological Review and, later, the Presbyterian Quarterly and Princeton Review.

See also L. (Mrs H. B.) Smith, Henry Boynton Smith, His Life and Works (New York, 1884), and Lewis F. Stearns, Henry Boynton Smith (Boston, 1892), in the American Religious Leaders series.

SMITH, SIR HENRY GEORGE WAKELEY, Bart. (1787-1860), British general, son of John Smith, surgeon, of Whittelsey, Cambridgeshire, was born at that place on the 28th of June 1787.

Harry Smith—for throughout life he adopted the more familiar form of his Christian name—was educated privately and entered the army in 1803. His first active service was in South America in 1806, and he subsequently served through the Peninsular War from the concentration at Salamanca in November 1808 to the battle of Toulouse on the 18th of April 1814. On the day following the storming of Badajoz (the 6th of April 1812) a well-born Spanish lady, whose entire property in the city had been destroyed, presented herself at the British lines seeking protection from the licence of the soldiery for herself and her sister, a child of fourteen, by whom she was accompanied. The latter, whose name was Juana Maria de Los Dolores de Leon, had but recently emerged from a convent; but notwithstanding her years she was married to Harry Smith a few days later. She remained with him throughout the rest of the war, accompanying the bigoted Spaniards, sleeping in the open on the fields of battle, moving freely among the troops, and sharing all the privations of campaigning. Her beauty, courage, sound judgment and amiable character endeared her to the officers, including the duke of Wellington, who spoke of her familiarly as Juana; and she was idolized by the soldiers. At the close of the war Harry Smith volunteered for service in the United States, where he was present at the battle of Bladensburg (the 24th of August 1814), and witnessed the burning of the capitol at Washington; which, as he said, "horrified us coming fresh from the duke's humane warfare in the south of France." Returning to Europe he was brigade-major and in 1828 was ordered to the Cape of Good Hope, where he commanded a division in the Kaffir War of 1834-36. In 1835 he accomplished the feat of riding from Cape Town to Graham's Town, a distance of 600 m., in less than six days; and having restored confidence among the whites by his energetic measures, he was appointed governor of the new Province of Queen Adelaide, where he gained unbounded influence over the native tribes, whom he vigorously set himself to civilize and benefit. But though supported by Sir Benjamin D'Urban, the high commissioner, the ministry in London reversed his policy and—to quote Smith's own words—"directed the Province of Queen Adelaide to be restored to barbarism."

Smith himself was removed from his command, his departure being deplored alike by the Kaffirs and the Dutch; and numbers of the latter, largely in consequence of this policy of Lord Gienel, began the migration to the interior known as "the great trek."

Harry Smith was now appointed deputy-adjudant-general of the forces in India, where he took part in the Gwallor campaign of 1843 (for which he received a K.C.B.) and the Sikh War of 1845-46. He was in command of a division under Sir Hugh Gough at the battles of Moodkee and Ferozeshah, where he conspicuously distinguished himself, but was insufficiency supported by the commander-in-chief. After the second of these actions Sir Harry Smith was appointed to an independent command, and on the 28th of January 1846 he inflicted a crushing defeat on the Sikhs at Alivaw on the Sutlej. At Sobraon on the 10th of February he again commanded a division under Gough. For the great victory of Alivaw he was awarded the thanks of parliament; and the speech of the duke of Wellington was read in the House of Commons by that great commander on a meritorious officer. Sir Harry was at the same time created a baronet; and as a special distinction the words "of Alivaw" were by the patent appended to the title. In 1847 he returned to South Africa as governor of Cape Colony and high commissioner, to grapple with the difficulties he had foreseen eleven years before (see CAPE COLONY: History). He took command of an expedition to deal with the disaffected Boers in the Orange River Sovereignty, and fought the action of Boomplaats on the 29th of August 1848. In December 1852 war was declared between the colony and Smith was insufficiency supplied with troops from England; and though his conduct of the operations was warmly approved by the duke of Wellington and other military authorities, Lord Grey, in a despatch never submitted to the queen, recalled him in 1852 before the Kaffirs had been completely subdued. He protested strongly against the abandonment of the Orange River Sovereignty to the Boers, which was carried out two years after his departure, and he actively furthered the granting of responsible government to Cape Colony. His Spanish wife was his constant companion in his second as in his earlier sojourn in South Africa, where her memory is recalled by the town of Lady Grey in Natal (rendered famous by the Boer War of 1899-1902), as is that of his wife by Harrismith in the Orange Free State; while Alivaw North, founded in 1849 and named after his great Indian victory, further commemorates Sir Harry Smith. On his return to England he held a military appointment for some years, and died in London on the 12th of October 1860. Juana, Lady Smith, survived till 1872.

SMITH, HENRY JOHN STEPHEN (1826-1883), English mathematician, was born in Dublin on the 2nd of November 1826, and was the fourth child of his parents. When Henry Smith was just two years old his father died, whereupon his mother left Ireland for England. After being privately educated by his mother and tutors, he entered Rugby school in 1841. Whilst under the first of these tutors, in nine months he read all Thucydides, Sophocles and Sallust, twelve books of Tacitus, the greater part of Horace, Juvenal, Persius, and several plays of Aeschylus and Euripides. He also studied the first six books of Euclid and some algebra, besides reading a considerable quantity of Hebrew and learning the Odes of Horace by heart. On the death of his elder brother in September 1843 Henry Smith left Rugby, and at the end of 1844 gained a scholarship at Balliol College, Oxford. He won the Ireland scholarship in 1848 and obtained a first class in both the classical and the mathematical schools in 1849. He gained the senior mathematical scholarship in 1851. He was a New fellow of Balliol in 1850 and Savilian professor of geometry in 1861, and in 1874 was appointed keeper of the university museum. He was elected F.R.S. in 1861, and was an LL.D. of Cambridge and Dublin. He served on various royal commissions, and from 1877 was the chairman of the managing body of the meteorological office. He died at Oxford on the 9th of February 1883.

After taking his degree he wavered between classics and mathematics, but finally chose the latter... After publishing a few papers relating to theory of numbers and to geometry, he devoted himself to a thorough examination of the writings of K. F. Gauss,
SMITH, H. P.—SMITH, JOHN

P. G. Lejeune-Dirichlet, E. E. Kummer, &c., on the theory of numbers. The main results of these researches, which occupied him from 1854 to 1864, are contained in his Report on the Theory of Numbers, which appeared in the British Association volumes from 1859 to 1864. This report contains not only the complete investigation of all the theorems that have been added to this branch of mathematics, but also original contributions of his own. Some of the most important results of his discoveries were communicated to the Royal Society in a series of two memoirs on "the algebraic determination and congruence forms" and upon the "Orders and Genera of Ternary Quadratic Forms" (Phil. Trans., 1861 and 1867). He did not, however, confine himself to the consideration of forms involving only two variables, but succeeded in establishing a number of cipules on which the extension to the general case of n indeterminates depends, and obtained the general formulæ, thus effecting what is probably the greatest mathematical subject since the invention of the Le Scais' Disquisitiones arithmeticae. A brief abstract of Smith's methods and results appeared in the Proc. Roy. Soc. for 1864 and 1868. In the second of these notices he gives the general formulæ without demonstrations. As corollaries to the general formulæ he adds the formulæ relating to the representation of a number as a sum of five squares and also of seven squares. This class of representation ceases when the number of squares exceeds eight. The cases of two, four, and six squares had been given by K. G. J. Jacobi and that of three squares by F. G. Eisenstein, who had also given without demonstration some of the results for five squares. Fourteen years later L. Kronecker gave the, in general, the most beautiful demonstration of these theorems, and in a memoir he published in 1867, as a corollary from his general formulæ governing the whole class of investigations to which it belonged, showed how far in advance of his contemporaries his early researches had carried him. Many of the propositions contained in his dissertation are general, but the demonstrations are not supplied for the methods of proof. He was also the author of a number of papers in which he extended to complete quadratic forms many of Gauss's investigations relating to real quadratic forms. After 1864 he devoted himself chiefly to elliptic functions, and numerous papers on this subject were published by him in the Proc. Lond. Math. Soc. and elsewhere. At the time of his death he was engaged upon a memoir on the Theta and Omega Functions, which he left nearly complete. In 1868 he was awarded the Steiner prize of the Berlin Academy for a geometrical memoir. Sur quelques problèmes critiques et biographiques. He also wrote the introduction to the collected edition of Clifford's Mathematical Papers (1882). The three subjects to which Smith contributed relate to one another, to the theory of number functions and modern geometry; but in all that he wrote an "arithmetical" mode of thought is apparent, his methods and processes being arithmetical as distinguished from algebraic.

He was born in the town of Philadelphia, where he was graduated in the mathematical and physical section of the British Association at Bradford in 1873 and of the London Mathematical Society in 1874-1876. His Collected Papers were edited by J. W. L. Glaisher and published in 1884.

SMITH, HENRY PRESERVED (1812-1884). American Biblical scholar, was born in Troy, Ohio, on the 23rd of October 1847. He graduated at Amherst College in 1869 and studied theology in Lane Theological Seminary in 1860-1867, in Berlin in 1872-1874 and in Leipzig in 1876-1877. He was instructor in church history in 1874-1875, and in Hebrew in 1875-1876, and was assistant-professor in 1877-1879 and professor in 1879-1883 of Hebrew and Old Testament exegesis in Lane Theological Seminary. In 1892 he was tried for heresy by the Presbytery of Cincinnati, was found guilty of teaching (in a pamphlet entitled Biblical Scholarship and Inspiration, 1891) that there were "errors of historic fact," "suppressions of ‘historic truths,’ &c., &c., in the books of Chronicles, and that the Scripture is not "inspired with the unprofitableness of portions of the sacred writings,"—in other words, that inspiration does not imply inerrancy,—and he was suspended from the ministry. Dr. Smith retired from the denominational, and in 1893, upon becoming a professor at Andover Theological Seminary, entered the ministry of the Congregational Church. From 1897 to 1906 he was a professor in Amherst College, and in 1907 became a professor in the Meadville (Pennsylvania) Theological School.

He published The Bible and Islam (1897), Commentary on the Books of Samuel (1890, in the "International Critical Commentary") and Old Testament History (1903, in the "International Theological Library"). In Inspiration and Inerrancy (1893), he reviewed the papers on which the heresy charge was made, and outlined the case.

SMITH, JAMES (1775-1839), and HORACE (1770-1849), authors of the Rejected Addresses, sons of a London solicitor, were born, the former on 10th February 1775 and the latter on 31st December 1779, both in London. The occasion of their happy "jeu d’esprit" was the rebuilding of Drury Lane theatre in 1812, after a fire in which it had been burnt down. The managers had offered a prize of £50 for an address to be recited at the reopening in October. Six weeks before that date the happy thought occurred to the brothers Smith of feigning one of the popular poets of the time had been among the competitors and issuing a volume of unsuccessful addresses in parody of their various styles. They divided the task between them, James taking Wordsworth, Southey, Coleridge and Crabbe, while Byron, Moore, Scott and Bowles were assigned to Horace. Seven editions were called for within three months. The Rejected Addresses are the most widely popular parodies ever published in England, and take classical rank in literature.

The brothers fairly divided the honours: the elder brother's Wordsworth is evenly balanced by the younger's Scott, and both hold a hand in Byron. A striking feature is the absence of satire; none of the poets caricatured took offence, while the imitation is so clever that both Byron and Scott are recorded to have said that they could hardly believe they had not written the addresses ascribed to them. The only other undertaking of the two brothers was Horace in London (1813). James Smith made another hit in writing Country Cousins, A Trip to Parts, A Trip to America, and other lively skits for Charles Mathews who said he was "the only man who can write clever nonsense." His social reputation as a wit stood high. He was reputed one of the best talkers of his time and his talks are famous. Horace, in 1826, contain many witty essays both in prose and in verse, but the only single piece that has taken a permanent place is the "Address to the Mummy in Belzoni's Exhibition." In private life Horace Smith was not less popular than his brother, though less ambitious as a talker. It was of him that Shelley said: "It is not odd that the only truly generous person I ever knew who had money enough to be generous with should be a stockbroker? He writes poetry and pastoral dramas and yet knows how to make money, and does make it, and is still generous." Horace Smith lived at Tunbridge Wells. He was usually distinguished as Captain John Smith, sometime president of the English colony in Virginia, was the eldest son of George Smith, a well-to-do tenant-farmer on the estate of Lord Willoughby d'Eresby at Willoughby, near Alford in Lincolnshire. The life of this Virginian hero falls conveniently into five periods. The first of these, up to 1566, that of his early youth, is thus described by himself in his Travels: "He was born (1570) in Willoughby in Lincolnshire, and was a scholar in the two free schools of Alford and Louth.

1 The particulars of the authorship are given in the 18th edition (1820), and in the memoir of his brother by Horace prefixed to a posthumous edition of the poems (1870).
His parents, dying (April 1596) when he was thirteen (or rather sixteen) years of age, left him a competent means, which he, not being capable to manage, little regarded. His mind being even then set upon brave adventures, he sold his satchel, books and all he had, intending secretly to get to sea, but that his father’s death stayed him. But now the guardians of his estate more regarding it than he, had liberty enough, though no means, to get beyond the sea. About the age of eighteen, Thomas bound an apprentice to Master Thomas Sendall of [King’s] Lynn, the greatest merchant of all those parts; but, because he would not presently send him to sea, he never saw his master in eight years."

The second period, 1596-1604, is that of his adventures in Europe, Asia and Africa. He first went to Orleans in attendance on the second son of Lord Willoughby. Thence he returned to Paris, and so by Rouen to Havre, where, his money being spent, he began to learn the life of a soldier under Henry IV. of France. On the conclusion (1599) of peace with the League, he went with Captain Joseph Duxbury to Holland and served there some time, probably with the English troops in Dutch pay. By this time he had gained a wide experience in the art of war, not merely as an infantry officer, but also in those more technical studies which are now followed by the Royal Engineers. At length he sailed from Enkhuizen to Scotland, and on the voyage had a narrow escape from shipwreck upon Holy Island near Berwick. After some stay in Scotland he returned home to Willoughby, "where, within a short time being glutted with too much company, wherein he took small delight, he retired himself into a little woody pastures, a good way from any town, environed with many hundred acres of other woods. Here by a fair brook he built a pavilion of boughs, where only in his clothes he lay. His study was Machiavelli’s Art of War and Marcus Aurelius; his exercise a good horse with his lance and ring; his food was thought to be more of venison than anything else; what [else] he wanted his man brought him. The country wondering at such a hermit, his friends persuaded one Signior Theadora Polaloga, rider to Henry, earl of Lincoln, an excellent horseman and a noble Italian gentleman, to insinuate [himself] into his woodland acquaintances, whose languages and good discourse and exercise of riding drew Smith to stay with him at several times. …Thus—when France and the Netherlands had taught him to ride a horse and use his arms, with such rudiments of war as his tender years, in those martial schools, could attain unto, he was desirous to see more of the world, and try his fortune against the Turks, both lamenting and repenting to have seen so many Christians slay another one."

Next came his wanderings through France from Picardy to Marseilles. There he took ship for Italy in a vessel full of pilgrims going to Rome. These, cursing him for a heretic, and swearing they would have no fair weather so long as he was on board, threw him, like another Jonah, into the sea. He was able to get to a little uninhabited island, from which he was taken off the next morning by a Breton ship of 200 tons going to Alexandria, the captain of which, named La Roché, treated him as a friend. In this ship he visited Egypt and the Levant. On its way back the Breton ship caught a Venetian argosy of 400 tons and captured it. Reaching Antibes (Var) later on, Captain La Roché put Smith ashore with 500 sequins, which he then proceeded to see Italy as he had already seen France. Passing through Tuscany he came to Rome, where he saw Pope Clement VIII. at mass, and called on Father K. Parsons. Wandering over the Alps and mountains through Tuscany and Venice, he went to Grazt in Styria. There he received information about the Turks who were then skirmishing through Hungary, and passing on to Vienna, entered the emperor’s service.

In this Turkish war the years 1601 and 1602 soon passed away; many desperate adventures do he narrate (unconfirmed by contemporary records, and doubted by some modern critics), and one in particular covered him with honour. At Regal, in the presence of two armies, as the champion of the Christians, he killed three Turkish champions in succession. On 18th November 1602, at the battle of Rothenburg, a pass in Transylvania, where the Christians fought desperately against an overpowering force of Crim Tatars, Smith was left wounded on the field of battle. His rich dress saved him, for it showed that he would be worth a ransom. As soon as his wounds were cured he was sold for a slave and then marched to Constantinople, where he was presented to Charazta Tragedibzganda, who fell in love with him. When her lest her mother should sell him, she sent him to her brother Timor, pasha of Nablitis, on the Don, in Tatar. "To her unkind brother this kind lady wrote so much for his good usage that he half suspected as much as she intended; for she told him, he should but sojourn to learn the language, and what it was to be a Turk, till time made her master of herself. But the Timor, her brother, diverted all this to the worst of cruelty. For, within an hour after his arrival, he caused his ‘drubman’ to strip him naked, and shave his head and beard so bare as his hand. A great ring of iron, with a long stalk-bowed like a sickle, was riveted about his neck, and a coat [put on him] made of ulgy’s hair, guarded about with a piece of an undressed skin. There were many more Christian slaves, and nearly a hundred farsades of Turks and Moors, and he being the last was the slave of slaves to them all.” While at Nablitis the English captain kept his eyes open, and his account of the Crim Tatars is careful and accurate. "So long he lived in this miserable estate, as he became a thresher at a grange in a great field, more than a league from the Timor’s house. The pasha, as he oft used to visit his granges, visited him, and took occasion so to beat, spurn and revile him, that forgetting all reason Smith beat out the Timor’s brains with his threshing bat, for they have no hallis, and, seeing his estate could be no worse than it was, considered himself in the Timor’s clothes, hid his body under the straw, filled his knapsack with corn, shut the doors, mounted his horse and ran into the desert at all adventure." For eighteen or nineteen days he rode for very life until he reached a Moscovite outpost on the river Don; here his irones were taken off him, and the Lady Callamata largely supplied all his wants. Thence he passed, attracting all the sympathy of an escaped Christian slave, through Muscovy, Hungary and Austria until he reached Leipzig in December 1603. There he met his old master, Prince Sigismund, who, in memory of his gallant fight at Regal, gave him a grant of arms and 500 ducats of gold. Thence he wandered on, sightseeing, through Germany, France and Spain, until he came to Saffi, from which seaport he made an excursion to the city of Morocco and back. While at Saffi he was blown out to sea on board Captain Merharn’s ship, and had to go as far as the Canaries. There Merham fought two Spanish ships at once and beat them off. Smith came home to England with him, having a thousand ducats in his purse.

The third period, 1605-1609, is that of Captain Smith’s experiences in Virginia. Throwing himself into the colonizing projects which were then coming to the front, he first intended to have gone out to the colony on the Oyapok in South America; but, Captain Leigh dying, and the reinforcement miscarrying, "the rest escaped as they could." Hence Smith did not leave England on this account. But he went heartily into the Virginian project with Captain Bartholomew Gosnold and others. He states that what he got in his travels he spent in colonizing. "When I went first to these desperate designs, it cost me many a forgotten pound to hire men to go, and procrastination caused more to run away than went. I have spared neither pains nor money according to my ability, first to procure His Majesty’s letters patents, and a company there, to be the means to raise a company to go into Virginia, which beginning here and there cost me nearly five years [1604-1609] work, and more than five hundred pounds of my own estate, besides all the dangers, miseries and incumbrances I endured gratis." Two colonizing associations were formed—the London Company for South Virginia and the Western Company for North Virginia. Smith was one of the patentees of the Virginia charter of 1609. The colony which Sir W. Raleigh had established at Roanoke Island off the American coast had perished, mainly for want of supplies from England, so that really nothing at all was known of
the Virginian coast-line when the first expedition left London on 19th December 1606; and therefore the attempt was bound to fail unless a convenient harbour should be found. The expedition consisted of three ships (the "Susan Constant," 100 tons, Captain C. Newport; the "God Speed," 40 tons, Captain B. Gosnold; and a pinnace of 20 tons, Captain J. Ratcliffe), with about 140 colonists and 40 sailors. They made first for the West Indies, reaching Dominica on 24th March 1607.

At Nevis, their next stopping-place, a gallows was erected to hang Captain Smith on the false charge of conspiracy; but he escaped, and afterwards the lives of all the men who plotted against him were at his mercy, he spared them. Sailing northwards from the West Indies, not knowing where they were, the expedition was most fortunately, in a gale, blown into the mouth of Chesapeake Bay, discovering land on 26th April 1607. Anchoring, they found the James river, and, having explored it, fixed upon a site for their capital in the district of the chief or weroance of Paspaheh, his chief recommendation being that there were 6 fathoms of water so near to the shore that the ships could be tied to the trees. Orders had been sent out for the government of the colony in a box, which was opened on 26th April 1607. Captain B. Gosnold, E. M. Wingfield, C. Newport, J. Smith, J. Ratcliffe, J. Martin and G. Kendall were named to be the council to elect an annual president, who, with the council, should govern. Wingfield was, on 15th May, elected the first president; and the next day they landed at James Town and commenced the settlement.

All this while Smith was under restraint, for thirteen weeks in all. His enemies would have sent him home, out of a sham commiseration for him; but he challenged their charges, and so established his innocence that Wingfield was adjudged to give him £200 as damages. After this, on 20th June 1607, Smith was admitted to the council.

As in going to America in those days the great difficulty was want of water, so in those colonizing efforts the paramount danger was from want of food. "There were never Englishmen left in a foreign country in such misery as we were in this new discovered Virginia. We watched every three nights [every third night], lying on the bare cold ground, what weather soever came, and warded all the next day, which brought our men to be most feeble wretches. Our food was but a small can of barley sodden in water to five men a day. Our drink, cold, at 30° and a 48°, very salt, at a low tide, full of slime and filth, which was the destruction of many of our men." So great was the mortality that out of 105 colonists living on 22nd June 1607 67 died by the following 8th January. The country they had settled in was sparingly populated by many small tribes of Indians, who owned as their paramount chief, Powhatan, who lived at Werowocomoco, a village on the Pamunkey river, about 12 m. by land from James Town. Various boat expeditions left James Town, to buy food in exchange for copper. They generally had to fight the Indians first, to coerce them to trade, but afterwards paid a fair price for what they bought.

On 10th December 1607 Captain Smith, of whom it is said "the Spaniard never more greedily desired gold than he victual," with nine men in the barge, left James Town to get more corn, and also to explore the upper waters of the Chickahominy. They got the barge up as far as Apocan. Seven men were left in it, with orders to keep it in midstream. They disobeyed, went into the village, and one of them, George Cassen, was caught; the other six, barely escaping to the barge, brought it back to James Town. It so happened that Opechancanough (the brother of Powhatan, whom he succeeded in 1618, and who carried out the great massacre of the English on Good Friday 1622) was in that neighbourhood with two or three hundred Indians on a hunting expedition. He ascended from Cassen where Smith was, who, ignorant of all this, had, with John Robinson and Thomas Emery, gone in a canoe 20 m. farther up the river. The Indians killed Robinson and Emery while they were sleeping by the camp fire, and went after Smith, who was away getting food. They surprised him, and, though he bravely defended himself, he had at last to surrender. He then set his wits to confound them with his superior knowledge, and succeeded. Opechancanough led him about the country for a wonder, and finally, about 5th January 1608, brought him to Powhatan at Werowocomoco. "Having feasted him after their best barbarous manner they could, a long consultation was held; but the conclusion was two great stones were brought before Powhatan; then as many as could laid hands on Smith, dragged him to them, and thereon laid his head. And, being ready with their clubs to beat out his brains, Pocahontas, the king's daughter, when her father would have laid him dead in her arms and laid her own upon his to save him from death. Whereat the emperor was contented Smith should live, to make him hatchets, and her bells, beads and copper; for they thought him as well of all occupations [handi- crafts] as themselves."

The truth of this story was never doubted till 1859, when Dr Charles Deane of Cambridge, Mass., edited Wingfield's Discourse; in reprinting Smith's True Relation of 1609, Deane pointed out that it contains no reference to this hairbreadth escape. Since then many American historians and scholars have concluded that it never happened at all; and, in order to be consistent, they have tried to prove that Smith was a blustering braggadocio, which is the very last thing that could in truth be said of him. The rescue of a captive doomed to death by a woman is not such an unheard-of thing in Indian stories. If the truth of this deliverance be denied, how then did Smith come back to James Town loaded with presents, when the other three men were killed, George Cassen in particular, in a most horrible manner? And how is it, supposing Smith's account to be false, that Pocahontas afterwards frequently came to James Town, and was next to Smith himself, the salvation of the colony? The fact is, nobody doubted the story in Smith's lifetime, and he had enemies enough!

Space fails to describe how splendidly Smith worked after his deliverance for the good of the colony, how he explored Chesapeake Bay and its inflows, how [when all others had failed] the presidency was forced on him on 10th September 1608; how he tried to get corn from Powhatan at Werowocomoco on 12th January 1609, but he fled to Orapakes, 40 m. farther off; how with only eighteen men he cowed Opechancanough in his own house at Pamunkey, in spite of the hundreds of Indians that were there, and how he made the colony a little more than a month after he came, by the peaceful means employed by others, the colony, making the lazy work or starve.

Meanwhile the establishment of this forlorn hope in Virginia had stirred up a general interest in England, so that the London Company were able in June 1606 to send out 9 ships with 300 colonists. Smith had now got the Indians into splendid order; but from the arrival on 11th August of the new-comers his authority came to an end. They refused to acknowledge him, and robbed and injured the Indians, who attacked them in turn. Smith did his best to smooth matters, while the rioters were plotting to shoot him in his bed. In the meantime he was away up the river. On his return, "sleeping in his boat, accidentally one fired his powder bag, which tore his flesh from his body and thighs, 0 or 10 in. square, in a most pitiful manner; but to quench the tormenting fire he fainted in his clothes he leaped overboard into the deep river, where, ere they could recover him, he was nearly drowned." Thus disabled, he was sent home on 4th October 1609 and never set foot in Virginia again. Nemesis followed him. Before his departure in April 1613 by Captain S. Argall, who had obtained possession of her by treachery on the Potomac river. The colony, while treating her well, used her as a means to secure peace with the Indians. In the meantime, before 1615, Powhatan died, she fell in love with an English gentleman, John Rolfe, apparently at that time a widower. They were married about 1st April 1614. Subsequently she embraced Christianity. Sir T. Dale, with Rolfe and his uncle, removed to Virginia on 12th March. Smith petitioned Queen Anne on her behalf; and it is in this petition of June 1616 that the account of his deliverance by the Indian girl first appears. Before a pleasant sojourn of about seven months, being well received both by the court and the people, Pocahontas with her husband embarked for Virginia in the George, Captain S. Argall (her old captor), but she died off Gravesend about February 1617.
overtook the rioters the winter after he left, which is known in Virginian story as "the starving time." Out of 490 persons in the colony in October 1609 all but 60 died by the following March. The rest of Smith's life was briefly touched upon. The fourth score of, 1610-1617, was chiefly spent in exploring Nusconoc, Canada and Pemaquid or North Virginia, to which, at his solicitation, Prince Charles gave the name of New England. His first object was to fish for cod and barter for furs, his next, to discover the coast-line with the view to settlement. Two attempts, in 1615 and 1617, to settle at Caspawick failed, but through no fault of his. It was in connexion with these projects that the Western Company for North Virginia gave him the title of admiral of New England. We cannot better conclude this sketch of his active operations than by his own words written in 1631. It might be called slavery to the Turks; prisoner among the barbarous savages; after my deliverance commonly discovering and ranging those large rivers and unknown nations with such a handful of ignorant companions that the wiser sort often gave me up for lost; always in mutinies, wants and miseries; blown up with gunpowder; a long time a prisoner among the French pirates, from whom escaping in a little boat by myself, and adrift all such a stormy winter night, when their ships were split, more than £100,000 lost which they had taken at sea, and most of them drowned upon the Isle of Rhélon, not far from whence I was driven on shore, in my little boat &c. in pitchy weather [I lived in] the fields; yet to have lived near thirty-seven years [1593-1630] in the midst of wars, pestilence and famine, by which many a hundred thousand have died about me, and scarce five living of them that went first with me to Virginia, and yet to see the fruits of my labours thus well begin to prosper (though I have but my labour for my pains), have I not much reason, both privately and publicly to acknowledge it, and give God thanks?"

The last period, 1618-1631, of Smith's life was chiefly devoted to authorship. In 1618 he applied (in vain) to Francis Bacon to be numbered among his servants. In 1619 offers himself to the Pilgrims to North Virginia; but they would not have him, he being a Protestant and they Puritans. The charter of the London Virginia Company was annulled in 1624. A list of his publications will be found at the end of this article. Thus having done much, endured much and written much, while still contemplating a History of the Sea, Captain John Smith died on 21st June 1631, and was buried in St Sepulchre's Church, London.

Two of the sixty survivors of "the starving time," Richard Potts and William Phetplace, thus nobly expressed in print, so early as 1612, their estimate of Smith: "What shall I say? but thus we lost him [4th October 1609], in all his admirably passionate writings, his gallantry and experience his second; ever-hating baseness, sloth, pride and indignity more than any dangers; that never allowed more for himself than his saddlers with him; that no danger would send them where he would not lead them himself; that would never see us want what he either had, or could by any means get us; that would rather want than borrow or starve than not pay; that loved actions more than words, and hatred falsehood and cozenage than death; whose adventures were our lives, and whose loss our deaths."

A high appreciation of Smith's life and work is found in Professor Edward Arber's reprint of Smith's Works (Birmingham, 1884), 8vo. The order of their first appearance is, A True Relation, &c. (1608) (first attributed to a gentleman of the colony, next to Th. Watson, and finally to Captain Smith); A Map of Virginia, ed. by William Strickland; (Oxford, 1612); A Description of New England (1616); New England's Trials (1620); New England's Trials, 2nd ed. (1622); The General History of Virginia, New England and the Summer Isles (1624); An Accidence for all Young Seamen (1626); the same recast and enlarged as A Sea Grammar (1627), both works continuing on sale for years, side by side; The True Travels, &c. (1630); A True and Briefe Narrative; and the Discriminated History (1631).

Of some of the smaller texts limited 40 editions have been published by Dr C. Deane and J. Carter Brown, See the MacLeod edition (1897) of the General History, True Travels and Sea Grammar; C. Bradley's Captain John Smith (1905), Charles Poindexter's Captain John Smith and his Critics (1893), John Fiske's Old Virginia (1897), and for criticism of Smith's credibility L. L. Kropp in Notes and Queries for 1909, Alexander Brown's Genits of the United States (1890) and E. D. Nell's History of the Virginia Company of London (1869). (E.A.)

SMITH, JOHN RAPHAEL (1762-1812), English painter and mezzotint engraver, a son of Thomas Smith of Derby, the landscape painter, was born in 1752. He was apprenticed to a linen-dyer in Derby, and afterwards pursued the same business in London, adding, however, to his income by the production of miniatures. He then turned to engraving and executed his plate of the "Public Ledger," which had great popularity, and was followed by his mezzotints of "Edwin the Minstrel" (a portrait of Thomas Haden), after Wright of Derby, and "Mercury Inventing the Lyre," after Barry. He reproduced some forty of the works of Reynolds, some of these plates ranking among the masterpieces of the art of mezzotint, and he was appointed engraver to the prince of Wales. Adding to his already existing extensive connexion as a print-dealer and publisher, he would soon have acquired wealth had it not been for his dissipated habits. He was a boon companion of George Morland, whose figure-pieces he excellently mezzotinted. He painted subject-pictures such as the "Unsuspecting Maid," "Inattention" and the "Moralist," exhibiting in the Royal Academy from 1770 to 1790. Upon the decline of his business as a printer he made a tour through the N. and midland counties of England, producing much hasty and indifferent work, and settled in Doncaster, where he died on the 2nd of March 1812.

As a mezzotint engraver, Smith occupied an important position. His prints are delicate, excellent in drawing and finely expressive of colour. His small full-lengths in crayons and his portraits of Fox, Horne Tooke, Sir Francis Burtett and the group of the duke of Devonshire and family—an accurate and successul draughtsman and painter. He had a very thorough knowledge of the principles and history of art, and was a brilliant conversationalist.

SMITH, JOSEPH, Jr. (1805-1844), the founder, in April 1830, of the Church of Jesus Christ of Latter-Day Saints, was born in Sharon, Vermont, on the 23rd of December 1805. He was killed by a mob in a jail at Carthage, Illinois, on the 27th of June 1844. (See Mormons.)

SMITH, MORGAN LEWIS (1822-1874), American general, was born in Oswego county, New York, on the 8th of March 1822. In 1843 he settled in Indiana, and later had some military experience in the United States army. At the outbreak of the Civil War he raised the 8th Missouri regiment, of which he was elected colonel in 1861. He commanded a brigade at the capture of Fort Donelson, and did good service at Shiloh. In July 1862 he was made a brigadier-general U.S.V., and served under Sherman in the river expedition against Vicksburg. At the battle of Chickasaw Bayou he received a severe wound, from which he recovered only in time to join the Army of the Tennessee before Chattanooga. He led his division in the battles of the Chattanooga campaign, as also, in the following year, in the disastrous defeat of General Forrest's cavalry and successive adventures with Logan's corps. Afterwards he was placed in charge of Vicksburg. General Sherman said of M. L. Smith, "he was one of the bravest men in action I ever knew." He died at Jersey City on the 20th of December 1874.

His brother, GILES ALEXANDER SMITH (1829-1876), also a distinguished soldier of the Federal army, was born in Jefferson county, N.Y., on the 29th of September 1829. At the beginning of the Civil War he joined the Missouri volunteers, in which he became a captain. He took part in the capture of Fort Donelson, the battle of Shiloh and the operations against Corinth, becoming, later in 1862, colonel of a regiment which he led at Chickasaw Bayou. After the final campaign against Vicksburg he was promoted brigadier-general of volunteers. He was wounded at the battle of Chattanooga. He took part in the Atlanta campaign, the "March to the Sea" and the Carolinas campaign, rising to the rank of major-general of volunteers. After the war he declined the offer of a colonelcy in the regular army, and was subsequently engaged in politics, retiring from public life in 1872. He died at Bloomington, Ill., on the 8th of November 1876.

SMITH, RICHARD BAIRD (1816-1861), British engineer officer, son of a surgeon of the royal navy, was born on the 31st of December 1816. He was educated at Lasswade and Addiscombe, and joined the Madras Engineers in 1838. Being transferred to the Bengal Engineers, he served through the second
Sikh war, and was present at the battles of Badiwal, Alliwal and Sobran. He was then for some years employed on canal work, and when the Mutiny broke out was in charge of Roorkee. He promptly concentrated the Europeans in the workshops, and though the nativeappers deserted, his forethought prevented between the two junior B.A.'s who had been appointed chief engineer in charge of the siege works. He reached Delhi on the 2nd of July, and immediately ordered General Barnard to assault the city. Barnard died while the advice was still under consideration, and his successor, General Reed, could not be induced to follow it; and when Reed in turn was succeeded by Archdale Wilson, the besiegers were so weakened by losses that the moment for a successful attack had passed. Baird Smith, however, prevented Wilson from relaxing his hold on Delhi until the arrival of John Nicholson with reinforcements from the Punjab, and of the siege train from Phillour. Nicholson then joined Baird Smith in compelling Wilson to make the assault, which proved successful, on the 14th of September. Baird Smith was ably assisted by Captain Alexander Taylor, but Nicholson was unjust to Baird Smith in assigning to Taylor the chief credit for the siege operations. After the capture of Delhi he returned to Roorkee and to civil employment, and for a time the value of his military services was insufficiently recognized. After the Mutiny he was made A.D.C. to Queen Victoria, became secretary to the government of India in the public works department, and gained well-deserved credit in the famine of 1866. But while he was strongly recommended for promotion and illness at Delhi, broke down his constitution, and he died at sea on the 13th of December 1861. He married a daughter of De Quincey, who long survived him.

**SMITH, ROBERT** (1689–1769), English mathematician, was born in 1689, probably at Lea near Gainborough. After attending Lincoln grammar school he entered Trinity College, Cambridge, in 1708, and becoming minor fellow in 1714, major fellow in 1715 and senior fellow in 1725, was chosen in succession to Richard Bentley. From 1716 to 1762 he was Plumin professor of astronomy, and he died in the master's lodge at Trinity on the 2nd of February 1768. Besides editing two works by his cousin, Roger Cotes, who was his predecessor in the Plumin chair, he published a *Compleat System of Opticks* in 1738, which gained him the sobriquet of "Old Focus," and *Harmonics, or the Philosophy of Musical Sounds* in 1749. He was the founder of the Smith's prizes at Cambridge, having by his will left £3200 South Sea stock to the university, a portion of the interest from which was to be divided yearly between two junior B.A.'s who had made the greatest progress in mathematics and natural philosophy.

**SMITH, SYDNEY** (1771–1845), English writer and divine, son of Robert Smith, was born at Woodford, Essex, on the 3rd of June 1771. His father, a man of restless ingenuity and activity, "very clever, odd by nature, but still more odd by design," who bought, altered, spoiled and sold about nineteen different estates in England, had talent and eccentricity enough to be the father of such a wit as Sydney Smith on the strictest principles of heredity; but Sydney himself attributed not a little of his constitutional gaiety to an infusion of French blood, having, as a boy, been a servant to a Protestant refugee by the name of Olier. Sydney was the second of a family of four brothers and one sister, all remarkable for their talents. While two of the brothers, Robert Percy, known as "Bobus," afterwards advocate-general of Bengal, and Cecil, were sent to Eton, Sydney was sent with the youngest to Winchester, where he rose to be captain of the school, and with his brother so distinguished himself that their schoolfellows signed a round-rob in "refusing to try for the college prizes if the Smiths were allowed to contend for them any more, as they always gained them." At some time during his Oxford career he spent six months in France, being duly enrolled for safety's sake in the local Jacobin club. In 1798 he had become a scholar of New College, Oxford; he received a fellowship after two years' residence, took his degree in 1792 and proceeded M.A. in 1796. It was his wish then to read for the bar, but his father would add nothing to his fellowship, and he was reluctantly compelled to take holy orders. He was ordained priest at Oxford in 1796, and became a curate in the small village of Nether Avog, near Amesbury, in the midst of Salisbury Plain. The place was uncleared and the Fitzroy Chapel was for the inhabitants, providing the means for the rudiments of education, and thus making better things possible. The squire of the parish, Michael Hicks-Beach, invited the new curate to dine, was astonished and charmed to find such a man in such a place, and engaged him after a time as tutor to his eldest son. He was arranged that they should proceed to the university of Weimar, but, before reaching their destination Germany was disturbed by war, and "in stress of politics" said Smith, "we put into Edinburgh." This was in 1798. While his pupil attended lectures, Smith was not idle. He studied moral philosophy under Dugald Stewart, and devoted much time to medicine and chemistry. He also preached in the Episcopal chapel, where his practical brilliant discourses attracted many hearers.

In 1800 he published his first book, *Six Sermons, preached in Charlotte Street Chapel, Edinburgh*, and in the same year, married, against the wishes of her friends, Catharine Amelia Pybus. They settled at No. 46 George Street, Edinburgh, where, as everywhere else, Smith made numerous friends, among them the future Edinburgh Reviewers. It was towards the end of his five years' residence in Edinburgh, in the eighth or ninth storey of a house in Buccleuch Place, the elevated residence of the then Mr Jeffrey, that Sydney Smith proposed the setting up of a review as an organ for the young malcontents with things as they were. "I was appointed editor," he says in the preface to the collection of his contributions, "and remained long enough in Edinburgh to edit the first number (October 1802) of the Edinburgh Review. The motto I proposed for the Review was 'Tenui musam meditamus areum.'—'We cultivate literature on a little oatmeal.' But this was too near the truth to be admitted, and so we took our present grave motto from Plutius Syrus, of whom, none of us, I am sure, had ever read a single line. He continued to write for the Review for the next quarter of a century, and his brilliant articles were a main element in its success.

He left Edinburgh for good in 1803, when the education of his pupils was completed, and settled in London, where he rapidly became known as a preacher, a lecturer and a social lion. His success as a preacher, although so marked that there was often not standing-room in Berkeley Chapel, Mayfair, where he was morning preacher, was not gained by any sacrifice of dignity. He was also "alternate evening preacher" at the Foundling Hospital, and preached as in Buccleuch Place, and the Fitzroy Chapel, and at St Saviour's Church, Fitzroy Square. He lectured on moral philosophy at the Royal Institution for three seasons, from 1804 to 1806; and treated his subject with such vigour, freshness and liveliness of illustration that the London world crowded to Albemarle Street to hear him. He followed in the main Dugald Stewart, whose lectures he had attended in Edinburgh; but there is more originality as well as good sense in his lectures, especially on such topics as imagination and wit and humour, than in many more pretentious systems of philosophy. He himself had no high idea of these entertaining performances, and threw them in the fire when they had served their purpose, providing the money for furnishing his house. But his wife rescued the charred MSS, and published them in 1830 as *Elementary Sketches of Moral Philosophy*.

With the brilliant reputation that Sydney Smith had acquired in the course of a few seasons in London, he would probably have obtained some good prebend had he been on the powerful side in politics. Sydney Smith's elder brother "Bobus" had married Caroline Vernon, aunt of the 3rd Lord Holland, and he was always a welcome visitor at Holland House. His Whig friends came into office for a short time in 1806, and presented him with the living of Foston-le-Clay in Yorkshire. He shrunk from this banishment for a time, and discharged his parish duties through a curate; but Spencer Perceval's Residence Act was
passed in 1808, and after trying in vain to negotiate an exchange, he quitted London in 1809, and moved his household to York-  
shire. The Ministry of "All the Talents" was driven out of office in 1807 in favour of a "no popery" party, and in that year appeared the first instalment of Sydney Smith's most famous publication, Peter Pymly's Letters. Smith's opposition to Catholic emancipation, ridiculing the opposition of the country  
clergy. It was published as A Letter on the Subject of the Catholics to my brother Abraham who lives in the Country, by Peter Pymly. Nine other letters followed before the end of 1808, when they  
appeared in collected form. Peter Pymly's identity was a secret, but rumours got abroad of the real authorship. Lord  
Holland wrote to him expressing his own opinion and Grenville's, that there had been nothing like it since the days of Swift (Memoir, i. 151). He also pointed out that Swift had lost a bishopric for  
his witless performance. The special and temporary nature of the topics advanced in these pamphlets has not prevented them  
from taking a permanent place in literature, secured for them by the vigorous, picturesque style, the generous eloquence and  
clearness of exposition which Sydney Smith could always command. In his country parish of Foston, with no educated  
neighbour within 7 m., Sydney Smith accommodated himself cheerfully to his new circumstances, and won the hearts of his  
parishioners as quickly as he had conquered a wider world. There had been no resident clergyman in his parish for 150 years;  
he had a farm of 300 acres to keep in order; a rectory had to be built. All these things were attended to beside his contributions  
to the Edinburgh Review. "If the chances of life ever enable me to emerge," he nevertheless writes to Lady Holland, "I will  
show you I have not been wholly occupied by small and sordid pursuits." He continued to serve the cause of toleration by  
spreading sermons in favour of Catholic emancipation; his eloquence being specially directed against those who maintained that a  
Roman Catholic could not be believed on his oath. "I defy Dr Duigenan," he pleaded, addressing a meeting of clergy in 1823,  
in the full vigour of his incapacity, in the strongest access of that Protestant epilepsy with which he was so often convulsed,  
to add a single authority to the security of that truth. At this time appeared one of his most vigorous and effective  
polemics, A Letter to the Electors upon the Catholic Question (1826).

Sydney Smith, after twenty years' service in Yorkshire,  
 obtained preferment at last from a Tory minister, Lord Lynd-  
hurst, who presented him with a prebend in Bristol cathedral  
 in 1828, and afterwards enabled him to exchange Foston for the  
living of Combe Florey, near Taunton, which he held conjointly  
with the living of Halberton attached to his prebend. From  
this time he discontinued writing for the Edinburgh Review on  
the ground that it was more becoming in a dignitary of the church  
to put his name to what he wrote. It was expected that when  
the Whigs came into power Sydney Smith would be made a bishop.  
There was nothing in his writings, as in the case of Swift, to stand in the way. He had been most sedulous as a parochial clergyman.  
Doctoring his parishioners, he said, was his only rural amuse-  
ment. His religion was wholly of a practical nature, and his  
fellow-clergy had reasons for their suspicion of his very limited  
he said, "has no enthusiasm." His scorn for enthusiasts and  
dread of religious emotion found vent in middle life in his  
strictures on missionary enterprise, and bitter attacks on Method- 
ism, and later in many scoffs at the followers of Pusey. Still,  
though he was not without warm friends at headquarters,  
the opposition was too strong for them. One of the first things  
that Lord Grey said on entering Downing Street was, "Now I shall  
be able to do something for Sydney Smith"; but he was not  
able to do more than appoint him in 1831 to a residuary  
canony at St Paul's in exchange for the prebendal stall he held  
at Bristol. He was as eager a champion of parliamentary reform  
as he had been of Catholic emancipation, and one of his best  
fighting speeches was delivered at Taunton in October 1831 when  
he made his well-known comparison of the House of Lords, who  
had just thrown out the Reform Bill, with Mrs Partington of  
Sidmouth, setting out with mop and pattens to stem the Atlantic  
in a storm. Some surprise must be felt now that Sydney Smith's  
reputation as a humorist and wit should have caused any  
hesitation about elevating him to an episcopal dignity, and  
perhaps even was right that Works (2 vols., 1839), including the  
his being known as "a high-spirited, honest, uncompromising man,  
whom all the bench of bishops could not turn upon vital ques- 
tions." With characteristic philosophy, when he saw that the  
promotion was doubtful, he made his position certain by resolv- 
ing not to be a bishop and definitely forbidding his friends to  
tercede for him.

On the death of his brother Courtenay he inherited £50,000,  
which put him out of the reach of poverty. His eldest daughter,  
Saba (1802-1866), married Sir Henry Holland. His eldest son,  
Douglas, died in 1829 at the outset of what had promised to be  
a brilliant career. This grief his father never forgot, but nothing  
could quite destroy the cheerfulness of his later life. He retained  
his high spirits, his wit, practical energy and powers of argu- 
mentative ridicule to the last. His Three Letters to Archdeacon  
Singleton on the Ecclesiastical Commission (1837-38-39) and  
his Petition and Letters on the repudiation of debts by the state  
of Pennsylvania (1843), are as bright and trenchant as his best  
contributions to the Edinburgh Review. He died at his house  
in Green Street, London, on the 22nd of February 1845 and  
was buried at Kensal Green.

Sydney Smith's other publications include: Sermons (2 vols.,  
1810); He was right in the Works (2 vols., 1839), including the  
the Pymly and the Singleton Letters and many articles from the Edinburgh Review: A Fragment on the Irish Roman Catholic Church (1845); Sermons at St Paul's . . . (1830) and some other pamphlets and sermons. Lady Holland says (Memoir, i. 190) that her father left an  
unpublished MS., compiled from documentary evidence, to exhibit  
the history of English misrule in Ireland, but had hesitated to  
published. This was suppressed by his widow in deference to the  
opinion of Lord Macaulay.

See A Memoir of the Reverend Sydney Smith by his daughter, Lady  
Holland, with a Selection from his Letters edited by Mrs [Sarah]  
Houghton (1853); Sydney Smith's Miscellaneous Works (4 vols.,  
1855); Sydney Smith: His Life and Letters (1888) by Stuart J. Reid; a chapter on "Sydney Smith" in Lord Houghton's Monographs Social and Personal (1873); A. Chevrillon, Sydney Smith et la renaissance des idées libérales en Angleterre au XIX^e siècle (1894); and especially the monograph,  
with a full description of his writings, by G. W. E. Russell in Sydney  
Smith (English Men of Letters series, 1909). There are numerous  
references to Smith in contemporary correspondence and journals.

SMITH, SIR THOMAS (1513-1577), English scholar and diplomatist,  
was born at Safron Walden in Essex on the 23rd of December 1513. He became a fellow of Queens' College, Cambridge, in 1530, and in 1533 was appointed a public reader or professor. He lectured in the schools on natural philosophy, and on Greek in his own rooms. In 1540 Smith went abroad, and,  
having been living in France and Spain three years, returned  
and took up a public conduct in Italy. In 1543 he was  
professed of Eton and dean of Carlisle. He early adopted  
Protestant views, a fact which brought him into prominence  
when Edward VI. came to the throne. During Somerset's  
protectorate he entered public life and was made a secretary  
of state, being sent on an important diplomatic mission to Brussels.  
In 1548 he was knighted. On the accession of Mary he was  
deprived of all his offices, but in the succeeding reign was promi- 
nently employed in public affairs. He became a member of parlia-  
ment, and was sent in 1562 as ambassador to France, where he  
remained till 1566; and in 1572 he again went over to France in  
the same capacity for a short time. He remained one of Elizabeth's  
most trusted Protestant counsellors, being appointed in 1572  
chancellor of the court of the Garter, and in 1573  
He died on the 12th of August 1577. In 1661 the grandson of his
brother George was created a baronet, and from him the title has descended to the Smith family of the present day.

His best-known work, entitled De recta et emendata lingua Graecae pro nuncupatione Romanicarum, was published in 1751, and bore the same title as a work by Guillaume le Védrine, his dialogue De recta et emendata lingua Anglicae scripturæ. A number of his letters from France are in the foreign state papers. See A. F. Pollard's article in the Dict. Nat. Bioj. A life by Smythe was published in 1898 (Oxford edition, 1820).

SMITH, THOMAS SOUTHWICK (1788-1861), English physician and sanitary reformer, was born at Martock, Somersetshire, on the 21st of December 1788. While a medical student in Edinburgh he took charge of a Unitarian congregation. In 1816 he took his M.D. degree, and began to practice at Yeovil, Somerset, also becoming minister at a chapel in that town, but removed in 1820 to London, devoting himself principally to medicine. In 1824 he was appointed physician to the London Fever Hospital, and in 1830 published A Treatise on Fever, which was at once accepted as a standard authority on the subject. In this book he established the direct connexion between the impoverishment of the poor and epidemic fever. He was frequently consulted in fever cases in the dispensaries of the country, and his reports on quarantine (1843), cholera (1850), yellow fever (1852), and on the results of sanitary improvement (1854) were of international importance. He died at Florence on the 10th of December 1861.

SMITH, WILLIAM (fl. 1590), English sonneteer. He published in 1590 a sonnet sequence entitled Chloris, or the Complaint of the passionate despaired Shepherd. He was a disciple of Spenser, to whom the two first sonnets and the last are addressed. He signed his name W. Smith, and has sometimes been confused with the playwright Wentworth Smith, who collaborated with John Day, William Haughton and others (1601-1603).

SMITH, WILLIAM (c. 1730-1819), English actor, the son of a city tea merchant, was educated at Eton and went up to Cambridge, but his wild pranks soon ended his college career and brought him back to London. His first stage appearance was in 1753 at Covent Garden, where he remained for twenty years, playing important parts. In 1774 he was at Drury Lane under Garrick's management. His forte was gay comedy, and he was the original, indeed unrivalled, Charles Surface. It was in this part that he made his farewell appearance in 1788. He died on the 7th of September 1819. His sporting tastes and social connexions—he married the sister of a peer—led to his being called "Gentleman Smith," a sobriquet his manners seem to have justified. He is to be distinguished from an older English actor, William Smith (d. 1666), the friend of Betterton.

SMITH, WILLIAM (1769-1830), English geologist, appropriately termed "the Father of English geology," and known among his acquaintances as "Strata Smith," was born at Churchill in Oxfordshire on the 23rd of March 1769. Deprived of his father, an ingenious mechanic, before he was eight years old, he depended upon his father's eldest brother, a farmer at Over Norton, who was but little pleased with his nephew's love of collecting "pundibs" (Terebratulae) and "stone-stones" (the large Echinoid Clypeus, then frequently employed as a pound weight by dairywomen), and with his propensity for carving sundials on soft brown "oven-stone" of his neighbourhood. The uncle was, however, better satisfied when the boy, after studying the rudiments of geometry and surveying, began to take interest in the draining of land; and there is no doubt that William Smith profited in after life by the practical experience he gained with the reliefs. At the age of eighteen he became assistant to Edward Webbe, the Surveyor of Stow-on-the-Wold, and traversed the Oolitic lands of Oxfordshire and Gloucestershire, the Lias clays and red marls of Warwickshire and other districts, studying their varieties of strata and soils. In 1791 his observations at Stowey and High Littleton in Somersetshire first impressed him with the regularity of the strata. In 1793 he executed the surveys and levellings for the line of the Somerset Coal Canal, in the course of which he con-
classics, and when he entered University College he carried off both the Greek and Latin prizes. He was entered at Gray's Inn in 1830, but gave up his legal studies for a post at University College school, and began to write on classical subjects. He next turned his attention to lexicography. His first attempt was the *Dictionary of Greek and Roman Biography*, and the *Greek and Roman Geography* in 1837. The greater part of this was written by himself. In 1840 followed the *Dictionary of Greek and Latin Biography*, and the *Greek and Roman Geography* in 1837. In this work some of the leading scholars of the day were associated with him. In 1850 he published the first of the school dictionaries; and in 1853 he began the *Principia* series, which marked a distinct step in the school teaching of Greek and Latin. Then came the *Students' Manuals of History and Literature*, in which the Greek history was the editor's own work. In carrying out this task Smith was most ably seconded by John Murray, the publisher, who, when the original publishers of the dictionaries got into difficulties, volunteered to take a share in the undertaking. The most important, perhaps, of the books edited by William Smith were those that dealt with ecclesiastical subjects. These were the *Dictionary of the Bible* (1860-1865); the *Dictionary of Christian Antiquities* (1875-1880); undertaken in collaboration with Archdeacon Cheetham; and the *Dictionary of Christian Biography* (1877-1887), jointly with Dr Henry Wace. The *Atlas*, on which Sir George Grove collaborated, appeared in 1875. From 1835 to 1869 Smith was classical examiner to the University of London, and on his retirement he became a member of the Senate. He sat on the Committee to inquire into questions of copyright, and was for several years registrar of the Royal Literary Fund. He edited Gibbon, with Guitzot's and Millman's notes, in 1854-1855. In 1867 he became editor of the *Quarterly Review*, which he directed with marked success until his death on the 7th of October 1893, his remarkable memory and accuracy, as well as his tact and courtesy, specially fitting him for such a post. He was D.C.L. of Oxford and Dublin, and the honour of knighthood was conferred on him the year before his death.

SMITH, WILLIAM FARRAR (1824-1903). American general, was born at St Albans, Vermont, on the 17th of February 1824, and graduated from West Point in 1845, being assigned to the engineer branch of the army. He was twice assistant professor of mathematics at West Point (1846-1848 and 1855-1856). During the first campaign of the Civil War he was employed on the staff, in August 1861 became brigadier-general of volunteers, and was brevetted lieutenant-colonel U.S.A. for his gallantry at the action of White Oak Swamp. In July 1862 he received promotion to the rank of major-general U.S.V. Smith led his division with conspicuous valour at Antietam, and was again brevetted in the regular army. On the assignment of General Franklin to a superior on the Committee to inquire into questions of copyright, and was for several years registrar of the Royal Literary Fund. He edited Gibbon, with Guitzot's and Millman's notes, in 1854-1855. In 1867 he became editor of the *Quarterly Review*, which he directed with marked success until his death on the 7th of October 1893, his remarkable memory and accuracy, as well as his tact and courtesy, specially fitting him for such a post. He was D.C.L. of Oxford and Dublin, and the honour of knighthood was conferred on him the year before his death.

SMITH, WILLIAM F.—SMITH, W. R. 271

the Virginian campaign of 1864 Smith was specially assigned by Grant to command the XVIII. corps, Army of the James, and he took part in the battle of Cold Harbor and the first operations against Petersburg, after which, while absent on leave, he was suddenly deprived of his command by Grant. He resigned from the volunteer service in 1865, and from the U.S. army in 1867. From 1864 to 1875 he was president of the International Telegraph Company, and in 1875-1881 served on the board of police commissioners of New York, becoming president of this in 1877. After 1881 he was engaged in civil engineering work. He died at Philadelphia on the 28th of February 1903.

SMITH, WILLIAM HENRY (1808-1872). English author, was born at Hammersmith, London, in 1808. He was educated at Radley School, and in 1827 was sent to Glasgow University. In 1853 he entered a lawyer's office, in which he remained for five years. He was called to the bar, but had no practice. He contributed to the *Literary Gazette* and to the *Athenaeum*, under the name of "Wool-gatherer," attracting some attention by the delicacy and finish of his style. Ernesto, a philosophical romance, appeared in 1835, two poems, *Guidone* and *Solitude*, in 1836, and in 1839 he formed a connexion with *Blackwood's Magazine*, for which he acted as philosophical critic for thirty years. In 1846 a visit to Italy led to the writing of a tale entitled *Mildred*, which was too purely reflective to be successful. In 1851 he declined the chair of moral philosophy at Edinburgh, being unwilling to abandon his quiet, studious life in the Lake District. There he completed his philosophic romance *Thorndale* (1857), which he considered at the time to be a work of real intellectual value. A similar production, *Gravenhurst*, appeared in 1862; a second edition contained a memoir of the author by his wife. Smith died at Brighton on 28th March 1872. He also wrote two plays, one of which, *Athelwold*, was produced by Macready in 1843. It was published with his other tragedy, *Sir William Crichton*, in 1846.

SMITH, WILLIAM HENRY (1825-1891), English man of business and statesman, was born in London on the 24th of June 1825. His father was the founder of the great distributing firm of W. H. Smith & Son, in the Strand, and at an early age he became a partner and devoted himself to the business. He betrayed no political aspirations until 1865, when he came forward as a Conservative to contest Westminster against John Stuart Mill and the Hon. Mr Grosvenor. Defeated on that occasion, he triumphed in 1868, winning a victory when his party was in general vanquished on all sides. The prestige thus obtained combined with wealth and his business abilities to recommend him to Disraeli, who in 1874 made him secretary to the Treasury. In 1877 he gained cabinet rank as first lord of the Admiralty; in 1885 he was successively secretary for War and then secretary for Ireland; in 1886 he was again at the War Office, and in 1892, when Lord Randolph Churchill resigned necessitated a reconstruction of the ministry, Mr Smith found himself first lord of the Treasury and leader of the House of Commons. He was no orator, and made no pretence to genius, but his success in these high offices was complete, and was admittedly due, not merely to business ability, but to the universal respect which was gained by his patience, good temper, zeal for the public service, and thorough kindness of heart. He died at Walmer Castle (which he occupied as Warden of the Cinque Ports) on the 6th of October 1891. In recognition of his services a pecuniary in his own right was conferred on his widow, with the title of Viscountess Hambleton. Lady Hambleton (b. 1828) had been a Miss Danvers, and before marrying Mr Smith had been the wife of Mr B. A. Leach, by whom she had a family. Her eldest son by the second marriage, the Hon. W. F. D. Smith (b. 1868), rowed in the Oxford boat, and on his father's death became head of the business; in 1891 he was elected Conservative M.P. for the Strand (London), and was re-elected in 1892, 1895, 1900 and 1906. He married in 1864 Lady Esther Gore, daughter of the earl of Arran.

SMITH, WILLIAM ROBERTSON (1824-1893). Scottish philosopher, essayist, Biblical critic, and editor, from 1881, of the 9th edition of this Encyclopaedia, was born on the
8th of November 1846 at Keig in Aberdeenshire, where his father was Free Church minister. He was educated at home and at Aberdeen University, where he attained the highest academic distinctions, winning among other things the Ferguson mathematical scholarship, which is open to all graduates of Scottish universities under three years' standing. In 1866 he entered the Free Church College at Edinburgh as a student of theology. During two summer sessions he studied philosophy and theology at Bonn and Göttingen, making friends in all branches of learning. From 1868 to 1870 he acted as assistant to the professor of natural philosophy in Edinburgh University. During this period he was not only most successful as a teacher, but produced much original work—especially in the experimental and mathematical sciences, electricity, and meteorology. He was awarded the firstclass degree in mathematics in 1870. In 1879 he was appointed and ordained to the office of professor of Oriental languages and Old Testament exegesis at the Free Church College, Aberdeen, and here he began that series of theological investigations which, characterized as they were by learned research and the use of the most scientific methods, were destined to make his name famous. He was the pupil and personal friend of many leaders of the higher criticism in Germany, and from the first he advocated views which, though now widely accepted, were then regarded with apprehension. This series included biblical subjects which he contributed to the 9th edition of the English edition of the Encyclopaedia Britannica, and he also produced the standard authorities of the Free Church.

In 1876 a committee of the General Assembly of that Church reported on them so adversely that Smith demanded a formal trial, in the course of which he defended himself with consummate ability and eloquence. The indictment dropped, but a vote of want of confidence was passed, and in 1881 Smith was removed from his chair. During this long struggle he was sustained by the conviction that he was fighting for freedom, and at the end of the trial he was probably the most popular, if not the most powerful, man in Scotland. Marks of esteem and regret were recorded on him from all sides.

In 1875 he was appointed one of the Old Testament revisers; in 1880–1882 he delivered by invitation, to very large audiences in Edinburgh and Glasgow, two courses of lectures on the criticism of the Old Testament, which he afterwards published (The Old Testament in the Jewish Church, first edition 1881, second edition 1883, and The Prophets of Israel, 1883, which also passed through two editions); and soon after his dismissal from his chair he joined Professor Baynes in the editorship of the Encyclopaedia Britannica, and after Professor Baynes's death remained in supreme editorial control till the work was completed. His versatility, firmness, and tact, as well as his contribution to the maintenance of its high standard. But he did not let his other duties interfere with his Semitic studies. He visited Arabia, Egypt, Syria, Palestine, Tunis and southern Spain, and had an intimate knowledge of, and personal acquaintance with, not only the literature, but the life of the East. His early friendship with J. F. McLennan, that most original student of primitive marriage, had a great influence on Smith's studies, and his attention was always strongly attracted to the comparative study of primitive customs and their meaning. His chief contributions to the ancient learning were his articles SACRIFICE in the Encyclopaedia Britannica, his Kinship and Marriage in Early Arabia (Cambridge, 1885), and above all his Lectures on the Religion of the Semites (1st edition 1889, 2nd edition 1894). His originality and grasp of mind enabled him to seize the essential among masses of detail, and he had in a marked degree the power of carrying a subject further than his predecessors.

In 1883 Robertson Smith was appointed Lord Almoner's Professor of Arabic at Cambridge, which henceforth became his home. He occupied rooms in Trinity College till 1885, when he was elected to a professorial fellowship at Christ's College. In 1886 he became university librarian, and in 1889 Adams Professor of Arabic. In 1888–1891 he delivered, as Burnett lecturer, three courses of lectures at Aberdeen on the primitive religion of the Semites. Early in 1890 grave symptoms of constitutional disease manifested themselves, and the last years of his life were full of suffering, which he bore with the utmost courage and patience. He never ceased to work, and when near his end was actively engaged in planning the Encyclopaedia Biblica, which he had hoped to edit. He died at Cambridge on the 31st of March 1894, and was buried at Keig. Small as he had been and never robust in health, Robertson Smith was yet a man of ceaseless and fiery energy; of an intellect extraordinarily alert and quick, and as sagacious in practical matters as it was keen and piercing in speculation; of an erudition astonishing both in its range and in its readiness; of a temper susceptible of the highest enthusiasm for worthy ends, and able to inspire others with its own ardour; endowed with the warmest affections, and with the kindest and most generous disposition, but impatient of stupidity and ready to blaze out at whatever savoured of turn to end injustice. The greatness of his nature combined with his brilliant conversational powers to render him the most delightful of friends and companions.

See also James Bryce, Studies in Contemporary Biography (1903).

(SIR W. S.)

SMITH, SIR WILLIAM SYDNEY (1764–1830), English admiral, was the second son of Captain John Smith of the Guards, and was born at Westminster on the 21st of July 1764. He entered the navy, according to his own account, "at the beginning of the American War," being only about eleven years of age. For his bravery under Rodney in the action near Cape St Vincent in January 1780, he was on the 29th of September appointed lieutenant of the "Alcide," 74. After serving in the actions against the French fought by Graves off Chesapeake in 1781 and by Rodney at the Leeward Islands in 1782, he was on the 6th of May of the latter year promoted to be commander of the "Fury" sloop, and on the 18th of October advanced to the rank of captain. His ship having been paid off in the beginning of 1784, he spent two years in France and afterwards visited Spain. From 1790 to 1792 he advised the king of Sweden in the war with Russia, receiving for his services the honour of knighthood. After his return he was sent on a mission to the Baltic, and having joined Lord Hood at Toulon from Smyrna in December 1793, he, though only on half pay, was actively employed in the attempt to burn the enemy's ships and arsenal. In the following year he was engaged in the Channel hunting French privateers; but, having the boats of his squadron boarded in Havre-de-Grâce harbour a lugger which was driven by the tide above the French forts, he was on the 10th of April 1796 compelled to surrender and send a prisoner to Paris. By means of forged orders for his removal to another prison he made his escape from the enemy's power, and landing in Holland, crossing the Channel in a small skiff picked up at Havre, arrived in London on the 8th of May 1798. In October he was appointed to the command of the "Tiger," 80, and was sent to the Mediterranean. By a very curious decision of the government he was joined in commission with his brother Spencer Smith, minister at Constantinople. Learning of Bonaparte's approach to St Jean d'Acre, he hastened to its relief, and on the 10th of March 1799 captured the enemy's flotilla, after which he successfully defended the town, compelling Napoleon on the 20th of May to raise the siege and retreat in disorder, leaving all his artillery behind. For this brilliant exploit he received the special thanks of the House of Parliament and the Order of 5th class for services.

On the 24th of January 1800 he took upon himself to make the convention of El Arish, by which the French were to have been allowed to evacuate Egypt. His action was disallowed by his superiors, who insisted that the French must surrender. Subsequently he co-operated with Abercomby, under whom he commanded the naval brigade at the battle of Aboukir, where he was wounded. On his return to England he was in 1802 elected M.P. for the city of Rochester. In March 1803 he was commissioned to watch the preparations of the French for an invasion of England. Having on the 9th of November 1803 been promoted to be rear-admiral of the blue, he was in the following January despatched on secret service for the protection of Sicily and Naples. His conduct was as usual brilliant, but, also as usual, his vanity and self-assertion led him into quarrels with the military officers. He relieved Gaeta and captured Capri, but
on the 25th of January 1807 received orders to proceed to Malta, where he joined Sir John Duckworth, who was sent to act against the Turkish squadron on the 7th of February, with the rear division of the squadron, he destroyed the Turkish fleet and spiked the batteries off Abidos. In November following he was sent to blockade the Tagus, and was mainly instrumental in embarking the Portuguese prince regent and royal family for Rio de Janeiro, after which he was sent as commander-in-chief to the coast of S. America in February 1808. At Rio he was entangled in another quarrel with the British minister, Lord Strangford, and was summarily recalled in 1809. On the 31st of July 1810, he was made vice-admiral of the blue, and on the 7th of July 1812 was in our fleet as rear-admiral, and went under Sir Edward Pellew (afterwards Viscount Exmouth) to the Mediterranean, but the expedition was uneventful. His term of active service practically closed in 1814. He was made K.C.B. in 1815 and in 1821 admiral. The later years of his life were spent at Paris, where he died on the 26th of May 1840. His restless self-assertion brought him into collision with many of his contemporaries, including Nelson and Sir John Moore. Colonel Bunbury's Narrative of some Passages in the Great War with France contains a most amusing account of his theatrical vanity. But though by nature a boaster he was both droll and ingenious.

See Barrow, Life of Admiral Sir W. S. W. Smith (2 vols., 1848).

SMITH, a worker in metals. The O, Eng. smid, Du. smid, Ger. Schmied, &c., are from an obsolete Teut. verb smiehten, to forge. The root is seen in Gr. σμίλα, a graver's tool. It is apparently not connected with "smooch," where an original m has been lost. There is no foundation for the old etymological guess which identifies "smith" with "to smile," as the one who smites or beats iron. When used without such qualification as in "goldsmith," "silversmith," &c., the term means a worker in iron, especially as indicating a "blacksmith," one who forges iron, as opposed to "whitesmith," the finisher and polisher of iron, or "tinsmith," a worker in tin. The word has originated one of the commonest joking-words (sometimes taking various archaic forms, Smyth, Smythe, Smith, &c.; also German Schmid).

SMITH COLLEGE, an American institution for the higher education of women, at Northampton, Massachusetts. It was founded by the will of Sophia Smith (1796-1870) of Hatfield, who gave money to Smith Academy in Northampton and to Andover Theological Seminary, and who left about $365,000 "for the establishment and maintenance of an institution for the higher education of young women, with the design to furnish them means and facilities for education, to afford them instruction and to teach them to be good women"; she chose Northampton as the site of the college and selected the trustees. The college was chartered in 1871 and was opened in 1875.

On the college campus in the central part of Northampton are: College Hall, with administrative offices, an assembly hall, and lecture rooms; Seelye Hall, with department offices and recreation rooms; a library, completed in 1910 and containing 30,000 volumes in that year; an auditorium, with a large organ and a seating capacity of 2500; the Lilly Hall of Science; Chemistry Hall; an astronomical observatory; Music Hall; the Hillyer Art Gallery, with an endowment of $50,000 for the increase of its collections; the Students' Building for the social life of the students; the Lyman Plant House and the Botanic Garden; the Alumniae Gymnasium; the Allen Research Building, which contains the American Museum for the students; the on private homes, in dormitories; an infirmary; and Sunnyside, a home for convalescents. Entrance requirements differ little from those of the College Entrance Examination Board. All undergraduate courses are largely elective and lead to the degree of Bachelor of Arts. Graduate courses lead to the degrees of Master of Arts and Doctor of Philosophy, the latter degree being rarely conferred and "only in recognition of high scholarly attainment and Doctor of Philosophy need be held in order to carry on original research." In 1900-1901 there were 104 teachers and 1653 students (of whom 8 were graduate students), and the college had an endowment of about $1,300,000. The annual tuition charge was $100 until 1900, when it was raised to $200. There are six fellowships, of $500 each, which are granted for graduate research; and there are many undergraduate scholarships and loans are made to needy students by the Smith Students' Aid Society (1858). Contributions to the American Classical School, Athens and Rome, to the Zoological Station at Naples, and to the Marine Biological Laboratory at Woods Hole, Massachusetts.

first president of the college from 1873 to September 1910 was Lawrence Clark Seelye (b. 1837), a graduate of Union College and of Andover Theological Seminary.

SMITH'S FALLS, a town and outport of Lanark county, Ontario, Canada, on the Rideau river and canal, and the Canadian Pacific railway, 28 m. N.W. of Brockville. Pop. (1951) 1,155. It contains sawmills, planing mills, and lumber, and agricultural implement works, and has regular steamer connexion with Kingston and Ottawa by the Rideau river and canal.

SMITHSON, HENRIETTA CONSTANCE (1800-1854), Irish actress, was the daughter of a theatrical manager. She made her first stage appearance in 1815 at the Crow Street theatre, Dublin, as Albina Mandeville in Reynolds's Will. Three years later she made her first London appearance at Drury Lane as Letitia Hardy. She had no particular success in England, but in Paris, in 1828 and 1835, whither she first went with Macready, she was now rarely immured. In 1838 she accompanied her cousin, Desdemona, to Vienna, Juliet and Jane Shore. She had a host of admirers, among them Hector Berlioz (p.e.), whom she married in 1833. They separated in 1840. At the time of her marriage her popularity was already over and she was deeply in debt. A benefit was given her, but she had the mortification of seeing a rival applauded when she herself was coldly received. She retired from the stage, and died on the 3rd of March 1854.

SMITHSON, JAMES (1765-1829), British chemist and mineralogist and founder of the Smithsonian Institution at Washington, a natural son of Hugh Smithson, 2nd Duke of Northumberland, by Dorothy, daughter of Sir Henry Scrope Smythe, 1st Viscount Scrope of Masham, and grandson of Sir George Hungerford of Studley, who was born in France in 1765. He was educated at Pembroke College, Oxford, where he graduated in 1786, and was known in early life as James Lewis (or Louis) Macie. He took the name of James Smithson about the year 1800. His attention was given to chemistry and mineralogy, and he published analyses of calamines and other papers in the Annals of Philosophy and Phil. Trans. The mineral name "smithsonite" was originally given in his honour by Beudant to zinc carbonate, but having also been applied to the carbonate, the name is now rarely used. In 1784 he accompanied his cousin, Francis de la Peinture, to the Western Isles, and in the English translation of the Travels in England, Scotland and the Hebrides (1790) Smithson is spoken of as "M. de Mecies of London." He was elected F.R.S. in 1787. He died at Genoa on the 27th of June 1820. By his will he bequeathed upwards of £100,000 to the United States of America to found the Smithsonian Institution. The institution (see below) was founded by act of Congress on the 10th of August 1846.

SMITHSONIAN INSTITUTION, an American institution of learning in Washington, D.C., founded by the bequest of James Smithson (q.e.), who seems to have known of Joel Barlow's plan for a national institution of learning in the city of Washington in accordance with George Washington's recommendation in his farewell address of 1796. His estate was left to a nephew, Henry James Hungerford, with the stipulation that should Hungerford die without issue the whole estate should go to the United States of America to found a national university under the name of the Smithsonian Institution, an establishment for the increase and diffusion of knowledge among men." Hungerford died without issue in 1835. There was much opposition in America to the acceptance of Smithson's bequest, especially by John C. Calhoun and others who held that Congress had no power under the Constitution to accept such a gift, but the Senate eventually accepted, largely through the efforts of John Quincy Adams; and Richard Rush, sent to England as agent for the United States, quickly obtained a verdict for the American claim to the estate. In September 1838 £104,600 in gold sovereigns was delivered from the clipper 'Mediator' to the Philadelphia mint, where it was recoined into American money, $508,318.46; in 1867, after the death of Hungerford's mother, a residuary legacy of $26,210 was received and the fund then
amounted to $650,000. An act of the 7th of July 1838 (repealed in 1841) directed the investment of the money in state bonds, and $550,000 was invested in Arkansas bonds which proved worthless, but Congress, considering that it was a trust fund of the government, made an appropriation to cover the loss. By other gifts, notably that of $216,000 from Thomas George Hodgkins (d. 1802) of Setauket, Long Island, New York, the fund was increased; in 1910 it amounted to $944,918, drawing interest at 6%.

There were many different suggestions as to how the fund should be used. The character of the National Institute (called National Institution before 1843), which was organized in 1840 "to promote science and the useful arts and to establish a national museum of history," had a great influence in shaping the act (approved on the 10th of August 1846) establishing the Smithsonian Institution and providing for an "establishment," by this name composed of the president, vice-president, secretaries of state, treasury, war and navy, the postmaster-general, the attorney-general, the chief-justice of the supreme court and the commissioner of the patent office of the United States, the mayor of the city of Washington (amended in 1871 to read: governor of the District of Columbia), and such other persons as they may elect honorary members. The same act provided for the government of the Institution by a Board of Regents composed of the vice-president of the United States, the mayor of the city of Washington (constituted in 1846), three members of the Senate (appointed by its president), three members of the House of Representatives (appointed by its speaker), two members of the National Institute of the City of Washington (chosen by joint resolution of the Senate and House of Representatives), and four others, inhabitants of four different states; the Board chose from its members a chancellor (in practice the vice-president of the United States until 1850 and since then the chief-justice). The act provided for the delivery to the Board of Regents and the maintenance in the buildings, which were to be erected and belonging to the "establishment," of a "great collection of curious and all objects of natural history," &c., belonging to the United States, including the collections of Smithsonian; and that any applicant for copyright should deliver one copy of the work to be copyrighted to the librarian of the Smithsonian Institution and another to the Librarian of Congress. Thanks to the efforts of J. Q. Adams, provision was made for the use of the income of the fund only and the principal was permanently invested.

The Regents met on the 7th of September 1846. Those appointed were: General Evans, Sidney Breese and Isaac S. Pettibey, senators; Robert Dale Owen, William J. Hough and Henry W. Hilliard, members of the House of Representatives; Rufus Choate, Gideon Hawley, Richard Rush and William C. Preston, by joint resolution, from four different states; and Alexander Dallas Bache and General Joseph G. Totten, from the National Institute. They elected (Dec. 1846) as first secretary and director of the Institution, Joseph Henry, then professor of natural philosophy in the College of New Jersey (Princeton University), who presented in his first annual report (Dec. 1847) a "program of organization." The first act of the Institution was "To Improve Knowledge." It is proposed (1) to stimulate men of talent to make original researches, by offering suitable rewards for memoirs containing new truths; and (2) to appropriate annually a portion of the income for particular researches, under the direction of suitable persons. To Diffuse Knowledge: It is proposed (1) to publish a series of periodical reports on the progress of different branches of knowledge; and (2) to publish occasionally special treatises on the subject.

Henry was executive head (secretary) of the Institution from 1846 until his death in 1878 and its organization is due largely to him. He opposed the scheme for the gradual formation of a general library under the charge of the Institution, and in 1855 committed the Board of Regents to the idea that it would be preferable to devote the whole of the annual income on the museum and library, and this action was approved by an investigating congressional committee. But he was not only the promotor of the enterprise, but in 1846 when Henry was at the Albany Academy, and partly through the influence of James Pollard Esq. (1785-1860), in 1846 a plan was presented for the unification and systematization of weather observation under the auspices of the President of the Institution (then President John Tyler), yet in 1865 the establishment of such meteorological research; in 1849 telegraphic transmission of meteorological intelligence collected by the Institution was begun; in 1845 a standard Smithsonian barometer (Arnold Guyot's improvement of Ernst's improved Fortin "cister barometer") was first distributed; weather maps were successfully made in 1856; and in 1870 the meteorological work of the Institution was incorporated as a National Gallery and turned this collection over to the National Institute. After 1854 Henry's annual reports contained a "general appendix" with reports of lectures, such as were held under the auspices of the Institution until 1865, summaries of correspondence, special papers, &c., of 1870 mentioned that they were devoted to the scheme that there was more North American archaeology and ethnology.

Spencer F. Baird, Henry's successor, incorporated in the general appendix annual reports on the progress of the sciences, and he published Henry's annual reports under the auspices of the Institution, through agents in the principal cities of Europe, exchanges its own publications, those of other departments of the United States government, and those of all branches of natural and foreign publications. Baird had been at the head of the United States National Museum, a branch of the Institution, before he became secretary of the Institution, and it was particularly during his administration that a map was hung up around the collections of the United States Patent Office, which were turned over to it in 1858, and those of the National Institute, transferred to the Smithsonian Institution in 1861, when the office was dissolved. A part of the collections included in the annual report of 1853. The small art collection which remained was exhibited in the Corcoran Gallery until 1896. A new building for the Museum was found by J. E. Johnston (1833-1902) as the first art collection to a national gallery of art, when such a gallery should be established, and in 1906 the Supreme Court of the District of Columbia decreed that the art collection of the National Museum was held as a "National Gallery" and turned this collection over to the National Museum, whose art collections have been called since that time the National Gallery of Art and have been enlarged by the gift from Charles L. Freer of Detroit of more than 2300 pieces (since 1945), including the world's finest collection of art in the United States, and T. W. Dewing, of Japanese and Chinese masters, and by the gift of about 90 American paintings from W. T. Evans of New York City. The museum gained much valuable archaeological and ethnological material from the United States, from the United States, and from the American government; it has a good herbarium. The Bureau of American Ethnology was established as a branch of the Institution in 1879, when the various organizations doing survey work in the West united as the United States Geological Survey and anthropological and ethnological research was transferred to the Smithsonian Institution. The director of the Bureau of Ethnology in 1879-1902 was W. J. Powell; he was succeeded by William H. Holmes.

Secretary Baird planned an astronomical observatory and in 1887 appointed as assistant secretary of the Institution, to take charge of the observatory, Samuel P. Langley (q.v.), who succeeded as secretary of the Smithsonian Institution in 1890. The observatory was founded in 1847, when a bequest was made for astronomical work and $5000 was contributed by the executors of Dr. J. H. Kidder (1842-1889). Langley's principal work was the observation of the meteoric showers for the meteoric shower section of the spectrum. His name is also closely connected with his paper entitled Experiments in Aerodynamics (1891), and with the experiments and mathematical studies carried on under the Institution, which proved that the motor could be made which would produce enough mechanical power to support itself and fly. Under the terms of the Hodkinson bequest prizes were awarded to scientists who made important contributions.

Congress was long jealous of the power of the Board of Regents; and in 1897 he presided at the meeting of the Institution on the part of Andrew Johnson, to the very existence of the Institution.

In January 1900, after Langley's death, Charles Doolittle Walcott (b. 1850), a geologist, director of the U.S. Geological Survey in 1893-1904, became secretary of the Institution.
offered in 1893 for research and investigation of atmospheric air in connexion with the welfare of mankind; in 1895 an award of $5,000 was made to Lord Rayleigh and Sir W. H. Roscoe for the discovery of neon, and one was made to Sir James Dewar in 1899 and one to Sir J. J. Thomson in 1901. During Langley's administration the American Historical Association was incorporated in 1880, and the Institution was also directed to publish its annual reports; and the National Society of the Daughters of the American Revolution was similarly incorporated in 1896. By acts of Congress the 2nd of March 1889 and the 30th of April 1890 the National Museum was established under the Institution, and in a park of 266 acres in the valley of Rock Creek a small collection was installed. In Langley's Annual Reports the summaries of the advance of science were omitted in 1889 and thereafter, and paper reports were published in their place. The Smithsonian Park occupies a square equivalent to nine city blocks, almost exactly the same size as the Capitol grounds. The Smithsonian Institution was chartered by an act of Congress, March 3, 1841; it is Seneca brown stone in a mingled Gothic and Romanesque style, designed by James Renwick, and occupies the S.W. corner of the grounds. E. of it is the building of the United States National Museum (30 ft. sq.), erected in 1881; and on the N. side of the park is the new building of the National Museum (1903). On the grounds is a bronze statue of Joseph Henry by W. W. Story.

The Institution publishes: Annual Reports (1846 seq.), in which the Reports of the National Museum were included until 1886—since then they appeared as "part ii." of that Report; The Smithsonian Contributions to Knowledge (quarto, 1848 seq.); The Smithsonian Miscellaneous Collections (Papers and Reports: 1871-1897); The United States National Museum (1878 seq.); Bulletin of the United States National Museum (1875 seq.), containing larger monographs than those printed in the Proceedings; and occasional Special Bulletins and Miscellaneous Collections. The American Historical Association (1850 seq.); Bulletin (1857 seq.), including The Handbook of American Indians North of Mexico (1907), part 1, being Bulletin 30; and Contributions to North American Ethnology (1877 seq.); Annuals of the Astrophysical Observatory (1895 seq.); and Annual Reports of the American Historical Association (1890 seq.).

SMOHALLA, or SMISCOULA (i.e. 'preacher'), chief of the Wanapum tribe of North American Indians and founder of the religious sect called Dreamers, was born about 1820. On one occasion after a tribal fray he was left for dead, but recovered and journeyed through California, Mexico, Arizona and Nevada to his old home on the upper Columbia, Washington, where he announced that he had been in the spirit world and had returned with a new revelation. This consisted in a return to primitive Indian customs, and a priesthood and ritual based on the Roman Catholic type. Besides Sunday services the Dreamers hold a service for the commemoration of the dead in early spring, and thanksgivings for salmon and for berries in April and in October respectively. Smohalla had frequent trances and his influence extended over most of the tribes of eastern Washington, and Oregon and western Idaho. The sect gave some trouble in 1870 by refusing to come under reservation restrictions. A church was established at Priest's Rapids on the upper Columbia, and one at Union Gap on the Yakima reservation.

SMOKE (from O. Eng. smōcan, to smoke, smoke, cf. Dutch suipen, Latin spargere, to scatter). The vapour or other matter which escapes from a burning substance during combustion, especially the visible vapour produced by the burning of coal, wood, peat or vegetable substances generally.

This article the various legislative and other measures recommended or adopted for the abating of the nuisance caused by the excessive production of smoke are dealt with. For smoking of tobacco see TOBACCO and PIPE, and for opium-smoking OPiUM.

Smoke Abatement.—The nuisance created by coal smoke seems to have been recognized in London since 1536, when a city ordinance required the use of "smoke holes" in the city of London; but it is only in more modern times that the question has been regarded as one of real practical importance. In 1785 the first smoke-abating invention was patented by James Watt, and in 1800 a mechanical stoker was patented by Robertson. In 1815 Cutler patented the first wood-steam grate for domestic purposes; and his principle of feeding underneath was afterwards adopted by Dr Neil Arnott. In 1819 a parliamentary select committee was appointed "to inquire how far persons using steam-engines and furnaces could erect them in a manner less prejudicial to public comfort than hitherto." In 1843 another select committee recommended the introduction of a bill prohibiting the production of smoke from furnaces and steam-engines. In 1845 yet another select committee reported that such an act could not in the existing state of affairs be made to apply to dwellings.

The Acts of 1843 and 1847 followed as the results of these inquiries; and since then there has been much legislation brought to bear on factories and railways.

The Public Health Act 1875 contains the statutory law as to the emission of smoke and applies throughout the country, except to London and a few large provincial towns such as Manchester, Liverpool, Leeds, Bradford and Nottingham, where local nuisances are controlled by special local acts. The law applying to the Metropolis is identical with that which governs the country at large, and is contained in the Public Health (London) Act 1891. Changes as regards special sub-sec. 8, 1890, of the Act contain the following provisions:

"Any fireplace or furnace which does not, as far as practicable, consume the smoke arising from the combustible used therein, and whenever the smoke is not consumed for winter heating, for any in mill, factory, dyehouse, brewery, bakehouse or gasworks, or in any trade process whatsoever"; and sub-sec. 8, "any chimney not being the chimney of a private dwelling-house" sending forth black smoke in such quantity as to be a nuisance, shall be deemed to be a nuisance liable to be dealt with summarily in manner provided by this Act."

A further clause provides that for the purposes of sub-sec. 7 the offence is not merely the emission of smoke, but the use of a fireplace or furnace which does not as far as practicable consume the smoke," and this enables a technical defence to be raised which in practice has been found to destroy the efficacy of sub-sec. 7. Under sub-sec. 8, with the more precise description of black smoke in such quantity as to be a nuisance or offence, unless it be emitted from the chimney of a private dwelling-house. This sub-section is therefore always resorted to by sanitary authorities who initiate prosecutions for smoke nuisances. It has been decided that where black smoke issued from a chimney several times a day for varying periods the magistrate was justified in finding that the smoke issued in such quantity as to be a nuisance, although it was not shown that it caused any "nuisance per se," but that it was sufficient to be injurious to health in order to be a nuisance. (Gaskell v. Cashmore, 30 L.T.N.S., 316.) It therefore follows that the mere issue of black smoke from a factory chimney is per se a nuisance. From a practical point of view, however, it is often founddifficult to identify exactly the source of the smoke, and it has been held by the courts that it is not necessary to establish the presence of the observer, and the light behind or in front of the smoke. To aid inspectors various smoke charts and instruments have been devised, none of which is wholly satisfactory. The best that can be obtained is a single beam of light, and a rule marking black lines at right angles on a white background. It has six shades, numbered 0-5, obtained by gradating the thickness of the lines.

The difficulty of accurately defining the colour of smoke has led to a movement, initiated by the London County Council, for securing the deletion of the word "black" from the Public Health Act, so as to leave to magistrates the duty of deciding a question of fact—whether the smoke complained of constituted a nuisance. The Nottingham Improvement Act 1874 (sec. 74) contains the most efficacious provisions in regard to smoke nuisances which are to be met with in England. It enables steps to be taken in cases where the engines or furnaces are not suitable, and if they are properly constructed, may be allowed to remain, providing they are of such a style, etc., that when used, it enables the fireman or other responsible employee to be fined.

Although steam-engines and factories consume individually much more coal than dwellings-houses, they alone are not responsible for the smoke nuisance, for there is little doubt that domestic fires are mainly responsible for the smoky condition of the atmosphere of our towns, for they continue to evolve smoke unchecked by legislation. In 1881, however, a movement was begun by the National Health Society and the Kyrele Society, which resulted in a smoke abatement exhibition being held at...
South Kensington. At the close of the exhibition a national smoke abatement institution, with offices in London, was formed. In the United Kingdom the subject takes an important place in the programme of the Royal Sanitary Institute, whilst the Coal Smoke Abatement Society is devoted to improving the prevailing conditions, especially in the Metropolis, and has organized a number of exhibitions and conferences on the subject. Several smoke abatement committees exist in the provinces.

A knowledge of the nature of coal and of its combustion is essential for an understanding of the smoke problem. For the purposes of this article, coals may be classified as smoking and smoky, and smokeless, the former including all those varieties most commonly used as fuel. The elementary constituents of such coals are carbon (generally about 80%), hydrogen, nitrogen, and oxygen, and they contain a varying quantity of earthy impurity or ash. The process which occurs in a coal fire consists of two distinct operations. The first, which requires a comparatively low temperature and is independent of the presence of air, is one of destructive distillation, similar to that which occurs in the retorts of gasworks. In its result the decomposition of the coal, and the formation of the following substances:—(1) hydrogen, marsh-gas, carbon monoxide, ethylene, benzene, other hydrocarbons of the paraffin and benzenoid series, water—all of which are either gaseous at the temperature at which they are formed or capable of being converted into gas at somewhat higher temperatures, and all are combustible, as is the carbon, (2) and other nitrogenous compounds and certain compounds of sulphur, which are also volatile and combustible; (3) coke, which consists of carbon (and ash) and is non-volatile; (4) water vapour, and (5) a portion of the ash; (6) a black incrustation on the coal itself, that burn, in the strict sense of the word; and this second process requires the presence of air and also a much higher temperature than the first. If the combustion is perfect, the only products are carbon dioxide, carbon dioxide, (3) nitrogen and (4) sulphur dioxide, the first of which contains all the hydrogen originally present in the coal, the second all the carbon, the fourth all the sulphur, while the nitrogen is liberated as such together with very much larger volumes of nitrogen derived from the air which has supplied the necessary oxygen. These products are discharged through the chimney.

(5) Dust, necessary for ensuring such complete combustion viz., an adequate, but not too large, supply of air, properly administered, and the maintenance of the requisite temperature. In practice, however, these conditions are never perfectly fulfilled, and consequently the combustion of coal is always more or less imperfect and gives rise to a complex mixture of vapours. This mixture contains not only the combustion products already mentioned, but also the following unburnt or partly burnt distillation products:—(5a) unburnt carbon, (6a) carbon monoxide, (6b) unburnt carbon in a very finely divided state, and also considerable volumes of unused air.

Usually the name “smoke” is applied to this vaporous mixture discharged from a chimney only when it contains a sufficient amount of finely divided carbon to render it dark-coloured and distinctly visible. The quantity, however, of this particular ingredient is apt to be overrated. It always bears an extremely small proportion to the vast volumes of water-vapour, carbon dioxide and nitrogen with which it is mixed; it probably never amounts, even in the worst cases, to 3% of the weight of the coal from which it is formed; and its importance, reckoned in terms of so much fuel wasted, is certainly not greater than that of the unburnt hydrogen and hydrocarbons. It is perhaps best to use the name “smoke” for all the products of imperfect combustion (5 to 8) which are avoidable, as contrasted with the necessary and unavoidable ingredients (1 to 4). The problem of smoke abatement is thus seen to resolve itself into the problem of the production of perfect combustion.

The solution of this problem would lead to an important saving in fuel. It has been calculated that at least twice as much coal is used in boiler fires and six times as much in domestic fires as is theoretically required for the production of the effects obtained. A considerable portion of this loss is certainly unavoidable; nevertheless, much of this enormous waste could be prevented by improved methods of combustion, and the other advantage is the gain in cleanliness and public convenience; not only would there be an end to sooty chimneys, but the atmosphere of towns would no longer be polluted by unburnt carbon, whose total quantity is enormous, though the amount contained in a given puff of smoke is very small. The “London” or “sea-soup” fog would be avoided, not because fogs would become any less frequent than now in London and other large cities, but because they would lose their distinctive grizzly quality.

An investigation of London fogs was made in 1901–1903 by the Meteorological Council with the assistance of the London County Council, from which it appeared that 20% of fogs were entirely due to smoke, and that in every case the density and duration of fogs was enormously added to by smoke.

It is often stated that these fogs are caused by the smoke that blackens them; but this is an error. The combustion of coal is certainly responsible for their existence, but it is the sulphur of the coal, oxidized ultimately to sulphuric acid, that is the active agent. So long as coal is burnt at all this manufacture of sulphuric acid and of fogs must continue; it is not to be got rid of by improving the oxygen and the temperature of the fire, but the fumes may be materially improved. The evil effects of town air on plant life and human lungs, also attributed to preventible smoke, are in like manner due to this non-preventible sulphuric acid.

Sixteen million tons of coal are annually used in London for lighting purposes, and it has been shown by Dr. Riddle that, as the sulphur content of this coal ranges from 1 to 2%, there is diffused in the air of the metropolis from half a million to a million tons of sulphuric acid every year. The extent to which smoke and fog affect life and injure property is, perhaps, a matter of opinion. It has, however, been proved that the death-rate enormously expands in foggy weather, and that the fog will burn the metropolitan programme, showing the extra cost which the smoke nuisance annually imposes on London. The figure at which he has arrived is £5,470,000, including damage to buildings, fabrics and works of art.

The consumption of coal in the United Kingdom was calculated by the Royal Commission on coal supplies to amount to 160,000,000 tons, of which 36,000,000 or 19·2% are consumed for domestic purposes, and 53,000,000 tons are used in ordinary factories. The amount of unburnt coal is therefore equal to at least 56,000,000 tons, being equal to about one-fifth of the total annual consumption. It is sought so as to be able to supply the appliances for the burning of bituminous coal, and those that propose to abolish its use and substitute for it some other kind of fuel. The proposals of the first class may be divided into those based on the substitution of coke as a fuel, and those that propose to abolish boiler fires and other large-scale operations. Those of the second class may be divided according to the nature of the fuel which they suggest. The innumerable inventions of the first class depend for their success (so far as they are successful) on the attention bestowed on the scientific requisites for complete combustion, viz., sufficient but not too great supply of air, the thorough admixture of this air with the products of the destructive distillation of the coal, and the maintenance of a high temperature within the fire.

In the old and crude methods the facts which most militate against the attainment of this desiderata are:—(1) that large masses of fresh air are blown out, whose oxygen is useless, and whose heat to the highest temperature is required; (2) that the products of the distillation of this fresh air, heated from below, do not get properly mixed with air till they have been drawn up the chimney; (3) that the unburnt volatile products are not getting up through the fire, cooling it and carrying its heat away from where it is wanted, and yet without remedying the second evil. In the improved methods regularity and balance of both are sought. A steady supply of distillation products, a steady temperature, and a steady and complete combustion. In many cases it is sought to warm fresh air before it enters the room by a regenerative system, the heat being taken from the escaping gases which would otherwise carry it up the chimney; and in some cases the air which feeds the fire is heated in the same way.

Tests applied at the South Kensington Examination of 1882 and in recent years by the Coal Smoke Abatement Society acting in conjunction with the Office of Works, for domestic grates and stoves, have included a chemical examination of the chimney gases, observations of the “smoke” and “fogs,” the temperature of the bottom and other grates, and of the smoke from the chimney and the amount of coal used. Measurements have been taken at ordinary bottom grids and upward draught; (2) open grates having solid floors (adapted for “slow combustion”) and upward draught; (3) open grates left from below, supplemeted by present feeding from the back or from the sides or from hoppers; (5) open grates having downward or backward or lateral draught; (6) close stoves. Each of these classes of stoves and grates has been subjected to varying degrees of “non-air-heating,” i.e., according as an attempt is or is not made to save heat on the regenerative principle. The following conclusions, among others, have been arrived at:—(a) the air-heating principle is excellently applied in small stoves (class 6) superior to open grates (total average of classes 1-5).
they are greatly inferior in radiating power; (c) the "slow-combustion" principle gives a high radiation factor, with a lower concentration of other gases. The Alfreti and air-heating grates with downward, backward, or lateral draughts and with a large surface of fire-brick for radiating heat is, on the whole, most efficient (see HEATING).

The use of locomotives and for fixed appliances, the desiderata are essentially the same as in the case of domestic fires; the principles involved are consequently also the same, though the appliances are necessarily different. These improvements may be all considered as of two kinds: (1) according as the mode of supplying the fuel or the mode of supplying the air is the subject of the improvement. These two kinds of improvement may of course be combined.

In the old forms of furnace fresh fuel, as it is wanted, is supplied by hand labour, the furnace doors being opened and large quantities of coal thrown in. One result of this is the ingress of great volumes of cold air from the buildings. It may be expected that by keeping a low temperature in the furnace, mechanical stokers meet this difficulty by supplying the coal regularly in small quantities at a time. They may be divided into "cutting" stokers, which deliver the coal at the front and gradually push it backward; "sprinkling" stokers, which scatter it generally over the surface of the grate; and "undercutting" stokers, which raise it from below so that the products of its distillation pass through the already incandescent fuel. The mechanism by which these results are attained is often of a complex nature. It is generally recognized that air cannot be efficiently supplied to the furnace if admitted only in front, and accordingly many plans have been devised for supplying air continually back again. In some cases currents of air are induced by steam-jets; but this plan has not always proved successful. The inventions on the regenerative principle are more generally satisfactory. In them the air, before entering the furnace, is made to circulate through chambers heated externally by the products of combustion, and, having thus acquired a high temperature and absorbed heat that would otherwise have been wasted, is blown upon the grate. Heating and ventilation of the applications are almost absolutely smokeless, and they are much in use, as they have been shown to effect great economy in coal consumption.

It must not be forgotten, however, that with the use of trained stokers a high degree of boiler efficiency is reached by hand-lit stokers alone. Indeed, it has been proved by actual tests that, when pitted against untrained men, skilled stokers have raised the thermal efficiency of their plant by over 16%, without creating smoke nuisance. Skilled stokers are under careful state supervision, and similar work has been started at the Borough Polytechnic Institute by the London County Council.

The advocates of the total or partial disuse of smoke-producing coals are variously in favour of anthracite, coke, electric power, liquid fuel or gas.

In some factories, such as oiling works, anthracite and other coals containing much volatile matter are used. The coals are used in large quantities, both for its own sake and as a by-product in the manufacture of gas for lighting purposes, and is largely used in various kinds of furnaces. It gives no smoke; but it resembles anthracite also in being but ill adapted for use in open grates on account of the difficulty of ignition and the absence of flame. Liquid fuel or natural gasoline, which has come into exceptional prominence during recent years as a heating agent, owes its success to its relatively smokeless combustion and high efficiency. The same applies to gaseous fuel, which includes in addition to ordinary coal gas other mixtures of gases which.

SMOLENSK burn with a high heating value and with no deleterious vapours or smoke (see FUEL, Liquid and Gaseous). Electricity is now also being largely utilized in factories for power purposes, and is thus bearing its share in solving the problem of smoke abatement.

See Official Report of the Smoke Abatement Committee (London, 1882); W. C. Popplewell, The Prevention of Smoke (1901); W. Nicholls, Smoke Abatement (1903); and the London Coal Smoke Abatement Society: Booth and Kershaw, Smoke Prevention and Fuel Economy (1904); Reports of the Laws on Foreign Countries in regard to Emission of Smoke from Chimneys (Foreign Office Returns, Cdl. 2347, 1905); London Fog Inquiry (1901–1902) (Reports to and by the Meteorological Council).

SMOLENSK, a government of middle Russia, belonging partly to Great Russia and partly to White Russia, bounded by the seaways of the Don, Shina, Vyazma, Obzha, Kasplya, and Tver on the N. It covers an area of 21,632 sq. m. in the W. of the great central plateau, its N. districts extending towards the hilly region of the Valdai. The rivers being deeply cut in the plateau, the surface is also hilly in the W. districts (Smolensk, Dorogobuzh), whence it slopes away gently towards vast plains on the E. and S. Carboniferous limestones, containing a few deposits of coal (in Yukhnov) and quarried for building purposes, occupy the E. of Smolensk; chalk appears in the S. extremity; while sandy terraces, marls and ferruginous clays cover all the W. of the whole. The rivers, over which is spread a thick sheet of boulder clay, with irregular extensions to the N., possess little fertility of soil; many other wide surfaces; and peat-bogs fill the marshy depressions. The soil, mostly clay, is generally unfertile, and stony and sandy in several districts. The rivers Vazuza and Ghat, both flowing into the Volga, and the Moskva and the Ugra, tributaries of the Oka, are channels for floating timber. The two tributaries of the Dvina—the Kasplya and the Meza—are of much more importance, as they and their affluents carry considerable numbers of boats to Riga. The Dnieper takes its origin in Smolensk and drains it for more than 300 m.; but neither this river nor its tributaries (the Don, V. V. Dvina), whose upper courses belong to Smolensk, are navigable; timber only is floated down some of them. Many small lakes and extensive marshes occur in the N.W. More than one-third of the area is under forests. The climate is like that of middle Russia generally, although the moderating influence of the damp climate of W. Europe is felt to some extent. The average yearly temperature at the city of Smolensk is 45° Fahr. (January, 13°; July, 67°2').

The estimated population in 1906 was 1,762,400. It is chiefly composed of White Russians (55%) in the W., and Great Russians (20%) in the Gostiny (20%) belt, the lower part of which belongs to the Orthodox Greek Church (see Orthodox church). The government is divided into twelve districts, the chief towns of which are Smolensk, Byelyi, Dorogobuzh, Dukhovshina, Elnya, Ghat, Kasplya, Pertseh, Roslavli, Sychevka, Vyzama and Yukhnov.

Notwithstanding the unproductive soil and the frequent failures of crops (especially in the N.W.), the chief occupation is agriculture. Out of the total area 38% is held by the village communities, 42% by private persons and 2% by the crown; 7% is uncultivable. Nearly 30% of the surface is arable land, and over 20% is under meadows. The principal crops are rye, wheat, oats, barley, buckwheat and potatoes. Grain has to be imported. Improved agricultural implements are beginning to be manufactured within the government, and to be used by the landlords, and partly also by the peasants. Flax and hemp, the important crops, and some tobacco is grown. The live stock of the peasantry suffer from a want of meadow and pasture land, which is chiefly in private ownership. The peasantry are mostly very poor, in consequence not only of the condition in which they are kept by the landlords, but of the insufficient allotments and want of meadows. In the way of mining phosphate only is extracted. The most important industries are cotton, oil and paper mills, distilleries and breweries. The timber trade and lumber-building are important, although not more than one-half of the male population of west Smolensk leave their homes every year in search of work. Practically all navies throughout the navy have been built on the Strug river in the vicinity of Kasplya, the Obzha and the Ugra, corn, hemp, hempseed, linseed and especially timber being shipped. A considerable quantity of corn is imported into the W. districts.
SMOLESK—SMOLLETT

SMOLESK, a town of Russia, capital of the government of the same name, on both banks of the Dnieper, at the junction of the railways from Moscow to Warsaw and from Riga to Orel, 252 m. by rail W.S.W. of Moscow. Pop. (1900) 57,405. The town, with the ruins of its old kreml, or citadel, is built on high crags on the left bank of the Dnieper. Its walls, built during the reign of Boris Godunov (1598–1605), are rapidly falling into decay. But the city has much improved of late years. It has monuments in commemoration of the war of 1812 and of the Russian musical composer, M. I. Glinka (1826–1857). It has three public libraries, an historical and archaeological museum, a people’s palace, and several scientific societies. The cathedral was erected in 1676–1727, and is considered as the best example of a more primitive building (dating from 1101), which was blown up in 1611 by the defenders of the city during a siege by the Poles. The picture of the Virgin brought to Russia in 1046, and attributed to St Luke, which is kept in this cathedral, is much venerated throughout central Russia. Two other churches, built in the 11th century, have been spoiled by recent additions. Smolensk is neither a commercial nor a manufacturing centre.

Smolensk is one of the oldest towns of Russia, and is mentioned in Nestor’s Chronica as the chief town of the Slav tribe of the Kricwitsch, situated on the great commercial route from the Volga to the Greek frontier. It maintained a lively traffic with Constantinople down to the 11th century, when the principality of Smolensk included Vitebsk, Moscow, Kaluga and parts of the present government of Pskov. The princes of Kiev were often recognized as military chiefs by the yevches (council) of Smolensk, who mostly preferred Mstislav and his descendants and Rostislav, son of Mstislav, became the ancestor of a series of nearly independent princes of Smolensk. From the 14th century these fell under the influence of the Lithuanian rulers, and in 1408 Smolensk was annexed to Lithuania. In 1440 the Moscow princes recovered the Smolensk lands, but in 1458, after the expedition of Peter the Great against his wars with Sweden. In 1582 it was well fortified; but the French, after a two days’ battle, defeated the Russians here, and took the city, when it suffered much damage.

SMOLESKIN, Perez [Perek] (1842–1885) was born near Mogilev (Russia) in 1842; he died at Meran (Austria) in 1885. His story is the Odyssey of an erring son of the Ghetto. He joined and left the opposite parties of the rationalists and the mystics, and followed a variety of precarious occupations. He settled in Odessa, where he familiarized himself with several European languages, and became an anti-nomian in religion, though he never left the Jewish fold. He became the rallying-point for the revolt of young Jewry against medievalism, the leader, too, in a new movement towards Jewish nationalism. This burst upon Smolenskin; nevertheless this important city, with nearly 100,000 inhabitants, was a constant source of contention between Moscow and Lithuania. In 1514 it fell under Russian dominion; but during the disturbances of 1611 it was taken by Sigismund III of Poland, and it remained under Polish rule until 1654, when the Russians retook it. In 1686 it was definitely annexed to Russia. In the 18th century it played an important part as a basis for the military operations of Peter the Great during his wars with Sweden. In 1812 it was well fortified; but the French, after a two days’ battle, defeated the Russians here, and took the city when it suffered much damage.

SMOLLETT, Tobias George (1721–1771), British novelist, was born in the old grange of Dalquhurn, near Bonhill, in the vale of Leven, parish of Cardross, Dumbartonshire, and was christened on the 19th of March 1721. His father Archibald (youngest son of Sir James, the laird of Bonhill, a zealous Whig judge and promoter of the Union of 1707) had made what was deemed in the family an imprudent marriage. Archibald died in 1723, and Sir James did what he could for the widow and her family during his lifetime. The elder son James was sent into the army. Tobias was sent to Dumbarton school, then in excellent repute under the grammarian John Love. When the grandfather died in 1731 there was no further provision, and after qualifying for a learned profession at Glasgow University, Tobias was apprenticed in 1736 for five years to a well-known surgeon in that city. This early "deception" conspired to make him angry, resentful and suspicious of motive; but he was neither vindictive nor ungenerous. If his tendency to satire and caricature made him enemies, his enthusiasm for Scottish history made him friends, and in spite of peccadilloes, the "bubly-nosed castigant with a stance in his pocket," as Dr Gordon called him, seems to have made the most of his master’s regard. The lad’s ambition would not allow him to remain in Glasgow. The example of Thomson and Mallet was contagious, and at the age of eighteen Smollett crossed the border in set form to conquer England with a tragedy, The Regicide, based on Buchanan’s description of the death of James I.

The story of the journey is told with infinite spirit in the early chapters of Roderick Random. The failure of the play, his daring composition and certainly the worst thing he ever wrote, drove him back to Scotland. But Smollett’s life was a consuming fire, no one could be induced to read it, and the unrequited author would have been reduced to starvation had not a friend of the family procured him the position as surgeon’s mate on H.M.S. "Cumberland." The fleet was ordered to attack Cartagena, the great stronghold of Spanish America, and the siege, which occupied most of the year 1743, proved the Walcheren expedition of the 18th century. Smollett as an eye-witness has left us a memorable picture of the miseries endured by soldiers and sailors, which historians have been content to accept as a first-hand authority in spite of the fact that it is embellished in the pages of a novel. When the enterprise was abandoned the fleet returned to Jamaica. There Smollett fell in love with the daughter of a planter, Nancy Lascelles, whom he married on returning to England. Before this, having removed his name from the navy books (May 1744), he had set up as a surgeon in Downing Street; but he attracted attention more as a wit than as a leech. "Jupiter" Carlyle testifies to his brilliant accomplishments, and to the popularity he attained by his indignant verses "The Tears of Scotland," resenting Culloden. In the same year (July 1746) his name appeared upon the title-page of a political satire entitled Advice, first issued characteristically Down to the Devil; by Reproof, both of them "imitations from Juvenal" in the manner of Pope. He revenges himself in his satires on the should-have-been patrons of his play.

Disappointed alike in the drama, his profession and his wife’s dowry, Smollett devoted his attention in a happy hour to fictitious adventure. Richardson had published the first part of Pamela in 1741, and Fielding his Joseph Andrews in 1742. But Smollett owed less to these models than to his studies in Cervantes, Swift, Defoe and above all Le Sage. His hero, who gives his first novel its capital name, Roderick Random, recounts like Gill Blas a life of varied adventure, his company of a servant, in which he enters the service of a physician and meets with old schoolfellows, thieves, notes of the bank of engraving, prison, semi-starvation and in the end an unexpected fortune. The author draws on
his adventures on the English highway and in the cockpit of a king's ship. Virtually he revealed the seaman to the reading world—divining this character, sketched his outlines, formulated his lingo, discovered his possibilities to such purpose that, as Scott says, every one who has written about the navy since seems to have copied more from Smollett than from nature. Pungent observation allied to a vigorous prose, emancipated to a rare degree from provincialism or archaism, were perhaps the first of Smollett's qualifications as a novelist. Such coherence as his novels have owes more to accidental accumulation than to constructive design. The wealth of amusing incident, the rapidly moving crowd of amusing and eccentric figures, atones for a good many defects. Smollett's peculiar counsels unequivocally exemplify what may be called “true” English fiction, but from Tom Jones right down to Great Expectations his work was regularly ransacked for humour. There was no author's name on the title of the two small volumes of Random; Lady Mary Wortley Montagu thought a work so delightful could only be by Fielding, in whose name it was actually translated into French. But Smollett made no secret of the authorship, went to Paris to ratify his fame, and published his dedicat play as "by the author of Roderick Random," hoping thus, as he said, to intimidate his discarded patrons. The incident well reveals the novelist's "dubia, siccum maxime irritabile," of which his medical advisers spoke.

Smollett now became a central figure among the group of able doctors who hailed from north of the Tweed, such as Clephane, Macaulay, Hunter, Armstrong, Pitcairne and William Smelle, in the revision of whose system of Midwifery the novelist bore a part. He must have still designed to combine medicine with authorship, for in June 1750 he obtained the degree of M.D. from Marischal College, Aberdeen. But in the autumn of this year he already had another novel in prospect, and went over to Paris with a new acquaintance, Dr Moore (author of Zeluco), who soon began to outstrip in fame the author of Prospects of Advice. The influence of this visit is marked in Smollett's second novel, The Adventures of Peregrine Pickle (4 vols., 1751). Like its predecessor, a loosely constructed string of episodes and adventures in which a still greater scope is afforded to the author for eccentric display, Pickle proved from the first a resounding success, both in England and France. The chief centres of attraction are the grotesque misanthrope of Bath, Cadwallader Crabtree, the burlesque scenes afforded by the physician (a caricature of Akenside) and Pallet the painter in Paris, and the so-called "garrison," with its inhabitants, Hatchway and Pipes and the inimitable Trunnion—whose death-scene was defended by Smollett's powers for the first time—the prototype of so many character portraits from Uncle Toby to Cap'n Cuttle. Trunnion's grotesque ride to church reappears in John Gilpin; the misanthrope, practising satire under cover of feigned deafness, reappears in the Mungo Malagrowther of Scott, who frankly admits further debts to Smollett in the preface to the Legend of Montrose. The "garrison" unquestionably suggested the "castle" of Tristram Shandy and the "fortress" of Mr Wemmick. Indeed it is no exaggeration to say that the tawdry of subsequent fiction is steeped on every hand with the objects and manner of Smollett's happy phrases and farcical inventions. Pickle himself is as possible a bigger ruffian than Random; in this respect at any rate Smollett clings to the cynical tradition of the old romances of roguey. The novel is marred to an even greater extent by interpolations and personal attacks than its predecessor; the autobiographical element is lighter and the literary quality in some respects inferior.

Smollett's third novel, Fardnament Count Fathom, appeared in 1753, by which time the author, after a final trial at Bath, had definitely abandoned medicine for letters, and had settled down at Monmouth House, Chelsea, a married man, a father and a professional writer, not for patronage, but for the trade. In this capacity he was among the first to achieve a difficult independence. In Fathom Smollett endeavours unquestionably to organize a novel upon a plan elevated somewhat above mere agglomeration. It looks as if he deliberately set himself to show that he too, as well as the author of Tom Jones, could make a plot. The quibbler and irony of the piece repel the reader, but it is Smollett's greatest feat of invention, and the descriptive power, especially in the first half, reveals the latent imaginative power of the author. Few novels have been more systematically plundered, for Fathom was the studio model of all the mystery and terror school of fiction commencing with Radcliffe and Lewis. With Fathom the first jet of Smollett's original invention was spent. The novel was not particularly remunerative, and his expenses seem always to have been profuse. He was a great frequenter of taverns, entertained largely, and every Sunday threw open his house and garden to unfortunate "brothers of the pen," whom he regaled with beef, pudding and potatoes, pot, punch and "Calves' heads entire but cooked." To sustain these expenses Smollett consented to become a literary impresario upon a hitherto unparalleled scale. His activity during the next six years was many-sided, chiefly in the direction of organizing big and saleable "standard" works for the booksellers and contracting them out to his "myrmidons." Thus we see him almost simultaneously editing Don Quixote, making a triumphant visit to Scotland, inaugurating a new literary periodical the Critical (Feb. 1756) by way of corrective to Griffith's Monthly Review, organizing a standard Library of History of England in quartos and octavo, and a seven-volume compendium of Voyages, for which he wrote a special narrative of the siege of Cartagena, supplementary to his account in Roderick Random. In 1758 he projected and partly wrote a vast Universal History, and in January 1760 he brought out the first number of a new sixpenny magazine, the British, to which he contributed a serial work of fiction, the mediocre Adventures of Sir Launcelot Greats. By these Herculean labours as a compiler Smollett must have amassed a considerable sum, to which the £200 received from the now forgiven "Mar- mozet" (Garrick) for the sixth performance of the patriotic Reprisal, or the Tars of Old England, must have come as a welcome addition. The Critical Review was already responsible for plenty of thorns in the editorial cushion when in 1762 Smollett undertook the additional task of editing the Briton. He had already been ridiculed, insulted, fined and imprisoned in the Marshalsea (this last for an attack on Admiral Sir Charles Knowles). He was now to support the North British favourite of George III. in the press against all comers, not we may reasonably suppose without substantial reward. Yet after incurring all this unpopularity, at a time when the London mob was more inflamed against Scotsmen than it has ever been before or since, and having aroused the animosity of such former allies as Wilkes and his friend Churchill, Smollett was to find himself unceremoniously thrown over by his chief, Lord Bute, on the ground that his paper did more to invite attack than to repel it.

The Briton expired or was killed by the North Briton in February 1753, and for the moment Smollett allowed himself to be beckoned back by the booksellers to such tasks as a universal gazetteer and a translation of Voltaire in 38 volumes, and we hear of him prescribing work to his minions or receiving their homage and encomiums. The Briton, or the Tars of Old England, must have been an effort to show himself unceremoniously thrown over by his chief, Lord Bute, on the ground that his paper did more to invite attack than to repel it.

The Briton expired or was killed by the North Briton in February 1753, and for the moment Smollett allowed himself to
as the 

Travels were out of hand Smollett resolved on a summer journey to Scotland. The society of Edinburgh, then at the apogee of its brilliance, paid due attention to the famous Dr Smollett. He was visited by Hume, Home, Robertson, Adam Smith, Blair, Carlyle, Cullen and the Monros. He went to Glasgow to see Dr Moore (where he patted the head of the future hero of Corfu), and stayed with his cousin, James Smollett, in his newly built mansion of Langhorn. His mother, who hardly knew his toil-worn visage until it relaxed into his old roguish smile, died in this autumn, and he was still in a precarious state of health when he proceeded to Bath, spending the Christmas of 1766 in Gay Street, where his complaint at last took a turn for the better, and where it is possible that he may have commenced a rough draft of Humphry Clinker.

In 1768 he was again in London, and with a return of his vital energy came a recrudescence of the old savagery. The History and Adventures of an Atom is a very clever, but abominably coarse, Rabelaisian satire upon the whole conduct of public affairs in England from the beginning of the Seven Years' War down to the date of publication. He lashes out on all sides without fear or favour. The king, Chatham, Bute and North are bespattered with filth, the acridity of which owes something to Gulliver, with aid as to local colour from the Jesuit and other accounts of Japan which had come under his ken as a compiler of travels. After its publication in 1769, without other serious consequences, Smollett's health completely relapsed, and in December (a consolate in the Mediterranean having been refused him) he returned to Edinburgh. Shortly after, and sailed first at Fisa and then near Antignano, a few miles out of Leghorn. There, during the autumn of 1770, he penned his immortal Humphry Clinker, in which he reverted to his favourite form of itinerant letters, a rare example of late maturity of literary power and fecundity of humour. The sardonic humour, persistent curiosity and keen faculty of observation shown in the Travels are here combined with the mellow contentment of the voyager who has forgotten the small worries of transport and with the enthusiasm of the veteran who revisits the scenes of his youth. The character drawing, too, though still caustic, seems riper and more matured.

Smollett's speculative and involving the 18th century mind is here content for the most part, like Goldsmith's, merely to amuse. Smollett died at Leghorn aged fifty on the 17th of September 1771, and was buried in the old English cemetery there. Three years later the Smollett obelisk was put up at Renton (it now stands in the parish school-ground), half-way between Dumbarton and Balloch. The best portrait belongs to the Smollett family. Cameron House, Loch Lomond (engraved by Freeman, 1831) The genuineness of the others, if we except that in the Hunterian Museum, Glasgow, is doubtful. The novelist has been confused with the Dr Smollett, the contemporary of Dr William Hunter, who figures in Sanderson's "Dissecting Room" (Royal Coll. of Surgeons Cat., 1900).

Hume said that Smollett was like a coco-nut, rough outside, but full of human kindness within. He was easily ruffled by the rubs of fortune of which he had more than his fair share. Hence the adjectives corrosive and splenetic so often applied to a nature essentially both generous and tender. After Fielding, Smollett counts as the greatest purveyor of comic prose-epic of contemporary life to his generation, if not to his century. Scott and Dickens regarded him as fully Fielding's equal. Hazlitt and Thackeray thought equally rationalist and pagan with Fielding. Smollett is more of a pedagogue and master of the instinctive scholar and wit than his predecessor. His method in its broad outlines is similar, historic and ambulant rather than philosophic or poetic, but he has more potential romance or poetry about his make-up than the mystery-hating Fielding. In the recognized requirements of prose-epic such as plot, character, scene, reflection and diction, Smollett could fairly hold his own. His prose, which carries on the robust tradition from Swift and Defoe to Johnson and Jeffrey, is more modern in tone than that of his great rival. In fictions such as Tom Jones, Roderick Random and the like, England could at length feel that it possessed compositions which might claim kinship and comparison with Cervantes and Le Sage. Much that these writers attempted has been done again in a style better adjusted to the increasing refinement of a later age. But Smollett's great powers of observation and description, his caustic and indignant turn of speech, will long render him an invaluable witness in the century which he so well represents. Much that he did was mere hackwork, but at his best he ranks with the immortals.

The estimate formed of Smollett's work during the past generation has probably been a diminishing one, as we may infer in particular from the fact that there is no standard Life and no definitive edition of the works. The chief collective editions are as follows: 6 vols. 1790; 5 vols. London, 1796, with R. Anderson's Memoir; Works, ed. J. Moore, 1797 (re-edited 1872); Works, ed. Henley and Seccombe, Constable (2 vols., 1899-1902). To which must be added a one-volume Miscellaneous Works, ed. J. F. Laidler (1891); Smollett (with a careful life by David Herbert) (Edinburgh, 1879); Ballantyne's early edition of the Novels with Scott's judicial memoir and criticism (2 vols., 1821); and Professor G. Saintsbury's edition of the Novels (12 vols., 1895). There are short Lives by Robert Chambers (1865), David Hannay (1887) and O. Smeeaton (1897).

Additional information of recent date will be found in the article on Smollett in the Dict. Nat. Bio., Maseon's British Novelists (and other books on the development of English Fiction), H. Graham's Scottish Memoirs, The Scots Magazine, Blackwood's Mag. for May 1900; and the present writer's introduction to Smollett's Travels through France and Italy (World's Classics, 1907). (T. SE.)

SMUGGLING (O. Eng. smögan, smugian, to creep, with the idea of secrecy), a breach of the revenue laws either by the importation or the exportation of prohibited goods or by the failure to pay customs duties on goods liable to duty. Legislation on the subject in England has been very active from the 14th century downwards. In the reign of Edward III. the illicit introduction of base coin from abroad led to the provision of the Statute of Treasons 1351, making it treason to import counterfeit money as the money called "Lushburgh." Such importation is still an offence, though no longer treason. After the Statute of Treasons a vast number of acts dealing with smuggling were passed, most of which have been found recited in the repeating act of 1825. In the 18th and the early years of the 19th century, smuggling (chiefly of wine, spirits, tobacco and bullion) was so generally practised in Great Britain as to become a kind of national failing. The prevalence of the offence may be judged from the report of Sir J. Cope's committee in 1732 upon the frauds on the revenue. The smuggler of the 18th century finds an apologist in Adam Smith, who writes of him as "a person who, though no doubt highly blamable for violating the laws of his country, is frequently incapable of violating those of nature herself, and would have been in every respect an excellent citizen had he only known and observed a crime which nature never meant to be so." The gradual reduction of duties, however, lessened the offence in the United Kingdom into comparative insignificance, and it is now almost confined to tobacco, though the sugar duty has led to smuggling of saccharin. Most of the existing legislation on the subject of smuggling is contained in the Customs Consolidation Act 1876.

The main provisions are as follows. Vessels engaged in smuggling are liable to forfeiture and their owners and masters to a penalty not exceeding £500. Smuggled and prohibited goods are liable to forfeiture. Officers of customs have a right of search of vessels and persons. Fraudulent evasion or attempted evasion of customs duties renders an offender liable to the double the value of the goods or £100 at the election of the commissioner of customs. Heavy penalties are incurred by resistance to officers of customs, rescue of persons or goods, assembling to run goods, signalling smuggling vessels, shooting at vessels, boats, or officers of the naval or revenue service, cutting adrift customs vessels, offering goods for sale under pretence of being smuggled, &c. Penalties may be recovered either by action of information in the superior courts or by summary proceedings in the existing admiralty. The provisions are competent and compellable to give evidence. The Merchant Shipping Act 1894 makes any seaman or apprentice, after conviction for smuggling where it appears to the master or owner of a ship, liable to pay to such master or owner of ship as is sufficient to reimburse the master or owner for such loss or damage, and the whole or a proportional part of his wages may be retained by the master, if the satisfaction of his debt to the master or owner is insufficient to reimburse the master or owner. Smuggling is also contained in the Customs and Inland Revenue Act 1879, and the Customs and Inland Revenue Act 1881. A smuggling contract is generally illegal. But it may be valid, and the
Smyrnaean.

It was Smyrna temple still and after commerce of C. Smyrna, it is said to have been a Lelegian city before the Greek colonists settled in Asia Minor. The name, which is said to be derived from an Amazon called Smyrna, is indubitably Anatolian, having been applied also to a quarter of Ephesus, and (under the cognate form Myrina) to a city of Aeolis, and to a tumulus in the Troad. The Aeolic settlers of Lesbos, named Neonteichus, a blank, and he was by a bishop of Byzantium, bishop of the Hermus, and over the Hermus, seized the valley of Smyrna. It was the frontier city between Aeolis on the N. and Ionia on the S., and was more accessible on the S. and E. than on the N. and W. By virtue of its situation it was necessarily a commercial city, like the Ionian colonies. It is therefore not surprising that the Aeolic element grew weaker; strangers or refugees from the Ionian Colophon settled in the city, and finally Smyrna passed into the hands of the Colophonians and became the thirteenth of the Ionian states. The change had taken place before 688, when the Ionian Onomastus of Smyrna won the boxing prize at Olympia, but it was probably then a recent event. The Colophonian conquest is mentioned by Minnemus (before 600 B.C.), who counts himself equally a Colophonian and a Smyrnaean. The Aeolic form of the name, Συμνα, was retained even in the Attic dialect, and the epithet "Aeolian Smyrna" remained long after the conquest. The situation of Smyrna on the path of commerce between Lydia and the west raised it during the 7th century to the height of power and splendour. It lay at the head of an arm of the sea, which reached far inland and admitted the Greek trading ships into the heart of Lydia. One of the great trade routes, which ran from Anatolia, descends the Hermus valley past Sardis, and then diverging from the valley passes S. of Mt. Sipylus and crosses a low pass into the little valley, about 7 m. long and 2 broad, where Smyrna lies between the mountains and the sea. Milletus, and later Ephesus, situated at the sea end of the other great trade route across Anatolia, competed for a time successfully with Smyrna, but both cities long ago lost their harbours and Smyrna remains without a rival.

When the Mermnad kings raised the Lydian power and aggressiveness Smyrna was one of the first points of attack. Gyges (c. 689-652) was, however, defeated on the banks of the Hermus; the situation of the battlefield shows that the power of Smyrna extended far to the E., and probably included the valley of Nymphi. A strong fortress, the ruins of whose ancient and massive walls are still imposing, on a hill in the pass between Smyrna and Nymphi, was probably built by the Smyrnaean Ionians to command the valley of Nymphi. According to Theognis (about 500 B.C.), "pride destroyed Smyrna." A Mimmerian attack (620) and the death of the citizens of his day, who could no longer stem the Lydian advance. Finally, Alyattes III. (600-560) conquered the city, and Smyrna for 300 years lost its place in the list of Greek cities. It did not cease to exist, but the Greek life and political unity were destroyed, and the Smyrnaean state was organized on the village system (φιλαρχία). It is mentioned in a fragment of Pindar, about 500 B.C., and in an inscription of 388 B.C. A small fortification of early style, rudely but massively built, on the lowest slope of a hill N. of Burnabat, is perhaps a fortified village of this period. Alexander the Great conceived the idea of restoring the Greek city; the two Nemese who were worshipped at Smyrna are said to have suggested the idea to him in a dream. The scheme was, according to Strabo, carried out by Antigonus (316-301), and Lysimachus enlarged and fortified the city (301-281). The acropolis of the ancient city had been on a steep peak about 1250 ft. high, which overhangs the N.E. extremity of the gulf; its ruins still exist, probably in much the same condition as they were left by Alyattes. The later city was founded on the modern spot partly on the slopes of a rounded hill called Pagus near the S.E. end of the gulf, partly on the low ground between the hill and the sea. The beauty of the city, clustering on the low ground and rising tier over tier on the hillside, is frequently praised by the ancients and is celebrated on its coins.

The "crown of Smyrna" seems to have been an epithet applied to the acropolis with its circle of buildings. Smyrna is shut in on the W. by a hill now called Deirmen Tepe, with the ruins of a temple on the summit. The walls of Lysimachus crossed the summit of this hill, and the acropolis occupied the top of Pagus. Between the two the road from Ephesus entered the city by the "Ephesian gate," near which was a gymnasion. Closer to the acropolis the outline of the stadium is still visible, and the theatre was situated on the N. slopes of Pagus. The line of the wall on the E. side is unknown, but they certainly embraced a greater area than is included by the Byzantine wall, which ascends the castle hill (Pagus) from the Basmakanâh railway station. Smyrna possessed two harbours—the outer, which was simply the open roadstead of the gulf, and the inner, which was a small basin, with a narrow entrance closed by a rope in case of need, about the place now occupied by bazaars. The inner harbour was partially filled up by Timur in 1402, but it had not entirely disappeared till the beginning of the 19th century. The modern quay has encroached considerably on the sea, and the coast-line of the Greek times was about 900 yds. farther S. The streets were broad, well paved and laid out at right angles; many were named after temples: the main street, called the Golden, ran across the city from W. to E., beginning probably from the temple of Zeus Akraios on the W. side of Pagus, and running round the lower slopes of Pagus (like a necklace on the statue, to use the favourite terms of Aristides the orator) towards Tepejik outside the city on the E., where probably the temple of Cybele, the Metropolis, stood. Cybele, worshipped under the name ofMeter Sipyene, from Mt Sipylus, which bounds the Smyrna valley on the N., was the tutelary goddess of the city. The plain toward the sea was too low to be properly drained and hence the weather the streets were deep with mud and water.

The river Meles, which flowed by Smyrna, is famous in literature.
and was worshipped in the valley. The most common and consistent tradition connects Homer with the valley of Smyrna and the banks of the Meles; his figure was one of the stock types on Smyrnaean coins; one class of which was called Homerian; the epithet "Melesigenes" was applied to him; the cave where he was wont to compose his poems was shown near the source of the river; his temple, the Homereum, stood on its banks. The steady equable flow of the Meles, alike in summer and winter, and its short course, beginning and ending near the city, are celebrated by Aristides and Himerius. The description applies admirably to the stream which rises from abundant fountains, now known as Diana's bath, E of the city, and flows into the S.E. extremity of the gulf. The belief that the torrent, almost dry except after rains, which flows by Carian bridge, is the ancient Meles, flatly contradicts the ancient descriptions.

In the Roman period Smyrna was the seat of a conventus which included S. Aeolis and great part of the Hermus valley. It vied with Ephesus and Pergamum for the title "First (city) of Asia." A Christian church existed here from a very early time, having its origin in the considerable Jewish colony. Polycarp was bishop of Smyrna and was martyred there A.D. 155. The bishops of Smyrna were originally subject to the metropolitan of Ephesus; afterwards they became independent (αὐτοκράτορα), and finally were honored with metropolitan rank, having under them the bishops of Philomelion, Magnesia ad Sipylum, Clazomenae, Sosandrus (Nymphii), Archangelus (Temnos?), and Petra (Menemen)?

When Constantinople became the seat of government the trade between Anatolia and the W. lost in importance, and Smyrna declined apace. A Turkish freebooter named Tscha seized Smyrna in 1084, but it was recovered by the generals of Alexius Comnenus. The city was several times ravaged by the Turks, and had become quite ruinous when the emperor John Ducas Vatatzes about 1222 rebuilt it. But Ibn Batuta found it in such a state that part a ruin when the famous chieftain Aïdin had conquered it about 1330 and made his son Amur governor. It became the port of the Aïdin amirate. Soon afterwards the Knights of Saint John established themselves in the town, but failed to conquer the citadel. In 1402 Timur stormed the town and massacred almost all the inhabitants. The Mongol conquest was only temporary, but Smyrna was resumed by the Seljuks of Aïdin and has remained till the present day in Mahomedan hands. Until the reign of Abdul Mejid it was included for administrative purposes in the eyalat of Jezair (the Isles) and not in that of Anadolu. The representatives of the Grand Pasha, who resided there, however, less influential in the city than the head of the Kara Osman Oglu's of Manisa (see MANISA). From the early 17th century till 1829, Smyrna was the chief provincial factory of the British Turkey Company, as well as of French, Dutch and other trading corporations. The passages with gates at each end within which most Frank shops in modern Smyrna lie, are a survival of the semi-fortified residences of the European merchants.

2. The Modern City, capital of the Aïdin vilayet, and the most important town of Asia Minor. Pop. more than 100,000, of which fully a half is Greek. It is one of the principal ports of the Ottoman empire, and has a large trade, of which the greater part is with Great Britain. The chief items of export are figs, tobacco, valonia, carpets, raisins and silk, to the value of some three million sterling. The imports are estimated at a million more. About 7000 steamships visit the port annually. Until 1894 the two railways from Smyrna to the interior belonged to British companies; but in 1897 the Smyrna-Alaşehir line passed into the hands of a French syndicate, which completed an extension to Aïfüna Karhisar and virtually (though not actually) effected a junction with the Anatolian railway system. This line has branches to Burnabat and Soma. The Smyrna-Aïdin line has been extended to Dineir, and powers have been obtained to continue to Isbarta and Egerdir. It has branches to Buja, Seidikeu, Tırıc, Odemis, Sokia, Denizli and Işıklı.

Modern Smyrna is in all but government a predominantly Christian town (hence the Turks know it as glaçur Ismir). There is a large European element (including about 500 British subjects), a great part of which lives in two suburban villages, Burnabat and Soma, a mile or more out of the city. The two Greek and Greek quarters rapidly increase, mainly to the N.; while the fine quays, made by a French company, are backed by a line of good buildings. The streets behind, though clean and well kept, are very narrow and tortuous. A fine new Konak (government offices) has been built, and another important new structure is the pier of the Aïdin Railway Co. at Point. The development of this railway is the most conspicuous sign of progress.

Smyrna is a headquarters of missions of all denominations and has good schools, of which the International College is the best. There is a British consular-general, with full consular establishment, including a hospital.

See general authorities for Asia Minor, especially the travellers, almost all of whom describe Smyrna. Also B. F. Saars, Étude sur Smyrne (1868); and W. M. Ramsay, Letters to the Seven Churches (1904) and article in Hastings's Dict. of the Bible (1902).

W. M. KA; D. G. H.)

SMYTH, CHARLES PIAZZI (1810-1900), British astronomer, was born at Naples on the 3rd of January 1819. He was called Piazzi after his godfather, the Italian astronomer of that name, whose acquaintance his father, Admiral Smyth, had made at Palermo when on the Mediterranean station. His father subsequently settled at Bedford and equipped there an observatory, at which Piazzi Smyth received his first lessons in astronomy. At the age of sixteen he went out as assistant to Sir Thomas Maclear at the Cape of Good Hope, where he observed Halley's comet and the great comet of 1833, and took an active part in the verification and extension of La Caille's arc of the meridian. In 1845 he was appointed astronomer royal for Scotland and professor of astronomy in the University of Edinburgh. Here he completed the reduction and continuation of the observations made by his predecessor, Thomas Henderson (see Edinburgh Observations, vols. xi.-xv.). In 1856 he made experimental observations on the Peak of Teneriffe with a view to testing the astronomical advantages of a mountain station. The Admiralty made him a grant of £500 for the purpose, and a yacht—the "Triton"—of 140 tons and a fine 7½ in. equatorial telescope were placed at his disposal by friends. The upshot of the expedition was to verify Newton's surmise, that a "most serene and quiet air . . . may perhaps be found on the tops of the highest mountains, the great mountains of clouds." The scientific results were detailed in a Report addressed to the lords commissioners of the admiralty, 1858, in a communication to the Royal Society (Phil. Trans. cxtviii. 465) and in the Edinburgh Observations, vol. xii. A popular account of the voyage is contained in Teneriffe, ou Astronomer's Experiment, 1858. In 1871-1872 Piazzi Smyth investigated the spectra of the aurora, and zodiacal light. He recommended the use of the "rainband" for weather prediction (Journ. Scottish Meteor, Society, v. 84), and discovered, in conjunction with Professor A. S. Herschel, the harmonic relation between the rays emitted by carbon monoxide. In 1877-1878 he constructed at Lisbon a map of the solar spectrum (Edin. Phil. Trans. xxix. 289), for which he received the Macdougall-Brisbane prize in 1880. Further spectroscopic researches were carried out by him at Madeira in 1880 (Madeira Spectroscopic, 1882), and at Winchester in 1884 (Edin. Phil. Trans. vol. xxxii. pt. ii.) He published besides Three Cities in Russia (1862), Our Inheritance in the Great Pyramid (1864), Life and Work at the Great Pyramid (1867), and a volume On the Antiquity of Intellectual Man (1868). In 1888 he resigned his official position and retired to the neighbourhood of Ripon, where he died on the 21st of February 1900.

SMYTH (or SMIT), JOHN (c. 1570-1612), English non-conformist divine, commonly called the Sc-baptist, was born
about 1570, and was educated at Christ's College, Cambridge, where he proceeded M.A. in 1593. He was probably vicar of Hutton Cranwicke in the E. Riding of Yorkshire from 1593 to 1599, when he was elected lecturer or preacher of the city of Lincoln, an office of which he was deprived in 1605 for having "approved himself a factious man by personal preaching and that truly against divers men of good place." Two volumes of his Lincoln sermons, The Bright Morning Star (1603), an exposition of Psalm xxi., and A Pattern of True Prayer (1603), were dedicated to Lord Sheffield, who had acted as arbiter between the preacher and the corporation. While preparing these books he became connected with the Separatist movement in Scrooby and Gainsborough, joined the Gainsborough church, and became its pastor. With Thomas Helwys, John Smyth, John Pringle (and others), he migrated to Amsterdam at the end of 1607 to escape religious persecution, and in that city practised as a physician, and became the leader of "the second English church" (see Congregationalism). About this time he wrote his Principles and Inferences concerning the Visible Church in support of Robert Browne's theory of ecclesiastical polity, which was followed by Parallels, Censures and Observations, a reply to the Christian Advertisements of Richard Bernard (1568-1641), vicar of Workshop, a puritan who remained in the Anglican church. In 1608, too, appeared The Differences of the Churches of the Separation, in which he justified his non-communion, called the Retraction of his Error, and of the first of that no part of primitive and apostolic order to use a translation of scripture during worship, or at any rate to have it open before one while preaching (Christ having "closed the book" at Nazareth before His sermon). Under Mennonite influence he went farther, and by March 1609 when he published The Character of the Beast, he had become a Baptist (see Baptists, sect. II.), contending against infant baptism because (1) it has neither precept nor example in the New Testament, (2) Christ commanded to make disciples by teaching them and then to baptize them. He and his company were then faced by the dilemma that their own infant baptism did not count, and Smyth solved the problem by first baptizing himself (hence the name Se-Baptists), probably by affusion, and then administering the rite to Helwys and the others. Afterwards with 41 others he decided that instead of baptizing himself he should have been baptized by the Mennonites, in spite of their heretical view of the Person of Christ, and applied for admission to their fellowship. They were somewhat suspicious of a man who had never held one position for long, and demanded a statement of doctrines, which he gave them in twenty articles written in Latin, and in The Last Book of John Smyth, called the Reproachment of his Errors (1610). Smyth's views were really a repetition of the tenets of the Anabaptists, the sect which he termed the beautiful soul. None of them succeeded in expressing with so much reasonableness and consistency their aspirations after a spiritual system of religious belief and practice. None of them founded their opinions on so large and liberal a basis." In his last declaration he expressed his sorrow for the censures he had passed on Anglicans and Brownists alike, and wrote "All penitent and faithful Christians are brethren in the communion of the outward church, by which name we are known; we are known, indeed, with a holy kiss, being heartily grieved that we should be rent with so many sorts and schisms; and that only for matters of no moment." See J. H. Shakespeare, Baptist and Congregational Pioneers (London, 1906); H. M. Dexter, The England and Holland of the Pilgrims (London and Boston, 1906). (A. J. G.)

He was never vicar of Gainsborough, and must not be confused with the John Smyth who was imprisoned in the Marshalsea in 1592.

SMYTH, SIR W. W.—SNAIL

SMYTH, SIR WARINGTON WILKINSON (1817-1896), British geologist, was born at Naples on the 26th of August 1817, his father, Admiral W. H. Smyth (1788-1865), being at the time engaged in the Admiralty Survey of the Mediterranean. He was educated at Westminster and Bedford schools, and afterwards at Trinity College, Cambridge, where he graduated B.A. in 1839. Having gained a travelling scholarship he spent more than four years in Europe, Asia Minor, Syria and Egypt, paying great attention to mineralogy and mining, examining coalfields, metalliferous mines and salt-works, and making acquaintance with many distinguished geologists and mineralogists. On his return to England in 1844 he was appointed mining geologist on the Geological Survey, and in 1851 lecturer at the School of Mines, a post which he held until 1881 when he relinquished the chair of mineralogy but continued as professor of mining. In later years he became the chief of Bosworth, he was to the Office of Woods and Forests, and also to the Duchy of Cornwall. He was elected F.R.S. in 1858. He became president of the Geological Society of London in 1866-1868, and in 1879 he was chairman of a Royal Commission appointed to inquire into accidents in mines, the work in connexion with which continued until 1886. He contributed sundry papers to the Memoirs of the Geological Survey, the Quarterly Journal of the Geological Society and the Transactions of the Royal Geological Society of Cornwall. He was author also of A Year with the Turks (1854), and of A Treatise on Coal and Coal-mining (1867). He was knighted in 1887. He died in London on the 19th of June 1890, and was buried at St Erth, not far from his country home at Marazion in Cornwall.

A portrait and some reminiscences of W. W. Smyth will be found in the Memoir of Sir A. C. Ramsay (1893), by Sir A. Geikie.

SMYTH (or SMITH), WILLIAM (c. 1490-1514), bishop of Lincoln, was a Lancashire man by birth, and probably passed some of his early days at Knowsley under the roof of Margaret, countess of Richmond and Derby, the mother of Henry VII. He appears to have been a member of Lincoln College, Oxford, and in 1515, just after the battle of Bosworth, he was made to the Office of the hanaper of the chancery. Two of Edward IV's daughters were entrusted to his keeping; he was a member of the royal council and he obtained the livings of Combe Martin, Devon, of Great Grimsby and of Cheshunt, Hertfordshire. In 1491 he was made dean of St Stephen's, Westminster, and two years later bishop of Coventry and Lichfield. The bishop was a member of Prince Arthur's council in the marches of Wales, and in 1501, five years after he had been translated to the bishopric of Lincoln, he became lord president of Wales. About 1507 he and Sir Richard Cotton (d. 1524) set to work to found a new college in Oxford. They rebuilt Brasenose, and other existing halls, allotted others to it, and obtaining a charter in 1512, called it The King's hall and college of Brasenose. Smyth, who was one of the executors of Henry VII's will, retired from public life just after this King's death, owing probably to some differences between Bishop Richard Fox and himself; he was, however, president of Wales until his death at Buckden in Huntingdonshire on the 2nd of January 1514. Although an able and scholarly man, Smyth had little sympathy with the new learning. He bestowed rich livings upon his relatives, one of whom, Matthew Smyth, was made rector of Brasenose College. In addition to his liberal gifts to Brasenose College he gave money or land to Lincolns and to Oriel Colleges; he founded a school at Farnworth, Lancashire, and he refounded the hospital of St John at Lichfield. From 1500 to 1503 he was chancellor of Oxford University.

SNAIL In England the word "snail" in popular language is associated with Gasteropods which inhabit land or fresh water, and which possess large conspicuous spiral shells; terrestial Gasteropods, in which the shell is rudimentary and concealed, are distinguished as "slugs." In Scotland the word "slug" is absent from the vernacular vocabulary, both shell-bearing and shell-less inland molluscs being known as snails. Marine Gasteropods are occasionally termed "sea-snails," and the compounds "pond-snails," "river-snails," "water-snails" are in common use. The commonest land-snails are those species which
constitute the family Helicidae, order Pulmonata, sub-order Stylommatophora. The families Limacidae, Ariidae and \( \textit{Oncidiidae} \) of the same sub-order, include nearly all the slugs. The \( \textit{Oncidiidae} \) are entitled to the name "sea-slugs," as they are shell-less Pulmonates living on the seashore, though not actually in the sea. The term "water-snails" includes the whole of the remaining sub-order of the \( \textit{Pulmonata} \), namely, the Basommatophora, in which the eyes are sessile, with the exception of the \( \textit{Auriculidae} \). The latter are terrestrial and occur mostly near the seashore. Thus the whole of the \( \textit{Pulmonata} \) (which breathe air, are destitute of gill-plumes and operculum and have a complicated hermaphrodite reproductive system) are either snails or slugs. But there are a considerable number of snails, both terrestrial and aquatic, which are not Pulmonates. The land-snails which have no gill-plume in the mantle-chamber and breathe air, but have the sexes separated, and possess an operculum, belong to the orders \( \textit{Aspidobranchia} \) and \( \textit{Pectinibranchia} \), and constitute the families \( \textit{Helicionidae}, \textit{Proserpinidae}, \textit{Hydrocynidae}, \textit{Cyclomphoridae}, \textit{Cyclostomatidae} \), and \( \textit{Aeolidiidae} \). The fresh-water snails which are not Pulmonates are the \( \textit{Paludinidae}, \textit{Vavutidae} \), and \( \textit{Ampulinae} \), together with \( \textit{Neritina} \), a genus of the \( \textit{Neritidae} \). All these possess a fully developed gill-plume and are typical Pectinibranchs of the sub-order \( \textit{Taeniodoxa} \), most of the members of which are marine.

The family \( \textit{Helicidae} \) has a world-wide distribution. In \( \textit{Helix} \) the spire forms a more or less obtuse-angled cone; there are above 125 species of which are British. \( \textit{Helix pomatia} \), L., of which \( \textit{H. cornutus} \) is a variety, is one of the commonest forms; \( \textit{Helix pomatia} \), L., is the largest species, and is known as the "edible snail"; it is commonly eaten in France and Italy, together with other species which have been eaten by the Romans, but there is no doubt that it is a native. In \( \textit{Cuccinea} \) the cone of the spire is acute-angled; three species are British. In \( \textit{Vitrina} \) the spire is very flat and the surface glossy. In \( \textit{Bittium} \) the spire is elongated with a pointed apex. \( \textit{Paludina} \) is named from its resemblance to a chrysallis, the apex being rounded. The shell of \( \textit{Chausilia} \) is sinistral and its aperture is provided with a hinged plate. The commoner European slugs of small size all belong to the genus \( \textit{Limax} \), in which the opening of the mantle-chamber is posterior. \( \textit{L. flavus} \) is the cellular slug. \( \textit{L. aegeritis}, L. arborum, L. maximus \) occur in gardens and fields. The larger black slugs are species of \( \textit{Arianta}, \textit{Ariodonta} \), and \( \textit{Ariolimax} \). The genera \( \textit{Testaceus}, \textit{Batillaria} \) is common in Great Britain and throughout Europe.

The species of \( \textit{Helix} \) are all herbivorous, like the Pulmonata generally. Snails and slugs are well-known enemies to the gardener. The animals being hermaphrodite copulate reciprocally. The eggs of \( \textit{Helix} \) are laid separately in the earth, each contained in a calcified shell; those of \( \textit{Limax} \) are also separate, but the shell is gelatinous. \( \textit{Helix} \) relatives in a terrestrial condition for about four months, and during this period the aperture of the shell is closed by a calcareous membrane secreted by the foot.

In size and shape they are found in all parts of the world. \( \textit{Limax} \) contains the largest species. \( \textit{L. pereger}, \textit{Muller}, \) is ubiquitous in Great Britain and common all over Europe. All the species are usually infected with \( \textit{Cercariae} \) and \( \textit{Radix} \), the larval forms of Trematode parasites of vertebrates. \( \textit{L. truncatula} \) harbours the \( \textit{Cercaria} \) of \( \textit{Fasciola hepatica} \), the liver-fluke, which causes rot in sheep. \( \textit{Ancylus} \), which occurs in rivers, has a minute limpet-like shell. \( \textit{Planorbis} \) has the spire of the shell in one plane. \( \textit{Physa} \) is smaller than \( \textit{Limax} \) and has the upper part of the spire much shorter. In the \( \textit{Aeolidiidae} \) the aperture is denticulated. \( \textit{Auricula} \) is confined to the East Indies and Peru. \( \textit{Carychiunimum} \) is British.

The land slugs are the only ones of the species \( \textit{Curtosoma elegans}, \textit{Muller}, \) is British; it hides under stones and roots. The \( \textit{Helicionidae} \) are exotic, ranging from the West Indies to the Philippines. Of the \( \textit{Aeolidiidae} \), which are all minute, \( \textit{Acteolus lineata} \) is British.

The \( \textit{Basommatophora} \) are confined to the tropics. \( \textit{Achatinella} \) has very long tentacles and a long siphon formed by the mantle. \( \textit{Valvata} \) is common in fresh waters throughout Britain; the gill when the animal is expanded is protruded beyond the mantle-chamber, in \( \textit{Procambarus} \) in the Palaearctic; \( \textit{Paludina} \) and \( \textit{Bithynia} \) are both British genera. In \( \textit{Paludina} \) the whorls of the spiral are very prominent; the genus is viviparous. \( \textit{Bithynia} \) is small and has a smooth mother.

\( \textit{Nerita} \) has a very small spire, the terminal portion of the shell containing nearly the whole animal.

For the morphology and classification of snails, see \( \textit{Gastropoda}. \) Of the aquatic forms is given in \( \textit{Jeffreys's British Conchology} \) (1862), and by \( \textit{Forbes and Hanley in British Mollusca}. \) For specographical details, see \( \textit{Woodward's Manual of the Molusca} \) (1875), and \( \textit{Brown's Tierreich} \) (Weichert). For \( \textit{Fasciola hepatica} \) see \( \textit{Thomas, Quart. Journ. Mic. Sci.} \) (1882).

---

\[ 1 \] "Anhinga," according to Mearcevarg, who first described this bird (\( \textit{Hiss. er. nat. Brasiliae}, p. 218 \)), was the name it bore among the natives.

\[ 2 \] These feathers are very characteristic of each species of the genus, and in India they are worn by the Khasias as a badge of royalty.

\[ 3 \] This peculiarity, first pointed out to the writer by A. D. Bartlett, who observed it in birds in the Zoological Society's possession, doubtless suggested the name of "Water-Turkey" by which in some places \( \textit{Plautus anhinga} \) is said to be known.

---

**Snake-Bird**

Snake-Bird (the "darter" of many authors, and the \( \textit{Plautus anhinga} \) of ornithology), the type of a small but very well-marked genus of birds, \( \textit{Plautus} \), belonging to the family \( \textit{Phalacrocoracidae} \) which contains the cormorants and shags. The name commonly given to it by the English in N. America was derived from its "long slender head and neck," which, its body being submerged as it swims, "appears like a snake rising erect out of the water" (\( \textit{J. Bartram's MS.}, \) quoted by G. F. Ord in A. Wilson's \( \textit{Am. Ornithology}, \) ix. 81). Snake-birds bear a general resemblance both outwardly and in habits to Cormorants (\( \textit{g. p.} \)), but are much more slender in form and have both neck and tail much elongated.

The bill also, instead of being tipped with a maxillary hook, has its edges beset with serratures directed backwards, and is sharply pointed—in this respect, as well as in the attenuated neck, likening the Snake-birds to the Herons; but the latter do not generally transfix their prey as do the former.

The bird, which ranges from Illinois to the S. of Brazil, is in full breeding-plumage a very beautiful bird, with crimson irides, the bare skin round the eyes apple-green and that of the chin orange, the head, neck and most part of the body clothed in black glossed with green; but down each side of the neck runs a row of long hair-like white feathers, tinged with pale lilac. The much elongated scapulars, and the small upper wing-coverts bear each a median white mark, which on the former is a stripe pointed at either end, and on the latter a broad ovate patch. The larger wing-coverts are dull white, but the quill-feathers of the wings and tail are black, the last broadly tipped with brownish-red, passing into the chestnut, and once of a conspicuous hand where the tail is spread in form of a fan, as it often is under water. The hen differs much in appearance from the cock, having the head, neck and breast of a more or less deep buff, bounded below by a narrow chestnut band; but otherwise her plumage is like that of her mate, only not so bright in colour. The Snake-bird frequents the larger rivers or back-waters connected with them, where it may be seen resting motionless on some neighbouring tree, generally choosing a dead branch, or on a "snag" projecting from the bottom, whence it plunges beneath the surface, in pursuit of its prey, to emerge, in the manner before related, showing little more than its slender head and neck. Its speed and skill under water are almost beyond exaggeration, and it exhibits these qualities even in captivity, taking—apparently without effort—fish after fish, however rapidly they may swim and twist, and only returning to its perch when its supply of food is exhausted. At liberty it will indulge in long flights, and those of the male at the breeding-
SNAKE-FLY—SNAKES

season are ostentatiously performed in the presence of his mate, around whom he plays in irregular zigzag courses. The nest is almost always a rectangular mound covered with leaves and is a large structure of sticks, roots and moss, in which are laid four eggs with the white chalky shell that is so characteristic of most Scandinavian birds. The nest is closely built; the intervening spaces are built closely together, and the locality that suits the Snake- bird suits also many of the herons. The African snake-bird, *P. congessis* (or *leviathanii* of some authors), inhabits the greater part of eastern and southern Africa, together with the small St. Nile, it is not known to have occurred in Egypt, a fact the more remarkable seeing that Canon Tristram found it breeding in consider- able numbers on the Lake of Antioch, to which it is a summer visitor, and it can be easily caught in its northern passage across the intervening country. The male bird is easily distinguishable from the American species by its rufous coronal patch, its buff throat and a number of conspicuous external characters. A third species, *P. melanogaster*, ranges from Madagascar to India, Ceylon, Borneo, Java and China. This closely resembles the last-mentioned that the differences between them cannot be briefly expressed. The Australian region also has its snake-bird, which is by no means regarded as forming a fourth species, *P. nova-hollandiae*; but others unite it to that last mentioned, which is perhaps somewhat variable, and it would seem (P.Z.S., 1877, p. 349) that examples from New Guinea differ somewhat from those inhabiting Australia itself.

The anatomy of the genus *Pisces* has been dealt with by A. H. Garrod and A. A. Forbes in the Zoological Proceedings (1876, pp. 335-345, pl. xxvi.-xxvii.; 1878, pp. 679-681; and 1882, pp. 304-309). The SNAKE-ROOT. *SNAKE-FLY*, *SNAKES*.

The snakes are the most highly specialized branch of the *Saurio* or *Squamata*, i.e. of scaly reptiles with movable quadrate bones; with a transverse vent, near the posterior lateral corners of which open the eversible, paired copulatory organs. In the article LIZARD attention is drawn to the many characters which make it difficult, if not impossible, to give diagnoses applicable to all lizards and all snakes. Both these groups seem to have reached their climax but recently, while the tortoises, crocodiles and sphenodon are on the descending scale, mere remnants of formerly much more numerous and cosmopolitan development.

The number of recent species of snakes is about 1000. The order is practically cosmopolitan, with the exception of New Zealand and certain absolutely isolated oceanic islands, like the Hawaiian islands and the Azores. The N. limit approaches that of the permanently frozen subsoil, going into the arctic circle in Scandinavia, elsewhere sinking to about 54° N.; in the S. hemisphere the 45th parallel of latitude is their southern limit. The number of species and individuals steadily decreases in the cooler temperate zones, whilst it reaches its maximum in the tropics. Every kind of terrain is tenanted, from dense, moist and hot forests at the level of the sea to arid deserts, high plateaus and mountains. In accordance with this general distribution snakes show a great amount of differentiation with regard to their mode of life and general organization; and from the appearance alone of a snake a safe conclusion can be drawn as to its habits.

Dr. A. Günther characterizes the chief categories as follows:—

(1) Burrowing snakes, which live underground and but rarely appear on the surface. They have a cylindrical rigid body, covered with generally smooth and polished scales; a short strong tail; a short rounded or pointed head with narrow mouth; teeth few in number; small or rudimentary eyes; no abdominal scutes or only narrow ones. They feed chiefly on invertebrate animals, and none are poisonous. (2) Ground snakes rarely ascending bushes or entering water. Their body is cylindrical, flexible in every part, covered with smooth or keeled scales, and provided with broad ventral and subcaudal scutes. The non-poisonous kinds of ground snakes are the typical and least specialized snakes, and more numerous than any of the other kinds. They feed chiefly on terrestrial verte- brates. The majority are non-poisonous; but the majority of poisonous snakes must be referred to this category. (3) Tree snakes, which are able to climb bushes or trees with facility or pass even the greater part of their existence on trees. Their body is generally compressed and slender; their broad ventral scutes are often carinate on the sides. Those kinds which have a less elongate and cylindrical body possess a distinctly prehensile tail. The eye is generally large. Their coloration consists often of bright hues, and sometimes resembles that of their surroundings. They feed on animals which likewise lead an arboreal life, rarely on eggs. Poisonous as well as innocuous snakes are represented in this category. (4) Freshwater snakes, living in or frequenting fresh waters; they are excellent swimmers and divers. The nostrils are placed on the top of the snout and can be closed whilst the animal is under water. Their body is covered with small scales and the ventral scutes are mostly narrow; the tail tapers; head flat, rather short; and the eyes of small size. They feed on fish, frogs and other aquatic animals, and are innocuous and viviparous. (5) Sea snakes are
Distinguished by the compressed, rudder-shaped tail. They are unable to move on land, feed on fishes, are viviparous and poisonous.

The majority of snakes are active during the day, their energy increasing with the increasing temperature; whilst some delight in the moist sweltering heat of dense tropical vegetation, others expose themselves to the fiercest rays of the midday sun. Not a few, however, lead a nocturnal life, and many of them have, accordingly, their pupil contracted into a vertical or more rarely a horizontal slit. Those which inhabit temperate latitudes hibernate. Snakes are the most stationary of all vertebrates; as long as a locality affords them food and shelter they have no inducement to change it. Their dispersal, therefore, must have been extremely slow and gradual. Although able to move with rapidity, they do not keep in motion for any length of time. Their organs of locomotion are the ribs, the number of which is very great, nearly corresponding to that of the vertebrae of the trunk. They can adapt their motions to every variation of the ground over which they move, yet all varieties of snake locomotion are founded on the following simple processes. When a part of the body has found some projection of the ground which affords it a point of support, the ribs are drawn more closely together, on alternate sides, thereby producing alternate bends of the body. The hinder portion of the body being drawn after, some part of it (c) finds another support on the rough ground or a projection; and, the anterior bends being stretched in a straight line, the front part of the body is propelled (from a to d) in consequence. During this peculiar locomotion the numerous broad shields of the belly are of great advantage, as by means of their free edges the snake is enabled to catch and use, as points of support, the slightest projections of the ground. A pair of ribs corresponds to each of these ventral shields. Snakes are not able to move over a perfectly smooth surface. The conventional representation of the progress of a snake, in which its undulating body is figured as resting by a series of lower bends on the ground whilst the alternate bends are raised above it, is an impossible attitude, nor do snakes ever climb trees in spiral fashion, the classical artistic mode of representation. Also the notion that snakes when attacking are able to jump off the ground is quite erroneous; when they strike an object, they dart the fore part of their body, which was retracted in several bends, forwards in a straight line. And sometimes very active snakes, like the cobra, advance simultaneously with the remainder of the body, which, however, glides in the ordinary fashion over the ground; but no snake is able to impart such an impetus to the whole of its body as to lose its contact with the ground. Some snakes can raise the anterior part of their body and even move in this attitude, but it is only about the anterior fourth or third of the total length which can be thus erected.

With very few exceptions, the integuments form imbricate scale-like folds arranged with the greatest regularity; they are small and pluriordinal on the upper parts of the body and tail, large and uniserial on the abdomen, and generally biserial on the lower side of the tail. The folds can be stretched out, so that the skin is capable of a great degree of distension. The scales are sometimes rounded behind, but generally rhombic in shape and more or less elongate; they may be quite smooth or provided with a longitudinal ridge or keel in the middle line. The integuments of the head are divided into non-imbricate shields or plates, symmetrically arranged, but not corresponding in size or shape with the underlying cranial bones or having any relation to them. The form and number of the scales and scutes, and the shape and arrangement of the head-shields, are of great value in distinguishing the genera and species, and it will therefore be useful to explain in the accompanying woodcut (fig. 3) the terms by which these parts are designated. The skin does not form eyelids; but the epidermis passes over the eye, forming a transparent disk, concave like the glass of a watch, behind which the eye moves. It is the first part which is cast off when the snake sheds its skin; this is done several times a year, the epidermis comes off in a single piece, being, from the mouth towards the tail, turned inside out during the process.

The tongue in snakes is narrow, almost worm-like, generally of a black color and forked, and it terminates in an extremity of extremely fine filaments. It is often exerted with a rapid motion, sometimes with the object of feeling some object, sometimes under the influence of anger.

Snakes possess teeth in the maxillaries, mandibles, palatine and pterygoid bones, sometimes also in the intermaxillary; they may be absent in one or the other of the bones mentioned. In some of the poisonous snakes the teeth are simple and uniform in structure, thin, sharp like needles, and bent backwards; their function consists merely in seizing and holding the prey. In some all the teeth are nearly the same size; others possess in front of the jaws (Leyodonts) or behind in the maxillaries (Diceratherians) a tooth more or less conspicuously larger than the rest; these again are distinguished by this larger posterior tooth being grooved along its outer face.

The snakes with this grooved kind of tooth have been named thylaphites, and also Sasia, because their saliva is more or less poisonous. In the true poisonous snakes the maxillary dentition has undergone a special modification. The so-called colubrine venomous snakes, which retain in a great measure an external resemblance to the innocuous snakes, have the maxillary bone not at all, or but little, shortened, armed in front with a fixed, erect fang, which is provided with a deep groove or canal for the conveyance of the poison, the fluid being secreted by a special poison-gland. One or more small ordinary teeth may be placed at some distance behind this poison-fang. In the other venomous snakes (vipersines and crotalines) the maxillary bone is very short, and is armed on the outside with a single very long curved fang with a canal and aperture at each end. Although firmly anchylosed to the bone, the tooth, when at rest is laid backwards, is erectile,—the bone itself being mobile and rotated round its transverse axis. One or more reserve teeth, in various stages of development, lie between the folds of the gum and are ready to take the place of the one in function whenever it is lost, worn out, or detached, or broken off.

The poison is secreted in modified upper labial glands, or in a pair of large glands which are the homologues of the parotid salivary glands of other animals. For a detailed account see West, J. Linn. Soc. xxv. (1885), p. 419; xxvi. (1898), p. 517; and xxvii. (1900).

A duct leads to the furrow or canal of the tooth. The Elapinae have comparatively short fangs, while those of the vipers, especially the crotalines, are much longer, sometimes extending to the length of the first joint of the finger. The Viperidae alone have "erectile" fangs. The mechanism is explained by the diagrams (fig. 4). The poison-bag lies on the side of the head between the eye and the mandibular joint and is held in position by strong ligaments which are attached to this joint and to the maxilla so that the act of opening the jaws and concomitant erection of the fangs automatically squeezes the poison out of the glands.

Snakes are carnivorous, and as a rule take living prey only; a few feed habitually or occasionally on eggs. Many swallow...
snakes

their victim alive; others first kill it by smothering it between the coils of their body (constriction). The effects of a bite by a poisonous snake upon a small mammal or bird are almost instantaneous, preventing its escape; and the snake swallows its victim at its leisure, sometimes hours after it has been killed. The prey is always swallowed entire, and, as its girth generally much exceeds that of the snake, the progress of deglutition is very laborious and slow. Opening their jaws to their fullest extent, they seize the animal generally by the head, and pushing alternately the right and left sides of the jaws forward, they press the body through their elastic gullet into the stomach, its outlines being visible for some time through the distended walls of the abdomen. Digestion is quick and much accelerated by the quantity of saliva which is secreted during the progress of deglutition, and in venomous snakes probably also by the chemical action of the poison. The primary function of the poison-apparatus is to serve as the means of procuring their food, but

it also serves for defence. Only very few poisonous snakes (like Naja naja) are known to resent the approach of man so much as to follow him on his retreat and to attack him. Others are much less inclined to avoid collision with man than innocuous kinds. They have thus become one of the greatest scourges to mankind, and Sir J. Fayrer has demonstrated that in India alone annually some 20,000 human beings perish from snake-bites. Therefore it will not be out of place to add here a chapter on snake poison and on the best means (ineffectual though they be in numerous cases) of counteracting its deleterious effects. An excellent account of the nature and of the effect of the venom of snakes, by Charles J. Martin, is in Allbutt's System of Medicine. The following condensed account has been abstracted from it.

The poison is a clear, pale-yellow fluid which reacts acid, and contains about 30% of solids, but this varies according to the state of concentration. Most venoms are tasteless, but cobra poison is said to be disagreeably bitter. Dried venom is also said to keep indefinitively, and dissolves readily in water. It keeps in glycerine or alcohol. It dissolves in solution and is in fact a pure solution of two or more poisonous proteins, which are the active agents, with a small quantity of an organic acid or colouring matter. The venom is destroyed by reagents which precipitate proteins in an insoluble form, or which destroy them, e.g. silver nitrate or permanganate of potash. Hypochlorites have the same effect. But carbolic acid and caustic potash destroy it only after a day or two. Frequently they are not a remedy but a further injury, as the action of the finger is the best remedy of all if a large snake has bitten it.

Internal Remedies.—The administration of enormous doses of albumen, or blood, is condemned as being of no service, and in fact the animal is not prevented from swallowing its victim. Strychnine is said to have the property of destroying the poison at once. There are many other substances that have been tried, but not generally in a very methodical spirit. The injection of considerable quantities of serum of animals which have
been partially immunized by repeated doses of [that particular] snake-venom. Unfortunately this treatment will not often be available. Several mammals and birds are supposed to be immune by nature against snake-venom. Some more or less immune creatures are the mongoose, the hedgehog and the pig, the secretary-bird, the honey buzzard, the stork and probably other snake-eaters.

Snakes are oviparous; they deposit from ten to eighty eggs of an ellipsoid shape, covered with a soft leathery shell, in places where they are exposed to and hatched by moist heat. The parents pay no further attention to them, except the pythons, which incubate their eggs by coating their body over them, and fiercely defend them. In some families, as many freshwater sea snakes, Viperinae and Crotalinae, the eggs are retained in the oviduct until the embryo is fully developed. These snakes bring forth living young.

The classification of snakes has undergone many vicissitudes. J. Müller (Zeitschr. J. Physiol., 1831, p. 265) divided them into Ophidia macrostoma and O. microstomata. A. M. C. Duméril (Catal. méthodique, Mus. d'Hist. Nat., Paris, 1851, p. 199) distinguished between Opoterodonta, Aglychodontia, Proteroglyphia and Solenoglyphia. H. Stannius (Zoönomie d. Amphib., 1856) made a further improvement by combining the principles used by his predecessors, and he divided the Anguimorpha or narrow-mouthed snakes into Tortrixina, Typhlonipha and Uropeltacea; the Euryzomata into Iboola or poisonous, and Asinea or innocuous snakes. Meanwhile J. E. Gray (Cat. Snakes of Brit. Mus., 1864), in an article on the systematics of British snakes, divided between the Brit., Virgin and Cubulrina. A. Günther (Cat. Colubrine Snakes, Brit. Mus., 1858; "Reptiles of British India," Ray Soc., 1864; article Snakes, Ency. Brit., 9th ed.) recognized at last four sub-orders: —Hopoterodonta, Colubrinae, Colubroidea and Briformes. Viperiformes; the most serious drawback being the merging of the Peropoda in the non-poisonous Colubrinae.

E. D. Cope (Proc. Ac. Philad., 1864, p. 236) resorted to the modifications of the squamosal, ecto- and endopercygodry bones, the condition of the vestigial limbs, and the teeth: —Scelophysidea (Typhlopidae), Catodonta (Glaucognidae), Tortrixina (Ilyostomata and Uropodidae), Asinea, Proteroglyphia and Solenoglyphia. He adhered to this arrangement in his last comprehensive work (Crocodilia, Lizards and Snakes of North America, 1898, Smithsonian Inst., 1900), but combined the Asinea and Proteroglypha as Colubroidea, subdividing these into Peropoda, Aglychodontia, Glyphodonta, Proteroglyphia and Platycerca (Hydropodinae). In his last work he used, with doubtful success, the variations of the bones and the lengths as additional characters, chiefly for the grouping of the great mass of the Colubroid snakes. G. A. Boulenger (Cat. Snakes, Brit. Mus., 1893-1896) accepted Cope's principles, and mainly by combining the Asinea, Viperinae with the Opisthognatha and Proterodonta wherein he was followed by Cope, as mentioned above — and separating therefrom the Peropoda or Boïidae, he has produced a logically-considered system, by far the best hitherto proposed. It is followed in the present article.

Boulenger's phylogenetic system stands as follows:

**Snakes**

### Viperidae

- **Uropeltidae**
  - *C. Uropeltis*
  - *C. Proteroglypha*
  - *Amphibolidae*

- **Boidae**
  - *S. Xenopteris*
  - *Colubraidae* *Aplysa*

### Typhlopidae

- *Boilae* *Glaucidae*

This means that the Boidae retain most primitive characters. Likewise primitive, but in various respects degraded, mainly owing to burrowing habits, are the Typhlopidae with the Ilyidae, and Uropodidae as terminal branch, and on the other hand the Glaucidae. The solitary Xenopteris is in several ways intermediate between Boidae and Ilyidae. The rest of the snakes are supposed to have started from some primitive, non-degenerate, therefore boa-like group, leading by loss of the vestiges of the hind-limbs and loss of the coronoide bone of the mandible to the aglyphous or innocuous Colubridae, whence further differentiation in three new lines has taken place,—(1) the harmless Amblycephalidae as a side-issue, (2) the very poisonous Proteroglypha Elapidae, (3) the moderately or incidently poisonous Opisthognatha, out of some of which seem to have arisen the venomous Viperidae.

I. No ectopertogryd; pteryogyd not extending to quadrates; no supratemporal or squamosal; prefrontal forming a suture with nasal; coronoid present; vestiges of pelvis present.

- Maxillary vertical, loosely attached, toothed; mandible toothless; a single pair of pelvis bones: *Typhlopidae*

- Maxillary bordering the mouth, forming sutures with the pre-maxillary, prefrontal and frontal, toothless; lower jaw toothed; pabís and ischium present, the latter forming a symphys: *Glaucidae*.

II. Ectopertogryd present; upper and lower jaws toothed.

A. Coronoid present; prefrontal in contact with nasal.

1. Vestiges of hind-limbs; supratemporal present.
   - Squamosal large, suspending the quadrates: *Boilae*.
   - Squamosal small, intercalated in the cranial wall: *Ilyidae*.

2. No vestiges of limbs: squamosal absent: *Uropeltidae*.

B. Coronoid absent; squamosal present.

1. Maxillary horizontal; pteryogyd reaching quadrates or mandible.
   - Prefrontal in contact with nasal: *Xenopteris*.
   - Prefrontal not in contact with nasal: *Colubridae*.

2. Maxillary horizontal; pteryogyd not reaching quadrates or mandible: *Amphibolidae*.

3. Maxillary vertical; pteryogyd reaching quadrates or mandible: *Viperidae*.

For ordinary practical purposes this synopsis is useless, most of the anatomical characters being visible only in the muscled skull. The following characteristic of the families is based upon more accessible features.

- Eyes verti-gal or hidden; lower jaw toothless; without enlarged ventral scales: *Typhlopidae*.
- Eyes verti-gal; teeth restricted to the lower jaw; without enlarged ventral scales: *Glaucidae*.
- Eyes very small; head not distinct; teeth in the upper and lower jaws; ventral scales scarcely enlarged, tail extremely short, ending obtusely and covered with peculiar scales: *Uropeltidae*.
- Eyes functional, free, with vestiges of the hind-limbs appearing as claw-like spurs on each side: *Viperidae*.
- Ventral scales scarcely enlarged: *Ilyidae*.
- Ventral scales transversely enlarged: *Boilae*.
- Eyes free; with a pair of poison-fangs in the front part of the mouth, carried by the otherwise toothless, much shortened, and vertically erectile maxillaries; ventral scales transversely enlarged: *Viperidae*.

All the remaining snakes combine the following characters. The maxillaries are typically horizontal, not separately movable, with a series of teeth. The mandible is toothed but has no coronoid bone. There are no vestiges of limbs or of their girdles. The eyes are free.

- Dentine movable attached to the tip of the articular bone of the mandible. Skin beautifully iridescent: *Xenosetid*.
- Without a mental groove; the ends of the pteryogryds are free, not reaching the quadrates. Head thick and very distinct: *Amphibolidae*.
- With a median longitudinal groove between the shields of the skin: *Colubridae*.

**Family I. Typhlopidae.**—Burrowing snakes, mostly small, which have the body covered with smooth, shiny, uniform cycloid scales. The teeth are restricted to the small maxillary bones. The quadrates slant obliquely forward and are attached directly to the prootics, owing to the absence of squamosals. The prefrontals are in lateral contact with the nasals. The vestiges of the pelvis are reduced to a single bone on each side. There are no traces of limbs. The eyes are hidden by shields of the skin. The mouth is very narrow, and the halves of the under-jaw are not distensible. About ten species of these rather archaic snakes are known; in adaptation to their burrowing life and worm and insect diet, they have undergone degradation. The tail is mostly very short and sometimes ends in a boïny spine. They are widely distributed in all tropical and sub-tropical countries, even in such solitary places as Christmas Island, but they do not occur in New Zealand. The chief genus is *Typhlops*,

---

![FIG. 5—Typhlops orbicularis, from India, natural size.](image-url)
**SNAKES**

of which, for instance, *T. braminus* ranges from southern Asia, the islands of the Indian Ocean and the Malay Islands to southern Africa.

**Family 2. GLAUCONIIDAE.**—Burrowing like the Typhlopidae, which they much resemble externally, but the maxillaries retain their normal position and are toothless, teeth being restricted to the lower jaw. They are small, stout, and not distensible. The pelvic girdle and the hind limbs show the least reduction found in any recent snakes, ilia, pubes and ischii being still distinct, the ischiial bone is black and thinning down to the hypophyseal, and there are small vestiges of the femurs. About 30 species, mostly of the genus *Glaucosia*, in south-western Asia, Africa, Madagascar, the Antilles and both Americas. *G. carinata* extends northwards into Texas, *G. humilis* into California.

**Family 3. ILYSIDAE.**—Mostly burrowing. The scales of the long, cylindrical body are large and small, scarcely enlarged on the ventral side. The tail is extremely short and blunt. The head is very small and not distinct from the neck. There is a usual feature in burrowing snakes and lizards. The gape of the mouth is narrow. The quadrates are bones are short and stand rather vertically. The squamosals form part of the cranial wall, being firmly wedged in between the quadrate, prootic and occipital bones. Vestiges of the pelvis and hind limbs are small, but they terminate in club-like processes which protrude through the skin. The sides of the body are either poorly scaled, as in the Boidae. The small eyes are sometimes covered by transparent shields. About half of the species are snakes. *B. jaculus,* *B. casarca* (India), *B. corallus* (Australia), *B. aesculapii* (China) is beautiful coral-red with black rings, grows to nearly a yard in length, and is said sometimes to be worn as a necklace by native ladies.

**Family 4. UROPTERIDAE (RHINOPHIDAE).**—Burrowing snakes of Ceylon and southern India, with a very short tail which ends in a peculiar, often obliquely truncated, shield, hence the name. The eyes are very small, the scales are smooth, small, and flat, but little larger on the belly. The coloration is mostly beautiful, black and red. *Uropterus* is an ichthyophis, the eyes usually covered by transparent shields. *Rhinosaurus* is a live in southern India; it is black above with a bluish gloss, the belly is bright red with black spots, like the convex tail-shield.

**Family 5. Botoidae.**—Botoids, often very large, snakes, which have vestiges of pelvis and hind limbs, the latter appearing as claw-like spurs on each side of the vent. The scales of the upper surface are usually small and smooth, while those of the belly form one broad series. The quadrate is carried by the horizontally-elongated squamosal, which rests loosely upon the skull. The prefrontals are in contact with the nasals. Sharp, recurved teeth are carried by the mandibles, the prezygoids, palatines, maxillaries, and in the Pythoninae by the prezygymbles. The Boidae comprise some 60 species, which have been grouped into many fancy genera. The range of the family extends over all the tropical and subtropical countries, including the west and central Pacific and the Ryukyus.

Sub-family 1. Pythoninae.—With a pair of supraorbital bones between the prefrontal, frontal and postfrontal bones. The maxilla generally carries a few small teeth. The suboculars are small, and are restricted to the palatine and the basisphenoid.

Sub-family 2. Botoids. Without supraorbital bones. The premaxilla is toothless. The suboculars form mostly a single row. Widely distributed. *Boa* (g., *BOA*) in tropical America and with two species in Madagascar, *Eunectes marina*, the Amournda (g., *A. madagascariensis*), *Charina*, e.g., *botala* (s., *C. botala*), *Eryx juvencus* and *Eryx jucundus*, also a sand-snake, from North Africa to Central Asia, and extending into Greece. *Elaphrus*, ranging from New Guinea to the Fiji Islands. *Crotaphis duxentia* (from the Boa region) by the rock-climbing genus, restricted to the palatine and round Island near Mauritius. This makes the occurrence of a species of *Crotalus* in Madagascar less remarkable, while all the others live in Central and South America.

**Family 6. Xenopetalidae.**—One species, *Xenopeltes unicolor*, in south-eastern Asia and Malay Islands. Bowler rightly considers this snake in various ways intermediate between the Ilyosidae, *Boidae* and *Colubridae*. The prefrontal bones are still in contact with the nasals as in the previous families, but the coroid bones of the lower jaw are absent in the large size. It occurs in the Boine *Charina*. The most remarkable feature is the dentary bone, which is movable attached to the much-elongated bone (cf. *Polyodoncus*). The mobility being enhanced by the absence of the coroid bone. The tail is short and thick, and is carried by the broad and short squamosal, which lies flat against the skull, reminding in this respect of *Ilysa*. The genus is restricted to the Malay Peninsula, and hence the generic name of this peculiar snake, which reaches the length of one yard.

**Family 7. Colubridae.**—This family horizontal and forming the greatest number of species, the upper jaw, which is broader-like in *Boidae*; coroid of manible absent. Pterygoids connected with the quadrates which are carried by the squamosals, and these are loosely attached to the skull. Prefrontals in contact with the basals. Ectopterygoids present. No vestiges of limbs. Very generally comprises about nine-tenths of all recent species of snakes and is cosmopolitan, New Zealand being the most notable exception. The 1900 to 1400 species belong to arboreal and aquatic forms, many of which are highly specialized.

Boulenger, adopting Duméry's terms, has divided them into three parallel series.

—All the teeth are solid, and not grooved. Harmless, non-poisonous.

B. *Opisthoglypha.*—One or more of the posterior maxillary teeth are grooved. Most of these snakes, which number about 300 species, are aquatic.

C. *Protoglypha.*—The anterior maxillary teeth are grooved or perforated. About 200 very poisonous species, e.g., *cobras*, *corals*, and *sea- snakes.

The second and third series containing only about 400 species, the Aglypha still present the appalling number of 1000 species, and even the grouping of this mass into three sub-families does not greatly modify the number. Each sub-family consists of only one, and the other a very few species. We have therefore still 1000 species, all closely allied that they together are but of sub-family rank. They possess few reliable characters; surface modifications are not great, and it is almost certain that some of these characters, and their combinations, have been developed independently and in different countries. Many of the sub-tribes contain a single genus, or groups of genera, consequently not to be used either as witnesses of blood-relationship or of geographical distribution.

Of the usual characters employed for systematic purposes, for the making of convenient keys, are the following: The number of rows of scales across the body and in a longitudinal direction; shape and structure of scales, whether smooth or with a longitudinal keel; arrangement of the shields on the head; shape of the coronoid process; the form of the prezygoids; the shape of the postzygoids; the number of vertebrae. Above all, the dentition, which exhibits almost endless modifications, in most cases is difficult to ascertain and to appreciate in its subtle distinctions. Internal, skeletal characters, useless for ordinary practical purposes, are the various apophyses, the central side of the vertebrar and the penal armaments fancied by Cope.

It is impossible here to mention any but the more obvious genera and sub-tribes of the colubridae.

**Series A. AGLYPHA.**—Sub-family 1. *Acrochordinae.*—The few genera and species of these ugly-looking snakes are mostly aquatic, inhabiting rivers and estuaries of S.E. Asia; but *Boa*, *Nothobis*, *Loti* and *L. f. Darius* and another, *Sinoboa*, is found in the Khasia Hills of N.E. India. *Acrochordus javanicus* has no large vertebral shields; the flat, vipers-black looking head is covered with small granules, with the eyes and nostrils well on the upper surface. *Chersodrym* ranges from Madras to New Guinea; the body and tail are laterally compressed and form a ventral fold which is covered with tiny scales like the rest of the body. The main body of the snout is of the Atlantic and the *Colubridae* is restricted to the posterior border of the oribis, separating the latter from the frontals.

**Sub-family 2. Colubrinae.**—The postfrontal bones are restricted to the posterior border of the oribis. The maxillary and dentary bones carry teeth on their whole length. This sub-family contains about 1000 species; few of them reach a length of more than two feet. *Boa* (g., *Boa*), *Zoaca s. Coryphodon*, which grow to 10 ft. Most of them are oviparous. Some are more and less aquatic, others are absolutely arboreal, others again prefer dry, sandy or damp ground. They are mostly cosmopolitan, excepting the New Zealand sub-region, and finds its natural N. limit on the permanently frozen underground, where hibernation is of course impossible. Only a few out of the multitude belonging to *gastrophis*. *Echis* is a genus in the series, and is very peculiar. Its coloration varies from pale golden brown to black; the scales are
smooth and shiny. Its original home is Italy and S.E. Europe, whence it has spread N. into S. Germany. Its occurrence at widely distant and isolated localities was formerly supposed to be due to its introduction by the Romans. C. corais, from the S. states of North America, reaches 8 ft. in length. C. (Ptycho-
ophis) sayi, C. caldenfcr and others in N. America.

Coronella, widely distributed excepting Australia and S. America, C. austrica s. laevis, the "smooth snake" of Europe, in England, in Hampshire and Dorsetshire, eats chiefly lizards; owing to its coloration, which varies much, it is often mistaken for the viper. C. petrae is one of the many N. American species, e.g. Z. muscor the Indian "rat-snake," Z. constrictor in the United States. Some species of the Central and S. American genus Urobotha bear an extraordinary resemblance in coloration to the pretty, black, red and yellow poisonous Elap. Dendrophis of India and Australia (e.g. B. pictus of India) and Leptophis s. Ahaetulla (e.g. L. terrificus, neotropical) may be taken as examples of long and slender tree-snakes.

Tropidonotus, with near 100 species, is cosmopolitan with the exception of New Zealand. Some of the species, like the Indian T. quincuncis and T. stolatus of the N. American T. ordinatus, are perhaps more abundant as regards the number of specimens than any other snake. T. natrix, the grass or ringed snake, is very common in Europe, including England but not Scotland or Ireland; easily recognized even at a distance by two yellow or white spots which it has behind its head. It grows rarely to a length of 4 ft.; it never bites, and feeds chiefly on frogs, toads and fishes, but mice are never taken. Its eggs, which are of the size and shape of a slight part of an egg of a dove's egg, are from fifteen to thirty in number, are deposited in mould or under damp leaves, and are glued together into one mass.

Dendrophis of Madagascar, S.E. Asia and Central America is remarkable for having the dentary bones loosely attached to the apex of the elongated articular bone. Calamaria of Indo-China is an example of burrowing snakes, with a short tail and small eyes; In Typhlopsidae of the Philippines the eyes are concealed, and the subfamily 3. Rhachitodidae, represented by Dasypeltis scabra of tropical and S. Africa. Characterized by possessing only a few teeth, on the posterior part of the maxillaries, on the palatines and dentaries; some of the vertebrae in the lower region of the neck have strongly developed hypophyses (not provided with a cap of enamel, as has often been asserted), which are directed forwards and pierce the oesophagus. The principal diet of these peculiar snakes seems to consist of eggs. In Cape Colony they are known as "egg eaters." A Malayan species eats in capsules and with a body not thicker than a man's little finger, is able to swallow a hen's egg, a feat which seems quite impossible. As the egg passes at last through the alarmingly distended neck, the snake makes some slight contortions and the swelling collapses, the shell having been filed through by the saw-like apparatus. Whilst the contents are thus retained without loss, the crumpled shell is then vomited out. This peculiar arrangement occurs also in an Indian snake, Elachistodon, which represents, however, a sub-family of the Opisthophyidae. In another, probably also egg-eating snake, the Indian

Coronelline Nymphiphidium, the same effect is reached by two prominences at the base of the skull.

Series B. OPHTHALMOGLYPHA. One or a few, of the posterior maxillary teeth have a groove or furrow in front, which conducts the secretion of the enlarged upper labial glands. They are all more or less poisonous, paralysing their prey before, or during the act of swallowing; the poison-fangs are standing outwards, and, the teeth of these snakes cannot easily inflict wounds with them on man; moreover, the poison is not very strong and not available in large quantities. It may well be doubted whether Opisthophyphus form one genuine group instead of a heterogeneous assembly. They comprise about 300 species of terrestrial, arboreal and aquatic forms, and as a group they are almost cosmopolitan, including Madagascar, but excepting New Zealand.

Sub-family 1. Dipodophorinae.—Nostrils lateral; dentition well developed. Long-tailed, terrestrial and arboreal forms. The tree-snakes are mostly green above with the under parts white or yellow.

Coeolophis, with concave, or grooved scales; C. macrops, on of the largest European snakes in Mediterranean countries and south-western Asia.

Dipodophorus, Diphas, Leptognathus, Dryophis, Dendrophis and other closely allied genera are typical, very long-bodied and long-tailed tree-snakes, chiefly tropical. The graceful form of their body, the elegance and rapidity with which they pass from tree to tree, the exquisite beauty of their colours have been the admiration of all who have had the good fortune to watch them in their native haunts. The majority lead an exclusively arboreal life; only a few descend to the ground in search of prey. These few are found in the tree-snakes, or arboreal snake—birds, tree-frogs, tree-lizards, &c. All seem to be diurnal, and the larger kinds attain a length of about 4 ft. The most beautiful of all snakes is probably the arborescent variety of Chry-

ophis ornatus, a species extensively distributed in the more

dry forests of Central America, and also in Peru, Brazil and southern Brazil. Another species of Chry-

ophis, C. viridifemur, is found in the same parts. It is a

fairly large species, with a slender body, a yellow coloration, black or brown markings on the back and sides, and a black or brown tail. The head is small, with a smooth, shiny skin, and the eyes are large and round. The scales are flat and smooth, and the body is slender and graceful. The species is widely distributed in the Indomalayan region, from Japan to the Philippines, and also in India and Sri Lanka. It is a daytime snake, active and agile, and is found in forests and jungles, where it feeds on small birds, frogs, and lizards. The species is known for its gentle nature and lack of aggression, and is a popular pet among snake enthusiasts. It is also useful in removing pests from gardens and farms.

Sub-family 2. Elachistodonidae.—Represented by Elachistodon westermanni of Bengal, with the same peculiar dentition and with sharp hypophyses on the vertebrae of the lower neck, as described by the author.

Sub-family 3. Homalopsinae.—The nostrils of these absolutely aquatic, viviparous snakes are valvular and placed on the upper surface of the head, the eyes are subocular. About two dozen ugly-looking species inhabit rivers and estuaries from Bengal to Australia. Cerberus rhynchops; Hypotriphla plumbea, Homalopsis; Hipsites hydridus of Siam has a compressed body, and much resembles the Hydrophibidae and its partly marine life. Herpeton of Cambodia has a pair of long tentacles on the snout and is said to have a partly vegetable diet.

Series C. PTEROBOGLYPHA. The anterior maxillaries are deeply grooved, or so folded as to appear hollow or perforated. Behind these enlarged poison-fangs follows a series of smaller, solid

Fig. 7.—Dasypeltis scabra, in the act of swallowing an egg. Nat. size.
teeth, hence the term "proteroglypha," which is intended to mean that the anterior teeth are grooved. These snakes are all very poisonous, mostly viviparous and found in all tropical and sub-tropical countries, with the exception of Madagascar and New Zealand.

Sub-family 1. Elapinae.—Terrestrial, with a cylindrical tail, comprising about 150 species which have been grouped into numerous genera, mostly upon very slight differences. The most remarkable are the following. *Naja tripludans* and *N. haje*, the cobra (q.v.). The largest species is the *N. bungarus* s. elaps, the "hamadryad," "snake-eating cobra," or king-cobra of Indian countries, reaching more than 12 ft. in length, and living mainly upon other snakes. *Sepedon haemachates*, of S. Africa, is named by the Boers "roode koper kapel" or "ring-hals," i.e. banded neck, the latter name being, however, often applied also to the cobra. It resembles in colour some varieties of the latter snake, and, like this, it has the power, though in a less degree, of expanding its body. But its scales are keeled and its form is more robust. It is equally active and courageous, not rarely attacking persons who approach too near to its resting-place. In confinement it evinces great ferocity, opening its mouth and erecting its fangs, from which the poison is seen to flow in drops. During such periods of excitement it is even able, by the pressure of the muscles on the poison-duct, to eject the fluid to some distance; hence it shares with the cobra a third Dutch name, that of "spuw slang" (spitting snake). It grows to a length of 2 or 3 ft. Another kind is the "schapsticker" (sheep stinger), *S. rhombatus*. It is extremely common in S. Africa, and extends far N. along the E. as well as W. coast. It is of smaller size than the preceding, and causes more injury to animals, such as sheep, dogs, &c. than to man.

The species of *Bungarus*, four in number, are extremely common in India, Burma, and Ceylon, and are distinguished by having only one row of indistinct sub-caudal shields. Three of these species have the body ornamented with black rings, but the fourth and most common (*B. coeruleus*), the "tiger-snake," possesses a double and more uniform decoration. The fangs of the bungarums are shorter than those of the cobras, and cannot penetrate so deep into the wound. Their bite is therefore less dangerous and the effect on the general system slower, so that there is more prospect of recovery by treatment. Nevertheless, the krait is probably the most destructive snake to human life in India, since it is very common and often creeps into the houses. *Delophis intestinalis* of Indo-China has enormously developed poison glands, which extend down the whole anterior third of the body, in front of the heart.

No part of the world possesses so many snakes of this sub-family as Australia, where, in fact, they replace the non-vomous colubrine snakes; many of them are extremely common and spread over a great many areas. Fortunately the majority are of small size, and their bites are not followed by more severe effects than those from the sting of a hornet. Only the following are dangerous to man and larger animals: the "death-adder," *Acanthophis antarcticus*, easily recognised by the peculiar end of the tail, which is compressed and terminates in a thin horny spine; common throughout Australia to the Moluccas, scarcely one yard in length; the "black snake" (*Pseudonaja porphyriacus*), likewise common throughout the Australian continent, especially in low marshy places, and upwards of 6 ft. in length; it is black, with each scale of the outer series red at the base; when irritated it raises the fore part of its body and flattens out its neck like a cobra, the females are sometimes known as "brown adders"; the "tiger-snake," *Notechis scutatus* (s. *Hoplocephalus curtus*), with a similar distribution, and also common in Tasmania, from 5 to 6 ft. long, and considered the most dangerous of the tribe. Good descriptions and figures of all these snakes are given in Krefft's *Snakes of Australia* (Sydney, 1869, 4to).

Several genera of the Elapidae lead a more or less burying life; their body is of a uniform cylindrical shape, terminating in a short tail, and covered with short polished scales; their head is short, the mouth rather narrow, and the eye small. They are the tropical American *Elaps*, the Indian *Callophis*, the African *Poecilophis* and the Australian *Vermicella*. The majority are distinguished by the beautiful arrangement of their bright and highly ornamental colours; many species of *Elaps* have the pattern of the so-called coral-snakes, their body being encircled by black, red and yellow rings—a pattern which is peculiar to snakes, venomous as well as non-venomous, of the fauna of tropical America. Although the poison of these narrow-mouthed snakes is probably as virulent as that of the preceding, man has much less to fear from them, as they bite only under great provocation. Moreover, their bite must be frequently without serious effect, owing to their narrow mouth and the small size of their poison-fangs. They are also comparatively of small size, only a few species rarely exceeding a length of 3 ft., for instance *Elaps fulvius*, which extends into the S. states of N. America.
Sub-family 2. Hydrophinae.—Tail laterally compressed; marine. Of sea-snakes some fifty species are known. All are inhabitants of the tropical Indo-Pacific Ocean, and are found round the numerous islands of the Philippine Sea, Persian Gulf, in the East Indian Archipelago, and in the seas between S. Japan and N. Australia. One species which is extremely common (Pelamis bicolor), and which is easily recognized by the black colour of its upper and the yellowish tinge of its lower parts (but P. estreus being sharply defined), has extended its range W. to the sea round Madagascar, and E. to the Gulf of Panama. One species, however, Distius semperi, is confined to the western Lake Tadlac at Luzon in the Philippines. Sea-snakes are viviparous and pass their whole life in the water; they soon die when brought on shore. The scales are very small, often very much reduced, and there are frequently no enlarged ventrals on the compressed belly, but Pelamis has broad ventrals. Their motions in the water are almost as rapid as they are uncertain and awkward when the animals are removed out of their proper element. Their nostrils are placed quite at the top of the snout. These openings pass into small and minute slits in the valve interioiy, which is opened during respiration, and closed when the animal dives. They have very capacious lungs, extending backwards to the anus; by retaining air in these extensive lungs they are able to float on the surface of the water and to remain under water for a considerable length of time. Sea-snakes shed their skin frequently; but it peels off in pieces as in lizards, and not as in the freshwater snakes, in which the integuments come off entire. Several species are remarkable for the marked slenderness and pliability of their body; the anterior part of the body, and very small head. The eye is small, with round pupil, which is almost always of the light; and this in which it lies concealed opens near to the front margin of the lower jaw; scarcely more than two of the terminating sensory organs are exerted from the mouth when the animal is in the water. The mouth shuts in a somewhat different way from that of other snakes: the middle of the rostral shield is produced downward into a small lobe, which prevents the water from entering the mouth; there is generally a small flange on each side of the lobe for the passage of the two points of the tongue. The food of sea-snakes consists entirely of small fish; among them species with very strong spines. As all these animals are killed by the poison of the snake before they are swallowed, and as their muscles are perfectly relaxed, their armature is harmless to the snakeman who loses his prey to the head, and depresses the spines as a precaution. Sea-snakes belong to the most poisonous species of the whole order. Accidents are rarely caused by them, because they are extremely shy and swim away on the slightest alarm; but, when pressed in their natural retreat, they will, like any other poisonous terrestrial snake, dart at the disturbing object; and, when out of the water, they attempt to bite every object near them, even turning round to wound their own bodies. They cannot endure captivity, dying in the course of two or three days, even when kept in capacious tanks. The greatest size to which some species attain, according to positive observation, is about 12 ft., and therefore far short of the statements as to the length of the so-called sea-serpents (g.g.) Boulenger has written an interesting account of sea-snakes in *Natural Science*, i. (1892), p. 44 seq.

Family 9. Viperidae.—The sphenoids are widely separated from the quadrates, not reaching beyond the level of the occipital condyle. This condition can be ascertained without dissection, when the mouth is opened widely. The squamosals are reduced to part-like vestiges. Otherwise these snakes agree with the terrestrial Colubridae. Externally they are easily distinguished by the absence of a longitudinal groove on the skin. The head is thick, very distinct from the neck and the pupil is vertical. So that these harmless snakes look rather viperid. About 30 species, with several genera, are known from the oriental and neotropical regions. *Amblycephalus*, e.g. *monticola*, with compound body, in S.E. Asia.

Family 10. Hydrophidae.—The maxillaries are very short, movably pivoting upon the prefrontals and also attached to the ectopterygoids, so that they can be erected together with the large poison fangs, which, besides reserve teeth, are the only maxillary teeth. There are also teeth on the palatines, anterior portion of the pterygoids, and on the short dentaries. The short squamosals are very loosely attached to the skull. The prefrontals are in contact with the nasals. The poison-fangs are "solenoglyphous," perforated, having a wide hole on the anterior side at the base, in connexion with the duct of the large, paired, poison-glands, the presence of which adds considerably to the characteristic broadness of the head. The hole leads into a canal, which opens as a semi-canal towards the end of the tooth. The supply of reserve teeth is indefinite; frequently one or two are lying ready and of equal size to the functional fangs.

All the Viperidae are very poisonous and all, except the African *Abrasus*, are viviparous. They include terrestrial, semi-aquatic and burrowing types; none of them with any signs of degradation; on the contrary they belong to the most highly organized of snakes. The family is cosmopolitan, excepting Madagascar and the whole of the Australian region.

Sub-family 1. Vigorinae, vipers (g.r.) or adders.—Without an external pit between eye and nose, and the maxillary bone is not hollowed out above. Absolutely restricted to the Old World, with 9 genera comprising about 40 species.

Sub-family 2. Crotalinae.—With a deep cavity or pit on either side of the eye, and the nose, lodged in the hollowed-out maxillary bone. The lining of these pits is amply supplied with branches from the trigeminal nerves, but the function is still quite unknown. About 60 species of pit-vipers are recognizable. They can easily be divided into 4 genera: *Crotalus* and *Sistrurus* with a rattle at the end of the tail and restricted to America (see *Rattlesnake*); secondly, pit-vipers without a rattle: *Aesciutrodus*, with large shields covering the upper surface of the head; with about 10 species, e.g. *E. halys* in the Caspian district, others in the Himalayas, Ceylon and Sunda islands. Notable American species are the following: *A. piscivorus*, the "water moccasin," the "rattlesnake," and *Sistrurus mordax*, the "moccasin-snake," or "copper-head," so called because of its yellow to pink or pale-brown ground colour, with dark crossbars or triangular marks. The under surface is yellow to reddish, with dark specks. Full-grown specimens are about 1 yd. in length. The moccasin-snake ranges from Massachusetts and Kansas to Florida and Texas and into Mexico, preferring swampy localities or meadows with high grass, where it hunts for small mammals and birds. It is easily distinguished from other North
SNAPDRAGON—SNIPE

American pit-vipers by the possession of a loreal shield, i.e. a shield intercalated between the two preoculars and the posterior nasal; below the lorel lies the pit. And non-occipital vipers have occasionally been mentioned under the name of Trigonecephalus cenchris, one of the many synonyms. Lackeiris has the upper surface of the head covered with very small shields, or with scales, and contains about 40 species, in S. and Central America, the Antilles and also in S. E. Asia. The most ill-famed is L. s. Bettyrop’s C. erughephalus lanceolatus, which includes L. s. Anatra, grubbing into Mexico and the Lower Antilles, notably Martinique, Guadaloupe and Santa Lucia, where it is known as the ‘Fer de Lance’; Mexican call it ‘rato de hueso’ or bone-tail, on account of its curious yellow and grey tip of the tail. It is a very quick and highly irascible beast and even known to turn on its pursuer. It grows to a length of 6 ft., lives in swamps, plantations, forests, on the plains and on the hille, and is very prolific, producing dozens of young, which at birth are 10 in. long and as vicious as their parents.

L. s. Trimerurus gramineus s. viridis s. erythrus is one of the Asiatic species, ranging over the whole of India to Hong Kong, Timor and even to the Andaman and Nicobar Islands. It is arboreal, bright green above; the end of the prehensile tail is usually bright red. (H. F. G.)

SNAPDRAGON, or Antirrhinum (Gr. ἄντιρρηινον, native to central and south Europe, occurring as an alien on old walls in Britain. It is an old-fashioned garden perennial of easy cultivation. Antirrhinum majus, sown in heat, and forwarded until the general time for planting out, becomes a summer annual, and may be so treated; but under a slower and more hardly regime it may be sown in boxes in August, and pricked off into other boxes and wintered in a frame. So treated and planted out in well-prepared beds of good friable garden soil, it will become very showy and effective. The “Tom Thumb” or dwarf strain, obtainable in self and mixed colours, is a very valuable plant for bedding. The named sorts are propagated by cuttings, and wintered in a frame. Some of the double-flowered sorts are interesting. There are forms with white, yellow, rose, crimson, magenta, and variously motled and striped flowers, some of them of great beauty, but the named sorts are too fugitive to make it desirable to record a list.

SNEEK, a town in the province of Friesland, Holland, to the west of Sneek lake, 14 m. by rail S.S.W. of Leeuwarden, with which it is also connected by canal. Steam tramways connect it S.W. with Heerenveen and N.W. with Bolsward and Harlingen. Pop. (1900) 12,075. Sneek is one of the great butter and cheese markets of the province. One of the former city gates (1619) remains, and there are a town hall, communal buildings (1863), court-house, weigh-house, synagogue and churches of various denominations, in one of which is the tomb of the naval hero of the 16th century, Lange, or Groote Pier (Long or Great Peter). The horse-fair of Sneek is widely attended, and there is a considerable activity in trade and shipping.

SNEEZING (O. Eng. feven, from feven, to sneeze, cf. Dutch frieseen, allied to the obsolete nose, and ultimately to be referred to root seen in Gr. νύχτζ, to breathe; the initial s is due to association with numerous words, such as snort, snuff, sneer, &c.), a violent expiration of air from the nose and mouth; it is an involuntary reflex respiratory act; caused by irritation of the nerve-ends of the mucous membrane of the nose or by stimulation of the optic nerve by a bright light. The irritation may be due to the swelling of the nasal mucous membrane, which occurs in catching cold, sneezing being often a premonitory or accompanying symptom, or to foreign bodies in the nose, as by inhalation of snuff or other “earths” or “smoke.” A venerable and widespread belief survives in the custom of saying “God bless you” when a person sneezes. The Hindus say “Live!” to which the answer “with you” is given (E. B. Tylor, Primitive Culture, i. 101). A sneeze was considered a sign or omen from the gods by the Greeks and Romans; it was one of the many common everyday occurrences which if coming at an important moment could be interpreted as presaging the future. There are many allusions to it in classical literature, e.g. Homer, Od. xii. 501, Plutarch. Themist. 13, Xenophon, Anab. iii. 2 and Catullus, Carm. 45. There are references to it in Rabbinical literature, and it has been found in Otaheite, Florida and the Tonga Islands.

SNELL, HANNAH (1723-1792), the “female soldier,” was born at Worcester on the 23rd of April 1723, being the daughter of a hosier. In order to seek her husband, who had ill-treated and abandoned her, in 1745 she donned man’s attire and enlisted as a soldier in Givis’s regiment of foot, but soon deserted, and was named “Snell” or “Swallow” under her brother-in-law’s name of James Gray. The “Swallow” sailed in Boscawen’s fleet to the East Indies, and took part in the siege of Aeaxapong. Hannah served in the assault on Pondicherry and was wounded, but she succeeded in extracting the bullet without calling in a surgeon. When recovered she served before the mast on the “Tartar” and the “Eltham,” but when paid off she resumed woman’s costume. Her adventures were published as The Female Soldier, or the Surprising Adventures of Hannah Snell (1736), and she afterwards gave exhibitions in military uniform in London. She died insane in Bethlehem Hospital on the 8th of February 1792.

SNELL, JOHN (1620-1679), founder of the Snell exhibitions at Oxford, was born in 1620 in Ayrshire, Scotland, the son of a blacksmith. He joined the royalists during the civil war, and fought in several battles, including Worcester. Thereafter he took refuge in Cheshire, where he met Sir Orlando Bridgeman, whose clerk he became, being raised to the offices of court-crier and seal-bearer as his patron was promoted to those of judge and Lord Keeper. Later he was secretary to the Duke of Monmouth and had the management of his Scottish estates. He died at Oxford on the 6th of August 1679, leaving a bequest for sending students from Glasgow University to an Oxford college or hall. The Court of Chancery decided in 1693 that Balliol should receive the beneficiaries.

SNELL, WILLEBRORD (1592-1660), commonly known as Snellius, Dutch astronomer and mathematician, was born at Leiden in 1591. In 1613 he succeeded his father Rudolph Snell (1546-1613) as professor of mathematics in the university of Leiden. In 1615 he planned and carried into practice a new method of finding the dimensions of the earth, by determining the distance of one point on its surface from the parallel of another, by means of a triangulation. His work Eratosthenes Batavus, published in 1617, describes the method and gives the result of his observations between Amstel and Berghem-Zoom a degree of the meridian equal to 55,100 toises=117,449 yards. (A later recalculation gave 57,033 toises=121,509 yards, after the application of some corrections to the measures indicated by himself.) Snell also distinguished himself as a mathematician, and discovered the law of refraction, in 1621 (see Licht). He died at Leiden on the 30th of October 1660.

In addition to the Eratosthenes Batavus he published Cyclometria, sive de circuli dimensione (1621), and Trigynia Batavus s. Historiometria, de navium cursibus et re navibus (1621). He also edited Coeli et siderum in eo errantium observationes Hassiacae (1618), containing the astronomical observations of Landgrave William IV. of Hesse. A trigonomery (Doctrina triangulorum,) by him was published a year after his death.

SNIPE (O. Eng. Snipte, Icel. Snípta, Dutch Snijp, Ger. Schneepfe), one of the commonest Limicoline birds, in high repute no less for the table than for the sport it affords. It is the Scolopax gallinago of Linneaus, but by later writers it has been separated from that genus, the type of which is the Woodcock (q.v.), and has been named Gallinago gallinula. Though considerable numbers are still bred in the British Islands, but notwithstanding the number of those that fall to the gun are undoubtedly of foreign origin, arriving from Scandinavia towards the close of summer or later, and many will outstay the winter if the weather be not too severe, while the home-bred birds emigrate in autumn to return the following spring. Of later years British markets have been chiefly supplied from abroad, most from Holland.

The variegated plumage of the Snipe is subject to no considerable variation, especially in the extent of dark markings on the belly, flanks, and axillaries, while examples are occasionally seen in which no trace of white, and hardly any of buff or grey,
is visible, the place of these tints being taken by several shades of chocolate-brown. Such examples were long considered to form a distinct species, the _S. sabini_, but its invalidity is now admitted. Other examples in which buff or rust-colour predominates have also been deemed distinct, and to those has been applied the epithet _russoa_. Again, a slight deviation from the ordinary formation of the tail, whose rectrices normally number 14, and present a rounded termination, has led to the belief in a species, _S. brehmi_, now wholly discredited. But, setting aside two European forms, there is, at least a score, banded to various parts of the world. Thus _N. America produces G. wilsoni_, so like the English Snipe as not to be easily distinguished except by the possession of 16 rectrices, and Australia has _G. australis_, a larger and somewhat differently coloured bird with 18 rectrices. India, while affording a winter resort to the common species, which besides Europe extends its breeding range over the whole of _N. Asia_, has also at this season the Pin-tailed Snipe, _E. sturna_, in which the number of rectrices is still greater, ranging from 20 to 25, it is said, though 22 seems to be the usual number. This curious variety, considering the ornamental value which it has received, only occurs in the outer feathers of the series, which are narrow in form and extremely stiff, there being always 10 in the middle of ordinary breadth.

Those who only know the Snipe as it shows itself in the shooting-season, when without warning it rises from the boggy ground uttering a sharp note that sounds like _scope_, _scope_, and, after a few rapid twists, darts away, if it be not brought down by the gun, to disappear in the distance after a desultory flight, have no conception of the bird's behaviour at breeding-time. Then, though flushed quite as suddenly, it will fly round the intruder, at times almost hovering over his head. But if the pursuer has patience, he will see it mount aloft and there execute a series of aerial evolutions of an astounding kind. After wildly circling about, and reaching a height at which it appears a mere speck, where it winnows a random zigzag course, it abruptly shoots downwards and, as, and then as abruptly stops to regain its former elevation, and this process it repeats many times. A second season after each of these headlong descents a mysterious sound strikes his ear—compared by some to drumming, and by others to the bleating of a sheep or goat, which sound evidently comes from the bird as it shoots downwards, and then upward. These sounds are produced by the vibration of the webs of the outer tail-feathers, the webs of which are modified. A similar sound may be made by affixing those feathers to the end of a rod and drawing them rapidly downwards in the same position as they occupy in the bird's tail while it is performing the feat.

The air will also ring with loud notes that have been syllabled _tinker_, _tinker_, _tinker_, while other notes in a different key, something like _deip_, _deip_, _deip_ rapidly uttered, may be heard as if in response. The nest is always on the ground, and is a rather deep hollow wrought in a tuft of herbage and lined with dry grass-leaves. The eggs are four in number, of a dark olive colour, blotted and spotted with rich brown. The young when freshly hatched are beautifully clothed in down of a dark maroon, variegated with black, white and buff. The Double or Solitary Snipe of English sportsmen, _S. major_, a larger species, also inhabits _N. Europe_, and may be readily recognized by the white bars in its wings and by its 16 or occasionally 18 rectrices. It has also a very different behaviour. When flushed it rises without alarm-cry, and flies heavily. In the breeding season much of its love-performance is exhibited on the ground, and the sounds to which it gives rise are of another character, and such that in its "drumming" is effected has not been ascertained. Its gesticulations at this time have been well described by Professor Collett in a communication addressed to _H. E. Dresser's Birds of Europe_ (vii. 635-637). It visits Great Britain every year at the close of summer, but in very small numbers, and is almost always seen singly—not uncommonly in places where no one could expect to find a Snipe.

The third species of which any details can here be given is the Jack or Half-Snipe, _S. gallinula_, the smallest and most beautifully coloured of the group. Without being as numerous as the common or full Snipe, it is of frequent occurrence in Great Britain from September to April (and occasionally both earlier and later), but it breeds only, so far as is known, in _N. Scandinavia_ and Russia; and the first trustworthy information on that subject was obtained by J. Wolley in June 1853, when he found several of its nests near Muonioniska in Lapland. Instead of rising wildly as do most of its allies, it generally lies so close as to let itself be almost trodden upon, and then takes wing silently, to alight at a short distance and to return to the same place on the margin. In the breeding-season, however, it is as noisy and conspicuous as its larger brethren while executing its aerial evolutions.

As a group the Snipes are in several respects highly specialized. We may mention the sensitiveness of the bill, which, though to some extent noticeable in many Sandpipers (_q.v._), is in Snipes carried to an extreme by a number of filaments, belonging to the fifth pair of nerves, by which run, in a soft and delicate manner, tentacles. These last are secreted by a soft cuticle in a series of cells that give this portion of the surface of the premaxillaries, when exposed, a honeycomb-like appearance. The mechanism will become fully evident to the observer who takes the bird in the hand, and, without forcing its beak, is at once able to distinguish the nature of the objects it encounters, though these are wholly out of sight. So far as is known the sternum of all the Snipes, except the Jack-Snipe, deviates from the normal Limicoline formation by _S._, which tends to justify the removal of that species to a separate genus, _Limnocryptes_.

_SNP SNAP SNOREM_, an old game at cards, sometimes called _Earl of Coventry_. There are several methods of playing, but in the commonest a full whist pack is used and any number of players may take part. The pack is dealt, one card at a time, and the eldest hand places upon the table any one card not taken by the player in question, and then tries to match the card played just before his, making use of a prescribed formula if successful. Thus, if a king is played, the second player lays down another king (if he can) calling out "Snip!" The next player lays down the third king, saying "Snap!" and the next the fourth king with the word "Snorem." A player not being able to pair the card played may not discard, and the holder of "Snorem" has the privilege of beginning the next round. The player who gets rid of all his cards first wins a counter from his companions for each card still held by them.

_SNOILSKY_, CARL JOHAN GUSTAF, COUNT (1841-1903), Swedish poet, was born at Stockholm on the 8th of September 1841. He was educated at the Clara School, and in 1866 became a student at Upsala. He trained for diplomacy, which he quitted for work at the Swedish Foreign Office. As early as 1861, under the pseudonym of "Sven Tröst," he began to print poems, and he soon became the centre of the brilliant literary society of the capital. In 1862 he published a collection of lyrics called _Orchideer_ ("Orchids"). During 1864 and 1865 he was in Madrid and Paris on diplomatic missions. It was in 1869, when he first collected his _Dikter under his own name, that Snoilsky took rank among the most eminent contemporary poets.

_Though this word is clearly not intended as a nickname, such as is the prefix which custom has applied to the Daw, Pie, Redbreast, Titmouse or Wren, one can only guess at its origin or meaning. It may be, as in Jackass, an indication of sex, for it is a popular belief that the Jack-Snipe is the male of the common species; or, again, it may refer to the comparatively small size of the bird, as the "Jack" in the game of bowls is the smallest of the balls used, and as fisherman call the smaller of the various species of salmon by the same name._

_4. His account was published by Hewitson in May 1855 (Eggs Br. Birds, 3rd ed., ii. pp. 356-358)._
SNORRI STURLASON—SNOWDROP

SNORRI STURLASON (1170-1241), the celebrated Icelandic historian, the youngest son of a chief in the Vestfirdir (western fjords), was brought up by a powerful chief, Jon Loptsson, in Odda, who seems first to have awakened in him an interest for history and poetry. His career begins with his marriage, which made him a wealthy man; in 1206 he settled at Reykjabolt, where he constructed magnificent buildings and a bath of hewn stones, preserved to the present day, to which water was conducted from a neighbouring hot spring. He early made himself known as a poet, especially by glorifying the exploits of the contemporary Norse kings and earls; at the same time he was a learned lawyer, and from 1235 Snorri’s son-in-law, Snorri, president of the legislative assembly and supreme court of Iceland. The prominent features of his character seem to have been cunning, ambition and avarice, combined with want of courage and avarice from effort. By royal invitation he went in 1218 to Norway, where he remained a long time with the young King Hakon and his tutor Earl Skulli. When, owing to disputes between Icelandic and Norwegian merchants, Skulli thought of a military expedition to Iceland, Snorri promised to make the inhabitants submit to Hakon of their own free will. Snorri himself became the lendmâddr, vassal or boyar, of the country and held his land fieft under him. On his return home Snorri sent his son to the king as a hostage, and made peace between Norway and Iceland, but his power and influence were used more for his own enrichment and aggrandizement—he was læggumâddr again from 1222 to 1232—than for the advantage of the king. Hakon, therefore, stirred up strife between Snorri’s kinsman Sturla and Snorri, who had to fly from Reykjavik in 1236; and in 1237 he left the country and went back to Norway. Here he joined the party of Skulli, who was meditating a revolt. Learning that his cousin Sturla in Iceland had fallen in battle against Gissur, Snorri’s son-in-law, Snorri, also brought about by his liege lord, returned to Iceland in 1239 and once more took possession of his property. Meanwhile Hakon, who had vanquished Skulli in 1240, sent orders to Gissur to punish Snorri for his disobedience either by capturing him and sending him back to Norway or by putting him to death. Gissur took the latter course, attacked Snorri at his residence, Reykjavolt, and slew him on the 22nd of September 1241.

Snorri is the author of the great prose Edda (see EDDA), and of the Heimskringla or Saga of the Norwegian Kings, a connected series of biographies of the kings of Norway down to Sverri in 1177. The later work opens with the Ynglinga Saga, a brief history of the pretended immigration into Sweden of the Asir, of their successors in that country, the kings of Upsala, and of the oldest Norwegian kings, their descendants. Next come the biographies of the succeeding Norwegian kings, the most detailed being those of the two missionary kings Olaf Tryggvason and St. Olaf. Snorri’s sources were partly succinct histories of the realm, as the chronological sketch of Arb; partly more voluminous early collections of traditions, as the Norgar Kemunart (Fagrskgrím) and the Jaldabot; partly leggendaries of the biographies of the two Olafs; and, in addition to these, studies and collections which he himself made during his journeys in Norway. His critical principles are explained in the preface, where he dwells on the necessity of preserving the works of the poets, the preservation of contemporary poems, or at least from those nearest to antiquity—the touchstone by which verbal traditions can be tested being contained in the poems of contemporary sources. He makes an exception in the accounts of the introduction of Christianity into Norway and of the national saint St Olaf. Snorri strives everywhere to impart life and vigour to his narrative, and he gives the dialogues in the individual character of each person. Especially in this last he shows a tendency to epigram and often uses humorous and pathetic expressions. Besides his principal work, he was interested in other works; all his works are preserved in a manuscript of the History of St Olaf (the great Olaf’s Saga). In the preface to this he gives a brief extract of the earlier history, and, as an appendix, a short account of St Olaf’s miracles after his death; besides, too, he employs critical art, as appears from a comparison with his sources, the Latin legend. See further ICELAND, LITERATURE, and EDDA.

SNOW (in O. Eng. snaw; a common Indo-European word; cf. Teutonic languages, Ger. Schnee, Du. sneeuw; in Slavonic sněg, Lith. snegas; Gr. νιφα, Lat. nix, nivis, whence the Romanic forms, Ital. neve, Fr. neige, &c.; and Gael. snéachd), the original sense of the root may be to moisten, cf. Skt. maha, to find), by which are meant the forms of water that form on the freezing of the atmosphere which reaches the ground in a frozen and crystalline condition. Snow thus occurs when the processes of condensation and fall take place at a temperature below 32° F. The crystals, which vary greatly in form, belong to the hexagonal system. They are formed upon a nucleus, in the same way as a raindrop, and sometimes reach the ground singly, but more commonly in small coherent masses or flakes. If in its passage from the upper atmosphere snow passes through a temperature above 32° F. it reaches the ground as slat or rain (according to the degree of heat encountered), and thus after a fall of snow over lowlands, the higher parts of mountains in the vicinity may be seen to have received the fall as snow.

See further CLIMATE and METEOROLOGY; and for the transformation of snow into ice under pressure, see GLACIER.

SNOWDON (Wyddfa, view-place, Eryri, eagle-place), the highest elevation in N. Wales. It is formed chiefly of slates, grits and porphyries of the Cambrian and Silurian systems. It consists of five “ribs” converging at the summit, 3,560 ft. above sea-level. Between these lie such depressions as Cwm Glas (blue or green vale) to the N., and Cwm y llan (clearing, town or church vale) to the S. Snowdon is dammed in the surrounding hills by pavement-like slates, and is surrounded in its lower parts by large and voluminous collections of porphyries and porphyritic rocks. Other names for this peak are the Great Snowdon massif. Nan Colwyn runs N.W. to Carnarvon. A rack-and-pinion railway (opened in 1897) ascends from Llanberis to the summit of the mountain (4,423 ft.). Snowdonia, as the locality is sometimes called, contains several lakes, e.g. Peris and Padarn at Llanberis; Glaslyn and Llydaw between Cribogoch (red crest) and Lliwdedd; Cwellyn and others W. of the hill itself; and Gwynedd and Dinas (Y Dinas) in Nantgwynant. Other distinctive species of snowdrop are the Crimean snowdrop, G. limbata, with broad leaves folded like a fan, and G. Elwesi, a native of the Levant, with large flowers, the three inner segments of which have a much larger and more conspicuous green blotch than the commoner kinds. All the species thrive in almost
any soil or position, and when once planted should be left to themselves.

**SNOW-LEOPARD,** or ounce (Felis uncia,) a large member of the cat family, from the high mountain regions of Central Asia. It resembles the leopard in general conformation, but has longer fur, grey in colour, marked with large dark rosettes. The dimensions of the head and body are about 4 ft. 4 in., tail 2 ft., and the height 2 ft. This animal lives among rocks, and preys upon wild sheep and goats, and probably large rodents or birds. It carries off sheep, goats and dogs from villages, and even kills ponies, but, it is said, has never been known to attack man (Blanford). Examples shown in the Zoological Gardens of London have been fairly tame and playful.

**SNOW-LINE.** In the higher latitudes, and in the most elevated parts of the surface of the earth, the atmosphere may be normally so cold that precipitation is chiefly in the form of snow, which lies in great part unmelting. The snow-line is the imaginary line, whether in latitude or in altitude, above which these conditions exist. In the extreme polar regions they exist at sea-level, but below lat. 58° the snow-line begins to rise, since at the lower elevations the snow melts in summer. In N. Scandinavia the line is found at about 3000 ft. above the sea, in the Alps at about 8500 ft., and on high mountains in the tropics at about 15,000 to 19,000 ft. These figures, however, can only be approximate, as many considerations render it impossible to employ the term "snow-line" as more than a convenient generalization.

**SNOW-SHOES,** a form of footgear devised for travelling over snow-covered ground, especially in America. It consists of a sole of wood with its outer edge or shape of shoe, the simplest and most primitive being those of the far north. The Eskimos possess two styles, one being triangular in shape and about 18 in. in length, and the other almost circular. Southward the shoe becomes gradually narrower and longer, the largest being the hunting snow-shoe of the Cree, which is nearly 6 ft. long and turned up at the toe. Of snow-shoes worn by people of European race that used by lumbermen is about 33 ft. long and broad in proportion, while the tracker's shoe is over 5 ft. long and very narrow. This form has been copied by the Canadian snow-shoe clubs, who wear a shoe about 33 ft. long and 18 in. broad, slightly turned up at the toe and terminating in a kind of tail behind. This is made very light for racing purposes, but much stouter for touring or hunting.

Snow-shoes are made of a single strip of some tough wood, usually hickory, curved round and fastened together at the ends and supported in the middle by a light cross-bar, the space within the frame thus made being filled with a close webbing of dressed caribou or neat's-hide strips, leaving a small opening just behind the cross-bar for the toe of the mocassin foot. They are fastened to the mocassin by leather thongs, sometimes by buckles. The method of walking is to lift the shoes together and slide the overlapping inner edges over each other, thus avoiding the unnatural and fatiguing "straddle-gait" that would otherwise be necessary. Immediate snow-shoeing leads to serious lameness of the feet and ankles which the Canadian *voyageurs* call *mou de raquette.* Snow-shoe racing is very common in the Canadian snow-shoe clubs, and one of the events is a hurdle-race over hurdles 3 ft. 6 in. high. Owing to the thick forests of America the snow-shoe has been found to be more suitable for use than the Norwegian *ski*, which is, however, much used in the less-wooded districts.

**SNOUT** (from *Snuff*, "i.e. to inhale, to draw in through the nose;" cf. Dutch *snuft*, scent, Ger. *Schmuflen*, a cold, catarrh, and Eng. "snuff," "sniff," *&c.*), the name of a powdered preparation of tobacco used for inhalation (for the manufacture see *Tobacco*). The practice of inhaling snuff became common in England in the 17th century, and throughout the 18th century it was universal. At first each quantity inhaled was fresh grated (Fr. *raper*), whence the coarser kinds were later known as "rappee." This entitled the snuff-taker carrying with him a grater with a small spoon at one end and a box to hold the grated snuff. In the 18th century graters - and of ivory and other material are in existence. Later the box and the grater were separated. The art and craft of the miniature painter, the enameller, jeweller and gold- and silver-smith was bestowed upon the box. The humberl snuff-takers were content with boxes of silver, brass or other metal, horn, tortoise-shell or wood. The mull (*q.v.*), a silver-mounted ram's head, is a large table snuff-box. Though "snuff-taking" ceased to be fashionable at the beginning of the 19th century, the gold and jewelled snuff-box has continued to be a typical gift of sovereignty to those whom they delight to honour.

This word "snuff" must be distinguished from that meaning the charred inch of a candle or lamp, which is a variant of "snip" or "snop," to cut off, trim, cf. Dan. *snubbe.* Constant trimming or snuffing of candles was a necessity until obviated by the modern methods of candle manufacture, and the snuffers consisted of a pair of scissors with a closed box forming a receptacle for the charred wick cut off; the snuffers usually had three small feet which allowed them to stand on a tray. Made of silver, silver-gilt or other metal, "snuff" were formerly a decorative article of plate in the equipment of a household. There is a beautiful example of silver snuffers with enamel decorations in the British Museum. These belonged to Cardinal Bainbridge and date from the reign of Henry VIII.

**SNYDERS, FRANZ** (1579-1657), Flemish painter of animals and still life, was born and died at Antwerp. In 1593 he was studying under Pieter Breughel the younger, and afterwards received instruction from Hendrick van Balen, the first master of Van Dyck. He devoted himself to painting flowers, fruit and subjects of still life, but afterwards turned to animal-painting, and it has been said that he was the greatest spirit and spirit hunting pieces, and combats of wild animals. His composition is rich and varied, his drawing correct and vigorous, his touch bold and thoroughly expressive of the different textures of furs and skins. His excellence in this department excited the admiration of Rubens, who frequently employed him to paint animals, fruit and still life in his own pictures, and he assisted Jordaens in a similar manner. In the lion and boar hunts which bear the name of Snyders the hand of Rubens sometimes appears. He was appointed principal painter to the archduke Albert, governor of the Low Countries, for whom he executed some of his finest works. One of these, a "Stag-Hunt," was presented to Philip III, who commissioned the artist to paint several subjects of the chase, which are still preserved in Spain.

**SOANE, SIR JOHN** (1753-1837), English architect and art collector, was born near Reading of a humble family whose name of Swan he afterwards altered to Soan or Soane. His talent as a boy attracted the attention of George Dance, junior, the architect, who with other friends helped him on. He won the Royal Academy's silver (1772) and gold (1776) medals, and a travelling studentship, and went to Italy to study (1777-1780). Returning to England he got into partnership with an architect, and in 1784 married a rich wife. He became architect to the Bank of England, which he practically rebuilt in its present form, and did other important public work. He became an A.R.A in 1795, and R.A. in 1802, and professor of architecture to the Royal Academy in 1806. In 1831 he was knighted. In his house in Lincoln's Inn Fields he brought together a valuable antiquarian museum (now the Soane Museum), which in 1836 he presented to the nation with an endowment; and there he died in 1837. (See *Museums*.)

**SOAP,** a chemical compound or mixture of chemical compounds resulting from the interaction of fats and acids with alkalis. In a scientific definition the compounds of fatty acids with basic metallic oxides, lime, magnesia, lead oxide, &c., should also be included under soap; but, as these compounds are insoluble in water, while the very essence of a soap in its industrial relations is solubility, it is better to speak of the insoluble compounds as "plasters," limiting the name "soap" as the compounds of fatty acids with soda and potash. Soap both as a medicinal and as a cleansing agent was known to Pliny (*H.N.* xxviii. 51), who speaks of two kinds—hard and soft—as used by the Germans. He mentions it as originally a Gallic invention for giving a bright finish to the hair (see *Hair*). He must have been of this opinion to believe that soap came to the Romans from Germany, and that the deterrents in use in earlier times and mentioned as soap
in the Old Testament (Jer. ii. 22; Mal. iii. 2, &c.) refer to the ashes of plants and other such purifying agents (comp. vol. x. p. 697).

Soap appears to have been first made from goat's tallow and beechn ash; in the 13th century the manufacture was established at Marseilles from olive oil, and in England during the next century. The processes and extent of the manufacture were revolutionized at about the beginning of the 19th century by Chevreul's classical investigations on the fats and oils, and by Leblanc's process for the manufacture of caustic soda from common salt.

Previous to Chevreul's researches on the fats (1811–1823) it was believed that soap consisted simply of a binary compound of fat and alkali. Claude J. Geoffroy in 1741 pointed out that the fat or oil recovered from a soap solution by neutralization with a mineral acid differs from the original fatty substance by dissolving readily in alcohol, which is not the case with ordinary fats and oils. The significance of this observation was overlooked; and equally unheeded was a not less important discovery by Scheele in 1783. In preparing plaster by boiling olive oil with oxide of lead little water—a process palpably analogous to that of the soap-boiler—he obtained a sweet substance which, called by himself "Glycerin," ("principium dulce oleorum"), is now known as "glycerin." This discovery, however, was not much noticed, and the details of Chevreul's researches by which he established the constitution of oils and the true nature of soap. In the article Oils it is pointed out that all fatty oils and fats are mixtures of glycerides, that is, of oil and alkali esters, and that these esters contain fatty acids such as palmitic acid (CH\(_{16}\)O\(_2\))H. Under suitable conditions, C\(_{17}\)H\(_{31}\)OH+3C\(_{17}\)H\(_3\)O\(_2\)H give C\(_{17}\)H\(_{31}\)(C\(_{17}\)H\(_3\)O\(_2\))\(_3+3\)H\(_2\)O.

The corresponding decomposition of a glyceride into an acid and a glycerol takes place when the glyceride is distilled in superheated steam, or by boiling in water mixed with a suitable proportion of caustic potash or soda. But in this case the fatty acid unites with the alkali into a single substance, forming a soapsal

C\(_{17}\)H\(_{31}\)(C\(_{17}\)H\(_3\)O\(_2\))\(_3+3\)NaOH=3NaC\(_{17}\)H\(_3\)O\(_2\)-C\(_{17}\)H\(_{31}\)(OH)\(_3\).

Palmitin. Glycerin.

Of the natural fats or glycerides contained in oils the most important in addition to palmitin are stearin and olein, and these it may be sufficient to regard as the principal fatty bodies concerned in soap-making.

The general characters of a soap are a certain greasiness to the touch, ready solubility in water, with formation of viscid solutions which on agitation yield a tenacious froth or "lather," an indisposition to crystalize, readiness to amalgamate with small proportions of hot water into homogeneous slimes, which on cooling set into jellies or less or more constant pastes. Soaps give an alkaline reaction, and the soaps of the acids and alkalis are substances that state never reached in practice—they have neither smell nor colour. Almost without exception potash soaps, even if made from the solid fatty acids, are "soft," and sooner or later they melt, as many of the solid alkalis will only do by long continued boiling with water; there are considerable variations according to the prevailing fatty acid in the compound. Almost all alkali soaps are precipitated from their watery solutions by the addition of a sufficient amount of alkali, in a homogeneous mass. Potash soaps in the cold undergo double decomposition—a proportion being changed into a soap soda with the formation of potassium chloride. Ammonia soaps have also been made, but with little commercial success; in 1906 H. Jackson patented the preparation of ammonium oxalate directly in the washing water, and it is claimed that for cleansing articles it is only necessary to immerse them in the water containing the preparation and then rinse.

Soap when dissolved in a large amount of water suffers hydrolysis, with formation of a precipitate of acid salt and a solution containing free alkali. The reaction, however, is very complicated. Chevreul found that a neutral salt soap hydrolysed to an acid salt and free alkali, and a small amount of fatty acid. Rotondi in 1855, however, regarded a neutral soap as hydrolysing to a basic salt, soluble in both hot and cold water, and an acid salt, insoluble in cold and readily deposited, but with the sodium of the alkali. According to this view, weak cold solutions, in which the hydrolysis is considerable, should be the best cleansers, whilst experience points to the use of hot concentrated solutions. It is more than likely the cleansing power depends upon several factors, viz., the emulsifying power, the property of penetrating oily fabrics, and lubricating impurities so that they can be readily washed away.

Resin soaps are compounds of soda or potash with the complex acids (chiefly, abietic), which, on superheating, the resin solutions are converted into soaps. Their formation is not due to a true process of saponification; but they occupy an important place in compound soaps.

**Manufacture.**—Numerous varieties of soaps are made; the purposes to which they are applied are varied; the materials employed embrace a considerable range of oils, fats and other bodies; and the processes adopted undergo many modifications. As regards processes of manufacture soaps may be made by the direct combination of fatty acids, separated from oils, with alkaline solutions. In the manufacture of stearin for candles, &c., the fatty matter is decomposed, and the liquid olein, separated from the solid fatty acids, is employed as an ingredient in soap-making. A soap so made is not the result of saponification but of a simple combination, as is the case also with resin soaps. All other soaps result from the combination of fatty oils and fat with potash or soda solutions under conditions which favour saponification. The soap solution which results from the combination forms soap-size and is a mixture of soap with water, the excess alkali, and the glycerin liberated from the oil. In such condition ordinary soft soaps and certain kinds of hard soap are brought to the market. In curd soaps, however, which form the basis of most household soap, the uncombined alkali and the glycerin are separated by salting out, and the soap in the condition containing it is, after being framed and finished in this state, but almost invariably it receives a further treatment called "refining" or "fitting," in which by remelting with water, with or without the subsequent addition of other agents to harden the finished product, the soap may be made to contain from 60 to 70% of water and kept present a firm hard texture.

Almost any fatty substance can be employed in soap-making; but the choice is naturally restricted by the price of the fat and also the quality of the soap desired. The most important of the animal fats are (a) that from the ox and (b) that from the vegetable origin, coco-nut; it is also to be remembered that resin, although not a fat, is also important in soap-making. Ox and sheep tallow, with the addition of resin, are the primary materials for making the hard yellow or primrose soaps; these tallow are often adulterated. The cheaper mottled and brown soaps have for their basis bone fat, obtained by treating bones with superheated steam or other methods. Lard yields lard oil, which is mainly applied in making hard toilet soaps, while soap made from it is used for the manufacture of dyers; castor oil yields transparent soaps (under suitable treatment), whilst crude palm oil, with bone fat, is employed for making brown soap, and after bleaching it yields ordinary pale or mottled. The alkali used almost exclusively in the manufacture of soap solutions of their respective hydrates in water. Caustic soda is now obtained direct from the soda manufacturer, and one operation, caustizing the soda, is thus spared the soap-boiler. Potash lye also may be bought direct, but in some cases they are sharpened or caustized by the soap-boiler himself from the carbonate. The processes of soap manufacture may be classified (a) according to the temperatures employed into (1) cold processes and (2) boiling processes, or (b) according to the nature of the starting material—acid or oil and fat—and the relative amount of alkali, into (1) direct saturation of the fatty acid with alkali, (2) treating the fat with a definite amount of alkali, (3) removing the excess alkali, (4) effecting the reaction with an indefinite amount of alkali, also with no separation of fatty matter from the alkali, (5) treating the fat with an indefinite amount of alkali with separation of waste lye. In the second classification (2) is divided into (a) the "soaping" process, whilst (1), (3), (4) are effected by the "boiling" process.

The cold process, which is only applicable to the manufacture of soap from readily saponifiable oils, such as cod liver oil, but not ground and therefore not saponifiable, is as follows: take the fat ground and dissolved in hot water, and add an amount of acid to bring the reaction to the "cold" process, whilst (1), (3), (4) are effected by the "boiling" process.

The cold process, which is only applicable to the manufacture of soap from readily saponifiable oils, such as cod liver oil, but not ground and therefore not saponifiable, is as follows: take the fat ground and dissolved in hot water, and add an amount of acid to bring the reaction to the "cold" process, whilst (1), (3), (4) are effected by the "boiling" process.

The cold process, which is only applicable to the manufacture of soap from readily saponifiable oils, such as cod liver oil, but not ground and therefore not saponifiable, is as follows: take the fat ground and dissolved in hot water, and add an amount of acid to bring the reaction to the "cold" process, whilst (1), (3), (4) are effected by the "boiling" process.
of their liability to contain free alkali and unsaponified oil, the process has been largely given up.

The process of soap-boiling is carried out in large iron boilers called "crutching pans," the contents of which have capacity for charge of 30 or more tons. The pan is properly termed by a great cone or hopper called a curb, for providing the foaming up of the soap. In the process of soap boiling, the pans are heated by open firing from below; but now the almost universal practice is to boil the steam injected from perforated pipes coiled within the pan, such injection favouring the uniformity of heat. An excess of caustic carbonate is introduced to effect the ultimate mixture and saponification of the materials. Direct firing is used for the second boiling of the soap mixture; but for this superheated steam may with advantage be substituted, either applied directly to the surface of the soap or surrounding the pan by a closable jacket. In large pans a mechanical stirring apparatus is provided, which in some cases, as in Morfit's steam "twirl," is formed of a kind of paddle. In general, however, after the objects have been boiled under pressure, are also employed for certain soaps.

The process of manufacturing soaps by boiling fatty acids with caustic alkalis or soda carbonate came into practice with the development of the manufacture of candles by saponifying fats, for it provided a means whereby the oleic acid, which is valueless for candle making, could be worked up. The combination is effected in open vats heated by a steam coil and provided with a stirring apparatus if soda ash be used it is necessary to guard against boiling over.

(See under Curb Soaps.)

The soap is manufactured by boiling the fat with alkali and removing the unused lye, which is afterwards worked up for glycerin. The oil mixture used differs in the several manufacturing countries, and the commercial name of the product is consequently various. In Germany and France olive oil occupies the chief place in the product is known as Marseilles or Castile soap; and in England tallow and palm oil are largely used. In all countries a mixture of several oils enters into the composition of the soaps and the proportions used have no fixity. For each ton of soap to be made from 12 to 16 cwt. of oil is required. The soap pan is charged with the tallow or other fatty matter to be used, and the lye is added to the tallow in a quantity of weak lye is added, and the agitation of the injected steam causes the fat and lye to become intimately mixed and produces a milky emulsion. As the lye becomes absorbed, a condition is reached in which the greater part of the alkali is in solution, and increasing strength are added. After some time the contents of the pan begin to clear and become in the end very transparent. Lye still continues to be poured in till a sample tastes distinctly alkaline—a test which indicates that the whole of the fatty acids have been taken up by and combined with the alkali. Then without further addition of alkali the boiling is continued for a few minutes, when the soap is ready for sullying or graining. Either common salt or strong brine in measured quantity is added to the charge, and, the soap being insoluble in such salt solution, a separation of constituents takes place: the soap collects on the surface in an open gridiron, and the brine is run off. This operation has been left for a short time to settle. Suppose that a pure soap without resin is to be made—a product little seen in the market—the spent lye is run off, steam is again turned on, pure water or very weak lye solution is added, and the contents brought to the boiling point and clear. The soap is from this again ginned off or salted out, and the underlye so thrown down carries with it coloured impurities which may have been in the materials under the alkali or in the lye. Such washing process may have to be repeated several times when impure materials have been used. The spent lye of the washing being drained off, the soap is now "boiled for strength." Steam is turned on, and, the mass being brought to a clear condition with weak lye or water, strong lye is added and the boiling continued with close steam till the lye attains such a state of concentration that the soap is no longer soluble in it, and it will separate from the water. The"common salt," or common carbonate, the pan once more allowed to cool and settle, and the soap as now formed constitutes a pure curd soap, carrying with it some proportion of uncombined alkali, but containing the minimum amount of uncombined and unneutralised fat. The soap is then stored in the frames for solidification; but that is a practice scarcely at all followed, the addition of resin soap in the pan and the subsequent "graining" of the latter to the frame are operations in which features common to the manufacture. The lye from the strengthening boil contains much alkali and is used in connexion with other boilings.

Crumb Soaps.—A curd soap prepared from kitchen fat or bone grease always carries with it into the cooling frame a considerable amount of coloured impurity, such as iron sulphate, &c. When it is permitted to cool rapidly the colouring matter remains uniformly distributed throughout the deposit, but if the deposit is allowed to cool because the soap to cool and solidify slowly a segregation takes place: the stearate and palmitate form a semi-crystalline solid, while the oleate, solidifying more slowly, comes by itself into translucent veins, in which the greater part of the coloured matter is drawn. In this way curd, mottled or marbled soap is formed, and such mottled appearance was formerly highly valued as an indication of freedom from excess of water or other adulteration, because in fitted soaps the impurities are either washed out or fall to the bottom of the pan. In these soaps, however, the colours are produced by working colour matter, ultramarine for blue, and manganese dioxide for grey, into the soap in the frame, and many of them are heavily overfitted. Yellow Soap consists of a mixture of any hard fatty soap with a variable proportion—up to 40% or more—of resin soap. That substance by itself has a tenacious gluey consistence, and its inter- nal absorbing power is so great that it would be impossible to get rid of even so slight an admixture, but when used as a filler the ordinary method of adding resin consists in stirring it in small fragments into the fatty soap in the stage of clear-boiling; but a better result is obtained by separately preparing a fatty soap and the required quantity of resin soap is separated, each of these being salted out and removed from the fatty soap. The compound then receives its strengthening boil, after which it is fitted by boiling and cooling the manner already described. Artificial soaps may be made of a sample the proper consistence has been reached. On setting the product forms three layers: the uppermost is a thin crust of soap which is worked up again in the pan; the second is the desired soap; next there is a dark-coloured weak soap termed nigre, which, because it contains some soap and alkali is saved for future use; underneath these is a solution of alkaline salts with a little free alkali.

Treatise on Soap.—The upper layer having been removed, the middle layer is laid out on a pan off to a crust, and the iron pan provided with hand or mechanical stirring appliances. It is here stirred till it becomesropy, and the perfume, colour or any other admixture is added, and the mixture is worked up over a fire to the consistency of a mottled soap. The solidification is a gradual process, depending, of course, for its completion on the size of the block; but before cutting into bars it is essential that the whole should be set and hardened through and through, else the cut bars would not hold together. Many ingenious devices for forming bars have been produced; but generally a strong frame is used, across which steel wires are stretched, over which the soap is poured, to the size of the bars. the blocks being first cut into slabs and then into bars.

Marine Soap.—These soaps are so named because they are not insoluble in a strong solution of salt; hence they form a lather and are used for washing clothes. The soap, made from the waste of the cotton oil extraction process, which is very cheap and therefore suitable for making such compound soaps are employed. In the first way the ordinary oil and coco-nut oil are mixed and saponified together as described above. According to the second plan, the ordinary oil is extracted at the coco-nut press with water and the resulting mass, the coco-nut soap, is boiled and the soap further saponified and added to the pan; the coco-nut soap separately saponified is added in the pan and both are boiled together till they form a homogeneous soap.

Marine Soaps are formed by mixing a soap to contain large proportions of water and yet present a firm consistence is found in the use of silicate of soda. The silicate in the form of a concentrated solution is crutched or stirred into the soap in a mechanical stirring machine after the completion of the saponification, and it appears to enter into a distinct chemical combination with the soap. While silicate soaps bear heavy water, the soluble silicate itself is a powerful detergent, and it possesses certain advantages when used with less water.

Soft Soaps.—Soft soaps are made with potash lye, although in practice a small quantity of soda is also used to give the soap some consistence. The operation of soft soap making is that the product contains the whole constituents of the oils used, as the operation of salting out is quite impracticable owing to the double decomposition which results from the action of salt, soap, and water. Soft soap is made by mixing the oil or animal fat with an excess of potash and adding a certain quantity of water and stirring it on the frame. Owing to this circumstance it is impossible to make it or in any way purify soft soap, and all impurities which go into the pan of necessity enter into the finished product. The making of which, although it is peculiar to soft soap and soft soap making, is one that demands much skill and experience for its success. From the conditions of the manufacture care must be taken to regulate the amount and strength of the lye, the proportion of the concentration to which the boiling ought to be continued has to be determined with close observation.

Toilet Soaps, &c.—Soaps used in personal ablution in no way differ materially from those described, and the ordinary varieties. It is of consequence that they should, as far as possible, be free from excess of alkali and all other salts and foreign
ingredients which may have an injurious effect on the skin. The manufacturer of toilet soaps generally advertises his product as being of agreeable appearance and smell; the more weighty duty of having them free from uncombined alkali is in many cases entirely overlooked. Transparent soaps are prepared by dissolving the soap in a dilute lye solution and then adding a very minute portion of the alcohol till the residue comes to the condition of a thick transparent jelly. This, when cast into forms and allowed to harden and dry slowly, comes out as transparent soap. A class of transparent soaps is manufactured locally in the form of disability. Of the blending of the proportions of coco-nut oil, castor oil and sugar. It generally contains a large amount of uncombined alkali, and that, with its unpleasant odour of coco-nut oil, makes it a most undesirable soap for personal use. The soaps here employed are performed by simple melting and stirring into the mass some cheap ordinary body that is not affected by alkalis under the influence of heat. The finer soaps are perfumed by the addition of an extremely small proportion of the scents which are employed by the manufacturer. The proportions of ingredients are given in terms of percentage parts of pure hard soap and glycerin (the latter valuable for its emollient properties). The soap is melted by heat, the glycerin is stirred in, and the mixture strained and poured into forms, in which it hardens by the action of the air and cold. Sometimes, during this process, a large proportion of soaps, formed by being soluble in that body, and such fluid soap has only feeble lathering properties. Soap containing small proportions of glycerin, on the other hand, forms a very tenacious lather, and when soap bubbles have been formed by this in soaps employed in cases of skin ailments, as prophylactic washes and as disinfectant soaps. Among the principal varieties are those which contain carabolic acid and other ingredients of coal tar, salicylic acid, petroleum, borax, camphor, iodine, mercurial salts, sulphur and tannin. Arsenical soap is very much employed by taxidermists for the preservation of the skins of birds and mammals.

Soap—Section II. — The so-called “floating soaps” are soaps made lighter than water either by inserting cork or a metallic plate so as to form an air space within the tablet. The more usual method is to take milling soap, neutralize it with sodium bicarbonate or a mixture of sodium and potassium carbonates, and after the milk has set, cut up into small cakes and expose them to the air. When the hot soap with air in a specially designed cutter. Shaving soaps, which must obviously be free from alkali or any substance which imparts to the skin a characteristic by readily forming a permanent lather. This property is usually obtained by mixing soft and hard soaps, or, more rarely, by adding gum tragancan to a hard soap. In the textile trades the wool scourer employs a neutral olive-oil soap, or, on account of its cheapness, a neutral curd or curly mottled brand; the cotton cleanser, on the other hand, uses an alkaline soap, but for cleaning printed cottons a neutral olive-oil curd soap is used, for, in this case, free alkali and resin are objectionable; olive-oil soap, free from alkali, but often with sodium carbonate, is also used in cleansing silk fibres, although hard soaps free from resin are frequently employed for their cheapness. Soaps of smaller manufacture are the candle soaps used for removing tarny stains; ox-gall soaps for cleaning carpets; magnesium, rouge and chalk soaps for cleaning plate, &c.

Soap Analysis.—The most important points in soap analysis are (1) the amount of fats in the soap, which is measured and expressed in terms of its saponification value; (2) the amount of fatty substances insoluble in water, (3) of the water. The first is carried out by saponifying the soap with acid in the heat when the fatty acids come to the surface. If it fails to form a hard cake on cooling, a solution in the acid may be added. The insoluble milk may be filtered off, dried and weighed. This is a measure of the total alkalis. The cake on weighing gives the free acid. The total alkali is determined by incinerating a weighed sample in a platinum dish, dissolved in a weak acid and then titrating the filtrate with standard acid. The residue of the latter gives the amount of substances insoluble in water. The water in a soap is rarely directly determined; when it is, the soap, in the form of shavings, is heated to 100 C. until the weight is constant, the loss giving the amount of water. With genuine soaps, however, it suffices to calculate the amount of water to the soap by the method of saponification. The complete analysis involves an examination of the fatty matter, of the various forms in which the alkalis are present—free and combined glycerin, &c.

SOAP—BARK—SOBAT

The inner bark of Quillaja saponaria, a large tree which grows in Chile. Reduced to powder, it is employed as a substitute for soap, since it forms a lather with water, owing to the presence of a glucoside sapopin, sometimes distinguished as Quillaja saponin. The same, or a closely similar substance, is found in soapwort (Saponaria officinalis), in senega root (Polyscias senega) and in sarsaparilla; it appears to be chemically related to digitonin, which occurs in digitalis. The saponins (with few exceptions), have the general formula (C,H,==O), and by the action of dilute acids they are hydrolysed into sugars and sapogenins, which are usually inert pharmacologically. An alternative name for them, and especially for those which are pharmacologically active, is sapotoxins; on this nomenclature the hydrolytic products are termed saponins. Applied as a snuff to the mucous membrane of the nose, saponin (either in soap-bark or in senega root) promotes a violent sneezing. Solutions injected under the skin are violent local irritants and general depressants.

SOBAT, a river of N.E. Africa, the most southerly of the great eastern affluents of the Nile. It is formed by the junction of various streams which rise in the S.W. of the Abyssinian highlands and N.W. of Lake Rudolf. The length of the Sobat, reckoning from the source of the Baro, the chief upper stream, to the confluence with the Nile is about 460 m. The Baro rises in about 30° 10’ E., 7° 50’ N. at an altitude of some 7000 ft. It has a general W. direction with a slight N. tendency. It is joined by numerous other streams which also rise on the Abyssinian plateau. These mountain torrents descend the escarpment of the plateau between great walls of rock, the Baro dropping 3000 ft. in 43 m. It then flows through a narrow gorge at an altitude of about 2000 ft., the mountains on either side towering 3000 to 4000 ft. above the river bed. Just east of 35° E. the Birbir, descending from the plateau, joins the Baro and brings with it a large volume of water. Some 40 m. lower down the hills are left behind, the rocks and rapids in the bed of the Baro cease, and the river flows W. across a vast plain with many windings and several divergent channels. From Gambela, a town on its N. bank 29 m. below the Birbir junction, the river is
SOBRAON—SOCIAL CONTRACT

navigable by steamers during flood time (June-December) to the point of confluence with the White Nile. From the N., the Baro is joined by two considerable rivers which also rise in the rampart of hills that separates Abyssinia from the Sudan, but its chief tributaries are from the S. In about 33° 20' E., 8° 30' N., it is joined by the Pibor. This river issues from the swamp region east of Bor on the Bahr-el-Jebel stretch of the Nile and flows N.E. and N. It is joined from the E. and S. by various streams having their sources on the W. slopes of the Kaffa plateau. Of these the chief are the Gelo—which breaks through a gap in the mountains in a series of magnificent cascades—and the Akobo. The Akobo rises in about 6° 30' N., 33° 30' E., and after leaving the mountains flows N.W. through flat swampy tracts. The whole region of the lower Pibor and Baro is one of swamps, caused by the rivers overflowing their banks in the rainy season. At its junction with the Pibor the Baro is over 100 yds. wide, with a depth of 8 ft. and a speed of 2-3 ft. per second.

Below the confluence of the Pibor and Baro the united stream, now known as the Sobat, takes a decided N.W. trend, passing for some distance through a region of swamps. Just beyond the swamps and some 40 m. below the confluence, is the fortified port of Nasser. From this point the ground on either side of the river gradually rises, though on the S. it is liable to inundation during flood time. From Nasser to the junction of the Sobat with the Nile the river has a course of about 180 m. As it approaches the Nile the Sobat flows in a well-defined channel cut in the alluvial plains through which it passes. The banks become steep, the slope rapid and the current strong. Several khors join it from N. and S., some being simply spill channels. These channels or "loops" are a characteristic feature of the river. The Sobat enters the Nile almost at right angles in 9° 22' N., 31° 31' E. It is 400 ft. wide at its mouth and has a depth of 18 to 20 ft. at low water and of 30 ft. when in flood. The colour of the water when in moderate flood is that of milk, and it is from this circumstance that the Nile gets its name of Bahr-el-Abiad, i.e. "White River." When the flood is at its height, and the water level is 6 ft. above brick-red. The amount of alluvium brought down is considerable. For the part played by the Sobat in the annual rise of the Nile see Nile.

The Sobat was ascended for some distance in 1841 by the Egyptian expedition despatched in the previous year to explore the upper Nile. The post of Nasser (see above) was founded in 1874 by General C. G. Gordon when governor of the equatorial provinces of Egypt, and it was visited in 1876 by Dr W. Junker, the German explorer. The exploration of the river system above Nasser was carried out in the last decade of the 19th century by the Italian explorer V. Pollock, by Colonel (then Captain) Marchand, of the French army, who, on his way from Fashoda to France, navigated the Baro up to the foot of the mountains; and by Captain M. S. Welby, Majors H. H. Austin and R. G. T. Bright, of the British army, and others. By the agreement of the 15th of May 1902 between Great Britain and Abyssinia the lower courses of the Sobat and Pibor rivers to their point of confluence form the frontier between the Anglo-

Egyptian Sudan and Abyssinia.

See Nile, Sudan and Abyssinia.

(W. E. G.; F. R. C.)

SOBRAON, a decisive battle in the first Sikh War (see Sixth War). It was fought on the 17th of February 1846, between the British (15,000) under Sir Hugh Gough and the Sikhs (20,000) under Tej Singh and Lal Singh. The Sikhs had fortified themselves in a bend on the left bank of the Sutlej, with the river in their rear. The battle began with a two hours' artillery duel, in which the Sikh guns were the more powerful, and the British heavy guns expended their ammunition. Then the infantry advanced with the bayonet, and after a fierce struggle took the Sikh entrenchments. The Sikh losses were estimated at from 5000 to 8000. This battle ended the first Sikh War.

SOBRIQUET, a nickname or a fancy name, usually a familiar name given to persons as distinct from "soubriquet"...assumed as a by-name. Two early variants are found, sobriquet and soubriquet; the latter form is still often used, though it is not the correct modern French spelling. The first form suggests a derivation from sōri, foolish, and briquet, a French adaptation of Itál. brichetto, diminutive of brice, ass, knave, possibly connected with briçonne, rogue, which is supposed to be a derivative of Ger. brochen, to break; but Skeat considers this spelling to be due to the French etymology, and the real origin is to be sought in the form sobriquet. Littré gives an early 19th century soubriquit as meaning a "chuck under the chin," and this would be derived from soubs, mod. sous (Lat. sub), and, and briquet or bruchel, the brisket, or lower part of the throat.

SOCAGE, a free tenement held in fee simple by services of an economic kind, such as the payment of rent or the performance of some agricultural work, was termed in medieval English law a socage tenement. In a borough a similar holding was called a burgage tenement. Medieval law books derived the term from sōca, pagan, anglshere, and took it to denote primarily agricultural work. This is clearly a misconception. The term is derived from O. Eng. soc, which means peasant, suit, but can also signify jurisdiction and a franchise district. Historically two principal periods may be distinguished in the evolution of the tenure. At the close of the Anglo-Saxon epoch we find a group of freemen differentiated from the ordinary crofts because of their greater independence and better personal standing. They are classified as sokemen in opposition to the villani in Domeday Book, and are chiefly to be found in the Danegeld and in East Anglia. There can hardly be a doubt that previously most of the Saxo crofts in other parts of England enjoyed a similar condition. In consequence of the reduction in the size of the manor and of the formation of the common law the tenure was developed into the lowest form of freehold. Legal protection in the public courts for the tenure and services deemed certain, appear as its characteristic feature in contrast to villainage. Certainty and legal protection were so essential that even villain holdings were treated as villain socage when legal protection was obtainable for it, as was actually the case with the peasants on Ancient demesne who could sue their lords by the little writ of right called Monstroverant. The Old English origins of the tenure are still apparent, especially in the shape of some of its incidents, especially in the absence of feudal wardship and marriage. Minorers inheriting socage come under the guardianship not of the lord but of the nearest male relative not entitled to succession. An heiress in socage was free to contract marriage without the interference of the lord. Customs of succession were also peculiar in many cases of socage tenure, and the feudal rule of primogeniture was not generally enforced. Commutation, the enfranchisement of copyholds, and the abolition of military tenures in the reign of Charles II. led to a gradual absorption of socage in the general class of freehold tenures.

(S. V.)

SOCIAL CONTRACT, in political philosophy, a term applied to the theory of the origin of society associated chiefly with the names of Hobbes, Locke and Rousseau, though it can be traced back to the Greek Sophists. According to Hobbes (Leviathan), men lived originally in a state of nature in which there were no recognized criteria of right and wrong, no distinction of sex or age. Each person took for himself all that he could; man's life was "solitary, poor, nasty, brutish and short." The state of nature was therefore a state of war, which was ended by men agreeing to give their liberty into the hands of a sovereign, who thenceforward was absolute. Locke (Treatise on Government) differed from Hobbes in so far as he described the pre-social state as one of freedom, and held that private property must have been recognized, though there was no security. Rousseau (Contrat social) held that in the pre-social state man was unwarlike and even timid. Laws resulted from the combination of men who agreed for mutual protection to surrender individual freedom to a social act. Government must therefore rest on the consent of the governed, the "volonte generale." Though it is quite obvious that the theory of a social contract (or compact,
as it is also called) contains a considerable element of truth—that loose associations for mutual protection preceded any elaborate idea or structure of law, and that government cannot be based exclusively on force—yet it is open to the equally obvious objection that the very idea of contract belongs to a more advanced stage in human development than the hypothesis itself demands. Thus the doctrine, yielding as a definite theory of the origin of society to the evidence of history and anthropology, becomes interesting primarily as revolt against medieval and theocratic theories of the state.

SOCIALISM, a term loosely formed from the Latin adjective socialis ('socius, a comrade'), and first used of certain doctrines of Robert Owen (q.v.). "Socialist" occurs in a discussion between Robert Owen and J. Heywood at Manchester (publ. Heywood, Manchester, 1837), pp. 27, 133. From the context it seems a nickname. But the title "Owenist" was disliked by many supporters (see Co-operative Magazine, 1836, p. 28) and "Co-operator" was acquiring a different sense. The new term was used in 1838 in France (by Pierre Leroux), and figures in 1840 in Reybaud's Socialistes modernes.

Definition.—Socialism is that policy or theory which aims at securing by the action of the central democratic authority a better distribution, and in due subordination thereunto a better production, of wealth than now prevails.

It is not entirely or exclusively the ancient and medieval theories to which the name has been given by modern writers (see also Anarchism, Communism, Co-operation). It hardly covers the schemes of Robert Owen himself. But just as chemistry is not alchemy, or astronomy astrology, modern socialism is not to be identified with Utopian fancies, and need not be so defined as to embrace them. For a like reason it need not be so defined as to include every tenet of leading socialistic writers. We must disentangle their socialism from what is superadded to it and not involved in the socialistic idea.

The word begins in the days of Owen. But, as there were utilitarians before Mill made the name current, so there were socialists before Owen. Socialism, as a policy, begins with the beginnings of politics. As a theory, it begins whenever the state is perceived to have a distinct office from other factors in the order of society, and that office is so magnified that the whole or main charge of the economic resources of the people is assigned to the state, whether for production or distribution. There was anarchism among the Cyreniacs and Cynics. Phæas of Chalcedon was a communist. There is state socialism in the Republic of Plato, and much remains in the Laws. It is true that in those days society and state are not clearly distinguished. When Aristotle tells us that "man is by nature a political animal" (Politics, i. 1), the adjective is ambiguous. But the individual and the state are not confused; they are even, by the Cynics, too far separated.

State and individual were also well apart in Rome, under the Roman system of legal rights—public, private, real, and personal. There were socialistic measures in Rome, panis et circenses; and there were agrarian, to say nothing of usury laws. But trade and industry were not usually regarded as worthy subjects for the state and the state was to touch at all. There are instances of municipal regulation; but most of it was to protect the interests of the Roman Empire (S. Dill, Roman Society from Nero to Marcus Aurelius, 1905, pp. 218, 220, 222). In the middle ages feudalism was more akin to paternal government than to individualism; but it was, politically, too undemocratic to approach a true socialism. On its decadence something like a de facto municipal socialism made its appearance. The gilds of the great cities, imperium in imperio, regulated production and incidentally distribution. They did not prevent the existence of millionaires like the Fuggers, but they brought even these rich men under their rules. The equality was greater than the liberty, though neither was complete, to modern notions.

With the breaking up of the gilds came what is commonly called individualism. Thenceforward over against the controlling government of the monarch or the commonwealth was to stand the commercial competition of free individuals. It is one of our modern problems to determine whether this individualism is doomed or not. It has never existed pure and unmixed. Between the time of the gilds and the time of the trade union lies the time, say in England in the 16th and 17th centuries, when there were enterprising trade and busy industry, with enough of power surviving in the old organizations to prevent absolute anarchy. As invention followed invention in the 18th century, industry changed its form and became greater instead of small. That is to say, it tended to become more and more an affair of large capital and large workshops, and, instead of the industrial individualism of small masters and independent "manufacturers," who were still "hand"-workers, there was appearing the industrial collectivism of the factory system, the colossal division of labour and its strict technical discipline and drill.

There was a short period in England when employers were allowed to draw advantage from the change without any hindrance from the state. But in no greater time than one generation the regulation of factories began, the period of anarchy ended, and the commercial competition of free individuals began to be surrounded with safeguards, more or less effective.

Modern socialism, as defined above, is (a) opposed to the policy of laissez-faire, which aims at the least possible interference with industrial competition between private persons or citizens, and (b) opposed to the general indifference, or at least the lack of state direction, which aims at close surveillance and control of the proceedings of industrial competitors, but would avoid direct initiative in production and direct attempts to level the inequalities of wealth. The leading idea of the socialist is to convert into general benefit what is now the gain of a few. He shares this idea with the anarchist, the positivist, the co-operator and other reformers; but, unlike them, to secure his end he would employ the compulsory powers of the sovereign state, or the powers of the municipality delegated by the sovereign.

In the former case we have state socialism, in the latter municipal socialism. Where there is direction or control of a socialistic state, public force mainly for the benefit of a few, this is hardly socialism. It employs the same machinery, the public force; and it secures a revenue which may possibly be used for the general benefit, as in the case of protective duties. But in such cases the general benefit is only a possible incident. So far (for example) as protection succeeds in keeping out the foreign competitors, the main result is the assured gain or prevented loss of a few among the citizens. Socialism by intention and definition would secure benefits not for a few, a minority, or even a majority, but for all the citizens. Communism has the same end in view; and socialism and communism (q.v.) are often confused in popular thought. But the communist need not be a socialist; he may be an anarchist, an opponent of all government; while the socialist need not be a communist. The socialists of the 19th century rarely, if ever, demand that all wealth be held in common, but only that the land, and the large workshops, and the materials and means of production on a large scale shall be owned by the state, or its delegate the municipality. The despotic gilds of 16th century would not now be tolerated. The strictest public regulation of trade and industry will probably continue to be that of the state, rather than a co-operative municipal regulation. And so the state's power by migration, the state's only by emigration. But the smaller bodies are likely to display more adventurous initiative; and it is significant that they appear in the imagination nearer to the individual than the state even of a small people can ever appear to its own citizens. Yet it is not the smallest unit, the parish, that has shown most activity in England, but the county, a unit arithmetically nearer to the state than to the individual.

It might be plausibly argued that the movement of modern events has been rather towards a kind of anarchism (q.v.) than a kind of socialism, if it were not for the element of compulsion (quite contrary to anarchism). Even the English poor law, universally called socialistic, is administered locally and the degree of socialism varies with the parishes. When the state's regulation went further and further in a succession of Irish Land Acts (1870, 1881, 1903), it assumed a socialistic character; the
face of agricultural industry was transformed for the benefit of the majority, if hardly of the whole, by the action of the state. But the result has been a state-aided individualism. The attempt to transform all industries by protection has not been made by the English state in these days. It remains broadly true that, since the English state became more democratic (Reform Acts of 1832, 1867, 1884), its socialism has become more and more of the municipal character. The end in view having more to do with economics than with politics, it mattered little theoretically whether the power exercised was that of the central authority acting directly or the delegated power in the hands of the smaller public bodies.

This has been the course of events in England with little conscious theory or principle on the part of the people or even of its leaders. It is certainly a partial fulfilment of the topic which of those whose theory or principle is socialism. The most important form of modern socialism, which may be called for convenience “social democratic” socialism, is founded on economic theory more or less clearly understood; it is therefore often described as economic or scientific socialism. Many men have become socialists less from logic than from sympathy with suffering. But modern socialism without disowning sentiment knows the need of facts and sound reasoning better than its predecessors, whom it calls Utopian. While among civilized peoples the suffering has on the whole grown less, the influence of socialism has grown greater; for it was for the socialist to show that the efforts made by the best socialists to reason faithfully and collect facts honestly. The remarkable extension of socialism in Germany may be traced in great part to the special circumstances which have made social democracy the chief effective organizer of working men in that country. But modern socialism is not a purely German product. To scientific socialism England, France and Germany have all made contribution.

Its theoretical basis came, in two curiously different ways, from practical England. The idea that the underpaid labour of the poor was the source of the profits of the rich is not only in Godwin and Owen but in the minor English land-reformers and revolutionary writers of the 19th and early 20th centuries, such as T. Spence, W. Ogilvie, T. Hodgskin, S. Read, W. Thompson. The positions of Ricardo that value is due to labour and that profits vary inversely as wages were taken by Marx (without Ricardo’s modifications) as established doctrines of orthodox political economy. It was declared to be a scientific truth that under modern industrial conditions the “exploitation” of the labourer is inevitable. In the theory of rent the exploitation of the tenant by the landlord was already admitted by Ricardo, and modern fixes it. But it was for the socialists to show that the salvation both of tenant and labourer lay in the hands of the central authority, acting as the socialists would have it act.

France had been prepared for socialism by St Simon and Fourier. The revolutions of 1830 and 1848, though on the whole unsuccessful in directly organizing labour, made socialist ideas circulate widely in Europe. Men began to conceive of a political revolution which should be also a social revolution, or of a social and industrial revolution which should be also political. We may say broadly that the socialism of 1910 was either inspired by the ideal of St. Simon or coloured by the ideas of Fourier. Scientific socialism was thus about fifty years old towards the end of the first decade of the 20th century. It would have little claim to be scientific if it had undergone no change in that time; but the change was not greater than the change in orthodox economic doctrine, which indeed it had followed.

Its adherents may be classified (1) according to theory and (2) according to policy, though, as scientific socialism is really both theory and policy, being a political claim founded on an economic argument, the distinction is sometimes a matter of emphasis.

There are theorists who find the exploitation of the tenant by the landlord to be the main evil whether it involves the degradation of the labourer or not. As some theologians confine their criticism to the Old Testament, so Henry George and Professor A. Loria, shunning the name of socialist, would not directly attack the system of modern large capitals but the appropriation of land. The social-democrat attacks both. He either takes Marx as guide, or, allowing Marx to be vulnerable, he stands on received economic doctrines with the addition of a political theory. He may himself rest content with the nationalizing of the means of production or he may tend towards communism.

In policy there is a difference between those scientific socialists who admit of no compromise with the existing order and the other scientific socialists who are willing to work with the existing order. The straightest sect would keep quite aloof from ordinary politics. The first step towards compromise is to allow the formation of a socialist party in the legislature, bearing a protest against all other existing parties. This is the rule on the continent of Europe. The next step is to allow members of the party to be any members of a real existing political parties; this is common in England and her colonies. The political history of scientific socialism is to a large extent the history of its attempts to avoid, to effect and to utilize the compromise.

There is, of course, a large body of socialists outside any organization. Partly from the teachings of socialists and partly from literary descriptions of the aims and reasons of socialism, there are multitudes who think socially without defining their own position with the exactness of the scientific socialist. It is often these amateurs who fall readily into utopias and who confound the boundaries between socialism and communism. This is done for example by such writers as H. G. Wells and Upton Sinclair. The temptation is evident. The borderland between large production and small may be sometimes debateable; and, as soon as the socialistic nationalizing of large production is extended to small, the way is open to the Utopias of communism. Communism is an idea far more utopian than socialism. Like the idea of a kingdom of heaven or a millennium, it springs from a spiritual enthusiasm that feels sure of its end; and, at first at least, reckons little of the means.

The enthusiasm may spring from a real conversion of the sort described in the Republic of Plato (vii, 516). Even scientific socialism, depending theoretically on close adherence to economic principles, depends practically on this conversion. It is as with Christianity, which depends on its theology but also on its change of heart; till we have refuted both we have not refuted Christianity. So a change of heart, which is also a change of view, is to socialism, as a religion, what economic and political theory is to it as a creed. All that is best in anarchism shares this spiritual feature with socialism. It is of a higher type than the anarchist, who has need of reality, or in other words: it includes that sympathy and more. It requires a mental somersault of the kind taken by Hegel’s metaphysician and (analogically) by Dante at the earth’s centre. The observer begins to see the world of men all over again, throwing from him all the prejudice of his class and abstracting from all classes. This abstraction may be less hard for those who belong to a class that has little, than for those of a class that has much, as religious conversion is held to be easier for the poor. But it is not really easy for any. The observer tries to conceive what the suffering of his own class would be if he were born a rich man or into a poor one. Critics can show that the line is a vanishing one, and that there are large groups of cases where the distinction is unsubstantial. Such borderlands are still the sporting ground of economists and philosophers and biologists. We could hardly contend, however, that no distinctions are true which break down at the border. It seems unsafe to say there is no war of classes, because at their nearest extremities the classes pass into each other. At the utmost we might infer that the best way to bring the war to an end was to crowd the nearest extremities. At present, taking the contrast not as its least or greatest but its middle, we find it to a fancy. The features that make the lower are distinguished from the higher are of different quality and kind, not merely of amount. They are described perhaps most fully by Tolstoy in Que faire?, but they are brought to the ken of every one of the rich who can overhear the daily talk of the poor.
enter into their daily cares and put himself in their place. If he makes the somersault and is "converted," all the little and great privileges of the rich seem now to have as many presumptions against them as were before in their favour. Why should he have so much comfort and they so little? why should he be secure when they live from hand to mouth? why should art and science and refinement be thrown in his own way and be hardly within their reach at all? Such and similar ponderings are not far from a revolt against inequality, whether the revolt takes the shape of anarchism or of socialism. It carries on its back the paternalism of Carlyle and Ruskin or even of the author of Sybil, relying as Disraeli did on the "proud control" of the old English state, which was occasionally and spasmodically constructive as well as controlling, but was always actuated by a feeling like that of a chief to his clansmen. The exponents of paternal socialism have no clear consciousness of the change in the state itself. They think they can still use the old tools. They see that the people have changed, but they do not see that if the past cannot be revived for a people neither can it be revived for a state. The idea of lordship (as distinguished from leadership) is becoming intolerable; and this restiveness may contain a safeguard against one of the worst risks of socialism—bureaucracy. Before the governing bureaucracy had destroyed all originality and eccentricity, the sovereign people would have discovered for itself that "tyranny is a poor provider."

Great Britain.—In England a certain academic interest in socialism was created by Mill's discussions on the subject in his Political Economy (1838) and a more practical interest by the appearance of the Christian Socialists. "The red fool-fury of the Seine" caused prejudice even against such harmless enthusiasts. The People's Charter (in the 'fifties) had no socialist element in it. Socialism first showed signs of becoming a popular movement in England after the lecturing tour of Henry George (1881-1882) in advocacy of the nationalizing of the land. About that very time (1880) the Democratic (afterwards in 1883 the Social Democratic) Federation was formed by advocates of the whole socialist programme. A secession took place in 1884 when William Morris, H. M. Hyndman and Belfort Bax founded the Socialist League. William Morris parted company with the league in 1890, and seems to have become more anarchist than socialist. Edward Bellamy's Looking Backward (1887) made some impression among intellectual people in England, but was not a very popular book. It now seems that a more way amongst the multitude, followed up as it was by his newspaper the Clarion. There were still few signs of a strong party. The first members of the Fabian Society (1888) were by definition opportunists, and though the Fabian Essays (1889) were socialist they were the declarations of men willing to use the ordinary political machinery and accept reforms in the present that might point to a socialist solution in the very far distance. Most of the Fabians became hard-working radicals of the old type, with general approval. England does not love even the appearance of a revolution. Nevertheless a change comes over the spirit of English politics in the direction desired by socialists, though hardly through any efforts of theirs. The change was predicted by Herbert Spencer in 1860 (Weston, Rev. April) some years before household suffrage (1867). In The Man versus the State (1885) he demonstrates that liberal legislation which once meant the removal of obstacles now meant the coercion of the individual. Though a large part of the coercive measures enumerated by Spencer are rather regulation than socialism, undoubtedly there is here and there a socialist provision. Thomas Hill Green's dictum, "It is the business of the State to prevent the consequences of the exercise of the human faculties is impossible" (Liberal Legislation and Freedom of Contract, 1881), did not in appearance go much further than Herbert Spencer's that "it is a vital requirement for society and for the individual to recognize and enforce the conditions to a normal social life" (The Man versus the State, p. 102); but the former saw clearly that the policy of the future must go beyond mere regulation. Too much importance has been attached to a saying of Sir William Harcourt in 1888, "We are all Socialists now." He meant no more than that we are all social reformers who will use the aid of the state without scruple if it seems necessary. He did not mean that the English people had adopted a general principle of socialism. Except in the case of free trade, it is hard to discover a general principle in English politics. The English people judge each case on the merits, and as if no general principle ever affected the merits. Regulation and not initiative is the prevailing feature of the action of government even now. The railways are still in private hands. The state railways, canals and forests of India, though John Morley (afterwards Viscount Morley) "made a present of them to the Socialists" (House of Commons, 20th July 1906), are the public works of a modern benevolent despotism, and do not go very far beyond those of its ancient prototype. They are the works not of the Indian but of an alien democracy. Contrariwise, in England itself, possessed of a fair measure of self-government, crown lands, government dockyards, army, fleet, post office were in existence when there was no thought of state socialism; they are not modern innovations but time-honoured institutions. The same is true of a great part of municipal socialism. It existed in the middle of the 19th century, and no local community would have been deterred from having its own water-supply or gas works by any fear of socialism. The fear is still less deterrent now, and we have seen electric lighting, tramways, parks, markets, ferries, light railways, baths and wash-houses, house property, river steamers, libraries, docks, oyster beds, held by towns like Glasgow, Birmingham, Manchester, Liverpool, Leeds, Bradford, Huddersfield, Colchester. Sometimes the management is economical, sometimes wasteful; but in all cases the undertakings have been supported by a majority who care little for general theory and everything for local interests. The "unity of administration" successfully advocated by Edwin Chadwick in the later Victorian period, and requiring "competition for the field but not in the field," is not inconsistent with municipal socialism. This last has been provided with new machinery by the establishment of county and district councils (1888), parish councils (1894) and even the perhaps otherwise-intended metropolitan borough councils (1899). Till 1907, when the progressive party in the London County Council were heavily defeated, that council was certainly moving in the path of municipal socialism. But, in its achievements (the Metropolitan Boundary Acts, 1890, 1891, 1894), it had not overtaken, still less surpassed, Birmingham or Glasgow. Municipal socialism in Britain finds many critics; it has the drawbacks of all democratic self-government. It is sometimes wasteful; but it is seldom corrupt; and there is no general desire for a return to a less adventurous policy. In the country districts democracy is still imperfectly conscious of its own power. There are acts on the statute book that would well equip a parochial socialism; but socialists seem to be able to do little more than accelerate slightly what seems to be the inevitably slow pace of political reform in England. Whether the extension of the franchise to women will quicken the rate of reform is uncertain. With every allowance, the change in English politics has been real, and it has been due in a great measure to the growth of organization among working men. The old trade unionism passed out of its dark ages by the aid of legislation (in 1871), which was for thirty years (till the Taff Vale decision in 1901, the older view being restored by the Trades Disputes Act 1906) considered to give to the trade unions the advantages of a corporation without the drawbacks. At the same time, through a better law of small partnerships (Industrial and Provident Acts 1875, 1886, 1896), it had not overtaken, still making rapid progress. Compulsory education (1870) increased the intelligence of the labouring classes and therewith their power to use their opportunities. Labour legislation, removing truck, making inspection and regulation of factories more stringent (see the consolidating Act of 1878 and the Factory and Workshop Act 1901) and providing compensation for accidents (1906), was forwarded by both political parties. This was not socialism but regulation. The old unionists were
radicals of the old type. Not so the unionists who came first into prominence with the Dock Strike in London in 1889. The way had been prepared by demonstrations of the unemployed in 1887 and 1888. When unionism embraced unskilled labourers, and at the same time pressed on the federation of all trades and their joint action, when, too, in the trade union congresses the intervention of the state was repeatedly claimed as essential to the success not only of an eight hours’ day but of such socialistic measures as nationalization of the land, it was clear that there was a new leveng working. The larger the numbers included in the trades societies the more their organization was bound to depart from that of the mass meeting, and to become indirect instead of direct self-government, government by representatives, and more and more by specially trained representatives. This was a tendency towards bureaucracy, or government by officials, not the highest type of popular government. A better preparation for democratic government has been given by the co-operative societies. If it be true that under a coming socialism the working class must dominate, then every phase of organization must be welcomed which widens their experience of self-government, more especially in the handling of industrial and commercial affairs. This last kind of education has been well given by co-operation, though chiefly through capital and hired labour on the old pattern of the ordinary employers. Co-partnership societies, best exemplified in the midland districts of England, are more democratic; but their numbers are few. The claims of the workman are somewhat in advance of his education. On the other hand it seems impossible in England to secure moderate concessions without extravagant claims.

Germany.—In Germany it was long an axiom that socialists must leave ordinary politics and political machinery severely alone as an evil thing. The short and futile struggle for constitutional liberty in 1848-1849 had driven most of those who were “thinking socialistically” into abandonment of political reform and into plans of fundamental change amounting to revolution. Karl Marx (1818-1883) and K. J. Rodbertus (p. v.) contented themselves with laborious and profound studies not intended to bear immediate fruit in practice. Marx and Lassalle were not so pacific. The former was from the first (see his Manifesto of 1847) inclined to give socialism an international character, taking also no pains to distinguish it from communism. Lassalle desired it for his own nation first. Both of them were in a sense Hegelians. From Hegel they had learned that the world of men, like the world of things, was in constant process of development; but unlike Hegel they regarded human evolution as purely materialistic, effected always by a struggle between classes in society for the outward means of well-being. Feudalism, itself the result of such a struggle, had given place to the rule of the middle classes. The struggle to-day is between the middle classes and the working classes. At present those who do not possess capital are obliged to work for such wages as will keep them alive, and the gains from inventions and economies are secured by the employers and capitalists. The labourer works at his cost price, which is “the socially necessary wages of subsistence” (the bare necessities of a civilized life); but he produces much more than his cost, and the surplus due to his “unpaid labour” goes to the employer and capitalist. This is what Lassalle called the “brazen law of wages,” founded on Ricardo’s supposed doctrine that (a) the value of an article that is not a monopoly is determined by its cost in labour, and (b) the wages of labour tend to be simply the necessities of life. The tendency of the laborer’s cost to increase and of steady employment is a frequent benefit to the capitalists in the periodic expansions of investment and enterprise, arising in response to new inventions and discoveries. Large business in modern economy swallows up small. Not only the independent artisans and workers in domestic industries, but the small capitalists and employers who cannot afford to introduce the economies and sell at the low prices of their large rivals are disappearing. But the growth of the proletariat, together with the concentration of business into fewer hands and larger companies, will cause the downfall of the present system of industry. The proletariat will realize its own strength; and the means and materials of production will be concentrated finally into the hands of the commonplace for the good of all. This revolution, like that which overturned feudalism, is simply the next stage of an evolution happening without human will, fatally and necessarily, by virtue of the conditions under which wealth is produced and shared in our times.

Such was in substance the view of all the German socialists of the last decade of the 19th century. Even Rodbertus had advanced a claim of right on behalf of working men to the full produce of their labour, but thought the times not ripe for socialism. The others made no such reservations. Lassalle planned a centralized organization of workmen led by a dictator, and called on the government of Prussia to establish from the public funds co-operative associations such as his opponent Schulze-Delitzsch had hoped to plant by self help. His socialism was rather national than universal. Marx looked beyond his own nation. He founded the International Union of Working Men in 1864, the year of Lassalle’s tragic death. Before the common danger of police prosecutions and imprisonments the followers of Lassalle and Marx were united at the congress of Gotha in 1875. The name social democrats had crept into use about 1860 when the followers of Marx founded at a congress in Eisenach the social democratic working men’s party. The party began to be a power at the congress of Gotha. It is a power now, but its doctrines and policy have undergone some change.

The last quarter of the 19th century witnessed (1) the repressive laws of 1871, (2) their repeal in 1890, (3) the three Insurance Laws and (4) a quickened progress of German industry and wealth during thirty years of peace and consolidation.

Bismarck’s government, alarmed by attempts on the life of the emperor and by the increased number of votes given to socialist candidates for the Reichstag, procured the passing of the Exceptional Powers Act (Ausnahme Gesetz) in 1878. The legislation at this time resembled the Six Acts of 1819 in England. Combined action and open utterance in Germany became almost impossible; and for organs of the press the social democrats had recourse to Zurich. Liebknecht and Bebel could still raise their voices for them in parliament, for Bismarck failed in his attempt to deprive members of their immunities (March 1879). But the agitation as a whole was driven underground; and it speaks well for the patience and self-control of the people that no widespread excesses followed. The declaration of the Social Democratic congress at Wyden, Switzerland, in 1880, that their aims should be furthered “by every means” instead of the old phrase “by every lawful means,” was a natural rejoinder to the law that deprived them of the lawful means; and it seems to have had no evil consequences. In 1881 repression was so far relaxed that trade unions were allowed to recover legal standing. In 1890 the reichstag refused to renew the law of 1878 for a fifth period; and finally in 1890 it repealed the law forbidding the amalgamation of workmen’s unions, and specially aimed at the new socialist unions, the natural allies of the social democrats. The vexatious prosecutions and condemnations for Majestätbeleidigung (lèse majesté) following 1890 did the cause more good than harm. The socialistic voters increased from 437,438 in 1878 to 1,000,000 in 1894 and 2,120,000 in 1898, while the elected members increased from 12 in 1877 to 46 in 1894 and 56 in 1898. By 1903 the voters had increased to three millions and in the elections of February 1907 they were 3,240,000. The socialists, however, in 1907 found themselves represented by 43 members as compared with 489 in 1877, the measure of success in the combative combina of the other parties against them, the matters at issue not being industrial policy, but colonial government and naval expenditure. The increase in the number of voters remains a proof that the power of the party in Germany has rather been increased than diminished. In 1908 they gained seven seats in the Prussian Diet, where they had hitherto been unrepresented. Yet “remedial measures” had been passed which were intended to make socialism unnecessary. Bismarck, who admired Lassalle and had no scruples about the intervention of the state, had
planned a series of measures for the insurance of workmen against sickness, accidents and old age; measures duly carried out in 1883, 1884 and 1891, respectively. The socialists not unreasonably regarded the government as their convert. They could point to two other "unwilling witnesses," the Christian Socialists and the "Socialists of the Chair."

In the Protestant parts of Germany the socialists as a rule were social democrats, in the Catholic as a rule they were Christian Socialists. As early as 1863 and 1864 Dr. Döllinger and Bishop Ketteler, followed by Canon Moufang, had represented socialistic sentiment and doctrine. Ketteler, who had been under the influence of Lassalle, had hoped that the church would make productive associations her special care. Moufang would have depended more on the state than the church. All were wake to the risks of the workmen's position as described by the social democrats, and they were anxious that the Catholic church should not leave the cure of the evils to be effected without her assistance. Ketteler died in 1877, and the pope's encyclical of the 28th of December 1878 bore no trace of his influence, mixing up as it did socialists, nihilists and communists in one common condemnation. The encyclical De conditions opificum of 1891 might show that the views of the Christian Socialists had penetrated to headquarters; but the encyclical on Christian Democracy of 1901 (January) betrays no sympathy with them. The Protestant church in Germany has been hampere by fear of offending the government; but it contains a vigorous if tiny body of Christian Socialists. Rudolf Todt, a country pastor, was their prophet. His book on Radical German Socialism and Christian Society (1878) led Dr. Stöcker, the court chaplain, to found an association for "Social Reform on Christian Principles." This was denounced rather unfairly by politicians of all ranks as an organized hypocrisy. Its influence was shortlived, and its successor, the "Social Monarchical Union" (1890), shared the unpopularity of Stöcker, its founder. Even the Socialists of the Chair, middle class Protestants as they were, would have nothing to say to it, but preferred to go on with their own.

From the year 1858 there had existed a league of economists and statesmen called the "economic congress" (Volkswirtschaftlicher Kongress), a kind of English Cobden Club, though it aimed chiefly at free trade among all sections of the German people in particular. After the Empire its work seemed finished; and a new society was formed, the "Union for a Policy of Social Reform" (Verein für Sozialpolitik). Professors G. Schmoller, W. Roscher, B. Hildebrand, A. Wagner, L. J. Brentano, the statistician E. Engel and others met at Halle in June 1872, and a meeting of their supporters followed at Eisenach in October of that year. These Kiehleder-Socialists or Socialists of the Chair (academic socialists) agreed with the social democrats in recognizing the existence of a "social question," the problem how to make the labourers' condition better. To the old-fashioned economist this was no problem for the legislature; competition solved its own problems. But, while the social democrats looked for social revolution, the academic socialists were content to work for social reform, to be furthered by the state. The state was, to them, "a great moral institution for the education of the race." They were a company of moderate state socialists, realizing that the state was the servant less than the master. They did much gratuitous service to the government in the preliminary investigations preceding the great insurance laws.

The German people were made a little more inclined to state socialism than before by the efficiency displayed by the bureaucracy in the wars of 1866 and 1870. If the Insurance Laws are found to work well, this inclination may be confirmed, and the idea of a revolution may fall into the background. The attitude of the social democratic party became less uncompromising than in earlier days. Since they regained their liberty in 1859, its leaders have kept them well in hand. Their principal journal Vorwärts was conducted with great ability. Their agitation became as peaceful as that of trade unionists or co-operators in England. They ceased to denounce the churches. They tried to gain sympathy, quite fairly, by taking up the cause of any distressed workers, or even ill-used natives in colonies, and urging redress from the state. The present state had become to them almost unconsciously their own state, a means of removing evils and not a mere evil to be removed. The anarchists had been disowned as early as 1880. The extreme socialists who denounced return to the old tactics were cast out at Erfurt in 1891, and became "Independent Socialists."

The controversy between friends and critics of socialism still rages in learned circles, producing a prodigious quantity of literature year by year; but the old strictures of Treitschke and Schäffle seem now to have lost a little of their point. Though the programme adopted at Gotha in 1875 was not entirely or even seriously altered, the parts of it due to Lassalle fell into the background. For many years Marx and not Lassalle was the great authority of the party. Marx died in 1883, but remained an oracle till 1894, when (just before his own death in 1893) Engels published the last volume of his friend's book on capital. The volume was expected to solve certain logical difficulties in the system. Instead of this, it caused a feeling of disappointment, even among true believers. Many, like Bebel and Kautsky, kept up the old adoration of Marx; but many, like Eduard Bernstein, rightly felt that to give up Marx is not to give up socialism, any more than to give up Genesis is to give up theology. Bernstein openly proposed in congress that the old doctrines and policy of the party, involving as they do the despair of reform and insistence on the need of revolution, should be dropped. He had not carried his point in 1908, but his influence seemed to be increasing. The death of Liebknecht (August 1900) removed from the ranks of the social democrats one of their most heroic figures, but also one of the strongest opponents of such a change of front. Yet Liebknecht himself had made concessions. It was impossible for a man of his shrewdness to close his eyes to what the state had done for the German workman. It was impossible, too, to ignore the progress that Germany had made in wealth and industry since the creation of the Empire in 1871. Germany has been fast becoming a manufacturing country; and, though the growth of large manufacturing towns in the Rhine valley and elsewhere has multiplied socialists, it has added to the income of the German workman. He is further from poverty and distress; and his socialism means an endeavour after a larger lot, not, as formerly, a mere struggle against starvation. It is likely, therefore, to have less and less of mere blindness and violence in it.

The German socialists were chiefly interested in securing such an extension of the franchise in Prussia as would make their representation in the Prussian parliament correspond as near to the number of their adherents as in the Reichstag itself. They insisted on seven seats in the former, in June 1908, though they had perhaps half a million of adherents in Prussia. They seemed for good or for evil to be taking the place of the old radical party. The position in Austria was somewhat different. The first general elections held under a really democratic suffrage (May 1907) resulted in the return of eighty social democrats and sixty Christian socialists to the Reichsrath, as compared with eleven and twenty-six in the unreformed parliament. They were opposed (anti-clerical and clerical) on many questions, but they made it certain that economic and industrial policy among the whole nation would rival and perhaps out-rival the organization of military supremacy and Kriegepolitik that absorbed the attention of the old Reichsrath.

France.—In France the socialists have found it harder to work in the parliamentary harness. Marx had said long ago that for the success of socialism besides English help there must be "the crowing of the Gallic cock." French enthusiasm for social revolution is feeble in the country districts but very strongly pronounced in the large towns. The Communards of 1871 might be called municipal socialists of a sort, but their light went out in that année terrible. Something like a movement towards organized socialism began in 1850 on the return of some prominent members of the old commune from exile. A congress was held at Havre under the leadership of J. Guesde and J. A. Ferrout; it adopted a "Collectivist" programme, Collectivisme meaning state socialism. A minority under J. F. E. Brousse and J. F. A,
Joffrin broke away (in 1881) from the main body and stood out for municipal socialism, decentralization and, later (1887), self-governing workshops aided by public money. Co-operative workshops are already subsidized in France from the public funds, and favoured by preferences in public works and other privileges, without striking results. The Broussistes are also called Possibilistes, as content with such socialism as is immediately practicable. They supported, for example, agrarian reform on the present basis of private property (Marseilles, 1892).

After several unsuccessful negotiations, (the amalgamation of the Collectivists, Possibilists and Blanquistes (extreme revolutionaries)) was accomplished in 1890. But the body did not the collection of the new party. Though the leaders of the Chamber acted more or less loyally together, they were not closely controlled by the organization outside. In consequence (like Mr John Burns in England in 1905-1906) those who accepted office usually came under a cloud. This happened to M. Milleraud when he became minister of commerce in the Waldeck Rousseau government of 1890, and in a less degree to M. Jaurès when he became vice-president of the Chamber. M. Milleraud was, indeed, expelled from the party, and at the socialist congress of Amsterdam (August 1904) a strongly worded "resolution concerning the organization, by the collective (class) government. The vote was not unanimous, and the resolution itself was attributed to the German Befeb. An attempt was made in Paris (April 1905) to bind the various parties of French socialists more closely together by forming a new "Socialist party, the French Section of the International Labour Union." It laid down stringent rules for the guidance of socialist deputies. In comparison with the steady united action of the Germans, the proceedings of the French socialists, perhaps from their greater political liberty, seems a wayward guerilla warfare. The French state is not on principle averse from intervention. It has been always more ready than in England to interfere with competitive trade and to take the initiative on itself. It controls the Bank of France, owns most of the railways, and directs secondary as well as primary education. After the disputes at Carmaux (in 1892) it proposed to take over the mines. There is no general poor law; but old-age pensions have been voted, and workmen's compensation is as old as 1888. State socialism might have gone farther if French bureaucracy had not proved less efficient than German.

Though there are socialists in French professors there can hardly be said to be a body of academic socialists in France. The strongest economic writing is still that of the orthodox economists, P. E. Levasseur, P. P. Leroj-Beaulieu, Yves Guyot. Even Professor Charles Gide, though reformer, is not socialist. Of the two party periodicals La Revue socialiste is moderate, Le Mouvement socialiste hardly so. The latter is in many ways more akin to anarchism than state socialism. Socialism has its allies in the sporadic Christian socialism of the Churches, both Catholic and Protestant, and in the solidarists who would transform the existing system of employment without abolishing private property. The school of Le Play, though devoted to social reform, can hardly be called an ally of socialism.

Netherlands.—Socialism has found a kindler soil in Belgium and Holland, and these countries have been the favourite meeting-place in recent years of congresses of all denominations of socialists. In Belgium the Flemish social democratic party led by de Paepe united in 1879 with the Brabantine or Walloon. They organized trade unions. They helped the liberals in 1893 to procure the extension of the suffrage. In 1907 they had thirty representatives in parliament. The flourishing co-operative societies, Vooruit (Forwards) in Ghent and Maison du peuple of the Brussels bakers, were the work of their members. Its success in co-operation is almost the distinctive feature of Belgian socialism. Socialists helped to procure the adoption by Belgium of a system of old-age pensions for the poor in 1900, and of the cheap trains which do so much for the workmen in town and country. In Holland, which is not a crowded manufacturing country but even now largely agricultural and pastoral, the socialists are less formidable, if that be the right word. They came into line with the German socialists in 1889. Social reform proceeds with or without their aid. There has been a factory act since 1886 and the have been industrial legislation, against accidents since 1900. Municipal socialism has made progress. The great railway strike of 1903 aroused public interest in the condition of the workman, but the legislation that followed was rather regulative than socialistic.

Switzerland.—Switzerland, for generations a refuge to exiles, shows them hospitality without sharing their views. There is little legislation of a socialistic nature; socialists are to be found here and there, especially in the German cantons.

Scandinavia.—Scandinavia stands less apart from European movements than do the others. The industrial legislation is rather regulative than socialistic. Hjalmar Branting, one of the most prominent socialists, was in 1904 a member of the Swedish parliament. The trade unions of Denmark are largely socialistic, but Denmark is no nearer complete conversion than England.

Italy, Spain.—Socialism might be thought to find a better soil in Italy and Spain. Italy has been described as "all proletarian." But a great depth of poverty fits a people rather for the anarchism of violence than for socialism. The social democrats have made way, notwithstanding, and in 1893 returned the French general secretary. Milan is still the capital of the movement. Lavelle has the idea that the most hopeless condition in Italy because Rome was uninhabitable every summer. But social democracy in Germany, its own country, is not bound up with Berlin. Italy as a whole must make progress in social and political development before it can receive the new ideas and still more before it can grow beyond them. The burden of taxes leads to revolts of shear despair, followed by repression which has extended to socialistic clubs (fasci dei lavoratori) and even workmen's unions. State socialism in the form of state railways has not been very efficient. Factory legislation is behind that of other civilized countries, and is of very recent origin (1902). Old-age pensions were introduced in 1898, and accidents insurance on the German model in the same year. Municipal socialism, finding some tramsmels removed, had in the first decade of the 20th century begun to show itself in the large towns. In Spain there is a Socialist Federation; there are socialist newspapers; and there seems to be no doubt that the cause has gained ground, even as against anarchism. It may perhaps yet be a power in the legislature. It is mainly in Russia that anarchism has the field to itself.

In spite of the pressure exerted by the Duma, reformers in Russia have been strongly tempted to be anarchists, even of a violent type. Democracy had special difficulties in reaching legislative power. Partly for this reason, "social democracy" has had a subordinate place. The Russian socialists have, of some of them, rebelled against the view once essential to socialistic orthodoxy: that Russia must pass through the stage of "capitalism" before reaching the stage of "collectivism." Marx himself (in 1877) conceded that the progress might be direct from the system of village communities to the ideal of social democracy. Capitalism is already extending itself, and the consistency of the theory need not have been broken. Even so, in the absence of democratic government, the prospects of socialism are doubtful. In Finland there were in 1908 eighty socialist members in a parliament of two hundred. The party might console itself by the thought that over the whole Russian empire many more were socialists than could declare themselves so.

Australia.—In contrast to nearly all the countries of "Old Europe," the self-governing colonies of Greater Britain stand out as nothing if not democratic. Nowhere is democracy sturdier than in Australia, the separate states of which have since 1890 been federated as one commonwealth. But while it has a protective tariff and makes no pretence of a laissez-faire policy, the central government is less socialistic than the separate confederated states. The progress even of these has been, as in England, rather in municipal than in state socialism. It is true that crown lands, mines and railways figure more largely. But to find state socialism in its vigour we must pass to New Zealand.
New Zealand.—Removed 1200 m. from Australia, its nearest civilized neighbour, secured by English naval power and “compassed by the inviolate sea,” New Zealand is better suited for the experiment of a closed socialistic state than perhaps any other country in the known world. It began its new career in 1880-1890, too late for perfect success, but not too late to secure a large measure of public ownership of what elsewhere becomes private property. It owns not only the railways but two-thirds of the whole land, setting it on long leases. It sets a limit to large estates. It levies a progressive income tax and land tax. It has a labour department, strict factory acts and a law of compulsory arbitration in labour disputes (1895). There are old-age pensions (1858), government insurance of life (1871) and against fire (1905). Women have the suffrage, and partly in consequence the restriction of the liquor traffic is several. There is a protective tariff, and oriental labour is excluded. The success of the experiment is not yet beyond doubt; compulsory arbitration, for example, did not work with perfect smoothness, and was amended in 1908. But there has been no disaster. The decline of the birth-rate has been greater than in Britain. It is fair to add that the experiment is probably on too small a scale to show what might happen in larger countries. New Zealand has only 100,000 sq. m. of territory and about one million of inhabitants, mainly rural and of picked quality. The conditions of combined isolation and security are not easily obtained elsewhere. The action of the state has been in the great majority of instances rather regulative than constructive.

Canada.—This last feature is still more marked on the great North American continent. The Dominion of Canada, from its foundation by confederation in 1867, has given its land away too freely. The Dominion, indeed, has only had the land of new territories to dispose of; the original states are the owners of their own unsettled lands. The Dominion government owns the Intercolonial railway but contents itself with subsidies to the rest, over which it has a very imperfect control (by its Railway Commission). It levies royalties on Yukon gold, carries out socialistic experiments, etc. in the means of transport between province and province; and in theory whatever functions are not specially reserved to the provinces fall to the Dominion government. The provincial governments, however, show the greater activity. Ontario owns mines and railroads, Nova Scotia coal and iron fields. “The operation of public utilities” by the municipalities is encouraged. Over Canada with the rise of large towns there has been an advance of municipal socialism, not only in the largest, like Toronto, but in the newer and smaller, such as Port Arthur on Lake Superior, where half the local expenditure is paid by public funds, and the public administration is in the hands of the Social Democratic party. Yet the Dominion has a democratic franchise, paid members, a labour department and free education. The democratic basis is not lacking; but the nature of the country is not such as to make it likely that Canada will lead the way in socialistic experiments. The protective tariff, by developing groups of manufacturing industries before their time, introduced into Canada some of the troublesome features of urban civilization in older countries. Accordingly trade unions became better organized. Trusts (like that of the grocers, 1908) began to show themselves. But socialistic propaganda was mainly confined to the mining districts, especially in the far west.

United States.—The great American republic would seem a better field for socialistic experiment, having more men, more states and ample political liberty. But state socialism, in the strict sense of the action of the central supreme authority, is limited by the Federal constitution, and any functions unassigned to the central authority by the constitution fall to the separate states. The separate states have rarely gone farther in a socialistic direction than England itself. In the way of restriction and regulation they have often done more (see Bryce, Amer. Commonwealth, chap. 51). From 1876 the separate states have had an admitted right to control undertakings having the nature of monopolies. The railways are in private hands; and it was not until 1887 by the Interstate and Commerce Act (followed in 1888 by the Railway and Canals Act) that the Federal power secured control over the means of transport running beyond the state into another. In the same way the Anti-Trust Law of 1890 gave control over the great combinations for “forestalling and engrossing” the supply of articles of necessity or wide use. Socialists have regarded trusts as the stepping-stones to state socialism; but the American people would seem to prefer to see government controlling the trusts rather than itself displacing them.

Trade unionism has made better progress under the Federation of Labor than in the more ambitious Knights of Labor (1879). Like their English counterparts, the societies in the United States include numbers of socialists, and perhaps even more socialistic elements. Henry George’s idea of the “single tax” became law in the land and the “socialistic Labor Party” since 1877. Bellamy’s socialistic Utopia, Looking Backward (1888), caused nearly as great a sensation as Henry George’s Progress and Poverty (1879). It led to the movement called “Nationalism,” the scope of which was the nationalizing of the means of production generally. Of a less literary sort was the influence of “Pepulism” and the People’s party (formed in 1890). Mixed up with the politics of W. J. Bryan in 1896, it lost a little of its uncompromising socialistic flavour.

General Criticisms.—If the ideal of state socialism be viewed in an equally critical spirit, many of the objections brought by the moderate anarchists are seen to have their weight. A strong central government to which all power was given over all the chief industries in the country would, they say, be contrary to liberty. Our leaders would be too likely to become again our masters. Supervision would become irksome. Great powers would be a temptation to abuse of power. A democracy with a strong central government would need to leave much to its chosen guardians, and to retain the same men in the position of guardians till they fully learned the difficult business of their office; but this in the end means either what we have now, a government by elected leaders, who, once elected, consult our wishes only on rare occasions,—or a government by permanent officials, which means liberty to go on in the old ways but great fear and jealousy of new ways, in fact, order without progress, no liberty of change.

This criticism becomes rather stronger than weaker if we press the doctrine of the supremacy of the working-classes, a doctrine that figures largely with some socialists. We are told that having been nothing, the working-classes will be everything; having so long been the ruled, they will be the rulers. If they have produced for all the rest, the product will now be theirs instead of another’s. This doctrine is not essential to socialism; it is indeed hardly consistent therewith. It would not be fair to press it, for no men know better than the scientific socialists that under modern conditions it is in most cases quite impossible to say what is the product of one man’s labour. Articles are not made at one stretch by one individual. The contributions of the various hands and minds concerned from first to last in the production of a pocket-knife or a pair of trousers would travel over our stage like Banquo’s ghostly dots. We are told of a state in which the socialists demand, when they are not declaring to uncritical sympathizers, is not that a man should have what he makes but that what is made by great capitals or on great estates should be so distributed that it is not engrossed by individuals, but satisfies the wants of as many as possible. There is no superior enlightenment in the ordinary unskilled or even skilled manual labourer to fit him above others for supreme power. According to socialists and anarchists and indeed all of us who are not incorrigible optimists, the hungry generations have trodden the working man down too much to make him instantly or even speedily fit to do the work of government himself. He is of like passions with ourselves. He will be perfectly qualified in process of time to share in such responsible work. But at present he needs training.
SOCIAL SETTLEMENTS

The anarchists for their part do not desire the concentration of industry and the rule of it from the centre by anybody, working man or not—and they think the social democrats quite wrong in believing the concentration inevitable. They point to the fact that at the present moment there is a partial revival of domestic industries, assisted by gas and electricity. These are the small industries of people with small means; they make a less imposing figure before the public than the great trusts, such as the Steel Trust, and the Shipping Trust. The sums involved are so immense that it might seem impossible for competitors to cope with the trusts; therefore, it is thought, the trusts will soon rule alone, and, lest they should rule ill, the state should take their place. A great combination approaches monopoly, and a far-reaching, wide-stretching monopoly (say of the carrying trade) might mean a public danger. Should we listen to our friends the socialists and avert the danger by making the state the monopolist?

There seems no proof of the necessity of this extreme step. Where there is political danger the old-fashioned method of regulation and control by the state seems quite equal to the occasion. As yet the trusts are on their trial and their success is not certain, still less their abuse of the success when it comes. Their monopoly is not an absolute monopoly; and they have a wholesome consciousness of the possibility of competitors. A government trust would have none such. In some instances there would be the further difficulty that to prevent political friction it would need to be a trust of several nations—an idea difficult to realize on such a scale and in such matters.

The English mind does not turn naturally to state trusts; but it now finds no difficulty in municipal and local trusts. Private local monopolies, like those of the water companies in London, were as troublesome to the locality as any universal monopoly of the article could be; and the remedy which even London must find for the troubles will be the municipal trust. There are few instances in England of successful appropriation by the state of a business formerly competitive; railways are still only regulated. But there are so many examples of successful appropriation by the local authorities that the future absorption by them or the central authority of habitually unruly companies which have contrived in any way to abuse their monopoly may be deemed almost certain. The great demand of the scientific socialists is thus likely in England at least to break up into smaller separate demands that will obtain their answer separately by patent political action.

Socialism is making progress, but not to any great extent state socialism. New Zealand itself, where it has perhaps done most and best, is not a proof to the contrary, the province of Ontario in Canada having twice the area and population. Rather is it true that the state is more decidedly regulative. The ultimate result, to judge by the old countries, may be that each nation will include a community of groups more or less socialist in organization, but will not itself be a socialist state. The socialist experiment is more likely to be tried by provinces than by states, by districts than by provinces, by towns than by districts. They all get their compulsory powers, as delegated to them, from the central authority; but the central authority itself has shown little power of origative action, and it lacks the minute knowledge of the people on the spot. The one or two great industries and businesses (railways, post office, telegraphs, forests, census, coinage, in some countries) that have formed the chief public works that are everybody's business and nobody's business will probably remain a state concern; but the limits to the state's activity except in regulation soon arrive. On the other hand, there is no visible assignable limit to municipal or local socialism, as long as the state's parliament leaves it a free course. If the localities choose to make social experiments there seems no rule of general policy to prevent them, if we put aside experiences of financial failure or of the tendency to corruption. The great fear conjured up by the vision of socialism has been the fear of a new despotism. The despoticisms of some hundreds of local bodies are likely to checkmate one another, or at least always likely by their varieties of pattern to provide a means of escape for individuals unhappy under the rule of any one of them.

Anarchism, when at all rational, resolves the state into its component municipalities and small groups. The question which carries us beyond anarchism is how such groups can last and be secure without a central state. They could only be so on the assumption of a change in human nature of which their is no sign. It seems not improbable that the strong central government will be so democratic and at the same time so wise with the wisdom of a great representative council that all that is sound in the contents and aspirations of anarchists and socialists will be secured by it. Before such a future arrives, we can best prepare for it by seeing to it whether in a new country or an old that our representative system represents us at our best. Our small councils and our great councils will not of themselves become cleaner for having larger powers. If they are not clean they are a public danger. If they are clean, the coming socialism, whatever be its precise complexion, need have no terrors. It too will represent the people at their best.

Gide's "Economic Literature in France," Economic Journal (1907).

SOCIAL SETTLEMENTS, associations of men and women of the educated classes who take up residence in the poorer quarters of great cities for the purpose of bringing culture, knowledge, harmless recreation, and especially personal influence to bear upon the poor in order to better and brighten their lives. Practically, the watchword of such settlements is personal service. To Arnold Toynbee (q.v.) may be given the credit of leading the way in this direction, and the Hall which Canon Barnett established (in 1883) to his memory in the east end of London was the first material embodiment of the movement. Since then many settlements of the same or similar nature have sprung up in Great Britain and America, some too on the continent of Europe and some in India and Japan. The sympathies of young men at the universities have been enlisted towards the movement, and an Oxford house, a Cambridge house, and other university missions have been founded in London. There are also many in connexion with various religious bodies. The practical spirit is shown in the formation of gilds, camps and institutes. Lads and girls, and even children, are gathered together; efforts being made to organize for them not only educational and religious opportunities, but harmless recreation, while the dwellers in the settlements know in the game and identify themselves most sympathetically with all the recreations. Many of the residents take also a considerable share in the work of local administration. Women's settlements probably are more general in the United States than in Great Britain; but in both countries they carry out a great variety of useful work, providing medical mission dispensaries, district nurses, workrooms for needle-women, hospitals for women and children, &c.

See W. Reason, University and Social Settlements (1888); S. Coit, Neighbourhood Guilds (1892); G. Montgomery, Bibliography of College, Social, University and Church Settlements (Boston, 1900).
SOCIETIES, LEARNED. Under Academies will be found a general account of the principal bodies of which that word forms part of the titles, usually denoting some kind of state support or patronage. But that account excludes a number of important scientific, archaeological, and literary societies, chiefly founded and carried on by private collective effort. Most of the institutions hereinafter mentioned are still flourishing. Fine art societies are not included.

In their modern form learned and literary societies have their origin in the Italian academies of the Renaissance: private scientific societies arose chiefly during the 19th century, being due to the necessity of increased organization of knowledge and the desire among scholars for a common ground to meet, compare results, and collect facts for future generalization. These bodies rapidly tend to increase in number and to become more and more specialized, and it has been necessary to systematize and co-ordinate their scattered work. Many efforts have been made from time to time to tabulate and analyze the literature published in their proceedings, as, for instance, in the Reperatorium of Reuss (1801–1821) and the Catalogue of Scientific Papers of the Royal Society (1867–1902) for physics and natural science, with its subject indexes and the indexes of Walther (1845) and Koner (1852–1856) for German historical societies. A more recent example may be found in G. L. Gomme's Index of Archaeological Papers (1907). A further development of the work done by societies was made in 1822, when, chiefly owing to Humboldt, the Gesellschaft deutscher Naturforscher und Ärzte first met at Leipzig. This national association of medical men was followed in 1831 by the British Association for the Advancement of Science, which has served as the model for similar societies in France, America, Italy, Australia and South Africa. The merit of introducing the idea of migratory congresses into France is due to the distinguished archaeologist, M. Arcisse de Caumont (1802–1873), who established the Association Normande, which from 1834 held a reunion in one or other of the towns of the province for the discussion of matters relating to history, archaeology, science and agriculture, with local exhibitions. From the same initiation came the Congrès Archéologique de France (1834), which was organized by the Société Française pour la Conservation des Monuments Historiques, the Congrès Scientifique, which held its first meeting at Caen in 1833 (directed by the Institut des Provinces), and the Congrès des Sociétés Savantes des Départements, which for many years after 1850 held its annual sittings at Paris. The idea received the sanction of the French government in 1861, when a Congrès des Sociétés Savantes was first convoked at the Sorbonne by the minister of public instruction, who in 1846 produced an Annuaire des Sociétés Savantes. In Italy Charles Bonaparte, prince of Canino, started an association with like objects, which held its first meeting at Pisa in 1850. Russia has had an itinerant gathering of naturalists since 1867. International meetings are a natural growth from national congresses. Two remarkable examples of these cosmopolitan societies are the Congrès International d'Archiologie et d'Anthropologie Préhistoriques, founded at Spezia in 1865, and the Congrès International des Orientalistes (1873).

I. SCIENCE GENERALLY.

United Kingdom.—First in antiquity and dignity among English societies comes the Royal Society {4.e.} of London, which dates from 1660. In 1663 William Molyneux and John Locke went to Dublin to form a society in Dublin after the pattern of that of London. In consequence of his efforts and labours the Dublin Philosophical Society was established in January 1684, with Sir William Petty as first president. The members subsequently acquired a botanical garden, a laboratory and a museum, and placed themselves in communication with the Royal Society of London, which after the death of William III came to an end at the commencement of hostilities between James II and William III. The society was reorganized in 1693 at Trinity College, Dublin, where meetings took place. It was dissolved in 1742. On 25th March 1755 the philosopher and author of the exertions of Dr S. M. Maddox, the Dublin Society for Improving Husbandry, Manufactures, and other Useful Arts came into existence. In January 1737 they conquered a charter of incorporation from George II, and in 1746 the society was placed on the civil establishment, with an allowance of £500 a year from the government. A charter of incorporation was granted in 1759, and seven years later the Royal Dublin Society for the first time owned a house of its own, the house of Dunham. The Dublin society did not become an active body until a long interval had elapsed since its foundation, and in 1792 it was reorganized and merged with the Dublin Institution. The Royal Dublin Society has devoted itself to art. Between 1761 and 1767 government grants to the amount of £42,000 for promoting natural agriculture and manufactures were distributed by the society, which in 1792 merged with the Dublin Institution and assumed the name of the Royal Society of Ireland, being incorporated in 1802. It has published Transactions (1769, &c.), and Proceedings (1774–1775, 1814, &c.) and Journal (1859–1876, &c.) and is still issued. The Dublin Unit. Phil. Soc. issues Proceedings (for the Merchants' of the Royal Society of Ireland. The Physical Society of Edinburgh was instituted in 1771, and incorporated in 1788; it is exclusively devoted to natural history and the physical sciences. It has been merged many other bodies, as Chirurgico-Medical in the 1774, Ars Physica in 1796, the Hibernian Medical in 1799, the Chemical in 1803, the Natural History in 1812 (which brought in Brougham and Playfair), the Geographical and the Dublin Philosophical Institution (1858, &c.). From the Philosophical Society of Edinburgh (1731) was developed the Royal Society of Edinburgh, whose charter is dated 29th March 1783. It was to comprise a physical and a literary class; among the members of the latter were Robertson, Hume, Burke and Reid, and among those of the former Hutton, Black, Playfair, Dugald Stewart and Watt. The literary division has been much less productive than the other. A second charter was obtained in 1811. The society has published Transactions (4vo 1788, &c.), and Proceedings (8vo, 1832, &c.). The Royal Scottish Soc. Art (1821) publishes Transactions.

The Zoological Society of London, for the promotion of zoology and botany was founded in 1788 by Dr (afterwards Sir) J. E. Smith, in order to supplement the work of the Royal Society, and obtained a royal charter in 1802. The herbarium and collections of Linnaeus, with many additional specimens gathered abroad, were presented by Sir John Baptist's old house in Soho Square to Burlington House (London) in 1857, and assumed the apartments it now occupies in 1873. It has published Proceedings (1849, &c.), and Transactions (1856, &c.). The Zoological Society (1794) is divided into zoological and botanical sections. The Society for the Encouragement of Arts, Commerce, and Manufactures took its origin from the London Association, and was founded by the painter William Shipley. Attention was paid to the application of science to practical purposes, a subject passed over by the Royal Society. Exhibitions of pictures by native artists were held, and a competition was instituted for the Neadei Prize. A fresh start in a new career was made by the Society of Arts (since 1799 known as the Royal Society of Arts) in 1847, when it obtained a charter and the presidency of the Prince Consort. The International Exhibitions of 1851 and 1855 were held in its rooms. The East Indian section dates from 1869, the foreign and colonial and the chemical sections from 1874. Its organs have been Transactions (1783–1849) and the Journal (1853, &c.). Sir John Banks, Count Rumford and other fellows of the Royal Society started the Royal Institution in 1799, when a site was purchased in Albemarle Street for an establishment in London for the promotion of knowledge of the arts and sciences. "It shall be the principal object of the institution to "teach the application of science to the useful purposes of life." The institution was incorporated in the following year. One of the most important epochs in the history of chemistry must be dated from its establishment. The Royal Institution has pursued its investigations. Belonging to the institution are foundations for professorships in natural philosophy, chemistry and physiology. Courses of lectures on special subjects are given as well as discussions (once a week) of a more general and literary character. Its Journal has been issued since 1820. The London Institution was established on a similar basis in 1805 and incorporated in 1807. The building in Finsbury Circus was erected in 1819. The British Association for the Advancement of Science was instituted at York on 27th September 1831, an imitation of the itinerant scientific parliament held in Germany since 1822 (already referred to), and arose from a proposal by Dr Brewster. A meeting was held at one place in the British empire chosen at a previous meeting. The object of the association is to promote science, to direct general attention to scientific matters, and to facilitate intercourse between learned men in all parts of the empire. The Reports and committees are published in the annual Report (1833, &c.). The Historical Society of Science (1841) printed a couple of volumes; those of the Royal Historical Society have appeared with scarce old works in zoology and botany, still flourishes. The Royal Colonial Institute was founded in 1868 and incorporated in 1882. It provides a place of meeting for gentlemen connected with the colonies, and is in great part devoted to colonial matters relating to the British empire, has established a museum and library, and gives lectures in a new building in Northumberland Avenue (London). It has published Proceedings (1856–1876, &c.) and Transactions of Great Britain, was founded in 1865 to form a connecting bond between men of science and others engaged in investigating important questions of philosophy and religion, and is associated with the Holy Spirit. Its organ is the Journal (1867, &c.). The Royal Asiatic Society and the East India Association (1866) publishes Journals. The African Society meets at the Imperial Institute and publishes a

In the following
Plantations, issued by Dr Franklin in 1743.
year the American Philosophical Society was founded at Philadelphia, with Thomas Hopkinson as president and Franklin as
secretary. With it was united on 2nd January 1769 another Philadelphia society, The Junto (1758), the records of which have been
preserved. The American Philosophical Society is still in vigorous
life, and is an exclusively scientific body and the oldest organized
society in the United States for the pursuit of philosophical investigation in its broadest sense. It publishes Transactions (410, 1771, &c.)
and Proceedings (8vo, 1838, &c.). Second in point of date comes the
American Academy of Arts and Sciences of Boston, incorporated in
1780 with the object of furthering the study of the antiquities and
natural history of the country.
Its Memoirs (410, 1785, &c.) and
The Connecticut
Proceedings (8vo, 1846, &c.) are still published.
Academy of Arts and Sciences was incorporated at New Haven in
1799. At first only devoted to matters connected with the state of
Connecticut, it now embraces the whole field of the sciences and useful
arts.
It has issued Memoirs (1810-1816), and now publishes Transactions (1866, &c.). One of the leading societies in the United States,,
the Academy of Natural Sciences of Philadelphia, founded in 1812 and
incorporated in 1817, possesses an excellent library; the natural
history museum is especially rich in conchology. It issues a Journal
(1817, &c.) and Proceedings (1843, &c.). The American Entomological

1863), Memoirs (410, 1866, &c.) and Proceedings (1841, &c.). The
Lyceum of Natural History, New York, was incorporated in 1818
and has published Annals from 1823 (1824, &c.) and Proceedings
(1870, &c.). In 1875 the name was changed to New York Academy of
Sciences. A number of American naturalists and geologists, having
held meetings in various cities between 1840 and 1847, resolved

themselves at their Boston congress in the latter year into the
American Association for the Advancement
of Science, which was
"
in 1874.
Its object is
by periodical and migratory
incorporated
meetings to promote intercourse between American scientists." It
has published Proceedings (1849, &c.). The National Academy of
Sciences was incorporated at Washington in 1863 with a view to
making the knowledge of specialists available for the service of
government. There are two classes of members, those in matheIt has issued
matics and physics and those in natural history.
Annuals (Cambridge, 1865, &c.) and Reports, as well as Memoirs
(1866, &c.). The Academies of Sciences at San Francisco (1853), St

Louis (1856, incorporated 1857), and Chicago (1857, incorporated
1865) deserve special mention.
Among the remaining societies of a general scientific character are

SOCIETIES, LEARNED

under the Companies Act: it publishes Proceedings (1874, &c.).

The London Electrical Society (1836) did useful work in its Transactions (1837-1840, vol. i) and Proceedings (1841-1843). Sir W. Siemens was one of the originators of the Institution of Electrical Engineers (founded in 1871 and registered in 1873) and published a Journal in London. There are also the Faraday Soc. (1903), Trans. and Proc., and the Optical Soc.

V. CHEMISTRY

Pharmaceutical societies are placed in class xiii. (Medicine, &c.). The Chemical Society of London for the promotion of chemistry and the sciences immediately connected with it was founded on 19th February 1815 and incorporated in 1838. It publishes Memoirs (1843, &c.) and Quarterly Journal (1849, &c.). Chemistry and its connexion with the arts, and agriculture and technical industries have been the subject of societies founded on the 2nd of September 1877 and incorporated in 1885. It publishes Proc. The Society of Chemical Industry (1881) was incorporated in 1907, and publishes a Journal. The Society of Public Analysts published the Analyst (1876, &c.). The oldest of the numerous photographic societies is the Royal Photographic Society of Great Britain (1853), which issues a Journal. The Royal College of Chemistry was founded in July 1845, and has a brief career. The Photographic Society was founded in 1846 for the publication and translation of works and papers on chemistry. It came to an end in 1872 after having issued 30 vols.

VI. GEOLOGY, MINERALOGY AND PALAEOONTOLOGY

The first International Geological Congress took place at Bologna in 1878. The Geological Society of London, founded in 1807 and incorporated in 1826, is the largest and most important in Great Britain; it has published Proceedings (1834-1840). Transactions (1841-1887) and a Quarterly Journal (1845, &c.). The Geological Association was instituted in 1858, and issues Proceedings (1859, &c.). The Mineralogical Society (1876) has united with it the Crystallographic Society; it issues the Mineralogic Magazine (1873, &c.). It holds its meetings at Penzance. The Geological Society of Edinburgh (1834) issues Transactions (1870, &c.). The Royal Geological Society of Ireland (1832) principally studied the geology of the country. It published a Journal (1835, &c.) and Proceedings. There are also the Geological Associations of Leeds (1874) and Liverpool (1880), Trans., and the Societies of Liverpool (1859), Proc, and Manchester (1858), Trans.

VII. METEOROLOGY

X. ZOOLOGY

Societies dealing with natural history in general, or zoology and botany together, under class i. The first International Ornithological Congress was held at St Petersburg. The Zoological Society of London (1826, incorporated 1879) is famous for its collection of animals at Regent's Park. It publishes Proceedings (1860, 1860, &c.) and papers of the Zoologists' Union (1879); Entomological Society of London (1833, Trans. (1834, &c.); National Fish Culture Association (1883); Societe Zoologique de Paris; Manchester, &c.; the London Zoo; and a number of Societies in the United States, of which the New York Zoological Society of New York is the largest. The Marine Biological Association of Great Britain (1884), for the study of marine life, is also in Plymouth. The Zoological Society of London has its museum in the Regent's Park. In the United States there are many Zoological Gardens in the large cities, the largest being the one at Chicago. The Marine Biological Station is at Virginia, and the Philadelphia Zoological Garden at Philadelphia. The Zoological Society of London also maintains a Zoological Gardens in the United States, at Baltimore, Cincinnati, and other cities. The first International Zoological Congress was held at Brussels in 1848. New York, 1884; and later in London. The Marine Biological Station is at Plymouth. The Zoological Society of London has its museum in the Regent's Park. In the United States there are many Zoological Gardens in the large cities, the largest being the one at Chicago. The Marine Biological Association of Great Britain (1884), for the study of marine life, is also in Plymouth. The Zoological Society of London also maintains a Zoological Gardens in the United States, at Baltimore, Cincinnati, and other cities. The first International Zoological Congress was held at Brussels in 1848. New York, 1884; and later in London.

IX. BOTANY AND HORTICULTURE

British legal societies is the Law Society (1827, incorporated 1832, residence 100, Water Lane, London, W.C. 2), it being appointed registrar of solicitors two years later, and it obtained supplementary charters in 1845 and 1878. This society has a fine building, with library and examination hall in Chancery Lane, London. There are other English legal societies, both incorporated and those associated with the parent body. The Verulam Society (1846) published a few books and came to an end. The Selden Society, established in 1887 for the promotion of the study of the history of law, was incorporated in 1899. The British Association for the Advancement of Science and the Conformity of the Law of Nations are in London, but conferences are held in various continental towns. The Chartered Institute of Patent Agents (1851) and the Incorporated Council of 1851 issues Transactions. The Juridical Society of Edinburgh (1763) published five editions of a Complete System of Convancing. The Ascham Society was founded in 1879 for the improvement of educational methods and the Society for the Development of the Science of Education (1872) issued Transactions.

The first meeting of the Congrès Médical International was held at Paris in 1867, a Bulletin has been issued annually since 1868, and the first Surgical Congress was held in Paris in 1885. The first Congrès Péripéral International d'Ophthalmologie took place at Brussels in 1887. The Royal Colleges of Physicians and of Surgeons of London, Edinburgh and Dublin do not come within our scope. The Medical Society of London (1753) is the oldest in the metropolis; it has issued Memoirs (1787-1861), Transactions (1810, &c.), and Proceedings (1836, &c.). The British Medical Association, founded in 1859, by charter in 1907 by the amalgamation of the following societies: Roy. Med. and Chir. Soc. (1805), Pathological Soc. (1836), Epidemiological Soc. (1850), Ophthalm. Soc. of Gt. Britain (1856), Obstetrical Soc. (1858), Clinical Soc. (1867), Dermatological Soc. of London (1882), British Gynecological Soc. (1884), Neurolog. Soc. (1886), British Laryng. Rhinol. and Otological Assoc. (1888), Laryngol. Soc. (1893), Soc. of Anaesthetists (1893), Dermatol. Soc. of Gt. Brit. and Ireland (1897), Dental Soc. for the Children (1900), British Electric-therapeutic Soc. (1901) and the Therapeutical Soc. (1902). Most of these societies have separate Transactions or Proceedings. Other British Medical Associations: The Chartered Accountants (1880); Institute of Bankers (1870); the Society of Incorporated Accountants and Auditors (1885); the Faculty of Actuaries in Scotland and the Scottish Society of Economists (1897), both meeting at Edinburgh; and the Social and Statistical Inquiry Society of Ireland (1847), with a Journal at Dublin. After the INNS or COURT (q.v.), the most important of...
SOCIETIES, LEARNED

**MEDICO-PHYSICAL, ASSN. OF G. BRITAIN AND IRELAND (1841, Incorp. 1843). New Sydenham Soc. (1858), which published Retrospect (1867, &c.), and translations and reprints of books and papers of value, succeeded the old Sydenham Society (1844-1858), which issued 40 vols.; Ophtalmological Society (1847); Trans. Phys. & Chem. Soc. (1842, &c.); Physiological Association (1870), Journ. of Physiology (1875, &c.); Königl. Soc. Journal; Monats-Buch für die Physik, Chemie, und Physikalische Medizin (1857). The council of which appoints examiners, directs Parke's Museum, founded in 1876 in memory of Dr E. A. Parkes; Society of Medical Officers of Health (1856), and Public Health; Soc. of Recent Discoveries and Inventions: The present societies are as follows: and include: Bradford, Med. Chr. Soc. (1863); Bristol, Med. Chir. Soc.; Cardiff, Med. Soc. (1870); Liverpool, Soc. of Tropical Med. (1879, incorp. 1903); Memories; Manchester, Med. Soc. (1834); North London and Middlesex, Med. Soc. (1873); London, Medico-Chirurg. Soc. (1821), Trans. (1824, &c.); and Obstetrical Soc. (1840), Aberdeen, Med. Chr. Soc. (1784). Glasgow, Medico-Chirurg. Soc. (1866), based upon Med. Soc. and Medico-Chirurg. Soc. (both 1814), joined by the Sec. in 1897.

**XIV. ENGINEERING AND ARCHITECTURE**

The principal English society dealing with mechanical science is the Institution of Mechanical Engineers, which was founded in 1829, and removed in 1877, and registered under the Companies Act in 1878. It holds meeting and publishes Proceedings. The Society of Engineers (1854); with Transactions (1861, &c.); the Civil and Mechanical Engineers Society (1850); the Institution of Electrical Engineers (1871, incorp. 1883); Journal; the Institution of Mining Engineers (1881, incorp. in 1885). The Institution of Mining and Metallurgy, founded in 1885, is the youngest of the large number of mining and metallurgical societies, and is represented in all parts of the world. The principal ones are the Institute of Mining and Metallurgy, London, the Institute of Mining Engineers, Birmingham, and the Institute of Mining and Metallurgy, South Africa; and also the Institute of Mining and Metallurgy, New South Wales, Australia. The Institution of Mining and Metallurgy, London, is the largest and oldest of these societies, and is the only one in England that can properly be called a mining and metallurgical society.
SOCIETIES, 317

The Architectural Association of London publishes a Sketch Book (1876, &c.). The Architectural Publishing Society (1848) has published Essays (1848–1852), and since 1852 has been bringing out a Dictionary of Architecture. There is also a Society of Architects (1854, incorp. 1873). The Roy. Inst. of Architects of Ireland meets in Dublin and publishes an annual.

XV. NAVAL AND MILITARY SCIENCE

The Royal United Service Institution, first known as the Naval and Military Library and Museum (1831), took the name of the United Service Institution in 1839, and was incorporated in 1860; its professional museum is housed in the Southwark at Whitehall. It publishes a Journal (1857, &c.). The Institution of Naval Architects (1860) publishes Transactions (4to, 1860, &c.). The Royal Artillery Institution (1837, &c.) publishes Annuals of the Royal Artillery Institution, and the Royal Engineers’ Institute (1873, &c.) which issues Royal Engineers’ Professional Papers, at Chatham. The Navy Records Soc. (1893) publishes works connected with the history of the Navy in Britain: London, Toronto, Military Inst. United Service Institution, United Service Institution.

Christiania, Militære Samfund, Nordisk Milit. Tidsskrift (1848, &c.). Denmark: Copenhagen, Krigsvidenskabelige Selskab, Milit. Tidsskrift (1872, &c.).

XVI. AGRICULTURE AND TRADES

SOCIETY ISLANDS—SOZINI

SOCIETY ISLANDS (French: Archipel de la Société), an archipelago of the Pacific Ocean, in the eastern part of Polynesia, between 16° and 18° S, 148° and 153° W, with a total land area of 637 sq. m., belonging to France. (For map, see PACIFIC OCEAN.) The principal island is Tahiti (q.v.). Part of the archipelago was discovered by Dybowski and named by the Greek voyager Boudeuse Sozinus (Wallis's archipelago) in 1552; Samuel Wallis re-discovered it, and named it King George's Island. In 1768 Louis de Bougainville visited Tahiti, claiming it as French, and named it La Nouvelle Cytéhre. On the 12th of April 1769 the British expedition to observe the transit of Venus, under the naval command of James Cook, arrived at Tahiti. On this first voyage (he subsequently revisited the islands twice) he named the Leeward group of islands Society in honour of the Royal Society, at the instigation of which the expedition had been sent; Tahiti and the adjacent islands he called Georgians, but the first name was subsequently adopted for the whole group. In 1773 and 1774 the islands were visited by a Spanish government expedition, and some attempt was made at colonization. In 1788 Lieutenant Bligh of the "Bounty" spent some time at Tahiti, to which island the historical interest now passes.

The archipelago is divided into two groups—the Leeward (Îles sous le Vent) and the Windward Islands (Îles du Vent)—by a clear channel of 60 m. in breadth. The Leeward Islands are Tubuai and Motuotu, a small group of islands in the northern part of the archipelago. Marua or Maupiti—"Double Mountain," the most western, Bola-Bola or Bora-Bora—Huahine; Raiatea or Uîletata (Spanish Princess), the largest island of this cluster, and Tahaa, which approach each other closely, and are encircled by a coral reef. The following islands lie the small groups of coral islets—Mopîha (Lord Howe), Ura (Scilly) and Bellingshausen (discovered by Otto von Kotzebue, 1824). To this group belong Tahiti, Maiga and Charles Saunders's Island and Spanish Pelada; Moorea or Eimeo (Wallis's Duke of York Island and Spanish San Domingo); Tahiti—Cook's Otaheite (probably Quíroz's Sagitarria; Wallis's King George's Island), Nuku Hiva or Sagittaria; Tihoa or Pellican. The largest island is Raiatea—"The Distant Sea" (? Quíroz's Fugitiva; Bougainville's Umiatia and Spanish Tres Hermanos); and Maitea (? Quíroz's La Dezana, Wallis's Onsargub Island, Bougainville's Boudoir and Pic de la Boudeuse and Spanish Cristoval), the most eastern and southern of the archipelago. Teteuruia and Tubuai, besides the three western Leeward Islands, are coral atolls. The length of the Tetetuia reef ring is about six miles; it bears twelve palm-covered islets, of which several are inhabited, and has one narrow boat-landing leading into the lagoon. With the exception just named, the islands, which agree very closely in geological structure, are mountainous and present the same phenomena of volcanic rocks to be found on the globe. They are formed of trachyte, dolerite and basalt. There are raised coral beds high up the mountains, and lava occurs in a variety of forms, even in solid flows; but all volcanic agency has so long ceased that the craters have been almost entirely obliterated by denudation. Hot springs are unknown, and earthquakes are slight and rare. Nevertheless, volcanic action is not altogether removed, for instances of recent volcanic bursts are reported, and now living in the islands have been found—a proof that the formation as well as the denudation of the country is, geologically speaking, recent. In profile the islands are rugged and elevated (7349 ft. in Tahiti, Morea 9035 ft., Raiatea 9300 ft., Bola-Bola 8000 ft. and Mount Otemata 7117 ft.), usually with very steep peaks, forms the centre, if not the whole island; on all sides steep ridges descend to the sea, or, as is often the case, to a considerable belt of flat land. These mountains, excepting some stony crags and cliffs, are clothed with dense forest, the soil being exceptionally fertile. All voyagers agree that for varied beauty of form and colour the Society Islands are unsurpassed in the world. One of the most wonderful examples of volcanic rocks is the Polyeche, the reef itself, and, after heavy rains, torrents precipitate themselves in grand cascades from the mountain cliffs—a feature so striking as to have attracted the attention of all voyagers, from Wallis downwards. Right round the windward islands there are coral reefs, and these reefs lie at no great distance, and follow the line of the coast, the inter-island channels are comparatively safe. Maitea, which rises from the sea as an exceedingly abrupt cone, and Tapamana, another forming a cone, are without doubt the ancient cones of uneroded grottoes. The coasts are fairly indented, and, protected by these reefs, which often support a chain of green islets, afford many excellent anchorages. In respect of the Society Islands the Society Islands have the advantage of many Polynesian islands.

The populations of the chief islands are: Tahiti 10,300; Moorea 1600; Raiatea and Tahaa 2300; Huahine 1300; Bola-Bola 800; and the Marquesas 2165.

SOZINI, the latinized form of the Italian Sozini, Sozino or Soccini, a name born by two Italian theologians.

I. LEILO FRANCESCO MARIA SOZINI (1525–1562) was born at Siena on the 29th of January 1525. His family descended from Sozzo, a banker at Percona, whose second son, Mino Sozzi, settled as a notary at Siena in 1304. Mino Sozzi's grandson, Sozzino (d. 1405), was ancestor of a line of patrician jurists and canonists, Mariano Sozini senior (1397–1467) being the first and the most famous; he was traditionally regarded as the first freethinker in the family. Lelio (who spells his surname Sozini, latinizing it Sozinus) was the sixth son of Mariano Sozini junior (1482–1556) by his wife Camilla Salvetti, and was educated as a jurist under his father's eye at Bologna. He told Melanchthon that his desire to reach the fontes juris led him to Biblical research, and hence to rejection of "the idolatry of Rome." He gained some knowledge of Hebrew and Arabic (to Bibilander he gave a manuscript of the Koran) as well as Greek, but was never a laborious student. His father supplied him with means, and on coming of age he repaired to Venice, the headquarters of the evangelical movement in Italy. In 1552, pursuing his religious travels, his family name and his personal charm ensured him a welcome in Switzerland, France, England and Holland. Returning to Switzerland at the close of 1548, with commendatory letters to the Swiss churches from Nicolas Meyer, envoy from Wittenberg to Italy, he found him (1549–1550) at Geneva, Basel (with Sebastian Münster) and Zürich (lodging with Pellican). He is next at Wittenberg (July 1550 to June 1551), first as Melanchthon's guest, then with Johann Forster for improvement of his Hebrew. From Wittenberg he returned to Zürich (end of 1551), after visiting Prague, Vienna and the other republics. By 1552 he was in Italy, two visits to Siena (where freedom of speech was for the moment possible, owing to the shaming off of the Spanish yoke) brought him into fruitful contact with his young nephew Fausto. He was at Padua (not Geneva, as is often said) at the date ofServetus' execution (Oct. 27, 1553). Thence he made his way to Basel (January 1554), Geneva (April) and Zürich (May), where he took up his abode.

Calvin, like Melanchthon, received Sozini with open arms. Melanchthon (though a phrase in one of his letters has been strangely misconstrued) never regarded him with theological abhorrence; it is Calvin's keen grace Sozini's over-speculative tendency and the genuineness of his religious nature were equally apparent. A passage often quoted (apart from the context) in one of Calvin's letters (January 1, 1552) has been viewed as a rapture of amicable intercourse; but, while more than once uneasy apprehensions arose in Calvin's mind, there was no breach of correspondence or of kindness. Of all the Reformers, Bullinger was Sozini's closest intimate, his warmest and wisest friend. Sozini's theological difficulties turned on the resurrection of the body, predestination, the ground of salvation (on these points he is corresponded with Calvin), the doctrinal basis of the original gospel (his queries to Bullinger), the nature of repentance (to Rudolph Guether), the sacraments (to Johann Wolff). It was the fate of Servetus that directed his mind to the problem of the Trinity. At Geneva (April 1554) he made incutaneous remarks on the common doctrine, emphasized in a subsequent letter to Martinoengo, the Italian pastor, Bullinger, at the instance of correspondents (including Calvin), questioned Sozini as to his faith, and received from him an explicitly ortho-doxy confession (reduced to writing on the 15th of July 1555) with a frank reservation of the right of further inquiry. A manuscript before this Sozini had sent with Martinoengo to Basel, to secure Ochino as pastor of the Italian church at Zürich; and it is clear that in their subsequent intercourse the minds
SOCINUS

of Sozini and Ochino (a thinker of the same type as Camillo, with finer dialectic skill) acted powerfully on each other in the radical discussion of theological problems. In 1556 by the death of his father (who left him nothing by will), Sozini was involved in pecuniary anxieties. With influential introductions (one from Calvin) he visited in 1558 the courts of Vienna and Cracow to obtain support for an appeal to the reigning duke at Florence for the realization of his own and the family estates. Curiously enough Melanchthon's letter introducing Sozini to Maximilian II. invokes as an historic parallel the hospitable reception rendered by the emperor Constans to Athanasius, when he fled from Egypt to Trèves. Well received out of Italy, Sozini could do nothing at home, and apparently did not proceed beyond Venice. The Duke of Mantua had his eye on the family; his brother Cornelio was imprisoned at Rome; his brothers Celso and Camillo and his nephew Fausto were "reputati Luterani," and Camillo had fled from Siena. In August 1559 Sozini returned to Zürich, where his brief career was closed by his death on the 14th of May 1562, at his lodging in the house of Hans Wyss, silk-weaver. No authentic portrait of him exists; alleged likenesses on medals, &c., are spurious. The news of his uncle's death reached Fausto at Lyons through Antonio Maria Besozzo. Repairing to Zürich Fausto got his uncle's few papers, comprising very little connected writing but a great mass of letters. The fact is, Sozini had been a plagiarist from Lelio that it may be well to state that his indebtedness, somewhat over-estimated by himself, was twofold: (1) He derived from Lelio in conversation (1552-1553) the germ of his theory of salvation; (2) Lelio's paraphrase (1561) of ἐξήγησις in John i. 1 as "the beginning of the gospel" gave Fausto an exegetical hint for the construction of his Christology. Apart from these suggestions, Fausto owed nothing to Lelio, save a curiously far-fetched interpretation of John viii. 58 and the stimulus of his pure character and shining qualities. The two men were of contrasted types. Lelio, impulsive and inquisitive, was his uncle's last hope; Fausto, the despair of the family. The mind of Fausto sought in external authority nothing for the ethical teaching of Christianity.

Sozini's extant writings are: (1) De sacramentis dissertatio (1560), four parts, and (2) De resurrectione (a fragment); these were first printed in F. et L. Socini, item E. Soneri tractatus (Amsterdam, 1664). To these may be added his Confession (1555), printed in Hottinger, Hist. eccles. N. T. N. L. xi. (1667); and a work of letters, not collected, but may be found dispersed, and more or less correctly given in Ilgen, in Trechsel, in the Corpus reformatorum ed. Baudissin, in Socii, in Socinians, &c. The handwriting of the originals is exceedingly crabbed. Sand adds a Rhapsodia in Estiam prophetaem, of which nothing is known. Beza suspected that Sozini had a hand in the De hecateris, an sinit propter hominum (1584) issued in the name of Sozini. The innominate of these being that Lelio's sonnets. Sozini was also assigned to him (in 1567) an anonymous Explicatio (1562) of the proem of St John's Gospel, which was the work of Fausto; this error, adopted by Zanchi, has been a chief source of the misconception which treats Lelio as a heresiarch. In Franc. Guino's Defensio cath. duct. de S. Trin. (1590-1591) is an anonymous enumeration of motives for professing the doctrine of the Trinity, by some ascribed to Lelio; by others, with somewhat more probability, to Fausto. For the life of L. Sozini the best guide is Trechsel, Die prot. ansichten (1844), who has made valuing study of what is written in Ilgen, Vita L. Sozini (1841), and especially Symbola ad vitam et doctrinam L. Soc., &c. (1826). R. Wallace, Antitrinit. blog. (1850), gives the ordinary Unitarian view, relying on Beck, Da Forta and Lobiendeck. See also Theological Review (July 1870), and Bowes, Maury's Early Sources of Eng. Unit. Christ. (trans. E. P. Hall, 1884). Use has been made above of unprinted sources.

II. FAUSTO PAOLO SOZZINI (1559-1604) was born at Siena on the 3rd of December 1559, the only son of Alessandro Sozini, "princeps subtilissimum," by Agnese, daughter of Burchese Petracci, the Crownwill of Siena. Unlike his uncle Lelio, Fausto spells his surname Sozini, lethizing it Sozinos. His father died in 1541, in his thirty-seventh year. Fausto has no record of education, being brought up at home by his sister Fillide, and spent his youth in desultory reading at Scopeto, the family country-seat. To the able women of his family he owed the strong moral impress which marked him through life; his early intellectual stimulus came from his uncle Celso, a nominal Catholic, but an esprit fort, founder of the short-lived Accademia dei Sistiani (1554), of which young Fausto was a member. In 1566 his grandfather's will, leaving him one-fourth of the family estates, made him independent. Next year he entered the Accademia degli intronati, the centre of intellectual life in Siena, taking the academic name "Il Frastagliato," his badge Un mare turbato da venti, his motto Turbant sod exstaltant. About this time Paniziro (De claris legg. interpp., first published 1637) describes him as a young man of fine talent, with promise of a legal career; but he despised the law, preferring to write sonnets. In 1558-1559 the suspicion of Lutheranism fell on him in common with his uncles Celso and Camillo. Coming of age (1561) he went to Lyons, probably engaging in mercantile pursuits, and from there he entered the Inquisition, accused of heresy, which he displayed in the defence of his uncle Lelio's death; we find him in 1562 on the roll of the Italian church at Geneva; there is no trace of any relations with Calvin; to Lyons he returned next year. The evangelical position was not radical enough for him. In his Explicatio (1562) of the proem to St John's Gospel he already attributes to our Lord an official, not an essential, deity; a letter of 1563 rejects the natural immortality of man (a position subsequently developed in his dispute with Pucci). Towards the end of 1563 he returned to Italy, conforming to the Catholic Church, and for twelve years, as his unprinted letters show, was in the service of Isabella de Medici, daughter of the grand-duke of Tuscany (not, as Przykowski says, in the service of the grand-duke). This portion of his life he regarded as wasted; till 1567 he gave some attention to legal duties, and at the instance of "a great personage" wrote (1570) his treatise De auctoritate s. scripturae. In 1571 he was in Rome, probably with his patroness. He left Italy at the end of 1575, and after Isabella's death (strangled by her husband in 1576) he declined the overtures of her brother Francesco, now grand-duke, who pressed him to return. Francesco was doubtless aware of the motive which led Sozini to return to Italy; there is every reason to believe Przykowski's statement that the grand-duke agreed to secure to him the income of his property so long as he published nothing in his own name. Sozini now fixed himself at Basel, gave himself to close study of the Bible, began translating the Psalms into Italian verse, and, in spite of increasing deafness, became a centre of theological debates. His discussion with Jacques Coutet on the doctrine of salvation issued in a treatise De Jesu Christo servatore (finished July 1578), the circulation of which in manuscript commended him to the notice of Giorgio Blandrata (q.e.), court physician in Poland and Transylvania, and a Jesuitical wire puller in the interests of heterodoxy. Transylvania had for a short time (1559-1571) enjoyed full religious liberty under an anti-Trinitarian prince, John Sigismund. The existing ruler, Christopher Báthori, favoured the Jesuits; it was now Blandrata's object to limit the "Judaic" tendencies of the eloquent anti-Trinitarian bishop, Francis Dávid (1510-1579), with whom he had previously co-operated. A charge of the gravest sort against Blandrata's morals had destroyed his influence with Dávid. Hence he called in Sozini to reason with Dávid, who had renounced the worship of Christ. In Sozini's scheme of doctrine, terms in themselves orthodox were employed to express a heretical sense. Thus Christ was God perceived as a purely human, namely as un Dio subdello, al quale in un dato tempo il Dio supremo e detto il governo del mondo (Cantu). In matter of worship Sozini distinguished between adoratio Christi, the homage of the heart, imperative on all Christians, and invoocation Christi, the direct address of prayer, which was simply permissive (Blandrata would have made it imperative); though in Sozini's view, prayer, to whomsoever addressed, was received by Christ as mediator, for transmission to the father. In November 1578 Sozini reached Kolozsvár (Klausenburg) from Poland, and did his best, during a visit of four months, and a half under Dávid's roof, to argue him into this modified doctrine of invocation. The upshot was that Dávid from the pulpit exerted all his powers in denouncing all cults of Christ. His civil trial followed, on a charge of innovation. Sozini
hurried back to Poland before it began. He cannot be accused of complicity with what he calls the rage of Blandrata; he was no party to Dávid’s incarceration at Déva, where the old man miserably perished in less than three months. He was willing that Dávid should be prohibited from preaching pending the decision of a general synod; and his references to the case show that (as in the later instances of Jacobo Paleology, Christian Franken and Martin Schdel) theological aversions, though they never made him uncivil, froze up his native kindness and blinded his perceptions of character. Blandrata ultimately withdrew from the Catholic Church; hence Sozzini’s laudatory dedication to him (1584) of his De Jesu Christi natura in reply to the Calvinist Andrew Wolan, though printed in his works, was not used. The remainder (1579–1604) of Sozzini’s life was spent in Poland. Excluded at first by his views on baptism (which he regarded as applicable only to Gentile converts) from the Minor or anti-Trinitarian Church (largely anabaptist), he acquired by degrees a predominant influence in its synods. He converted the Arians from their avowal of our Lord’s pre-existence, and from their rejection of the incarnatio Christi; he repressed the semi-Judaizers whom he tried to convert one by one to a different faith; he opposed with force the synodical statutes of the Anti-Trinitarian Church in Transylvania. Forced to leave Cracow in 1583, he found a home with a Polish nobleman, Christopher Morzstyn, whose daughter Elizabeth he married (1586). She died in the following year, a few months after the birth of a daughter, Agnese (1587–1654), afterwards the wife of Stanislas Wyszowaty, and the progenitors of numerous descendants. In 1587 the grand-duke Francesco died; to this event Sozzini’s biographers attribute the loss of his Italian property, but his unpublished letters show that he was on good terms with Grand Duke Ferdinando. Family disputes had arisen respecting the interpretation of his grand-duke’s will; in October 1590 the holy office at Siena dispossessed him, allowing a pension, apparently never paid. Failure of supplies from Italy dissolved the compact under which his writings were to remain anonymous, and he began to publish in his own name. The consequence was that in 1598 a mob expelled him from Cracow, wrecking his house, and grossly ill-using his person. Friends gave him a ready welcome at Luslawice, 30 miles east from Cracow; and here, having long been troubled with colic and the stone, he died on the 4th of March 1614. His body was removed to Cracow and placed near his grave.\(^1\) His engraved portrait is prefixed to his works (the original is not extant); an oil-painting, formerly at Siena, cannot be considered authentic.

Sozzini’s works, edited by his grandson Andrew Wyszowaty and the learned printer F. Kuyper, are contained in two closely printed folios (Amsterdam, 1668). They rank as the first two volumes of the Bibliotheca fratrum polygonorum (the works of Cerulli and Schlichting were the first of the series to be printed). They include all Sozzini’s extant theological writings, except his essay on predestination (in which he deems that God foresees the actions of free agents) prefixed to Castello’s Dialogi IV. (1578, reprinted 1613) and his revision of a school manual Instrumentum doctrinarum aristotelicam (1586). His pseudonyms, usually interpreted, were Felix Turpio Urbantus, Prosper Margadantus, Gentianus Prosper and Gratianus Turpio Gerapolesis (=Senensis). Some of his early verse is in Ferentini’s Scelta di stanzie di diversi autori toscani (1579, 1594); other specimens are given in Cantù in the Athenaeum polyhistoricum (1577); more is preserved in his letter to Siena. Sozzini considered that his ablest work was his Contra athesos, which perished in the riot at Cracow (1598). Later he began, but left incomplete, more than one work designed to exhibit his system as a whole. His reputation as a thinker must rest upon (1) his De auctoritate s. scripturae (1579) and (2) his De Jesu Christo servatore (1578). The former was first published (Seville, 1588) by Lopez, a Jesuit, who was the first to translate it into Spanish (1592). The latter (contrary to a fundamental position of Sozzini) that man by nature has a knowledge of God. A French version (1592) was approved by the ministers of Basel; the English translation by Edward Locombe (1732, 1740) gives a clear account of the contents of the catechism, and the Latin charge (1728) by Bishop Smalbrooke, who observes that Grotius had borrowed from it in his De veritate Christi, red. in small

present interests of society to the future interests of society is accomplished. It is, however, characteristic of the last-mentioned principles that their operation extends beyond the political consciousness of the state or nation, and that this distinction becomes more and more marked in the higher societies. The scope and meaning of sociology as a science is, therefore, quite different from the scope and meaning of the science of politics. In other quarters, again, the word sociology is often incorrectly used as no more than a covering term for subjects which are fully treated in various subdivisions of social science. Thus when the science of society is defined from the point of view of the social sciences when it falls within its general purview, it may be considered, says Lester F. Ward, that "we may range the next most general departments as so many genera, each with its appropriate species—that is, the classification of the sciences may be made strictly synoptical. When this is done it will be possible for philosophers, like good systematists, to avoid making their ordinal characters include any properly generic ones, or their generic characters include any that are only specific. Thus understood, sociology is freed from the unnecessary embarrassment of having hanging about it in more or less disorder a burden of complicated details, in a great variety of attitudes which make it next to impossible to secure due attention to the fundamental principles of so vast a science. These details are classified and assigned each to its proper place (genus or species), and the field is cleared for the calm contemplation of the central problem of determining the facts, the law and the principles of human association" (Outlines of Sociology). This definition, good as it is in some respects, does not make clear to the mind the essential fact of the science, namely, that the principles of sociology involve more than the generalized total of the principles of the subordinate sciences which it is said to include. In Herbert Spencer's writings we see the subject in a period of transition. Spencer placed his Principles of Sociology between his Principles of Psychology and Principles of Ethics. This fact brings out the unsettled state of the subject in his time, while it also serves to exhibit the dominance of the ideas of an earlier stage. For psychology, which Spencer thus places before sociology, cannot nowadays be fully, or even in any real sense scientifically, discussed apart from sociological principles, once it is accepted that in the evolution of the human mind the principles of the social process are always the ultimate controlling factor. Sociology is thus true science regarded as a science occupied quite independently with the principles which underlie human society considered as in a condition of development. In this sense the conclusions of sociology cannot be fully stated in relation to the phenomena dealt with in any of the divisions of social science, and they must be taken as implying more than the sum total of the results obtained in all of them. The sociologist must always keep clearly before him that the claims of sociology in the present conditions of knowledge go considerably beyond those involved in any of the foregoing positions. As it is the meaning of the social process which in the last resort controls everything, even the evolution of the human mind and all its contents, so none of the sciences of human action, such as ethics, politics, economics or psychology can have any standing as a real science except it obtains its credentials through sociology by making its approach through the sociological method. It is in sociology, in short, that we obtain the ruling principles to which the laws and principles of all the social sciences stand in controlled and subordinate relationship.

The fathers of the science of society may be said to be the Greek philosophers, and in particular Plato and Aristotle. The Laws and the Republic of the former and the Ethics and Politics of the latter have, down to modern times, and notwithstanding the great difference in the standpoint of the world and the change in social and political conditions, exercised a considerable influence on the development of the theory of society. To the Greeks the science of society presented itself briefly as the science of the best method of attaining the most perfect life within the consciousness of the associated life of the State. "In this ideal of the State," says Bluntschi, "are combined and mingled all the efforts of the Greeks in religion and in law, in morals and social life, in art and science, in the acquisition and management of wealth, in trade and industry. The individual requires the State to give him a legal existence: apart from the State he has neither safety nor freedom. The barbarian is a natural enemy, and conquered enemies become slaves.... The Hellenic State, like the ancient State in general...was all in all. The citizen was nothing except as a member of the State. This whole existence depended on...and was subject to the State...The State knew neither individual nor legal limits to its power" (Theory of the State).

It was within the limits of this conception that most of the Greek theories of society were constructed. The fundamental conception of the Roman writers was not essentially different, although the opportunism of the Roman State, when it became a universal power embracing the social and religious systems of many peoples, in some degree modified it; so that with the growth of jus gentium outside the jus civile, the later writers of the empire brought into view the State of the ancient writers to some extent distinguished from State morality. With the spread of Christianity in Western Europe there commenced a stage in which the social structure, and with it the theory of society, underwent profound modifications. These changes are still in progress, and the period over which they extend has produced a great and increasing number of writers on the science of society. The conceptions of each period have been intimately related to the character of the influences controlling development at the time. The writers up to the 14th century are nearly all absorbed in the great controversy between the spiritual and temporal power which was defining itself during this stage into Western history. In the period of the Renaissance and the Reformation the modern development of the theory of society may be said to begin. Machiavelli is the first great name in this period. Bodin with other writers up to the time of Montesquieu carry the development forward in France. The Dutch writer Grotius, although chiefly recognized at the time as an authority on international law, had much influence in bringing into view principles which mark more directly the transition to the modern period, his De jure bellii et pacis, issued in 1625, being in many respects an important contribution to the study of international law. Hobbes is the great representative of the influential school of writers on the principles of society which the period of the political and religious upheaval of the 17th century produced in England. The ideas of Locke, in particular, exercised a considerable influence on the subsequent development of the theory of the State in Western thought. From the 17th century forward it may be said, strictly speaking, that all the leading contributions to the general body of Western philosophy have been contributions to the development of the science of society. At the time of Locke, and to a large extent in Locke's writings, there may be distinguished three distinct tendencies in the prevailing theory of society. Each of these has since become more definite, and has progressed along a particular line of development. There is first the empirical tendency, which is to be followed through the philosophy of Hume down to the present day, in what may be called—to borrow an idea from Huxley—the physiological method in the modern study of the science of society. A second tendency—which developed through the critical philosophy of Kant, the idealism of Hegel, and the historical methods of Sagniny in the field of jurisprudence and of the school of Schmoller in the domain of economics—finds its current expression in the more characteristically German conception of the organic nature of the modern State. A third tendency—which is to be followed through the writings of Rousseau, Diderot, d'Alembert and the literature of the French Revolution—found its most influential form of expression in the 19th century in the theories of the English Utilitarians, from Bentham to John Stuart Mill. In this development it is a theory of the utilitarian State which is principally in view.
SOCIOLoGY

its latest phase it has progressed to the expression which it has reached in the theories of Marxist Socialism, in which the corresponding conception of the ascendancy of the economic factor in history may now be said to be the characteristic feature. All of these developments, the meaning of which has now been absorbed into the larger evolutionary conception to be described later, must be considered to have contributed towards the foundation of modern sociology. The definition of the relations to each other of the positions they have severally brought into view is the first important work of the new science.

At the period between 1830 and 1842, when Comte published the Philosophical Positive, the conditions were not ready for a science of society. The Darwinian doctrine of evolution by natural selection had not yet been enunciated, and knowledge of social phenomena was limited and very imperfect. As an instance of the character of the change that has since been in progress, it may be mentioned that one of Comte’s main positions—that, indeed, to which most of the characteristic conceptions of his system of philosophy were related—was that “the anatomical and physiological study of individual man” should precede the theory of the human mind and of human society. Here the position is one already referred to which has prevailed in the study of the social sciences down into recent times. It was supposed that the governing principles of society were to be discovered by the introspective study of the individual mind, rather than that the clue to the governing principles of the individual mind was only to be discovered by the study of the social process. It must now be considered that no fundamentally new principle of human development can be formulated as the result of Comte’s position. For with the application of the doctrine of evolution to society a position is becoming defined which is almost the reverse of it, namely, that the development of the individual, and to a large extent of the human mind itself, must be regarded as the correlative of the social process in evolution. The study of the principles of the process of social evolution would therefore in this sense have to come before the complete study of the individual, and even to precede the construction of a system of psychology scientific in the highest sense. Comte, apart from his want of mastery of the historical method in dealing with sociological development, possessed, on the whole, little insight into the meaning of the characteristic problem in which the human mind is involved in its social evolution, and to the definition of which not only the processes of Western history, but the positions successively developed in Western thought, must all be considered as contributing. His great merit was the perception of the importance of the biological method in the science of society, the comprehension of the fact that there can be no science of society if its divisions are studied apart from each other; and finally, and although it led at the time to the formulation of no important principle of human development, the intuition that sociology was not simply a theory of the State, but the science of what he called the associated life of humanity.

It has to be observed that, preceding the application of the doctrine of evolution to society, most of the contributions to social science have a certain aspect in which they resemble each other. While in current theories society tends to be presented as evolving, consciously or unconsciously, under stress of natural selection, towards social efficiency, the earlier contributions were merely theories of the meaning and object of social life as a medium for the satisfaction of human desires. In this presentation of the subject the influence of the Greek conception of the State upon modern sociology may be traced down to the present day. At the beginning of the modern period it reappears in Machiavelli (Titus Livius, I, iii., and The Prince). It is represented in modified form in Hobbes (Leviathan), and in Locke (Two Treatises of Government), each of whom conceived man as desiring to leave the state of nature and as consciously founding civilized society, “in order that he might obtain the benefits of government” in the associated State. It is continued in Rousseau and the writers of the French Revolution, who similarly imagined the individual voluntarily leaving an earlier state of freedom to put “his person and his power under the direction of the general will” (Social Contract). It is characteristic of Jeremy Bentham (e.g. Principles of Morals and Legislation, I) and of J. S. Mill (e.g. Utilitarianism and Political Economy, iv., vi.). Finally, it survives in Herbert Spencer, who in like manner sees man originating society and submitting to political domination in the associated State “through experience of the increased satisfaction derived under it” (Data of Ethics). It continues at the present day to be characteristic of many European and some American writers on sociology, who have been influenced both by Spencer and the Latin theory of the State, and who therefore, conceiving sociology not so much as a science of social evolution as a theory of association, proceed to consider the progress of human association as the development of a process “of catering to human desire for satisfactions of varying degrees of complexity.” All these ideas of society bear the same stamp. They conceive the science of society as reached through the medium of the associated State being regarded only as a medium through which he obtains increased satisfactions. In none of them is there a clear conception of an organic science of society with laws and principles of its own controlling all the meaning of the individual.

With the application of the doctrine of evolution the older idea in which society is always conceived as the State and as existing to give increased “satisfaction” is replaced by a new and much more extended conception. In the evolutionary view the development of human society is regarded as the product of a process of stress, in which progress results from natural selection along the line not of least effort in realizing human desire, but of the highest social efficiency in the struggle for existence of the materials of which society is composed. In the intensity of this process society, evolving towards higher efficiency, tends to become increasingly organic, the distinctive feature being the growing subordination of the individual to the organic social process. All the tendencies of development—political, economic, ethical and psychological—and the contents of the human mind itself, have therefore to be regarded as having ultimate relations to the governing principles of the process as a whole. The science of social evolution has, in short, to be considered, according to this view, as the science of the causes and principles subordinating the individual to a process developing by inherent necessity towards social efficiency, and therefore as ultimately over-ruling all desires and interests in the individual towards the highest social potentiality of the materials of which society is composed. The conflict between the old and the new conceptions may be distinguished to an increasing degree as the scope of modern sociology has gradually become defined; and the opposing ideas of each may be observed to be sometimes represented and blended, in varying degrees of complexity, in one and the same writer.

It was natural that one of the first ideas to be held by theorists, as soon as sociology began to make progress to the position of a real science, was that society must be considered to be organic, and that the term “social organism” should be brought into use. An increasing number of writers have been concerned with this aspect of the subject, but it has to be noted as a fact of much interest that all the first ideas of society as an organism must have been better expressed by the term of the “society” just described. The “social organism” in this first stage of theory is almost universally confused with the State. The interests of the social organism are therefore confused with the interest of the individuals which men saw around them in the State. The science of society was accordingly regarded as no more than the science of realizing most effectively here and now the desires of those composing the existing State. Sidgwick, for instance, considered the science of politics and the science of sociology as practically coincident,
and his *Elements of Politics*, extraordinary to relate, contains only a few words in which it is recognized that the welfare of the community may be interpreted to mean the welfare not only of living human beings, but of those who are to come hereafter; while there is no attempt to apply the fact to any law or principle of human development. Bentham's utilitarian philosophy, like that of the two Mills, was based almost entirely on the idea of the State conceived as the social organism. Writers like Herbert Spencer (*Sociology*) and Schäffle, who was for a time minister of commerce for Austria (Bau und Leben des sozialen Körpers), instituted lengthy comparisons between the social organism considered as the State and the living individual organism. These efforts reached their most characteristic expression in the work of the sociologists who have followed G. Simmel in lengthy and ingenious attempts at classifying associations, considering them "as organizations for catering to human desire." In all these efforts the conception of the State as the social organism is vigorously represented, although it is particularly characteristic of the work of sociologists in countries where the influence of Roman law is still strong, and where, consequently, the Latin conception of the State tends to influence all theories of society as soon as the attempt is made to place them on a scientific basis. The sterilizing effect for long produced on sociology by this first restricted conception of the social organism has been most marked. It is often exemplified in ingenious attempts made, dealing with the principles of sociology, to construct long categories of human associations, based on quite superficial distinctions. None of the comparisons of this kind that have been made have contributed in any marked degree to the elucidation of the principles of modern society. Paul Leroy-Beaulieu's criticism of Schäffle's efforts at comparisons—analysational, physiological, biological and psychological—between the individual organism and the State as a social organism applies to most of the attempts of this period to institute biological comparisons between the life of the social organism and that of organisms in general, "the mind sinks overwhelmed under the weight of all these analogies, these endless divisions and subdivisions to which they give rise.... The result is not in proportion to the effort" (L'État moderne et ses fonctions).

In tracing the direction of this conflict between the newer and older tendencies in modern sociology, it is in Herbert Spencer's writings that the student will find presented in the clearest definition the characteristic difficulty with which the old view has tended to be confronted, as the attempt has continued to be made to enunciate the principles of human development from the standpoint that society is to be considered as a "social organism," but while as yet there is no clear idea of a social organism with its own laws and its own consciousness quite distinct from, and extending far beyond those governing the interests of the individuals at present comprising the State.

With the application of the doctrine of evolution to society considered as an organism, a position has been brought into view of great interest. It is evident in considering the application of natural selection to human society that there is a fact, encountered at the outset, which is so fundamental that it must be held to control all the phenomena of social evolution. It is nowadays a commonplace of knowledge, that the potential efficiency of an organism must always be taken to be greater than the sum total of the potential efficiency of all its members acting as individuals. This arises in the first instance from the fact, to be observed on all hands in life, of the effects of organization, of division of labour, and of specialization of work. But in an organism of indefinitely extended existence like human society, it arises in a special sense from the operation of principles giving society prolonged stability. By these principles individual interests are subordinated over long periods of time to the larger interests of the social organism in which the individuals for the time being cannot participate; and it is from this cause that civilization of the highest type obtains its characteristic potency and efficiency in the struggle for existence with lower types.

There follows from this fact, obvious enough once it is mentioned, an important inference. This is that in the evolution of society, natural selection will, in its characteristic results, reach the individual not directly, but through society. That is to say, in social evolution, the interests of the individual, qua individual, cease to be a matter of first importance. It is by development in the individual of the qualities which will contribute most to the efficiency of society, that natural selection will in the long run produce its distinctive results in the human individual. It is, in short, about this function of socialization, involving the increasing subordination of the individual, that the continued evolution of society by natural selection must be held to centre. Societies in which the individuals resist the process quickly reach the limits of their progress, and have to give way in the struggle for existence before others more organic in which the process of subordination continues to be developed. In the end it is the social organizations in which the interests of the individual are most effectively included and rendered subservient to the interests of society considered in its most organic aspect that, from their higher efficiency, are naturally selected. In other words, it is the principles subordinating the individual to the efficiency of society in those higher organic aspects which project far beyond the life-interests of its existing units which must ultimately control all principles whatever of human association.

Spencer, in an elaborate comparison which he made (Essays, vol. 1, and *Principles of Sociology*) between the social organism and the individual organism brought into view a position which in its relation to this capital fact of human evolution exhibits in the clearest manner how completely all the early evolutionists, still under the influence of old conceptions, failed at first to grasp the significance of the characteristic problems of the social organism. Spencer's comparison originally appeared in an article published in the Westminster Review for January 1860 entitled "The Social Organism." This article is in many respects one of the most noteworthy documents in the literature of the last half of the 19th century. In comparing the social with the individual organism Spencer proceeded, after noting the various aspects in which a close analogy between the two can be established, to make, as regards society, an important distinction by which the nature of the difficulty in which he is involved is immediately made apparent. While in an individual organism, he pointed out, it is necessary that the lives of all the parts should be merged in the life of the whole, because the whole has a corporate consciousness capable of happiness or misery, it is not so with society. For in society, he added, the "living units do not and cannot lose individual consciousness, since the community as a whole has no corporate consciousness." Spencer proceeded, therefore, to emphasize the conclusion that "this is an everlasting reason why the welfare of citizens cannot rightly be sacrificed to some supposed benefit of the State; but why, on the other hand, the State is to be maintained solely for the benefit of citizens." The extraordinary conclusion is indeed reached by Spencer that "the corporate life in society must be subservient to the lives of the parts, instead of the lives of the parts being subservient to the corporate life." It will be here clearly in evidence that the "social organism," which Spencer had in view was the State. But it will be noticed at the same time how altogether remarkable was the position into which he was carried. Spencer, like most thinking minds of his time, had at first espoused, constantly displayed in his writings, of the scientific importance of that development in history which has gradually projected the conception of the individual's rights outside all theories of obligation to the State. He wrote at a time when the attention of the Western mind in all progressive movements in Western politics had been for generations fixed on that development in which the liberties of the individual as against the State had been won. This development had involved nearly all Western countries in a titanic struggle against the institutions of an earlier form of society resting on force organized in the State. Spencer, therefore, like almost every advanced
writer of his period, had constantly before him the characteristic fact of his age, namely, that the meaning of the individual had come to be in some way accepted as transcending all theories of the State and all theories of his obligations to the State. The position was, therefore, very remarkable. Spencer has been for long accepted by the general mind as the modern writer who more than any other has brought into use the term "social organism," and who has applied the doctrine of evolution to the theory of its life. Yet here we see him involved in the apparent self-stultification of describing the social organism to us as that impossible thing, an organism "whose corporate life must be subservient to the lives of the parts instead of the lives of the parts being subservient to the corporate life." It was developed toward the found conclusion that the evolution of society was evidently destined to carry us much farther than this. If natural selection was to be taken as operating on society, and therefore as tending to produce the highest efficiency out of the materials that comprise it, it must be effecting the subordination of the interests of the units to the higher corporate efficiency of society. But one of only two conclusions could therefore result from Spencer's position. If we were to regard the "social organism" as an organism in which the corporate life must be subservient to the lives of the parts, instead of the lives of the parts being subservient to the corporate life, it would be necessary to hold that the individual had succeeded in arresting the characteristic effects of natural selection on society. But for the evolutionist, whose great triumph it had been to reveal to us the principles of natural selection in universal operation throughout life elsewhere, to have to regard them as suspended in human society would be an absurd anti-climax. Such being scarcely conceivable as a final position, it remained only to infer that natural selection must still be subordinating individual interests to some larger social meaning in the evolutionary process. But in this case, society must be subject to principles which remain beyond those of the subservient to the corporate life. It is indeed the reversal of the social organism as confined within the consciousness of ascendant interests in the political State must be considered to be a false one.

We had, in short, reached a capital position in the history of sociology from which an entirely new horizon was about to become visible. The principles of society organic in a wider sense than had hitherto been conceived were about to be brought into the discussion. All the phenomena of the creeds and ethical systems of humanity, of the great systems of religion and philosophy, with the problems of which the human mind had struggled over immense periods of time as the subordinating process had unfolded itself in history, were about to be brought into sociology. And not now as if these represented some detached and functionless development with which the science of society was not directly concerned, but as themselves the central feature of the evolutionary process in human society. The stage in the history of sociology characterized by the confusion of the principles governing the social organism with those governing the State, the stage which had lasted from the time of the Greeks to Spencer, and which had with it some consequence of its own. It is true, as Sidgwick's statement that the science of sociology was in effect coincident with the science of politics, was thus bound to be definitely terminated by the application to the science of society of the doctrine of evolution. Yet Spencer, despite his popular association with the doctrine of evolution, is thus not to be reckoned as the first of the philosophers of this new stage. His place is really with the last great names of the preceding period. For his conception of society was that of Bentham, Mill and Sidgwick. His Principles of Sociology as a contribution to modern evolutionary science is necessarily rendered to a large extent futile by the sterilizing conception of a social organism "in which the corporate life must be subservient to the lives of the parts." It is indeed in the inversion of this conception that the whole significance of the application of the doctrine of evolution to the science of society consists. Henceforward we shall have to regard the social process in evolution as a process with its own interests, its own psychology, its own consciousness and its own laws, all quite distinct from the political consciousness of the modern State, though indirectly controlling and governing the consciousness of the State so thoroughly that there can be no true science of the latter without a science of the former.

The new situation created in sociology as the doctrine of evolution began to be applied to the science had features of great interest. The advance had been made to a central position along two entirely distinct lines. The Darwinians army of workers was, in consequence, divided into two or more isolated camps, each largely in ignorance of the relation of its own work to that in the other section. It is often said as a reproach to sociology in the period through which we are passing that it attracts the kind of readers who are not best equipped for its work, while it repels the kind of mind of philosophical training and wide outlook which it ought to enlist in its service and for which it has most urgent need, the loss to sociology both in credit and efficiency being immense. This is the result of a peculiar situation. Those who are best qualified to understand the nature and scope of the problems with which sociology has to deal cannot fail to have the conviction strongly developed in them that the Darwinian principles of evolution which reveal to us what may be described as the dynamics of the universal life process have very important relations to the dynamics of the social process. The situation which has arisen in sociology, however, is a very curious one, although it is one easy to understand when the causes are explained. When the endeavour is made to follow Darwin and the early Darwinians through the facts and researches which led to the formulation of the law of natural selection it may be observed how their preoccupation was almost exclusively with the details of the struggle for existence not in societies, but as it was waged between individuals. This was so as a matter of course, from the character of the facts which will naturally be emphasized, reinforced by more observations on domestic animals and the practices of breeders.

Darwin made no systematic study of society; and outside human society the struggle through which natural selection has operated has been mainly between individuals. It is, of course, sometimes remarked that the social life exists among animals and that the laws of the social life and of the herd are to be observed there, but as a matter of fact there is nothing whatever elsewhere in life to compare with what we see taking place in human society, namely, the gradual integration—still under all the stress of natural selection expressing its effects in the person of the individual—of an organic social process resting ultimately on the law of the process are necessarily quite different from the laws of the other and simpler process in operation lower down in life. If we regard the classes from which sociology as a science should be able to draw its most efficient recruits we see that at the present day they fall mainly into two camps. There are in the one camp the exponents of biological principles, often trained in one or more of the departments of biological science, who are attempting the application to human society of the principles with which they have become familiar elsewhere in life. There are in the second camp the exponents of various aspects of social philosophy. When the exponent of Darwinian principles advances to the study of society he is naturally strong in the conviction that he has in his hands a most potent instrument of knowledge which ought to carry him far in the organization of the social sciences and towards the unification of the leading principles underlying the facts with which they deal. But what we soon begin to see is that his training has been, and that his preoccupation still continues to be, with the facts and principles of the struggle for existence between individuals as displayed elsewhere in life. He does not easily realize, if he has not been trained in social philosophy, how infinitely more complex all the problems of natural selection have become in the social institution as compared to societies taking place in human affairs; or how the social efficiency with which he has become now concerned is something quite distinct from the individual
efficiency with which he has been concerned elsewhere. He does not readily comprehend how the institutions which he sees being evolved in history have, in their effects on the individual, laws quite different from those which he applies in the breeding of animals; or how the dualism which has been opened in the human mind, as natural selection acts first of all on the Individual in his own struggle with his fellows, and then, and to a ruling degree, acts on his as a member of organic society in the evolution of social efficiency, has in the religious and ethical systems of the race a phenomenology of its own, stupendous in extent and absolutely characteristic of the social process, which remains a closed book to him and the study of which he is often apt to consider for his purposes as entirely meaningless. All this became rapidly visible in the first approach of the early Darwinians to the science of society.

Darwin, as stated, had attempted no comprehensive or systematic study of society. But in a few chapters of the Decent of Man he had discussed the qualities of the human mind, including the social and moral feelings, from the point of view of the doctrine of natural selection enunciated in the Origin of Species. The standpoint he took up was, as might be expected, practically that of Mill and Spencer and other writers of the period on social subjects, from whom he quoted freely. But the note of bewilderment was remarkable. The conclusion remarked upon as implied in Spencer's theory of the social organism, but which Spencer himself hesitated to draw, namely, that natural selection was to be regarded as suspended in human society, Darwin proposed. This as a first step. Thus in the earliest pages Darwin appeared to think that natural selection could effect but comparatively little in advanced society. "With highly civilized nations," he says, "continued progress depends to a subordinate degree on natural selection." While Darwin noted the obvious usefulness of the social and moral qualities in many cases, he felt constrained at the same time to remark upon their influence in arresting, as appeared to him, the action of natural selection in civilization. "We civilized men," he continues, "do our utmost to check the process of elimination (of the weak in body and mind); we build asylums for the imbeciles, the maimed and the sick; we institute poor laws; and our medical men exert their utmost skill to save the life of every one to the last moment." There is here in evidence no attempt to connect the phenomena thus brought into view with some wider principle of the evolutionary process which evidently must control them. There is no perception visible in Darwin's mind of these facts as constituting the phenomenology of a larger principle of natural selection; or of the higher organic efficiency in the struggle for existence of societies in which the sense of responsibility to life thus displayed has made most progress; or of the immense significance in social evolution as distinct from individual evolution of that deepening of the social consciousness of which this developing spiritual sense of responsibility to our fellow creatures is one of the outward marks characteristic of advanced societies.

In the year 1899 Alfred Russel Wallace in a statement of his conception of the doctrine of evolution in his book, Darwinism, brought more clearly into view the fundamental difficulty of the early Darwinians in applying the doctrine of natural selection to society. In the last chapter of the book Mr Wallace maintained that there were in "man's intellectual history...certain definite portions...which could not have been developed by variation and natural selection alone." Certain faculties, amongst which he classed the mathematical, artistic and metaphysical, the latter covering qualities with which he considered priests and philosophers to be concerned, were, he asserted, "altogether removed from utility in the struggle for life," and were, therefore, he thought, "wholly unexplained by the theory of natural selection." In this elementary conception which still survives in popular literature, the same confusion between individual efficiency and social efficiency has to be remarked upon. And there is in evidence the same failure to perceive that it is just these intellectual and moral qualities which are the absolutely characteristic products of natural selection in advanced society, that in that they contribute to the highest organic social efficiency. Wallace in the result proposed to consider man, in respect of these higher portions of his mind, as under the influence of some cause or causes wholly distinct from those which had shaped the development of life in its other characteristics. The weakness of this position was immediately apparent. To remove man as regards qualities so directly associated with his social evolution from the influence of the law of natural selection was felt to be a step backwards. The effect produced on the minds of the younger school of evolutionists was deep. It operated, indeed, not to convince them that Wallace was right, but to make them feel that his conception of natural selection operating in human society was still in some respect profoundly and radically incomplete.

A few years later, Huxley, though approaching the matter from a different direction, displayed a like bewilderment in attempting to apply the doctrine of evolution to the phenomena of organic society. With his mind fixed on the details of the individual struggle for existence among animals, Huxley reached in the Romanes lecture, delivered at Oxford in 1893, a position little different from that in which Wallace found himself. In this lecture Huxley actually proceeded to place the ethical process in human society in opposition to the cosmic process, to which latter alone he considered the struggle for existence and the principle of natural selection belonged. "Social progress," he went on to say, "means a checking of the cosmic process at every step and the substitution for it of another which may be called the process of the end of which is not the survival of those who may happen to be the fittest, in respect of the whole of the conditions which obtain, but of those who are ethically the best." Thus the remarkable spectacle already witnessed in Spencer, Darwin and Wallace of the evolutionist attempting to apply his doctrines to human society, but having to regard his own central principle of natural selection as having been suspended therein is repeated in Huxley. The futility of contemplating the ethical process as something distinct from the cosmic process was at once apparent. For the first lesson of evolution as applied to society must be that they are one and the same. So far indeed from ethical process checking the cosmic process, it must be regarded as the last and highest form of the cosmic process. The sense of subordination and sacrifice which forms the central principle of all the creeds of humanity, so far from being, as Wallace imagined, "altogether removed from utility" is, indeed, the highest form of social efficiency through which natural selection is producing its most far-reaching effects in the evolution of the most advanced and organic types of civilization. A similar tendency continued to be in evidence in other directions. In an effort made a few years later to found a society for the study of sociology in Great Britain a very characteristic feature of the first papers contributed was the attempt to apply elementary biological generalizations regarding natural selection to a highly complex organism like human society, the writers having in most cases made no previous extensive or special study of the social process in history. The confusion between what constitutes individual efficiency in the individual and that higher social efficiency in the individual which everywhere controls and overrules individual efficiency was very marked. An early paper contributed in this field in its other character by Mr. Wallace. Galton had made many original contributions to the doctrine of evolution, and had been occupied previously with researches into individual efficiency as displayed among families, his Hereditary Genius being a notable book of this type. The object of his paper was to explain the scope and aim of a new science, "eugenics," which he defined as the science which deals with all the influences that improve the inborn qualities of the race and develop them to the utmost advantage. Galton found no difficulty whatever in setting up his sociological standards for the best specimens of the race. Even the animals in the Zoological Gardens, he
SOCILOGY

said, might be supposed to know the best specimens of their class. In society the list of best qualities would include health, energy, ability, manliness and the special aptitudes required by various professions and occupations. Everything in "scientific breeding of the human race" was to be much as in the breeding of animals; for Galton proposed to leave morals out of the question as involving too many hopeless difficulties. This was the basis of the scheme of qualities from which he proposed to proceed to the improved breeding of society. The proposal furnishes one of the most striking and characteristic examples which have appeared of the deep-seated confusion prevailing in the minds of the early Darwinians between social efficiency and individual efficiency. Even from the few minor examples of society among the lower animals the true sociological criticism of such standards in eugenics might easily be supplied. For, at the point at which the social insects, for instance, began their social integration all their standards were in the qualities which gave success in the struggle for existence between individuals. Had they, therefore, understood eugenics only in this light and in Galton's sense, they would have condemned at the first the beginnings of the peculiar social efficiency of the queen bee which now makes her devote her life entirely to egg-laying; still more would they have condemned the habits of the drones, through long persistence in which they have become degenerate as individuals; and in particular they would have condemned the habits of the workers which have led to their present undeveloped bodies and abortive individual instincts. But all these things have contributed in the highest degree to the social efficiency of the social insects and have made the type a winning one in evolution. The social integration of the social insects has been comparatively simple and did not, like that of human society, rest ultimately on mind, yet even in this elementary example it was evident what ruin and disaster would result from a misgivings scientific breeding of the race if undertaken within the limits of such restricted conceptions of social efficiency. Galton's preoccupation, as in the case of most biological and medical schemes of improvement in the past, was with those individualistic qualities which contribute to the individual's success in the struggle for existence with his fellows. But it has been continuously obvious in history that individuals of the very highest social efficiency, the great organic minds of the race who, often quite unsuccessful in their lives as judged by individualistic standards, and who, often quite unperceived and unappreciated by their contemporaries, have been the authors of ideas, or moral conceptions or works of such organic importance that they have carried the race from one social horizon into another, have been just those individuals who would have entirely failed to pass the kind of prize-animal standards which were proposed to set the value of the qualities which gave success in the struggle for existence between individuals.

Galton's essay may be said to close that first epoch in the application of biological conceptions to sociology which opened with Spencer's essay in 1860. With the extending conception of the organic interests of society during the intervening period the idea of social efficiency had altered profoundly. For instance, a supposed standard of efficiency, which like Malthusianism represented to Mill at the opening of the period the last conclusion of science, had become towards the close scarcely more than the "race principle." It is not surprising that in these circumstances the representatives of those sciences which rested on a knowledge of the social process in history and philosophy continued to look coldly on the attempt of the first Darwinians to apply Darwinian principles to sociology. True, the development in their own sciences had been almost equally sterile, for they had themselves as yet no reasoned conception of the enormous importance of the Darwinian principle of evolution to these sciences in its capacity to reveal to them the dynamics of the social process. But they had watched the development of institutions in history; they had studied the growth of social evils and the spread of atheism systems of belief; and they had struggled with the capital problems of the human mind in psychology and philosophy as the process had continued. The two armies of workers continued to be organized into isolated camps, each with the most restricted conception of the nature and importance of the work done by the other and of its bearing upon their own conclusions.

One of the most remarkable results of such a situation—a result perhaps visible in the valuable collection of essays edited by Professor Seward which was issued from the Cambridge University Press in commemoration of the centenary of Darwin's birth—is the extremely limited number of minds in our time of sufficient scope of view to be able to cover the relation of the work of both sets of these workers to sociology.

It remains now to consider the relation to the position in modern sociology of the extended conception that society must be considered to be organic in some wider sense than the first Darwinians thus imagined it and also in some wider sense than that in which Sidgwick imagined it when he said that sociology was in effect coincident with the science of politics. The present writer has laid it down elsewhere (The Two Principal Laws of Sociology: Bologna) that there is a fundamental principle of sociology which has to be grasped and applied before there can be any real science of sociology. This principle may be briefly stated as follows:

The social process is primarily evolving in the individual not the qualities which contribute to his own efficiency in conflict with his fellows, but the qualities which contribute to society's efficiency in the conflict through which it is gradually rising towards a more organic and comprehensive forms of organization.

This is the first law of evolutionary sociology. It is this principle which controls the integration which is taking place under all forms in human society—in ethical systems, in all political and economic institutions, and in the creeds and beliefs of humanity—in the long, slow, almost invisible struggle in which under a multitude of phases natural selection is discriminating between the standards of nations and types of civilization.

Dealing first with political and economic institutions, the position argued in this part sociology may be said to represent the science of society in a state of transition. It represents it, that is to say, in a stage at which the Greek theory of society has become influenced by the doctrine of evolution applied to modern conceptions, but while as yet no synthesis has been achieved between the conflicting and even mutually exclusive ideals which are involved. The Greek theory of society is represented in Spencer in his practical identification of "the social organism" with the State. The modern idea, however, which carries Spencer far beyond the principles of Greek society—as these principles were summarized, for instance, in the passage from the Principles already quoted—lies in the idea of the State as a compound of all that is right and good in modern society, and may be observed to be expressed in the recognition of a principle resident in modern society which in some manner projects the individual's rights outside and beyond the whole theory and meaning of the State. In other words, in society as Spencer conceives it, "the welfare of citizens cannot rightly be sacrificed to some supposed benefit of the State"; whereas, according to the Greek theory and the theory of Roman law, the citizen's whole existence depended on and was subject to the State. The State knew neither moral nor legal limits to its power. If, however, it is considered that modern society has made progress beyond the Greek, and if it be accepted that the theory of evolution involves the conclusion that society progresses towards increased efficiency in a more organic type, there follows from the foregoing an important inference. This is that it now becomes the task of modern sociology, as a true science, to show that the principle in modern civilization which distinguishes it from society of the Greek period—namely, that principle which Spencer rightly recognized, despite the contradictions in which he became involved, as rendering the life of the individual no longer subservient to the corporate life of the State—is itself a principle of growth, not with individualism but with the increasing subordination of the individual to a more organic type of society. It must, in short, remain for the evolutionist, working by the
historical method scientifically applied, to present the intervening process in history—including the whole modern movement towards liberty and enfranchisement, and towards equality of conditions, of rights and of economic opportunities—not as a process of the increasing emancipation of the individual from the claims of society, but as a process of progress towards a more organic stage of social subordination than has prevailed in the world before.

When society is considered as an organism developing under the influence of natural selection along the line of the causes which contribute to its highest potential efficiency, and therefore tending to have the mean centre of its organic processes projected farther and farther into the future, it is evident that it must be the principles and ideas which most effectively subordinate over long periods of time the interests and the capacities of the individuals of which it is composed to the efficiency of the whole which will play the leading part in social evolution.

In primitive societies, the first rudiments of social organization undoubtedly arose, not so much from conscious regard to expediency or "increased satisfactions" as from fitness in the struggle for existence. "The first organized societies must have been developed, like any other advantage, under the sternest conditions of natural selection. In the flux and change of life the members of those groups of men which in favourable conditions first showed any tendency to social organization became possessed of a great advantage over their fellows, and these societies grew up simply because they possessed the elements of strength which led to the disappearance before them of other groups of men with which they came into competition. Such societies continued to flourish, until they in their turn had to give way before other associations of men of higher social efficiency" (Social Evolution, ii.). In the social process at this stage all the customs, habits, institutions, and beliefs contributing to produce a higher organic efficiency of society would be naturally selected, developed and perpetuated. It is in connexion with this fact that the clue must be sought to the evolution of those institutions and beliefs of which the purpose is not inherent in the outward necessities of life, but which grew up simply because the organized society, at length in researches like those of M'Lennan, Tylor, Lubbock, Waitz, Letourneau, Quatrefages, Frazer, and others of equal importance. For a long period in the first stages the highest potentiality of the social organization would be closely associated with military efficiency. For in the evolution of the social organism, as has been said, while the mean centre of the processes involving its organic identity would tend to be projected into the future, it would at the same time always be necessary to maintain efficiency in current environment in competition with rival types of lower future potentiality. Amongst primitive peoples, where a great chief, law-giver, and military leader appeared, the efficiency of organized society resting on military efficiency would, as a matter of course, make itself felt in the struggle for existence. Yet as such societies would often be resolved into their component elements on the death of the leader, the outliving importance—on the next stage of the advance towards a more organic type—of ideas which would permanently subordinate the materials of society to the efficiency of the whole would make itself felt. Social systems of the type in which authority was perpetuated by ancestor-worship—in which all the members were therefore hereditary—it was not an exclusive religious or tribal leadership founded on blood relationship to the deities who were worshipped, and in which all outsiders were accordingly treated as natural enemies, whom it would be a kind of sacrifice to admit to the rights of the State—would contain the elements of the highest military potentiality. The universal mark which ancestor-worship has left on human institutions in a certain stage of social development is doubtless closely associated with this fact. The new and the older tendencies in sociology are here also in contrast; for whereas Herbert Spencer has been content to explain ancestor-worship as arising from an introspective and comparatively trivial process of thought—originating from the human habit of taking a mental picture in the mind of early man in relation to a supposed belief in ghosts (Principles of Sociology, 68—207), the newer tendency is to consider science as concerned with it in its relation to the characteristic principles through which the efficiency of the social organization expressed itself in its surroundings. The social, political and religious institutions disclosed in the study of the earliest civilizations within the purview of history must be considered to be all intimately related to the ruling principles of this military stage. The wide reach and significance of the causes governing the process of social evolution throughout the whole of this period may be gathered from treaties like Seeborn's Structure of Greek Tribal Society, Maine's Ancient Law, History of Institutions, and Early Law and Custom, Fowler's City-State of the Greeks and Romans, and in a special sense from the comparative study of Roman law, first of all as it is presented in the period of the Twelve Tables, then as the jus civile begins to be influenced by the jus gentium, and lastly as its principles are contrasted with those of English common law in the modern period. In most of the philosophical writings of the Greeks, and in particular in the Ethics and Politics of Aristotle, and in many of the Dialogues of Plato, the spirit of the principles upon which society was constructed in this stage may be perceived as soon as progress has been made with comparative studies in other directions.

A very pregnant saying of T. H. Green was that during the whole development of man the command, "Thou shalt love thy neighbour as thyself" has never varied. What has varied is only the answer to the question—Who is my neighbour? If in the light of this profoundly true reflection we watch the progress of society from primitive conditions to the higher stages, it may be observed to possess marked features. Where all human institutions, as in the ancient civilizations, rested ultimately on force; where outsiders were regarded as natural enemies, and conquered enemies became slaves; where, as throughout all this phase of social evolution, a rule of religion was a rule of law identified with the principles of the State (Maine, Ancient Law); where the State itself was absolute as against the individual, knowing "neither moral nor legal limits to its power"; and where all the moral, intellectual and industrial life of the community rested on a basis of slavery—the full limits of the organic principle of social efficiency would in time be reached. The conditions would be inherent in which all social institutions would tend to become closed absolutisms organized round the conception of men's desires in the present. And the highest outward expression in which the tendencies in ethics, in politics, and in religion must necessarily culminate would be the military State, bounded in its energies only by the resistance of others, necessarily acknowledging no complete end short of absolute dominion, and therefore staying its course before no ideal short of universal acceptance. This was the condition in the ancient State. It happened thus that the outward policy of the ancient State to other peoples became, by a fundamental principle of its life, a policy of military conquest and subjugation, the only limiting principle being the successful resistance of the others. The epoch of history moved by inherent forces towards the final emergence of one supreme military State, in an era of general conquest, and culminated in the example of universal dominion which we had in the Roman world before the rise of the civilization of our era.

The influence upon the development of civilization of the wider conception of duty and responsibility to one's fellow men which was introduced into the world with the spread of Christianity can hardly be over-estimated. The extended conception of the answer to the question—Who is my neighbour? which has resulted from the characteristic doctrines of the Christian religion—a conception transcending all the claims of the family, group, state, nation, people or race, and even all the interests comprised in any existing order of society—has been the most powerful evolutionary force which has ever acted on society. It has tended naturally to break up the absolutisms inherited from an older civilization and to bring into being an entirely new type of social efficiency.
As society under this influence continued to be impelled to develop towards a still more organic type, the greatly higher potentiality of a state of social order which, while preserving the ideal of the highly organized state and the current efficiency of society in competition with lower types, was influenced by conceptions that dissolved all those closed absolutisms, and re-leas human energies into a free conflict of forces by projecting the principles of human responsibility outside the State, became apparent. In many of the religions of the East such conceptions have been inherent, Christianity itself being a characteristically Eastern religion. But no Eastern people has been able to provide for them the permanent defensive military milieu in history, in which alone their potentiality could be realized. The significance of modern Japan in evolution consists largely in the answer she is able to give to the question as to whether she will be able to provide in the future such a milieu for such a conception among an Eastern people.

The significance of the culmination of the military epoch in the ancient classic civilizations of the Western world, which preceded the opening of the era in which we are living, and of the fact that the peoples of the same descent who were destined to carry on the civilization of the existing era represent the supreme military stock by natural selection, not only of the entire world, but of the evolutionary process itself in human history, will therefore be evident.

With the spread, accordingly, amongst peoples of this origin, and in such a defensive military milieu in history, of a new conviction of responsibility to principles extending beyond the consciousness of the political State, there began a further and more organic stage of the evolutionary process in society. The gradual dissolution in the era in which we are living of all those closed absolutisms within the State, in which human action and ideas had hitherto been confined, is apparently the characteristic phenomenon of this stage. Progress is towards such a free and tolerant, but intense and efficient, conflict of forces as was not possible in the world before. It is, it would appear, in this light that we must regard the slow dissolution of the basis of ideas upon which slavery rested; the disintegration of the conceptions which supported the absolute position of the occupying classes in the State; the undermining of the ideas by which opinion was supported by the civil power of the State in the realm of the struggle of the middle ages; the growth of the conception that no power or opinion in the State can be considered as the representative of absolute truth; the consequent development of party government amongst the advanced peoples, with the acknowledgment of the right of every department of inquiry to carry results up to that utmost limit at which they are controlled only by the results obtained in other departments of activity with equal freedom; the growth of the conception, otherwise absurd, of the native equality of men; the resulting claim, otherwise similarly indefensible, of men to equal voting power irrespective of status or possessions in the State which has been behind the movement towards the abandonment of slavery; and, finally, the development of that conviction which is behind the existing conflict to all absolute tendencies in economic conditions in the modern world—namely, that the distribution of wealth in a well-ordered State should aim at realizing political justice. There are all the features of an integrating process in modern history. They must be considered as all related to a controlling principle inherent in the Christian religion which has rendered the evolutionary process in society more organic than in any past stage—namely, the projection of the sense of human responsibility outside the limits of all the creeds and interests which had in previous stages embodied it in the State (Kidd, *Prin. West. Civil.*). The meaning, in short, which differentiates our civilization from that of the ancient civilizations of Greece and Rome is that modern Western civilization represents an ever-increasing degree the enfranchisement of the future in the evolutionary process. So great is the principle of the modern civilization through the operation of this principle in that its methods and results are being eagerly borrowed by other peoples. It is thereby so materially influencing the standards of conduct and culture throughout the world that the developments which other nations are undergoing have in a real sense tended to become scarcely more than incidents in the expansion of Western civilization.

We live in the presence of colossal national armaments, and in a world, therefore, in which we are continually met with the taunt that force is still everywhere omnipotent. It may be perceived, however, that beneath all outward appearances a vast change has been taking place. In the ancient civilization the tenet that conquest was an inherent principle in life of the military State. It is no longer an inherent principle in the modern State. The right of conquest is indeed still acknowledged in the international law of civilized States; but it may be observed to be a right becoming more and more impracticable among the more advanced peoples. Reflection, moreover, reveals the fact that the right of conquest is tending to become impracticable and impossible, not, as is often supposed, because of the huge armaments of resistance with which it might be opposed, but because the sense of social responsibility has been so deepened in our civilization that it is almost apparent that one nation should attempt to conquer and subdue another after the manner of the ancient world. It would be regarded as so great an outrage that it would undoubtedly prove to be one of the maddest and one of the most unpardonable adventures in which a civilized State could engage. Militarism, it may be distinguished, is becoming mainly defensive amongst the more advanced nations. Like the civil power within the State, it is tending to represent rather the organized means of resistance to the methods of force should these methods be invoked by others temporarily or permanently under the influence of less evolved standards of conduct.

In thus regarding the social process in Western history, the projected efficiency of which now, after many centuries of development, begins to realize itself to an increasing degree in determining competition with other types of society throughout the world, it may be observed that the result by which a synthesis of the older and later views may be attained is already in sight. It was pointed out that if the principle which Spencer rightly recognized in modern society as rendering the life of the individual no longer subservient to the conception of the life of the State was to be accepted as a principle of progress distinguishing modern civilization from that of the Greek period, it would be necessary for the sociologist to exhibit it not as indicating the larger independence of the individual, but as a principle identified with the increasing subordination of the individual to a more organic type of society. Here, therefore, this result is in process of accomplishment. The intervening process in history—including the whole modern movement towards liberty and enfranchisement, towards equality of conditions, towards equality of political rights and towards equality of economic condition—was in the political process of the most advanced and organic stage of social subordination than has ever prevailed in the world before (Princ. West. Civil. xi.). In this light, also, it may be observed how the claim of sociology to be the most advanced of all the theoretical sciences is justified. For if the historical process in the civilization of the era in which we are living is thus to be regarded as a process implying the increasing subordination of the individual to a more organic type of society, then the study of sociology as embracing the principles of the process must evidently involve the perception and comparison of the meaning of the fundamental positions disclosed in the history of political progress, of the problems with which the human mind has successively struggled in the phases of religious development, and, lastly, of the positions with which the intellect has been confronted as the stages of the subordinating process have
graciously come to define themselves in history. The positions outlined in the developments already referred to which have come down through Hume and Huxley, through Kant and Hegel, through Marx, Engels, and Freud, are mentioned in the present work.

The Claim of the Master Science.

Socrates, son of the staid Sophroniscus and of the staid Sophronice, was born at Athens, not earlier than 471 nor later than May or May 470, A.D. Aristotle postulated the customary instruction in gymnastics and music; and in the following year he made himself acquainted with geometry and astronomy and studied the methods and the doctrines of the leaders of Greek thought and culture. He began life as a sculptor; and in the second century A.D. a group of the Graces, supposed to be his work, was still to be seen on the road to the Acropolis.

But the future of the Abandoned and gave himself to what may be called education, conceiving that he had a divine commission, witnessed by oracles, dreams and signs, not indeed to teach any positive doctrine, but to convict men of ignorance and to show by doing so to procure their spiritual, intellectual, and moral improvement. He was on terms of intimacy with some of the most distinguished of his Athenian contemporaries, and, at any rate in later life, was personally known to very many of his fellow citizens. His domestic relations were, it is said, unhappy. The shrewishness of his wife Xanthippe became proverbial with the ancients, as it still is with ourselves. Aristotle, in his remarks upon genius and its degeneracy (Rhet. ii. 15), speaks of Socrates's sons as dull and fatuous; and in Xenophon's Memorabilia, one of them, Lamprocles, receives a formal rebuke for undutiful behaviour towards his mother.

Socrates served as a hoplite at Potidaea (432 B.C.), where on one occasion he saved the life of Alcibiades, at Delium (424), and at Amphipolis (422). In these campaigns his bravery and endurance were conspicuous. But, while he thus performed the ordinary duties of a Greek citizen with credit, he neither attained nor sought political position. His "divine voice," he said, had warned him to refrain from politics, presumably because office would have entailed the sacrifice of his principles and the abandonment of his proper vocation. Yet in 460 he was a member of the senate; and on the first day of the trial of the victors of Arginusae, being president of the prytany, he resisted first, in conjunction with his colleagues, afterwards, when they yielded, alone-the illegal and unconstituted council of Callixenus, that the fate of the eight generals should be decided by a single vote of the assembly. Not less courageous than this opposition to the "civium arbor prava jubentium" was his disregard of the "vulturn instantis tyranni" two years later. During the reign of terror of 404 the Thirty, anxious to implicate in their crimes men of repute who might otherwise have opposed their plans, ordered five citizens, one of whom was Socrates, to go to Salamis and bring hence their destined victim Leon. Socrates alone disobeyed. But, though he was exceptionally obnoxious to the Thirty—as appears, not only in this incident, but also in their threat of punishment under a special ordinance forbidding "the teaching of the art of argument"—it was reserved for the reconstituted democracy to bring him to trial and to put him to death. In 309, four years after the restoration and the amnesty, he was indicted as an offender against public morality. His accusers were Meletus the poet, Anytus the Tanner and Lycon the orator, all of them members of the democratic or patriot party who had returned from Phyle with Thrasylus.

The accusation ran thus: "Socrates is guilty, firstly, of denying the gods recognized by the state and introducing new divinities, and, secondly, of corrupting the young." In his unpremeditated defence, so far from seeking to conciliate his judges, Socrates...
SOCRATES

The trial of Socrates was one of the most significant events in ancient Greek history. He was accused of impiety and corruption of the youth and was found guilty by 360 votes, with only 180 votes against. In his defense, Socrates argued that the court had failed to understand the true nature of wisdom and that his teachings were meant to guide and improve the lives of his students. He maintained that his only purpose was to lead others to virtue and that he had never done anything to harm the city.

The trial was a turning point in Socrates' life. He was sentenced to death by drinking hemlock, a poison that had been used in Greece for centuries. Socrates drank the poison willingly, declaring that he was unafraid because he knew that he had done nothing wrong and that his soul was pure. He died on the day of the Delphic festival, and his students continued to spread his teachings, forming the basis of the Platonic Academy.

Socrates' death had a profound impact on Athens and on philosophy. He was a man of great integrity and wisdom, and his teachings continue to influence people around the world today. His example of living a life of virtue and his commitment to knowledge and truth continue to inspire generations of thinkers and philosophers.
belief in a divine mission, (5) described "the inward voice of his individual tact, which in consequence partly of his experience and penetration, partly of his knowledge of himself and exact appreciation of what was in harmony with his individuality, had attained to spiritual accuracy." (6) There remained (to Diderot, Zeller and others, who were not only to hallucinations of sense but also to aberrations of reason. Xenophon's testimony that Socrates was plainly sincere in his belief excludes the first and second of these theories; the character of the recitals given of which are always concerned with the moral worth of actions, but with their uncertain results, warrants the rejection of the third and the fourth; the fifth, while it sufficiently accounts for the want of seriousness in his manner, the vocal utterance; the sixth, while it plausibly explains the manner of the warning, goes beyond the facts when it attributes to it irrationality of matter. It remains for us, then, to modify the hypothesis, the theory of Léslé and Littre, and combining the two, to suppose that Socrates was subject, not indeed to delusions of mind, but to hallucinations of the sense of hearing, so that the rational suggestion of his own brain, exceptionally valuing, in consequence, the accuracy and delicacy of his highly cultivated tact, seemed to him to be projected without him, and to be returned to him through outward ear. It appears that though in some of the best known instances—for example, those of Cowper and Sidney Walker—hallucinations of the sense of hearing, otherwise closely resembling Socrates's "divine sign," have been accompanied by partial derangement of reason, cases are not without in which he thought transformed into external sensorial impressions "are perfectly rational.

The eccentricity of Socrates's life was not less remarkable than the oddity of his appearance and the irony of his conversation. His whole time was spent in public—in the market-place, the streets, the gymnasium. Thinking with Dr. Johnson that "a great city is the school for studying life," he had no liking for the country, and seldom passed the gates. "Fields and trees," Plato makes him say, "will not teach me anything; the life of the streets will." He talked to all comers—to the craftsman and the artist as willingly as to the poet or the politician—questioning them about their affairs, about the processes of their several occupations, about their notions of morality, in a word, about familiar matters in which they supposed he was expert. The supposed purpose of these interrogatories was to test, and either refute or explain, the famous oracle which had pronounced him the wisest of men. Conscious of his own ignorance, he had at first imagined that the god was mistaken. When, however, experience showed that those who esteemed themselves wise were unable to give an account of their knowledge, he had to admit that, as the oracle had said, he was wiser than others, in so far as, whilst they, being ignorant, supposed themselves to know, he, being ignorant, was aware of his ignorance. Such, according to the Apology, was Socrates's account of his procedure and its results. It is only in this way that it is possible to reconcile the accustomed irony. When in the same speech Socrates tells his judges that he would never from fear of death or from any other motive disobey the command of the god, and that, if they put him to death, the loss would be, not his, but theirs, since they would not readily find any one to take his place, it becomes plain that he conceived himself to hold a commission to educate, and was consciously seeking the intellectual and moral improvement of his countrymen. His end could not be achieved without the sacrifice of self. His meat and drink were of the poorest; summer and winter his cost was the same; he was shoeless and shirtless. "A slave whose master made him live as you live," says a sophist in the Memorabilia, "would run away." But by the surrender of the luxuries and the comforts of life Socrates secured for himself the independence which was necessary that he might go about his appointed business, and therewith he was content.

His message was to all, but it was variously received. Those who heard him perform and occasionally were apt to regard his teaching either with indifference or with irritation, Contempo— with indifference, if, as might be, they failed to see in the elenchus anything more than a disquisition; with irritation, perhaps, because they perceived that, in spite of his assumed ignorance, Socrates was well aware of the result to which their enforced answers tended. Amongst 
those who deliberately sought and sedulously cultivated his acquaintance there were some who attached themselves to him as they might have attached themselves to any ordinary sophist, conceiving that by temporary contact with so acute a reasoner they would best prepare themselves for the logomachies of the law courts, the assembly and the senate. Again, there were others who saw in Socrates at once master, counsellor and friend, and hoped by associating with him to "become good men and true, capable of doing their duty by house and household, by relations and friends, by city and fellow-citizens" (Xenophon). Finally, there was a little knot of intimates who, having something of Socrates's enthusiasm, entered more deeply than the rest into his principles, and, when he died, transmitted them to the next generation. Yet even those who belonged to this inner circle were not any common theme, but only a common admiration for their master's intellect and character.

For, the paradoxes of Socrates's personality and the eccentricity of his behaviour, if they offended the many, fascinated the few.

Plato's Paeanic.

It is not easy for a man in my condition," says the intoxicated Alcibiades in Plato's Symposium, "to describe the singularity of Socrates's character. But I will try to tell his praises in similitudes. He is like the piping Sirens in the statuaries' shops, which, when you open them, are found to contain images of gods. Or, again, he is like the satyr Marsyas, not only in outward appearance—that Socrates, you will yourself observe—but in other ways also. Like you, him, you are given to frolic—I can produce evidence to that; and above all, like him, you are a wonderful musician. Only there is this difference—what he does with the help of his instrument you do with mere words; for whatsoever man, woman or child hears you, or even a feeble report of what you have said, is struck with awe and possessed with admiration. As for myself, were I not afraid that you would think me more drunk than I am, I would tell you on oath how his words have moved me—ay, and how they move me still. When I listen to him my heart beats with a more Corybantic excitement; he is only to speak and my tears flow. Orators, such as Pericles, never moved me in this way—never roused my soul to the thought of my servile condition; but this Marsyas makes me think that life is not worth living so long as I am what I am. Even now, if I were to listen, I could not resist. So there is nothing for me but to stop my ears against this siren's song and fly for my life, that I may not grow old sitting at his feet. No one would think that I had any shame in me; but I am ashamed in the presence of Socrates.

The Accusation and its Causes.—The life led by Socrates was not likely to win him either the affection or the esteem of the vulgar. Those who did not know him personally, seeing him with the eyes of the comic poets, conceived him as a "visionary" (μεταφορέας) and a "bore" (άδώνεχος). Those who had faced him in argument, even if they had not smarted under his rebukes, had at any rate winced under his interrogatory, and regarded him in consequence with feelings of dislike and fear. But the eccentricity of his genius and the ill he bore towards him by individuals are not of themselves sufficient to account for the tragedy of 399. It thus becomes necessary to study the circumstances of the trial, and the motives which led the accusers to seek his death and the people of Athens to acquiesce in it.

Socrates was accused (1) of denying the gods recognized by the state and introducing instead of them strange divinities (βασιλεύων), and (2) of corrupting the young. The first of these charges rested upon the notorious fact that he supposed himself to be guided by a divine visitor or sign (βασιλεύων). The second, Xenophon tells us, was supported by a series of particular allegations: (a) that he taught his associates to despise the institutions of the state, and especially by lot; (b) that he had numbered amongst his associates Critias and Alcibiades, the most dangerous of the representatives of the oligarchical and democratic parties respectively; (c) that he taught the young to disobey parents and guardians and to prefer his own authority to theirs; (d) that he was in the habit of quoting mischievous passages of Homer and Hesiod to the prejudice of morality and democracy.

It is plain that the defence was not calculated to conciliate a hostile jury. Nevertheless, it is at first sight difficult to understand how an adverse verdict became possible. If Socrates rejected portions of the conventional mythology, he accepted the established faith and performed its offices with exemplary regularity. If he talked of a βασιλεύων, the βασιλεύων was no new divinity, but a mantic sign divinely accorded to him, presumably by the gods of the state. If he questioned the propriety of certain of the institutions of Athens, he was prepared to yield an unhesitating obedience to all. He had never countenanced the misdeeds of Critias and Alcibiades, and indeed, by a sharp censure, had earned the unifying hatred of one of them. Duty to parents he inculcated he inculcated other virtues; and, if he made the son, as far as the father, surely that was not a fault. The citation of a few lines from the poets ought not to weigh against the clear evidence of his large-hearted patriotism; and it might be suspected that the accuser had strangely misrepresented his application of the familiar words.

To the modern reader Xenophon's reply, of which the fore-going is in effect a summary, will probably seem sufficient, and more than sufficient. But it must not be forgotten that Athenians of the old school approached the subject from an entirely different point of view. Socrates was in all things an innovator—in religion, inasmuch as he sought to eliminate from the theology of his contemporaries "those lies which poets tell"; in politics, inasmuch as he distrusted several institutions dear to Athenian democracy; in education, inasmuch as he waged war against authority, and in a certain sense made each man the measure of his own actions. It is because Socrates was an innovator that we, who see in him the founder of philosophic inquiry, regard him as a great man; it was because Socrates was an innovator that old-fashioned Athenians, who saw in the new-fangled culture the origin of all their recent disasters and disasters, regarded him as a great criminal. It is, then, after all in no wise strange that a majority was found first to pronounce him guilty, and afterwards, when he refused to make any submission and professed himself indifferent to any mitigation of the penalty, to pass upon him the sentence of death. That the verdict and the sentence were not in any way illegal is generally acknowledged.

But, though the popular distrust of eccentricity, the irritation of individuals and groups of individuals, the attitude of Socrates himself, and the prevalent dislike of the intellectual movement of which he represented himself as the standard of the State, or inasmuch as it was the occasion for the result of the trial, they do not explain the occasion of the attack. Socrates's oddity and brusquerie were no new things; yet in the past, though they had made him unpopular, they had not brought him into the courts. His sturdy resistance to the demos in 406 and to the Thirty in 404 had passed, if not unnoticed, at all events unpunished. His political heresies and general unorthodoxy had not caused him to be excluded from the amnesty of 403. Why was it, then, that in 399, when Socrates's idiosyncrasies were more than ever familiar, and when the constitution had been restored, the tolerant bitters and distresses were regarded as his great crime? What were the special circumstances which induced three members of the patriot party, two of them leading politicians, to unite their efforts against one who apparently was so little formidable?

For an answer to this question it is necessary to look to the history of Athenian politics. Besides the oligarchical party, properly so called, which in 411 was represented by the Four Hundred and in 404 by the Thirty, and the democratic party, which returned to power in 401 and 400, there was at Athens during the last years of the Peloponnesian War a party of "moderate oligarchs," antagonistic to both. It was to secure the co-operation of the moderate party that the Four Hundred in 411 promised to constitute the Five Thousand, and that the Thirty in 404 actually constituted
the Three Thousand. It was in the hope of realizing the aspirations of the moderate party that Themagenses, its most prominent representative, allied himself, first with the Four Hundred, afterwards with the Thirty. In 411 the policy of Themagenses (q.v.) was temporarily successful, the Five Thousand superseding the Four Hundred. In 404 the Thirty outwitted him; for, though they acted upon his advice so far as to constitute the Three Thousand, they were careful to keep all real power in their own hands. But on both occasions the "polity" —for such, in the Aristotelian sense of the term, the constitution of 411-410 was, and the constitution of 404-403 professed to be—was inscuriously based, so that it was not long before "unmixed democracy" was restored. The programme of the "moderates"—which included (1) the limitation of the franchise, by the exclusion of those who were unable to provide themselves with the panoply of a hoplite and thus to render to the city substantial service, (2) the abolition of payment for the performance of political functions, and, as it would seem, (3) the disuse of the lot in the election of magistrates—found especial favour with the intellectual class. Thus Alcidamas was amongst its promoters, and Thucydides commends the constitution established after the fall of the Four Hundred as the first in Athens that was truly enjoyed. Nor apparently stated that Socrates disdained election by lot; it is certain that, regarding paid educational service as a species of prostitution, he would not account paid political service not a whit less odious; and the stress laid by the accuser upon the Homeric quotation (IIiad ii. 188—202)—which ends with the lines θαύμαν, ἄρεμας, τὰ καθά, ἀλλ᾽ ἄλλων μικρὸν ἀνείκει ὁ σωφρόνιστος ἐκ οὐ δ ’ ἄντιδεξιας καὶ ἀνάλκης, οὔτε ποτ’ ἐν πολύματι ἐναρμάζεις οὔτ’ ἐν βουλῇ—becomes intelligible if we may suppose that Socrates, like Themagenses, wished to restrict the franchise to those who were rich enough to serve as hoplites at their own expense. Thus, as mignty populo, Socrates was a "moderate," and the treatment which he received from both the extreme parties suggests—even if with Grote we reject the story told by Diodorus (xiv. 5), how, when Themagenses was dragged from the altar, Socrates attempted a rescue—that his sympathy with the moderate party was pronounced and notorious. Even in the moment of democratic triumph the "moderates" made themselves heard. Phormisius proposing that those alone should exercise the franchise who possessed land in Attica; and it is reasonable to suppose that his position was stronger in 399 than in 403. These considerations seem to indicate an easy explanation of the insinuation of Socrates by the democratic politicians. It was a blow struck at the "moderates," Socrates being singled out for attack because, though not a professional politician, he was the very type of the malcontent party, and had done much, probably more than any man living, to make and to foster views which, if not in the strict sense of the term oligarchical, were confessedly hostile to the "unmixed democracy." His eccentricity and heterodoxy, as well as the personal animosities which he had provoked, doubtless contributed, as his accusers had foreseen, to bring about the conviction; but, in the judgment of the present reader, it was the fear of what may be called "philosophical radicalism" which prompted the action of Meletus, Anytus and Lycon. The result did not disappoint their expectations. The friends of Socrates abandoned the struggle and retired into exile; and, when they returned to Athens, the most prominent of them, Plato, was careful to confine himself to theory, and to announce in emphatic terms his withdrawal from the practical politics of his native city.

Method and Doctrine.—Socrates was not a "philosopher," nor yet a "teacher," but rather an "educator," having for his function "to arouse, persuade and rebuke" (Plato, Apology, 35 E). Hence, in examining his life's work it is proper to ask, not What was his philosophy, but What was his theory, and what was his practice, of education? It is true that he was brought to his theory of education by the study of his philosophy. It is also true that his practice led to the Platonic revival; but to attribute to him philosophy, except in that loose sense in which philosophy is ascribed to one who, denying the existence of such a thing, can give an account of his disbelief, is misleading and even erroneous.

Socrates's theory of education had for its basis a profound and consistent scepticism; that is to say, he not only rejected the conflicting theories of the physicists—of whom "some 45 Scepticism. have given an opinion that there is a certain affirmed perpetual motion, others perpetual rest; some declared becoming and perishing to be universal, others altogether denied such things"—but also condemned, as a futile attempt to reconcile the limits of the human faculties with their "pursuit of knowledge for its own sake." Unconsciously, or more probably consciously, Socrates rested his scepticism upon the Protagorean doctrine that man is the measure of all things, and that the philosopher has neither the number nor the power to convey instruction to one who had it not. Accordingly, whereas Protagoras and others, abandoning physical speculation and coming forward as teachers of culture, claimed for themselves the field of all intellectual teaching, Socrates, unable to reconcile himself to this inconsistency, proceeded with the investigation of principles until he found a resting-place, a φως ἔν (), in the distinction between good and evil. While all opinions were equally true, of those opinions which were capable of being translated into act some, he conceived, were as working hypotheses more serviceable than others. It was here that the founder of such a 'scientific' digamation was, in his proper right, neither the nor the power to force his opinions upon another, he might by a systematic interrogatory lead another to substitute a better opinion for a worse, just as a physician by appropriate remedies and by his patient example. In his practice he was not, as is supposed, a "talker " or "converter," for it was as positively and distinctly, positive and negative disputation, whether philosophers or sophists, called themselves "teachers" (δασκαλοί), but also positively indicated the method of question and answer (ἀναγνωστικόν) which he consistently preferred and habitually practised.

That it was in this way that Socrates was brought to regard "dialetic," "question and answer," as the only admissible method of education is evident from the passage, Diels K 424, where it is said that it was a matter of mere conjecture. In the review of theories of knowledge which has come down to us in Plato's Theaetetus mention is made (72 B) of certain "incomplete Protagorean" philosophers, who, "to use a vulgar and highly true, one opinion is better than another, and that the wise man" is one who by his arguments causes good opinions to take the place of bad ones, thus reforming the soul of the individual or the laws of a state by a process similar to that of the physician or the farmer (166 D seq.); and these "incomplete Protagoreans" are identified with Socrates and the Socratics by their insistence (167 D) on the "dialetic method." The closest approach to Protagoras; but the fact, once stated, hardly admits of question. In the application of the "dialetic" or "maieutic" method two processes are distinguishable—the destructive process, by which the worse opinion was eradicated, and the constructive process, by which the better opinion was induced. In general it was not mere "ignorance" with which Socrates had to contend, but ignorance mistaking itself for knowledge—or "false conceit of wisdom"—a more stubborn and a more formidable foe, who, safe so long as he remained in his intrenchments, must be drawn from them, circumvented, and surprised. Accordingly, taking his departure from some apparent extreme, the principle of which Socrates had really yielded a ready assent, Socrates would draw from it an unexpected and undeniable consequence which was plainly inconsistent with the opinions professed by his interlocutor. He was thus led, in his judgment upon himself, and reduced him to a state of "doubt" or "perplexity" (ἀσόφια). "Before I ever met you," says Meno in the dialogue which Plato called by his name (79 E), "I was told that you had spent your time in studying your intellect, and it is a fact that your witcheries and spells have brought me to that condition; you are like the torpor: as it benumbs any one who approaches and touches it, so do you. For myself, my soul and these verses are both of us, and I am not torpid another, or sleepless."

Even if, as often happened, the respondent, bafled and disgusted by the ἀσόφια or destructive process, at this point withdrew from the field of discussion, as he had previously done, as a sign that whereas formerly, being ignorant, he had supposed himself to have knowledge, now, being ignorant, he was in some sort conscious of his ignorance, and accordingly would be for the future more circumspect in action. If, however, having been thus convinced of ignorance,
the respondent did not shrink from a new effort, Socrates was ready to aid him by further questions of a suggestive sort. Consistent thinking with a view to consistent action being the end of the inquiry, Socrates made no distinction between the steps which were analogous to that in hand, and so led him to frame for himself a generalization from which the passions and the prejudices of the moment were, as far as might be, excluded. In this constructive process the form of question and way of broadening the interrogative form was studiously preserved, because it secured at each step the conscious and responsible assent of the learner.

On the one hand, Xenophon, having for his principal purpose the defence of his master against vulgar calumny, seeks to show by effective and excellent excellence of his positive teaching, and accordingly is not careful to distinguish, still less to emphasize, the negative procedure. On the other hand, Plato, his aim being not so much to preserve Socrates's positive teaching as rather by written words to stimulate the reader to self-scrutiny, just as the spoken words of the master had stimulated the hearer, is compelled by the very nature of his task to keep the argument down to the purest constructive process. Socrates would have drawn an unmistakable conclusion, to confine himself to etymological hints. For example, when we compare Xenophon, iv. 6, 23-25, with Plato's Euthyphro, we note in Plato, while in the former the interlocutor is led to five questions to define "piety" as "the knowledge of those laws which are concerned with the gods," in the latter, though on a further scrutiny it appears that "piety" is "that part of justice which is concerned with the service of the gods," the conversation is ostensibly inconclusive. In short, Xenophon, a mere reporter of Socrates's conversations, gives the results, but troubles himself little with the steps which led to the conclusion. Plato, who in early manhood was an educator of the Socratic type, withholds the results that he may secure the advantages of the elenctic stimulus.

What, then, were the positive conclusions to which Socrates carried his interlocutors? How were these conclusions so positively obtained? Turning to Xenophon for an answer to these questions, we note (1) that the recorded conversations are concerned with practical action, political, moral, or artistic; (2) that in general there is an approach from the known to the unknown through a generalization, expressed or implied; (3) that the generalizations are sometimes rules of conduct, justified by examination of known instances, sometimes definitions of objects or ideas, sometimes both.

Socrates argues from the known instances of horses and dogs that the best natures stand most in need of training, and then applies this knowledge to self-examination, thus, in iv. 6, 13-14, he leads his interlocutor to a definition of "the good citizen," and then uses it to decide between two citizens for whom respectively superiority is claimed. Now in the former of these cases Socrates makes "to be good" or "to be virtuous" ( ἀρετής) a modern might regard as "induction" of a sort—sufficiently explains itself. The conclusion is a provisional assurance that in the particular matter in hand a certain course of action is, or is not, to be adopted. But it is necessary to say a word of explanation about the latter case, in which, the generalization being a definition, that is to say, a declaration that to a given term the interlocutor attaches in general a specified meaning, the conclusion is a provisional assurance that the interlocutor may or may not, without falling into inconsistency, apply the term in question to a certain person or act. Moral error, Socrates conceived, is largely due to misapplication of the terms. It is not affixed to a person or to an act, possibly in a moment of passion or prejudice, too often stand in the way of sober and careful reflection. It was in order to exclude error of this sort that Socrates insisted upon the preliminary specification of the term, and in his demand requiring a definition and the reference to it of the act or person in question, he sought to secure in the individual at any rate consistency of terms. The doctrine of Eudoxus, a well-known instance, was that he spent his life in seeking and helping others to seek "the what" ( ὅ τι), or the definition, of the various words by which the moral quality of actions is described, valuing the results thus obtained much more than the specific knowledge, but as means to right action in the multifarious relations of life.

While, however, Socrates sought neither knowledge, which in the strict sense of the word he held to be unattainable, nor yet, in the results of observation assumed to lead to right action, true opinion, the "Incomplete Socratice" not a system of ethics, but at any rate a body of ethical doctrine. Himself blessed with a will so powerful that it moved almost without friction, he fell into the error of ignoring its operations, and was thus led to regard knowledge as the sole condition of well-doing. Where there is knowledge—that is to say, a true opinion, which is the Socratic recognized—right action, he conceived, follows of itself; for no one knowingly prefers what is evil; and, if there are cases in which men seem to act against knowledge, the inference to be drawn is, not that they don't know what they do; or (if knowledge is assumed in question the supposed knowledge was after all ignorance. Virtue, then, is knowledge, knowledge acquired at once of end and of means, irresolutely realizing itself. Whence it follows that the several virtues which are commonly distinguished are but worded different "Piety," "justice," "courage," and "temperance" are the names of which "wisdom" bears in different spheres of action: to be pious is to show that the end of religion is piety; to be just is to know what is just; to be courageous is to know what is to be feared and what is not; to be temperate is to know how to use what is good and avoid what is evil. Further, inasmuch as virtue is knowledge, it can be obtained by each man individually through the nature of the one soul has by nature a greater aptitude than another for such acquisition. If virtue is knowledge, what has this knowledge for its object?

To this question Socrates replies, Its object is the Good. What, then, is the Good? It is the useful, the advantageous. Utility, the immediate utility of the individual, thus becomes the measure of conduct and the foundation of all moral rule and legal enactment. Accordingly, each precept of which Socrates delivers himself is recommended on the ground that obedience to it will promote the pleasure, the benefit, or the advantage of the individual. Proclus in his paraphrase of the Choice of Heracles, with its commonplace offers of worldly reward, is accepted as an adequate statement of the doctrine of virtue in action. Of the graver difficulties of ethical theory Socrates has no comment. He had rather assumed perfectly absorbed, the lessons of what Plato calls "political virtue" that morality has become with him a second nature, and the scrutiny of its credentials from an external standpoint has long been to be possible. His theory is indeed so little systematic that, whereas, as has been seen, virtue or wisdom has the Good for its object, he sometimes identifies the Good, with virtue or wisdom, thus failing into the error which Plato (Republic vi, 505 E.) perhaps with distinct reference to Socrates, ascribes to certain "cultivated thinkers." In short, the ethical theory of Socrates, like the rest of his teaching, is by confession unscientific; it is the statement of the conclusions of a man, nor can there be much doubt that he had made some tentative contributions to a theory of morality; he had shown both in his life and in his death that his principles stood the test of practical application; he had invented a method of discovering the "true end" of human action short of the end of life; he had asserted the autonomy of the individual intellect. Accordingly, not one school but several schools sprang up amongst his associates, those of them who had a turn for speculation taking several from his teaching so much as their pre-existing tendencies and convictions allowed them to assimilate. Thus Aristippus of Cyrene interpreted hedonistically the theoretical morality; Antipatris of Eleusis identified the Cynegetic, as his doctrine of life, with that which is an attribute of a good life; Antipatris and Eudoxus of Megara practised and perverted the elenctic method; Plato the Academic, accepting the whole of the Socratic teaching, first developed it harmoniously in the socratic spirit of its author, until his later schools, containing elements of Platonism, began to be called"the Academy. From the latter half of the fourth century B.C. down to the middle of the second, the Academicians were the chief expositors of the Socratic doctrine. The influence of which he exercised upon Aristippus, Antisthenes and Eudoxus, the "incomplete Socratics," as they are commonly called, as well as upon the "complete Socratic," Plato, something like the following may be said.

The "incomplete Socratics" were, like Socrates, sceptics; but, whereas Aristippus, who seems to have been in contact with Protagoras, had to overthrow almost universally the view that man was the measure of all things, Protagoras had done, from the standpoint of the pluralists, Antisthenes, like his former master Gorgias, and Eudoxus, in whom the ancients
rightly saw a successor of Zeno, came to scepticism from the standpoint of Eleatic hermeneutics. In other words, Aristippus was sceptical because, taking into account the subjective element in his teaching, he accounted for such ' things' as sensations and things at the same moment bear various and inconsistent epiphanies, and consequently conceived all predication which was not identical to be illegitimate. Thus Aristippus recognized only feelings; he had no particularized knowledge and the denial of any denial of predication is legitimate, and it is probable that in this manner Euclides was at one with him. For, though since Schleiermacher many historians, unnecessarily identifying the older 300s of Plato's Sophist with the time of Socrates, have supposed that this was the first of all Aristippus' books, and only the strength of this single passage thus conjecturally interpreted, have added a new chapter to the history of Megarianism, it is difficult, if not impossible, to believe that the scepticism he caused by his break loose from the trammels of the Zonian paradox, his successors, and amongst them Stilpo, should have reconciled themselves, as they certainly did, to the Cynic denial of predication.

While the "incomplete Socrates" made no attempt to overpass the limits which Socrates had imposed upon himself, within those limits they occupied each his department. Aristippus, a citizen of the world, drawn to Athens by the fame of Socrates, and retained there by the sirens' song of Bignone, all supposed of him by himself. Nevertheless, the Socratic doctrine of Socrates in accordance with his own theory of pleasure, which in its turn came under the refining influence of the Platonic world, is a very rugged but not ungenerous nature, a hater of pleasure, troubled but not a hater of intellectual theory, and gave his life to the imitation of his master's asceticism. Virtue, he held, depended upon ' works,' not upon ' thoughts'; all his teachings, even his conception of the strength of a Socrates (Diog. Laërt. vi. 11). Yet here too the Socratic theory of peglen had a qualifying effect; so that Cyrenaic hedonism and the Socratic asceticism sometimes exhibit unexpected apportionments. As Socrates by his teaching had not supposed to be the highest object of knowledge, can hardly be said to have an ethical element; and in consequence of this deficiency the dialectic of Socrates degenerated in Meginian hands into a series of exercises in fallacies, secondly into a vulgus and futile eristic. In fact, the partial Socraticism of the incomplete Socrates necessarily suffered, even within their own narrow limits, by the dismemberment from their master. But the hypothesis that education was not valued by any of these; and, however, this may be, they deviated from Socratic tradition so far as to establish schools, and, as it would seem, to take fees like the professional educator, "called Sophists."

Of the relations in which the metaphysic of Plato stand to the Socratic search for definitions there are of necessity almost as many theories as there are interpretations of the Platonic doctrine, and the author of this book has been a busy man. He has set himself with a summary statement of his own views. Initiated into philosophical speculation by the Heracliteans, Plato, the absolute sceptic, the follower of Heraclitus having towards the end of the 5th century pushed to its conclusion the unconscious scepticism of their master. There would have been then nothing to be glad about, but the hypothesis was understood to be a mere theory of education was not valued by any of the three; and, however, this may be, they deviated from Socratic tradition so far as to establish schools, and, as it would seem, to take fees like the professional educator, "called Sophists."

SOCRATES, the name of a famous 5th-century church historian. In the course of the last twenty-five years (425-450) of the reign of Theodosius II. (the first thoroughly Byzantine emperor) at least six church histories were written in Greek within the limits of the Eastern Empire—those, namely, of Philostorgius the "Arian," of Philip of Side, of Socrates, of Sozomen, of Theodoret and of Hesychius. Of these the first, no longer extant except in fragments, seems to have been the most important. Those of Philip and of Hesychius (the former an untrustworthy and dreary performance mentioned by Socrates [vi. 26, 27]) have also perished. The remaining three are now our main sources for church history from Constantine to Theodosius II. None of them has ventured upon a fresh treatment of the period dealt with by Eusebius; all three begin their narratives about the point where his closes. In the West the Church History of that author had already been continued by Rufinus and his Chronicle by Jerome, and the work of Rufinus was certainly known to the Byzantines. Nor did these write independently of each other, for Sozomen (q.v.) certainly had before him the work of Socrates, and Theodoret (q.v.) knew both of them. The three histories together became known in the West from the 6th century through the selection which Cassiodorus caused to be made from them, and it is to this selection (if we leave Rufinus and Jerome out of account) that the middle ages were mainly indebted for all they knew of the Arian controversies, and of the period generally between the Councils of Nice and Ephesus.

In the Church History of Socrates, still extant in seven books, embracing the period from 336 to 430, was written in 439, or within a few years thereafter. He was born and brought up at Constantinople. The date of his birth is uncertain, but it cannot have been far from 380. Of the facts of his life we know practically nothing, except that he was not a clerical but a "scholastic" or advocate. Of the occasion, plan and object of his work he has himself informed us in the prologues to his first, second, fifth and sixth books. It is dedicated to one Theodoret, who had urged him to write such a history. He had no thorough preparation for the task, and for the period down to the death of Constantius (361) was practically dependent on Rufinus. After his work was finished he became a student of Athanasius' writings and came to see how untrustworthy his guide had been. He accordingly rewrote his first two books (see H. E. ii. i) certainly before 450 and probably before 444 (see Geppert p. 8), and it is only this revision that has reached us. The chief sources from which he drew were: (1) the Church History, the Life of Constantine and certain theological works of Eusebius; (2) the Church History of Rufinus; (3) certain works of Athanasius; (4) the no longer extant Επιμελεία τῶν κοινωνιών of the Macedonian and semi-Arian Sabinus—a collection of acts of council, with controversy for brought down to the reign of Theodosius I. (this was a main source); (5) the Constantinopolitan Chronicle; (6) possibly a collection of imperial biographies; (7) lists of bishops; (8) collections of letters by members of the Arian and orthodox parties. He also used writings of Gregory Thaumaturgus, Archelaus, Acacius, Didymus, George of Laodicea, Gregory Nazianzen, Timothy of Berytus (see Lietzmann, Απόλιτοι καὶ Λαοδεκαί, p. 44), Nestorius, Eusebius Scholasticus, Philip of Side, Evagrius, Palladius, Eutropius, the emperor Julian and orations of Libanius and Themistius; and he was apparently acquainted with some of the works of Origen and with Pamphilus' Apologia pro Origenes. (On his sources see Jep., and especially Geppert.) Jepflegues (pp. 140 sqq.), but without adequate proof, that he made use of Philostorgius. As regards profane history his materials were exceedingly defective. Thus, for example, he confesses that his reason for not giving an account of the wars of Constantine is his inability to ascertain anything certain about them (v. praef.). His reckonings by Olympiads are generally wrong, the error arising chiefly from carelessness. He is greatly indebted to oral tradition and to the testimony of eye-witnesses, especially of members of the Novatian community. In some things also he has set down from personal knowledge. The contents of the closing books are for the most part derived from oral tradition, from the narratives of friends and countrymen, from what was still generally known and current in the capital about past events, and from the ephemeral literature of the day.

The geographical position of Socrates, so far as he can be said to have had one, is at once disclosed in his unlimited admiration for Origen. All the enemies of the great Alexandrian he regards merely as empty and vain obscurantists; for the orthodoxy of his hero he appeals to Athanasius. Closely connected with his high regard for Origen are his investigations into his personality, and the moderation of his judgment on all dogmatic questions. According to him, Ἠρωδιανὴ καρδία is quite indispensable within the Church; many Greek philosophers were not far from the knowledge of God, as shown by their arguments; and he had his reason for regarding the gainayers of divine providence. The apostles did not set themselves against the study of Greek literature and science; Paul had even made a thorough study of them himself. The Scriptures, it is true, contain all the means to faith in the dispensation, but the use of the art of confuting gainayers. Greek science, therefore, must not be banished from the Church, and the tendency within the Church to deal with the world was wrong. The Church was, he seems to hold, a common one of the majority of educated Christians at that period, and is not to be regarded as exceptionally liberal. The holds true of the position of Socrates in regard to dogmatic questions. On the one hand, indeed, he offers the cloudiest view of his mind by the wheat and the tares respectively; he clings to the naive opinion of Catholicism, that contemporary orthodoxy has prevailed within the Church from the first; he recognizes the true faith only in the mystery of the Trinity; he judges heretics who have been already condemned as interlopers, as impudent innovators, actuated by bad and self-seeking motives; he apologizes for having so much as treated of Arianism at all in his history of the Church; he believes in the inspiration of the ecclesiastical councils as much as in that of the Scriptures themselves. But, on the other hand, he takes absolutely no interest in dogmatic subtleties and clerical disputes. He regards the position of the Church as "objective," and his craving for peace: "one ought to adore the ineffable mystery in silence." This attitude, which was that of most educated Byzantine laymen, has in particular cases made it possible for him to escape very freely from dogmatism. Even so, the amount of remains of ancient reserve may have contributed to this, and even although some of it is certainly to be set down to his disposition and temperament, still it is clear that he has moulded the character of Socrates and made him a typical example of the later Byzantine Christianity. If Socrates had lived about the year 325, he certainly would not have ranked himself on the side of Athanasius, but would have joined the party of mediation. But the hēdiosia has been laid down, and must be recognized as correctly expressing the meaning; only one ought to rest satisfied with that word and with the repudiation of Ariantism. Anything more, every new distinction, is unsatisfactory. The controversy in its details is a ρωματζήχικα to him, full of misunderstandings. Sometimes he gives prominence, and correctly, to the fact that the disputes were impartially fought, and not by one side against another, because they had separate interests at heart—those on the one side desiring above everything to guard against polytheism, those on the other being most afraid of Sabellianism. He did not fail, however, to recognize also the fact that the controversy was brought down to the point of the end and scandal and sophistry. Not infrequently he passes very sharp judgments on whole groups of bishops. In the preface to his fifth book he excuses his trenching on the region of political history on the ground of the desirability of his reader's being made acquainted with the endless disputes of the bishops could not fail to excite on the one side a desire for mediation, and that in to his sixth book he prides himself on never having flattered even the orthodox bishops. "The Church," he says, "is not of a certain measure of impartiality. Constantius, and even Julian—no Valens, it is true—are estimated very fairly. The Arian Goths who died for their religion are recognized as genuine martyrs. His characteristic position of Orthodoxy in his time, as that of the Christological controversy, are models of candour and historical conscientiousness. In frequent instances, moreover, he acknowledges his own incompetency to give an opinion
and hands the question over to the clergy. For the clergy as a whole, in spite of his criticism of individuals, he has the very highest respect, as also for the monks, without himself making any inordinate religious professions. In a special excursion of considerable length he describes the highest characterizations of monasticism in the characterization of Theodotus II. also (where he has made use of the brightest colours) he does not fail to point out that in piety the emperor could almost compete with the monks. But apart from this, however, it does not seem that one could learn from the pages of Socrates that there was such a thing as monasticism in those days. To his mind the convent is not far removed from the world, and as sacerdotalism is now the natural principle which Socrates accepted as a monasticism if as applying to the principles of monasticism as applying to himself or to square his views of history in accordance with them. He has even gone so far as formally to express his sympathy with Paphnutius, the author of bishop, and to relate some of his experiences in the world to his history. As a source for the period within which he wrote, the work of Socrates is of the greatest value, but as "history" it disapproves even the most modest expectations. Eusebius, after all, has hardly connected with what is meant by "church history," but Socrates has none. "As long as there is peace there is no material for a history of the church"; but, on the other hand, neither do heresies by rights come into the story. What, then, is left for a complete history? A new "church history" is topimpossible. But even so one hardly everything about state or court except great enterprises and anecdotes. Political interest is wholly wanting to Socrates; all that he loves and detests lies forth in a uniform light of dazzling splendour; even the miserable Acrisius is praised, and Theodosius II. figures as a saint whose exemplary piety turned the capital into a church. If in addition to all this we bear in mind that in his latest book he came too close to the city and the emperor of Constantinople, that he was exceedingly ill informed on all that related to Rome and the West, that in order to fill out his pages he has introduced narratives of the most extraordinary incidents, in short, that he has been influenced by his celebrity (although when compared with the majority of his contemporaries he is still entitled to be called critical), it becomes sufficiently clear that his History, viewed as a whole and as the literary product at it best taken only as a secondary place. One great excellence, however, cannot be denied him, his honest and sincere desire to be impartial, the thing, as far as he could, to distinguish between the certain, the probable, the possible, and the impossible. With a certain respect for the hearts of men and frequently decide on motives. He has made frank confession of his nescience, and in certain passages his critical judgment and sober sense of circumstances is striking as the case. He writes plainly and unadorned style and shuns superfluous words. Occasionally even there are touches of humour and of trenchant satire—always the sign of an honest writer. In short, there is knowledge, temperance, and a commendable goodwill and straightforwardness a great deal. Considering the circumstances under which he wrote, it can only be matter for congratulation that such a man should have become our informant and that his work has been preserved to us.

Finally, it looks as if Socrates was either himself originally a Novatianist who had afterwards joined the Catholic Church, or stood through his ancestors or by education in most intimate relations with the Novatianist Church. In his History he betrays great sympathy with that body, has gone with exactness into its history in Constantine and Phrygia, and is indebted for much of the material of his work to the Novatian and other training. He has been one of the number of the sect, as he himself tells us. But he has not, however, had only this result, that he himself afterwards fell under suspicion of Novatianism.

Editions and Literature.—Socrates's History has been edited by Stephanus (Paris, 1544; Geneva, 1612), Valesius (Paris, 1659 sqq.), Kober (Gottingen, 1790),Brightness (1841), and Bright, (1878). It is also to be found in volume 15 of Migne's Patrologia, and there is an Oxford school edition (1844) after Reading. The latest English translation, revised by Zeno, is published by the Rev. Mr. H. C. Nolte. There are two editions in Valesius and more fully in Hussey; and Nolte's paper in Tubing. Quartalschr. (1859, p. 518 sqq.), contains emendations in certain cases, and presents to modern students the text, together with text and notes and editions; see also Overbeck, in Teob. lit. Zant. (1789), no. 20. Special studies have been made by Baronius, Migne, Laplace, Valesius, Hallois, Scaliger, Cellier, Cave, Dupin, Pagi, Ittig, Tillemont, Walch, Gibbon, Groeschel, Lardner. See also Voss, De histor. graecis; Fabricius-Harless, Biblioth. gr., vol. vii.; Rössler, Bibliothek d. Kirchentafeln; Holzhausen, De fontibus quibus urbs Romae embellatur (Gottingen, 1825); Staedlin, Gesch. d. Lit. d. K.-G. (Hanover, 1827); Baur, Epochen (1852); Harnack, "Socrates u. Sozomen" in Herzog-Hauck's Reallexikon, s.v. Socrates, ed. IV. ('05). Some more details are given also in works upon Constantine (Manso), Julian (Mücke, Rode, Neumann, Rendall), Damascus (Rade), Arianism (Gwatkin's Studies of Ariantism), which gives a severe but true worth criticisms of Knefus and discusses the manner in which Socrates was related to him), the emperors after Julian (De Broglie, Richter, Clinton, the Weltgeschichte von Ranke, the Gesch. d. ost-römischen Reiches unter den Kaiser Arcadius u. Theod. II. (1885) of Siehe, and the Zeitschrift für die Kunde des Morgenlandes, where Loeschke, with Geldenpenning and Illand, the last-named work discussing the relation of Socrates to Sozomen), the barbarian migrations (Wietenstein, Dahoe), the Gotics (Walter, Basse), the Kaufmann and Walch, Ulfois, (1856). Lastly, reference may be made to Sarrasini, De Theodoro Lector, Theophani fonte paceippia (1850, 1889, 1891, 1894), the relations between Socrates and Sozomen, and of the completeness of the latest book of Socrates. The introduction of Socrates in Vol. III, p. 288, and the last years of the present book are a. R. A. (A. C. McG.)

SODALITE, a group of rock-forming minerals comprising the following isomorphous species:

Sodalite Na(Al,Sr)Al(SiO₄)₆(OH)₄
Habit a, b, c

Nasrite Na(Na,Sr)Al(SiO₄)₆(OH)₂

Lazurite Na(Sr,Al)(SiO₄)₆

They are thus sodium (or calcium) aluminium silicates, with chlorite, carbonate or sulphide. In their orthosilicate formulae, as above written, and in their cubic crystal form they present a certain resemblance to the members of the garnet group. Crystals usually have the form of the rhombic decahedron, and are often twinned with interpenetration on an octahedral plane. They are white, grey, or bluish in the plane of the cleavage; with oily lustre. The hardness is 5, and the specific gravity 2.2-2.4. These minerals are characteristic constituents of igneous rocks rich in soda, and they also occur in metamorphic limestones. The species sodalite (so named because it contains soda) occurs as well-formed, colourless crystals in the ejected limestone blocks of Monte Somma, Vesuvius, and in the sodalite-syenite of Juliano in southern Greenland. Massive blue material is common in the eulaoite-syenites of southern Norway; Gjøyr-Ditro in Transylvania, Miyask in the Urals, Litchfield in Maine, Dungannon in Ontario, Ice river in Kootenay county, British Columbia, and also at the three last-named localities it is found as large masses of a bright sky-blue colour and suitable for cutting as an ornamental stone. Recently, large masses with a pink colour, which quickly fades on exposure to light, have been formed in the Çagman quarries, near Kishangir in Rajputana. Hyatite, or hyatene (named after R. J. Halby), occurs as bright blue crystals and grains in the lavas (phonolite, tephrite, &c.) of Vesuvius, Rome, the Eifel, &c. Noseildite, a trachyte, in Sweden, is also blue and has a vitreous lustre. Lazurite is an important constituent, together with sapphireine and sodalite, of lapis-lazuli (q.v.).

SODEN, a town and spa of Germany, in the Prussian province of Hesse-Nassa, pleasantly situated in the valley of the Sulzbach under the southern slope of the Taunus range, 10 m. from Frankfurt-on-Main and 4 m. N. from Hœchst by rail. They are white, or often blue in colour, and have a nitreous brine springs which are largely impregnated with carbonic acid gas and oxide of iron, and are efficacious in chronic catarh of the respiratory organs, in liver and stomach disorders and women's diseases. The waves are used both internally and externally, and are largely exported. Soden lozenges (Sodenar Pastillen), condensed from the waves, are also in great repute. Soden has a large and well-appointed Kurhaus, an Evangelical and a Roman Catholic church, and a hospital for indigent patients.

See also, Soden am Taunus (Wurtzb., 1902); and Köhler, Der Kurfurst Soden am Taunus and seine Umgebungen (Frankfort, 1873).

SODEN, HERMANN, FREIHERR VON (1825— ), German biblical scholar, was born in Cincinnati on the 16th of August 1852, and was educated at the university of Tubingen. He was minister of Dresden-Streien in 1881 and in 1887 became minister of the Jerusalem Church in Berlin. In 1889 he became privat-dozen in the university of Berlin, and four years later was
SODERHAMN—SODIUM

appointed extraordinary professor of divinity. His earlier works include Philippibrief (1890); "Untersuchungen über neutestamentliche Texte" in the Protestant theolog. Studien und Kritik (1895-96). Sodermans Kirche? (3rd ed. 1890); Reisebriefe aus Palästina (2nd ed. 1901); Palästina und seine Gesch. (2nd ed. 1904); Die wichtigsten Fragen im Leben Jesu (1904); Urchristliche Literaturgesch. (1904). His most important book is Die Schriften des neuen Testaments, in ihrer ältesten erreichbaren Textstel. hergestellt unter gründ. ihrer Textgeschichte (Berlin, Bd. 1, 1902-1910); certainly the most important work on the text of the New Testament which had been published since Westcott and Hort's New Testament in the Original Greek (see Bible: New Testament).

Westcott introduces, besides a new notation of MSS. (see Bible, N.T. MSS.), new text-critical principles. He thinks that in the 4th century there were in existence three recensions of the text, which he distinguishes as K, H, and I, with the following characteristics and attestations:

K corresponds roughly to Westcott and Hort's Syrian Antiochian text; it was probably made by Lucian in the 4th century. This was the end of the most popular form of text, and is found in a more or less degenerate form in all MSS. The purest representatives are 61(0), 75 (V), 92, 461, 94, 1027 (S), 1126 (476 = scribner's k) e179 (661). Later recensions of K are called K* and K†, and there are several other minor recensions which represent the combination of K with other texts.

H represents Westcott and Hort's Neutral and Alexandrian text between which von Soden does not distinguish.

K and H are, in various recensions of purity: 41(B), 2 (e), 3 (C), 86 (W), 848 (33), 26 (Z), 56 (L), 76 (a) = 1026 (892), 8371 (1241) and 376 (579). Between these MSS. there is no very intimate connection except between 41 and 2 (B and e) which represents a good version of a 6th-7th century text. The best representative of H, but it has been contaminated by the Egyptian versions, and sometimes by the K and I texts and by Origen, though not to any great extent.

The other H MSS. are none of them equal in value to the two great uncials. They have all been influenced by K, I, and by the text of parallel passages, to a greater extent than 6th, or than either of the other MSS. to 6th, but some of them have less Egyptian corruption.

The origin of the H text must be regarded as unquestionably Egyptian, in view of the fact that it was used by all the Egyptian Church fathers after the end of the 3rd century, and von Soden adopts the well-known hypothesis, first made popular by Bousset, that it represents the recension of Hesychius.

I does not quite correspond to anything in Westcott and Hort’s system, but it has points of contact with their "Western" text. It is found in a series of subgroups of MSS. known as H, I, P, and others of less importance (about eleven subgroups are suggested). Of these the four books of Paul's Epistles Cod. 355, 254, 467, &c., e288 (22) and some allied MSS. e203 (572), e183 and e1131; J is the well-known Ferrar group; and P contains b 3 (D), 93 (565), e133 (700), e168 (39), e850 and some others. It is necessary to point out that von Soden is able to place D by a group because he regards it as one of its more remarkable readings to contamination with the Latin version. I is, according to von Soden, a Palestinian recension connected with Eusebius, Pamphilus and Origen.

After establishing the text of J, I, and K, von Soden reconstructs an hypothetical text, I-H-K, which he believes to have been their ancestor. He then tries to show that this text was used by the writers of the 3rd and 2nd centuries, and to explain for the fact that the quotations of these writers and the text of the early versions often diverge from it. He explains how, for instance, that the Diutiaion of Tatian was widely used and corrupted all extant texts, so that the Old Syriac, the Old Latin, the quotations of Irenaeus, Clement, Tertullian and others may be regarded as purely contemporaneous with the text used by the writers of the 3rd century. Finally, he tries to show how the Tatianic text is itself in the main merely a corrupt form of I-H-K altered in order to suit the necessities of Tatian's plan.

For the continuation of this important theory up to 1909 see Nestle's Einführung in das griechische neue Testament, pp. 274-278 (3rd ed., Göttingen, 1909), and K. Lake's Professor H. von Soden's Treatment of the Text of the Gospels, Edinburgh, 1908.

SÖDERHÄMN, a seaport of Sweden, in the district (län) of Gelleborg, on an inlet of the Gulf of Bothnia, near the mouth of the Ljusne River, 183 m. N. by W. of Stockholm by rail. Pop. (1900), 11,285. This is one of the principal centres of the timber export trade, having saw-mills, planing-mills and wood-pulp works. The river, which possesses navigable drawing 15 ft. has access to Branthäll, where they generally load. The harbour is at the suburb of Stugund. It is usually

ice-bound for some four months in winter. The town was given municipal privileges by Gustavus Adolphus in 1620, but is modern in appearance, having been rebuilt after fires in 1860 and 1865.

SODERINI, PIERO (1450-1514), Florentine statesman, was elected gonfalonier for life in 1502 by the Florentines, who wished to give greater stability to their republican institutions, which had been restored after the expulsion of Piero de' Medici and the martyrdom of Savonarola. His rule proved moderate and wise, although he had not the qualities of a great statesman. He introduced a system of national militia in the place of foreign mercenaries, and during his government the long war with Pisa was brought to a close with the capture of that city by the Florentines in 1509. Grateful to France, who had assisted him, he always took the French side in Italian politics. But in 1512 the Medici with the help of a Spanish army returned to Florence, deposed Soderini and drove him into exile. He took refuge at Ragusa in Dalmatia, where he remained until the election of Pope Leo X., who summoned him to Rome and conferred many favours on him. Soderini lived in Rome, working for the good of Florence, to which he was never allowed to return, until his death.

See Razzi, Vita di Pier Soderini (Padua, 1737), also the articles Florence and Medici in the Italian Encyclopaedia.

SÖDERTELE, a town of Sweden, in the district (län) of Stockholm, 23 m. W.S.W. of Stockholm by rail. Pop. (1900), 3,077. It is beautifully situated on a bay of Lake Mälar, which is here connected with the Baltic by the Södertele canal, 12 m. in length, with a minimum depth of 10 ft. This is on the route followed by the Göta Canal steamers between Stockholm and Gothenburg; it was opened in 1819, though a canal was begun here in the first half of the 15th century at the instigation of the patriot Engelbrecht. The town contains an ancient church, believed to date from c.1100. Here and in the neighbourhood are the residences of many of the business class of Stockholm; its hinterland is in fruit-growing and the manufacture of mineral waters, and is well supplied with springs and baths. There are engineering shops producing railway stock and motors, jute spinning and weaving mills, and match and joinery works.

SODIUM [symbol Na, from Lat. natrium; atomic weight 23-00 (0=16)], a chemical element belonging to the group of alkali metals. It is abundantly and widely diffused in nature, but always in combination. Sodium chloride, or common salt (q.v.), is exceedingly common, being the chief salt present in sea-water, besides occurring in extensive stratified deposits. Sodium carbonates are also widely dispersed in nature, forming constituents of many mineral waters, and occurring as principal saline components in natron or trona lakes, as efflorescences in Lower Egypt, Persia, and China, and as urao in Mexico, Colombia and Venezuela. The solid crusts found at the bottom of the salt lakes of the Araxes plain in Armenia contain about 16% of carbonate and 80 of sulphate. In Colombia there occurs a double salt, Na2CO3·CaCO3·5H2O, known as gay-lussite. In California, Nevada and Canada enormous deposits of carbonates, mixed in some cases with sulphate and with chloride, occur. About Szegedin in Hungary and all over the vast puszta (steppes) between the Thess and the Danube, sodium carbonate occurs in the Theselm and in the Duna and the Szamos. In the mountains of the Carpathians, the soil contains sodium carbonate, which frequently assumes the form of crude alkaline crusts, called "szekso," and of small saline ponds. A purified specimen of such Debreczin soda was found to contain as much as 90% of real carbonate, Na2CO3, and 4% of common salt. Natural sulphates occur in an anhydrous condition as thenardite, Na2SO4, at Tarapaca, Chile, and in the rock-salt deposits at Espartinas near Aranjuez, Spain. Hydrated sulphates occur at several localities in the province of Madrid and in other provinces of Spain, and at Mühlingen in Aargau, and copious deposits of glauberite, the double sulphate, of sodium and calcium, are met with in the salt-mines of Villarubia in Spain, at Stassfurt, and in the province of Tarapaca, Chile, &c. A native nitrate of soda is obtained in great abundance in the district of Atacama and the province of Tarapaca,
SODIUM

and is imported into Europe in enormous quantities as cubic nitre for the preparation of saltpetre. Cryolite, a fluohide of aluminium and sodium, is extensively mined in Greenland and elsewhere for industrial purposes. These form the principal natural sources of sodium compounds—the chloride as rock salt and in sea-water being of such predominating importance as to outweigh all the others. But it is questionable whether, taken altogether, the mass of sodium they represent is as much as that disseminated throughout the rocky crust in the form of soda felspar (i.e. as silicate of soda) and in other soda-containing rocks. From this source all soils contain small proportions of sodium in soluble form, hence the ashes of plants, although they preferably imbibe potassium salts, contain traces and sometimes notable quantities of sodium salts. Sodium salts also form essential ingredients in all animal juices.

Although many sodium compounds have been known from very remote times, the element was not isolated until 1807, when Sir H. Davy obtained it by electrolysis of caustic soda. This method was followed by that proposed by Gay-Lussac and Thénard, who decomposed molten caustic soda with red-hot iron; and this in turn was succeeded by Brunner's process of igniting sodium carbonate with charcoal. Deville made many improvements, but the method remained wasteful of material and uneconomical, and in 1872 the metal cost 48. a pound. In 1886, however, Castner replaced the carbonate by caustic soda, and materially cheapened the cost of production; but this method was discarded for an electrolytic one, patented by Castner in 1890. Electrolytic processes had, in fact, been considered since 1851, when Charles Watt patented his method for the production of sodium and potassium from fused chlorides. Among the difficulties here to be contended with are the destructive action of fused chlorides and of the reduced alkali metals upon most non-metallic substances available for the containing vessel and its partition, and also of the anode chlorine upon metal, when the low fused sodium (95° C. for sodium, and 62° C. for potassium) and the low specific gravity of the metals, so that the separated metal floats as a fused layer upon the top of the melted salt. Again, pure sodium chlorine melts at about 77° C., while sodium boils at 877° C., so that the margin of safety is but small if loss by vaporization is to be prevented. Borchers endeavoured to contend against the first difficulty by employing an iron cathode vessel and a chamotte (fire-clay) anode chamber united by a specially constructed water-cooled joint. The other difficulty is to some extent met by using mixed chlorides (e.g. sodium, potassium, and strontium chlorides for sodium extraction), as these melt at a lower temperature than the pure chloride. In Castner's process (as employed at Oldbury and Niagara Falls and in Germany) fused caustic soda is electrolysed. The apparatus described in the patent specification is an iron cylinder heated by gas rings below, with a narrower cylinder beneath, through which passes upwards a stout iron cathode rod cemented in place by caustic soda solidified in the narrower vessel. Iron anodes are suspended around the cathode, and between the two is a cylinder of iron gauze at the bottom with a sheet-iron continuation above, the latter being provided with a movable cover. Drums of electrolysed, oxygen-free molten sodium and chlorine at the anode and escapes from the outer vessel, while the sodium deposited in globules on the cathode floats upwards into the iron cylinder, within which it accumulates, and from which it may be removed at intervals by means of a perforated iron laddle, the fused salt, but not the metal, being able to pass freely through the perforations. The sodium is then cast into moulds. Sodium hydroxide has certain advantages compared with chloride, although it is more costly; its freezing-point is only 320° C., and no anode chlorine is produced, so that both containing vessel and anode may be of iron, and no porous partition is necessary.

Metallurgical sodium possesses a slivery lustre, but on exposure to moist air the surface is rapidly dulled by a layer of the hydroxide. It may be obtained crystallized in the quadratic system by melting in a sealed tube containing hydrogen, allowed to cool partially, and then pouring off the still liquid portion by inverting the tube. The specific gravity is 0.9735 at 13° (Baumbauer). At ordinary temperatures the metal has the consistency of wax and can be readily cut; on cooling it hardens. On heating it melts at 95-6° (Bunsen) to a liquid resembling mercury, and boils at 877-5° (Ruff and Johanssen, Ber., 1905, 38, p. 3601), yielding a vapour, colourless in thin layers but a peculiar purple, with a greenish fluorescence, when viewed through thick layers. (For the optics of sodium vapour see R. W. Wood, Physical Optics.) According to A. Matthiessen, sodium ranks fourth to silver, copper and gold as a conductor of electricity and heat, and according to Bunsen it is the most electropositive metal with the exception of caesium, rubidium and potassium. Its metal is very reactive chemically. Exposed to moist air it rapidly oxidizes to the hydroxide; and it burns on heating in air with a yellow flame, yielding the monoxide and dioxide. A fragment thrown on the surface of water rapidly disengages hydrogen, which gas, however, does not inflame, as happens with potassium; but inflammation occurs if hot water be used, or if the metal be dropped on moist filter paper. Sodium also combines directly, sometimes very energetically, with most non-metallic elements. It also combines with dry ammonia at 300-400° to form sodamide, NaNH₂, a white waxy mass when pure, which melts at 155°. Heated in a current of carbon dioxide the metal fuses and dissolves the gas, and with nitrogen it gives sodium azide; it decomposes with lead or silver nitrate and explodes with potassium chlorate. Sodamide was introduced by Claissen (Ber., 1905, 38, p. 693) as a condensing agent in organic chemistry, and has since been applied in many directions. Sodium is largely employed in the manufacture of cyanides and in reduction processes leading to the isolation of such elements as magnesium, silicon, boron, aluminium (formerly), &c.; it also finds application in organic chemistry. When potassium it forms a liquid alloy resembling mercury, which has been employed in high temperature thermometers (see Thermometry).

Compounds.

In its chemical combinations sodium is usually monovalent; its salts are generally soluble in water, the least soluble being the metatitanate.

Sodium hydride, NaH, is a crystalline substance obtained directly from sodium and hydrogen at about 400°. It burns when heated in dry air, and ignites in moist air; it is decomposed by water, giving caustic soda and hydrogen. Dry carbon dioxide is decomposed by it, free carbon being produced; moist carbon dioxide, on the other hand, gives sodium formate.

Several oxides are known. A suboxide, Na₂O, appears to be as a grey mass when a clean surface of the metal is exposed to the air, but pure air is passed through the metal just above its melting point (De Forcrand, Compt. rend., 1898, 127, pp. 364, 514). The monoxide, NaO, is obtained by heating the metal above 180°. Dioxide, Na₂O₂, is produced by mixing sodium and oxygen (Chem. Soc., 1894, i. 442); it may also be prepared by heating the nitrate or nitrite with metallic sodium, free nitrogen being eliminated (German patent, 124267, 1902). It forms a grey mass, solutions with alcohol. At a temperature of about 910° it yields a sodium salt and free oxygen to give the hydroxide. The hydroxide or caustic soda, NaOH, is usually manufactured from the carbonate or by electrolysis of salt solution (see Alkali Manufacture). When anhydrous it is a colourless opaque solid which melts at 310°, and decomposes at about 1100°. It is very soluble in water, yielding a strongly alkaline solution; it also dissolves in alcohol. It absorbs moisture and carbon dioxide from the air; it is soluble in a saturation of 7H₂O, from which 2NaOH·7H₂O is obtained as large monoclinic crystals by cooling a solution of specific gravity 1.365 to 8°; Pickering (Journ. Chem. Soc., 1893, 63, p. 590) obtained NaOH·H₂O from hot concentrated solution and NaOH·2H₂O from a solution of the hydroxide in 96.8% alcohol. (See also De Forcrand, Compt. rend., 1901, 133, p. 223.)

Sodium dioxide, Na₂O₃, is formed when the metal is heated in a stream of air or oxygen. In practice the metal is placed on aluminium trays traversing an iron tube heated to 300°, through which a current of air, freed from moisture and carbon dioxide, is passed. In the process the impure dioxide separates as large tabular hexagonal crystals, which, on drying over sulphuric acid give Na₂O₂·H₂O; the former is also obtained by precipitating a mixture of caustic soda and hydrogen peroxide solution and hydrogen peroxide solution and hydrogen peroxide; with carbon dioxide it gives sodium carbonate.
SODUM and GOMORRAH

Sodium is most distinctly recognized by the yellow coloration which volatile salts impart to a Bunsen flame, or, in the spectroscope, by its emission spectrum which has a line (double), the Fraunhofer D line, in the yellow (the wave-lengths are 5896 and 5890). The atomic weight of sodium is 22.987 (H = 1); T. W. Richards and R. C. Wells (Journ. Amer. Chem. Soc., 1905; 27, p. 459) obtained the value 23.006 (O = 16).

Medicine.

Pharmacology.—The metal sodium is not used in medicine, but many of its salts are employed. Besides liquor sodi ekahtylatis the following are important: (1) sodium chloride, NaCl (table-salt), is used in the treatment of water intoxication; it does not dissolve in cold water, but does not evolve oxygen unless heated to a high temperature. (2) Sodium bicarbonate, NaHCO₃, exists in two forms: one, Na-OH-CH₄CO₂, obtained by the action of hydrochloric acid on sodium carbonate; the other, O-Na-OH, from sodium carbonate and carbon dioxide. It is a strong oxidizing agent and yield alkaline solutions which readily evolve oxygen on heating. Sodium carbonate, Na₂O₃, is said to be used in the preparation of sodium chloride and in the treatment of sodium monium in liquid ammonia. Water decomposes it, giving oxygen and the bicarbonate.

Generally speaking, sodium salts closely resemble the corresponding potassium salts, and their methods of preparation are usually the same. For sodium salts not mentioned below reference should be made to articles wherein the acid is treated, unless otherwise noted.

Sodium combines directly with the halogens to form salts which are soluble in water and crystallize in the cubic system. The fluoride, NaF, is sparingly soluble in water (1 part in 25). For the chlorides, bromides, and iodides the salts are soluble in water, forming solutions in anhydrous cubes; from solutions at ordinary temperatures in monochloric prisms with 2H₂O; and at low temperatures with 5H₂O. According to M. Loeb (Journ. Amer. Chem. Soc., 1905, 27, 1121) the halides are absorbed by water, forming hydrated salt hydrates from solution in alcohols with "alcohol of crystallization." Sodium sulphide, Na₂S, obtained by saturating a caustic soda solution with sulphhydrated hydrogen and an additional equivalent of alkali, is slow in solution and acts as a source of sulphi:de. Sodium nitrite, NaNO₂, which is employed as an antichlor, is prepared by dissolving a sodium carbonate and crystallizing. The anhydrous salt may be prepared by heating a saturated solution of the hydrated salt. H. Hartley and W. H. Barrett (Journ. Chem. Soc., 1909, 95, p. 118) failed to obtain a decarboxylate which had been laid aside for 15 years, the latter salt was amorphous in nature. Sodium nitrite may be prepared by saturating a cold solution of the carbonate with sulphur dioxide and precipitating by alcohol, is employed for sterilizing beer casks. Sodium nitrate, NaNO₃, is used as a meteoric constituent of smoke. As sodium hydroxide, 10H₂O as Glauber's salt, is used in the manufacture of sodium carbonate or for a solution as a flux in the manufacture of porcelain, pottery, and glass. Sodium nitrate, 10H₂O is a form of silver nitrate, is sodium nitrate, 10H₂O, or as sodium carbonate and sodium bicarbonate, which is used in the manufacture of porcelain, pottery, and glass.

The manufacture of sodium carbonate, commonly called soda, is treated under Alkali Manufacture. The anhydrous salt is a colourless or porous mass, having an alkaline taste and reaction with acids, forming sodium salts, water, and carbonic acid, and hydrates formed. Common washing soda or soda crystals is the decarboxylate, Na₂CO₃·10H₂O, which appears as large clear monoclinic crystals on evaporation, it loses water and gives the monohydrate, Na₂CO₃·H₂O, a white powder sold as "crystal carbonate"; this substance, which is also formed on heating the decarboxylate to 34°, crystallizes in the rhombic system. Both these hydrates occur in the mineral kingdom, the former as natron and the latter as thermonatrite. The dehydrated, Na₂CO₃·7H₂O, is obtained by crystallizing a warm saturated solution in a vacuum; it appears to be dimorphous. The acid carbonate or bicarbonate of sodii, Na₂CO₃·10H₂O, is a valuable porcelain product in the manufacture. Another acid carbonate, Na₂CO₃·2NaHCO₃·3H₂O, is the mineral trona or urao. We may here notice the "percarbonates" obtained by Wolfenstein and Peltner (Ber., 1908, 41, pp. 275, 280) on acting with gaseous or solid carbon dioxide on Na₂O₃, Na₂O₄, or Na₂O₅ at low temperatures; the same authors obtained a perborate by adding sodium carbonate to a 50% solution of hypobromite, which is preparative to the preparation of copper.
Sea area; but no certain identification can be based on these similarities. The most striking coincidence is Jebel Usdum, by some equated with confidence to Sodom. The names are radically identical; but the hill is merely a salt-ridge 600 ft. high and 7 m. long, and cannot possibly represent an ancient city. The most that can be said is that the names have lingered in the Jordan valley in a vague tradition—very likely helped by, if not entirely due to, literary accounts of the catastrophe, just as has the name of Lot himself in the Arab name of the Dead Sea. The catastrophe has been explained as a volcanic eruption, or an explosive outburst of gas and oil stored and accumulating at high pressure. The latter, to which parallels in geologically similar regions in America is not, is the most probable natural explanation that can be offered. (R. A. S. M.)

SODOMA, IL (1477-1549), the name given to the Italian painter Giovanni Antonio Bazzi (who until recent years was erroneously named Razzì). He is said to have borne also the name of "Sodoma" as a family name, and likewise the name Tizzioni; Sodona is signed upon some of his pictures. While "Bazzi" was corrupted into "Razzì", "Sodona" may have been corrupted into "Sodoma"; Vasari, however, accounted for the name differently, as a nickname from his personal character. This version appears to have been inspired by Bazzi's pupil and subsequent rival Beccafumi. In R. H. Cust's recent work on the painter another suggestion is made. Vasari tells a story that, Bazzi's horse having won a race at Florence, a cry of "Who is the owner?" went up, and Bazzi contemptuously answered "Sodona," in order to insult the Florentines (Catastrophe of 1498). But, as well as the surnames of northern Italian friends, that the racing name was really a clipped form of So doma, "I am the trainer." Whatever the real origin, the name was long supposed to indicate an immoral character.

Bazzi was of the family de Bazzis, and was born at Vercelli in Lombardy in 1477. His first master was Martino Spantozzo, by whom one single picture is known; and he appears to have been in his native place a scholar of the painter Giovenone. Acquiring thus the strong colouring and other distinctive marks of the Lombard school, he was brought to Siena towards the close of the 15th century by some agents of the Spannocchi family; and, as the bulk of his professional life was passed in this Tuscan city, he counts as a member of the Sieneese school, although not strictly affiliated to it in point of style. He does not seem to have been a steady or laborious student in Siena, apart from some attention which he bestowed upon the sculptures of Jacopo della Quercia. Along with Pinturicchio, he was one of the first to establish there the matured style of the Cinquecento. His earliest works of repute are seventeen frescoes in the Benedictine monastery of Monte Oliveto, on the road from Siena to Rome, illustrating the life of St Benedict, in continuation of the series which Luca Signorelli had begun in 1498; Bazzi completed the set in 1502. Hence he was invited to Rome by the celebrated Sieneese merchant Agostino Chigi, and was employed by Pope Julius II. in the Camera della Segnatura in the Vatican. He executed two great compositions and various ornaments and grotesques. The latter are still extant; but the larger works did not satisfy the pope, who engaged Raphael to substitute his "Justice," "Poetry," and "Theology." In the Chigi Palace (now Farnesina) Bazzi painted some subjects from the Life of Alexander the Great; "Alexander in the Tent of Darius" and "The Nuptials of the Conqueror with Roxana" (both by signs, however, perhaps the work of Marituccio). When Leo X. was made pope (1513) Bazzi presented him with a picture of the "Death of Lucretia" (or of Cleopatra, according to some accounts); Leo gave him a large sum of money in recompense and created him a cavalier. Bazzi afterwards returned to Siena and at a later date went in quest of work to Pisa, Volterra, and Lucca. From Lucca he returned to Siena, not long before his death, which took place on the 14th of February 1549 (the older narratives say 1554). He had squandered his property and is said (rather dubiously) to have died in penury in the great hospital of Siena. Bazzi had married in youth a lady of good position, but the spouses disagreed and separated pretty soon afterwards. A daughter of theirs married Bartolommeo Neroni, named also Riccio Sanese or Maestro Riccio, one of Bazzi's principal pupils.

It is said that Bazzi jeered at the History of the Painters written by Vasari, and that Vasari consequently traduced him; certainly he gives a bad account of Bazzi's morals and demeanour, and is naturally more partial towards the art of his own time. Bazzi, in his time, made a remarkable medallion of a very sick Cardinal's face, owing to the strange miscellany of animals which he kept there. He was a crack of jokes and fond of music, and sang some poems composed in praise of some inconsiderable pictures. In his art he always alleged that Bazzi was an able master in expression, motion, and his taste was something like that of Da Vinci, especially in the figures of women, which have grace, sweetness and uncommon Earnestness. He is not eminent for drawing, grouping or elegance of his art: according to Vasari, his paintings are rare; there are two in the National Gallery in London.

It is uncertain whether Bazzi was a pupil of Leonardo da Vinci, though Morelli (in his Italian Pictures in German Galleries) speaks of a picture of "only about 8 by 10 ft." (1498-1500) he spent at Milan with Leonardo; and some critics see in Bazzi's "Madonna" in the Brera (if it is really by Bazzi) the direct influence of this master. Modern criticism follows Morelli and Alessandro Bazzi, that Bazzi studied the Schools of Athens; and a drawing at Christ Church is supposed to be a portrait of Raphael by Bazzi.

His most celebrated works are in Siena. In S. Domenico, in the chapel of St Catherine of Siena, are two frescoes painted in 1526, showing Catherine in ecstasy, and painting as she is about to receive the Eucharist from an angel—a beautiful and pathetic treatment. In the cathedral at Pisa is the "Deposition of the Christ" (1515); and "Christ Secured", by many critics one of the rarest of these paintings is regarded as Bazzi's masterpiece. In the choir of the cathedral at Pisa is the "Sacifice of Abraham," and in the Uffizi Gallery of Florence are "St Sebastian," seen for further details, Giovanni Antonio Bazzi, by Robert H. Hobart Cust (1906), which contains a full bibliography. (W. M. R.)

SODOR AND MAN, the name of the bishopric of the Church of England which includes the Isle of Man and adjacent islets. In 1154 the diocese of Sodor was formed to include the Hebrides and other islands west of Scotland (Norse Sdrur-eyjar, Sudreys, or southern isles, in distinction from Norðr-eyjar, the northern Isles of Orkney and Shetland) and the Isle of Man. It was in the archdiocese of Trondheim in Norway. (The con- vention of the Isle of Man to the diocese of Sodor continued, however, after the reformation.) A Norwegian diocese of Sodor had been in existence previously, but its history is obscure, and the first union of Man with it in 1098 by Magnus Barefoot is only traditional. The Norwegian connexion was broken in 1266, and in 1334 Man was detached from the Scottish isles. The cathedral of Sodor was on St Patrick's Isle at Peel (q.v.), and it is possible that the name Sodor being lost, its meaning was applied to the isle as the seat of the bishop. The termination "and Man" seems to have been added in the 17th century by a legal draughtsman ignorant of the proper application of the name of Sodor to the bishopric of Man. By the latter part of the 17th century the terms Sodor and Man had become interchangeable, the bishopric being spoken of as that of Sodor or Man. Till 1606 the bishops invariably signed themselves Soderensis; after that date and till 1684, sometimes Soderensii and sometimes "Sodor and Man," and after 1684 always "Sodor and Man." The see, while for some purposes in the archdiocese of York, it has its own convocation. The bishop sits in the House of Lords, but has no vote.

See A. W. Moore, History of the Isle of Man (London, 1900).
of Dortmund, on the main railway Cologne-Elberfeld-Berlin. Pop. (1905), 17,304. Its early importance is attested by its seven fine churches (six Protestant), of which the most striking are St Peter’s, the Wiesenkirche, a gem of Gothic architecture, Maria zur Höhe—St Mary-on-the-height—with beautiful mural frescoes, founded in 1314 and restored in 1850-1852, and the Roman Catholic cathedral, founded in the 10th century by Bruno, brother of Otto the Great (the present building was erected in the 12th century). This last, with its very original façade, is one of the noblest ecclesiastical monuments of Germany. Remains of the broad wall, now partly enclosing gardens and fields, and one of the gates remains; but the thirty-six strong towers which once defended the town have disappeared and the moats have been converted into promenades. The town-hall (1701) contains valuable archives, and among the numerous educational establishments must be mentioned the gymnasium, founded in 1534, through the instrumentality of Melanchthon, an evangelical teachers’ seminary, an agricultural school, and a blind asylum. Iron-working, the manufacture of soap, hats, sugar, cigars, bricks and tiles, linen-weaving, tanning and brewing, together with market-gardening and farming in the neighbourhood, and trade in cattle and grain are the leading industries.

Mentioned in documents as early as the 9th century, Soest was one of the largest and most important Hanseatic towns in the middle ages, with a population estimated at from 30,000 to 60,000. It was one of the chief emporiums on the early trading route between Westphalia and Lower Saxony. Its code of municipal laws (Schram; jus susaetense), dating from 1144 to 1165, was one of the earliest and best, and served as a model even to Lübeck. On the fall of Henry the Lion, duke of Saxony, Soest passed with the rest of Angria to Cologne. In the 15th century the strife between the towns—men and the archbishops broke out in open war, and in 1444 the strong fortifications of the town withstood a long siege by an army of 60,000 men. The women of Soest are said to have distinguished themselves in this contest (Soester Fehde). Papal intervention ended the strife, and Soest was permitted to remain under the protection of the dukes of Cleves. The prosperity of the town waned in more modern times: in 1763 its population was only 3,800; in 1815 it was 6,687.

See Vogeler, Soest, seine Altämer und Sehenswürdigkeiten (Soest, 1860); Hausberg, Die soester Fehde (Trier, 1882); Schmieden, Die Wandmalereien in der Kirche Maria zur Höhe im Soest (Soest, 1890); Aldendorf und Vogeler, Kunstdenkmäler des Kreises Soest (Soest, 1905).

SOFA, a long couch with stuffed back, arms and seat, to hold two or more persons. The word is of Arabic origin, and is an adaptation of suffah, couch, from root soff—a to draw up in line. According to Richardson, Dict. of Engl. Lang. quoted by Skeat, the Arabic suffah was particularly a reclining place of wood or stone placed before the doors of Oriental houses. In the history of furniture the sofa was a development of the straight backed settee. It was not so much therefore a long chair or combination of chairs, as a seat or couch for reclining. The early 19th-century type had a back with a single arm at one end, the other being left open. The most favoured modern form is that known as the Chesterfield, with double arms and back, heavily padded. (See also SETTEE.)

SOFALA, a Portuguese seaport on the east coast of Africa, at the mouth of a river of the same name, in 26° 12' S. Pop. (1900), about 1,000. The town possesses scarcely a trace of its former importance, and what trade it had was nearly all taken away by the establishment of Beira (q.v.) a little to the north in 1896. Sofala Harbour, once capable of holding a hundred large vessels, is sitting up and is obstructed by a bar. Ruins exist of the strong fort built by the Portuguese in the 16th century. Previous to its conquest by the Portuguese in 1595 Sofala was the chief town of a wealthy Mahommedan state, Arabs having established themselves there in the 12th century or earlier. At one time it formed part of the sultanate of Kilwa (q.v.). Sofala was visited by the Portuguese Jew, Pero de Covilhão, in 1450, who was attracted thither by the report of gold-mines of which Sofala was the port. The conquest of the town followed, the first governors of the Portuguese East African possessions being entitled Captains-General of Sofala. (See PORTUGUESE EAST AFRICA.) Thomé Lopes, who accompanied Vasco da Gama to India in 1502 and left a narrative of the voyage (first printed in Ramusio, Viaggi e Navigationi), identifies Sofala with Solomon’s Ophir and states that it was the home of the Queen of Sheba. This identification of Sofala with Ophir, to which Milton alludes (Par. Lest., xi. 390-401) is untenable.

A small island of Chiliano, with a good harbour, 40 m. S. of Sofala, has been named picture-Sofala (the township being named Chingune) as has also the island Santa Carolina, in the Bazaruto archipelago.

See Bull. Geogr. Soc. Mozambique (1882) for an account of the Sofala mines; and generally, Idrisif, Climate, i. § 8, O. Dapper, Description de l’Afrique (Amsterdam, 1866); T. Baines, The Gold Regions of South Africa (1877); G. McC. Theal’s Records of South Eastern Africa (1898-1903); Sir R. Burton’s notes to his edition of Camoes.

SOFFIONI (sometimes spelt Suffioni), a name applied in Italy to certain volcanic vents which emit jets of steam, generally associated with hydrogen sulphide and carbon dioxide, sometimes also with a little ammonia and marsh-gas. The soffioni are usually arranged in groups, and are best represented in the Maremma of Tuscany, where they contain a small proportion of boric acid, for which they are utilized industrially. For such natural steam-holes, the French geologists often use the term soufflards in place of the Italian suffioni.

SOFFIT (from Fr. sofite, Ital. soffita, a ceiling, formed as if from sufficitus for suffexus, Lat. suffigere, to fix underneath), a term in architecture given to the underside of any constructed feature; as for instance that of an arch or an architrave whether supported by piers or columns; also to the underside of a flight of stairs, and in the classic entablature to the underside of the projecting cornice.

SOFIA (Bulgarian Sredets, the middle town, a name now little used), the capital of Bulgaria, situated almost in the centre of an upland plain, about 1700 ft. above sea-level, between the Western Balkans on the N. and Mt Vitosh on the S. Pop. (1907) 83,167. Two small tributaries of the river Isker, the Perloveta and the Eleshnitsa or Boyana, flow respectively on the east and west sides of the town. Since 1880 the city has been almost entirely renovated in the "European" style; the narrow tortuous lanes and mean houses of the Turkish epoch have almost disappeared, and a new town with straight parallel streets has been constructed in the eastern suburb. The oldest building in Sofia is the little round chapel of St George in the Jewish quarter—originally, it is said, a Roman temple; then a church, then a mosque, and now a church once more. Of the principal mosques the large Buyuk Djamfa, with nine metal cupolas, has become the National Museum; the Tcherna Djamfa or Black Mosque, lately used as a prison, has been transformed into a handsome church; the Banyabaish Djamfa, with its long domed roof, is still used by Moslem worshippers. Close to the last-named in the centre of the town, are the public baths with hot springs (temperature 115° F.). In the cathedral or church of Sveti Kral (the Saint King), a modern building, are preserved the remains of the Servian king Stefan Urosh II. A large new cathedral dedicated to St Alexander Nevski was in course of construction in 1907; the foundation stone was taken from the church of St Sophia. The palace of the prince, occupying the site of the Turkish konak was built by Prince Alexander in 1850-1852; it has been greatly enlarged by King Ferdinand. In front of the palace is the public garden or Alexander Park. The theatre, the largest in south-eastern Europe, was completed in 1906. Other important buildings are the Sobranie, or parliament house, the palace of the synod, the ministries of war and commerce, the university with the national printing press, the national library, the officers’ club and several large military structures. A small
SOGDIANA—SOIL

mausoleum contains the remains of Prince Alexander; there are monuments to the tsar Alexander II., to Russia, to the medical officers who fell in the war of 1877 and to the patriot Levsky. A public park has been laid out in the eastern suburbs. The city is well drained and possesses a good water supply; it is lighted by electricity and has an electric car system. It contains breweries, tanneries, sugar, tobacco, cloth, and silk factories, and export skins, cloth, cocoons, cereals, attar of roses, dried fruit, &c. Sofia forms the centre of a railway system radiating to Constantinople (300 m.), Belgrade (206 m.) and central Europe, Varna, Rustichuk and the Danube, and Kiustendil near the Macedonian frontier. The climate is healthy; owing to the elevated situation it is somewhat cold, and is liable to sudden diurnal and seasonal changes; the temperature in January sometimes falls to -3° F. below zero and in August rises to 100°. The population, of which more than two-thirds are Bulgarians, and about one-sixth Spanish Jews, was 20,501 in 1881, 30,428 in 1888, 46,953 in 1893 and 82,187 in 1907.

History.—The colony of Serdica, founded here by the emperor Trajan, became a Roman provincial town of considerable importance in the 3rd and 4th centuries A.D., and was a favourite residence of Constantine the Great. Serdica was burnt by the Huns in A.D. 447; few traces remain of the Roman city, but more than one hundred types of its coins attest its importance.

The town was taken by the Bulgarians under Krum in A.D. 809; the name Serdica was converted into Sredets by the Slavs, with the junction of certain words, and Slavonic form subsequently became the Byzantine Triaditza. The name Sofia, which came into use towards the end of the 14th century is derived from the early medieval church of St Sophia, the massive ruins of which stand on an eminence to the east of the town. The church, which was converted into a mosque by the Turks, was partly destroyed by earthquakes in 1818 and 1858. The town successfully resisted the attacks of the emperor Basil II. in 987; between 1018 and 1186, under Byzantine rule, it served as a frontier fortress. During this period a number of prisoners of the Pecheneg tribes used as slaves became the ancestors of the modern Bulgarian population.

SOFISCHENBEUR (Sofischtzen, S. Pers. Soghdana), a province of the Achaemenian Empire, the eighteenth in the list in the Behistun inscription of Darius (i. 16), corresponding to the modern districts of Samarkand and Bokhara; it lay north of Bactriana between the Oxus and the Jaxartes, and embraced the fertile valley of the Zerashan (anc. Polytemus). Under the Greeks Sogdiana was united in one satrapy with Bactria, and subsequently it formed part of the Bactrian Greek kingdom till the Scythians (see SCYTHIA) occupied it in the middle of the 2nd century B.C. The valley of the Zerashan about Samarkand retained even in the middle ages the name of the Soghd of Samarkand. Arabic geographers reckon it as one of the four fairest districts in the world.

SOGNE FJORD, a great inlet of the west coast of Norway, penetrating the mainland to a distance of 136 m. It is the longest fjord in Norway, and the deepest, approaching 700 fathoms in some parts. Sognestaf est its entrance is 50 m. by water from Bergen; in sq. N. The general direction from the sea is easterly. For the first 50 m. the fjord, flanking mountains are unbroken by any considerable branch, but from this point several deep, narrow inlets ramify, penetrating the Jostedalsbrae and Jotunfeld to the north and the north-west extension of the Hardangerfjord to the south, walled in at their heads by snow-clad mountains and frequented by travellers on account of the magnificent scenery. The principal are Fjærlands, Sognsdals and Lyster fjords to the north, Aardals fjord to the east, Lærdals and Aurlands fjords to the south. From the last branches the Naeró fjord, with a precipitous wall of rock, serves as an entrance to the fjord, traversed by a road, from Gudvangen on the fjord, across the Stokelby Pass to Vossevangen. The other principal villages are Vadsheim on the outer fjord, the terminus of the road from Nordfjord; Balholm and Fjaerland (centres for visiting the fine glaciers of Jostedal); Lekanger, Sogndal, and Lærdalsören, where a road strikes south-east for the Valders and Hallingdal districts.

SOHAM, a town in the Newmarket parliamentary division of Cambridgeshire, England, 5 m. S.E. of Ely by a branch of the Great Eastern railway. Pop. (1901), 4350. It lies in the midst of the flat fen country. To the west a rich tract, still known as Soham Moor, marshy at the time of the moorlands, and wide and shallow sheets of water in the district now drained. The church of St Andrew is cruciform and had formerly a central tower; the existing western tower is of fine and ornate Perpendicular work. The body of the church, however, is mainly transitional Norman with additions principally Decorated, including a beautiful east window, much ancient woodwork, and other details of interest. The grammar school dates from 1687. The road from Soham to Ely was constructed as a causeway across the fens by Hervey le Breton, first bishop of Ely (1199-1131). This trade of the trade of the town in agricultural, fruit-growing and market-gardening being largely carried on in the vicinity.

SOIGNIES (or SOIGNES, the Walloon form), a busy and flourishing town of the province of Hainaut, owing its prosperity to the important blue granite quarries in the neighbourhood. It contains a fine abbey church of the 12th century and in the cemetery connected with it are many tomstones of the 13th and 14th centuries. Pop. (1904), 16,480.

The forest of Soignies extended in the middle ages over the southern part of Brabant up to the walls of Brussels, and is immortalized in Byron's Childe Harold. Originally it was part of the Ardennes forest, and even at the time of the French Revolution it was very extensive. The first blow towards its gradual contraction was struck when Napoleon ordered 22,000 oaks to be cut down in it to build the celebrated Boulogne flotilla for the invasion of England. King William I. of the Netherlands continued the process in the belief that he was thus adding to the prosperity of the country, and from 29,000 acres in 1820 the forest was reduced to 11,200 in 1830. A considerable portion of the forest in the neighbourhood of Waterloo was assigned in 1815 to the duke of Wellington, and to the holder of the title as long as it endured. This portion of the forest was only converted into farms in the time of the second duke. The Bois de la Cambre (456 acres) on the outskirts of Brussels was formed out of the forest, and beyond it stretches the Forêt de Soignies, still so called, to Tervueren, Groenendael, and Argenteuil close to Mont Saint Jean and Waterloo.

SOIL, the term generally applied to that part of the earth's surface which is worked by man and contains the humus derived from vegetable remains.
The soil is unsatisfactory, rubble the the abundance of soluble materials is usually greater in the subsoil than in the surface, and roots descending into it may absorb and convey these poisonous substances to other parts of the plant or be themselves damaged by contact with them. On this account deeper tillage than usual, which allows of easier penetration of roots, or the carrying out of operations which bring the subsoil to the surface, must always be carefully considered.

At first sight few natural materials appear to be of less interest than the soil; yet its importance is manifest on the slightest reflection. From it, directly or indirectly, are obtained all food materials needed by man and beast. The inorganic materials within it supply some of the chief substances utilized by plants for their development and growth, and from plants animals obtain much of their sustenance.

Origin of the Soil.—It is a matter of common observation that stones of monuments, walls or buildings which are exposed to the air sooner or later become eaten away or broken up into small fragments under the influence of the weather. This disintegration is brought about chiefly by changes in temperature, and by the action of the rain, the oxygen, and the carbon dioxide of the air. During the daytime the surface of the stone may become very warm, while at night it is speedily cooled. Such alterations in temperature produce strains which frequently result in the chipping off of small fragments of the material composing the stone. Moreover the rain penetrates into the small interstices between its particles and dissolves out some of the materials which bind the whole into a solid stone, the surface then becoming a loose powdery mass which falls to the ground below or is carried away by the wind. The action of frost is also very destructive to many stones, since the water within their cracks and cervices expands on freezing and splits off small pieces from their surfaces. In the case of lime-stones the carbon dioxide of the air in association with rain and dew eats into them and leads to their disintegration. The oxygen of the air may also bring about chemical changes which result in the production of soluble substances removable by rain, the insoluble parts being left in a loosened state.

These “weathering” agents not only act upon stones of buildings, but upon rocks of all kinds, reducing them sooner or later into a more or less fine powder. The work has been going on for ages, and the finely comminuted particles of rocks form the main bulk of the soil which covers much of the earth's surface, the rest of the soil being composed chiefly of the remains of roots and other parts of plants.

If the whole of the soil in the British Islands were swept into the sea and the rocks beneath it laid bare the surface of the country would ultimately become covered again with soil produced from the rocks by the weathering processes just described. Moreover where there was no transport or solution of the soil thus produced it would necessarily show some similarity in composition to the rock on which it rested. The soils overlying red sandstone rocks would be reddish and of a sandy nature, while those overlying chalk would be whitish and contain carbonates of lime. Soils overlying sandstones and siltstones exhibit such relationships, and known as sedentary soils, are prevalent, the transition from the soil to the rock beneath being plainly visible in sections exposed to view in railway cuttings, quarries and other excavations. The upper layer or soil proper consists of material which has been subjected to ages of weathering; the bulk of it is composed of finely comminuted particles of sand, clay and other minerals, among which are imbedded larger or smaller stones of more refractory nature. On descending into the substratum the finer material decreases and more stones are met with; farther down are seen larger fragments of unaltered rock closely packed, and this brash or rubble grades insensibly into the unbroken rock below.

In many districts the soil is manifestly unconnected in origin with the rock on which it rests, and differs from it in colour, composition and other characters. There are transported or drift soils, the particles of which have been brought from other areas and deposited over the rocks below. Some of the stiff boulder clays or “till” so prevalent over parts of the north of England appear to have been deposited from ice sheets during the glacial period. Perhaps the majority of drift soils, however, have been moved to their present position by the action of the water of rivers or the sea.

As fast as the rock of a cliff is weathered its fragments are washed to the ground by the rain, and carried down the slopes by small streams, ultimately finding their way into a river along which they are carried until the force of the water is insufficient to keep them in suspension, when they become deposited in the river bed or along its banks. Such river-transported material or alluvium is common in all river valleys. It is often of very mixed origin, being derived from the detritus of many kinds of rocks, and usually forms soil of a fertile character.

Quality of Soil.—The good or bad qualities of a soil have reference to the needs of the crops which are to be grown upon it, and it is only after a consideration of the requirements of plants that a clear conception can be formed of what characters the soil must possess for it to be a suitable medium on which healthy crops can be raised.

In the first place, soil, to be of any use, must be sufficiently loose and porous to allow the roots of plants to grow and extend freely. It may be so compact that root development is checked or stopped altogether, in which case the plant suffers. On the other hand it should not be too open in texture or the roots do not get a proper hold of the ground and are easily disturbed by wind: moreover such soils are liable to blow away, leaving the underground parts exposed to the air and drought.

The roots like all other parts of plants contain protoplasm or living material, which cannot carry on its functions unless it is supplied with an adequate amount of oxygen: hence the necessity for the continuous circulation of fresh air through the soil. If the latter is too compact or has its interstices filled with carbon dioxide gas or with water—as is the case when the ground is water-logged—the roots rapidly die of suffocation just as would an animal under the same conditions. There is another point which requires attention. Plants need very considerable amounts of water for their nutrition and growth; the water-holding capacity is, therefore, important. If the soil holds too much it becomes water-logged and its temperature falls below the point for healthy growth, at any rate of the kinds of plants usually cultivated on farms and in gardens. If it allows of too free drainage drought sets in and the plants, not getting enough water for their needs, become stunted in size. Too much water is bad, and too-little is equally injurious.

In addition, the temperature of the soil largely controls the yield of crops which can be obtained from the land. Soil whose temperature remains low, whether from its northerly aspect or from its extreme proximity to water, is less satisfactory, because the germination of seeds and the general life processes of plants cannot go on satisfactorily except at certain temperatures well above freezing-point.

A good soil should be deep to allow of extensive root development and, in the case of arable soils, easy to work with implements. Even when all the conditions above mentioned in regard to texture, water-holding capacity, aeration and temperature are suitably fulfilled the soil may still be barren; plant food-material is needed. This is usually present in abundance although it may not be available to the plant under certain
The pore-space within the soil, i.e. the space between the particles composing the soil, varies with the size of these particles and with the way they are arranged or packed. It is important, since upon it largely depends the movement of air and water in the land. The pores generally from 30 to 50% of the total volume occupied by the soil.

Where the soil grains are quite free from each other the smaller grains tend to fill up the spaces between larger ones; hence it might be concluded that in clays the pores of potters mud would be less than in coarser sands. This is the case in "puddled" clays, but in ordinary clay soils the excessively minute particles of which these clays consist tend to form independent comparatively large composite grains and it is in such natural soils that the pore-space is largest.

Chemical Composition of the Soil.—It has been found by experiment that the soil needs for its nutritive process and their growth, certain chemical elements, namely, carbon, hydrogen, oxygen, nitrogen, sulphur, phosphorus, potassium, magnesium, calcium and iron. With the exception of the carbon and a small proportion of the oxygen and nitrogen, which may be partially derived from the air, these elements are taken from the soil by crops. The following table shows the amounts of the chief constituents removed by certain crops in lb per acre:

<table>
<thead>
<tr>
<th>Crop</th>
<th>Nitrogen</th>
<th>Phosphoric Acid</th>
<th>Potash</th>
<th>Lime</th>
<th>Magnesia</th>
</tr>
</thead>
<tbody>
<tr>
<td>Wheat</td>
<td>50</td>
<td>21</td>
<td>29</td>
<td>9</td>
<td>7</td>
</tr>
<tr>
<td>Meadow hay</td>
<td>49</td>
<td>12</td>
<td>51</td>
<td>34</td>
<td>3</td>
</tr>
<tr>
<td>Mangel</td>
<td>149</td>
<td>53</td>
<td>300</td>
<td>43</td>
<td>42</td>
</tr>
</tbody>
</table>

Plants also remove from the soil silicon, sodium, chlorine, and other elements which are, nevertheless, found to be unessential for the growth and may therefore be neglected here.

Leguminous crops take some of the nitrogen which they require from the air, but most plants obtain it from the nitrates present in the soil. The sulphur exists in the soil chiefly in the form of sulphates of magnesium, calcium and other metals; the phosphorus mainly as phosphates of calcium, magnesium and iron; the potash, soda, and lime are mostly carbonates and nitrate, and magnesiu carbonate are also common constituents of many soils.

In the ordinary chemical analyses of the soil determinations are made of the nitrogen and various carbonates present as well as of the amount of phosphoric acid, potash, soda, magnesia and other compounds soluble in strong hydrochloric acid.

Below are given examples of the analyses of a poor sandy soil and an ordinary loam:

<table>
<thead>
<tr>
<th>Nitrogen</th>
<th>Phosphoric Acid</th>
<th>Potash</th>
<th>Carbonate of Lime</th>
</tr>
</thead>
<tbody>
<tr>
<td>19 %</td>
<td>18 %</td>
<td>19 %</td>
<td>23 %</td>
</tr>
</tbody>
</table>

Since the dry weight of the first foot of soil over an acre is about 4,000,000 lb the poor sandy soil contains within it:

<table>
<thead>
<tr>
<th>Nitrogen</th>
<th>Phosphoric Acid</th>
<th>Potash</th>
<th>Lime</th>
</tr>
</thead>
<tbody>
<tr>
<td>7,600</td>
<td>7,200</td>
<td>7,600</td>
<td>9,200</td>
</tr>
</tbody>
</table>

From the figures given previously of the amount of nitrogen, potash and phosphoric acid removed by a wheat or mangel crop it would appear that this soil has enough of these ingredients in it to yield many such crops; yet experience has shown that these crops cannot be grown on such a poor sandy soil unless manures containing nitrogen, potash and phosphoric acid are applied.

Many attempts have been made to correlate the results of the analyses of a soil with its known cropping power, but there is yet much to be learnt in regard to these matters. A great proportion of the food constituents which can be extracted by strong hydrochloric acid are not in a condition to be taken up by the roots of plants; they are present, but in a "dormant" state, although by tillage and weathering processes they may in time become "available". Many of these salts of various metals have been used to indicate the permanent productive capacity of the soil rather than its immediate power of growing a crop.

In all of these the need of potash fertilizers is endorsed.
SOIL

compounds. Similarly soils with less than 1% of nitrogen are likely to require application of this material. Too much stress, however, cannot be laid upon these figures, since the fertility of a soil is very greatly influenced by texture and physical constitution, perhaps more so by these factors than by chemical content.

At present it is not possible to determine with accuracy the amount of immediately available plant food-constituents in a soil; no doubt the various species of plants differ somewhat in their preferences, even towards the same soil. This problem is introduced by Dyer of dissolving out the mineral constituents of the soil with a 1% solution of citric acid, which represents about the amount of citric acid that would be removed by normal manuring or by crop rotation. In case of arable soils, where the amount of phosphoric acid determined by this method falls below 0.1% phosphoric manuring is essential for good crops. The writer has found that it is much better to make use of manuring materials available freely to applications of phosphates; probably in such cases even the weak acid is capable of dissolving out phosphates from the humus or other compounds which yield little or none to the roots of grasses and clovers. In soils where the potash available to citric acid is less than 0.05%, kainite and other potash fertilizers are needed.

Water in the Soil.—The importance of an adequate supply of water to the growing crops cannot be over-estimated. During the life of a plant there is a continuous stream of water passing through it which enters by the root-hairs in the soil and after passing along the stem is given off from the stomata of the leaves into the open air. This stream is supplemented to a large extent by water which the plants will absorb from the land and transpire from its leaves more than ten tons of water per day when the weather is fine.

In addition to its usefulness in maintaining a turgid state of the young fruiting growth, water, in a degree, acts as a plant-food material and as absorbed from the soil contains dissolved in it all the mineral food constituents needed by plants for nutrition. The amount of mineral matter in the soil at any time is equal to the crop yield is seriously reduced, as we see in dry seasons when the rainfall is much below the average. If one condition is more necessary than another for good crops it is a supply of water, for no amount of manuring or other treatment of the soil will make up for a deficient rainfall. The amount needed for the most satisfactory nutrition varies with different plants. In the case of fair average farm crops it has been shown that for the production of an acre of corn the water containing in them from 500 to 600 tons of water has been absorbed and utilized by the plants. This may be more than the rainfall, in which case irrigation or special control of the water supply will be necessary.

The water-holding capacity of a soil depends upon the amount of free space between the particles of which it is composed into which water can enter. In moist cases this amounts to from 30 to 50% of the volume of the soil.

When the pore-space of the soil is filled with water it becomes water-logged and few plants can effect absorption by their roots under such conditions. The root-hairs, which are the first to suffer from water deficiency, recover after a week’s submergence, but orchards and many trees do not recover after a long time, and such plants suffer still more when water is present in such a manner that it is not easily available to the plants. The soil water holding capacity is not more than 60% to 70% of what would saturate it. Under such conditions each particle of soil is surrounded by a thin film of water, the absorbed portion is filled up by capillary action, and such films that the root-hairs absorb all that plants require for their growth. The movement of water into the root-hairs is brought about by the osmotic action of certain salts in their cell-sap. Crops, however, unable to absorb all the water present in the soil, for when the films become very thin they are held more firmly or cling with more force to the soil particles and resist the osmotic action of the root-hairs. Plants have been found to wither and die in sandy soils containing 14% of water, and in clay soils in which there was still present 8% of water.

When a long glass tube open at both ends is filled with soil and contains a capillary. When the water falls upon the top of the tube the water will move upwards through the soil column just as oil will rise in an ordinary lamp wick. By this capillary action water may be transferred to the upper layers of the soil a depth of several feet below the surface. An organism, however, does not like to breathe in air, and if it will rise is comparatively small. In clays whose particles are exceedingly minute the water travels very slowly but may ultimately reach a height of many feet above the level of the water-table by means of these first movements. It is of great importance in supplying the needs of plants it has its disadvantages, since water may be transferred to the surface of the soil, where it evaporates into the air and is lost to the land or the crop growing upon it.

One of the most effective means of conserving soil moisture is by "mulching," i.e. by placing on the ground some loosely compacted material such as straw, leaf-refuse or stable-manure. The space between the parts of such substances is too large to admit of capillary action; hence the water conveyed to the surface of the land is not readily absorbed by the roots, or stirred to a depth of one or two inches with harrow or other implements. The hoe and harrow are therefore excellent tools, for use in dry weather. Rolling the land is beneficial to young crops and the fruits of capillary action, since it is simply a cover of straw or of the mulch used in the soil spaces. It should, however, be followed by a light hoeing or harrowing.

In the semi-arid regions of the United States, Argentina and other countries where the average annual rainfall lies between 10 to 20 in., irrigation is necessary to obtain full crops every year. Good crops, however, can often be grown in such areas without irrigation. Only a little of the proper circulation of water in the soil and means for retaining it or preventing excessive loss by evaporation. Of course care must be exercised in the selection of plants—such as sorghum, maize, wheat, and alfalfa or lucerne—where water is scarce.

So far as the water supply is concerned—and this is what ultimately determines the yield of crops—the rain which falls upon the surface of the soil should be made to enter it and percolate rapidly through the soil to the root zone, a process which can be made more effective by the use of a mulch, preferably straw, hay or other material used for animal feeding and this should consist of fine particles which lie close to each other without any tendency to stick together and "puddle" after heavy rains. Without such a mulch it is almost impossible to make a good, neat, firm, by suitable ploughing, harrowing and consolidation.

In the operation of ploughing the furrow slice is separated from the soil below, and although in humid soils this layer may be left to settle by degrees, in semi-arid regions this loosened layer becomes dry if left alone even for a few hours and valuable water evaporates into the air. To prevent this various implements, such as disk harrows and specially constructed rollers, may be used to consolidate the upper stratum of the soil and to make it more similar in appearance and relationship with the lower unmoved layer. If the soil is allowed to become dry and pulverized, rain is likely to run off or "puddle" the surface without penetrating it more than a very short distance in. Constant hoeing or harrowing to maintain a natural soil mulch layer of 2 or 3 in. deep greatly conserves the soil water below. In certain districts where the rainfall is low a crop can only be obtained once in many years, it is then necessary to tillage with a view of getting the rain into the soil and retaining it there for the crop in the following year.

Bacteria in the Soil.—Recent science has made much progress in the determination of the bacterial population of soils. At present the soil used to be looked upon solely as a dead, inert material containing certain chemical substances which serve as food constituents for all higher plants, whereas it is now known that certain bacteria are responsible for myriads of minute living organisms upon whose activity much of its fertility depends. They are responsible for many important chemical processes which make the soil constituents more available to the higher plants, and which have been regarded as the secret of decomposition of organic matter. A little of the nitrogen of soil taken within a foot or so from the surface contains from 1 to 2 millions of bacteria of many different kinds, as well as large numbers of fungi. In the lower depths of the soil the numbers decrease, few being met with at a depth of 5 or 6 ft.

The efficiency of many substances, such as farm-yard manure, guano, bone-meal and all other organic materials, which are spread over the farm field, to be used for the benefit of farm and garden crops, is bound up with the action of these minute living beings. Without their aid most manures would be useless for plant growth. Farm-yard manure, guano and other fertilizers are primarily fertilizer in the way they supply the plants with those compounds of simple chemical composition better suited for absorption by the roots of crops, the changes involved being directly due to the activity of bacteria and fungi. Much of the work carried on by these soil organisms is still not understood, nor do we know what important processes which have been extensively investigated and of which it is necessary to refer to it.

It has been found by experiment that the nitrogen needed by plants is generally in the form of nitrate, except leguminous ones is best supplied in the form of a nitrate; the rapid effect of nitrate of soda when used as a top dressing to wheat or other plants is well known to farmers. It is the same with the application of dung and urine of animals, or even the bodies of animals and plants, are applied to the soil, the nitrogen within them becomes oxidized, and ultimately appears in the form of nitric oxide, nitrate or some other nitrate. The nitrogen from the dead stems and leaves of plants, and in humus generally is sooner or later changed into a nitrate, the change being effected by bacteria. That
the action of living organisms is the cause of the production of nitrates is supported by the fact that the change does not occur when the soil is heated nor when it is treated with disinfectants which have been shown to inhibit the growth of bacteria. The results in the formation of nitrates in the soil is spoken of as nitrification.

The steps in the breakdown of the highly complex nitrogenous proteins found in the humus of the soil, or applied to the latter by the farmer in the form of dung and organic refuse generally, are many and varied; most frequently the insoluble proteins are hydrolyzed and converted into amino acids and soluble proteins (peptides, etc.), these into simpler amide-bodies, and these again sooner or later into compounds of ammonia. The urea in urine is also rapidly converted by the urea-bacteria into ammonia. Furthermore, the complex compounds of nitrogenous matter formed from the complex substances by many varied kinds of micro-organisms are ultimately oxidized into nitrates. The change takes place in two stages and is effected by two special groups of nitrifying bacteria, the Nitrosomonas, or nitrite-oxidizing, and the Nitrobacter, or nitrate-oxidizing bacteria, which, as shown before, are most abundant in the soil during the summer, when the temperature is about 24° C. (75° F.), nitrification proceeds at a rapid rate. The organisms do not carry on their work in soils deficient in air; hence the process is checked in those portions of the soil which remain unoxidized. The presence of ammonia (or their carbonates) is also essential, as well as an adequate degree of moisture; in dry soils nitrification ceases.

Most soil microbiologists are agreed as to the function of the bacteria in promoting the activity of these organisms by good tillage, careful drainage and occasional application of lime to soils which are deficient in this substance. It is only when these conditions are attended to that denitrification of dung, guano, fish-manure, sulfuric acid and other manures take place, and the constituents which they contain become available to the crops whose benefit they have been applied to the land.

Nitrates, when left in water and are therefore liable to be washed out of the soil by heavy rain. They are, however, very readily absorbed by growing plants, so that when, in summer, nitrates are most active, the nitrates present are usually made use of by crops before they can take place. In winter, however, and in fallow loss takes place in the subsoil water.

There is also another possible source of loss of nitrates through the activity of denitrifying bacteria. These organisms reduce nitrates to nitrites and finally to ammonia and gaseous free nitrogen which escapes into the atmosphere. Many bacteria are known which are capable of denitrification, some of them being abundant in fresh dung and in manure straw. They can, however, only in summer, and not in winter. Nitrates are very soluble in water and are therefore liable to be washed out of the soil by heavy rain. They are, however, very readily absorbed by growing plants, so that when, in summer, nitrates are most active, the nitrates present are usually made use of by crops before they can take place. In winter, however, and in fallow loss takes place in the subsoil water.

An important group of soil organisms are now known which have the ability to fix atmospheric nitrogen into nitrates for the formation of the complex nitrogenous compounds of which their bodies are largely composed. By their continued action the soil becomes enriched with nitrates and other nutritive substances; eventually, nitrifying bacteria become available to ordinary green crops. This power of 'fixing nitrogen,' as it is termed, is apparently not possessed by higher green plants. The bacterium, *Clostridium pasteurianum*, common in most soils, is able to utilize free nitrogen under anaerobic conditions, and an organism known as *Azotobacter chroococcum* and some others closely allied to it, have similar powers which they can exercise under aerobic conditions. For the carrying on of these processes it is not only necessary that the air be supplied with carbohydrates or other carbon compounds which they obtain ordinarily from plants and from the soil, but in some instances from carbohydrates manufactured in the earth, that the carbon dioxide is available to these micro-organisms. Certain bacteria of the nitrogen-fixing class enter into association with the roots of green plants, the best-known examples being those which are met with in the nodules of clover, beans, sainfoin and other plants belonging to the leguminous order.

That the fertility of land used for the growth of wheat is improved by growing upon it a crop of beans or clover has been long recognized by many agriculturists, which has been the subject of these investigations. When wheat, barley, turnips and similar plants are grown, the soil upon which they are cultivated becomes depleted of nitrates and the crop of the following leguminous plant will be the soil is found to be richer in nitrogen than it was before the crop was grown. This is due to the nitrogenous root residues left in the land. Upon the roots of leguminous plants characteristic swollen nodules are present, in which the bacteria lodged. These bacteria are of a number of bacteria termed *Bacillus radicicola* or *Pseudomonas radicicola*. The bacteria, which are present in almost all soils, enter the root-hairs of their host plants and stimulate the production of an excreta of nodules, in which they live. For a time after entry they multiply, obtaining the nitrogen necessary for their nutrition and growth from the free nitrogen of the air, the carbon dioxide being used by the pea or clover plant in whose tissues they make a home. The nodules increase in size, and analysis shows that they are exceedingly rich in nitrogen up to the time of flowering of the host plant. During this period the bacteria produce large amounts of nitrogen, which is largely used by the plant, and finally becomes digested and transformed into soluble nitrogenous compounds which are conducted to the developing roots and seeds. After the decay of the roots some of the unchanged bacteria are left in the soil where the remain ready to infect a new leguminous plant.

The nitrogen-fixing nodule bacteria can be cultivated on artificial media, and many attempts have been made to utilize them for practical purposes. Pure cultures may be made and after dilution in water they can be mixed in the composts and guano or manure spread over the land which is to be infected. The method of using them most frequently adopted consists in applying them to the seeds of leguminous plants before sowing, the soil being damped for a time in a liquid containing the bacteria. In this manner organisms obtained from red clover can be grown and applied to the seed of red clover; and similar inoculation can be arranged for other species, so that an application of the bacteria most suited to the particular crop to be cultivated can be assured. In many cases it has been found that inoculation, whether of the soil or of the seed, has not made any appreciable difference to the growth of the crop, a result which is most likely to be due to the fact that it is an abundant supply of suitable organisms. But in other instances greatly increased yields have been obtained where inoculation has made a material difference. Many of the pure cultures of the nitrogen-fixing bacteria belonging to the *Azotobacter chroococcum* genus are already recommended for application to poor land in order to provide a cheap supply of nitrogen. The application of pure cultures of bacteria for improving the fertility of the land is still in an experimental stage. There is little doubt, however, that in the near future the methods will be devised to obtain the most efficient work from these minute organisms, either by special artificial cultivation and subsequent application to the soil, or by improved methods of encouraging their healthy growth and activity in the land where they already exist.

**Improvement of Soils**—The fertility of a soil is dependent upon a number of factors, some of which, such as the addition of fertilizers or manures, increase the stock of available food materials in the soil (see MANURE), while others, such as application of clay or humus, chiefly influence the fertility of the land by improving its physical texture.

The chief processes for the improvement of soils which may be discussed here are: liming, claying and marling, warping, paring and burning, and green manuring. Most of these more or less directly improve the land by adding to it certain plant food constituents, or by improving methods of encouraging the healthy growth and activity of the bacteria and other microorganisms. The process is in reality very complex. In the majority of cases the good results obtained are more particularly due to the setting free of "dormant" or "latent" food constituents and to the amelioration of the texture of the soil, so that its aeration, drainage, temperature and water-holding capacity are altered for the better.

The material which chemists call calcium carbonate is met with in a comparatively pure state in chalk. It is present in variable amounts in limestones of all kinds, although its white- ness is not due to it, but rather to the presence of certain other white materials and other coloured substances. Carboante of lime is also a constituent to a greater or lesser extent in almost all soils. In certain soils and in a few still clays it may amount to less than 1%, while in others in lime land it may be as high as 80%. Pure carbonate of lime when heated loses 44% of its weight, the decrease being due to the loss of carbon dioxide gas. The resulting white product is termed calcium oxide lime, burnt lime, quicklime, or lime. This substance absorbs and combines with water very readily, at the same time becoming very hot, and falling into a fine dry powder, calcium hydroxide or slaked lime. The chief advantage of calcium carbonate is that it neutralizes the carbon dioxide of the air and becomes calcium carbonate, from which we began.

Lime, whatever form it is applied has a many-sided influence in the fertility of the land. It tends to improve the tilth and the
capillarity of the soil by binding sands together somewhat and by opening up clays. If applied in too great an amount to light soils and peat land it may do much damage by rendering them too loose and open. The addition of small quantities of lime, especially in small light lands, is sometimes found to be useful in making them more firm and pliable. A lump of clay, which if dried would become hard and intractable, crumbles into pieces when dried after applying to it ¾ of lime. This is caused by the size of the particles of clay being smaller from the repeated application of lime. A pernicious practice, especially on land which contains little humus to begin with. The more or less dormant nitrogen and other constants are being returned to the humus in the form of humus and lime immediately available to the succeeding crop, but the capital of the soil is rapidly reduced, and unless the loss is replaced by the addition of more manures the land may become sterile. Although good crops may be obtained from the application of lime, the latter is no direct fertilizer or manure and is not a substitute for such. Its best use is obtained on land in good condition, but not where the soil is poor. When used on light dry land it tends to make the land drier, since the lime causes the water to be held up in the soil. Lime is a base and neutralizes the acid materials present in badly drained meadows and boggy pastures. Weeds, therefore, which need sour conditions for their growth, are checkered out, and clover and vetches are encouraged. It also sets free potash and possibly other useful plant food-constituents of the soil. Liming tends to produce earlier crops and destroys the fungi which causes finger-and-toe or club-root among turnips and cabbages.

Land which contains less than about ¾ of lime usually needs the addition of this material. The particular form in which lime should be applied for the best results depends upon the nature of the soil. In practice the proximity to chalk pits or lime kilns, the cost of the lime and cartage, will determine which is most economical. Generally speaking, light sandy lands deficient in organic matter will need the less caustic form or chalk, while quicklime will be most satisfactory on the stiff clays and richer soils. On the stiff soils overlying the chalk it was formerly the custom to dig a trench in which to spread the quicklime and then rock or dray the lime over the surface. If these were then sunk, and the chalk taken from horizontal tunnels was brought to the surface and spread on the land at the rate of about 60 loads per acre. Chalk should be applied in autumn, so that it may be split by the action of frost during the winter. Quicklime is best applied, perhaps, in spring at the rate of one ton per acre every six or eight years, or in larger doses—4 to 8 tons—every 15 to 20 years. Small dressings applied at short intervals give the most satisfactory results. The quicklime should be placed in small heaps and covered with soil if possible until it is slacked and the heaps have fallen into powder, after which it may be spread and harrowed. The chalk may be thrown on the surface or broadcast. There will always be slight effects can be obtained by applying 5 or 6 cwt. of ground quicklime.

Gas-lime is a product obtained from gasworks where quicklime is used to purify the gas from sulphur compounds and other objectionable substances. It contains 0.5% sulphur. The chief advantage of gas-lime is that it is free from calcium and slacked lime, along with sulphates and sulphides of lime, some of which have an evil odour. As some of these sulphur compounds have a poisonous effect on plants, gas-lime cannot be applied to land directly without great risk or rendering it incapable of growing crops of any sort—even weeds—for some time. It should therefore be kept a year or more in heaps in some waste corner and turned over once or twice so that the air can gain access to it and oxidize the poisonous ingredients in it.

Many soils of a light sandy or gravelly or peaty nature and liable to drought and looseness of texture can be improved by the addition of a mixture of sand, peat and slag. Similarly soils can be improved by applying to them marl, a substance consisting of a mixture of clay with variable proportions of lime. Some of the chalk marls, which are usually of a yellowish or greyish colour, contain clay and 50 to 80% of carbonate of lime with a certain proportion of phosphoric of lime. Such a material would not only have an influence on the texture of the land, but would also possess the properties of lime. In the phosphate of lime supply one of the most valuable factors of plant food constituents. The beneficial effects of marls may also be partially due to the presence in them of available potash. It contains 2 to 3% of sulphates of iron of yellowish-red or brownish colour and generally contain less than 50% of lime. When dry they crumble into small pieces which can be readily mixed with the soil by ploughing. Many soils of this nature are light and sandy, others stony or full of the remains of small shells. The amount and nature of the clay or marl to be added to the soil will depend largely upon the original composition of the latter, the lighter sands and gravel requiring more clay than those of firmer texture. Even stiff soils deficient in lime are greatly improved in fertility by the addition of marls. In some cases as little as 40 loads per acre have been used with benefit, in others 180 loads have not been too much. The material is dug from neighbour- ing marl pits or large heaps of marl and spread on the land in autumn and winter. When dry and in a crumbly state it is harrowed and spread and finally ploughed in and mixed with the soil.

On some of the strongest land it was formerly the practice to add to and plough into it burnt clay, with the object of making the land work more easily. The burnt clay moreover carried a number of useful clays and iron oxide in it which were available to the crops. The clay is dug from the land or from ditches or pits and placed in heaps of 60 to 100 loads each, with laggot wood, refuse coals or other fuel. Great care is necessary to prevent the heaps from becoming too hot, in which case the clay becomes baked into hard lumps of brick-like material which cannot be broken up. With careful management, however, the clay dries and becomes crumbled into (which readily crumble into a fine powder, in which it is spread over and worked into the land at the rate of 40 loads per acre.

The paring and burning of land, although formerly practised as an ordinary means of improving the texture and fertility of arable fields, can now only be looked upon as a practice to be adopted for the purpose of bringing rapidly into cultivation very foul leys or land covered with a coarse growth of weeds. Certain crops are thus introduced in place of them, such as beets covered with furze and bracken or fens and clay areas, smothered with rank grasses and sedges. To reduce such land to a cropable state is a difficult and slow process without resort to paring and burning. The operation consists of paring off the tough sward to a depth of 1 to 2 in. just sufficient to effectually damage the roots of the plants forming the sward and then exposing the earth to drying the land. The old growth of material and ashes over the land. The turf is taken off either with the breast plough—a paring tool pushed forward from the breast or thighs by the workman—or with specially constructed paring ploughs or shins. The depth of the soil removed should not be too thick or burning is difficult and too much humus is destroyed unnecessarily, nor should it be too thin or the roots of the herbage are not effectively destroyed.

The operation is best carried out in spring and summer. After being pared off the turf is allowed to dry for a fortnight or so and is then placed in small heaps a yard or two wide at the base, a little of the turf being left on the middle of each heap. This is set on fire in the open air. As burning proceeds more turf is added to the outside of the heaps in such a manner as to allow little access of air. Every care should be taken to burn and char the sod thoroughly without permitting the heap to blaze. The ashes should be spread as soon as possible and covered by a shallow ploughing. The land is then usually sown with some rapidly growing green crop, such as rape, or with turnips.

Paring and burning improves the texture of clay lands, particularly if draining is carried out at the same time. It tends to destroy insects and weeds, and gets rid of acidity of the soil. No operation brings a greater return of time to the farmer for it can be rapidly done. The most obvious and immediate effects are seen in the first crop and last for many years. Many of the mineral plant food-constituents locked up in the coarse herbage and in the upper layers of the soil are made immediately available for the roots of the plants. The chief disadvantage is the loss of lime, which, as the clay contains this element being given off into the air in a free gaseous state. It is best adapted for application to clays and other lands and should not be practised on shallow light sands or gravelly soils, since the humus so necessary for the fertility of such areas is reduced too much and the soil rendered too porous and liable to suffer from drought.

Many thousands of acres of low-lying peaty and sandy land adjoining the tidal rivers which flow into the Humber have been improved by a process termed "warping." The warp consists of a line of silt and peat which separates the tidal rivers from the cultivated land. The rivers are surrounded by a circular mound of earth, the height of which is from the bed of the Humber by the action of the tide and a cement amount of deposit brought down by the tributary streams which join the Humber some distance from its mouth. The field or area to be warped must lie below the level of the water in the river at high tide. It is first surrounded by an embankment, after which the water from the river is allowed to flow through a properly constructed dam or bank, along a drain or ditch to the land which is prepared for warping. By a system of carefully laid channels the water flows gently over the land, and deposits its warp with an even level surface. At the ebb of the tide the more or less clear water flows back into the river. The whole operation is not altogether a clean one, for it is necessary to clean out any deposit which may have accumulated in the drain leading to the warped area, thus allowing free access of more warp- laden water to the new warped area. The whole area may be covered with a large layer of rock soil capable of growing excellent crops.

The amount of deposit laid over the land reaches a thickness of two or three feet in one season of warping, which is usually practised
between March and October, advantage being taken of the spring tides during these months. The new warp is allowed to lie fallow during the winter after being laid out in four-yard "lands" and becomes dry enough to be sown with oats and grass and clover seeds in the fall. Sometimes, especially with clover, potatoes or two with sheep, after which wheat and potatoes are the chief crops grown on the land.

Green manures available are those which are grown especially for the purpose of ploughing-in on the land in a green or actively growing state. The crop during its growth obtains a considerable amount of carbon from the carbon dioxide of the air, and builds it up in the form of dry matter of which it may be said that the growth which has侦查而 was not consumed becomes humus. The carbon compounds of the latter are of no direct nutritive value to the succeeding crop, but the decaying vegetable tissues very greatly assist in retaining moisture in light sandy soils, and provide a large proportion of the nitrogen and other plant food which is lost from the same through the rapidity of drainage and the ground-water. The ploughing-in of green crops is in many respects like the addition of farm-yard manure. Their growth makes no new addition of mineral food-consumitions to the land, but they bring useful substances from the subsoil nearer to the surface, and after the decay of the buried vegetation these become available to succeeding crops of wheat or other plants. Moreover, where deep-rooting plants are grown the subsoil is aerated and rendered more open and suitable for the development of future crops.

Organic Manuring.

Lupins are the plants most frequently used are white mustard, rape, buckwheat, spurry, rye, and several kinds of leguminous plants, especially vetches, lupins and sarradella. By far the most satisfactory crops as green manures are those of the leguminous class, since they add to the soil an abundant amount of carbohydrate and a considerable constituent, nitrogen, which is obtained from the atmosphere. By nitrification this substance rapidly becomes available to succeeding crops. The disintegration of the dead parts of the Leguminous Soil, made use of sarradella, yellow lupins and vetches as green manures for enriching the land in humus and nitrogen, and found the addition of potash salts and phosphates very profitable for the subsequent growth of potatoes and wheat. He estimated that by using leguminous crops in this manner for the purpose of obtaining cheap nitrogen he reduced the cost of production of wheat more than 50%.

The growing crops should be ploughed in before flowering occurs; those not so buried deeply, rapidly decay and nitritification takes place most rapidly and satisfactorily when there is free access of air to the decaying material. When the crop is luxuriant it is necessary to dig it over at first, to facilitate proper draining of the plough. The best time for the operation appears to be late summer and autumn.

Soil and Disease.—The influence of different kinds of soil as a factor in the production of disease requires to be considered, in regard not only to the nature and number of the microorganisms they contain, but also to the amount of moisture and air in the soil. The soil, therefore, as to its capacity to retain moisture, is derived from two sources—the rain and the ground-water. Above the level of the ground-water the soil is kept moist by capillary attraction and by evaporation of the water below, by rainfall, and by movements of the ground-water; on the other hand, the upper layers are constantly losing moisture by evaporation from the surface and through vegetation. When the ground-water rises it forces air out of the soil; when it falls again it leaves the soil moist and full of air. The nature of the soil will largely influence the amount of moisture which it will take up or retain. In regard to water, all soils have two actions—namely, permeability and absorbability. Permeability is practically identical with the speed at which percolation takes place; through clay it is slow, but increases in rapidity through marls, loams, limestones, chalks, coarse gravels and fine sands, reaching a maximum in soil saturated with moisture. The amount of moisture retained depends mainly upon the absorbability of the soil, and as it depends largely on capillary action it varies with the coarseness or fineness of the pores of the soil, being greater for soils which consist of fine particles. The results of many analyses show that the capacity for soils and air in the soil with the amount of organic substances present; decomposability being the criterion of the latter. The amount of moisture is about 4%, but can continue when it is as low as 2%, while it appears to be retarded by any excess over 4%

Above the level of the ground-water all soils contain air, varying in amount with the degree of looseness of the soil. Some sands contain as much as 50% of air of nearly the same composition as atmospheric air. The oxygen, however, decreases with the depth, while the carbon dioxide increases.
Dublin to the soil becoming saturated with fecal matter and specifically infected. The ratio of cases to population living in Dublin was loose porous gravel soil for the ten years 1881-1891 was 1 in 94, while that of those on stiff clay soil was but 1 in 145. "This is as we should expect, since the movements of ground air are much greater in loose porous soils than in stiff clay soils." A foul gravel soil is a most dangerous one on which to build; for warmth, for dryness, for absence of fog, and for facility of walking after rain, just before the air is at its height and its best, the soil is drying out rapidly equal to gravel; but when gravel has been rendered foul by infraction with organic matters it may easily become a very hotbed of disease.

SOISSONS, a city of northern France, in the department of Aisne, 83 m. N.E. of Paris by the railway to Liévin. Pop. (1906), 11,586. Soissons, pleasantly situated amongst wooded hills, stands on the right bank of the Aisne, the suburbs of St. Vaast and St. Médard lying on the right bank. The cathedral of Notre-Dame was begun in the second half of the 12th century and finished about the end of the 13th. It is 282 ft. long and 87 wide, and the vaulting of the nave is 100 ft. above the pavement. The single tower dates from the middle of the 13th century and is an imitation of those of Notre-Dame of Paris, which it equals in height (216 ft.). The south transept, the oldest and most graceful portion of the whole edifice, terminates in an apse. The façade of the north transept dates from the end of the 13th century. The apse and choir retain some fine 13th-century glass. Considerable remains exist of the magnificent abbey of St. Jean-des-Vignes, where Thomas Becket resided for a short time. These include the ruins of two cloisters (the larger dating from the 13th century), the refectory, and above all the imposing façade of the church (restored). Above the three portals (13th century) runs a gallery, over which again is a large window; the two unequal towers (230 and 240 ft.) of the 13th and early 14th centuries are surmounted by beautiful stone spires, which command the town. The church of St. Léger, which belongs to the 13th century, was formerly attached to an abbey of the Génovéfains. Beneath are two Romanesque chapels, and the crypt of St. Médard, apostle of Vermandois, and St. Clotilde, the celebrated mayor of the palace. The number of the nuns (216 in 858), the wealth of the library in manuscripts, the valuable relics, the high birth of the abbesses, the popularity of the pilgrimages, all contributed to the importance of this abbey, of which there exist only inconsiderable remains. The wealthiest of all the abbies in Soissons, and one of the most important of all France during the first two dynasties, was that of St. Médard, on the right bank of the Aisne, founded about 560 by Clotaire I., beside the villa of Syagrius, which had been the palace of the Frankish kings. St. Médard, apostle of Vermandois, and St. Clotilde, sister of Childebert, were buried in the monastery, which became the residence of 400 monks and the meeting-place of several councils. It was there that Childebert III., the last Merovingian, was deposed and Pippin the Short was crowned by the papal legate, and there Louis the Pious was kept in captivity in 833. The abbeys of St. Médard coined money, and in Abélard's time (12th century) were lords of 220 villages, farms and manors. At the battle of Bouvines (1214) the abbots commanded 1300 vassals. In 1530 St. Médard was visited by a procession of 30,000 pilgrims, and the relics of St. Médard were carried to Paris and, although it was restored by the Benedictines in 1637, it never recovered its former splendour. Of the churches and the conventual buildings of the ancient foundation there hardly remains a trace. The site is occupied by a deaf and dumb institution, the chapel of which stands over the crypt of the great abbey church, which dates from about 840. In the crypt is a stone coffin, said to have been that of Childebert II., and close at hand is an underground chamber, reputed to have been the place of captivity of Louis the Pious.

The civil buildings of the town are not of much interest. The hôtel-de-ville contains a library and a museum with collections of paintings and antiquities. The foundation of the hôtel-de-ville dates back to the 13th century. The town has a large botanical garden. Soissons is the seat of a bishop and a sub-prefect, and has tribunals of first instance and of commerce, a communal college and higher ecclesiastical seminary. Among the industrial establishments are iron and copper foundries, and factories for the production of boilers, agricultural implements and other iron goods, straw hats, glass and sugar. Grain, barley and beans of exceptional quality, and timber are the principal articles of trade.

Soissons is generally identified with the oppidum of Gallia Belgica, called Noviodunum by Caesar. Noviodunum was the capital of the Susesiones, who occupied twelve towns, and whose king, Divitiacus, one of the most powerful in Gaul, had extended his authority even beyond the sea among the Britons. In 58 B.C. Galba, king of the Susesiones, separated from the confederation of the Belgians and submitted to the Romans. At the beginning of the empire Noviodunum took the name of Augusta Suessionum, and afterwards that of Suessionum and became the second capital of Gallia Belgica, of which Reims was the metropolis. The town was before long surrounded with a regular wall and defended by a citadel, and it became the starting-point of several military roads (to Reims, Château-Thierry, Meaux, Paris, Amiens and St. Quentin). Christianity was introduced by St. Crispin and St. Crispinian, men of noble birth, who, however, earned their livelihood by shoemaking, and thus became patrons of that craft. After their martyrdom in 297 their work was continued by St. Sulpitius, the first bishop of Soissons. After the barbarians had crossed the Rhine and the Meuse Soissons was given back to the metropolis of the Roman possessions in the north of Gaul, and on the defeat of Syagrius by Clovis the Franks seized the town. It was at Soissons that Clovis married Clotilde, and, though he afterwards settled at Paris, Soissons was the capital of his son Clotaire, and afterwards of Chilperic I., king of Neustria. It was not till the time of Chilperic's son, Clotaire II., that the kingdom of Soissons was incorporated with that of Paris. Pippin the Short was at Soissons proclaimed king by an assembly of leudes and bishops, and he was there crowned by the papal legate, St. Boniface, before being crowned at Saint Denis in 754. In 832 the town was taken by Charles the Fat, and after being deposed by the assembly at Compiègne. Under Charles the Fat (886) the Normans failed in an attempt against the town, but laid waste St. Médard and the neighbourhood. In 923 Charles the Simple was defeated outside the walls by the supporters of Rudolph of Burgundy, and Hugh the Great besieged and partly burned the town in 948. Under the first Capets Soissons was held by hereditary counts (see below), frequently at war with the king or the citizens. The communal charter of the town dates from 1131. At a synod held at Soissons in 1121 the teachings of Abélard were condemned, and he was ordered to retract them. In 1155, at an assembly of prelates and barons held at Soissons, Louis VII. issued a famous decree forbidding all private war for a space of ten years; and in 1235 Charles the Fair replaced the mayor of Soissons by a royal provost dependent on the bailiwick of Vermandois, the inhabitants retaining only the right of electing four échevins. The town had to suffer severely during the war of the Hundred Years; in 1414, when it was held by the Burgundians, it was captured and sacked by the Armagnacs under the dauphin; and this same fate again befell it several times within twenty years. The Treaty of Arras (1453) brought it again under the French authority. It was sacked by Charles V. in 1544 and in 1565 by the Huguenots, who laid the churches in ruins, and, supported by the prince of Condé, count of Soissons, kept possession of the town for six months. During the League Soissons eagerly joined the Catholic party. Charles, duke of Mayenne, made the town his principal residence, and died there in 1611. A European congress was held there in 1728. In 1814 Soissons was captured and recaptured by the allies and the French. In 1815, after Waterloo, it was a rallying point for the vanquished, and it was not occupied by the Russians till the 14th of August. In 1870 it capitulated to the Germans after a bombardment of three days.

COUNTS OF SOISSONS.—In the middle ages Soissons was the chief town of a countship belonging in the 10th and 11th centuries to a family which apparently sprang from the
counts of Vermandois. Renaud, count of Soissons, gave his property in 1141 to his nephew Yves de Noyel. By successive marriages the countship of Soissons passed to the houses of Hainaut, Châtillon-Blois, Coucy, Bar and Luxembourg. Marie de Luxembourg brought it, together with the counties of Marie and St Pol, to Francis of Bourbon, count of Vendôme, whom she married in 1487. His descendants, the princes of Condé, held Soissons and gave it to their cadets. Charles of Bourbon, count of Soissons (1556–1612), son of Louis, prince of Condé, whose political vacillations were due to his intrigues with Henry IV’s sister Catherine, became grand master of France and governor of Dauphiné and Normandy. His son, Louis of Bourbon (1609–1641), took part in the plots against Marie de Medici and Richelieu, and attempted to assassinate Richelieu. He had only one child, a natural son, known as the Chevalier de Soissons. The countship passed to the house of Savoy-Carignan by the marriage in 1625 of Marie de Bourbon–Soissons with Thomas Francis of Savoy, Éugène Maurice of Savoy, count of Soissons (1635–1673), married the beautiful and witty Olympia Mancini, a niece of Cardinal Mazarin, and obtained high military posts through his wife’s influence. He defeated the Spaniards at the battle of the Dunes in 1658; took part in the campaigns at Flanders (1667), Franche-Comté (1667–68); and established himself as an ambassador extraordinary of France at the coronation of Charles II of England. His wife led a scandalous life, and was accused of poisoning her husband and others. She was the mother of Louis Thomas Amadée, count of Soissons, and of the famous Prince Eugène of Savoy. In 1734 the male line of the family of Savoy–Soissons became extinct, and the heiress, the princess of Saxe-Hildburghausen, ceded the countship of Soissons to the house of Orleans, in whose possession it remained until 1789.

**SOKE** (O. Eng. soke, connected ultimately with saxon, to seek), a word which at the time of the Norman Conquest generally denoted jurisdiction, but was often used vaguely and is probably incapable of precise definition. In some it denoted the right to hold a court, and in others only the right to receive the fines and forfeitures of the men over whom it was granted when they had been condemned in a court of competent jurisdiction. Its primary meaning seems to have been "seeking"; thus "soka faldac" was the duty of seeking the lords court, just as "secta ad molendinum" was the duty of seeking the lords mill. The "Leges Henrici II" also speaks of pleas in "socna, id est, in soke", ascribed in his investiture instruction. It is evident, however, that not long after the Norman Conquest considerable doubt prevailed about the correct meaning of the word. In some versions of the much used tract *Interpretationes vocabilorum* soke is defined "aver fruncu court," and in others as "interpellacio maioris audienciae," which is glossed somewhat ambiguously as "claim a justis et requeste." Soké is also frequently associated to "sak" or "sake," in the alliterative jingle "sake and soke," but the two words are not etymologically related. "Sake" is the Anglo-Saxon "sacu," originally meaning a matter or cause (from sacan, to contend), and later the right to have a court. Soke, however, is the commoner word, and appears to have had a wider range of meaning. The term "sake," unlike "sake," was sometimes used of the district over which the right of jurisdiction extended.

Mr Adolphus Ballard has recently argued that the interpretation of the word "sake" as jurisdiction should only be accepted where it stands for the fuller phrase, "sake and soke," and that soke standing by itself denoted services only. There are certainly many passages in Domesday Book which support his contention, but there are also other passages in which soke seems to be merely a short expression for "sake and soke." The difficulties about the correct interpretation of these words will probably not be solved until the normal functions and jurisdiction of the various local courts have been more fully elucidated.

"The sokemen" were a class of tenants, found chiefly in the eastern counties, occupying an intermediate position between the free tenants and the bond tenants or villains. As a general rule they were personally free, but performed many of the agricultural services of the villagers. It is generally supposed they were called sokemen because they were within the lord’s soke or jurisdiction. Mr Ballard, however, holds that a sokeman was merely a man who rendered services, and that a sokeland was land from which services were rendered, and was not necessarily under the jurisdiction of a manor. The law term, socage, used of this tenure, is a barbarism, and is formed by adding the French age to soc.

(G. J. T.)

**SOKOTO,** an important Fulani state of west central Sudan, now a province of the British protectorate of Nigeria. The sultan of Sokoto throughout the 19th century exercised an overlordship over the Hausa states extending east from the Niger to Bornu and southward to the Benue and Adamawa. These states and Sokoto itself, known variously as the Sokoto or Fula empire and Hausaland, came (c. 1500–1903) under direct British control, but the native governments are maintained. The pro- vinces of Sokoto occupies the north-western corner of the British protectorate, and is bounded on the north by Sokoto, South and east it adjoins other parts of the British protectorate.

Bordering north on the Sahara, it contains much arid land, but south-west the land is very fertile. Running through it in a south-westerly direction is the Gubrin Kebbi or Sokoto river, which joins the Niger in 11° N. 4° E. On a tributary of this river is the town of Sokoto.

The Sokoto or Fula empire was founded at the beginning of the 16th century. The country over which the Fula ruled has, however, a history going back to the middle ages. Between the Ng and the kingdom of Bornu (q.v.) the country was inhabited by various black tribes of whom the Sokoto claimed the plains. Under the influence of Berber and Arab tribes, whomembraced Mahommedanism, the Hausa advanced in civilization, founded large cities, and developed a considerable trade, not only with the neighbouring countries, but, via the Sahara, with the Barbary states. The various kingdoms which grew up round each large town had their rulers, but in the first half of the 16th century they all appear to have owned the sway of the Songhoi kings (see TIMBUKTU). On the break up of the Songhoi empire the north-eastern part of Hausaland became more or less subject to Bornu, whose sultans in the 17th century claimed to rule over Katsena and Kano. In this century arose a dynasty of the Habé, a name now believed to be identical with Haussa, who obtained power over a large area of the northern portion of the present British protectorate. The Hausa, whose conversion to Mahomedanism began in the 12th century, were still in the 18th century partly pagans, though their rulers were followers of the Prophet. These rulers built up an elaborate system of government which left a considerable share in the management of affairs to the body of the people. Dwelling in the Ng the Hausa hired a number of Fula, mostly herdsmen, and these were devout Mahommedans. Among the most distinguished of these semi-converted teachers of affairs of this race, named Othman Dan Fodio, had been tutor to the king of Gobir (a district north of Sokoto). He incurred the wrath of that king, who, angered at some act of defiance, ordered the massacre of every Fula in his dominions. The Fula flocked to Fodio’s aid, and in the battle of Koto or Rugga P’ako (1804) the king of Gobir was utterly defeated. Thereupon Fodio unfurled the green banner of Mahomet and preached a jihad or religious war. For less than a year the Fula had subdued most of the Hausa states, some, like Kano, yielding easily in order to preserve their trade, others, like Katsena, offering a stubborn resistance. Gobir and Kebbi remained unconquered, as did the pagan hill tribes. The Fulas were also defeated in their attack on Bornu. In most places they continued the system of government which had grown up under the Habé, the chiefs or emirs of the various
states being, however, tributary to Dan Fodio. This sheik established himself at Sokoto, and with other titles assumed that of Sarakin Muslimin (king of the Mahommendans). As such he became the recognized spiritual head of all the Mahommendans of west central Sudan, a headship which his successors retained unimpaired, even after the loss of their temporal position to the British in 1903. On the death of Fodio (c.1819) the empire was divided between a son and a brother, the son, famous under the name of Sultan Bello, ruling at Sokoto, the brother at Gando. All the other Fula emirs were dependent on these two sultanates. The Fula power proved, before many years had gone by, in many respects harmful to the country. This was especially the case in those districts where there was a large pagan population. Slave-raiding was practised on a scale which devastated and almost depopulated vast regions and greatly hampered the commercial activity of the large cities, of which Zaria and Kano were the most important. The purity of the ancient administration was abandoned. The courts of justice became corrupt, administrative power was abused and degenerated into a despotism controlled only by personal considerations, oppressive taxes destroyed industry and gradually desolated the country. Soon after the Fula had established themselves Europeans began to visit the country. Hugh Clapperton, an Englishman, was at Sokoto in 1823 and again in 1827, dying there on the 13th of April of that year. Heinrich Barth made a prolonged stay in various Hausa cities at dates between 1851 and 1853. To Barth is due a great deal of our knowledge of the region. Sokoto had established on the Niger, bartering goods in exchange for slaves. This traffic was carried on through Nupe "to the great damage," says Barth, "of the commerce and the most unqualified scandal of the Arabs, who think that the English, if they would, could easily prevent it." The over-seas traffic in slaves did not continue long after the date (1854) to which Barth referred, but slave-raiding by the Fula went on unchecked up to the moment of the British occupation of the country. At Sokoto the sultanship continued in the hands of Fodio's descendants, and the reigning sultan concluded in 1881 a treaty with the Royal Niger Company (then called the National African Company) which gave to the company certain rights of sovereignty throughout its dominions.

In 1890 the rights of the company were transferred to the Crown. In the course of the years 1900, 1901, 1902, British authority was established in the states bordering on the Niger and the Benue and in Bornu. The northern states declined to fulfil the conditions of the treaties negotiated with the Niger Company or to submit to the abolition of the slave trade, and in 1902 Sokoto and Kano were attacked by the British. An agreement was undertaken against them in the opening months of 1903 in which the British troops were entirely successful. Kano was taken in February 1903, and Sokoto after some resistance made formal submission on the 22nd of March following. From that day British authority was substituted for Fula authority throughout the protectorate. The emir of Sokoto took an oath of allegiance to the British Crown and Sokoto became a British province, to which at a later period Gando was added as a sub-province—thus making of Sokoto one of the double provinces of the protectorate.

The double province thus constituted has an area of about 35,000 square miles, with an estimated population of something over 500,000. It includes the ancient kingdoms of Zamfara on the east and Argungu or Kebbi on the west. The dominions of the emir of Sokoto have suffered some diminutions by reason of British agreements with France relating to the common frontier of the two European powers in the western Sudan. The emir felt deeply the loss of territory ceded to France in 1904 but accepted the settlement with much loyalty. Like the emir of Kano the new emir of Sokoto worked most loyally with the British administration. He has been permitted to govern on the same principle as the other provinces of Northern Nigeria.

A British resident has been placed at Sokoto and assistant residents at other centres. British courts of justice have been established and British governors are quartered in the province. Detachments of civil police are also placed at the principal stations. The country has been assessed under the new system for taxes and is being opened as rapidly as possible for trade. After the establishment of British rule formerly inherited by local chiefs by treaty during the interregnum of cities flocked back to the land, rebuilding villages which had been deserted for fifty years. Horse breeding and cattle raising form the chief source of wealth in the province. There is some ostrich farming. Except in the sandy areas there is extensive agriculture, including rice and cotton. Special crops are grown in the valleys by irrigation. Weaving, dyeing and tanning are the principal native industries. Fair roads are in process of construction through the province. Trade is increasing and a cash currency has been introduced.

The period of the same terms as the emirs of Kano and Sokoto, proved less loyal to his oath of allegiance and had to be deposed. Another emir was installed in his place in the whole double province of Sokoto-Gando prosperity has been general. In 1906 a rising attributed to religious fanaticism occurred near Sokoto in which unfortunately three white officers lost their lives. The emir heartily repudiated the leader of the rising, who claimed to be a Mahdi inspired to drive the white man out of the country. A British force marched against the rebels, who were overthrown with great loss in March 1906. The leader was condemned to death in the emir's court and executed in the market place of Sokoto, and the incident was chiefly interesting for the display of loyalty to the British administration which it evoked on all sides from the native rulers. (See also NIGERIA; FULA; and HAUSA.)

SOKOTRA (spelt Socotra and formerly Socotara), an island in the Indian Ocean belonging to Great Britain. It is cut by 13° 30' N., 54° E., lies about 130 m. E.N.E. of Cape Guardafui and about 196 m. S.E. of the nearest part of the coast of Africa, and is on the trade route from India to Suez. It is 72 m. long by 22 m. broad and has an area estimated at from 2000 to 3000 square miles. It is the largest and most easterly member of a group of islands rising from adjacent coral banks, the others being Abd el Kuri, The Brothers (Sembha and Darzi), and Kal Farun.

Physical Features.—From the sea Socotra has an imposing appearance. The centre culminates in a series of rugged pinnacles and cliffs of the Hughes mountains, which rise nearly 5000 ft. above a high (1900 ft.) abutting and undulating limestone plateau, deeply channelled by valleys. At many parts of the north coast the edges of this plateau reach the shore in precipitous cliffs, but in others low plains, dotted with bushes and date-palms, from the heights behind. The southern shore is bordered nearly its entire length by a belt of drifted sand, forming the Nugut plain. On this side of the island there are two large lakes, and these only during the north-east monsoon. On the north coast there are no harbours; but fairly safe anchorages, even in the north-east winds, are available off Hadilou or under Haulaf, a few miles distant, and at Kalansayla, at the north-west end of the island.

Geology.—The fundamental rocks of the island are gneisses, through which cut the foldspathic granites which form the Hughes mountains. Through this granite other granites in dikes or lava flows, and overlying the whole are limestones of Cretaceous and Tertiary age, themselves cut through by later volcanic eruptions. The Hughes mountains, to quote Professor Bonney, "we have probably a fragment of a continental area of great antiquity, and of a land surface which may have been an 'ark of refuge' to a terrestrial, tropical fauna and flora from one of the very earliest periods of this world's history.'" Climate.—From October to May the weather is almost rainless except in the mountains, where there are nightly showers and heavy mists. During this season the rivers, which are running torrents throughout the monsoon, are almost all lost in the dry, absorbent
SOKOTRA

is highly esteemed; in the middle ages the trade was mostly in these products and in ambergris. The people live mainly on dates and milk. They own large numbers of cattle, sheep and goats. Dates are both home-grown and imported.

History.—Sokotra has claims to be reckoned one of the most ancient incense-supplying countries. Among the "harbours of incense" exploited by various Pharaohs during some twenty-five centuries it is impossible to believe that the island could be missed by the Egyptian galleys on their way to the "Land of Pun," identified by several writers with Somaliland; nor that, though the roadsteads of the African coast were perhaps oftener frequented, and for other freights besides myrrh and frankincense, the shores of Sokotra were neglected by such ardent explorers as those, for instance, of Quirinius Hadschen and the 18th dynasty. They would have found on the island, which is probably referred to under the name "Terraces of Incense" (from its step-like contours), the precious "auta trees"—whose divine dew, for use in the service of their gods, was their special quest—in greater abundance and in a larger number of species than any other country.

To the Greeks and Romans Sokotra was known as the isle of Dioscorides; this name, and that by which the island is now usually known, is probably originally Latin, having been used by the Arab geographers who have usually traced back a Sanskrit form, Dwipa-Saktabharak, "the island of the daughter tongues." This name is still used by the inhabitants of the island, and the indigenous Arabs in the region call the place "El-Mahra" (which again suggests an identification with the Μηρα etalawes of Agatharchides, § 103). The Periplus of the Erythraean Sea speaks of the island as peopled only in one part by a mixed race of Arab, Indian and Greek traders. It was subject to the king of the Incense Country, and was a meeting-place of Arabian and Indian ships. Cosmas in the 6th century says that the people spoke Greek and were largely Christian, with a bishop sent from Persia. The Arab geographers also had a tradition of an early Greek settlement (which they ascribe to Alexander), but also of later Persian influence, followed by a settlement of Mahra tribes, who partly adopted Christianity. The Sokotri appear to have remained Nestorian Christians, with a bishop under the caliph of Persia, through the middle ages, though there are indications pointing to a connexion with the Jacobite church. As early as the 10th century Sokotra was a haunt of pirates; in the 13th century Abulfeda describes the inhabitants as "Nestorian Christians and pirates" but the island was rather a station of the Indian corsairs who harassed the Arab trade with the Far East. The population seems in the middle ages to have been much larger than it is now; Arabian writers estimate the fighting population in the 13th century at 12,000.

The Portuguese under Tristão da Cunha and Albuquerque seized Sokotra in 1507 in pursuance of the design to control all the trade routes between Europe and the East, Sokotra being supposed to command the entrance to the Red Sea. But on the capture of Goa and the building of a fortress there Albuquerque caused the fort which da Cunha had built at Coco (Tamarida to be dismantled (1511), and though Portuguese ships subsequently raided the island they made no other settlement on it. The Portuguese found that Sokotra was held by Arabs from Fartak, but the "natives" (a different race) were Christians, and there was a sad need of conversion. This pious work Portuguese priests attempted, but with little effect; during the reversion of the island to the Mahra in 1652, under the 18th dynasty of the 17th century the Carmelites P. Vincenzo found that the people still called themselves Christians, and had a strange mixture of Jewish, Christian and Pagan rites. The women were all called Maria. No trace of Christianity is now found in the island, all the inhabitants professing Islam.

A certain dependence (at least of places on the coast) on some sovereign of the Arabian coast had endured before the occupation of Tamarida by da Cunha, and on the withdrawal of the Portuguese this dependence on Arabia was resumed. In the 19th century Sokotra formed part of the dominions of the sultan of Kishin. The opening of the Suez Canal route to India led to the island being secured for Great Britain. From 1876 onwards a small subsidy has been paid to the sultan of Kishin by the authorities at Aden; and in 1886 the sultan concluded...
a treaty formally placing Sotkotra and its dependencies under the protection of Great Britain. Sokotra is regarded as a dependency of Aden, but native rule is maintained, the local governor or viceroy of the sultan of Kishin being a member of that chief's family, and also styled sultan. Since it came under British control the island has been visited by various scientific expeditions, among them, Professor Balfour's. Balfour's investigations in eastern expeditions were headed by Drs Riebeck and Schweinfurth in 1881, by Theodore Bent in 1897, and by Dr H. O. Forbes and Mr Ogilvie-Grant (who also visited Abd-el-Kuri) in 1898-1899. Simultaneously with the last named a further expedition, conducted by Professor D. H. Muller, under the auspices of the Imperial Academy of Sciences of Vienna, visited Sokotra, Abd-el-Kuri and some other islets of the group to investigate their geology and languages. With the Indian government the relations of the Sotkotri have occasionally been strained, owing to their irritable tendencies.

ABD-EL-KURI island lies 60 m. W.S.W. of Sokotra, and 53 m. E.N.E. from Cape Guardalfi, is 20 m. long, 31 m. wide. Attributable to the hills rises to 1670 ft. It is largely arid and there are no permanent streams. Its zoology resembles that of Sokotra, but the fauna includes land shells and scorpions peculiar to Abd-el-Kuri. Sokotri, who are entirely dependent on Sokotri and Arabic and are chiefly engaged in diving for pearl shell on the Bancahs Bank N.E. of the island. They live chiefly on turtle (which abounds in the island), fish and molluscs. The land is in part cultivated.

Kal Furun is the name of two rocky islets rising nearly 300 ft. above the sea 13 m. N.N.E. of the western end of Abd-el-Kuri. Birds flock to them in great numbers; in consequence they are completely covered with guano, which gives them a snow-white appearance. The Brothers (often called by the older navigators, The Sisters) lie between Abd-el-Kuri and Sokotra. Semha is 69 m. long, and rises 8 ft. above the rocky coast; Tifin rising in the mountain to 2440 ft. As in Abd-el-Kuri ambergris is found on its shores and turtles abound. There is running water all the year. It is a fishing ground of the Sokotri. Darzi lies 9 m. E. by S. of Semha and is 50 m. broad. It is visited by the Sokotri and almost an island. The height above the sea to 1500 ft. The top is flat. The coral banks which surround Sokotra and The Brothers are united and are not more than 30 fathoms below sea-level; a valley some 100 fathoms deep divides them. The banks around Abd-el-Kuri while between Abd-el-Kuri and Cape Guardalfi are depths of over 500 fathoms.

SOLANACEAE. In botany, an order of Dicotyledons belonging to the sub-class Sympetalae (or Gamopetalae) and to the series Tubiflorae, containing 75 genera with about 1500 species, widely distributed through the tropics, but passing into the temperate zones. The chief centre of the order lies in Central and South America; 32 of the genera are endemic in this region. It is represented in Britain by three genera including a species: Hyoscyamus niger (henbane), Solanum Dulcamara (Bittersweet) and S. nigrum and Atropa Belladonna (Deadly Nightshade).

The plants are herbs, shrubs or small trees. Solanum nigrum, a common weed in waste places, is a low-growing annual herb; S. Dulcamara is an irregularly climbing herb perennial by means of creeping rhizomes; Atropa Belladonna is a climbing perennial herb. The genus Solanum, to which belong more than half the number of species in the order, contains plants of very various habits including besides herbs, shrubs and trees. The leaves are generally alternate, but in the flower-bearing parts of the stem are often in pairs, an arrangement which, like the extra-axillary position of the flowers or cymes, results from a congenital union of axes. This in Potamogeton (hairy pondweed) (fig. 1 A), where the branching is dichasial, the leaf which originates at any given node becomes raised upon its axillary shoot as far as the next higher node, from which it appears to spring. In Atropa Belladonna (fig. 1 H) one of the branches at each node is undeveloped and there is a pair of unequal leaves; the smaller subtends the branch which has not developed, the larger has been carried up from the node below.

An interesting anatomical feature is the presence in the stem of bicollateral bundles—that is, the vascular bundles have phloem on the inside as well as on the outside of the xylem.

The hermaphrodite, generally regular, flowers have the parts in fives, 5 sepals, 5 petals, 5 stamens in alternating whorls, and two carpels, which are generally placed obliquely (see fig. 2, floral diagram). The sepals persist and often become enlarged in the fruit. The corolla is regular and rotate as in Solanum (fig. 2), or bell-shaped as in Atropa, or somewhat irregular as in Hyoscyamus; in the tribe Salpiglossideae, which forms a link with the closely allied order Scrophulariaceae, it is zygomorphic, forming, e.g. as in Schizanthus (fig. 3), a two-lipped flower. The stamens are inserted on the corolla tube and alternate with its lobes; in zygomorphic flowers only two or four fertile stamens are present; the bilocular anthers open by slits or pores (fig. 4). The flowers are generally conspicuous and adapted to insect pollination; honey is secreted on the disk at the base of the ovary or at the bottom of the corolla tube between the stamens. The ovary is usually bilocular, but in Capsicum becomes unilocular above, while in some cases an in-growth of a secondary septum makes it 4-celled as in Datura, or irregularly 3- to 5-celled as in Nicandra. The anatropous ovules are generally numerous on swollen axile placents, sometimes few as in Cestrum, a large American genus with tubular flowers, species of which are grown in Britain as greenhouse plants; the simple style bears a bilobed or sometimes capitulate stigma (fig. 5). The fruit is a many-seeded berry, as in Solanum, or

capsule, as in Datura, where it splits lengthwise, and Hyoscyamus (fig. 6), where it opens by a transverse lid forming a pyxidium. The embryo is bent or straight and embedded in endo-
sperm. The persistent calyx may serve to protect the fruit or aid in its distribution, as in the bladdery structure enveloping the fruit of Physalis or the prickly calyx of species of Solanum.

The order is divided into 5 tribes; the division is based on the greater or less curvature of the embryo, the number of ovary cells and the regular or zygomorphic character of the flower. The great majority of the genera belong to the tribe Solanaceae, which is characterized by a 2-celled ovary. Lycium is a genus of trees or shrubs, often thorny, with a cylindrical or narrowly bell-

The warmer parts of North and South America, includes P. akhenengi, "winter cherry," and P. peruviana, "Cape gooseberry." Capsicum (q.v.) is widely cultivated for its fruit, which are the so-called chillies. Solanum contains 900 species, among which are S. tuberosum (potato; q.v.), S. Lycopersicum (tomato; q.v.), and the two British species already mentioned. For Mandragora see Mandrake. To the tribe Daturaee, characterized by a 4-celled ovary, belong Datura and D. Stramonium (thorn apple), sometimes found as an escape in Britain, is official. Nicotiana, to which belong the tobacco plant (N. tabacum) and other cultivated species, and Petunia, are American genera belonging to the tribe Cestreae, in which the embryo is straight or only slightly bent, as it is also in the tribe Salpiglossideae, which is characterized by the zygomorphy of the flowers; Salpiglossis and Schizanthus are known in cultivation.

SOLAR, SOLLER (Lat. solarium, Fr. goélets, Ital. solaio), in architecture, a room in some high situation, a loft or garret, also an elevated chamber in a church from which to watch the lamps burning before the altars. The Latin solarium was used principally of a sundial, but also of a sunny part of a house.

SOLARIO, ANTONIO (c. 1536–1435), Italian painter of the Neapolitan school, commonly called Lo Zingaro, or The Gipsy. His father is said to have been a travelling smith. To all appearance Antonio was born at Civita in the Abruzzi, although it is true that one of his pictures is signed "Antonio de Solaro Venetus," which may possibly be accounted for on the ground that the signature is not genuine. Sollario is said to have gone through a love-adventure similar to that of the Flemish painter, Quintin Massys. He was at first a smith, and did a job of work in the house of the prime Neapolitan painter Colantonio del Fiore; he fell in love with Colantonio's daughter, and she with him; and the father, to stave him off, said if he would come back in ten years an accomplished painter the young lady should be his. Sollario studied the art, returned in nine years, and claimed and obtained his bride. The fact is that Colantonio del Fiore is one of those painters who never existed; consequently his daughter never existed, and the whole story, as relating to those particular personages, must be untrue. Whether it has any truth, in relation to some unidentified painter and his daughter, is a separate question which we cannot decide. Sollario made an extensive round of study—first with Lippo Dalmasio in Bologna, and afterwards in Venice, Ferrara, Florence and Rome. On returning to Naples he rapidly took the first place in his art. His principal performance is in the court of the monastery of S. Severino—twenty large frescoes illustrating the life of St Benedict, now greatly decayed; they present a vast variety of figures and details, with dexterous modelling and colouring. Sometimes, however, Lo Zingaro's colour is crude, and he generally shows weakness of draughtsmanship in hands and feet. His tendency is that of a naturalist—the heads lifelike and individual, and the landscape backgrounds better invented and cared for than in any contemporary. In the Studi gallery of Naples are three pictures attributed to this master, the most remarkable one being a "Madonna and Child Enthroned with Saints." The heads here are reputed to be mostly portraits.

SOLAR SYSTEM, in astronomy, the group of heavenly bodies, comprising the sun and the bodies which move around the sun as a centre of attraction, of which the Earth is one. These bodies may be classified as follows: first the Sun, distinguished as containing much the greater part of all the matter composing the system, being more than 600 times as massive as all the other bodies combined. It is this great mass which makes it the central one of the system. It is also, so far as is known, the only incandescent body of the system, and therefore the only one that shines by its own light. Secondly, planets. The bodies of this class consist of eight major planets moving around the sun at various distances, and of an unknown number of minor planets, much smaller than the major planets, forming a separate group. Thirdly, satellites, or secondary planets revolving around the major planets, and therefore accompanying them in their revolutions around the sun. A fourth class of bodies, the constitution of which is still in some doubt, comprises comets and meteors. These differ in that comets are visible either in a telescope or to the naked eye, and seem to be either wholly or partially of a nebulous or gaseous character, while meteors are, individually at least, invisible to us except as they become incandescent by striking the atmosphere of the earth. It is, however, an open question whether a comet is other than an accumulation of meteoric bodies (see Comet).

The major planets are separated into two groups of four each, between which the minor planets, for the most part, revolve. The arrangement of the major planets, with the numbers of their respective satellites thus far known, in the order of distance from the sun, is as follows:

- The first group in order—the smaller major planets—comprises:
  - Mercury, 8, with no known satellite;
  - Venus, 9, with no known satellite;
  - The Earth, 10, with one satellite, the moon;
  - Mars, 11, with two satellites.

Outside of this group lies the zone of minor planets or asteroids.

The outer group of major planets comprises:

- Jupiter, 12, with eight satellites;
- Saturn, 13, with ten satellites;
- Uranus, 14 or 15, with four satellites;
- Neptune, 16, with one satellite.

The distances separating the individual orbits in each group seem to approximate to a certain order of progression, expressed in Bode's law (see Bode). But there is an obvious gap between the two groups of major planets which is filled by the group of minor planets. Taking the mean distance of this group as that of a planet, the distance of the major planets closely approximates to Bode's law, except in the case of Neptune.

A remarkable feature of the solar system, which distinguishes it from all other known systems in the universe, is the symmetry of arrangement and motion of its greater bodies. All the major planets and many of the minor planets revolve in elliptic
orbits so nearly circular in form that the unaired eye would not notice the deviation from that form. But as the orbits are not centred on the sun, which is in a focus of each, the displacement of the seeming circle would be readily seen in the case of Mercury and of Mars. The same statements are true of the orbits of the satellites around their primaries. The major plaeats all move around the sun in the same direction, from west to east, in orbits but little inclined to each other, but are known to minor planets have the same common direction, but their orbits generally have a greater eccentricity and mutual inclination. The general rule is that the satellites also move round in the same direction, and in orbits of moderate inclination. Exceptions occur in the case of the satellites of Uranus, which are nearly perpendicular to the plane of the orbit. The satellite of Neptune, and one satellite, Phoebe, of Saturn, are also quite exceptional, the direction of motion being retrograde.

For the elements of the orbits, and the general character of the several planets see PLANET. Details as to each are found under the respective names of the several planets. (S. N.)

SOLDER (derived through the French from Lat. solde, to make solidus, firm), an alloy easily melted and used for uniting as by a metallic cement two metal surfaces, joints, edges, &c. (See Brazing and Soldering.)

SOLE (Solea), the most valuable of European flat-fishes.1 People who make fish merely from the culinary point of view, soles are of two kinds: true soles, with such varieties as Dover soles and Brixham soles (slips being the name applied to young specimens), and lemon soles, an inferior fish, which is no sole at all, but a sort of dab (Glyptocephalus microcephalus). Leaving out the latter, there are five species on the British coasts: the common sole (Solea vulgaris) the French sole, or sand sole lemon sole of Yardell (S. lascaris), the thick-back (S. variegata), and the solenette or little sole (S. luteo). All these agree in the right side being coloured and bearing the eyes, in the elongate form, in the small eyes (separated by a space covered with scaly skin, in the small, twisted mouth, with minute teeth on the colourless side only), and with the snout projecting beyond the mouth and more or less hooked. All true soles are excellent, but the common species is the only one which, from its larger size, growing to a length of 26 in. and attaining maturity at a length of about 10 in., regularly appears on all the markets. It occurs from the south-west coast of Scandinavia, Mecklenburg and Great Britain to the Mediterranean. Most of the best fishing grounds for soles lie comparatively near land, though the spawning takes place some miles away.

Much information on the life history of the sole will be found in the monograph by J. T. Cunningham (Plymouth, 1890).

SOLEMN (Lat. sollemnis, less correctly solennis, yearly; annual; from solius = solus, whole, entire, Gr. ὅσος, and ἀνεύω, year), properly that which occurs annually, hence stated intervals, regular, established; the term being particularly used of religious rites or ceremonies which recur at stated intervals, hence festive, sacred, marked by religious ceremony or ritual, and so grave, impressive, serious, the most general current aspect. Another branch of meaning stresses the formal, customary aspect; and hence in such phrases as "solemn act," "probate in "solemn form," it means that which is done with all due forms and ceremonies.

SOLENT, THE, a strait of the English Channel, between the mainland (the coast of Hampshire, England), and the northwestern coast of Wight. It is the western entrance to Southampton Water, Spithead being the eastern. Its length, from the eastern shore of Southampton Water to the Needles rocks off the western extremity of Wight, is 15 m. The general breadth is from 1/2 to 3 m., but between Stone Point on the mainland and Egypt Point on the north coast of Wight it narrows to 1/2 m.; and 33 m. north of the Needles there springs from the mainland a great shingle bank, mostly only a few yards in breadth above water, but nearly 2 m. in length.

1 The American sole (Achirus fasciatus) is a small-flat fish of inferior quality.

It reduces the breadth of the Solent to a little over 2 m., and broadens at the end, on which stands Hurst Castle, an important fortification dating from the time of Henry VIII. Here Charles I. was imprisoned in 1648. The coast of the mainland is low but picturesque, and is broken by the shallow estuaries of the Beaulieu River and the Lym, with the small port of Lymington upon it. The coast of Wight rises more steeply. On this side the Medina estuary opens northward, and those of the Newtown and the Yar north-westward into the strait. At the mouth of Southampton Water is a projecting bar resembling but smaller than that of Hurst Castle, and like it bearing a Tudor fortress, Calshot Castle. The Solent is frequently the scene of yacht races. The configuration of the coast causes a double tide in the strait.

SOLESMES, a village of western France on the left bank of the Sarthe in the department of Sarthe, 29 m. W.S.W. of Le Mans by road. In 1010 a priory was founded at Solesmes and placed under the authority of the abbey of La Couture of Le Mans. Suppressed at the revolution, it was established as a Benedictine monastery in 1857. In 1837 it was raised to the rank of abbey and became a centre of learning; the music here was also famous. A nunnery was afterwards founded beside it, but both institutions were abandoned after the passing of the associations law in 1901. The monastery, rebuilt at the end of the 19th century, forms a lofty mass of buildings on the river bank. Its church (14th and 16th centuries) is interesting only for the possession of two masterpieces of sculpture of uncertain authorship, executed approximately between 1490 and 1550. The most striking represents the burial of Christ and is sheltered by a stone structure the front of which is beautifully carved. An arched opening in this front reveals the central group of eight figures surrounding the tomb, that of Mary Magdalene in the foreground being remarkably lifelike and expressive. The other work similarly enclosed represents the burial of the Virgin and is the later of the two in date and in the pure Renaissance style. Sculptures representing Jesus among the Doctors and other scenes are also in the church.

SOLETO, a village of Apulia, Italy, in the province of Lecce, from which it is 11 m. S. by rail, situated 299 ft. above sea-level. Pop. (1911), 3349. The Romanesque church of St. Stefano contains Byzantine frescoes of the 14th century similar to those in the subterranean chapel of the Santi Stefani at Vaste, south of Otranto, and others showing the formation of an independent style. The fine, richly decorated campanile adjoining the former cathedral was erected in 1397.

SOLEURE (Ger. Solothurn), one of the cantons of northwestern Switzerland. Its total area is 359.5 sq. m., of which 294 sq. m. are reckoned as "productive," 115.3 sq. m. being covered by forests and 29 sq. m. by vineyards. Save two small districts in its southern portion the whole canton is situated in the Jura range, while it is said to be the most irregular in shape of all the Swiss cantons, this being accounted for by the fact that it consists simply of the territories won at different dates by the town from which it takes its name. It includes most of the Aar valley between the towns of Bienne and Aarau, neither of which is in the canton, while in its northern portion the waters join the Birs River, and in its southern portion is the last bit of the Emme before its junction with the Aar. It comprises three isolated districts, of which one (Steinhof) on the south is an "enclave" in the canton of Bern, while the others, Hofstetten, that includes the famous pilgrimage resort of Maristetten, are on the Alsatian frontier, and bounded by the cantons of Bern and of Basel. The highest point in the canton is the Hasennatt (4748 ft.) that forms the culminating summit of the Weissenstein ridge, that rises just north-west of the town of Soleure, and boasts of an hotel well-known as a great centre for the air and whey cure. The canton is well supplied in its southern portion with railways, the main line from Bienne to Aarau running through it past the great junction of Olten, where the direct lines from Lucerne by the St Gotthard, from Bern, from Zürich, and from Basel all unite. Formerly the districts composing the canton were in the dioceses of Lausanne,
Soleure, the capital of the Swiss canton of that name, is an ancient little town, almost entirely situated on the left bank of the Aar. It was a Roman castrum, remains of which still exist, on the highway from Avenches to Basel, while its position at the foot of the Jura and close to the navigable portion of the Aar has always made it a meeting-point of various routes. Five railway lines now branch there, while a sixth has been recently added, the tunnel beneath the Weissenstein to Moutier Grandval having been completed. It was strongly fortified in 1667–1727, but since 1830 these defences have been removed for reasons of practical convenience. Its chief building is the minster of SS Ursus and Victor, which dates from the 12th century, though it stands on the site of a far older edifice. Since 1828 it has been the cathedral church of the bishop of Basel, but in 1874 its chapter was suppressed. The ancient clock tower has a quaint 16th-century clock, while the older portions of the town-hall date still further back. The early 17th-century arsenal contains the finest collection of armour and old weapons in Switzerland, while the modern museum houses a splendid collection of fossils from the Jura, the specimens of Alpine rocks collected by F. J. Hugi (1706–1855), a native of Soleure, and a Madonna by the younger Holbein. The building now used as the cantonal school was formerly the residence of the French ambassadors to the Swiss confederation from 1550 to 1797. There are some fine 16th-century fountains in the little town, which in its older portions still keeps much of its medieval aspect, though in the modern suburbs and in the neighbouring villages there is a certain amount of industrial activity. The Polish patriot Kosciuszko died here in 1817; his heart is preserved at Rapperswil, but his body is buried at Cracow. In 1900 the town had 10,025 inhabitants, almost all German-speaking, while there were 6098 "Catholics" (either Romanists or Christian Catholics), 8314 Protestants, and 81 Jews. In 1904 there were twenty churches or chapels in the town itself. One mile north of the town is the Hermitage of St Verena, in a striking rock gorge, above which rises the Weissenstein ridge, the hotel on which (4223 ft.) is much frequented in summer for the air and whey cure as well as for the glorious Alpine panorama that it commands.

A 16th-century rhyme claims for the town of Soleure the fame of being the oldest place in "Celts" save Trier. Certainly its name, "Salodurum," is found in Roman inscriptions, and its position as commanding the approach to the Rhine from the south-west has led to its being more than once strongly fortified. Situated just on the borders of Alamannia and Burgundy, it seems to have inclined to the allegiance of the latter, and it was at Soleure that in 1038 the Burgundian nobles made their final submission to the German king, Conrad II. The medieval town grew up round the house of secular canons founded in the 10th century in honour of St Ursus and St Victor (two of the Theban legion who are said to have been martyred here in 302) by Queen Bertha, the wife of Rudolph II., king of Burgundy, and was in the diocese of Lausanne. The prior and canons had many rights over the town, but criminal jurisdiction remained with the kings of Burgundy, then passed to the Zähringen dynasty, and on its extinction in 1218 reverted to the emperor. The city thus became a free imperial city, and in 1252 shook off the jurisdiction of the canons and took them under its protection. In 1295 we find it allied with Bern, and this connexion is the key to its later history. It helped Bern in 1298 in the great fight against the nobles at Dornbirn, and again at Laufen in 1339 against the jealous Burgundian nobles. It was besieged in 1318 by Duke Leopold of Austria, but he was compelled to withdraw. In the 14th century the government of the town fell into the hands of the gilds, whose members practically filled all the public offices. Through Bern, Soleure was drawn into association with the Swiss Confederation. An attempt to surprise it in 1382, made by the Habsburgs, was foiled, and resulted in the admittance of Soleure in 1385 into the Swabian League and in its sharing in the Sempach War. Though Soleure took no part in that battle, it was included in the Sempach ordinance of 1393 and in the great treaty of 1394 by which the Habsburgs renounced their claims to all territories within the Confederation. In 1411 Soleure sought in vain to be admitted into the Confederation, a privilege only granted to her in 1481 at the diet of Stans, after she had taken part in the Aargau, Italian, Toggenburg, and Burgundian Wars. It was also in the 15th century that by purchase or conquest the town acquired the main part of the territories forming the present canton. In 1529 the majority of the "communes" went over to the reformed faith, and men were sent to fight on Zwingli's side at Kappel (1531), but in 1533 the old faith regained its sway, and in 1586 Soleure was a member of the Golden, or Borromean, League. Though the city ruled the surrounding districts, the peasants were fairly treated, and hence their revolt in 1653 was not so desperate as in other places. Soleure was the usual residence of the French ambassador from 1530 to 1797, and no doubt this helped on the formation of a "patrie," for after 1681 no fresh citizens were admitted, and later
we find only twenty-five ruling families distributed over the eleven gilds. Serfage was abolished by Soleure in 1785. The old system of the city ruling over eleven bailiwicks came to an end in March 1798, when Soleure opened its gates to the French army, and it was one of the six "directional" cantons under the 1803 constitution. In 1814 the old aristocratic government was set up again, but this was finally broken down in 1831, Soleure in 1832 joining the league to guarantee the maintenance of the new constitutional laws. Though distinctly a Roman Catholic canton, it did not join the "Sonderbund," and voted in favour of the federal constitutions of 1848 and 1874.

(W. A. B. C.)

Solfatara, a volcanic vent emitting vapours chiefly of sulphuric character, whence the name, from the Italian solfo (sulphur). The typical example is the famous Solfatara, near Puzzuoli, in the Phlegrean Fields, west of Naples. This is an old crater which has not been in active eruption since A.D. 1198, but which is continuously exhaling heated vapours, chiefly hydrogen sulphide, sulphur dioxide and steam. These issue from orifices in the crust, on the walls of which are yellow incrustations of sublimed sulphur, sometimes orange-red by association with arsenic sulphide, whilst the trachytic rocks of the volcano are bleached and corroded by the effluent vapours, with formation of such products as gypsum and alum. Sal ammoniac occurs among the sublimates. The term solfatara has been extended to all dormant volcanoes of this type; and a volcano which has ceased to emit lava or ashes but still evolves heated vapours is said to have passed into the "solfataric stage." Examples are to be found in many volcanic districts.

By French geologists the term souffrière is used instead of the Italian solfatara. (See Volcanoes.)

Solférino, a village of Lombardy, Italy, in the province of Mantua, 5 m. S.W. of San Martino della Battaglia (a railway station 72 m. E. of Milan on the line to Verona), situated 410 ft. above sea-level, on the south-west edge of the hills bordering the Lake of Garda on the south. Pop. (1891), 1350.

It was the scene of a battle fought on the 24th of June 1859 between the allied Franco-Sardinian army under Napoleon III. and the Austrian army commanded by Francis Joseph II., in which, after a severe contest, the latter retired over the Mincio (see Italian Wars). The battle fought by the Sardinians on the left wing of the allied army is often called by the separate title of San Martino, from a hamlet near the Brescia-Verona railway, about which it was fought. From this battle, a certain shade of blue was designated by the name of Solferino, and was very popular for some years, though now, unlike its companion "magenta," it is forgotten.

Soli (mod. Mezzetli), an ancient town of Asia Minor, on the coast of Cilicia, between the rivers Lamus and Pyramus, of each of which it is about 60 miles from the mouth, and the Austrian army commanded by Francis Joseph II., in which, after a severe contest, the latter retired over the Mincio (see Italian Wars). The battle fought by the Sardinians on the left wing of the allied army is often called by the separate title of San Martino, from a hamlet near the Brescia-Verona railway, about which it was fought. From this battle, a certain shade of blue was designated by the name of Solferino, and was very popular for some years, though now, unlike its companion "magenta," it is forgotten.

From this battle, a certain shade of blue was designated by the name of Solferino, and was very popular for some years, though now, unlike its companion "magenta," it is forgotten.

Soli, a Greek city on the north coast of Cyprus, lying at Solais in the metalliferous country round Karavortasi near Lefka, on the south side of Morocco Bay. Its kingdom was bounded by the territories of Marion, Paphos, Tamassus and Laphatha. It was believed to have been founded after the Trojan War (c. 1186 B.C.) by the Attic hero Acamas; but no remains have been found in this district earlier than the Early Iron Age (c. 1000-800). The town of "Silla," whose king Irisus was an ally of Assur-bani-pal of Assyria in 608 B.C., is commonly supposed to represent Sola. In Hellenic times Soli had little political importance, though it stood a five months' siege from the Persians soon after 500 B.C.; its copper mines, however, were famous, and have left copious slag heaps and traces of small scattered settlements. A neighbouring monastery is dedicated to "Our Lady of the Slagheaps" (Panagia Skouras) and is legend. It was exhausted in Roman times, and thereupon Soli became desert.

Solicitor, in England, an officer of the Supreme Court of Judicature qualified to conduct legal proceedings for his clients. See also Attorney. The common law considered it indispensable that the parties to a suit should be actually present, but the privilege of appearing by attorney was conceded in certain cases by special dispensation. The passing of the statute of Merton and subsequent enactments made it competent for both parties in all judicial proceedings to appear by attorney. Prior to the passing of the Judicature Act of 1873 there was a distinction between the terms "solicitor" and "attorney." Solicitors appear to have been at first distinguished from attorneys, as not having the attorney's power to bind their principals, but latterly the distinction was blurred. The term "solicitor" was generally applied to persons appointed in actions at law, and solicitors who took care of proceedings in parliament, chancery, privy council, &c. In practice, however, and in ordinary language, the terms were synonymous. Down to the 17th century the solicitor of the chancery courts was considered inferior to the attorney of the common law courts, but the rapid growth of equity jurisdiction gave the solicitor an importance in no degree inferior to his fellow practitioner at the common law. Until 1873 it was usual for attorneys to be admitted as solicitors as well, but the Judicature Act of that year enabled all persons admitted as solicitors, attorneys or proctors of an English court shall henceforth be called solicitors of the Supreme Court. Regulations regarding the qualification of attorneys are found as far back as the 20 Edward I. (1293), and the profession has been stringently regulated by a series of statutes passed during the 19th century, notably the Solicitors Act 1874 and the Solicitors Acts 1877 and 1888.

Every person, before he can become a duly qualified solicitor, must serve an apprenticeship or clerkship to a practising solicitor for a period of years varying from three to five; he must pass all the necessary examinations, he must be duly admitted and entered on the roll of solicitors kept by the Incorporated Law Society, and must take out an annual certificate to practice. The organization of the profession is in the hands of the Incorporated Law Society. Established originally in 1827, in succession to an earlier society dating back to 1739, it was incorporated in 1831. It began courses of lectures for students in 1833 and ten years later was constituted registrar of attorneys and solicitors. In 1860 it obtained the power of suing unqualified solicitors and in 1888 it was given the custody of the roll of solicitors, on the abolition of the office of the clerk of the Incorporated Law Society. The Solicitors Act 1874 enabled the Incorporated Law Society to authorize complaints as to the professional conduct of solicitors, as well as power to refuse to renew the annual certificate of a solicitor's practising licence. A committee of the Incorporated Law Society may make application to the court to strike a solicitor off the rolls without preliminary inquiry by the committee where he has been convicted of a criminal offence, but where he is alleged to have been guilty of unprofessional conduct or a statutory offence the committee first hold a preliminary inquiry. Apart from its judicial administrative authority it has exercised powerful influence in raising the standard of conduct and attitude which it has frequently taken towards proposed legislation. Membership of the society, which is not compulsory, is open to any duly qualified practising solicitor, on approval by the council. No person, however duly qualified, can be admitted to the solicitor till he has attained the age of twenty-one years. Though admitted as a solicitor and his name entered on the roll he is not at liberty to practise until he has taken out his annual certificate, the fees for which vary according as the applicant

SOLICITOR-GENERAL—SOLIS

361

Düsseldorf, and 20 m. N.E. of Cologne by rail. Pop. (1905), 49,018. Solingen is one of the chief seats of the German iron and steel industry, its specialty consisting in all kinds of cutlery. Solingen sword-blades have been celebrated for centuries, and are widely sold outside Germany, while bayonets, knives, scissors, surgical instruments, files, steel frames and the like are also produced in enormous quantities. These articles are largely made by the workmen at their own homes and supplied to the dépôts of the large dealers; there are about 20,000 workers in steel in Solingen and the vicinity. Solingen received its municipal charter in 1374. Sword-blades have been made here since the early middle ages, and tradition affirms that the craft of sword-making was introduced during the Crusades by smiths from Damascus.

SOLINUS, GAUS JULIUS, Latin grammarian and compiler, probably flourished during the first half of the 3rd century A.D. He was the author of the Collectanea rerum memorabilium, a description of curiosities in a chorographical framework. Adventus, to whom it is dedicated, is identified with Ocatinius Adventus, consul A.D. 218. It contains a short description of the ancient world, with remarks on historical, social, religious and natural history questions. The greater part is taken from Pliny's Natural History and the geography of Pomponius Mela. The work is also used by Mommsen (1844), and was followed (by Cornelius Bocchus) and a Chorographia Bithyniae, an epitome of Pliny's work with additions made about the time of Hadrian. Schanz, however, suggests the Roma and Pratrum of Suetonius. The Collectanea was revised in the 6th century under the title of Polyhistor (subsequently taken for the author's name). It was popular in the middle ages, hexameter abridgments being current under the names of Theodectes and Petrus Diaconus.

The commentary by Saumaise in his Pliniusae exercitationes (1689) is indispensable; best edition by Mommsen (1869), with valuable introduction on the MSS., the authorities used by Solinus, and subsequent compilers. See also Teufel, Hist. of Roman Literature (Eng. trans., 1900), 389; and Schanz, Geschichte der romanischen Literatur (1904), iv. 1. There is an old English translation by A. Golding (1587).

SOLIPSISM (Lat. solus, alone, ipse, self), a philosophical term, applied to an extreme form of subjective idealism which denies that the human mind has any valid ground for believing in the existence of anything but itself. "It may best be defined, perhaps, as the doctrine that all existence is experience, and that there is only one experient. The Solipsist thinks that he is the one!" (Schiller). It is presented as a solution of the problem of explaining the nature of our knowledge of the external world. We cannot know things-in-themselves: they 'exist for us only in our cognition of them, through the medium of sense-given data'.—H. B. Fuller. (Appearance and Reality): "I cannot transcend experience, and experience is my experience. From this it follows that nothing beyond myself exists; for what is experience is its (the self's) states."

See IDEALISM; also F. C. S. Schiller, Mind, New Series (April 1909).

SOLIS, ANTONIO DE (1610-1656), Spanish dramatist and historian, was born in 1610 at Alcalá de Henares (less probably, Plasencia), and studied law at Salamanca, where he produced a comedy entitled Amor y obligación, which was acted in 1627. He became secretary to the count of Oropesa, and in 1654 was appointed secretary of state as well as private secretary to Philip IV. Later he obtained the lucrative post of chronicler of the Indies, and, taking orders in 1667, severed his connexion with the stage. He died at Madrid on the 10th of April 1686. Of his ten extant plays, two have some place in the history of the drama. El Amor al uso was adapted by Scarron and again by Thomas Corneille as L Amour à la mode; while La Gitana de Madrid, itself founded on the novela of Cervantes, has been utilized directly or indirectly by F. A. Wolff, Victor Hugo and Longfellow. The titles of the remaining seven are Triunfos de amor y fortuna, Euridice y Orfeo, El Aldear del secreto, Las Amazonas, El Doctor Carlin, Un Bobo hace ciento, and Amparar el enamorado. Amor y obligación survives in a manuscript at the Biblioteca Nacional. The
SOLITAIRE (Fr. for "solitary"), a game played on a board indented with 33 or 37 hemispherical hollows, with the same number of balls or marbles. An unoccupied hollow is left by removing one ball, and the balls, or pieces, are then captured as in draughts. No moves are allowed in diagonal directions or over more than one space at a time.

SOLO, or Solo Whist, a card game which is a modification of whist, the chief distinctive feature being that a single player generally has to oppose the other three. The game came into vogue in England towards the end of the 19th century. The following "declarations" can be made, the order being important: (1) proposition; (2) acceptance; (3) solo; (4) misère; (5) abundance (or abundance); (6) misère ouverte; (7) abundance déclarée (declared abundance). Proposition and acceptance go together, as will be seen; of the rest "solo" can be declared over "proposition," misère over solo, and so on. The stakes—regarding sixpence as the unit—are: for proposition, sixpence; for solo, sixpence (sometimes a shilling); for misère, a shilling; for abundance, eighteenthpence; for open misère, two shillings; for declared abundance, three shillings. A further stake may be arranged for "overtricks," to be paid to the player for every trick made above the number proposed, and for "undertricks," to be paid by the player for every trick below that number. A full pack is used; players cut as at whist for deal and seats; the cards may be dealt singly, but are more commonly dealt by threes, with a single card for the last round. The last card is turned up and left exposed for a round, whether it is used for trumps or not. One deal constitutes a game. The laws of whist obtain, where applicable, in such matters as following suit, revoking, the passing of the deal, &c. The player on the dealer's left may take the cards in an attempt to make eight tricks. (2) Solo: Here a player undertakes to win five tricks, playing against the other three in combination. (3) Misère: This is a declaration by a player that he will not win a single trick. There are no trumps, but the turn-up card is left exposed for the first round. If the caller wins a trick the game is at an end (there are no overtricks or undertricks), but he has a right to see the opponents' hands, to be sure that no revoke has been made. A trick that has been turned may not be seen afterwards. (4) Abundance is a declaration that a player will make nine tricks single-handed. The caller makes any suit trumps, but abundance in the turn-up suit takes precedence over abundance in other suits. The trump suit must be declared after the other players have passed, before the first round is played. (5) Misère ouverte: This is a declaration to lose all thirteen tricks; but after the first trick the caller's cards are placed on the table, though he may play them as he pleases. (6) Declared Abundance: This is a declaration of the caller to make all thirteen tricks by his own hand. He takes his own trumps and always leads, but a declaration in the suit of the turn-up card takes precedence over others. The game ends when the caller loses a trick. There are no undertricks.

SOLONE (Socalaunia from Lat. secule, rye), a region of north-central France extending over portions of the department of Loiret, Loir-et-Cher and Cher. Its area is about 1800 sq. m., and its boundaries are, on the N. the river Loire, on the S. the Cher, on the E. the districts of Sancerre and Berry. The Sologne is included between the Béarnais, tributary of the Loire, and the Saundre, an affluent of the Cher, all three having a west-south-westerly direction. The pools and marshes which are characteristic of the region are due to the impermeability of its soil, which is a mixture of sand and has been greatly mitigated since the middle of the 19th century, when Napoleon III. led the way in the reclamation of swamps, the planting of pines and other trees and other improvements. Arable farming and stock-raising are fairly flourishing in the Sologne, but there is little manufacturing activity, the cloth manufacture of Romorantin being the chief industry. Game is abundant, and the region owes much of its revived prosperity to the creation of large sporting estates.

SOLOLA, the capital of the department of Sololá, in Guatemala; on the northern shore of lake Atitlán, 46 m. W.N.W. of Guatemala city. Pop. (1905), about 17,000. Sololá is the ancient capital of the Cakchiquel Indians, who form the bulk of the population. In the city coarse cloth, pottery, cigars and an orange market are manufactured, and there is a large prison and reformatory. Among the surrounding mountains are large and successful coffee plantations, owned by German settlers. On the 18th of April 1902 Sololá was wrecked by an earthquake, but as most of the houses were constructed of wood it was speedily rebuilt.

SOLOMON (10th century B.C.), the son of David by Bathsheba, and his successor in the kingdom of Israel. The many floating and fragmentary notes of various dates that have found a place in the account of his reign in the book of Kings (a.t.) show how much Hebrew tradition has been in the book of the monarch under whom the throne of Israel reached its highest glory; and that time only magnified in popular imagination the proportions of so striking a figure appears from the opinions entertained of him in subsequent writings. The magnificence and wisdom of Solomon (cf. Matt. vi. 29; Luke x. 31) and the splendour of his reign present a vivid contrast to the troublous ages which precede and follow him, although the Biblical records prove, on closer inspection, to contain so many incongruous elements that it is very difficult to form a just estimate of his life and reign. There are of all God's people which shone with the glory of the kingdom and the royal succession, and the palace of the king was completed (contrast the summary notices, 1 Kings xxii. 41 seq., 2 Kings xv. 1, xxi. 24, xxiv. 18, &c.). He was not the true heir to the throne, but was the son of David by Bathsheba, wife of Uriah the Hittite, whom David sent to his death in the forefront of the battle. The child of the illegitimate union died; the second was called Jedidiah ("beloved of Yah [well]") or Shélohôm (the idea of requital or recompense may be implied); according to 1 Chron. iii. 5, on the other hand, Solomon was the fourth, or rather the fifth, child of Bathsheba and David. The episode forms the prelude to family rivalries. David's son, Amnon, killed his own half-brother, Absalom, who lost his life in his revolt (2 Sam. xiii.—xx.). The second, Chileab, is not mentioned in the history, and the fate of the fourth, who regarded himself as the future king, is described in 1 Kings i., ii. Bathsheba, relying upon David's promise that Solomon should succeed him, vigorously advanced her son's claims with the support of Zadok the priest, the military officer Beniah, and David's bodyguard; Adonijah, for his part, had David's old priest Abiathar, the commander Joab, and the men of Judah. A more serious breach could scarcely be imagined. The adherents of Solomon gained possession of the throne, and he was crowned, not, however, without bloodshed. Solomon's age at his accession is not recorded. The tradition that he was only twelve (1 Kings ii. 12 Septuagint; or fourteen, Jos. Ant. viii. 7, 8) may rest upon iii. 7 ("I am but a little child"); if it is not hyperbole, it is far from chronologically embodied in 2 Sam. xii. 23, 38, xiv. 28, xxv. 7. It agrees with his subordinate position in portions of ch. i., but his independent actions in ch. ii. suggest a more mature age, and according to xl. 42, xlv. 21, xv. 10 Solomon was already born (but contrast again xii. 24 Septuagint, 2 Chron. xiii. 7). See further, Ency. Bib. col. 4681, n. 5.

1 Heb. Shléômôh, as though "his peace"; but the true meaning is uncertain; evidence for its connexion with the name of a god is given by H. Winckler and Zimmermann, Keilschr., u. das Alte Test., 3rd ed., pp. 224, 474 seq. The English form follows the 20th edition of the Latin Solome agrees with Sélome (one of several variant forms given in MSS. of the LXX.).
The acute observation that 2 Sam. ix.—xx.; 2 Kings i. ii. 9, 13 sqq., were evidently incorporated after the Deuteronomical re- 
duction of the books of Samuel (K. Budde, Samuel, p. xi.) is con- 
firmed by the form of certain numerals and their finitiae, which are 
similar to that preserved in 2 Sam. v.—viii., xxii.—xxiv.; 1 Kings 
ii. 10—12. With this may belong iii. 3 (the compiler's judgment); and 
especially v. 3 sqq., where reference is made to David's incessant 
warfare against his subjects (see 2 Sam. ii. 2—iv. 19), which has 
been omitted by the Deuteronomical redactor himself (Budde) cannot 
be proved. These post-Deuteronomical narratives preserve older 
material, but with several insertions from later prophetic and 
historic traditions of David's reign and the rise of Solomon 
(see I. Benzinger's commentary on Kings, p. xi.; C. Holzhey, Buch 
d. Könige, p. 17). The latter, however, is their present aim, and 
some of the material which has been made in them to exculpate 
one whose accession finds a Judaean parallel in Jehoram (2 Chron. 
xxi. 1—4). Thus it has been held that David's charges (ii. 1—9) 
were written to absolve Solomon, and there is little probability in 
the view that they are to be spliced into his present history. Of 
Abishag (ii. 13—25), since in Oriental ideas this would be at once 
viewed as a direct encroachment upon Solomon's rights as heir 

Every emphasis is laid on the wisdom of Solomon and his kingdom. Yahweh appeared to Solomon in a dream and offered to 
grant whatever he might ask. Confessing his inexperience, the 
king prayed for a discerning heart, and was rewarded with the 
gift of wisdom together with riches and military glory.

There follows an example of his sagacity: the famous story of the 
steps he took to determine which of two claimants was the 
mother of a child (iii. 16—28). His wisdom excelled that of 
Egypt and of the children of the East; by the latter he meant 
Babylonia, or more probably the Arabs, renowned through 
all ages for the richness of their wisdom. Additionally, he 
manifested his superiority over four renowned 
sages, sons of Mahol; but the allusion to these worthies (who 
are incorporated in a Judaean genealogy, 1 Chron. ii. 6) is no 
longer intelligible. He is also credited with an interest in 
botany and natural history (iv. 33), and later Jewish legend 
improved this by ascribing to him lordship over all beasts 
and birds and the power of understanding their speech. To 
it added the sovereignty over demons, from a wrong 
interpretation of Eccles. ii. 8 (see Lane, Arabian Nights, introd., 
n. 21, and ch. 1, n. 25). As his fame spread abroad, people 
came to hear his wisdom, and their costly presents were 
showered upon him. The sequel was the visit of the Queen of Sheba 
(1 Kings iv. 20—34; x.). The interesting narrative appears in 
another light when we consider Solomon's commercial activity 
and the trading intercourse between Palestine and south 
Arabia. His wealth was in proportion to his wisdom. 
Trading journeys were conducted with Phoenician help to 
Ophir and Tarshish. With the horse-breeding districts of the north 
he traded in horses and chariots (x. 28 sqq.; see MIZRAIM), and gold 
accumulated in such enormous quantities that the income for 
one year may be reckoned at about £4,100,000 in weight (x. 11 
seq., 14 sqq.). Silver was regarded as stones; the precious 
cedars of Lebanon as sycamores. His realm extended from 
Taphispa (Thapsacus) on the Euphrates to the borders of Egypt (iv. 21, 24), 
and it agrees with this that he gains important conquests in the 
north (2 Chron. viii. 3 sqq.; but see 1 Kings ix. 18). He 
maintained a very large harem (xii.), and among his wives was 
the daughter of an Egyptian Pharaoh. For his distinguished 
court, which brought Gezer as a dowry, a special palace was built 
(ii. 1, ix. 16, 24), and this was only one of many building enter- 
prises.

The description of the magnificent temple of Jerusalem, 
with its glowing parallels, see E. Reitzenstein in Hastings's Dict. Bib., iv. 562, n. 1. 
For the Pompeian wall-painting representing Solomon's judgment 
(the figures are pygmies), see A. Jeremias, Altes Text. im Lichte d. alt. Orteis 2nd ed., p. 492 seq. (with illustration and references).

The building of the temple of Solomon, the hoard and 
the queen of Sheba, see the Koran, Sur. xxvii., which closely follows 
the second Targum to Esther i. 2, where the Jewish fables may 
read in full. On this story, see also J. Halévy, École pratique 
des hautes langues, ii. 246 sqq. Additional point is 
made by emphasizing his superiority over 

Solomon, which occupies considerable space in Solomon's history (v.— 
iii.), appears in more elaborate form in the chronicler's later 
work. The detailed record stands in contrast to the brief 
account of his other buildings, e.g. the palace, which, from 
an Oriental point of view, was of the first importance (vii. 1—12). 
But the Temple and palace were adjoining buildings, separated 
only by a wall (cf. Ezek. xiii. 20, xliii. 7 seq.), and it cannot 
be said that the former had originally the prominence now ascribed 
to it. Nor can the accounts given by Deuteronomical writers 
for an estimate of contemporary religion (v. 1—6, vii.). Whatever 
David had instituted at Jerusalem, it is at Gibeon 
that Solomon observed the opening sacrificial ceremonies, 
and there he received the divine revelation, "for that was the 
great high-place" (i. 4 sqq.). Though this is justified by a late 
writer (iii. 2), subsequent history shows that the high-places, 
like the altars to heathen deities in Jerusalem itself, long 
remained undisturbed; it was the Deuteronomical reformation, 

which is laid upon the Jerusalem Temple to be associated 
with the accession of the new superiority of Zadok, the traditional ancestor of the 
Zadokites, the Jerusalem priests, whose supremacy over the other 
Levitical families now enters into the history of a much later 
age (see Levites).

In fact, Solomon, the pious saint, is not the Solomon of the 
earlier writings. Political, commercial and matrimonial alli-
ances inevitably left their mark upon national religion, and the 
introduction of foreign cults which ensued is characteristically 
viewed as an apostasy from Yahweh of which he was guilty in 
his old age. The Deuteronomist writer finds in it the cause 
of the subsequent separation of the two kingdoms (xi. 1—3), 
and he connects it with certain external troubles which prove 
to have affected the whole course of his reign. The general 
impression of Solomon's position in history is in fact seriously 
disturbed when the composite writings are closely viewed. 
On the one side we see genial internal conditions prevailing in 
the land (iv. 20, 25), or the exalted position of the Israelites as 
officials and overseers, while the remnant of the pre-Israelite 
inhabitants serve in labour gangs (ix. 20 seq.). On the other 
hand is the mass of tolerable Israelites, whose oppressed condition 
was a prelude to the later dissensions (1 Kings xi. 13—25). Solomon 
(see the description of the throne in 2 Chron. ii.). The description of Solomon's administration 
not only ignores the 

tribal divisions which play an important part in the separation 
of Israel from Judah (xii. 16; cf. 2 Sam. xix. 43—xx. 2), but 
represents a kingdom of modest dimensions in which Judah 
apparently is not included. Some north Judaean cities might 
be named (iv. 9 seq.), but south Judah and Hebron the seat of 
David's early power find no place, and it would seem as though 
the district which had shared in the revolt of Adonijah was 
freed from the duty of furnishing supplies. But the document 
has intricate textual peculiarities and may be the 

adaptation of a list originally written from the standpoint of 
the north-Israelite monarchy. Further speculation is 
caused when it is found that Solomon fortifies such cities as Megiddo, 
Beth-horon and Tamar, and that the Egyptian Pharaoh had 
slain the Canaanites of Gezer (ix. 15 sqq.). We learn, also, that 
Hadad, a young Edomite prince, had escaped the sanguinary 
campaign in the reign of David (2 Sam. viii. 13 seq.), and had 
taken refuge in Egypt. He was kindly received by the Pharaoh, who 
gave him the sister of his queen Tahpenes to wife. On David's 
death he returned and ruled over Edom, thus not merely 
controlling the post of Edath as the trade-routes, but even 
the very title of the Septuagint opposing Israel (xi. 14—22, 25, 
see Septuagint on v. 22). Moreover, an Aramaean dependant 

on the relation between trade and religion in old Oriental life, 
see the valuable remarks by G. A. Smith, Ency. Bib. col. 157 seq. 
The narrative contains composite features (see the literature 
cited at the end of the article King6). There is a curious resemblance between 

one form of the story and the Septuagint account of the rise of 
Jeroboam (q.v.).
SOLOMON ISLANDS

of Hadadezer, king of Zobah, to the north of Palestine (see David’s war, 2 Sam. viii. 3 sqq., x. 6 sqq.), deserted his lord, raised a band of followers and eventually captured Damascus, where he established a new dynasty. Like Hadad, “he was an adversary to Israel all the days of Solomon” (x i. 23-25). To these notices must also be added the cession of territory in north Palestine to Hiram, king of Phoenicia (ix. 11). It is parenthetically explained as payment for building materials, which, however, are otherwise accounted for (v. 6, 11); or it was sold for 120 talents of gold (nearly £750,000 sterling), presumably to assist Solomon in continuing his varied enterprises—but the true nature of the transactions is both obscure, and consequently the cession involved in the loss of the territory is unattakable. If these situations can with difficulty find a place in our picture of Solomon’s might, it is clear that some of them form the natural introduction to the subsequent history, when his death brought internal discontent to a head, when the north under Jeroboam refused allegiance to the south, and when the divided monarchy enters upon its eventual career by the side of the independent states of Edom, Damascus and Phoenicia.

It is now generally recognized in histories of the Old Testament that a proper estimate of Solomon’s reign cannot start from narrative or religious materials. The Hebrew accounts of his conduct, although, in so far as late narratives may rest upon older material more in accordance with the circumstances of their age, attempts are made to present reconstructions from a combination of various elements. Among the recent critical attempts to recover the underlying traditions may be mentioned those of T. K. Cheyne (Enyc. Bib., art. “Solomon”) and H. Winckler (Kelt.-tischr. u. d. Allc Test., 3rd ed., pp. 233 sqq.). But, in general, where the traditions are manifestly in a later form they are in agreement with later backgrounds, and it is questionable whether earlier forms can be satisfactorily recovered. When it is held that they have been rewritten or when the historical kernel has been buried in legend or myth. It is impossible to be struck with the growing development of the Israelite tribes after the invasion of Palestine, their strong position under David, the sudden expansion of the Hebrew monarchy under Solomon, and the subsequent slow decay, and this, indeed, is the picture as it presented itself to the last writers who found in the glories of the past both consolation for the present and grounds for future hopes. But this is not the original picture, and, since very contradictory representations of Solomon’s reign can be clearly discerned, it is necessary to base any historical evaluation of him upon independent examination of the history of the preceding and following periods where, again, serious fluctuation of standpoint is found. Much therefore depends upon the estimate which is formed of the position of David (q.v.). See also Jews: History, § 7 seq.; Palestine: Old Testament History.

Solomon’s relation to philosophical and proverbial literature, see Proverbs. Another aspect of his character appears in the remarkable “Song of Solomon,” on which see Canticles. Still another phase is represented in the monologue of Ecclesiastes (q.v.). In the Book of Wisdom, again the composition of an Egyptian Hellenist, who from internal evidence is judged to have lived somewhat earlier than Philo, Solomon is introduced uttering words of admonition, imbued with the spirit of Greek philosophers, to heathen sovereigns. The so-called Psalter of Solomon, of the other early Christian Papyrus, preserved in Hebrew soon after the taking of Jerusalem by Pompey, and preserved to us only in a Greek version, has nothing to do with Solomon or the traditional conception of his person, and seems to owe its name to a transcriber who thus distinguished these newer pieces from the older “Psalms of David” (see Solomon, Psalms of). (S. A. C.)

SOLOMON ISLANDS (Ger., Salomonsinseln), an archipelago of the Western Pacific Ocean, included in Melanesia, and forming a chain (in continuation of that of the Admiralty Islands and New Mecklenburg in the Bismarck Archipelago) between 14° 50’ and 14° 30’ S. and 160° and 166° E., with a total land area of 17,000 sq. m. (For map, see Pacific Ocean.) A comparatively shallow sea surrounds the islands and indicates physical connexion with the Bismarck Archipelago and New Guinea, whereas directly east of the Solomons there are greater depths. The principal island at the north-west end of the chain is Bougainville (12,000 sq. m.), and that at the south-east San Cristoval or Bauro. Between these the chain is double, consisting (from the north-west) of Choiseul (2260 sq. m.), Isabel (Ysabel, of about the same area as Choiseul) and Malaita (2400 sq. m.) to the north, and Vella Lavella, Ronogo, Kolambangra, Kausagi, Marovo (New Georgia or Rubiana) and the Hammond Islands, and Guadalcanal or Guanabata (2500 sq. m.). Between and around these main islands there are many smaller islands. Ongong Java, a coral reef of many islets, lies considerably north of the main group to which, generally speaking, it can hardly be said to belong. Guadalcanal, the largest of the group, contains Mt Balbi (10,170 ft.), and two active volcanoes. In Guadalcanal is Mt Lamiarn (3000 ft.), while the extreme heights of the other islands range between 2500 and 5000 ft. The islands (by convention of 1899) are divided unequally between Great Britain and Germany, the boundary running through Bougainville Strait, so that that island and Buka belong to Germany (being officially administered from Kaiser Wilhelm’s Land), but the rest (South Solomons) are British.

The islands are well watered, though the streams seem to be small; the coasts afford some good harbours. All the large and some of the small islands appear to be composed of ancient volcanic material and lie east of the main island chain. Off the east coast of Bougainville there is a gap in the mountains which runs down to the sea, terminating frequently in bold rocky headlands 800 to 1000 ft. in height, as in San Cristoval (north coast). On the small high island of Florida there is much uncultivated grass-land interspersed with fine clumps of trees; patches of cultivated land surround its numerous villages, and plantations on the hill-sides testify to the richness of its soil. The whole chain of islands appears to be fringed by coral reefs. Some of the smaller islands are of recent calcareous formation. Barrier and fringing reefs, as well as atolls, occur in the group, but the channels between the islands are dangerous chiefly from the strong currents which set through them. The climate is very damp and debilitating. The rainfall is unusually heavy. Fever and ague prevail on the coast. The healthiest portions are the highlands, where most exposed to the south-east trades. The dry season, with north-west winds, lasts from December to May. Vegetation is luxuriant; magnificent forests clothe the mountains, and sandwood, ebony and lignum vitae, besides a variety of palms, are found in them. Mangrove swamps are common on the coasts. The probable geological connexion with New Guinea would account for the Papuan character of the fauna of the Solomons, which form the eastern limit of certain Papuan types. The existence of peculiar types in the Solomons, resembling the Papuans but different from them in many respects, they include the cusкус, several species of bat, and some rats of great size. There are various peculiar species of frogs, lizards and snakes, including the great frog Rana Guppy, from 3 to 3 1/2 lb. in weight. Of birds, cuculs and other genera characteristically Papuan and are unknown east of the Solomons.

Population.—The Solomon islanders are of Melanesian (Papuan) stock, though in different parts of the group they vary considerably in their physical characteristics, in some islands approaching the pure Papuan, in some showing Polynesian crossings and in others resembling the Malays. As a race they are small and sturdy, taller in the north than in the south. Projecting brows, deeply sunk dark eyes, short noses, either straight or broad and arched; rounded or moderately thick lips, with a somewhat receding chin, are general characteristics. The mesocephalic appears to be the preponderant form of skull; though this is unusual among Melanesian races. In colour the skin varies from a black-brown to a copperish hue, but the darker are the most common shades. The hair is naturally dark, but is often dyed red or fawn, and crisp, inclining to woolly. The islanders of the Bougainville Straits have hair almost straight, black hair and very dark skins.

The islanders are very treacherous. They are cannibals, infanticide is common, and head and body markings. Strangers the natives have long had the reputation of being treacherous. They are cannibals, infanticide is common, and head and body markings. Strangers the natives have long had the reputation of being treacherous. They are cannibals, infanticide is common, and head and body markings.
SOLOMON, ODES OF—SOLOMON, PSALMS OF

hunting was formerly prevalent. The average lot of the women is that of slaves. In some cases there is belief in a good spirit inhabiting a pleasant land, and an evil spirit associated with a volcanic island called Ysabel. The language is of the Austronesian type, though a number of dialects are spoken. The natives are good agriculturists. The Solomon Islands are, in the Pacific, the eastern limit of the use of the shield. The canoes are skillfully built of plants sewn together. The Melanesian canoes, with some cocoa and coffee, are cultivated on small areas. The German islands have a small trade in sandalwood, tortoise-shell, &c. The total population may be roughly estimated at 180,000.

History.—The Spanish navigator Alvaro Mendaña must be credited with the discovery of these islands in 1567, though it is somewhat doubtful whether he was actually the first European who set eyes on them. In anticipation of their natural riches he named them Islas de Salomon. The expedition surveyed the southern portion of the group, and named the three large islands San Cristoval, Guadalcanal, and Ysabel. On his return Mendaña endeavoured to organize another expedition to colonize the islands, but it was not before June 1595 that he, with Pedro Quiros as second in command, was able to set sail for this purpose. The Marquesas and Santa Cruz islands were discovered; but on one of the latter, after various delays, Mendaña died, and the expedition collapsed.

Even the position of the Solomon Islands was now in uncertainty, for the Spaniards, fearing lest they should lose the benefits expected to accrue from these discoveries, kept secret the narratives of Mendaña and Quiros. The Solomon Islands were thus lost sight of until, in 1767, Philip Carteret lighted on their eastern shores to the north of a large island, and passed to the north of the group, without, however, recognizing that it formed part of the Spanish discoveries. In 1768 Louis de Bougainville found the way thither. He discovered the three northern islands (Buka, Bougainville and Choiseul), and sailed through the channel which divides the two last and bears his name. In 1769 a French navigator, M. de Surville, was the first, in spite of the hostility of the natives, to make any lengthened stay in the group. He gave some of the islands the French names they still bear, and brought home some detailed information concerning them, which has been of the greatest use in the later development of the history of the group; but their identity with Mendaña’s Islas de Salomon was soon established by French geographers. In 1778 the English lieutenant Shortland coasted along the south side of the chain, and supposing it to be a continuous land, named it New Georgia; and in 1792 Captain Edward Manning sailed through the strait which separates Ysabel from Choiseul and now bears his name. In the same year, and in 1793, d’Entreccasteaux surveyed portions of the coast-line of the large islands. Dumont d’Urville in 1838 continued the survey.

Traders now endeavoured to settle in the islands, and missionaries began to think of this fresh field for labour, but neither met with much success, and little was heard of the islanders save accounts of murder and plunder. In 1845 the French Marist Fathers went to Isabel, where Mgr. Epauille, first vicar-apostolic of Melanesia, was killed by the natives soon after landing. Three years later this mission had to be abandoned; but in 1851 work was again resumed. In 1856 John Coleridge Patteson, afterwards bishop of Melanesia, had paid his first visit to the islands, and native teachers trained at the Melanesian mission college subsequently established themselves there. About this date the yacht “Wanderer” cruised in these seas, and her owner, Mr Benjamin Boyd, was kidnapped by the natives and never afterwards heard of. In 1873 the “foreign-labour” traffic in plantation hands for Queensland and Fiji extended its baneful influence from the New Hebrides to these islands. In 1893 the islands Malaita, Marovo, Guadalcanal and San Cristoval, with their surrounding islets were annexed by Great Britain, and the final delimitation of German and British influence in the archipelago was made by the convention of the 14th of November 1890.

See H. B. Guppy, The Solomon Islands (London, 1887), where full references to earlier works are given; C. Ribbe, Zwei Jahre unter den Kainabilen der Solomons-Inseln (Göttingen, 1889).

SOLOMON, ODES OF, a collection of 42 hymns, probably dating from the end of the 17th century, known to the early Christian Church (as is proved by the quotations and comments in the 3rd century gnostic book, Pistis Sophia, and a short extract in the Institutes of Lactantius). They were recovered by Dr Ryzen in 1908 from a 16th-century Syriac manuscript (containing also the Psalms of Solomon, see below) in his possession.

The first and second psalm are the simplest and shortest, but the first has been restored from the Pistis Sophia. Of their authorship nothing is known, “Solomon” being a recognized pseudonym. While there are thoughts and expressions which lend themselves to gnostic use, there is nothing in the odes which is of distinctively gnostic origin. Many of them, indeed, are unmistakably Christian, and the writer of the Pistis Sophia seems to have regarded them as almost if not quite canonical, a fact which securest at latest a 2nd-century origin.

Dr Harris indeed would date several of them between A.D. 70 and 100. They contain few traces of the New Testament, and none of the “gospel of the church” as later used, although there a Johannine atmosphere is detected, though not sufficiently to justify the assumption that the author knew the writer of the Fourth Gospel. References to the life and teaching of Christ are rare, though the Virgin Birth is alluded to in Ode 19 in a passage marked by legendary embellishment, and the descent into Hades is spoken of in quite the apocalyptic style in Ode 42. These odes are probably among the latest in the book. There are no clear allusions to baptism and none at all to the eucharistic celebration. One passage speaks of ministers (perhaps—deacons) who are entrusted with the water of life to hand to others;” the words “minister” occurs in the translation of Ode 20, “I am a priest of the Lord, and to Him I do pledge service, and to Him I offer the sacrifices of His thought.”

The odes, which are perhaps the product of a school of writers, and were originally written in Greek, vary in execution and spiritual tone, but are generally characterized by a buoyant feeling of Christian joy. Harnack considers that they form a Jewish Grundschrift, with a number of Christian interpolations; only two are “purely Christian,” while several “colourless” ones are more likely Jewish. He finds in them a link between the piety and theology of the Testaments of the Twelve Patriarchs, that of the Johannine gospel and epistles.

See J. Rendel Harris, The Odes and Psalms of Solomon (1909); An Early Christian Psalter (1909); Joh. Flemming and A. Harnack, Ein jüdisch-christliches Psalmbuch aus dem ersten Jahrhundert (Leipzig, 1910); The Times (April 7, 1910); W. E. Barnes, in Journal of Theol. Studies, xi. 615, and The Expositor (July 1910); F. Spitta, in Zeitschrift für NT. Wissenschaft, xi. 193.

SOLOMON, PSALMS OF. These psalms, eighteen in all, enjoyed but small consideration in the early Christian Church; for only six direct references to them are found in early Christian literature, though in the Jewish Church they must have played an important rôle; for they were used in the worship of the synagogue.

They were of course not written by Solomon, but were subsequently ascribed to him. The fact that they do not contain a single reference to Solomon is in favour of their having been first published anonymously. On the other hand, their author (or authors) may have placed over them the superscription “Psalms of Solomon” in order to gain currency for this new collection under the shelter of a great name of the past.

MSS. AND TEXTS.—Before the publication of Sweet’s second edition and the edition of von Golzhardt, only five MSS., A, H, V, M, P (of which H represents the Copenhagen MS.) were known, and these were utilized to the full in the splendid edition of Ryle and Ham’s (Wahld Theologian, Psalms of the Psalters commonly called the Psalms of Solomon, the text newly revised from all the MSS., 1891). In Swete’s edition (The Old Testament in Greek, 1894) there was given in addition to the above a collation of the Vatican
Thus H is the only MS. common to this edition and that of Rylands; for Gebhardt regards the secondary MSS. V, M, P as not so much a firmer critical training for the student in the textual discussions and retrievings in the latter edition than in the former.\footnote{In addition to Ryle and James, \textit{Introduct. pp. lxxvii.-lxxxvii.}, see Pericles, \textit{Die Erklärung der Psalm. Sal.} \textit{(Oriental. Literaturzeitung,} \textbf{102}, \textit{v. 7-10).}}

**Translations.**—Wellhausen, \textit{Die Pharisäer und die Sadducäer} (1874), \textit{132 sqq.} This translation is unfortunately based on the \textit{edito princeps} of De La Cerdra published in 1826. Pick's translation, which appeared in the \textit{Presbyterian Review} for October 1883, pp. 778-813, is based on the same text and is imperfect owing to a faulty knowledge of English. Ryle and James (op. cit.), Kittel's translation (Kautsch, \textit{Apokr. u. Pseudep. i.} 1900, ii. 127 sqq.) was made from Gebhardt's text.

**The Original Language.**—All modern scholars are practically agreed that the Psalms were written in Hebrew. It is unnecessary to enter into this question here, but a point or two might be mentioned which call for such a presupposition. (i.) First we find that, after the manner of the canonical Psalms, the musical symbol διάφαλον (57) is inserted in xvii. 31 and xviii. 10, a fact which points to their use in the divine worship in the synagogue. (ii.) Next we find that a great number of passages cannot be understood unless by retroversion into Hebrew, when the source of the error becomes transparent. One of the most instructive is in li. 16: \textit{εἰς τὰ δάκρυα πάντων ἄνθρωπων} θεῦ. Here εἰκόν, which is utterly meaningless, =σπα in a corruption of τοῖς εἰκόν to "change," "turn" (Wellhausen). Thus we arrive at the sense required, "To turn the pride of the dragon into dishonour." (iii.) Finally, there are several passages where the text exhibits the future tense, when it ought to give the past imperfect. This phenomenon can easily be explained as a false rendering of the Hebrew imperfect.\footnote{Thus is the only MS. common to this edition and that of Rylands; for Gebhardt regards the secondary MSS. V, M, P as not so much a firmer critical training for the student in the textual discussions and retrievings in the latter edition than in the former.}

**Date.**—The date can be determined from references to contemporary events. Thus the book opens with the alarms of war (i. 2, viii. 1), in the midst of a period of great prosperity (i. 3, 4, viii. 7), but the prosperity is merely material, for from the king to the vilist of his subjects they are altogether sinful (xvii. 21, 22). The king, moreover, is no descendant of David, but has usurped his throne (xvi. 6-8). But judgment is at hand. "A mighty striker" has come from the ends of the earth (16), who when the princes of the land greeted him with words of welcome (viii. 18), seized the city (viii. 21), cast down its walls (ii. 1), polluted its altar (ii. 2), put its princes and counsellors to the sword (viii. 23), and carried away its sons and daughters captive to the west (viii. 24, xvii. 14). But the dragon who conquered Jerusalem (ii. 29), and thought himself to be more than man (ii. 32, 33), at last meets with shameful death on the shores of Egypt (ii. 30, 31).

The above allusions are easy to interpret. The usurping kings who are not descended from David are the Maccabees. The "mighty striker" is Pompey. The princes who welcomed his approach are Aristobulus II. and Hyrcanus II. Pompey carried off princes and people to the west, and finally perished on the coast of Egypt in 48 B.C. Thus Ps. ii. was written soon after 48 B.C., while Ps. i., viii., xvii. fall between 63 and 48 B.C., for they presuppose Pompey's capture of Jerusalem, but show no knowledge of his death. Ps. v., vii., ix., xiv., xv.

...belong apparently to the same period, but iv. and xii. to an earlier one. On the whole Ryle and James are right in assigning 70-26 B.C. as the date when the psalms were written.

**Authorship.**—The authors were the Pharisees. They divide their countrymen into two classes—"the righteous" (ii. 38-39, iii. 5-7, 8), and "the sinners" (ii. 38, iii. 13, iv. 9), "the saints" (iii. 10) and "the transgressors" (iv. 11). The former are the Pharisees; the latter the Sadducees. The authors protest against the Asmonaean (i.e. the Maccabeans) for usurping the throne of David and laying violent hands on the high priesthood (xvii. 5, 6, 8), and proclaim the coming of the Messiah, the true son of David (xvii. 23-25), who is to set all things right and establish the supremacy of Israel. The Messiah is to be pure from the first (xvii. 21, 22), and to be the heir of the throne of sinners and of the Gentiles (xvii. 29, 30, 36), destroy the hostile nations and extend his righteous rule over all the remaining peoples of the earth (xvii. 27, 31, 32, 34, 38).\footnote{Ps. xvi., xviii. and i.-xvi. can hardly be assigned to the same authors. The hopes of the Messiah are confined to the former, and a somewhat different eschatology underlies the two works (see Charles, \textit{Eschatology: Hebrew, Jewish and Christian,} 220-223).}

In addition to the literature mentioned above, also in Ryle and James' edition and Schr"{o}er, \textit{Gesch. des jüd. Volkes}, 3rd ed., ii. 150 sqq, see \textit{Encyc. Bib.}, i. 241-245.

**SOLON** (7th and 6th century B.C.), Athenian statesman, the son of Exceldites of the family of Codrus, was born about 658 B.C. The prodigality of his father made it necessary for Solon to maintain himself by trade, especially abroad. In his youth he became well known as the author of several works of patriotic and didactic verse. Hence his inclusion among the Seven Sages. Solon's first public service was the recovery of Salamis from the Megarians. A law had been passed forbidding any reference to the loss of the island; Solon solved the difficulty by feigning madness, and reciting an inflammatory poem in the agora. It appears that Solon was appointed to recover the "fair island" and that he succeeded in expelling the Megarians. Sparta finally arbitrated in favour of the Athenians (c. 590), who ascribed their success to Solon. About a year later he seems to have moved a decree before the Amphictyons declaring war on Cirrha. At this period the distress in Attica and the accumulating discontent of the poorer classes, for whom Draco's code had proved inadequate, reached its height. Solon was summoned by all classes unanimously to discover a remedy; under the legal title of Archon, he received unlimited powers which he exercised in economic and constitutional reforms (see below). From various sources we learn that these reforms met with considerable opposition, to escape from which Solon left Athens for ten years. After visiting Egypt, he went to Cyprus, where Philocypres, king of Cyprea, received him with honour. Herodotus (v. 113) says that Philocypres, on the advice of Solon, built himself a new town called, after his guest, Soli. The story that Solon visited Creousus in Lydia, and made to him the famous remark—"Call no man happy till he is dead!"—is unfortunately discredited by the fact that Croesus seems to have become king nearly thirty years after Solon's legislation, whereas the story must be dated within ten years of it. Subsequently Solon returned to Athens, to find civil strife renewed, and shortly afterwards his friend (perhaps his relative) Peisistratus made himself tyrant. About 558 B.C. Solon died, and, according to the story in Dionnes Laëritius i. 63 (but see Plutarch's \textit{Solon}, 32), his ashes were scattered round the island of Salamis. If the story is true, it shows that he was regarded as the oecist of Salamis.

**Reforms.**—The date of Solon's archonship has been usually fixed at 594 B.C. (\textit{Ol.} 46. 3), a date given by Diog. Laërt. (i. 62) on the evidence of the Rhodian Sociocrates (\textit{fl.} 200-128 B.C.; see Clinton, \textit{Past. Hist.} ii. 298, and Busolt, 2nd ed., ii. 259). The date 593 is confirmed by statements in the Aristotelian \textit{Constitution of Athens} (ch. 14). For various reasons, the dates 592, 591, and 590, allusive to the right conception of the Messiah is vigorous, but the influence of such a conception was hurtful; for by connecting the Messianic with the popular aspirations of the nation, the former were secularized and the way prepared for the ultimate destruction of the nation.
the land was in the hands of a few." It should be noted (1) that from this releasing of the land it follows that Solon's law against the mortgaging of land remained secure (i.e. in order to provide a sufficient number of freeholders for the land released); (2) that it is one of the most remarkable facts in the history of democracy, that when a monarchical power, as in the Persian War a proposal was brought forward to limit the franchise to freeholders, it was found that only five thousand failed to satisfy this requirement.

B. Constitutional Reforms.—It is on this part of his work that Solon may be considered a great statesman is founded. By his new constitution he laid the foundations of the Athenian democracy and paved the way for its later developments. It should be noted that the first new law which Solon's accounts (written on the assumption that the Draconian constitution described in chapter iv. of the Constitution of Athens had never existed (see Draco). In some respects that alleged constitution is more elemental than Solon's; but with Solon, who had always spoken of as the founder of the democracy, is one of the strongest reasons for rejecting the Draconian constitution. It will be seen that Solon's state was by no means a perfected democracy, but it was classified in terms of the existing social contrary, to which the introduction of a sliding scale of taxation. Against this, it is known that Peisistratus, whose faction was essentially the poorer classes, established a uniform 5% tax, and it is highly unlikely that he would have reversed an existing arrangement which was particularly beneficial to his family. The Athenian assembly of the Thetes to the Ecclesia was an important step in the direction of democracy (for the powers which Solon gave to the Ecclesia, see IG II 2 3 1254). But the principle was still secondary and the institution of the Heliaea (or courts of justice). The jury were appointed by lot from all the citizens (including the Thetes), and thus the same people elected the magistrates in the Ecclesia must necessarily be considered as amongst the magistrates of the citizen as a whole. Further, as the archons, at the expiry of their year of office, passed into the areopagus, the people exerted control over the personnel of that body also (see Areopagus). In spite of the alleged Draconian constitution, alluded to above, it is still very generally held that Solon invented the Boule or Council of Four Hundred, one hundred from each of the old tribes as this body as an advisory committee of the Ecclesia, and the functions of the Prytaneis are explained under Boule. It is sufficient here to point out that, according to Plutarch's Solon, Solon was to state hereafter that Solon introduced the idea of giving the large landowners the right to exercise and that the large powers exercised by the Cleisthenic Boule were not exercised by the Solonian. From this, and the articles Areopagus, Boule, Ecclesia and Cretan Law, it will be seen that Solon contrived an absolute step to the years after Solon's constitution, which had in it the seeds of the great democratic growth which reached its maturity under Pericles. It should be added here, in reference to the election of magistrates under Solon's constitution, the last of the two chapters, the Politics and the Constitution; the latter says that Solon gave to the Thetes nothing but a share in the Ecclesia and the courts of justice, and that the former, if he were effective, would come to be considered as (diarchia to the contrary, whereas the Politics says that Solon gave them only the power to elect the magistrates and try them at the end of their year. It seems likely for other reasons that the former should be accounted from the year after Solon's time, that the account in the Politics is correct (but see Archon).

C. Miscellaneous.—The miscellaneous laws of Solon are interesting primarily as throwing light upon the social condition of Athens at the time (see Evelyn Abbott, History of Greece, 1. xiii. § 18).
In the matter of trade it has been said that he favoured one export only, that of olive oil, in which Athens was peculiarly rich; further he encouraged the settlement of aliens (meteors) on the mountain farms, and compelled fathers to teach their sons a useful trade under penalty of losing all right to support in old age. The influence of women Solon regarded as most pernicious. Wealth and position brought with more than three changes of raiment and a little light furniture to the brothels and gymnasia were put under stringent state-control (see Prostitution). Solon also regulated interstate succession, the marriage of adopted children, and simplified bee-farming, the planting of olives and figs, the cutting down of olive trees, the calendar. Further, he ordained that each citizen must show how he obtained his living (Herod. ii. 177) and must, under penalty of driving the foreigner out, have one or the other party in a sedition (for these laws see Plutarch's Solon, chs. 20–24).

The laws were inscribed on Kyreis or tablets framed in wood with a richly carved frieze (see ch. 12). They bore as a body to observe the laws, and each archon succeeded to set up a life-size golden statue at Delphi if he should be convicted of transgressing them.

Solon appears to have supplemented his enactments by a law that they should remain in force for one hundred years, and according to another account that his laws, though not the best, should stand unchallenged for ten years (Plut. Solon, 25; Herod. i. 25). Yet according to the Constitution of Athens (chs. 11–13) (without which the period from Solon to Peisistratus was a blank), when Solon went abroad in 593 B.C. the city was disturbed, and in the fifth year dissolution became so acute that no archon was elected (for the chronology of the ten archon elections see J. E. Sandys, Constitution, ch. 13, note); again four years later the same anarchia (i.e. no archon elected) occurred. Then four years later the archon Damastis (585) was set in office in an illegal manner, and the whole of Athens was agitated.

The office of the archon was then put into commission of ten: five from the Eupatrids, three from the Agroeci and two from the Demiurgi, and for twenty years the state was in a condition of strife. This may be seen in the twelve years of strife (owing to Solon's financial reforms) ended in the reversal of Solon's classification by assessment. We are, therefore, driven to conclude that the practical value of his laws was due to the strong and enlightened government of Peisistratus, whose tyranny put an end to the quarrels between the Shore, the Upland and the Plain, and the stasis of rich and poor.

With observations with notes of Constitution of Athens (q.v.); histories of Greece later than 1891 (e.g. Busolt, &c.). See also Gilliard, Quelques réformes de Solon (1907); Cavaignac, in Revue de Phil., 1908. All works anterior to the publication of the Constitution are so far out of date, but reference should be made to the work of Grote.

**SOLISTIC** (Lat. solstitium, from sol, sun, and sextere, to stand still), in astronomy either of the two points at which the sun reaches its greatest declination north or south. Each solstice is upon the equinoxial midway between the equinoxes, and therefore 90° from each. The term is also applied to the moment at which the sun reaches the point thus defined.

**SOLIST** (Lat. solistus, or solistus, an island town of Sicily, one of the three chief Phoenician settlements in the island, situated on the north coast, 10 m. E. of Panormus (Palermo), 600 ft. above sea-level, on the S.E. side of Monte Cattalafio (1225 ft.), in a naturally strong situation, and commanding a fine view. The date of its first occupation is, like that of Panormus, unknown. It continued to be a Carthaginian possession almost uninterrupted until the First Punic War, when, after the fall of Panormus, it opened its gates to the Romans. In the Roman period it seems to have been of no great importance; according to Strabo it was in the time of the Caesars a village of about 1000 houses. Cecilia, the wife of Caracalla, was bethought of there in 215. It was perhaps destroyed by the Saracens and is now entirely deserted. Excavations have brought to light considerable remains of the ancient town, belonging entirely to the Roman period, and a good deal still remains unexplored. An archaic oriental Artemis sitting between a lion and a panther; found here, is in the museum at Palermo, with other antiquities from this site. With the exception of the winding road by which the town was approached on the south, the streets, despite the unevenness of the ground, which in places is so steep that steps have to be introduced, are laid out regularly, running from east to west and from north to south, and intersecting at right angles. They are as a rule paved with slabs of stone. The houses were constructed of rough walling, which was afterwards plastered over; the natural rock is often used for the lower part of the walls. One of the largest of them, with a peristyle, is currently, though wrongly, called the Gymnasium. Near the top of the town are some cisterns cut in the rock, and at the summit is a larger house than usual, with mosaic pavements and paintings on its walls. (T. As.)

**SOLUTION** (from Lat. solvere, to loosen, dissolve). When a solid such as salt or sugar dissolves in water to form a uniform substance from which the components may be regained by evaporation the substance is called a solution. Gases too dissolve in liquids, while mixtures of various liquids show similar properties. Certain solids also consist of two or more components which are united so as to show similar effects. All these cases of solution are to be distinguished from chemical compounds, on the one hand, and from simple mixtures on the other. When a substance contains its components in definite proportions which can only change, if at all, by sudden steps, it may be classed as a chemical compound. When the relative quantities of the components can vary continuously within certain limits, the substance is either a solution or a mixture. The distinction between these two classes is not sharp; though when the properties of the resultant are sensibly the sum of those of the pure components, as is nearly the case for a complex gas such as air, it is usual to class it as a mixture. When the properties of the resultant are different from those of the components and it is not a chemical compound we define it as a solution.

**Historical.**—Solutions were not distinguished from definite chemical compounds till John Dalton discovered the laws of definite and multiple proportions, but many earlier observations on the solubility of solids in water and the density of the resulting solutions had been made. As early as 1788 Sir Charles Blagden (1748–1820) made measurements of the freezing points of salt solutions, and showed that the depression of freezing point was roughly proportional to the amount of salt dissolved. About 1850 Thomas Graham published his famous experiments on this subject both with and without a separating membrane. In 1860 botanical investigations by M. Traube, and in 1877 chemical experiments by W. Pfeffer, made known the phenomena of the osmotic pressure which is set up by the passage of solvent through a membrane impermeable to the dissolved substance or solute. The importance of these experiments from the physical point of view was recognized by J. H. van't Hoff in 1885, who showed that Pfeffer's results indicated that osmotic pressure of a dilute solution conformed to the well-known laws of gas pressure, and had the same absolute value as the same number of molecules would exert as a gas filling a space equal to the value of the solvent.

The conception of a semi-permeable membrane, permeable to the solvent only, was used by van't Hoff as a means of applying the principles of thermodynamics to the theory of solution.

Another method of applying the same principles is due to J. Willard Gibbs, who considered the whole problem of physical and chemical equilibrium in papers published in 1877, though the application of his principles only began to make extensive progress about twenty years after the publication of his purely theoretical investigations. The phenomena of solution and of vapour pressure constitute cases of equilibrium, and conform to the laws deduced by Gibbs, which thus yield a valuable method of investigating and classifying the equilibria of solutions.

**Solvility.**—Some pairs of liquids are soluble in each other in all proportions, but, in general, when dealing with solutions of solids or gases in liquids, a definite limit is reached to the amount which will go into solution when the liquid is in contact with excess of the solid or gas. This limit depends on the nature of the two components, on the temperature and on the pressure. When the limit is reached the solution is said to be saturated, and the system is in equilibrium. If the solution of a solid more soluble when hot be cooled below the saturation point, the whole of the solid sometimes remains in solution. The liquid is then said to be supersaturated. But here the conditions are different owing to the absence of solid. If a crystal of the solid be added, the condition of supersaturation is destroyed,
and the ordinary equilibrium of saturation is reached by precipitation of solid from solution.

The quantity of substance, or solute, which a given quantity of liquid or solvent will dissolve in presence of excess of the solute measures the solubility of the given solute in the conditions of temperature and pressure. The solubilities of solids may be expressed in terms of the mass of solute which will dissolve in 100 grammes of water.

The following may be taken as examples:

When dealing with gases it is usually more convenient to express the solubility as the ratio of the volume of the gas absorbed to the volume of the absorbing liquid. For gases such as oxygen and nitrogen dissolved in water the solubility as thus defined is independent of the pressure, or the mass of gas dissolved is proportional to the pressure. This relation does not hold for very soluble gases, such as ammonia, at low temperatures. As a general rule gases dissolve less soluble at a given temperature in the majority of solids. Thus oxygen, 4-89 volumes of which dissolve at atmospheric pressure in 1 volume of water at 0° C., only dissolves to the extent of 3-10 volumes at 20° and 1-70 volumes at 100°.

\[ \text{Cause of Solubility.} \quad \text{At the outset of the subject we are met by a fundamental problem which no complete answer can be given: Why do some substances dissolve in certain other substances and not in other substances? Why are some pairs of liquids miscible in each other in all proportions, while other pairs do not mix at all, or only to a limited extent? No satisfactory correlation of solubility with chemical or other properties has been made. It is possible to state the conditions of solubility in terms of the theory of available energy, but the result comes to little more than a re-statement of the problem in other terms. Nevertheless, such a re-statement is in itself sometimes an advance in knowledge. It is certain then that when dissolution occurs the available energy of the whole system is decreased by the process, while when equilibrium is reached and the solution is saturated the available energy is a minimum. When a variable quantity is at a minimum a slight change in the system does not affect its value, and therefore, when a solution is saturated, the increase in the available energy of the liquid phase produced by dissolving in it some of the solid must be equal to the decrease in the available energy of the solid phase, caused by the abstraction from the bulk of that part dissolved. The general theory of such equilibria will be studied later under the head of the phase rule.} \]

It is possible that a correlation may be made between solubility and the energy of surface tension. If a solid is immersed in a liquid a certain part of the energy of the system depends on, and is proportional to, the area of contact between solid and liquid. Similarly with two liquids like oil and water, which do not mix, we have surface energy proportional to the area of contact. Equilibrium requires that the available energy and therefore the area of contact should be a minimum, as is demonstrated in Plateau’s beautiful experiment, where a large drop of oil is placed in a liquid of equal density and a perfect sphere is formed. If, however, the energy of surface tension between the two substances were negative the surface would tend to a maximum, and complete mixture would follow. From this point of view the natural solubility of two substances involves a negative energy of surface tension between them.

Gibb’s Phase Rule.—A saturated solution is a system in equilibrium, and exhibits the thermodynamic relations which hold for all such systems. Just as two electrified bodies are in equilibrium when their electric potentials are equal, so two parts of a chemical and physical system are in equilibrium when there is equality between the chemical potentials of each component present in the two parts. Thus water and steam are in equilibrium with each other when the chemical potential of water substance is the same in liquid as in the vapour. The chemical potentials are clearly functions of the composition of the system, and of its temperature and pressure. It is usual to call each part of the system uniform composition throughout a phase; in the example given, water substance, the only component is present in two phases—a liquid phase and a vapour phase, and when the potentials of the component are the same in the phase equilibrium exists.

If in unit mass of any phase we have \( n \) components instead of one we must know the amount of \( n-1 \) components present in that unit mass before we know the exact composition of it. Thus if in one gramme of a mixture of water, alcohol and salt we are told that the weight of water in solution, we can tell the amount of alcohol. If, instead of one phase, we have \( r \) phases, we must find out the values of \( r(n-1) \) quantities in order to know the composition of the whole system. Thus, to investigate the composition of our system we must be able to calculate the value of \( r(n-1) \) unknown quantities. To these must be added the external variables of temperature and pressure, and then as the total number of variables, we have \( r+1 \).

To determine these variables we may form equations between the chemical potentials of the different components—quantities which are functions of the variables to be determined. If \( m \) and \( \mu \) denote the number of any one potential in one given contact, when there is equilibrium, we know that \( m = \mu \). If a third phase is in equilibrium with the other two we have also another equation which will involve the third relation \( \mu = \mu_3 \), which therefore is not an independent equation. Hence with these phases we can form two independent equations for each component. With \( r \) phases we can form \( r \) - 1 equations for each component, and with \( n \) components we can therefore obtain \( n(r-1) \) equations.

Now by elementary algebra we know that if the number of independent equations be equal to the number of unknown quantities all the unknown quantities can be determined, and can possess each one value only. Thus we shall be able to specify the system completely when the number of variables, viz. \( r(n-1) + 2 \), is equal to the number of equations, viz. \( n(r-1) + 1 \), that is when \( r = n + 2 \). Then when a system possesses two more phases than the number of its components, all the phases will be in equilibrium with each other at one definite composition, one definite temperature and one definite pressure, and in no other conditions. To take the simplest case of the introduction of one more phase, the composition of the phases of solid ice, liquid water and gaseous vapour in equilibrium with each other at the freezing point of water under the pressure of its own vapour. If we attempt to change either the temperature or the pressure ice will melt, water will evaporate or vapour condense until one or other of the phases has vanished. We then have in equilibrium two phases only, and the temperature and pressure may change. Thus, if we supply heat to the mixture of ice, water and vapour the water will melt and eventually vanish. We then have water and vapour in equilibrium, and, as more heat enters, the temperature rises and the vapour-pressure rises with it. But, if we cool the mixture, the water will freeze until there is one phase only. Thus by fixing one variable we fix the state of the whole system. This condition is represented in the algebraic theory when we have one more unknown quantity than the number of equations, viz. \( r(n-1) + 2 = n(r-1) + 1 \), and the number of phases is one more than the number of components.

Similarly if we have \( F \) more unknowns than we have equations to determine them, we must fix arbitrarily \( F \) coordinates before we fix the state of the whole system. The number \( F \) is called the number of degrees of freedom of the system, and is measured by the excess of the number of unknowns over the number of variables. Thus if \( F = n(r-1) + 2 - n(r-1) \) is equal to \( r \), a result which was deduced by J. Willard Gibbs (1839-1903) and is known as Gibbs’s Phase Rule (see ENERGETICS).

The phenomena of equilibrium can be represented on diagrams. Thus we take our axes to represent pressure and temperature, the state of the system on a map with ice, water and vapour in equilibrium is represented by the point \( O \) where the pressure is that of the vapour of water at the freezing point and the temperature is the freezing point under that pressure. If all the ice be melted, we pass along the vapour-pressure curve of water until we reach the point \( P \) on the boundary of equilibrium and then along the OC of equilibrium between the pressure and the freezing point of water. The slope of these curves is determined by the so-called “latent heat equation”.

\[ t \]

\[ C \]

\[ B \]

\[ A \]
denote freezing the liquid 2 solid pure the

Phenol such the so aqueous hydrates.

The curve OP represents the varying solubility of the hydrate as the temperature rises from the cryohydric point to 23°C. At that temperature crystals of the hydrate of NaSO₄·10H₂O and a new fixed equilibrium exists between the four phases—hydrate, anhydrous salt, solution and vapour. As heat is supplied, the hydrate is transformed gradually into the anhydrous salt and water. When this process is complete the temperature rises, and we pass along a new curve giving the equilibrium between anhydrous crystals, solution and vapour. In this particular case the solubility decreases with rise of temperature. This behaviour is exceptional.

Two Liquid Components.—The more complete phenomena of mutual solubility are illustrated by the case of phenol and water.

In fig. 4 A represents the freezing point of pure water, and AB the freezing point curve showing the depression of the freezing point as phenol is added. At B is a non-variant system made up of ice, solid phenol, saturated solution and vapour. BCD is the solubility curve of phenol in water. At C a new liquid phase appears—the solution of water in liquid phenol, the solubility of which is represented by the curve DE. At D the composition of the two liquids becomes identical, and at temperatures above D, 68°C the liquids are soluble in each other in all proportions, and only one liquid phase can exist. If the two substances are soluble in each other in all proportions at all temperatures above their melting points we get a diagram reduced to the two fusion curves cutting each other at a non-variant point. This behaviour is illustrated by the case of silver and copper (fig. 5).

At the non-variant point the two metals freeze out together and the composition of the liquid is the same as that of the mixed solid which crystallizes from it. The solid is then known as a eutectic alloy.

A liquid in which the composition is nearly that of the eutectic shows the changes in the rate of fall of temperature as it is allowed to cool. First a small quantity of one of the pure components begins to crystallize out, and the rate of cooling is thereby diminished owing to the latent heat liberated by the change of state. This process continues till the composition of the liquid phase reaches that of the eutectic, when the whole mass solidifies on the further loss of heat without change of temperature, giving a very definite freezing point. The process of cooling is thus represented by a path which runs vertically downwards till it cuts the
freezing point curve, and then travels along it till the non-variant point is reached. In this way two temperature points are obtained in the investigation—the higher giving a point on the equilibrium curve, the lower showing the non-variant point.

Other pairs of alloys, showing more complicated relations, are described in Alloy. Experiments on alloys are, in some ways, easier to make than on pairs of non-metallic substances, partly owing to the possibility of polishing sections for microscopic examination, and the investigation of alloys has done much to elucidate the general phenomena of solution, of which metallic solution constitutes a special case.

When the two components form chemical compounds with each other, the phenomena of mutual solubility become more complex. For a simple case to serve as an introduction, let us again turn to alloys. Copper and antimony form a single compound \( \text{SbC}\). If another compound be added to this compound, the freezing point is lowered just as it would be if a new substance were added, to a solvent. Thus on each side of the point representing this compound, the curve falls. Proceeding along the curve in either direction, we arrive at another eutectic point. In one case the solid which effloresces out is a conglomerate of crystals of the compound with those of antimony, in the other case with those of copper. Thus in interpreting the complicated freezing point curves, we must look for chemical compounds where the curve shows a maximum, and for a eutectic or cryohydrate where two curves meet at a minimum point.

We are now ready to study a case in which several compounds are formed between the two components. A good example is the equilibrium of ferric chloride and water, studied by B. Rooszboom. The experimental curve of solubility is shown in fig. 7. At \( A \) we have the freezing point of pure water, which is lowered by the gradual addition of ferric chloride in the manner shown by the curve \( AB \). As \( B \) we have the non-variant cryohydrate point at which ice, the hydrate \( \text{FeCl}_3 \cdot 12\text{H}_2\text{O} \), the saturated solution and the vapour are in equilibrium at 25°C. As the proportion of water is increased, the melting point of the conglomerate rises, till, at the maximum point \( C \), we have the compound cryohydrate with twelve molecules of water. Beyond \( C \), the addition of salt lowers the freezing point of the compound to the melting point again, till at \( D \) we obtain another non-variant point. This indicates the appearance of a new compound, which should exist pure at \( E \), the next maximum, and, led by these considerations, Rooszboom discovered and isolated a previously unknown hydrate, \( \text{FeCl}_7 \cdot \text{H}_2\text{O} \). In a similar way the curve \( FGH \), between 30° and 58°, shows the effect of the hydrate \( \text{FeCl}_3 \cdot 5\text{H}_2\text{O} \), and the curve \( HIJK \) of that of the hydrate \( \text{FeCl}_4 \cdot 4\text{H}_2\text{O} \), which, when pure, melts at 73°, the point \( J \) on the diagram. At the point \( K, 65° \), begins the solubility curve of the anhydrous salt, \( \text{FeCl}_3 \), the fusion point of which when pure is beyond the limits of the diagram. Let us now trace the behaviour of a solution of ferric chloride which is evaporated to dryness and allowed to reconstitute at 31°. The phenomena may be investigated by following a horizontal line across the diagram. When the curve \( BC \) is reached, \( \text{FeCl}_3 \cdot 12\text{H}_2\text{O} \) separates out, and the solution solidifies. Further renewal of water will cause first liquefaction, as the curve \( CD \) is passed, and then solidification to \( \text{FeCl}_3 \cdot 7\text{H}_2\text{O} \) when \( DE \) is cut. Again the solid will liquify and once more become solid at \( \text{FeCl}_3 \cdot 5\text{H}_2\text{O} \). Still further evaporation of these solutions will force them to pass into the anhydrous salt. As we have seen, the maxima of the various curve-branches at \( C, E, G \), and \( J \) correspond with the melting points of the various hydrates at 37°, 52.5°, 56° and 73.5° respectively; and at these points the eutectic relation of the whole mass can occur at constant temperature. But we have also found this behaviour to be characteristic of the non-variant or transition points, which, in this case, are represented by the points \( B, D, F, H \) and \( K (35°, 27.4°, 30.5°, 55° \text{ and } 65°) \). Thus in two ways at least a constant melting point can be obtained in a two-component system.

Solid Solutions.—In all the cases hitherto considered, the liquid phase alone has been capable of continuous variation in composition. The solid phases each have been of one definite substance. Crystals of ice may lie side by side with crystals of common salt, but each crystalline individual is either ice or salt, no one crystal contains both components in proportions which can be varied continuously. But, in other cases, crystals are known in which both components may enter. Such phenomena are well known in the alums—double sulphates of aluminium with another metal. Here the other metal may be one, such as potassium, or two, such as potassium and sodium, and, in the latter case, the proportion between the two may vary continuously throughout wide limits. Such structures are known as mixed crystals or solid solutions.

The theoretical form of the freezing point diagrams when solid solutions are present depends on the relation between the available energy and the composition in the two phases. This relation is known when the amount of either component present in the other is very small, for it is then the relation for a dilute system and can be calculated. But at intermediate compositions we can only represent the form of the energy-composition curve, and the freezing point composition curve, deduced from it, will vary according to the supposition which we make. With the most likely forms for the energy curves we get the accompanying diagrams for the relation between freezing point and composition.

It will be noticed that in all these theoretical curves the points of initial fusion and solidification do not in general coincide; we reach a different curve first according as we approach the diagram from below, where all is solid, or from above, where all is liquid. Again, it will be seen that the addition of a small quantity of one component, say \( B \), to the other, \( A \), does not necessarily lower the melting point, as it does with systems with no solid solutions; it is quite as likely to cause it to rise. The second and third figures, too, show that the presence of solid solutions may simulate the phenomena of chemical combination, where the curve reaches a maximum, and of non-variant systems where we get a minimum.

The fourth figure shows that, in some cases, it should be possible for solid solutions to be present in a limited part of the field only, being absent between the two nearly vertical lines in fig. 11. Experiment has revealed the existence of systems in which these phenomena are displayed. As an example we may take the case of mixtures of naphthalene and \( \beta \)-naphthalene, substances which form solid solutions in each other. The freezing and melting point curves are exactly similar to theoretical curves of fig. 8, the point \( A \) representing pure naphthalene and \( B \) pure \( \beta \)-naphthalene. When the equilibria become more complex difficulties of interpretation of the experimental results often arise. It is often very difficult to distinguish between a chemical compound, for example, and the case of solid solution represented by fig. 9. All available evidence, from the freezing point curve and from other sources must be scrutinized before an opinion is pronounced. But the elucidation of the complicated phenomena of solid solutions would have been impossible without the theoretical knowledge deduced from the principle of available energy.
for the intrinsic energy of a system will contain terms depending on the area of contact between different phases, and, for a given mass of material, the area will be greater if the substance is finely divided. Hence the conditions necessary to secure equilibrium when the solid phase is present are not the same as those necessary to cause crystallization to start in a number of crystals at first excessively minute in size. The corresponding phenomenon in the case of vapours is well known. Dust-free air will remain supersaturated with water until the conditions where a dense cloud would be formed in presence of solid dust nuclei or electric ions which serve the same purpose.

If a solution of a salt be stirred as it cools in an open vessel, a thin shower of crystals appears at or about the saturation temperature. These crystals grow steadily, but do not increase in number. When the temperature has fallen about 10° C. below this point of saturation, a dense shower of new crystals may be formed. These crystals may be dense enough to make the liquid, quite opaque. These phenomena have been studied by H. A. Miers and Miss F. Isaac. If the solution be confined in a sealed glass tube, the first thin shower is not formed, and the system remains liquid till the secondary dense shower comes down. From this and other evidence it has been shown that the first thin shower in open vessels is produced by the accidental presence of tiny crystals of the solid in the liquid, while the second dense shower marks the point of spontaneous crystallization, where the decrease in total available energy caused by solidification becomes greater than the increase due to the large surface of contact between the liquid and the potentially existing multitudinous small crystals of the shower.

If the temperature at which this dense spontaneous shower of crystals is found be determined for different concentrations of solution, we can plot a "solvability curve," which is found generally to run roughly parallel to the "solvability curve" of steady equilibrium between liquid and already existing solid. When two substances are soluble in one another in an infinitely small degree, we get solubility curves like those of copper and silver shown in fig. 5. We should expect to find solubility curves lying below the solubility curves, and this has been realized experimentally for the supersolubility curves of mixtures of salol (phenyl salicylate) and betol (β-naphthol salicylate) represented by the dotted lines of fig. 12.

In practical cases of crystallization in nature, it is probable that these phenomena of supersaturation often occur. If a liquid mixture of A and B (fig. 12) were inoculated with crystals of A when its composition was that represented by x, cooled very slowly and stirred, the conditions would be those of equilibrium throughout. Whatever the temperature change was, we might assume that the liquid would become richer in B, and the temperature and composition would pass along the curve till E, the composition represented, was reached. The liquid would then become saturated with B also, and, if inoculated with B crystals, will deposit B alongside of A, till the whole mass is solid. But, if no solid be present initially, or if the cooling be rapid, the liquid of composition x becomes supersaturated and may cool till the supersaturation curve is reached at h, and a cloud of A crystals comes down. The temperature may then rise and the concentration of B increase in the liquid in a manner represented by some such line as b f. The conditions may then remain those of equilibrium along the curve b f if solution and deposit be continuous. But, if the solution be supersaturated with B and deposit B crystals spontaneously. The eutectic point may never be reached. The possibility of these phenomena should be borne in mind when attempts are made to interpret the structure of crystalline bodies in terms of the theory of equilibrium.

Osmotic Pressure.—The phase rule combined with the latent heat equation enables us to trace the general phenomena of equilibrium in solutions, and to elucidate and classify cases even of great complexity. But other relations between the different properties of solutions have been investigated by another series of conceptions which we shall proceed to develop. Some botanical experiments made about 1870 suggested the idea of semi-permeable membranes, i.e., membranes which allow a solution to pass freely but are impervious to a solute when dissolved in that solvent. It was found, for instance, that a film of insoluble copper ferrocyanide, deposited in the walls of a porous vessel by the inward diffusion and mixing of solutions of copper sulphate and potassium ferrocyanide, would allow water to pass, but retained sugar dissolved in that liquid. It was found, too, when water was placed on one side of such a membrane, and a sugar solution in a confined space on the other, that water entered the solution till a certain pressure was set up when equilibrium resulted.

The importance of these experiments from the point of view of the theory of solution, lay in the fact that sugar, not previously conceived of a perfect or ideal semi-permeable partition, and that of an equilibrium pressure representing the excess of hydrostatic pressure required to keep a solution in equilibrium with its pure solvent through such a partition. Articles have been written which is permeable to the solvent but not to the solute when dissolved in it, and we connect the solution and solvent of fig. 13 with each other through such a partition. If solvent were to flow one way or the other through the partition, the

Dilute Solutions.—Before considering the more complicated case of a concentrated solution, we will deal with one which is very dilute, when the theoretical relations are much simplified. The vapour pressure of a solution may be measured experimentally by two methods. It may be compared directly with that of the pure solvent, as the vapour-pressure of a pure liquid is determined, by placing solution and solvent respectively above the mercury in two barometer tubes, and comparing the depressions of the mercury with the height of a barometer tube, both at the same temperature. This method was used by Raoult. On the other hand, a current of dry air may be passed through the series of weighed bulbs containing solution and solvent respectively, and the loss in weight of each determined. The loss in the solution bulbs gives the mass of solvent absorbed from the solution, and the loss in the solvent bulbs the additional mass required to raise the vapour pressure in the air-current to equilibrium with the pure solvent. The relative lowering of vapour pressure of the solution compared with that of the solvent is measured by the ratio of the extra mass absorbed from the solvent to the total mass absorbed from both series of bulbs. Experiments by this method have been made by G. F. G. Wolfrath and J. Walker, and by Lord Berkeley and E. G. J. Hartley.

The vapour pressure of the solution of a non-volatile solute is less than the vapour pressure of the pure solvent. Hence if two vessels, one filled with solution and one with solution, be placed side by side in an exhausted chamber, vapour will evaporate from the solvent and condense on the solution. The solution will thus gain solvent, and will grow more and more dilute. Its volume will also increase, and thus its upper surface will rise in the vessel. But as we ascend in an atmosphere the pressure diminishes, hence the pressure of the vapour in the chamber is less the higher we go, and thus eventually we reach a state of equilibrium where the column of vapour is in equilibrium at the appropriate level both with solvent and solution. Neglecting the very small buoyancy of the vapour, the hydrostatic pressure P at the foot of the column of solution is h p where h is the height of the column and P the mean density of the solution. If the height be not too great, we may assume the density of the vapour to be uniform, and write the difference in vapour pressure at the surfaces of the solvent and of the solution as p – p = h p where p is the mean density of the solution. If the height be not too great, we may assume the density of the vapour to be uniform, and write the difference in vapour pressure at the surfaces of the solvent and of the solution as p – p = h p. For a very dilute solution, where the difference p – p is small and the height of the balancing column of solution small.

In practice the time required to reach these various conditions of equilibrium would be too great for experimental demonstration, but the theoretical consideration of vapour pressures is of fundamental importance. Let us suppose that we possess a partition, as described above, which is permeable to water but not to the solute when dissolved in it, and let us connect the solution and solvent of fig. 13 with each other through such a partition. If solvent were to flow one way or the other through the partition, the
height of the column of solution would rise or fall and the equili-

brium with the vapour be disturbed. A continual circulation might 

thus be set up in an isothermal enclosure and maintained with the 

performance of an unlimited supply of work. This result would be 

counter to all experience of the impossibility of "perpetual motion," 

and hence we may conclude that such a semi-permeable wall, the solvent and the solution at the foot of the column would 

be in equilibrium under the excess of hydrostatic pressure repre-

sented when the solution is very dilute by \( p = \rho \frac{dT}{L} \). But 

such a pressure represents the equilibrium osmotic pressure discussed 

above. Therefore the equilibrium osmotic pressure of a solution is 

connected with the vapour pressure, and, in a very dilute solution, is 

expressed by the simple relation just given.

Another relation becomes evident if we use as a semi-permeable partition a "vapour sieve" as suggested by G. F. Fitzgerald. If a 

number of small enough holes be drilled through a solid substance 

which is not wetted by the liquid, our knowledge of the phenomenon 

capillarity shows us that it needs pressure to force the liquid 

into the holes. A piston made of such a perforated substance, 

therefore, may be used to exert pressure on the liquid, while all the 

air remains in the vessel. The idea is to pass the air in, "perforate" the 

partition, then, the solvent can pass through this perforated partition, 

which thus acts as a perfect semi-permeable membrane. When the 

solution and solvent are in equilibrium across the partition, the 

vapour pressure of the solution has been increased by the application 

of pressure till it is equal to that of the solvent. In any solution, 

then, the osmotic pressure represents the excess of hydrostatic pressure which it is necessary to apply to the solution in order to 
increase its vapour pressure to an equality with that of the solvent 
in the given conditions.

Similar considerations show that, since at its freezing point the 
vapour pressure of a solution must be in equilibrium with that of 

ice, the depression of freezing point produced by dissolving a sub-

stance in water can be calculated from a knowledge of the vapour 

pressure of ice and water below the freezing point of pure water. 

But another method of investigation will illustrate new ways of 
treating our subject.

By imagining that a dilute solution is put through a thermo-
dynamic cycle we may deduce directly relations between its 

osmotic pressure and its freezing point. Let us 

Freezing 

Point. freeze out unit mass of solvent from a solution at its 

freezing point \( T - dT \) and remove the ice, which is 

assumed to be the ice of the pure solvent. Then let us heat 

both ice and solution through the infinitesimal temperature 

range \( dT \) to the freezing point \( T \) of the solvent, melt the ice 

by the application of an amount of heat \( L \), which measures its 

latent heat of fusion, and allow the solvent so formed to enter the 
solution reversibly through a semi-permeable wall into an 

engine cylinder, doing an amount of work \( P \)\( dT \). By cooling 

the resultant solution through the range \( dT \) we recover the 

original state of the system. The well-known expression for the 
efficiency of the cycle of reversible operation gives us 

\[
\frac{PdL}{L} = \frac{dT}{T} \text{ or } dT = \frac{PdL}{L},
\]

as a value for the depression of the freezing point of the 
solution compared with that of the pure solvent.

The freezing point of a solution may be determined experimentally.

The solution is contained in an inner tube, surrounding which is an 

air space. Then comes an outer vessel, in which a freezing mixture 

can be placed. If the inner tube be heated sufficiently, the temper-

ature falls slowly below the freezing point, till the saturation point 
is reached, or until a crystal of ice is introduced. The solution 

then freezes, until the heat liberated is enough to raise the tem-

peratur to the point of equilibrium given by the tendency of the 
solution taken in contact with ice to approach the true freezing point 
on one side and the temperature of the enclosure on the other. 

To get the true freezing point then, it is well to arrange that the 
temperature of the enclosure should finally be nearly that of the 
freezing point to be observed. One way in which this has been 

achieved is by introducing by a flexed tube of the air space by a 
spiral tube in which ether may be evaporated, the outer vessel being filled with ice in contact with a solution of 
equivalent concentration to that within. Modifications of this 
method have been used by many observers, among others, 

Loomis, H. C. Jones, and by E. H. Griffiths and T. C. Bedford, who 

compared directly the freezing points of dilute solutions with those 
of the solvent in similar conditions by the accurate methods of 

platinum thermometry.

Another application of the theory of energy enables us to co-

ordinate the osmotic pressure of a dilute solution with the 

pressure of a gas occupying the same space. On 

the fundamental hypotheses of the molecular theory, we must regard a solution as composed of a number of 

separate particles of solute, scattered throughout the vessel. Each particle may react in some way on the 
solute in its neighborhood, but if the solution be so dilute that each of those molecules of influence are unaffected 

by the rest, no further addition of solvent will change the connexion between one particle of solute and its associated 

solvent. The only effect of adding solvent will be to separate further from each other the systems composed of 

solute particle as nucleus and solvent as atmosphere; it will not 

affect the action of each nucleus on its atmosphere. Thus the 

result will be the same whatever the nature of the inter-

action may be. If solvent be allowed to enter through a semi-

permeable wall into an engine cylinder, the work done when the 
solution is already dilute will be the same whatever the nature of the interaction between solute and solvent, that is, 

whatever be the nature of the solvent itself. It will even be 

the same in those cases where, with a volatile solute, the presence 
of a solvent may be dispensed with, and the solute exist in 

the same volume as a gas. Now the work done by allowing a 

small quantity of solvent to enter reversibly into an osmotic 

cylinder is measured by the product of the osmotic pressure into 

the change in volume. Hence the osmotic pressure is measured 

by the work done per unit change of volume of the solution. 
The result of our consideration, therefore, is that the osmotic 

pressure of a dilute solution of a volatile solute is the same 

as the gaseous pressure the same number of solute 

particles would exert if they occupied as gas a volume equal to 

that of the solution.

The reasoning given above is independent of the temperature, 

so that the variation with temperature of the osmotic pressure 
of a dilute solution must be the same as that of a gas, while 

Boyle's law must equally apply to both systems. Experimental 

evidence confirms these results, and extends them to the cases 

of non-volatile solutes—as is, indeed, to be expected, since 

volatility is merely a matter of degree. When the solution ceases 

to be dilute in the thermodynamic sense of the word, that is, when 

the spheres of influence of the solute particles intersect each 

other, this reasoning ceases to apply, and the resulting modification 
of the gas laws as applied to solutions becomes a matter for 

further investigation, theoretical or experimental. In the limit 

then, when the concentration of the solution becomes vanishingly 

small, theory shows that the osmotic pressure is equal to the 

pressure of a gas filling the same space. Experiments 

with membranes of copper ferrocyanide have verified this result 

for solutions of cane-sugar of moderate dilutions. But the most 

accurate test of the theory depends on measurements of freezing 

points.

A quantity of gas measured by its molecular weight in grammes 

when confined in a volume of one litre exerts a pressure of 22.2 

atmospheres, and thus the osmotic pressure of a dilute solution 
divided by its concentration in gram-molecular units is a corre-

sponding value. But we have seen that the depression of \( dT \) 

of the freezing point of a dilute solution is measured by \( T \)\( P \)\( dL \)/L 

and the absolute freezing points of saturated solutions of 

273°, the osmotic pressure P as 22.2 atmospheres or 22.4 \( \times 10^4 \) 

C.G.S. units per unit concentration, L the latent heat as 79.4 \( \times 

4.184 \times 10^7 \) in the corresponding units, and \( dT \) the volume change.
SOLUTION

in the solution for unit mass of solvent added we get for the quantity $d\gamma /\gamma$, where $\gamma$ is the concentration of the solution, the value $1.857C$. per cent. Experimental measurements of freezing points of various non-electrolytic solutions have been made by Raoult, Loomis, Griffiths, Bedford and others and numbers ranging round 1-85 found for this concentration. Equally good concordance has been obtained in opposition in solutions in liquids such as acetic acid 3-88, formic acid 2-84, benzene 5-30, and nitrobenzene 6-95. Such a concordance between theory and experiment not only verifies the accuracy of thermodynamic reasoning as applied to dilute solutions, but gives perhaps one of the most convincing experimental verifications of the general validity of thermodynamic theory which we possess.

The relative value may be obtained from the phenomena of vapour pressure. Since, in dilute solutions, the osmotic pressure has the gas value, we may apply the gas equation $PV = nRT = np$ to osmotic relations. Here $n$ is the number of gramme-molecules of the solute, $V$ is the volume of the gas contained in the usual "gas" value, $p$ the vapour pressure of the solvent and $nV$ the volume in which one gramme-molecule of the vapour is confined.

In the vapour pressure equation $P = P^* + P_{osm}$ we have the vapour density $\rho$ equal to $M/V$, where $M$ is the molecular weight of the solvent. The density of the liquid is $MN/V$, where $N$ is the number of solvent molecules, and $V$ the total volume of the liquid. Substituting these values, we find that the relative lowering of vapour pressure in a very dilute solution is equal to the ratio of the numbers of solute and solvent molecules, or $(\rho - \rho)/\rho = n/N$.

The experiments of Raoult on solutions of organic bodies in water, however, showed that in many cases some difficult organic solvents have confirmed this result, and therefore the theoretical value of the osmotic pressure from which it was deduced.

Although even good membranes of copper ferrocyanide are rarely perfect, the importance of the osmotic pressures such as rubber, &c., which have been used, the defects from the theoretical values of the equilibrium pressure are very great, yet, in the light of the verification of theory given by the experiments described above, it is evident that such failures to reach the limiting value in no wise invalidate the theory of osmotic equilibrium. They merely show that, in the conditions of the particular experiments, the thermodynamic equilibrium value of the osmotic pressure cannot be reached—the thermodynamic or theoretical osmotic pressure (which must be independent of the nature of the membrane provided it is truly semi-permeable) is a different thing from the equilibrium pressure actually reached in a given experiment, which measures the balance of ingress and egress of solvent through an imperfect semi-permeable membrane.

Dilute solutions of substances such as cane-sugar, as we have seen, give experimental values for the characteristic osmotic properties—pressure, freezing point and vapour pressure—in conformity with the theoretical values.

All these solutions are non-conductors of electricity. On the other hand, solution of mineral acids and salts conduct the current with chemical decomposition—they are called electrolytes. In order to explain the electrical properties of a solution, for instance of potassium chloride, we are driven to believe that each molecule of the salt is dissociated into two parts, potassium and chlorine, each associated with an electric charge equal in amount but opposite in sign. The movement in opposite directions constitutes the current produced by the electrolyte in the solution. To explain the electrical properties of sulphuric acid in aqueous solution, the supposition of three ions, two of hydrogen and one of the chemical group $SO_4^-$, is necessary. Now measurements of osmotic properties of these solutions show that their osmotic pressures are abnormally great and that, at extreme dilution, the ratio of their osmotic pressures to that of equivalent solutions of non-electrolytes is equal to the number of ions indicated by the electrolytic properties. From the osmotic side also, then, electrolytic dissociation is indicated, and indeed, it was from this side that the idea was first suggested by F. Arhenius in 1887. The subject is dealt with in ELECTROLYSIS AND CONDUCTION. ELECTRIC.

§ 15. Liquids.

Concentrated Solutions.—Having dealt with the relations between the properties of an ideally dilute solution, we now turn to the consideration of the general case where the simplifying assumption of great dilution is not made.

The height of the column of solution in fig. 13 required for osmotic equilibrium through a semi-permeable wall below is now very great, since the osmotic pressure of strong solutions may reach many hundred atmospheres. Hence we must not assume that the density of the vapour in the surrounding atmosphere is constant, or that the solution, when equilibrium is reached, is of uniform concentration throughout. The osmotic pressure (defined as the difference in the hydrostatic pressures of the solution and solvent when their vapour pressures are equal and they are consequently in equilibrium through a perfect semi-permeable membrane) may also depend on the absolute values of the hydrostatic pressures, as may the vapour pressure of the liquids.

To investigate the osmotic pressure of a strong solution we may consider the hydrostatic pressure required to increase its vapour pressure to an equality with that of the solvent. The relation between hydrostatic pressure and the vapour pressure of a pure liquid may be obtained at once by considering the rise of liquid in a capillary tube. The difference in vapour pressure at the top and at the bottom of the column is $\rho g H = p_{osm}$, as shown above for a column of solution. Writing $H$ for $1/\rho$, the specific volume of the vapour at the pressure $p$, and $V$ for $1/\rho$, the specific volume of the liquid at the pressure $P$, and restricting the result to small changes, we get $dp = VdP$.

In considering the corresponding relation for a solution instead of a pure liquid, possible differences in concentration make the column method difficult of application, and it is better to attach the problem by means of an imaginary cycle of isothermal operation. The simplest way to do this is to imagine a vapour-sieve piston through which the vapour but not the liquid can pass. As we have explained above, such a vapour sieve may be constructed by boring a number of small enough holes through a solid not wetted by the liquid.

Let us imagine unit mass of solution of volume $V$ confined in a cylinder ABC between a fixed vapour sieve B and a solid piston A B C

**FIG. 14.**

by which a pressure $P$ is applied. The vapour at pressure $p$ in equilibrium with the liquid is condensed in a piston C, which we may also move to change the pressure or volume.

With such an imaginary apparatus, H. L. Callendar has shown that the variation of vapour pressure of a solution with pressure is given by the expression $V\Delta P = \Delta V$, where $V$ is the change in volume of the solution when unit mass of solvent is mixed with it. The corresponding relation for a pure liquid can be regained by considering that at infinite dilution the liquid becomes pure solvent, and the change of volume becomes equal to the volume $V$ of solvent added.

The osmotic pressure $P$ of a solution and solvent corresponding to the same value $\rho_0$ of the vapour pressure is obtained by integrating the equation $V\Delta P\gamma = \Delta V$ between corresponding limits for solution and solvent. We get

$$\int_{\rho_0}^{\rho} \rho V d\rho = \int_{\rho_0}^{\rho_0} \rho V d\rho = \int_{\rho_0}^{\rho} \rho V d\rho,$$

whence

$$\int_{\rho_0}^{\rho} \rho V d\rho = \int_{\rho_0}^{\rho_0} \rho V d\rho = \rho V \rho_0,$$

where $\rho$ and $\rho_0$ are the vapour pressures of solvent and solution each under its own vapour pressure only.

If we measure the osmotic pressure $P$ at the solvent under its own vapour pressure only, that is, when $P = \rho_0$, the term involving $V$ vanishes, and the limit of integration $P$ becomes $P_0$. If we assume that $V$, the volume change on dilution, varies regularly or not appreciably with pressure, we may write the first integral $\rho_0 \rho V d\rho = \rho_0 V \rho_0$, where $V'$ now denotes its mean value between the limits, but given by $\rho_0$.

To evaluate the second integrals $\rho V d\rho$ we may subtract a constant $b$ to represent the defect of the volume of the vapour from the ideal value $R\ln \rho_0 /\rho_0$.

$$V'(\rho - \rho) = R\ln (\rho_0 /\rho - b(\rho - \rho)).$$

For most experimental purposes the small terms involving the factor $(\rho - \rho)$ may be neglected, and we have, approximately,

$$PV' = R\ln (\rho_0 /\rho).$$

From this equation the osmotic pressure $P$ required to keep a solution in equilibrium as regards its vapour and through a
Semi-permeable membrane with its solvent, when that solvent is under its own vapour pressure, may be calculated from the results of observations on vapour pressure of solvent and solution at ordinary low hydrostatic pressures. The chief difficulty lies in the determination of the quantity \( V \), the change in volume of the solution under the pressure \( P_0 \) when unit mass of solvent is mixed with it. This determination involves a knowledge of the density and of the compressibility of the solution; the latter property is difficult to measure accurately.

In some solutions such as those of sugar the change in volume on dilution is nearly equal to the volume of solvent added; \( V \) then becomes equal to \( V_1 \), the specific volume of the solvent. The osmotic pressures of strong sugar solutions were measured successfully by a direct method with semi-permeable membranes of copper ferrocyanide by Lord Berkeley and E. C. J. Hartley, who also determined the vapour pressures by passing a current of air successively through weighed vessels containing solution and water respectively. Their table of comparison published in 1906 shows the following agreement:

| Concentration in grammes per litre of solution | Osmotic pressure at \( o^\circ \) C. in at.

It seems likely that measurements of vapour pressure and compressibility may eventually enable us to determine accurately osmotic pressures in cases where direct measurement is impossible.

The slope of the temperature vapour pressure curves in the neighbourhood of the freezing point of the solvent is given by the latest heat equation. The difference in the two slopes for water and ice is \( \frac{dP}{dT} - \frac{dP}{dT} \) \( T = 1/T_s \), where \( T_s \), the latent heat of fusion, is the difference between the heats of evaporation for ice and water, and \( v \) is the specific volume of the vapour.

The difference in the lowering of vapour pressures \( dP - d\theta \) may be put equal to \( \nu dl/dT \), where \( P \) is the osmotic pressure, and \( v \) the specific volume of the solvent. We then get \( dP = \nu dl/dT \).

In order to integrate this expression we need to know \( l \) and \( v \) as functions of the temperature and pressure. The latent heat \( L \) at any temperature is given by \( L = L_0 - \int (s - s')dT \), where \( L_0 \) is value at \( T_s \) and \( s - s' \) is the difference in the specific heats of water and ice. The probable error in neglecting any variation of specific heat is small, and we may calculate \( L \) from the values of \( L_0 - (s - s') \) \( T = 1/T_s \), which is about 0-5 calories. The variation of \( L \) with pressure is probably small.

The volume of a gramme of water also depends on temperature and pressure. Approximately one degree lowering of freezing point corresponds with a change of 12 atmospheres in the osmotic pressure. From the known coefficients of compressibility and thermal expansion we find that \( V \) may be represented by the linear equation \( V = 1-000 + 0-0008 \Delta \), where \( \Delta \) is the lowering of the freezing point below \( 0^\circ \).

Putting in these values and integrating we have, neglecting terms involving \( \Delta^2 \), \( P = 12-06 \Delta - 0-021 \Delta^2 \) where \( P \) is the osmotic pressure in atmospheres.

H. W. Morse and J. C. W. Frazer, who have made direct measurements of osmotic pressure of solution of cane-sugar, have also measured the freezing points of corresponding solutions. From these results the equation just given has been examined by G. N. Lewis.

Thus the theory of the connexion of osmotic pressure with freezing point (like that with vapour pressure) seems to give results which accord with experiments.

At the limit of dilution, when the concentration of a solution approaches zero, we have seen that thermodynamical theory, verified by experiment, shows that the osmotic pressure has the same value as the gas pressure of the same number of molecules in the same space. Gases at high pressures fail to conform to Boyle's law, and solutions at moderate concentrations give osmotic pressures which increase faster than the concentration. The variation of gases from Boyle's law is represented in the equation of Van der Waals by subtracting a constant \( b \) from the total volume to represent the effect of the volume of the molecules themselves. The corresponding correction in solutions consists in counting only the volume of the solvent in which the solute is dissolved, instead of the whole volume of the solution.

In fig. 15 the curve I represents Boyle's law if the volume is taken to be that of the solution, and the curve II if the volume is that of the solvent. Even this correction is not sufficient in solution of sugar, where the theoretical curve II lies below the experimental observations. A further correction may be made by adding more empirical terms to the equation, but a more promising idea, due to J. H. Poynting and H. L. Callendar is to trace the effect of possible combination of molecules of solute with molecules of the solvent. These combined solvent molecules are thus removed from existence as solvent, the effective volume of which is reduced to that of the remaining free molecules of solvent. The greater the number of water molecules attached to one sugar molecule, the less the residual volume, and the greater the theoretical pressure. Callendar finds that five molecules of water in the case of cane-sugar or two molecules in the case of dextrose are required to bring the curves into conformity with the observations of Berkeley and Hartley, which in fig. 15 are indicated by crosses.

**Solubility and Heat of Solution.**—The conceptions of osmotic pressure and ideal semi-permeable membranes enable us to deduce other thermodynamic relations between the different properties of solutions. As an example, let us take the following investigation.

An engine cylinder may be imagined to possess a semi-permeable bottom and to work without friction. If it be filled with a solution and the bottom immersed in the pure solvent, pressure equal to the osmotic pressure must be exerted on the piston to maintain equilibrium. Such a system is in the thermodynamic equilibrium. The slightest change in the load will cause motion in one direction or the other—the system is thermodynamically reversible. Such an arrangement may be put through a cycle of operations as in Carnot's engine (see Thermodynamics) and all the laws of reversible engines applied to it. If the solution in the cylinder be kept saturated by the presence of crystals of the solute, crystals will dissolve as solvent enters and the solution remains saturated throughout. By an imaginary cycle of operations we may then justify the application to solutions of the latent heat equation which we have already assumed as applicable. In the equation \( dP/CT = \lambda(T - T_0) \), \( P \) is the osmotic pressure, \( \lambda \) the heat of solution of unit mass of the solute when dissolving to form a volume \( v_1 - v_0 \) of saturated solution in an osmotic cylinder. This process involves the performance of
solutions, based on the idea that the mean energy of translation of a molecule should be the same in the liquid as in the gaseous state. But, whether or not the assumption underlying this demonstration be accepted, the similarity between solution and chemical action remains, and the osmotic law has been examined from this side by J. H. Poynting and by H. L. Callendar. The fundamental phenomenon they take to be the identity of vapour pressure, and consider the combination necessary to reduce the vapour pressure of a solution to the right value. If each molecule of the solute combines with a certain number of molecules of the solvent in such a way as to render them inactive for evaporation, we get a lowering of vapour pressure. Let us assume that the vapour pressure of a solution with a definite number of molecules of solute and solution is equal to the ratio of the number of free molecules of solvent to the whole number of molecules in the solution. Each molecular complex, formed by solution and solvent, is treated as a single molecule. If there are \( n \) molecules of solute to \( N \) of solvent originally, and each molecule of solute combines with a molecule of solvent, we get for the ratio of vapour pressures

\[
p/p' = (N-an)/(N-an+n),
\]

while the relative lowering of vapour pressure is

\[
(p-p')/p = n/(N-an).
\]

In the limit of dilution when \( n \) is very small compared with \( N \) this reduces to Raoult’s equation, which shows that the relative lowering is

\[
N/n,
\]

which we deduced from the osmotic pressure of a dilute solution, while for more concentrated solutions agreement is obtained by assigning arbitrary values to \( a \), which, as we have seen, is \( s \) in the case of cane-sugar.

Certain solvents, such as water, liquid ammonia or liquid hydrocyanic acid, possess the power of making some solutes, such as mineral salts and acids, when dissolved in them, conductors of electricity. The special properties of these solutions are dealt with under Electrolysis and Conduction, ELECTRICITY, § In Liquids. Attempts have been made to co-ordinate that the power of dissolved electrolytes to conduct electricity, or with their chemical properties. On the lines of Poynting’s theory of solution, each ion in electrolytes must combine with one or more molecules of solvent.

Diffusion in Solutions.—The passage of dissolved substances through animal and vegetable membranes was the subject of many early experiments. It was found that substances like mineral salts, which crystallize well from solution, passed such membranes with comparative ease, while the jelly-like substances such as albumen passed with extreme slowness if at all. The first discovery of the system of the solution and diffusion was made, with the help of a dilute solution of a gas, which was Thomas Graham (1804–1869), who immersed in a large volume of water a wide-mouthed bottle containing a solution, and after some time measured the quantity of substance which had diffused into the water. Again the two classes of substances mentioned above were found to be distinguished, and Graham called the slowly diffusible non-crystalline bodies colloids, in contrast to the quickly diffusible crystalloids. Graham showed that the diffusion was approximately proportional to the difference in concentration, and on these lines a theory of diffusion was founded on the lines of Fourier’s treatment of the conduction of heat.

The quantity of substance which diffuses through unit area in one second may be taken as proportional to the difference in concentration between the fluids at that area and at another parallel area indefinitely near it. This difference in concentration is proportional to the rate of variation \( dc/dx \) of the concentration \( c \) with the distance \( x \), so that the number of gramme-molecules of solute which, in a time \( dt \), cross an area \( A \) of a long cylinder of constant cross section is

\[
J = DA(c/dx)dt,
\]

where \( D \) is a constant known as the diffusion constant or the diffusivity.

The osmotic pressure of a solution depends on the concentration, and, if we regard the difference in that pressure as the effective pressure on the solute molecules, we are able to obtain the equation of diffusion in another form. When the solution is dilute enough for the osmotic pressure to possess "the gas" value the equation becomes

\[
J = R \left( 1 - \frac{c}{c_0} \right) T \frac{\partial c}{\partial x} dt,
\]

where \( R \) is the usual gas constant, \( T \) the absolute temperature, and \( F \) the force required to drive one gramme-molecule of the solute through the solution with unit velocity.
SOLUTRIAN EPOCH—SOLWAY FIRTH

By comparison with the first equation we see that RT/F is equal to 2kT/F the constant. This constant can be measured experimentally, and for such a substance as sugar or water comes out about 0.3 at 20° C, the unit of time being the day. Hence the force required to drive one gramme-molecule of sugar through water at 20° C, in a second may be calculated as some thousands of millions of kilogrammes weight.

In the case of electrolytes we can go further, and calculate the diffusion constant of any substance from the values of the osmotic pressure of the solution (see ELECTRICITY, § In Liquids). On that theory the ions of a dilute solution migrate independently of each other. Since some ions are more mobile than others, a separation will ensue when water is placed in contact with such a solution, the faster moving ions penetrating quicker into the water under the driving force of the osmotic pressure gradient. This separation causes a decrease of potential, which can be calculated and is found to agree with the values usually obtained experimentally. Thus also sets in motion the coagulation of colloidal solutions, which increase until they are strong enough to drag the slower moving ions along faster, and to retard the naturally faster ions till they travel at the same rate. The resistance offered by the liquid, and therefore the force F, required to drive one gramme-molecule through the liquid with unit velocity is the sum of the corresponding quantities for the individual ions. Now the velocities w and v of the opposite ions under unit potential gradient, and therefore U and V under unit force, are known from electrical data. Thus F, which is equal to 1 U + 1 V, is known. The osmotic pressure of an electrolyte consisting of two ions is double that of a solution of one ionic electrolyte in a liquid medium. The result is constant by measuring 2RT/F or 2UVRT(U + V). This result follows a value of D for dilute hydrochloric acid equal to 2.49 to compare with the observed value of 2.30. Other substances give exceedingly good agreement. Thus in electrolyte solutions there is a calculated constant of 1.12 and an observed one of 1.11. Such concordance gives strong support to the theory of diffusion outlined above.

Colloidal Solutions.—Besides a large number of animal and vegetable substances, many precipitates formed in the course of inorganic chemical reactions are non-crystalline and appear in the colloidal state. Examples are the sulphides of antimony and arsenic and the hydroxides of iron and alumina. Some of these colloids dissolve in water or other liquids to form solutions called by Graham hydrolys; Graham named the solids formed thereby by the general term of colloidal substances. Solutions of colloids in solvents such as water and alcohol seem to be divisible into two classes. Both mix with warm water in all proportions, and will solidify in certain conditions. One class, represented by gelatin, will redissolve on warming or diluting, while the other class, containing such substances as silica, albumen, and metallic, hydroxides, will solidify on heating or on the addition of electrolytes to form a solid “gel” which cannot be redissolved. Solidification of the first kind may be termed “setting”; that of the second “coagulation.”

The power of coagulation of colloids by electrolytes depends greatly on the manner in which the electric charges are balanced by the effective ion. The average of the coagulative powers of salts of univalent, divalent and trivalent metals have been found by experiment to be proportional to the numbers 1 : 35 : 1023. If we assume that a certain minimum electric charge must be brought into contact with a group of colloidal particles to produce coagulation, twice as many univalent ions must collect to produce the same effect as a number of divalent ions, and three times as many as an effective number of trivalent ions. We can calculate, by the help of the kinetic theory and the theory of chances, the frequency with which the necessary combinations of ions will occur, and if this frequency is small enough that the law of chance will be obeyed, the coagulative powers should be in the ratios of 1 : 1 x 35 : 1023. Putting x = 32, we get 1 : 32 : 1024 to compare with the experimental numbers. The ordinary surface energy of a two-phase system tends to diminish the area of contact, and thus to help the growth of the larger aggregates required for coagulation. A natural electric charge on the particles would oppose this tendency, and tend to increase the free surface and thus promote disintegration and solution. The function of the electrolyte may be to annul such a natural charge and thus allow the non-electric surface energy to produce coagulation. This explanation may cover some of the experiments by W. B. Hardy and his son found that certain colloids did possess electric charges, the sign of which depended on whether the surrounding liquid was slightly acid or slightly alkaline. At the neutral point, when the particles possessed no charge, their stability was destroyed, and they were precipitated. But recent experiments have shown that the simple theory of coagulation here outlined needs amplification in certain directions. The phenomena seem to be dependent on variables such as time, and are more complicated than seemed likely at first sight.

The size of the suspended particles in colloidal solutions varies greatly. In some solutions they are visible under a good microscope. In other cases, while too small to be directly visible, they are large enough to scatter and polarize a beam of light. In yet other solutions, the particles are smaller again, and seem to approach in size the larger molecules of crystalloid substances. It is not yet agreed whether colloidal solution is the same in kind though different in degree from crystalloid solution or is a phenomenon of an entirely different order.

REFERENCES.—The properties and theory of solutions are treated in all works on general physical chemistry; Ostwald’s discussion in his Lehrbuch was translated into English in 1891 by M. M. Taix entitled Solution. Special works are W. C. D. Whetham, Theory of Solutions (1902); W. Rothmund, Löslichkeiten (1907). Solubility tables are given in Landolt, Bornstein and Meyerhoffers, Tabellen (1905); A. M. Comey, Dictionary of Solubilities (Inorganic) (1886); A. Seidell, Dictionary of the Solubilities of Inorganic and Organic Substances (1907). (W. C. D. W.)
SOMA

The preparation of the soma juice was a very
ceremony, and the worship of the god is very old, old,
being identifiable with the Avestan homa, prepared and
celebrated in the Indo-Iranian period. The plant's true home
is heaven, and soma is drunk by gods as well as men, and it is under
its influence that Indra is related to have created the universe
and fixed the earth and sky in their place. In post-Vedic literature
soma is a regular name for the moon, which is regarded as being
drunk up by the gods and so waning, till it is filled up again by
the sun. In both the Rig Veda and Zend Avesta soma is the
king of plants; in both it is a medicine which gives health, long
life and removes death. In both the celestial is distinguished
from the terrestrial soma, and the liquor from the god.
The first soma is supposed to have been stolen from its guardian
demon by an eagle, this soma-bringing eagle of Indra being
comparable with the nectar-bringing eagle of Zeus, and with the
eagle which, as a metamorphosis of Odín, carried off the mead.
See A. A. Macdonell, *Vedic Mythology* (Strassburg, 1897).

SOMALILAND, a country of East Africa, so named from its
Somali inhabitants. It is also known as the "Eastern Horn of
Africa," because it projects somewhat sharply eastwards
into the Indian Ocean, and is the only section of the continent
which can be spoken of as a peninsula. In general outline it
is an irregular triangle, with apex at Cape Guardafui. From
the apex the north side extends over 600 m. along the south shore
of the Gulf of Aden westwards to Tadjura Bay, and the east side
skirts the Indian Ocean south-west for over 1,000 m. to the
mouth of the Juba. Somali also inhabit the coast region and
considerable areas inland; the far south of the Tana river. The
country between the Tana and Juba rivers now forms part of
British East Africa (q.v.), and in this article is not included in Somaliland.
Inland the limits of Somaliland correspond
roughly with the Shoa and Harrar Hills, and the Galla
district south of Shoa and east of Lake Rudolf. The 40th east
may be taken as the western limit of Somali settlements. The
triangular space thus roughly outlined has a total area of about
356,000 sq. m. The population is estimated at about 1,100,000,
but no trustworthy data are available. It is partitioned over
Great Britain, Italy, France, and Abyssinia as under—

Somaliland was not generally adopted as the name of the
country until the early years of the 19th century. The northern
and central districts were previously known as Adal, the
north-east coast as Ajan. By the ancients the country was called
regio romatica, from the abundance of aromatic plants which
it produced.

**Physical Features.**—The whole region is characterized by a
remarkable degree of physical uniformity, and may be broadly
described as a vast plateau of an average elevation of 3,000 ft.,
bounded westwards by the Ethiopian and Galla highlands and
northwards by an inner and outer coast range, skirting the south
shore of the Gulf of Aden (fig. 1). The plateau is a vast
steppe clothed with a scanty vegetation of scrubby plants and
herbs and grass.

The incline is uniformly to the south-east, and apart from the
few coast streams that reach the Gulf of Aden during the rains,
the running water is collected in three river systems. The Naga
in the north, the Webi Shebeli in the centre, and the Juba (g.g.)
in the south—which have a parallel south-easterly direction towards
the Indian Ocean. But there is a slight impression that the Juba
alone has the perpetual discharge of a distinct river, the
water coming down a turbulent stream during the freshets, while the Shebeli,
notwithstanding the far greater extent of its basin, does not reach
the sea. In the north and a distance of about 200 m. the river
is accepted by a lone line of dunes, which it fails to pierce and is thus
defeated southwards, flowing in this direction for nearly 170 m.
parallel with the coast, and then disappearing in a swampy
depression. The Bali may be roughly compared with a sandy river
by a cherry lime

SOMA

1 See also AFRICA.

2 It is probable that a divergent branch leaves the Shebeli some distance above the swamps and that at high water an overflow into the Juba occurs (see *Geog. Journ.*, Nov. 1909).
and a weasel-like animal which hunts in packs. Ostriches are found in the open plains; the rivers swarm with crocodiles, but hippopotami are rare. Birds of prey are numerous and include eagles, vultures, kites, ravens and the carion stork. Among game birds are three varieties of bustard, guinea fowl, partridges, sand grouse and wild goose. Snakes are common, an adder, a variegated rock snake and a Hadramut with forty followers about the 13th century. Other traditions trace their origin to the Himyaritic chiefs Sanhāj and Samamah, said to have been coeval with a King Afrikus, who is supposed to have conquered Africa about A.D. 400. These legends should perhaps be interpreted as pointing to a

black snake called mūša being those most dreaded. Mosquitoes are rarely troublesome; gadflies, and a large spider (hangeyu), which spins a web resembling golden silk, are common, as are scorpions and centipedes. Termites rear sharp pointed "hills," often over 20 ft. high. A species of lizard grows nearly 4 ft. long.

Inhabitants.—The Somali belong to the Eastern (Ethiopic) Hamitic family of tribes, of which the other chief members are the neighbouring Galla and Afar, the Abyssinian Agau and the Beja tribes between the Nubian Nile and the Red Sea. They have been identified with the people of Punt, who were known to the Egyptians of the early dynasties. The Somali, however, declare themselves to be of Arab origin, alleging their progenitor to have been a certain Sherif Ishak b. Ahmad, who crossed from series of Arab immigrations, the last two of which are referred to the 13th and 15th centuries. But these intruders seem to have been successively absorbed in the Somali stock; and the Arabs never succeeded in establishing permanent communities in this region. Their influence has been very slight even on the Somali language, whose structure and vocabulary are essentially Hamitic, with marked affinities to the Galla on the one hand and to the Dankali (Afar) on the other.

The present Somali peoples are possessed of no general type. They are not pure Hamites, and their physical characteristics vary considerably, showing signs of interbreeding with Galla, Afar, Arabs, Abyssinians, Bantus and Negroes. They are a
SOMALILAND

race of magnificent physique, tall, active and robust, with fairly regular features, but showing Negro blood in their frequently black complexion and still more in their kinky and even woolly hair. Their colour varies from the Arab hue to black, and occasionally in between. The most regular features to be found among the darkest groups.

There are four classes in Somaliland: (1) nomads who breed ponies, sheep, cattle and camels, live entirely on milk and meat, and follow the rains in search of grass; (2) settled Somalis, comparatively few, living in or near the coasts; (3) outcast races, not organized in tribes but living scattered all over Somaliland; they are hunters, workers in iron and leather, and the chief collectors of gum and resin; (4) traders. The national dress is the "tobe," a simple cotton sheet of two breadthsewnt together, about 15 ft. long. Generally it is thrown over one or both shoulders, a turn then round the waist, and allowed to fall to the ankles. The "tobes" are of all colours from brown to white. A ceremonial "tobe" of red, white and blue, each colour in two shades, with a narrow fringe of light yellow, is sometimes worn. Old men shave the head and sometimes grow a beard. Middle-aged men wear the hair about an inch and a half long; young men and boys in a huge mop; while married women wear it in a chignon, and girls in mop-form but plaited.

The Somalis are a fighting race and all go armed with spear, sword and short sword (and guns when they can get them). During the rains incessant intertribal lootings of cattle take place. Among certain tribes those who have killed a man have the right to wear an ostrich-feather in their hair. They are great talkers, keenly sensitive to ridicule, and quick-tempered.

Women hold a degraded position among the Somalis (wives being often bought with sheep), doing most of the hard work. The Somali love display; they are inordinately vain and avaricious; but they make loyal and trustworthy soldiers and are generally bright and intelligent.

They have very little political or social cohesion, and are divided into a multiplicity of rata or fakidas (tribes, clans). Three main divisions, however, have been clearly determined, and these are important both on political and ethnical grounds.

I. The Hashiya (Abud's Asha), with two great subdivisions: Darada, with the powerful Mijertins, War-Sangeli, Dolbohanti and others; and Isikak, including the Gadabursi, Issa (Issa), Habr-Wal, Habr-Tol, Habr-Masi, Balibii, Bewarri. All these claim descent from a member of the Hashiya branch of the Korash (Mahomet's tribe), who founded a powerful state in the Zaila district. All are Sunnites, and, although still speaking their Somali language, are indigenously enough to maintain their blood in their physique, somewhat light skin, and remarkably regular features. Their domain comprises the whole of British Somaliland, and probably most of Italian Somaliland.

II. The Hwaya comprises several numerous sub-groups, such as the Habr-Jaale, Habr-Gader, Der-Dollo, Dajji, Karaman, Badbun, Kunli, Bajimal and Ugas Elmi; mostly fanatical Mahomedans forming the powerful Taraka sect, whose influence is felt throughout all the central and eastern parts of Somaliland. The Hwaya district comprises the Ogaden plateau and the region generally between the Nogal and Wehi-Shebeli rivers. Here contact has been chiefly with the eastern Galla tribes.

III. The Rahanwín, with numerous but little-known sub-groups, including, however, the powerful and warlike Abgas, Barawas, Goobons, Tuni, Jilin and Kalallas, occupy in part the region between the Baraytub and Juba, but chiefly the territory extending from the Juba to the Tana, where they have long been in contact, mostly hostile, with the Wa-Pokomo and other Bantu peoples of the British East Africa Protectorate. Of all the Somali tribes the Rahanwín betray the largest infusion of Negroid blood.

Of the outcast races the best known are the Midgan, Yebir, and Tomal. The Midgan, who are of slightly shorter stature than the average, are the most numerous of these peoples. They are great hunters and use small poisoned arrows to bring down their game. The Yebir are noted for their leather work, and the Tomal are the blacksmiths of the Somali.

Prehistoric Remains.—The discovery of flint implements of the same types as those found in Egypt, Mauritània, and Europe show Somaliland to have been inhabited by man at the same advent of civilization. These ruins have been found among more highly civilized people than the Somali of to-day is evidenced by the ruins which are found in various districts. Many of these ruins are attributable to the Arabs, but older remains are traditionally ascribed to a people who were "before the Gallas." Blocks of dressed stone overthrown by grass lie in regular formation; a series of parallel revetment walls on hills commanding passes exist, as do relics of ancient water-tanks. Part of the common civilization of Somaliland. Meanwhile the greater part of this -area was held by Mahomedan conquerors; before that event the people, in the opinion of several travellers, professed a degraded form of Christianity, which they had acquired from their Abyssinian neighbours. Of more recent origin are the ruins known as Galla graves (Taalla Galla). These are cairns of piled stones, each stone about the size of a man's head. The cairns are from 12 to 15 ft. high and about 8 yds. in diameter. Each is circular with a central depression.

Exploration.—Somaliland was one of the last parts of Africa to be explored by Europeans. The occupation of Aden by the British in 1839 proved the starting-point in the opening up of the country, Aden being the chief port with which the Somali of the opposite coast traded. The task of mapping the coast was largely undertaken by officers of the Indian navy, while the first explorers of the interior were officers of the Indian army quartered at Aden—Lieut. Cruttenden (1845), Lieut. (afterwards Captain Sir Richard) Burton, and Lieut. J. H. Speke (the discoverer of the Nile source). In 1854 Burton, unaccompanied, penetrated inland as far as Harrar. Later on the expedition was attacked by Somali near Berbera, both Burton and Speke having to return to Aden. Speke himself was killed in 1862, Lieutenant Stroyan, R.N., killed. For twenty years afterwards no attempt was made to open up the country. The occupation of Berbera by the Egyptians in 1875 was, however, followed by several journeys into the interior. Of those who essayed to cross the waterless Haud more than one lost his life. In 1883 a party of Englishmen—F. L. and W. D. James (brothers), G. P. V. Aylmer, and E. Lort-Phillips—penetrated from Berbera as far as the Wehi-Shebeli, and returned in safety. At the instance of the Indian government surveys of the country between the coast and the Wehi-Shebeli and also east towards the Wadi Nogal were executed by Major H. G. C. Swayne and his brother Captain E. J. E. Swayne between 1886 and 1892. Meanwhile a French traveller, G. Révoil, had (1878–1881) made three journeys in the north-east corner of the protectorate, especially in the Harra valley. The first person who reached the Indian Ocean, going south from the Gulf of Aden, was an American, Dr A. Donaldson Smith (b. 1864). He explored (1894–1895) the headstreams of the Shebeli, reached Lake Rudolf, and eventually descended the Tana river to the sea, his journey thus taking him through some of the most important of the ancient cairns. In 1896–1897 another expedition was made under the charge of Dr Stroyan, who was succeeded by Dr Swayne, who in turn was succeeded by his brother Captain E. J. E. Swayne. In 1898 Bottge explored to its source, the Zingelijke, which was also reached in 1903 by H. G. C. Swayne. In 1892 Captain Ruspoli was sent by the Italian government to the eastward of Berbera, and in 1896–1897 Bottge explored to its source, the Zingelijke, which was also reached in 1903 by H. G. C. Swayne. In 1892 Captain Ruspoli was sent by the Italian government to the eastward of Berbera, and in 1896–1897 Bottge explored to its source, the Zingelijke, which was also reached in 1903 by H. G. C. Swayne. In 1892 Captain Ruspoli was sent by the Italian government to the eastward of Berbera, and in 1896–1897 Bottge explored to its source, the Zingelijke, which was also reached in 1903 by H. G. C. Swayne. In 1892 Captain Ruspoli was sent by the Italian government to the eastward of Berbera, and in 1896–1897 Bottge explored to its source, the Zingelijke, which was also reached in 1893 by H. G. C. Swayne.
to the Upper Nile (1899-1900). In 1902-1903 a survey of the Galla-Somali borders between Lake Rudolf and the upper Juba was executed by Captain P. Maud of the British army. Military operations during 1901 led to a more accurate knowledge of the southern and eastern parts of the British protectorate and of the adjacent districts of Italian Somaliland.

**BRITISH SOMALILAND**

The British Somaliland protectorate extends along the Gulf of Aden for about 400 m. from the Labado Wells, near Jibuti, in the west, to Bandar Ziyada in 49° E., 180 m. W. of Cape Guardafui, and stretches from the coast inland for a breadth varying from 80 to 220 m. The protectorate is bounded W. by French Somaliland, S.W. by Abyssinian territory, and S.E. and E. by Italian Somaliland. About 50,000 persons are settled in the coast towns; the rest are nomads.

**Topography.**—Physically the protectorate may be described as almost mountainous in contrast with the somewhat monotonous plains of the interior. Between the Harrar plateau and Cape Guardafui the coast ranges maintain a mean altitude of from 4000 to 3000 ft., and fall generally in steep escarpments to the sea. The South Somali, partly of rolling grass plains, called ban, and partly of semi-desert country called arar. Westward of Berbera the ascent to the high country in great parts is made by several steps, the mountains forming a chaotic mass. Eastward the mountain system, the Jebel Sangeli, maintains the same general character as far as Bandar Gori (Las Koral), where the precipitous northern cliffs are interrupted by a narrow gap, their height, their bare rocks and cliffs presenting the same uninviting appearance as the light brown hills skirting the Red Sea. Immediately south of the Jebel Sangeli are the comparatively fertile Jidali and Gebi districts of palms and date palms, as in the east, made by several steps, the mounds forming a chaotic mass. Eastwards the mountain system, the Jebel Sangeli, maintains the same general character as far as Bandar Gori (Las Koral), where the precipitous northern cliffs are interrupted by a narrow gap, their height, their bare rocks and cliffs presenting the same uninviting appearance as the light brown hills skirting the Red Sea. Immediately south of the Jebel Sangeli are the comparatively fertile Jidali and Gebi districts of palms and date palms, as in the east, made by several steps, the mounds forming a chaotic mass.

**Trade.**—The trade of the protectorate is largely in hides and skins, coffee, live stock, and skins; the hides being mainly sent to Egypt, Arabia, and other countries. The trade is carried on by the Arabs, who are the principal inhabitants of the country. The trade is carried on by the Arabs, who are the principal inhabitants of the country. The trade is carried on by the Arabs, who are the principal inhabitants of the country. The trade is carried on by the Arabs, who are the principal inhabitants of the country.

**History.**—An Arab sultanate, with its capital at Zaila (Zeyla), was founded by Koreishite immigrants from the Yemen in, it is said, the 7th century A.D. In the 13th century it had become a comparatively powerful state, known as the empire of Adel. In the 16th century the capital of the state (in which Arab influence was a decreasing factor) was transferred to Harrar (q.v.). The state was greatly harassed by Galla invaders in the 17th century, and broke up into a number of dependent emirates and sultanates under Somali chiefs. Zaila became a dependency of Yemen and thus nominally part of the Turkish empire. The British connexion with the Somali coast dates from the early years of the 19th century; the first treaty between the British and Somali having been signed in 1827 after the plundering of an English ship by the Habr-Wal. In 1849 various treaties were concluded by Captain Robert Moresby of the Indian Navy "on the part of the English Government in India " with the sultan of Tajura and the governor of Zaila, who engaged not to enter into treaties with any other foreign power. At the same time Masha Island, at the entrance to the Gulf of Tajura, was bought by the British "for ten bags of rice, " Bab Island, in the same gulf, and Aubad Island, off Zaila, were also purchased, the object of the East India Company being to obtain a suitable place "for the harbour of their ships without any prohibition whatever." From this time onwards the Indian government exercised considerable influence on the Somali coast, but British authority was not definitely established, and in 1854 Richard Burton's expedition was attacked at Barba. In 1874-1875 the ambition of Ismail Pasha, khedive of Egypt, who claimed jurisdiction over the whole coast of the Somali, was frustrated by the signalling to the port of Buurao, which was occupied by the British. In 1875 the British protectorate was established and the port of Buurao was occupied. In 1884, 1885, 1886 treaties guaranteeing British protection were concluded with various Somali tribes and in 1888 the limits of the British and French spheres were defined, all claims to British jurisdiction in the Gulf of Tajura and the islands of Musha and Bab being abandoned. The other inland boundaries of the protectorate were defined by agreements with Italy (1894) and Abyssinia (1897).

In 1899 troubles arose between the administration and a mullah of the Halab Suleiman Ogaden tribe, who had acquired great influence in the Doolbahana country and had married into the Doolbahana Ali Gheri. This mullah, Mohammed bin Abdullah by name, had made several pilgrimages to Mecca, where he had attached himself to a sect which enjoined strict observance of the tenets of Islam and placed an interdiction on the use of the leaves of the kat plant—much sought after by the coast Arabs and Somali for their stimulating and inquito-proofing properties. At first the mullah's influence was exerted for good, and he kept the tribes over whom he had control at peace; he also accredited the power of the British protectorate and gained a strong following. In 1899 the mullah began raiding tribes friendly to the British; in August of that year he occupied Burao, 80 m. south and east of Berbera, and declared himself the mabdi. In the autumn of 1900 the mullah was again harassing the tribes on the southern border of the British protectorate and the neighbouring Abyssinian districts. The tribes hostile to the mullah sought British protection, and Colonel (afterwards Sir) E. J. E. Swaye raised a Somali levy of 1500 men, and in May 1901 occupied Burao.
On the 2nd of June a small force, zerbased under Captain Malcolm McNeill, was attacked by the mullah's followers but repulsed after desperate fighting. Colonel Swainey thrice defeated the enemy, who lost 1,200 men and 600 taken prisoners, and the mullah fled across the Haud, taking refuge with the Mijertins in Italian territory. In December 1906 the mullah was, however, once more raiding in the neighbourhood of Burma, and in May 1907 with the Mullah, Mohammed King's African Rifles, consisting of Yos from Nyasa-Abdullah, Arab. Overcoming in a remarkable manner the difficulties of operating in the dry season, Colonel Swainey harried the mullah incessantly, and followed him across the Haud into the more fertile region of Mudug in Italian territory, permission so to do being granted by Italy. On the 6th of October, while marching through dense bush at Erigo, the British force was ambuscaded. The British lost 101 killed and 83 wounded, but put the enemy to flight. The mullah lost some 700 men and retreated to Galadi, west of Mudug, a place with ample water supplies. Colonel Swainey was not able to continue the pursuit, and returned to Berbera. It was then determined that in the further operations against the mullah the main advance should be from a base on the east coast of Italian Somaliland—the open roadstead of Obbia being chosen. The command was given to Brigadier-General W. H. Manning, and small numbers of British and Boer mounted infantry, Indian and African troops were employed, while an Abyssinian force bearing the name of the Weli Shebeli, a native, advanced from Obbia in February 1903, and in March got in touch with the northern column, the line of communication stretching over 500 m. The mullah was west of this line in the neighbourhood of Galadi. The wells at Galadi were occupied by the British early in April without opposition. A reconstituting force of 500 men under Lieut.-Colonel A. S. Cobbe (who had gained the V.C. at Erigo) was pushed west to Gumburu, and came into contact with the enemy. A detachment of this force, consisting of 200 Yos and Sikhs under Lieut.-Colonel Plunket, was attacked on the 17th of April and overpowered. Of the whole party only 40 Yos, of whom 36 were wounded, escaped; to British officers being among the slain. Meanwhile from Bohote a force had advanced under Major Gough to Daratole, a spot not far from Gumburu. It had a stiff fight on the 23rd of April and was obliged to fall back. After these events the Obbia line of communication was closed up, and Manning's force concentrated at Bohote. The mullah now broke away to the north, and, crossing the line of the British communication, established himself in the Nogal district.

Another campaign being deemed necessary, reinforcements bringing the fighting force up to 7,000 men were sent out, and Major-General Sir C. C. Egerton assumed supreme command, Manning retaining command of the first column. In October 1903 a new forward movement was begun, the mullah being still in the eastern Nigel, while he had also seized the Italian seaport of Illig, north of Obbia. In a pitched battle fought on the 10th of January 1904 at Jidballi in the Nogal country the enemy were routed, losing over 1,000 men in killed alone, while the British loss in killed and wounded was 38. The mullah and his chief adviser, a Haji Sudi, formerly an interpreter on a British warship, were not at the battle, and with his Ahi followers he now fled north across the hot, apparently intending, if further pressed to retreat, to Illig. This part was accordingly for a short time (April 1904) occupied by a British naval force. By May the mullah had been driven out of the British protectorate and became a refugee among the Mijertins. It was decided therefore to abandon offensive operations. In 1905 the Italians effected an arrangement apparently satisfactory to all parties (see § Italian Somaliland). For some three years the mullah remained quiescent, but in 1908 he quarrelled with the Mijertins and in 1909 he was again raiding tribes in the British protectorate. The British government (the Asquith cabinet) came to the conclusion that another expedition against the mullah would be useless; that they must either build a railway, make roads and effectively occupy the whole of the protectorate, or else abandon the interior completely.

The latter course was decided upon, and during the first months of 1910 the advanced posts were withdrawn and the British forces concentrated in the south of the protectorate. In support of this decision it was urged that it was no good pursuing people whom it was impossible to catch, that the isolated posts in the interior had not been able to protect the friendly tribes; and that the semi-desert nature of the country did not justify any attempt at economic development. (The proposal to build a railway from Zalla or Berbera to Harrar, which would have competed with the French line from Jibuti for the trade of southern Abyssinia, had been vetoed on grounds of general policy.) Before the withdrawal arrangements—more or less ineffective—were made for arming and organizing the tribes in the protectorate and help them defend themselves.

From 1884 to 1898 the protectorate was attached for administrative purposes to Bombay, and was immediately dependent on Aden; in the last-named year it was transferred to the Foreign Office, and in 1905 passed under the control of the Colonial Office. From 1902 the protectorate was called Jibuti, a name previously used. Colonel Swainey led another expedition against the mullah, who was succeeded by Captain H. E. S. Cordeaux, who had served in Somaliland since 1898. Legislative power is in the hands of the commissioner, and revenue is obtained largely from customs. The revenue, £120,000 in 1905, was increased to £151,000 in the first-named year, £134,000 in 1908-9. Deficits are made good by grants from the imperial treasury.

FRENCH SOMALILAND

French Somaliland (Côte française des Somalis) lies at the entrance to the Red Sea. The sea frontier extends from Ras Dumeere on the Straits of Bab-el-Mandeb, a little north of Perim Island, to Ras Garmarle, a few miles south of the Gulf of Tajura. The protectorate is bounded N. by the Danakil country; S. by British Somaliland; W. by the Harrar province of Abyssinia. It extends inland at its greatest depth about 130 m.

The country consists chiefly of slightly elevated sand plains, largely waterless save along the southern frontier. The only good harbour along the coast is at Jibuti. The Gulf of Tajura is 28 m. across at its entrance and penetrates inland 36 m. At its western end an opening 870 yds. wide leads into the circular bay of Gubbat-Kharab (Hell's Mouth), behind which rise a chaotic mass of volcanic rocks, destitute of vegetation and presenting a scene of weird desolation. A pass through the hills gives access to Bahr-Assal; the last of a chain of salt lakes, embracing 60 m. inland. In the depression in which the waters of the Hawash (see Abyssinia) lose themselves. It is conjectured that at some remote period the Hawash flowed into Tajura Bay and that the present condition of the country is the result of a gigantic geologic upheaval. The present lake has formed part of the sea bed. It is now 5 m. inland from Gubbat-Kharab, is 5 m. long by 4 broad, and lies 490 ft. below sea level. About 160 ft. above the surface level of the lake is a white band marking the unwatered, salt marshes. The section of the water is carried on by the wadi Bahr-Assal. The name is derived from the word Bahr (sea) and Assal (a salt lake). The water is salty, being in temperature of 104°F., flow into the lake. The climate of the protectorate is very hot, but not unhealthy for Europeans if reasonable precautions are taken. Inhabitants and Towns—The inhabitants are, on the north side of the Gulf of Tajura, chiefly Danakils (Afrs., q.v.); on the southern shore Galia and Somal. There are a number of Arabs, Abyssinians, Indians, and about 2000 Europeans and Levantines. The chief town and seat of administration is Jibuti (q.v.), which has taken the place of Obok (q.v.), on the northern side of the Gulf of Tajura. Also situated on the gull are the small towns of Tajura, Sagallo, Boud and Ambalo.

The town and Commercial centre of salt from Bahr-Assal is an industry of some importance. In 1903 a beginning was made in the cultivation of cotton in the dry river beds, where water can always be obtained at a depth of 10 ft. On the sandy tundra and sand-pebbly beaches carried by the sea, the value of the protectorate depends upon the cultivation of the cotton and the purchasing of victuall and coals to French warships. In 1897 the building of a railway line towards Jibuti was commenced. On 10th July 1902 the railway, called the Imperial Ethiopian railway, was completed to Dire Dawa (or Adis Harrar), 30 m. short of Harrar, and 88 by rail from Jibuti, of which but 64 are m. in French territory. The French class 3,400 m. per 24 hours at a cost of £20,000 a year for fifty years was granted to the company owning the railway (see further Abyssinia). The exports are chiefly coffee, hides, ivory (all from Abyssinia), gum, mother-of-pearl and a little gold; the imports cotton and other
European stuffs, cereals, beverages, tobacco and arms and ammunition for the Abyssinians. The total volume of trade in 1902, the year of the completion of the railway, was £225,000, in 1905 it had risen to £1,208,000—imports £450,000, exports £758,000.

History.—French interest in the Somali and Danakil coasts dates from the days of the Second Empire. Count Stanislas Raspail, the French consul to the Red Sea from 1857, and he reported strongly on the necessity of a French establishment in that region in view of the approaching completion of the Suez Canal. The only result of his enterprise was the abortive treaty for the cession to France of Zula (q.v.), now in the Italian colony of Eritrea. In 1856, however, M. Monge, vice-consul of France at Zalla, had bought Ambobo, and shortly afterwards Henri Lambert, French consul at Aden, bought the town and territory of Obok. Lambert (who was assassinated by Arabs, June 1859) had the support of his government, which viewed with alarm the establishment (1857) of the British on Perim Island, at the entrance to the Red Sea. The cession of Obok was ratified by a treaty (signed on the 11th of March 1863) between the French government and various Danakil chiefs. It was not, however, until 1883 that, in consequence of events in Egypt and the Sudan (see Egypt: History), formal possession was taken of Obok by the French government. In 1884 Léonce Lagarde, subsequently French minister to Abyssinia, was sent to administer the infant colony. Between 1883 and 1887 treaties with Somali sultans gave France possession of the whole of the Gulf of Tadjur. An agreement with Great Britain (5 Feb. 1885) fixed the southern limits of the protectorate; protocols with Italy (June 1891) and the Sudan (1893) fixed the northern limits. The frontier towards Abyssinia was fixed by a convention of March 1897 with the Negus Menelik. In 1899 a Cossack chief, Captain Atchinoiff, who had occupied Sagallo, was forcibly removed by the French authorities (see SAGALLO). The transference of the seat of government to Jibuti in May 1896 and the building of the railway to Harrar gave the protectorate a stability which it had previously lacked. Its importance to France is, nevertheless, chiefly strategic and political. It serves as a coal station for men-of-war and as a highroad to Abyssinia.

ITALIAN SOMALILAND

Italian Somaliland extends on the coast from Bandar Ziyada, a point on the Gulf of Aden intersected by 40° E., eastward to Cape Guardafui, and thence southward to the mouth of the river Juba in 12° 15' S. Bounded N. and E. by the Indian Ocean it is separated S. from British East Africa by the Juba. Westward it is bounded by Abyssinian and British Somaliland. From the east coast the protectorate extends inland from 100 to 300 m.

The coast-line is largely rocky and little indented, and throughout the 1200 m. of it there is not one good harbor. The northern shore, along the Gulf of Aden, is backed by tablelands separated by the beds of mountain torrents—generally dry. From the table-land rise hills, such as Jebel Kurma, which have an altitude of 4000 ft. or more. The coast rises in a succession of hills (fringed by a narrow margin of beach) until Cape Guardafui is reached. Cape Guardafui is in 17° 75' N., 51° 26' 32'' E., and forms, as it were, a point of Africa on the rim of the cape, which faces north and east, presents on its northern face a nearly vertical wall of rock rising from the sea to a height of 900 ft. The water is deep right to the base of the cliff and owing to the winds and the strength of the ocean currents, navigation is dangerous. The headland is known to the Somali as Girdil or Yardaf—whence in all probability comes the European form Guardafui. But in the Italian, guardia means "watch," a meaning also attached to the Portuguese word guardia.

Guardafui is the extreme point of the Somali coast; the French forts in the Gulf of Tadjur are not included in it. Cape Guardafui is at the southern limit of the region, that of the lower Nogal, included the port of Illig. Henry Mohamoud X. Abdullah established himself under Italian surveillance, and by an agreement dated the 5th of March 1905, peace was declared between the mullah, the Italians, British and Abyssinians, and all other Somali tribes. In 1908-1909, however, fighting was renewed, the mullah and the Mijertins failing to agree. Italian (native) troops were sent to the district to restore order. The mullah also attacked tribes living in the British protectorate (see § 2).

The station of Lugh, the most advanced post occupied by Italian Somaliland, was founded by Captain Bottego in 1895. After the treaty of Adis Adowa, recognizing the independence of Abyssinia, had been concluded in 1896, negotiations were opened for defining the Italian-Abyssinian frontier in the Somali regions. In 1897 an agreement was come to that from the point on the coast.

Warcheik (1000) and Yub. These are in all the southern part of the protectorate between 4° S. and 2° N., and are known generically as El-Bebedir (the ports), a name also applied to the coast between the ports. Yub (Jub) is a small town at the mouth of the Juba river. In every case the port is much exposed and unapproachable for months together. Obba, 5° S. and 13° N., and Illis in 7° 60' N., are points of departure for the Ogaden and Doldabaha countries. Aula, on the Gulf of Aden, is the chief town of the Mogadbish.

In the interior is Lugh, a populous city on the left bank of the Juba, about 240 m. from the coast, and further inland is Dolo at the confluence of the Daaw and Gaalale to form the Juba. These towns are important as depôts for the trade of the interior, especially with the Boran district.

In the coast towns of the eastern seaboard there are Swahili, Arab and Indian settlements, and tribes, such as the Amanar, of mixed Abissino, Somali and Bantu blood.

Agriculture and Trade.—Though much of the land is barren, the soil is fairly fertile in the valleys of the Webi Sheheli and Wadi Nogal. But the whole fertile district is the valley of the lower Juba, where for over 100 m. is a strip of land varying from 50 to 60 ft. and yards to some 4 m. wide, annually inundated by the rise of the river. Here are cultivated rich crops of millet and other grains. In other districts lack of water impedes cultivation, though after the rains pastureage is abundant, and resinous plants are so varied and numerous as to justify the ancient name of the region.

Ivory, cattle, butter, coffee, cotton, myrrh, gums and skins are exported to the Benadir. The Juba is navigable for about 130 m. and for a similar but smaller trade and one also in ostrich feathers. The chief imports are textile fabrics, rice and petroleum. During 1896-1897 the value of the Benadir trade was £120,000; in 1906- 1907 it was raised to over £300,000 annually.

History.—The Somali coast, as has been seen, early fell under Moslem influence. The towns on the eastern seaboard, of which Muckdishu and Brava were the chief, formed part of the Zenj (see ZANZIBAR) and shared its fate, being conquered in turn by the Portuguese (16th century), the imans of Muscat (17th century), and the sultans of Zanzibar (1866). On account, probably, of the inhospitable nature of the shore the northern portion of the protectorate appears to have been little subject to hostile invasion. By treaties with Somali sultans in 1890 and subsequent agreements with Great Britain, Zanzibar and Abyssinia, the coast east of the British Somali protectorate fell within the Italian sphere of influence (see AFRICA, § 3). In August 1892 the sultan of Zanzibar leased the Benadir ports for Italy for fifty years. They were administered first by the Filonardi Company, and from 1898 by the Benadair Company. By an agreement dated the 13th of January 1905 the sultan of Zanzibar ceded his sovereign rights in the Benadir ports to Italy in return for the payment of a lump sum of £144,000. Thereafter the Italian government assumed the direct administration of the ports, a purely commercial undertaking replacing the Benadir Company.

The coast of Benadir was leased to Italy a piece of land near Kismayu to facilitate communications with the Benadir country. In 1908 a royal decree placed that part of the country between the Juba and the sultanate of Oibba under a civil governor.

A notable event in the history of the protectorate was the co-operation of the Italian authorities in the campaigns against the Mullah Abdullah. In 1904 negotiations were opened with the mullah by the Italians, and by arrangement with the sultan of Oibba and the sultan of the Mijertins the territory between Ras Aswad and Ras Bowen, which was claimed by both parties, was ceded to Great Britain, and over to the south of this region, that of the lower Nogal, included the port of Illig. Henry Mohamoud X. Abdullah established himself under Italian surveillance, and by an agreement dated the 5th of March 1905, peace was declared between the mullah, the Italians, British and Abyssinians, and all other Somali tribes. In 1908-1909, however, fighting was renewed, the mullah and the Mijertins failing to agree. Italian (native) troops were sent to the district to restore order. The mullah also attacked tribes living in the British protectorate (see § 2).

The station of Lugh, the most advanced point occupied by Italian Somaliland, was founded by Captain Bottego in 1895. After the treaty of Adis Adowa, recognizing the independence of Abyssinia, had been concluded in 1896, negotiations were opened for defining the Italian-Abyssinian frontier in the Somali regions. In 1897 an agreement was come to that from the point on the coast.
British Somaliland frontier where 47° E. intersected 8° N. the frontier line should be drawn, at a distance of about 180 m. from the Indian Ocean, to the Juba. At the close of 1897 the Negus Menelik, in return for a pecuniary indemnity (£120,000), agreed to a modification of the 1897 line, whereby the Italian protectorate was extended north of Lugh to Dehej (proximity frontier). The line modified in 1897, thence the 1897 line is followed to the British-Abyssinian frontier. By this arrangement (ratified by a convention dated the 16th of May 1908) the Benadir coast obtained a suitable hinterland.

SOMBRERO—SOMMERS, BARON

A wide-brimmed hat, made of felt, largely worn throughout South and Central America, but originating in Spain. The Spanish word is derived from sombrero, shade, generally taken to be from Lat. sub umbra, beneath the shade; but the etymology, like that of "sombre," dark, gloomy, has been disputed.

SOMMERS, JOHN SOMMERS (or SOMMERS), BARON (1651-1716), English lord chancellor, was born on the 4th of March 1651, and was the eldest son of Henry Sommer, who was in large practice in that town, who had formerly fought on the side of the Parliament, and of Catherine Cavenerne of Shropshire. After being at school at Worcester he was entered as a gentleman commoner at Trinity College, Oxford, and afterwards studied law under Sir Francis Winnington, who became solicitor-general, and joined the Middle Temple. He appears, in addition to his legal studies, to have written several poems and pamphlets. He soon became intimate with the leaders of the country party, especially with Essex, William Russell, and Algernon Sidney, but never entered into their plans so far as to commit himself beyond the position of a supporter. He wrote an essay on the succession of the Crown of England, collected out of Records, &c., and was reputed to have written the Just and Modest Vindication of the Two Last Parliaments, which was put forward as the answer to Charles II.'s famous declaration of his reasons for dissolving them. This, however, was by Sidney, though probably Somers was responsible for the final draft. When the grand jury of Middlesex threw out the bill against Shaftesbury, and were vehemently attacked for so doing, Somers wrote in defence of the rights of grantees, and to disprove the sheriff's petition. Pilkington and Somers were the two members of the House of Commons who opposed the Bill, and secured a reputation which continually increased until the trial of the seven bishops, in which he was junior counsel. "Somers rose last. He spoke little more than five minutes, but every word was full of weighty matter; and when he sat down his reputation as an orator and a constitutional lawyer was established." In the secret councils of those who were planning the revolution Somers took a leading part, and in the Convention Parliament was elected a member for his native town. He was immediately appointed one of the managers for the Commons in the conference with the House of Lords; and inquiring the questions whether James II. had left the throne vacant by abdication and whether the acts of the Convention Parliament were legal—that parliament having been summoned without the usual writs—he displayed great learning and legal subtlety. He was further distinguished by being made chairman of the committee which drew up the celebrated Declaration of Right.

In May 1689 Somers was made solicitor-general. He now became William III.'s most confidential adviser. In the controversy which the king carried on with the Dutch, in which the question of the legality of the decision of the court of King's Bench regarding Titus Oates, and of the action of the Lords in sustaining this decision, Somers was again the leading manager for the Commons, and has left a clear and interesting account of the debates. He was next employed in January 1690 as chairman of the select committee of the House of Commons on the Corpora Bill, by which those corporations which had surrendered their charters to the Crown during the last two reigns were restored to their rights; but he refused to associate himself with the violent measures of retaliation which the Whigs on that occasion endeavoured to include in the bill. In April a speech by him carried through the lower house, without opposition, the bill which declared all the laws passed by the Convention Parliament to be valid. As solicitor-general he had to conduct the prosecution of Preston and Ashton in 1691, and did so with a moderation and humanity which were in marked contrast to the customs of the former reigns. He was soon after appointed attorney-general, and in that capacity strongly opposed the bill for the regulation of trials in cases of high treason. On the 23rd of March 1693, the great seal having meanwhile been in commission, Somers was appointed to the House of Commons, and was a member for six years, and in 1696 for one year from the day on which he should quit his office, and at the same time was made a privy councillor. He had previously been knighted. Somers now became the most prominent member of the Junto, the small council which comprised the chief members of the Whig party. When William left in May 1695 to take command of the army in the Netherlands, Somers was made one of the seven lords-justices to whom the administration of the kingdom during his absence was entrusted; and he was instrumental in bringing about a reconciliation between William and the princess Anne.

In April 1697 Somers was made lord chancellor, and was created a peer by the title of Baron Somers of Evesham. When the discussion arose on the question of disbarring the army, he summed up the case against disbarring, in answer to Trenchard, in a remarkable pamphlet called "The Balancing Letter." In August 1698 he went to Tunbridge Wells for his health. While there he received the king's letter announcing the first Partition Treaty, and at once replied with a memorandum representing the necessity in the state of feeling in England of avoiding further war. When the king, on the occasion of the Disbanding Bill, expressed his determination to leave the country, Somers boldly remonstrated, while he clearly expressed in a speech in the Lords the danger of the course that was being taken. Hitherto Somers's character had kept him free from attack at the hands
of political opponents; but his connexion in 1699 with the notorious Captain William Kidd, to the cost of whose expedition Somers had given £1000, afforded an opportunity; the vote of censure, however, proposed upon him in the House of Commons for giving Kidd a commission under the great seal was rejected by 199 to 131. The attack was renewed shortly on the ground of his having accepted grants of Crown property to the amount of £1600 a year, but was again defeated. On the subject of the Irish forfeitures a third attack was made in 1700, a motion being brought forward to request the king to remove Somers from his counsels and presence for ever; but this again was rejected by a large majority. In consequence, however, of the incessant agitation William now proposed to resign this he refused to do, but gave up the seals to William's messenger. In 1701 he was impeached by the Commons on account of the part he had taken in the negotiations relating to the Partition Treaty in 1668, and defended himself most ably before the house, answering the charges seriatim. The impeachment was voted and sent up to the Lords, but was there dismissed. On the death of the king Somers retired almost entirely into private life. He was president of the Royal Society from 1699 to 1704. He was, however, active in 1703 in opposing the Occasional Conformity Bill, and in 1706 was one of the managers of the union with Scotland. In the same year he carried a bill regulating and improving the proceedings of the law courts. He was made president of the council in 1708 upon the return of the Whigs to power, and retained the office until their downfall in 1710. He died on the 26th of April 1716.

For a contemporary character of Somers Addison's paper in the Freeholder for the 14th of May 1716 should be referred to; and there is in the Beaufort family dated from 1397, in which year it was granted by Richard II. to John Beaufort (c. 1373-1419), the eldest of the three illegitimate, afterwards legitimated, sons of John of Gaunt, duke of Lancaster, by Catherine, wife of Sir Hugh Swnford, and daughter of Sir Payne Roelt. He was followed in the earldom successively by his three sons: Henry, who died unmarried in 1418; John (1404-1444), who in 1443 was created earl of Kendal and duke of Somerset, both of which titles became extinct at his death; and Edmund, who was created earl of Dorset in 1444, marquess of Dorset in 1443, and duke of Somerset in 1448. (See Somerset, Edmund Beaufort, Duke of.) On the execution of Edmund's son Henry, 5th earl and 2nd duke of Somerset, by the Yorkists in 1454, his titles were forfeited by act of parliament; but his brother Edmund was from that date styled duke of Somerset by the Lancastrian party till his death in May 1471, when the house of Beaufort became extinct. (See Beaufort.) In 1499 Henry VII. nominated his infant son Edmund to the dukedom of Somerset at his baptism, but the child, who died within a few months, was probably never formally created a peer; the title, conjoined with the dukedom of Richmond, was, however, borne by Henry Fitzroy, illegitimate son of Henry VIII., from 1525 till his death without heirs in 1566.

Edward Seymour, duke of Somerset (g.v.), known as the Protector, was the first of the line of dukes to which the holder of the title at the present day belongs, having been created Viscount Beauchamp of Hache, Co. Somerset, in 1536; earl of Hertford in 1537; and in 1547 Baron Seymour and duke of Somerset. His honours, which were entailed on the issue of his second in priority to that of his first marriage, being forfeited by attainer in 1552, Robert Carr became earl of Somerset (g.v.) in 1613, but died without male issue in 1615, when his title became extinct. A curious incident in the history of this title was the grant by Charles I. in 1644 of a commission to Edward Somerset, son of Henry, 1st marquess of Worcester, empowering him to fill up certain blank patents of peerage with a promise of the title of duke of Somerset for himself. After the Restoration this instrument was cancelled in consequence of a resolution of the House of Lords declaring it to be "in prejudice to the peers"; and the grantee, who had meantime succeeded to the marquessate of Worcester, surrendered his claim to the dukedom of Somerset to the king. In the same month the dukedom of Somerset and barony of Seymour was restored to Edward Seymour (1588-1660), great-grandson of the Protector, who in 1621 inherited the titles of earl of Hertford and Baron Beauchamp which had been granted to his grandfather Edward Seymour in 1559, and who, in 1640, had himself been created marquess of Hertford. This nobleman, who in early life had incurred the displeasure of James I. by marrying the king's cousin, Lady Arabella Stuart, and had been imprisoned in the Tower for the offence, had later an exceptional claim on the gratitude of the royal house of Stuart, for he fought with distinction on the royalist side in the civil war, and was one of the Lords (the others being the duke of Richmond, and the earls of Lindsey and Southampton) who petitioned the Commons to be allowed to assume responsibility for the actions of Charles I. and to suffer death in his place. He died in November 1660, a few weeks after his restoration to the dukedom, and, having outlived his three eldest sons, was succeeded by his grandson William, 3rd duke of Somerset (c. 1651-1761). As the latter died unmarried, his sister Elizabeth brought to her husband, Thomas Bruce, 2nd earl of Ailesbury, the great estates of Tottenham Park and Savernake Forest in Wiltshire; while the Somerset title devolved on the 2nd duke of Beaufort (c. 1667-1706), the 2nd duke's fifth and youngest son. At the death of the latter without issue in April 1715 the marquessate of Hertford became extinct, and his cousin Francis Seymour (1658-1678) became 5th duke of Somerset. This nobleman was the eldest surviving son of Charles Seymour, 2nd Baron Seymour of Trowbridge, whose father Sir Francis Seymour (c. 1590-1664), a younger brother of the 2nd duke of Somerset, was created a baron in 1641.

Charles Seymour, 6th duke of Somerset (1662-1748), succeeded his brother Francis, the 5th duke, when the latter was slain in 1678 at the age of twenty, by a Genoese gentleman named Antonio Botti. The title of Seymour was said to have been insulted at Lerici. Charles, who thus inherited the barony of Seymour of Trowbridge along with the dukedom of Somerset, was educated at Trinity College, Cambridge; and in 1682 he married a great heiress, Elizabeth, daughter of Joceline Percy, earl of Northumberland, who brought him immense estates, including Alnwick Castle, Petworth, Sutton House and Northumberland House in London. (See Northumberland, Earls and Dukes of.) In 1683 Somerset received an appointment in the king's household, and two years later a colonelcy of dragoons; but at the time of the revolution he was the prince of Orange. Having befriended Princess Anne in 1672, he became a great favourite with her after her accession to the throne, receiving the post of master of the horse in 1702. Finding himself neglected by Marlborough, he made friends with the Tories, and succeeded in retaining the queen's confidence, while his wife replaced the duchess of Marlborough as mistress of the robes in 1711. In the memorable crisis when Anne was at the point of death, Somerset acted with Agyll, Shrewsbury and other Whig nobles who, by insisting on their right to be present in the privy council, secured the Hanoverian succession to the Crown. He retained the office of master of the horse under George I. till 1716, when he was dismissed and retired into private life; he died at Petworth on the 2nd of December 1748. The duke's first wife having died in 1722, he married secondly, in 1726, Charlotte, daughter of the 2nd earl of Nottingham. He was a remarkably handsome man, and inordinately fond of taking a
conspicuous part in court ceremonials; his vanity, which earned him the sobriquet of "the proud duke," was a byword among his contemporaries and was the subject of numerous anecdotes; Macaulay's description of him as "a man in whom the pride of birth and rank amounted almost to a disease," is well known. His son Algernon (1684–1730), by his first wife Elizabeth Percy, was called to the House of Lords as Baron Percy in 1722; and after succeeding his father as 7th duke of Somerset in 1748, was on account of his maternal descent, created Baron Warkworth and earl of Northumberland in 1749, with remainder to Sir Hugh Smithson, husband of his daughter Elizabeth; and also Baron Cockermouth and earl of Egremont, with remainder to the children of his sister, Lady Catherine Wyndham. At his death without male issue in February 1750 these titles therefore passed to different families in accordance with the remainders in the patents of their creation; the earldom of Hertford, the barony of Beauchamp, and the barony of Seymour of Trowbridge became extinct; and the dukedom of Somerset, together with the barony of Seymour, devolved on a distant cousin, Sir Edward Seymour, 6th baronet of Berry Pomeroy, Devonshire. (See Seymour, or St Maur.)

The Seymours of Berry Pomeroy were the elder branch of the family, being descended from the protector Somerset by his first marriage, the issue of which had been excluded from succession to the titles and estates until after the failure of the issue of his second marriage (see above), which failure occurred on the death of the above-named Algernon, 7th duke. Sir Edward Seymour (1695–1757), who thus became 8th duke of Somerset, was educated at Eton and Christ Church, Oxford, and from 1830 till he succeeded to the peerage in 1835 he was a mathematician and scientist of some distinction. The latter's son Edward Adolphus, 12th duke (1804–1885), was educated at Eton and Christ Church, Oxford, and from 1830 till he succeeded to the peerage in 1835 he was a Liberal member of the House of Commons as Lord Seymour, first for Oxford, and afterwards for Totnes. He held various offices in Lord Melbourne's administration from 1835 to 1841; was a member of Lord John Russell's cabinet in 1851; and first lord of the admiralty from 1859 to 1860. In 1858 he married Jane Georgiana, youngest of the three celebrated daughters of Thomas Sheridan, who was the "Queen of Beauty" at the famous Eglington Tournament in 1839. The duke was the author of Christian Theology and Modern Scepticism (1872), and Monarchy and Democracy (1886). As his two sons both died unmarried in his lifetime, the family titles, except the baronetc of St Maur, which became extinct, devolved on his two brothers successively; the younger of whom, Algernon Percy Banks, 14th duke (1813–1894), was succeeded by his son Algernon (b. 1846) as 15th duke of Somerset.

The title of Earl St Maur adopted by the 12th duke in 1863 is said to have been the original form of the family name of which Seymour was a later corruption, and since the last-mentioned date it has been assumed as the family surname of the dukes of Somerset. See Seymour, or St Maur, and the authorities there cited.

**SOMERSET, EDMUND BEAUFORT, DUKE OF (c. 1404–1455), was the younger son of John, earl of Somerset, and grandson of John of Gaunt, duke of Lancaster. He was taken prisoner at Bauge in 1421 during his first campaign, and did not return to England till 1431. He was then styled earl of Mortain, and in 1432 was one of the envoys to the council of Basel. In 1436 he served at the relief of Calais, two years later he commanded with some success in Maine, and in 1440 recovered Harfleur. Next year he was made earl, and in 1443 marquess of Dorset. In 1444 on the death of his elder brother he became duke of Somerset. As head of the Beaufort party he was the rival of Richard of York, whom in 1446 he superseded as lieutenant of France. He lacked statesmanship, and as a general could do nothing to stop French successes. The loss of Rouen and Normandy during the next four years was precipitated by his incompetence, and his failure naturally made him a special object of Yorkist censure. The fall of Suffolk left Somerset the chief of the King's ministers, and the Commons in vain petitioned for his removal in January 1451. In spite of York's active hostility he maintained his position till William's illness brought his rival the protectorate in March 1454. For a year he was kept a prisoner in the Tower "without any lawful process." On the king's recovery he was honourably discharged, and restored to his office as captain of Calais. Mistrust of Somerset was York's excuse for taking up arms. The rivalry of the two leaders was ended by the defeat of the Lancasterians and death of Somerset at St Albans on the 22nd of May 1455. Though loyal to his family, Somerset was without capacity as a leader. It was a misfortune for Henry VI. that circumstances should have made to the throne his chief minister. Thomas Basia, the French chronicler, describes Somerset as a handsome, courteous and kindly man. By his wife, Eleanor, daughter and co-heiress of Richard Beauchamp, earl of Warwick, he had two sons, Henry and Edmund, who were executed by Edward IV. after the battles of Hexham and Tewkesbury.

**SOMERSET, EDMUND SEYMOUR, DUKE OF (c. 1506–1532), third son of John, earl of Somerset, and Mary Tudor, was the eldest surviving son of Sir John Seymour of Wolf Hall, Wiltshire, by his wife Margaret, eldest daughter of Sir John Wentworth of Nettlestone, Suffolk. The Seymours claimed descent from William the Conqueror, who took his name from St Maur-sur-Loire in Touraine; and the protector's mother was really descended from Edward III. His father was knighted by Henry VII. for his services against the Cornish rebels at Blackheath in 1497, was present at the two interviews between Henry VIII. and Francis I. in 1520 and 1525, and died on the 21st of December 1536. Edward was "enfant d'honneur" to Mary Tudor at her marriage to Louis X. of France (1514). He was afterwards a member of the council of the duke of Suffolk, and in 1523 was a privy councillor. In 1525 he was knighted by the duke at Roze on the 1st of November, and accompanied Wolsey on his embassy to France in 1527. Appointed equerry of the body to Henry VIII. in 1529, he grew in favour with the king, who visited his manor at Elvedon in Hampshire in October 1535. On the 5th of June 1536, a week after his sister Jane's marriage to Henry, he was created Viscount Beauchamp of Hache in Somerset, and a fortnight after Edward VI.'s birth in October 1537, he was raised to the earldom of Hertford.

Queen Jane's death was a blow to his prospects, and in 1538 he was described as being "young and wise" but of "small power." He continued, however, to rise in political importance. In 1541, during Henry's absence in the north, Hertford, Cranmer and Audley had the chief management of affairs in London; in September 1542 he was appointed warden of the Scottish marches, and a few months later lord high admiral, a post which he almost immediately relinquished in favour of the future duke of Northumberland (q.v.). In March 1544 he was made lieutenant-general of the north and instructed to punish the Scots for their repudiation of the treaty of marriage between Prince Edward and the infant Mary Queen of Scots. He landed at Leith in May, captured and pillaged Edinburgh, and retreated a month later. In July he was appointed lieutenant of the realm under the queen regent during Henry's absence at Boulogne, but in August he joined the king and was present at the surrender of the town. In the autumn he was one of the commissioners sent to Flanders to keep Charles V. to the terms of his treaty with England, and in January 1545 he was placed in command at Boulogne, where on the 26th he brilliantly repelled an attempt of Marshal de Biez to recapture the town. In May he was once more appointed lieutenant-general in the north to avenge the Scottish victory at Anercur Moor; this he did by a savage foray
into Scotland in September. In March 1540 he was sent back to Boulogne to supersede Somerset, whose command had not been a success; and in June he was engaged in negotiations for peace with France and for the delimitation of the English conquests. From October to the end of Henry’s reign he was in attendance on the king, engaged in that unrecorded struggle for predominance which was to determine the complexion of the government during the coming minority. Personal, political and religious rivalry separated him and Lisle from the Howards, and Surrey’s hasty temper precipitated his own and his father’s ruin. They could not acquiesce in the Imperial ambassador’s verdict that Hertford and Lisle were the only noblemen of fit age and capacity to carry on the government; and Surrey’s attempt to secure the predominance of his family led to his own execution and to his father’s downfall in the Tower.

Their overthrow had barely been accomplished when Henry VIII. died on the 28th of January 1547. Preparations had already been made for a further advance in the ecclesiastical reformation and for a renewal of the design upon Scotland; and the new government to some extent proceeded on the lines which Chapuys anticipated that Henry VIII. would have followed had he lived. He had no statutory power to appoint a protector, but in the council of regency which he nominated Hertford and Lisle enjoyed a decisive preponderance; and the council at its first meeting after Henry’s death determined to follow precedent and appoint a protector. Hertford had his only possible choice; he represented the predominant party, he was Edward VI.’s nearest relative, he was senior to Lisle in the peerage and superior to him in experience. Seven weeks later, however, after Lord-Chancellor Wrothley, the leading Catholic, had been deprived of office Hertford, who had been made duke of Somerset, succeeded in emancipating himself from the trammels originally imposed on him as protector; and he became king in everything but name and prestige.

His ideas were in striking contrast with those of most Tudor statesmen, and he used his authority to divest the government of that apparatus of absolutism which Thomas Cromwell had perfected. He had generous popular sympathies and was by nature averse from coercion. “What is the matter, then?” wrote Paget in the midst of the commotions of 1549. “By my faith, sir, . . . liberty, liberty. And your grace would have too much gentleness.” In his first parliament, which met in November 1547, he procured the repeal of all the heresy laws and nearly all the treason laws passed since Edward III. Even with regard to Scotland he had protested against his instructions of 1544, and now ignored the claim to suzerainty which Henry VIII. had received, seeking to win over the Norweyans to English influence. He was for a period of autonomy, free trade, and equal privileges with England, which many years later eventually reconciled them to union. But the Scots were not thus to be won in 1547; “What would you say,” asked one, “if your lad were a lass, and our lass were a lad?” and Scottish sentiment backed by Roman Catholic influence and by French intrigues, money and men, proved too strong for Somerset’s amiable invitations. The Scots turned a deaf ear to his persuasions; the protector led another army into Scotland in September 1547, and won the battle of Pinkie (Sept. 10). He trusted to the garrisons he established throughout the Lowlands to wear down Scottish opposition; but their pressure was soon weakened by troubles in England and abroad, and Mary was transported to France to wed Francis II. in 1557.

Somerset apparently thought that the religious question could be settled by public discussion; and throughout 1547 and 1548 England went as it pleased so far as church services were concerned; all sorts of experiments were tried, and the country was involved in a grand theological debate, in which Protestant refugees from abroad hastened to join. The result convinced the protector that the government must prescribe one uniform order which all should be persuaded or constrained to obey; but the first Book of Common Prayer, which was imposed by the first Act of Uniformity in 1549, was a studious compromise between the new and the old learning, very different from the aggressive Protestantism of the second book imposed after Somerset had been removed, in 1552. The Catholic risings in the west in 1549 added to Somerset’s difficulties, but were not the cause of his fall. The factions and treasonable conduct of his brother, the lord high admiral, in whose execution (March 20, 1549) the protector weakly acquiesced, also impaired his authority; but the main cause of his ruin was the divergence between him and the majority of the council over the questions of constitutional liberty and enclosures of the commons. The majority scouted Somerset’s notions of liberty and deeply resented his championship of the poor against greedy landlords and capitalists. His efforts to check enclosures by means of parliamentary legislation, royal proclamations, and commissions of inquiry were openly resisted or secretly foiled, and the popular revolts which their failure provoked put the ground from Somerset’s feet. He was divided in mind between his sympathy with the rebels and his duty to maintain law and order. France, which was bent on ruining the protector’s schemes in Scotland and on recovering Boulogne, seized the opportunity to declare war on August the 8th; and the outlying forts in the Boulonnais fell into their hands, while the Scots captured Haddington.

These misfortunes gave a handle to Somerset’s enemies. Warwick combined on the same temporary platform Catholics who resisted the Book of Common Prayer, Protestants who thought Somerset’s midday policies were a denial of God’s truth, and the wealthy classes as a whole. In September he concerted measures with the ex-lord-chancellor Wrothley; and in October, after a vain effort to rouse the masses in his favour, Somerset was deprived of the protectorate and sent to the Tower. But the hostile coalition broke up as soon as it had to frame a constructive policy; Warwick jockeyed the Catholics out of the council and prepared to advance along Protestant lines. He could hardly combine proscription of the Catholics with that of Somerset, and the duke was released in February 1550. For a time it seemed to agree with Warwick to have the protector’s daughter, but growing discontent with Warwick made Somerset too dangerous. In October 1551, after Warwick had been created duke of Northumberland, Somerset was sent to the Tower on an exagerrated charge of treason, which broke down at his trial. He was, however, as a sort of compromise, condemned on a charge of felony for having sought to effect a change of government. Few expected that the sentence would be carried out, and apparently Northumberland found it necessary to forgo an instruction from Edward VI. to that effect. Somerset was executed on the 22nd of January 1552, dying with exemplary patience and fortitude. His eldest son by his second wife was re-created earl of Hertford by Elizabeth, and his great-grandson William was restored as 2nd duke of Somerset in 1660. His children by his first wife had been disinherited owing to the jealousy of his second; but their descendants came into the titles and property when the younger line died out in 1750.

SOMERSET, ROBERT CARR (or KER), EARL OF (c. 1590-1643), Scottish politician, the date of whose birth is unrecorded, was a younger son of Thomas Ker of Drumhead by his second wife, Janet, sister of Sir Walter Scott of Buccleuch. He accompanied James I. as page to England, but being then discharged from the royal service, sought for a time to make his fortune in France. Returning to England he happened to break his arm at a tilting match, at which James was present, and was recognized by the king. Entirely devoid of all high intellectual qualities, Carr was endowed with good looks, excellent spirits, and considerable personal accomplishments. These advantages were sufficient for James, who knighted the young man and at once took him into favour. In 1607 an opportunity enabled the king to confer upon him a more substantial mark of his affection. Sir W. Raleigh had through his attendant forfeited his life-interest in the manor of Sherborne, but he had previously executed a conveyance by which the property was to pass on his death to his
eldest son. This document was, unfortunately, rendered worthless by a flaw which gave the king eventual possession of the property. Acting on Salisbury's suggestion, James resolved to confer the manor on Carr. The case was argued at law, and judgment was in 1609 given for the Crown. Lady Raleigh received some compensation, apparently inadequate, and Carr at once entered upon possession. His influence was already such that in 1610 he persuaded the king to dissolve the parliament which had been called to consider the Scottish threats. On the 25th of March 1611 he was created Viscount Rochester, and subsequently a privy councillor, while on Lord Salisbury's death in 1612 he began to act as the king's secretary. On the 3rd of November 1613 he was advanced to the earldom of Somerset, on the 23rd of December was appointed treasurer of Scotland, and in 1614 lord chamberlain. He supported the earl of Northampton and the Spanish party in opposition to the old tried advisers of the king, such as Lord-Chancellor Ellesmere, who were endeavouring to maintain the union with the Protestants abroad, and who now in the height of their guilt there can be no calls for the king's favour. Somerset, whose head was turned by the sudden rise to power and influence, became jealous and prevaricating, and feeling his position insecure, obtained in 1615 from the king a full pardon, to which, however, the chancellor refused to put the Great Seal. He still, however, retained the king's favour, and might possibly have remained in power for some time longer but for the discovery of the murder of Sir Thomas Overbury. Before 1609, while still only Sir Robert Carr, Somerset had begun an intrigue with Lady Essex. Supported by the king, the latter obtained a secret marriage in the marriage of Essex in September 1613, and in December she married the earl of Somerset. Ten days before the court gave judgment, Sir Thomas Overbury, who apparently knew facts concerning Lady Essex which would have been fatal to her success, and had been imprisoned in the Tower, was poisoned. No idea seems to have been entertained at the time that Lady Essex and her future husband were implicated. The crime, however, was not disclosed till September 1615. Coke and Bacon were set to unravel the plot. After four of the principal agents had been convicted and punished, the earl and countess were brought to trial. The latter, however, and of her guilt there can be no doubt. Somerset's share is far more difficult to discover, and probably will never be fully known. The evidence against him rested on mere presumption, and he consistently declared himself innocent. Probabilities are on the whole in favour of the hypothesis that he was not more than an accessory after the fact. James, who had been threatened by Somerset with damaging disclosures, let matters take their course, and both earl and countess were found guilty. The sentence was not carried into effect against either culprit. The countess was pardoned immediately, but both remained in the Tower till January 1622. The earl appears to have refused to buy forgiveness by concessions, and it was not till 1624 that he obtained his pardon. He only once more emerged into public view when in 1630 he was prosecuted in the Star Chamber for communicating a paper of Sir Robert Dudley's to the earl of Clare, recommending the establishment of a parliament government. He died in July 1645, leaving one daughter, Anne, the sole issue of his ill-fated marriage, afterwards wife of the 1st duke of Bedford.

SOMERSET, LORD R. E. H.—SOMERSETSHIRE

388

SOMERSET, LORD ROBERT EDWARD HENRY (1776-1842), British soldier, was the third son of the 5th duke of Beaufort, and elder brother of Lord Raglan. Joining the 13th Light Dragoons in 1793, he became captain in the following year, and received a majority after serving as alde-de-camp to the duke of York in the Dutch expedition of 1799. At the end of 1800 he became a lieutenant-colonel, and in 1801 received the command of the 4th Light Dragoons. From 1799 to 1802 he represented the Monmouth boroughs in the House of Commons, and from 1803 to 1823 sat for Gloucestershire. He commanded his regiment at the battles of Talavera and Busaco, and in 1810 received a colonelcy and the appointment of A.D.C. to the king. In 1811, along with the 3rd Dragoon Guards, the 4th Light Dragoons fought a notable cavalry action at Usagre, and in 1812 Lord Edward Somerset was engaged in the great charge of Le Marchant's heavy cavalry at Salamanca. His conduct on this occasion (he captured five guns at the head of a single squadron) won him further promotion, and he made the remaining campaigns as a major-general at the head of the Hussar brigade (7th, 10th, and 1st Hussars). At Orthes he won further distinction by his pursuit of the enemy; he was made K.C.B., and received the thanks of parliament. At Waterloo he was in command of the Household Cavalry Brigade, which distinguished itself not less by its stern and patient endurance of the enemy's fire than by its celebrated charge on the cuirassiers of Milhau's corps. The brigadier was particularly mentioned in Wellington's dispatches, and received the thanks of parliament as well as the Maria Theresa and other much-prized foreign orders. He died a general and G.C.B. in 1842.

SOMERSETSHIRE, a south-western county of England, bounded N. and N.W. by the Bristol Channel, N. and E. by Gloucestershire, N.E. and E. by Wiltshire, S.E. by Dorsetshire, S.W. and W. by Devonshire. The area is 1630 sq. miles. In shape the county resembles an ill-drawn crescent, curving inward where Bridgewater Bay bends south-west and broader at its eastern than at its western horn. It falls into three natural divisions, being in fact a broad alluvial plain bordered by two hill-regions. The Mendip range, breaking off from the high ground near Wiltshire, extends north-west towards the channel, where it ends with Brean Down; while the island of Steep Holme stands more isolated off the heights of Somerset and Glamorgan. The summit of the Mendips is a long table-land, reaching an extreme height, towards the western end, of 2608 ft. in Black Down, sloping away gently towards the lower hills of the north, but rising on the south in an abrupt line, broken by many coombes or glens; the most striking of which are the cliffs of Ebbor Rocks, near Wells, and the gorge of Cheddar (q.v.), which winds for nearly a mile between huge and fantastic rocks. South of the Mendips lies a broad plain watered by the Parrett and the Brue, and known generally as Sedgemoor, but with different names in different parts. This plain, intersected by some rich in peat, is broken by isolated hills and lower ridges, of which the most conspicuous are Brent Knoll near Burnham, the Isle of Avalon, rising with Glastonbury Tor as its highest point, and the long low ridge of Polden ending to the west in a steep bluff. West of Sedgemoor the second great region of hills extends from Devonshire to the sea. It consists of the Black Down, Brendon and Quantock hills, with Exmoor Forest (q.v.) in the extreme west. This entire district is famous for the grandeur of its bare and desolate moors, and the bold outlines and height of its mountains. The chief of which are Dunkery, in Exmoor (1727 ft.); Lyte Hill, the westernmost point of the Brendon range (1301 ft.); and Will's Neck, among the Quantocks (1296 ft.). The two principal rivers of Somerset are the Avon and the Parrett. The Avon, after forming for a short distance the boundary with Wiltshire, crosses the north-eastern corner of the county, encircling Bath, and forms the boundary with Gloucestershire till it reaches the sea 6 m. beyond Bristol. It is navigable for barges as far as Bath. The Parrett from South Perrott in Dorset, on the borders of Somerset, crosses the centre of the county north-westwards by Bridgewater, receiving the Yeo and Cary on the right, and the Isle of Tone on the left. Among other streams are the Axe, which rises at Wookey Hole in the Mendips and flows northward along their base to the Bristol Channel near Blackrock; the Brue, which rises to the east of Bruton, near the borders of Wiltshire, and enters the Bristol Channel near the mouth of the Parrett; and the Exe (with its tributary the Barle), which rises in Exmoor forest and passes southward into Devon. Some of the Somersetshire streams, especially the Exe and Barle, are in high favour with trout fishermen. Weston-super-Mare is a flourishing seaside resort, and Minehead and other coastal villages are also frequented.
Geology.—The oldest formation in the county is the Devonian, which extends eastwards from Devonshire across Exmoor to the Brendon and Quantock hills, and consists of sandstones, slates and limestones of marine origin. The Old Red Sandstone, the so-called “sandstone district” (largely true “sandstone” in the Devonian), consists of a series of red sandstones, marls and conglomerates, which rise as an anticline in the Mendips (where they contain volcanic rocks), and also appear in the Avon gorge and at Portishead. The Carboniferous rocks of Somersetshire and its neighbour, the county (Cheddar Cliffs, &c.) and in the Avon gorge; at Weston-super-Mare it contains volcanic rocks. The Coal Measures of the Mendips are described for the purposes of this article by T. Bayly (see page 392). They consist of two series of coal-bearing sandstones and shales separated by the Pennant Sandstone; locally the beds have been intensely folded and faulted, as at Vocton. Indeed, all the formations have suffered from the same syneutal process: the deposition of the Triassic rocks. These consist of red marls, sandstones, breccias and conglomerates, which spread irregularly over the edges of the older rocks; the so-called Dolomitic Conglomerate is an old shingle-bench of Triassic (Keuper Marl) age. The Rhætic beds are full of fossils and mark the first invasion of the district by the waters of the Jurassic sea. The Liassic consists of clays and limestones; the latter are quartered and famous for their fish. Above the Liassic comes the Lower or Bath Oolite Series (Inferior Oolite group, Fuller’s Earth and Great Oolite group), chiefly clays and oolitic limestone; the famous Bath stone is derived from this series. The Oxford Clay Series, which marks the chief member of the Middle or Oxford Oolite Series. Above these follow the Upper Cretaceous rocks, including the Gault, Hembsreth, Greensand and Chalk, which extend into the county from Wiltsire near Bruton. These beds are relatively thin, and there are no true glacial deposits. Low-lying alluvial flats and peat-bogs occupy much of the surface west of Glastonbury. Caves in the Carboniferous Limestone (e.g. Wookey Hole, near Westonsuper-Mare) are the world’s chief lime-impregnating formations. The thermal waters of Bath (120° F.) are rich in calcium and sodium sulphates, &c. The chief minerals are coal, freestone and limestone, and ores of lead, zinc and copper.

Agriculture.—The climate partakes of the mildness of the south-western counties generally. A high proportion, exceeding four-fifths of the total area of the county, is under cultivation. In a county where cattle-rearing and dairy-farming are the principal branches of farming, Bath and Bridgwater are the chief dairy conurbations. There are large tracts of rich meadow land along the rivers, where many of the Devonshire farmers place their herds to graze, and many of the Somerset ones do the same. The Act was passed by parliament on the 11th of June 1872, providing for the appointment of commissioners to take measures for the drainage of land in the valleys of the Parrett, Isle, Yeo, Brue, Axe, Cary and Tone. Cheese is made in various parts, notably the famous Cheddar Cheese, which is made in the farms lying south of the Mendips. Sheep-farming is practised both in the lowlands and on hill pastures. Lecisters and Southdowns being the favourable breeds. In the levelling operations the Chestnut, black, rye and barley are raised on about equal areas. Turnips, swedes and mangolds occupy most of the area under green crops. Somerset rape has been used for several years, and at one time attained a larger acreage than any other county in England. Oranges and lemons are raised from these apples forms the common drink of the peasantry, besides being largely exported. Wild deer are still found on Exmoor, where there is a peculiar breed of ponies, known as the Exmoor. The Bridgwater and West Somerset fishing districts, besides being rich in white- and shell-fish; salmon and herring are also caught, the principal fishing stations being Porlock, Minehead and Watchet.

Other Industries.—Coal, from the Mendips, and freestone, largely quarried near Bath, are the chief mineral products of Somerset, although brown ironstone, zinc, limestone and small quantities of slate, gravel, sand, sulphate of strontia, gypsum, ochre, Fuller’s earth, marl, cement, copper and manganese are also found. Lead mining is carried on in the Mendips and Mendip Hills. There are the chief of these industries, like the working of spathose iron ore among the Mendon hills, are on the wane. The chief manufactures are those of woolen and worsted goods, formed in a large number of towns; silk made at Frome, Taunton and Shropshire Mallet; gloves at Yeovil, Stoke, Martock and Taunton; lace at Chard; linen and silkcloth at Crewkerne; horsehair goods at Bruton, Castle Cary and Crewkerne;elope at Dulverton and Shepton Mallet. Tobacco, snuff and spirits are also manufactured; and there are large pigeonries at Batcombe; where the celebrated bath-brick is made, and at Westonsuper-Mare; carriage works at Bath and Bridgwater: engineering and manufacturing at Taunton. Bath and Bridgwater; copper bars are smelted, while several other rivers provide power for cotton, worsted and paper mills. The bulk of the export trade passes through Bristol, which is situated mainly in Gloucestershire, though it has considerable docks on the River Avon, and others at Portishead.

Communication.—Somerset is well furnished with railways. The department of the Great Western Railway between London and Bristol, and from Bristol it curves south-west through Weston-super-Mare and Bridgwater to Taunton, dividing there and passing on into Devon.

Branches leave the main line for Portishead, Clevedon and Minehead on the north, and for Witham Friary via Wells, Yeovil via Langport, and Chard via Ilminster on the south. The South-Western main line from London passes through the south-west of Somerset, running from Templecombe to Axminster in Devon, and the Somerset and Dorset runs from Bath to Shepton Mallet via Radstock. The Kennet and Avon Canal flows from Bradford in Wiltshire to Bath, and there joins the Avon, meeting on its way the two branches of the Somerset and Avon Canal which flow from Paulton and Radstock. The Taunton and Bridgwater Canal flows into the River Parrett.

Population and Administration.—The area of the ancient county is 1,043,409 acres, with a population in 1851 of 484,337, in 1891 of 508,236. The area of the administrative county is 1,037,484 acres. The county contains 46 hundreds and two liberties. The municipal boroughs are—Bath, a city and county borough (pop. 49,839), Bridgewater (15,200), Chard (4437), Glastonbury (4016), Taunton (21,087), Wells, a city (1840), Yeovil (8961). The urban districts are—Burnham (2807), Clevedon (5900), Crewkerne (4226), Frome (11,057), Highbridge (2233), Ilminster (2887), Midsomer Norton (5800), Minehead (3511), Portishead (2544), Radstock (3355), Shepton Mallet (5278), Street (4018), Watchet (1880), Wellington (7285), Weston-super-Mare (19,845), Wiveliscombe (1471). Among other towns are the so-called Bonded boroughs of Bridgwater (10,046), Cheddar (1972), Keynsham (3512) and Wincanton (1802). The county is in the western circuit, and assizes are held at Taunton and Wells. It has one court of quarter sessions, and is divided into 22 petty sessional divisions. The boroughs of Bath and Bridgwater have separate courts of quarter sessions and commissions of the peace, and those of Taunton, Wells and Yeovil have separate commissions of the peace. The total number of civil parishes is 485. Somerset is in the diocese of Bath and Wells, excepting small parts in the dioceses of Bristol and Salisbury; it contains 508 ecclesiastical parishes or districts, wholly or in part. There are seven parliamentary divisions—Northern, Wells, Frome, Eastern, Western, Exmoor, and Southern. Central (1902), Bridgwater (1919), Cheddar (1925), Keynsham (3512) and Wincanton (1802). There is no Parliamentary borough in the county.

History.—In the 6th century Somerset was the debatable borderland between the Welsh and Saxons, and the latter of whom pushed their way slowly westward, fighting battles yearly and raising fortifications at important points to secure their conquered lands. Their frontier was gradually advanced from the Axe to the Parrett, and from the Parrett to the Tamai, Taunton being the last fortified point. The county was part of the Hyndeberge by the time of the Domesday Survey, 1086. It was certainly holden by the West Saxons as far as the Parrett, and there followed a struggle between the kingdoms of Wessex and Mercia, decided by a great victory of Ine in 710, which led to the organization of the lands east of the Parrett as part of the kingdom of Wessex. There were still occasional inroads by the Welsh, Taunton Castle being captured in 721, but from the 9th century the West Saxon kings were rulers of what is now known as Somersetshire. About this time the bishopric of Wells was founded, and the monastery of Glastonbury restored by Ine. The next hundred and fifty years were the period of Danish invasions. Egbert, the Danish king, was given a share of all England in 827, and under him Wessex with the other frontier kingdoms was organized for defence against the Danes, and later the assessment of danegeld led to the subdivision of Wessex for military and financial purposes, which crystallized into the divisions of hundreds and tithings, probably with the system of assessment by hiodon. King Alfred’s victory in 878, followed by the Peace of Wedmore, ended the incursions of the Danes for a time, but a hundred years later they were again a great danger, and made frequent raids on the west coast of Somerset. At some time before the Conquest, at a date usually given as 1016, though evidence points to a much earlier and more gradual establishment, England was divided into shires, one of which was Somerset, and tradition gives the name of the first earl as Hun, who was followed by Earnulf and Sweyn, son of Godwin. There has been curiously little variation in the territory...
in Somerset from the county, from the date of the Gpled Inquest in 1084 to the second half of the 19th century, when certain minor alterations were made in the county boundary. These have been practically the only changes in the county boundary for 900 years, if we except the exclusion of Bristol from the county jurisdiction in 1373.

At the Conquest Somerset was divided into about 700 fee-s held almost entirely by the Normans. The king's lands in Somerset were of great extent and importance, and consisted in addition to the ancient demesne of the Crown of the lands of Godwin and Earl Harold and the estates of Queen Edith who died in 1074. The bishop of Winchester owned a vast property of which Taunton was the centre, and about one-tenth of the county was included in the estates of the bishop of Coutances, which were alienated by his foundation and did not decline as a whole at the bishop's death. The churches of Glastonbury, Athelney and Muchelney still owned vast lands, but Norman spoliation had deprived them of much that they had held before the Conquest. Among the great lay tenants who divided the conquered lands were the count of Mortain (the conqueror's half-brother), Roger de Corcelles, Walter de Douai, Roger Arundel and William de Mohun. About this time or a little later many Norman castles were built, some of which have survived. The castles at Richmont (near West Harptree), Nunney, Farleigh, Bridgwater, Stoke Courey, Taunton and Dunster were probably the most important. Somerset was very rich in boroughs at the time of Domesday, which points to a considerable development of trade before the Conquest; Bath, Taunton, Ilchester, Frome, Milborne Port, Bruton, Langport and Axbridge were all boroughs in 1087, and there was the nucleus of a borough at Yeovil. Somerset, Ilchester and Taunton were successively the meeting-places of the shire court. There were joint sheriffs for Somerset and Dorset until 1566 when a separate sheriff for each county was appointed. In the 14th century Somerset, as part of the kingdom of Wessex, was included in the diocese of Winchester. The new bishopric was founded in the county, and the see of the bishop of Dunster was transferred to Taunton in 910 when the see was divided into the dioceses of Salisbury, Exeter and Wells, the latter including the whole county of Somerset. The diocese was divided into three archdeaconries, Bath with two deaneries, Wells with seven and Taunton with four. Disputes between the chapters of Bath and Wells as to the election of the bishop led to a compromise in 1245, the election being by the chapters jointly, and the see being known as the bishopric of Bath and Wells. There has always been a strongly marked division of the county into East and West Somerset, a relic of the struggles between the Welsh and Saxons, which was recognized for parliamentary purposes by the act of 1832. Somerset contained 37 hundreds in 1087, and now contains 41. There have been considerable modifications of these hundredal divisions by aggregation or subdivision, but since the 15th century there has been little change. The meeting-place of the hundred courts was at the village or town which gave its name to the hundred in the cases of Bruton, Cannington, Carhampton, Chew, Chewton, Crewkerne, Frome, Glaston Twelve Hides, Huntspill, Kilmington, Kingsbury East, Milverton, North Curry, North Petherton, Norton Ferris, Pitney, Portbury, Somerton, South Petherton, Taunton, Tintinhull, Wellow, Wells Forum and Winterstoke. The hundred of Axbridge included Birnbeck, met at Ilford Bridges in Stocklinch Magdalen, Andersfield hundred court was held at the hamlet of Andersfield in the parish of Goathurst, Bath Forum hundred met at Wedcombe, Bempstone at a huge stone in the parish of Allerton, Brent and Wrington at South Brent, Catsash at an ash tree on the road between Castle Cary and Yeovil, Hartcliffe and Bedminster at a lofty cleft between the parishes of Barrow Gurney and Winford, Horethorne or Horethorne Down near Milborne Port, Whiston at a hill of the same name near Shepton Mallet, Wilton and Freeman's in the village of Wilton in the parish of St Decumans, and Whitley at Whitley Wood in Walton parish. In the case of Kingsbury the meeting-place of the hundred is not known. The great liberties of the county were Cranmore, Wells and Leigh, which belonged to the abbey of Glastonbury; Eason and Amtrill and Hampton and Claverton, which were the liberties of the abbey of Bath; Hinton and Nether Stowey, which belonged to the Carthusian priory of Hinton; Witham Priory, a liberty of the house of that name; and Williton Freeman, which belonged for a time to the Knights Templars.

The chief families of the county in the middle ages were those of De Mohun, Malet, Revel, De Courcy, Montacute, Beauchamp and Beaufort, who bore the titles of earls or dukes of Somerset from 1396 to 1472. Edward Seymour was made duke of Somerset in 1547, and in 1660 the title was restored to the Seymour family, by whom it is still held. The marquess of Bath is the representative of the Thynne family, which has long been settled in the county, and the predecessors of the earl of Morven and his successors were granted the barony of Somerton. Hinton St George has been the seat of the Poult family since the 16th century. The De Mohun family were succeeded in the 14th century by the Luttrells, who own great estates round Dunster Castle. The families of Hoo, Wyndham, Acland, Strachey, Brokeley, Portman, Hobhouse and Trevelyan have been settled in Somerset since the 16th century. Somerset was too distant and isolated to take much share in the early baronial rebellions or the Wars of the Roses, and was really without political history until the end of the middle ages. The attempt of Perkin Warbeck in 1497 received some support in the county, and in 1547 and 1549 there were revolts against enclosures. Somerset was a considerable part in the Civil War, and with the exception of Taunton, was royalist, all the strongholds being garrisoned and held for the king. Waller was defeated at Lansdown near Bath in 1643, and Goring at the battle of Allermoor in 1645. This defeat was followed by the capture of the castles held by the royalists. Bridgewater and Bath fell in July 1645, Sherborne Castle was taken in August, and after the capture of Nunney, Farleigh and Bristol in September 1645 the whole county was subdued, and very heavy fines were inflicted upon the royalists, who included nearly all the great landowners. This, with many other events, led to Morenemouth's rebellion, and he was proclaimed king at Taunton in 1685. The battle of Sedgemoor on the 4th of July was followed in the autumn by the Bloody Assize held by Judge Jeffreys.

Somerset has always been an agricultural county. Grain was grown and exported from the 11th to the end of the 18th century. Cider-making has been carried on for centuries. Among other early industries, salmon and herring fisheries on the west coast were very important, and the Malvern and Cheddar lead-mines are of great Roman period. Stone quarrying at Hamdon Hill and Bath began very early in the history of the county; and the lead mines at Wellington and the slate quarries at Wiveliscombe and Trowbridge have been worked for more than a century. Coal has been mined at Radstock from a very remote date, but it did not become of great importance commercially until the county was opened up by canals and railways in the 19th century. Sheep-farming was largely carried on after the period of enclosures, and the woolen trade flourished in Frome, Bath, Bridgewater, Taunton and many other towns from the 14th to the 19th centuries. Glove-making was centred at Stoke and Yeovil at the end of the 18th century and became an important subsidiary occupation in many country districts. The county was represented in the parliament of 1720 and probably in the earlier parliamentary councils of Henry III. In 1295 it was represented by two knights, and twelve boroughs returned two burgesses each. There have been many fluctuations in the borough representation, but the county continued to return two members until 1832, when it was divided into North-East, South-East and Somerset West, each of which divisions returned two members. Two additional members were returned after 1867 for a third—the Mid-Somerset—division of the county, until by the act of 1885 the whole county was divided into seven divisions.

Antiquities.—The great possessions of the bishopric and of the abbey of Glastonbury led to a remarkable lack of castles in the mid part of the county, and also tended to overshadow all other ecclesiastical foundations. Even in the other parts of the county castles are not a prominent relic, and most of the monastic churches remain perfect except those of Bath and its cell, Dunster. At the dissolution of monasteries Bath was suppressed, the monastery of Glastonbury was destroyed, as were most of the smaller monasteries also. Of those which have left any remains, Woodspring, Montacute (Cluniac) and Old Cleeve (Cistercian)
are the most remarkable. Athelney, founded by Alfred on the
spot where he found shelter, has utterly perished. Montacute
and Dunster fill a place in both ecclesiastical and military history.
The castle of Robert of Mortain, the Conqueror’s brother, was
built on the peaked hill (mons acutus) of Lodgaresbury, where the
holy cross of Waltham was found. The priory arose at the foot.
Dunster, one of the few inhabited castles in England, stands on
a hill crowned by an English mound. Besides these there are
also remains at Nunney and Castle Cary. In ecclesiastical
architecture the two great churches of Wells and Glastonbury
supply a great study of the development of the Early English
style out of the Norman. But the individual architectural
interest of the county lies in its great parish churches, chiefly
in the Perpendicular style, which are especially noted for their
magnificent towers. They are so numerous that it is not easy
to select examples, but besides those at Bath, Taunton and
Glastonbury, the churches at Bridgewater, Cheddar, Crewkerne,
Dunster, Ilminster, Kingsbury, Leigh-on-Mendip, Martock
and Yeovil may be specially indicated. Of earlier work there is
little Norman, and hardly any pre-Conquest, but there is a
characteristic local style in some of the smaller buildings of the
14th century. The earlier churches were often cruciform, and
sometimes with side towers. In domestic remains no district is
ricer, owing to the abundance of good stone. Clevedon
Court is a very fine inhabited manor-house of the 14th century,
and the houses, great and small, of the 15th, 16th and 17th
centuries are very numerous. Indeed, the style has never quite
gone out, as the gable and the mullioned window have lingered
on to this day. Barrington Court in the 16th century and
Montacute House in the 17th are specially fine examples. There
are also some very fine barns, as at Glastonbury, Wells and
Pilton.

SOMERSWORTH—SOMERVILLE

SOMERSWORTH, a city of Strafford county, New
Hampshire, U.S.A., on the Salmon Falls river, 5 m. N. of Dover,
and opposite the town of Berwick, Maine, industrially a part of
Somersworth. Pop. (1890) 6507; (1900) 7073 (3160 foreign-
born); (1910) 6704. Somersworth is served by the Boston &
Maine railroad, and is connected by electric line with Rochester
and Dover. The river furnishes good water power, and the city’s
chief interests are in the manufacture of cotton and wooden
goods, and boots and shoes. It has a public library. In the south-
west part is Central Park, lying along the shore of Willand’s
Pond. The municipality owns and operates the waterworks.
A settlement was established here in the latter part of the 17th
century, when the territory was a part of Dover. In 1729
the parish of Summersworth was organized; in 1754 this parish
was erected into the town of Somersworth; in 1818 the first company
was formed to develop the water-power and establish cotton
and wooden mills; in 1849 the southern half of the town was set-
off and incorporated as Rollinsford; and in 1893 Somers-
worth was chartered as a city.

See O. Knapton, Somersworth, an Historical Sketch (1893).

SOMERVILLE, WILLIAM (1655-1742), English poet, eldest son of
a country gentleman, was born at Edstone, Worcestershire,
the 2nd of September 1655. He was educated at Winchester
College and at New College, Oxford. After his father’s death
in 1705 he lived on his estate, devoting himself especially to
field sports, which supplied the subjects of his best-known poems.
His publications were The Two Springs (1725), a fable; Occa-
sional Poems... (1727); The Chase (1735) Hobnobil, or the Rural
Gardens (1740), a burlesque poem; and Field Sports (1742), a
poem on hawking. Somerville died on the 10th of July 1742.

His Chase passed through many editions. It was illustrated by
Bewick (1796), by Scottard (1800), and by Hugh Thomson (1866),
with a preface by R. F. Sharp.

SOMERVILLE, MARY (1780-1872), British scientific writer,
was the daughter of Admiral Sir William George Fairfax, and
was born on the 26th of December 1780 in the manse of Jedburgh,
the house of her mother’s sister, wife of Dr Thomas Somerville
(1744-1805), author of My Own Life and Times, whose son
was her second husband. She received a rather desultory education,
and mastered algebra and Euclid in secret after she had left
school, and without any extraneous help. In 1804 she married
her cousin, Captain Samuel Greig, who died in 1806; and
in 1812 she married another cousin, Dr William Somerville
(1771-1860), inspector of the army medical board, who
encouraged and greatly aided her in the study of the physical sciences.
After her marriage she made the acquaintance of the most
eminent scientific men of the time, among whom her talents
had attracted attention before she had acquired general fame.
Laplace paying her the compliment of stating that she was the
only woman who understood his works. Having been requested
by Lord Brougham to translate for the Society for the Diffusion
of Useful Knowledge the Mécanique Céleste of Laplace, she
greatly popularized its form, and its publication in 1831,
under the title of The Mechanism of the Heavens, at once
made her famous. Her other works are the Connexion of
the Physical Sciences (1834), Physical Geography (1848),
and Molecular and Microscopic Science (1866). Much of
the popularity of her writings was due to their clear and crisp
style and the underlying enthusiasm for her subject which
prevailed them. In 1835 she received a pension of £300 from
government. She died at Naples on the 28th of November
1872. In the following year there appeared her Personal Recol-
tections, consisting of reminiscences written during her old
age, and of great interest both for what they reveal of her own
character and life and the glimpses they afford of the literary
and scientific society of bygone times.

SOMERVILLE, a city of Middlesex county, Massachusetts,
U.S.A., on the Mystic river, adjoining Boston (Charlestown),
Cambridge, Medford and Arlington. Pop. (1890) 40,152;
(1900) 61,043, of whom 17,732 were foreign-born; (1910
ceensus) 77,236. Of the foreign-born in 1900 6400 were
English, 7500 were French-Canadians, 5500 were Italians,
576 were Scotch and 556 were Swedish. Somerville is served by
the Boston & Maine railroad and by suburban electric railroad lines.
It is a residential and manufacturing suburb of Boston, of which,
industrially, it forms a part; it is included in the metropolitan
water, sewar and park districts, and in the Boston postal
district. It comprises an irregular (land) area of 4.66 sq. m. in the Mystic Valley and along a range of hills or rides,
of which the largest are Prospect, Spring, Winter, Central and
Clarendon hills. Among its public buildings and institutions
are a fine public library (1875) with 80,000 volumes in 1908;
the city hall, a state armory, Somerville Hospital, the city poor
house, a Roman Catholic home for the aged, and two high
schools (English and classical). Among the parks are Broadway
Park, Central Hill Park, Prospect Hill Park, Lincoln Park,
and Nathan Tufts Park. The total value of the city’s factory
product in 1900 was $22,095,197, an increase of 14.4 per
cent. over that of 1900; in 1890 the product value was only
$7,307,352. The establishments include slaughtering and meat-packing
houses, whose product is by far the most valuable in the city,
bleachers, finishing factories, glassworks, machine shops, tube
works, oil refineries, and laundry factories, and several large
lumber and coal yards. Blue slate-stone used for building
purposes is quarried.

Somerville, originally a part of Charlestown, was settled in
1630. Six hundred acres, the “Ten Hills Farm,” were granted
here in 1631 to John Winthrop, who built and launched here
in that year the “Blessing of the Bay,” the first ship built
in Massachusetts. For more than a century it was a sparsely
settled farming community, the only article of manufacture

being bricks. On the 10th of April 1775 the British columns returning from Concord were harassed by the farmers here, as in the other towns along the line of march. Several of the hills of Somerville (e.g. Prospect and Central Hills) were fortified during the siege of Boston. On Prospect Hill on the 18th of July 1775 Israel Putnam raised the Appeal to Heaven flag, and here also is said to have been raised on the 1st of January 1776 one of the earliest of the Continental standards of the Union Jack and Stripes.

On Powder House Hill (originally Quarry Hill), in Nathan Tufts Park, there still stands an interesting old slate-stone powder house, a circular building, 30 ft. high, with a conical cap, originally built about (1703) for a windmill, deeded in 1747 to the Massachusetts Bay Colony, used in 1756-1822 as a powder house, and now marked by a bronze tablet erected by the Massachusetts Society of the Sons of the Revolution; on the 1st of September 1774, General Gage seized 250 half-barrels of powder stored here in anticipation of the outbreak of hostilities; in 1775 the powder house became the magazine of the American forces besieging Boston, and at that time Nathanael Greene maintained his headquarters at the Samuel Tufts House, and Charles Lee had his headquarters at the Oliver Tufts House, in Somerville. After the battle of Saratoga some of Burgoyne's officers were housed here. The opening of the Middlesex Canal through the town in 1803 and of the Boston & Lowell railroad in 1835 gave it an impetus to the town's growth. In 1834 an Ursuline Convent, built in 1827 on Mt. Benedict, was sacked and destroyed by an anti-Catholic mob. In 1842 Somerville was separated from Charlestown and incorporated under its present name; it was chartered as a city in 1871.

See T. H. Hurd, History of Middlesex County (3 vols., Philadelphia, 1890); S. A. Drake, History of Middlesex County (2 vols., Boston, 1880); E. A. Samuels, Somerville Past and Present (Boston, 1897); Miss M. A. Haley, The Story of Somerville (Boston, 1903).

SOMERVILLE, a borough and the county-seat of Somerset county, New Jersey, U.S.A., in the north central part of the state, on the Raritan river, about 35 m. S.W. of New York City. Pop. (1890), 3861; (1900), 4843, of whom 560 were foreign-born; (1905), 4782; (1910), 5060. It is served by the Central Railroad of New Jersey and by inter-urban electric lines. Adjoining the borough on the east is the town of Raritan (pop. in 1905, 3954). Places of interest in Somerville are the Old Parsonage of the Dutch Reformed Church, built in 1751-1753 of brick imported from Holland by the Rev. Theodorus Jacobus Frelinghuysen, the first pastor; the Wallace House, built in 1778 and occupied by General Washington as his headquarters during the following winter, when the main army was in camp at Bound Brook; and Duke's Park (partly in Raritan), the immense private estate (paid out as a park and open to the public) of James B. Duke, president of the American Tobacco Company. Somerville has a fine county house court house (1909) of Alabama white marble. Among the borough's manufactures are stoves, ranges, soil pipe, brick, woolen goods and shirts. Settlements were made within the present limits of Somerville in the last quarter of the 17th century, and the village was at first called Raritan, all that part of the Raritan Valley from Bound Brook to the junction of the north and south branches of the river, and including the present Somerville and Raritan, then being popularly called "Raritans." The present name was adopted in 1801. Somerville became the county-seat in 1783, after the destruction in 1782 in what is now the borough of Millstone (in Hillsborough township, about 6 m. south of Somerville) on the 27th of October 1779 by British troops under Colonel John Graves Simcoe; it was incorporated as a town in 1863, and as a borough in 1909.

SOMME, a department of northern France, formed in 1790 of a large part of the province of Picardy (comprising Vermandois, Santierre, Amiénois, Ponthieu, Vimeu, and Marquetterie) and a small portion of Artois. Pop. (1906), 532,567. Area 2423 sq. m. It is bounded on the N. by Pas-de-Calais, E. by Aisne, S. by Oise, and S.W. by Seine-Infrérieure, and its sea-coast extends 28 m. along the English Channel. Two streams flowing into the Channel—the Authie on the north and the Bresle on the southwest—bound it in these directions. The surface consists of great rolling plains, generally well cultivated and very fertile. The highest point, about 700 ft. above the sea, lies in the southwest, not far from Aumale. From the mouth of the Authie to the Bay of the Somme the coast is lined with a belt of sand dunes about 2 m. broad, behind which is the Marquetterie, a large marshy area traversed from top to bottom by the Bresle and separated by dunes and gravel banks. The Bay of the Somme, obstructed by dangerous sandbanks, contains the three fishing ports of Crotot, St Valery, which is also the chief commercial port, and Le Houreul. Next come the shingle banks, behind which the low fields of Cayeux (25,000 acres) have been reclaimed; and then at the mouth of Ault commence the chalk cliffs, which continue onwards into Normandy.

The river Somme rises to the N.N.E. of St Quentin in the department of Aisne, where it has a course of about 25 m.; it enters the department of Somme from the south-east to the north-west for a distance of about 125 m., through a marshy valley abounding in peat. Commanded by Ham, Péronne, Amiens and Abbeville, this valley forms a northerly line of defence for Paris. Apart from the water-power it supplies, the Somme is of great commercial value, being accompanied by a canal all the way from its source wherever it is not itself navigable. From Abbeville to St Valery its lower course forms a maritime canal 163 ft. wide, 12 ft. deep, and 8 to 10 m. long, capable of bearing at high tide vessels of 300 tons burden. From St Valery to the open sea the current hollows out a very wide bed accessible at certain times for vessels of 500 m. or more. The most important affluents of the Somme—the Ancre from the north-east by way of Albert and Corbie, the Avre from the south-east by Roye, and the Somme from the south by Conty—join the main streams at Amiens. The Authie and the Bresle are respectively 63 and 45 m. long. The latter ends in a maritime canal about 2 m. long between Eu and Tréport.

The mean temperature is lower than that of Paris (59° F. at Abbeville). The mean annual rainfall is 33 in. at Abbeville. The department, especially in the north-east, is one of the best cultivated in France, especially suitable to sugar beet and sugar; potatoes also are grown on a large scale. The vineyards and apple orchards are extensive; the best orchards are near Abbeville. TheSomme is also an important mineral product. The manufacture of a great variety of textile goods, especially velvet (Amiens), of beet sugar and sugar beets, and of locks (the like of which is found nowhere else in France) is considerable. The Somme is a chief centre of the flax foundries of the Somme, which also carries on saw-milling, flour-milling, brewing, dyeing, iron founding and forging, printing and the manufacture of paper, chemical products, medicines and ironmongery, hosiery (in the Santiere), &c. Cereals, horses of the Boulogne or Normandy breed, cattle, hemp and linen, and the manufactured goods are the exports of the department. St Valery (pop. 3389) exports vegetables and farm-products (to England), and shingles for the manufacture of thatch. Besides the raw materials for the manufacturing industries, wines and timber, the latter largely imported at St Valery, dyestuffs and coal are imported. The chief department of Somme is principally supplied by the Somme, and its canals and rivers provide 140 m. of navigable waterway. Administratively the department comprises 5 arrondissements (those of Amiens, the capital, Abbeville, Doullens, Montdidier and Péronne), 4 cantons, 79 communes, and the University of Picardie (founded in the 7th century) the church of which (16th-18th century) is still to be seen; L’Etoile, with the well-preserved remains of a Roman camp; Folleville, which has a church (15th century) containing the fine Renaissance tomb of Raoul de Lainory; Picquigny, with...
the remains of a château of the 14th, 15th and 16th centuries, once one of the chief strongholds of Picardy; Rue, where there is a fine
chapel of the 15th century; and Tillod, which has a Renaissance
church.

SOMMER, in architecture, a girder or main beam of a floor;
if supported on two storey posts and open below, it is called a
bress or brassi-summer. The word is also spelled 'summer;'
and is the same as 'sumer,' a pack-horse. Fr. somnier, O. Fr.,
somme, from Low Lat. salma, pack, burden, Gr. σαμήν, σάμην,
to fasten a pack on a horse.

SOMMELDORF, a town of Germany, in the Prussian province
of Brandenberg, on the Lubis, 40 m. S.E. of Frankfort-on-Oder,
by the railway from Berlin to Breslau. Pop. (1905), 12,251.
It has a Roman Catholic church, three Evangelical churches,
several schools and a hospital. Its manufactures of woolen
cloth are important; and it also contains finishing and dye-
works, an ironfoundry, boiler-works and breweries.

SOMMERS, WILLIAM (d. 1560), court fool of Henry VIII.,
also is said to have been brought to the king at Greenwich
by Richard Fermor, about 1523. He was soon in high favour with
Henry, whose liberality to Sommers is attested by the accounts
of the royal household. The jester possessed a shrewd wit,
which he exercised even on Cardinal Wolsey. He is said to have
warned his master of the wasteful methods of the exchequer and
to have made himself the advocate of the poor. His portrait is
shown in a painting of Henry VIII. and his family at Hampton
Court, and he again appears with Henry VIII. in a psalter
which belonged to the king and is now in the British Museum.
He was probably the William Sommers whose death is recorded
in the parish of St Leonard's, Shoreditch, on the 15th of June
1560.

For his position in 16th- and 17th-century literature see T. Nash,
Pleasant Comedie called Summers last Will and Testament (pr. 1600);
S. Rowland's, Good News and Bad News (1622); and a popular
account, A Pleasant Historie of the Life and Death of William Som-
mer, reprinted 1794. See also John Doran, History of Court Fools
(1858).

SOMNAMBULISM (from Lat. somnus, sleep, and ambulare,
to walk), or sleep-walking, the condition under which people
are known to walk along while asleep, apparently unconscious
of external impressions, return to bed, and when they awake
have no recollection of any of these occurrences. Sometimes
the actions performed are of a complicated character and bear
some relation to the daily life of the sleeper. Thus a cook has
been known to rise out of bed, carry a pitcher to a well in the
garden, fill it, go back to the house, fill various vessels carefully
and without spilling a drop of water, then return to bed, and have
no notion of having gone. Farad and transparence of sleep have
been observed to write letters or reports, execute drawings,
and play upon musical instruments. Frequently they have
gone along dangerous paths, executing deliberate movements
with precision.

Four types of somnambulists may be noticed: (1) those who
speak without acting, a common variety often observed in
children and not usually considered somnambulistic; (2) those
who act without speaking, also well known and the most common
type; (3) those who both act and speak, more exceptional; and
(4) those who both act and speak and who have not merely the
sense of touch active but also the sense of sight and hearing.
The fourth class is the most extreme type and merges into the
physiological condition of mesmerism or hypnotism (q.v.),
and it is necessary here only to notice it in connexion with the
subject of sleep. Many observations indicate that, at all
events in some cases, the somnambulist engaged, for example,
in writing, has a mental picture of the page before him and of
the words he has written. He does not see what he really
writes. This has been proved by causing persons to write on a
sheet of paper lying on the top of other sheets. After he had
been allowed to write for a few sentences, the sheet was carefully
withdrawn and he continued his writing on the next sheet;
beginning on the new sheet at the corresponding point where
he left off on the first one. Moreover, the somnambulist, by
force of habit, stroked t's and dotted i's at the exact places
where the t's and i's would have been had he written continuously
on one sheet, showing that what he was conscious of was not
what was before him, but the mental picture of what he had
done.

The following table, modified from two such tables given by
Benjamin Ball (b. 1833) and Chambard in their classical article
"Somnambulism" in the Dictionnaire encyclopédique des sciences
médicales, shows the relation of the various intermediate conditions
of sleeping and waking and of the dreaming and somnambulistic
states. The horizontal stroke indicates the presence of the condition
the name of which heads the column:—

The somnambulist acts his dream. His condition is that of a
vivid dream in which the cerebrum is so active as to influence
centres usually concerned in voluntary movements. Under the
dominant idea he executes the movements that this idea would
naturally excite in the waking state. Many of his movements are
in a sense purposive; his eyes may be shut so that the movements
are executed in the dark, or the eyes may be open so that there
is a picture on the retina that may awaken no consciousness, and
yet may, by reflex mechanisms, be the starting-point of definite
and deliberate movements. In many cases he does not hear, the aud-
itory centres not responding; but in others suggestive words may
alter the current of his dream and lead him to perform other actions
than what he intended to do. On waking there is either no
memory of what has taken place or the dim recollection of a fading
dream.

It is important to notice that there is scarcely any action of
which a somnambulist may not be capable, and immoral acts from
which the individual would shrink in waking hours may be per-
formed with indifference. Considering the abrogation of self-con-
control peculiar to the physiological condition, it is evident that no
moral responsibility can be attached to such actions. In cases with
somnambulistic propensities place a person in danger, an endea-
voire should be made to induce him to return to bed without
awakening him; as a rude awakening may produce a serious shock to
the nervous system. Inquiry should then be made into the exciting
cause of the somnambulistic dream, such as a particular train of
thought, over-excitement, the reading of special books, the recol-
lection of an accident or of a crisis in the person's history, with the view
of removing the cause if possible. It should never be forgotten that
somnambulism, like chorea, hysteria and epilepsy, is the expression
of a general morbid predisposition, an indication of a nervous
diathesis, requiring careful treatment so as to avoid more dangerous
misdemeanors.

SOMNATH, an ancient decayed city of Kathiawar in the
province of Bombay, India. Pop. (1907), 8,341. It is situated
on a bay of the Arabian Sea. The port, which is called Ver-
val, is distinct from the city proper (Deva-Pattan, Somnáth-
Pattan, or Prabhas). The latter occupies a prominence on the
south side of the bay, is surrounded by massive fortifications,
and retains in its ruins and numerous tombs many traces of its
former greatness as a commercial port. But the city was most
famous for the temple just outside its walls in which stood the
great idol of rather columnar emblem of Siva called Somnáth
(Moon's lord), which was destroyed by Mahamb 12 of Ghazni.
The famous "Gates of Somnath," which were supposed to
have been carried off by Mahãmbî to Ghazni, had probably no
connexion with Somnath. They are built of deodor (1 ft.
in height and $\frac{1}{2}$ in width) and are richly carved in geometric
of the newly published slow movements, the normal Scarlatti sonata is that which the concert-player popularizes; fireworks in binary form, with a perfunctory opening; a crowd of pregnant ideas in the complementary key, and, after the double bar, a second part reproducing these ideas as soon as possible in the tonic. The sonatas of Paradies are mild and elongated works of this type with a graceful and melodious little second movement added. The manuscript on which Longo bases his edition of Scarlatti frequently shows a similar juxtaposition of movements, though without definite indication of their connexion. The style is still traceable in the sonatas of the later classics, whenever a first movement is in a uniform rush of rapid motion, as in Mozart’s violin sonata in F (Kochel’s Catalogue, No. 377), and in several of Clementi’s best works.

SONATA FORMS, in music. The sonata forms (see SONATA) cover the whole ground of instrumental music from C. P. E. Bach to the advent of the instrumental lyric as matured by Schumann and of the symphonic poem originated by Liszt. They also have a profound influence on classical opera and vocal music, and, hence, by repulsion, upon Wagner, whose life-work consisted in emancipating the music-drama from them. The conditions which developed them were the conditions which made Gluck’s reform of opera possible; for they are at once the means and the end. The sonata form is an essential change in the language of music which made it a truly dramatic medium. Hence our present task is the discussion of the largest and most central problems pure music has ever dealt with; and, while the external technicalities are numerous and prominent, they are significant only so long as we maintain their connexion with those problems with which the true masters (and only the true masters) of the sonata forms are concerned. Much, then, that is essential to the true sonata forms must come under the headings of instrumentation, harmony, and other musical categories. But here we must confine ourselves to the purely formal aspect, allowing out such allusions, and other aspects as will help us to see behind superficial appearances.

1. The Sonata Style.—The sonata forms are representative of the type of music that attracts us primarily by its design and its larger contrasts, and only in the second place by the vitality of its texture. In Bach’s art the reverse is the case; we listen chiefly to the texture, and our delight in the larger designs, though essential, is seldom more than subconscious. Art-forms existed already in Bach’s time, in which the shape, and not the texture, was the object of attention, but these were lighter forms. Bach himself was the greatest master of these, and he never transcended what was then their legitimate limit as an art which is related to his larger work much as decorative designs are related to architecture. Bach’s suites and partitas (see SUITE) contain (apart from their great preludes, in which other principles are involved) one form embodied in several different dance rhythms, which is the germ from which the sonata was developed. It is sometimes known as the “binary” form; but as some eminent writers classify its later development as “ternary,” we shall here avoid both terms, and refer to it in its earlier manifestations as the “suite” form, and in its later as the “sonata” form. In the suite it may be represented by the following diagram:
SONATA FORMS

where the long horizontal line represents the main key, the short horizontal lines represent a second key, the perpendicular line represents the division into two portions, and the letters represent the phrases. This form is often typified in the compass of a single melody without change of key or marked division, as in that beautiful English tune "Barbara Allen," where the half-close on the dominant in the fourth bar is symmetrically reproduced as the full close on the tonic at the end (see Melody, example 1). On a larger scale it admits of great variety and elaboration, but the style of the classical suite never allows it to become more than the musical analogue of a pattern on a plate. The passage from the material in the main key to that in the foreign key (from A to B in the above diagram) is continuous and unnoticeable, nor is the second part of the design which leads to the return of B in the tonic noticeably different in style or movement from the earlier part. It has a slightly greater range of key, for the sake of variety, but without striking contrast. Lastly, the rhythms, and such texture as is necessary to keep the details alive, are uniform throughout.

Now, the essential advance shown by the true sonata forms involves a direct denial of all these features of the suite style. No doubt one natural consequence of working on a larger scale is that the sonata composer tends to use several contrasting themes where the suite composer used only one; and an equally natural consequence is that the shape itself is almost invariably amplified by the introduction of a recapitulation of A as well as of B in the tonic, so that our diagram would become modified into the following:

![Diagram of Sonata Form]

B

| A | B |

But these facts do not constitute a vital difference between sonata and suite forms. They do not, for instance, enable composers like Boccherini and the later Italian violin writers to emancipate themselves from the influence of the suite forms, though the designs may be enlarged beyond the bursting point. The real difference lies, indeed, in every category of the art, but primarily in a variety of rhythm that carries with it an entirely new sense of motion, and enables music to become not only, as hitherto, architectural in grandeur and decorative in detail, but dramatic in range. The gigue of Bach's C major suite for violoncello, and the allegro of his D major clavier partita, will show that the suite forms were amply capable of digesting a non-polyphonic style and a group of several contrasted themes; but they still show the uniformity of rhythm and the figures by which composer to composer in which the visible symmetry of form is admissible only on a small scale. Haydn can write a movement, perhaps shorter than some of Bach's larger dance movements, containing only one theme and mainly polyphonic in texture, as in the finale of his tiny string quartet in D minor, Op. 42; but the transformations of his one theme will be contrasted in structure, the changes of rhythm will be a continual surprise, the passage from the first key to the second will be important and emphatic, and at every point the difference in scope between his sonata music and Bach's suite is evident as the difference between epic drama and lyric poetry.

The process of this change was gradual; indeed, no artistic revolution of such importance can ever have been accomplished more smoothly and rapidly. Yet Philipp Emmanuel Bach, the first to realize the essentials of the new style, obtained his object only at the cost of older elements that are essential to artistic completeness. And Haydn himself was hardly able to reinstate such vitality of texture as would give the new form permanent value, before he was forty years of age.

Haydn's earlier string quartets, from Op. 1 to Op. 33, present one of the most fascinating spectacles of historical development in all music. He was content to begin at a lower level of brilliance than some of his contemporaries; because from the outset his object was the true possibilities of the new style, and no luxuriance of colour could blind him to the lifelessness of an art that is merely suite-form spun out. Haydn's earliest quick movements in sonata forms are often as short as any suite movement, except when he writes for orchestra, where he is influenced by the style of the operatic overture as we find it in Gluck and in the symphonies of Philipp Emmanuel Bach. In his slow movements he at first more often than not worked in the style and form of the operatic aria; and in so mature a piece as the quartet in G major, Op. 17, No. 5, he not only endorses Philipp Emmanuel Bach's evident conviction that operatic recitative is within the scope of the sonata, but convinces us that he is right. It was easy for the early composers of sonatas to introduce theatrical features into their instrumental music; for the very fact that the sonata forms were in polyphonic days the forms of lighter music is a consequence of their original identity with the forms of stage-music and dance (see Overture and Symphony). But it needed a very great composer to realize not only the radically dramatic character of a sonata form in which the rhythm and texture is emancipated from the metrical bondage of the suite, but also its true limitations as pure instrumental music. As Haydn's work proceeded, so did the freedom of his rhythm and its consequent inner dramatic life increase; while the external operatic influences soon disappeared, no so much because they were out of place, as because opera itself "paled its ineffectual fires" in the daylight of the pure instrumental drama with its incomparably swifter and terser action. Polyphony, on the other hand, steadily increased, and was so openly encouraged that in the first set of Haydn's quartets which is entirely free from archaisms (Op. 20) three of the finales are regular fugas. And from that time onward there is hardly a work of Haydn's in which highly organized fugato passages are not a frequent means of contrast.

2. The Sonata Form.—In the last-mentioned quartets of Haydn and the works of Mozart's boyhood, the normal sonata form, as we now accept it, is firmly established, and may be represented as follows:

![Diagram of Sonata Form]

This diagram is, no doubt, equally true of Philipp Emmanuel Bach's form; and thus we see how little the external shape of a movement tells us as to the ripeness of genuineness of the specimen. Apart from this, much confusion of thought is caused by the unfortunate terms "first and second subject," which have misled not only many teachers but nearly all pseudo-classical composers into regarding the exposition of the movement as consisting essentially of two themes expanded to the requisite size by appropriate discourse. When we use the terms "first and second subject," then, let us be understood to mean any number of different themes, in any variety of proportion, but separable into two groups of which the first is in the tonic while the second is in another related key, which is called the complementary key. The exposition of a movement in sonata form contains, then, these two "subjects" and represents these two keys; and unless the work is too large or too emotional for merely decorative emphasis, the exposition is generally repeated. Then the development follows. It is normally founded on the materials of the exposition, but neither continues itself steadily in any key nor leaves its material as it found it. On the contrary, its function is to provide a wide range of modulation, and to put the materials into fresh light by regrouping them (see Melody, examples 2–7). It cannot be too strongly insisted that in the sonata forms there are no rules whatever for the number of themes and their relative prominence among themselves and in their development. After the development the first subject returns in the tonic, with an effect which, after so many changes of key, is always reassuring as regards...
design, and sometimes intensely dramatic. The second subject
follows, also in the tonic. This recapitulation is normally very
exact, except for the alteration necessary to bring the
second subject into the tonic instead of the complementary
key, an alteration which, of course, will chiefly affect the first
subject, if, indeed, the original transition was not so simple
that it could be merely suppressed. In highly organized works,
however, this point is often marked by some special stroke of
genius, and even in the most exact recapitulations the great
masters make minute changes which throw the second subject
into higher relief. Modern criticism tends to dismiss the
recapitulation as a conventional and obsolescent feature; but
this is a great mistake. The classics, from Scarlatti to Brahms,
give overwhelming proof that it is a primary instinct of com-
posers with a living sense of form to conceive of all kinds of
exposition as predestined to gain force by recapitulation,
especially in any part that resembles a second subject. Haydn
we shall find to be an extreme case; but we have only to regard
his true second subject as residing in the very end of his exposi-
tion, and his mature works will then illustrate the second
subject special force. Beethoven seems to give one notable detail
to the contrary effect, in the first movement of his C minor
symphony, but the passage only proves the rule more forcibly
when seen in its context. The powerful phrase that announced
the second subject is in the recapitulation transferred from the
resounding triumph of the horns to the impotent croaking fury
of the bassoons. This looks like a mere inconvenient result of
the fact that in 1808 the horns could not transfer the phrase
from E flat to C without a change of crook. But in earlier
works Beethoven has made the change out of the need of
provocation; and besides, he could easily have contrived a
dozen tone-colours more dignified than that of the bassoons.
The point must, then, be one of Beethoven’s touches of Shake-
spearian grotesqueness; and certainly it draws attention to
the recapitulation. But even if we dismiss it with impatience we
are then immediately confronted with a new melodic and
harmonic poignancy in the subsequent crescendo, produced by
changes as unobtrusive and as essential to the life of the whole
as are the deviations from mechanical symmetry in the forms
of leaves and flowers. With the recapitulation the bare, essential,
and of sonata form ends; but a material will persist, if even in
works on a large scale, furnish ample means of adding a more
emphatic conclusion, which is then called the coda. In Beetho-
ven’s hands the coda ranges from a dramatic non-existence,
as in the distant thunder in which the first movement of the
D minor sonata expires, to the mighty series of new develop-
ments and climaxes which, in the 3rd and 9th symphonies and
many other works, tower superbly above the normal structure.

Haydn’s later treatment of sonata form is very free. He
shows a sense of space and breadth which, if second to Beetho-
ven’s, can only be said to be so because the terms of Haydn’s
art did not give it fuller expression. The scale on which he
worked was so small that he soon found that a regular recapitula-
tion took up all the room he wanted for larger growths to a
brilliant climax. Moreover, he found that if his second subject
began with material in sharp contrast to the first, it tended to
make his movements sound too undeveloped and sectional for
his taste; and so in his later works he generally makes his second
subject on the same material as his first, until the very end of
the exposition, where an exquisitely neat new theme forms the
close. This cadence-theme also runs off the whole movement
with an appoggiatura for the dominant, a form which leads to the beli-
ting, but more, like Mozart, observes a custom of rigid recapita-
tion from which Beethoven was the first to emancipate the
form. The truth is that the brilliant new developments which
oust the recapitulation almost entirely in Haydn’s form are more
like Beethoven’s codas than anything else in earlier music, and
the final appearance of the neat cadence-theme at the end is,
from its very formality, the most brilliant stroke of all. Lastly,
these tendencies are characteristic, not of Haydn’s early, but
of his late work. They have been described as “showing form
in the making”; but this is far from true. They show
form in an advanced state of development; and further
progress was only possible by the introduction of new qualities
which at first had a decidedly restraining effect.

Mozart’s greater regularity is due, not to a more formalizing
tendency than Haydn’s, but to the fact that he works on a
larger scale and with a higher polyphony. In actual length,
Mozart’s movements are so much greater than Haydn’s that
sharply contrasted themes and regular recapitulations do not
harm him. On the contrary, they give his designs the necessary
breadth and effect, and even more so than Haydn’s, could he
have had the opportunities of a later generation and the
example of Haydn’s own earlier work, besides a vast experi-
ence of composition (both in contrapuntal and sonata forms)
that began in his miraculous infancy and made all technical
difficulties vanish before he was fifteen. At sixteen he was
writing string-quartets in which his blending of polyphonic and
sonata style is more surprising, though less subtle, than Haydn’s.
At twenty-two he was treating form with an expansiveness
which sometimes left his music perilously thin, though he was
mystically, but magnificently reserved, and so reconciles us as
he best can to the enjoyment of a lighthearted finale which has
only here and there a note of warmth to suggest to us any
pretension of compatability with what went before.

Beethoven discovered all the new resources needed to make
the sonata a means of tragic expression, and with this a means
of expressing a higher rapture than had ever been conceived in
music since Palestrina. He did not, as has sometimes been
said, emancipate sonata forms from the stiffness of the recapitu-
lation. On the contrary, where he alters that section it is almost
invariably in order to have, not less recapitulation, but more,
by stating some part of the second subject in a new key before
bringing it into the tonic. Here, as has been suggested above,
the effect of his devices is, both in minuets and in surprises, to
throw the second subject into higher relief. Every one of the
changes which appear in the outward form of his work is a
development from within; and, as far as any one principle is more
fundamental than others, that development is primarily har-
nomic. We have elsewhere mentioned his practice of organizing
remote or apparently capricious modulations on a steady
sequential progression of the bass, thereby causing such har-
nomies to appear not as mere surprises or special effects (a
form in which they have a highly artistic function in Mozart
and Haydn) but as inevitable developments (see BEETHOVEN
HARMONY). The result of this and a host of similar principles
is an incalculable intensification of harmonic and emotional
expression. Let us compare the opening of the second subject
of Haydn’s quartet in A major, Op. 20, No. 6, with the corre-
sponding passage in the first movement of Beethoven’s sonata,
Op. 2, No. 2. Haydn executes the masterly innovation of
a second subject that before establishing its true key passes
through a series of rich modulations. He begins in E minor,
rapidly passing through G and A minor, and so to the dominant of E, in various phases of tender humour and cheerful climax. The keys are remote but not unrelated, the modulations are smooth, and the style is that of a witty improvisation. Beethoven's second subject is intensely agitated; its modulation begins like Haydn's as regards key, but its harmonies are startling and its pace tremendous. Its regular rising basis carries it in two-beat rhythm, a rhythmic pattern which it is urged by the same relentless process with increasing speed, and when it is at last driven to the threshold of the key which it seeks as its home there is a moment of suspense before it plunges joyfully into its cadence. Such resources as this enable Beethoven to give rational dramatic force to every point in his scheme, and so they soon out those almost symbolical formulas of transition and cadence which are a natural feature in Mozart's music and a lifeless convention in imitations of it. The growth of Beethoven's forms is externally most evident in his new freedom of choice for the complementary key. Hitherto the only possible key for the second subject was in major movements the dominant, and in minor movements the relative major or dominant minor. A sonata which begins by treating all directly related keys as mere incidents in establishing the tonic, will very probably choose some remoter key as its main contrast; and it is worth while trying the opening of the Waldstein sonata (Op. 53) with the simple alteration of C sharp and A natural for C natural and A sharp in the bass of the twenty-first bar, so as to bring the whole transition to the second subject on to the orthodox dominant of G. In order to see, on the one hand, how the composer can utilize the theme of the first movement, and, on the other hand, how unnecessarily long the transition seems when that is the key which it is intended to establish.

3. The Sonata as a whole.—The history of the Waldstein sonata marks the irrevocable transition from Mozart to Beethoven (see iv. 88); and in his rejection of the well-known Andante in F (which was originally intended for its slow movement) Beethoven draws attention to the problem of the sonata as a whole, and the grouping of its movements. The normal sonata, in its complete (or symphonic) form, consists of four movements; firstly, a quick movement in that sonata form par excellence to which our discussion has hitherto confined; then two middle movements, interchangeable in position, the one a slow movement in some lighter form, and the other a dance movement (the minuet, or scherzo) which in earlier examples is of hardly wider range than a suite movement. The finale is a quick movement, which may be in sonata form, but generally tends to become influenced by the lighter and more sectional rondo form, if indeed it is not a set of variations, or even, in the opposite extreme, a fugue. Aesthetically, if not historically, this general scheme is related to that of the suite, in so far as it places the most elaborate and highly organized movement first, corresponding to the allemande and courante; while the slow movement, with its more lyric character and melodious expression, corresponds to the sarabande; the minuet or scherzo to the lighter dance tunes or "Galanterien" (such as the gavotte and bourrée), and the lively finale to the gigue. But just as the whole language of the sonata is more dramatic, so are the contrasts between its movements at once sharper and more essential to its unity. Hence, the diversity of outward forms within the limits of these four movements is incalculable.

The first movement is almost always in the sonata form par excellence (or sonata-allegro form), and always admits of lower organization and more concentrated dramatic interest than any other. Often after such a movement a slow piece in the form conveniently known as A B A, or simple "ternary" form (i.e. a broad melody in one key, followed by a contrasted melody in another, and concluded by a recapitulation of the first) is found to be a welcome relief, and of great breadth of effect. Of course in all true classics the very simplicty of such movements will be inspired by that sense of rhythmic freedom and possibility of development that permanently raises sonata forms from the level of a mere decorative design; or, on the other hand, is there any limit to the complexity of form possible to a slow movement, except that imposed by the inevitable length of every step in its slow progress. Still, the tendency of slow movements, even more than of finales, is to prefer a loose and sectional organization. Sonata form is frequently used in them by Haydn and Mozart with the success attainable only by the greatest masters of rhythmic flow; but even in their works the development is apt to be episodic in character, and is very often omitted.

The minuet, in Haydn's and Mozart's hands, shows a surprising amount of rhythmic variety and freedom within the limits of a dance tune; but Haydn, as is well known, sighed for its development into something larger; and, though Beethoven had long emerged from his "first period" before he could surpass the splendid minuet in Haydn's quartet in G major, Op. 77, No. 1, he achieved in the scherzo of his Eroica symphony the first of a long line of movements which establish the scherzo (q.v.) as an essentially new art-form.

The only condition that affects the forms of finales is that a sonata involves a considerable stretch of time, and therefore its end must be so designed as to relieve the strain on the attention. In a drama or a story the deeper artistic necessity for this is masked by the logic of cause and effect, which automatically produces the form of an intrigue ending in a dénouement. In music the necessity appears in its purest form. There is no need for finales to be less serious than first movements; or even, in certain ways, less complex; but the attention which could be aroused at the outset by problems must be maintained at the end by something like a solution. Hence the use of the lighter rondo forms, which, by dividing the work into shorter and more distinct sections, make the development easier without unduly limiting its range. Hence, also, the influence of rondo style upon such finales as are cast in true sonata form; and hence, lastly, the paradox that the fugue has occasionally been found a possible means of expression for the finale of a dramatic sonata. For the complexity of the fugue, though incessant, is purely a complexity of texture, and the mind in following that texture instinctively abandons any effort to follow the form at all, finding repose in the change of its interests.

Now, just as within the typical scheme of first and second subject development and recapitulation in the first movement, there is room for genius in the contrasting of different rhythms and proportions, so, within the limits of the simple four-movement scheme of the whole sonata is there room for genius in the contrast of various types and degrees of organization. The complete four-movement scheme seldom appears in works for less than three instruments. Beethoven was the first to adopt it for solo sonatas, and he soon thought fit to make omissions. In Haydn's work for less than four instruments it was not even necessary that the "sonata" form itself should be represented at all. Its essential spirit could be realized in the melodic and rhythmic freedom of a group or couple of more sectional movements, nor did Beethoven (in Op. 26 and Op. 27, No. 1) consider such works unworthy of the name of sonata, or (in Op. 54) incapable of expressing some of his most original ideas. No design is known to pure instrumental music that is not possible as a movement of a sonata, if it has the characteristic freedom of rhythm and is not much over a quarter of an hour in length. There is no form that has not been so applied; and, indeed, only the instrumental form that has maintained a larger development outside than inside the scheme of the sonata is that of variations (q.v.).

The simplicity and complexity of the sonata style grew, so did the interdependence of its movements become more evident. With Mozart and Haydn it is already vital, as we have seen in the crucial case of Mozart's G minor quintet; but the differences between one scheme and another are not remarkable until we study them closely; and, except in key-relationship, it would be difficult to trace anything more concrete than principles of contrast as interacting between one movement and another. But Beethoven's dramatic power finds as free expression in the contrasts between whole movements as it finds within the movements themselves. In his later works, the increase in harmonic
SONATA FORMS

range, with the consequent prominence of remotest key-relationships, necessitating the dwelling on these keys at greater length causes the key-system of each movement to react on the others to the extent that it would be purposeless in the art of Haydn and Mozart. Thus in the B flat trio, Op. 97, we find such remote keys as G major, D flat and D major placed in positions of great functional importance, until we come to the finale, which keeps us in suspense by its very low and quiet key-colour, contrasting so oddly with its bacchanalian temper. But when the whole main body of this finale has passed before us in the drab colours of tonic, dominant and sub-dominant, the coda marvellously explains everything by opening with an enharmonic modulation to the most distant key yet attained except as a transitory modulation.

Beethoven having proceeded, his growing sense of the functional expression of musical forms enabled him to modify and strengthen them until their interaction was as free as its principles were exact. In the C sharp minor quartet (Op. 131) the opening fugue is functionally an enormously developed introduction. The following allegro, in the startling key of D major, the "artificial" flat supertonic, is a first movement, with its development suppressed, and with certain elements of rondo style as a necessary contrast to the preceding fugue. The startling effect produced by this key of D major necessitates a simple and limited key-system within the movement itself, thus accounting for the absence of a development. The remaining movements fall into their place among the keys that lie between the keys of D major and C sharp minor. Thus the slow movement (to which the brief allegro moderato forms a dramatic introduction) is a great set of variations in A major, and the strictness of its variation form allows no change of key until the two brilliant bursts of reminory harmony, F and C, in the coda. Then follows a scherzo of extremely simple design, in E major, with a small part of its trio in A. A short introduction in G sharp minor, the dominant, completes the circle of related keys and leads to the finale which (though cast in a rondo form) forms a free range of modulation) contents itself with very simple changes, until towards the end, where it systematically demonstrates the exact relationship of that first surprising key of D major to C sharp minor.

4. The Unity of the Sonata.—The gigantic emotional range of Beethoven’s work is beyond the scope of technical discussion, except in so far as the technical devices themselves suggest their emotional possibilities. The struggle between decadence and reaction since the time of Beethoven indicates on the one side the desire to rival or surpass Beethoven in emotional expression without developing the necessary means; and, on the other side, a tendency to regard form as a scheme which the artist first sets up and then fills out with material. Early in the 19th century these tendencies gave rise to controversies which are not yet settled; and before we discuss what has taken place since Beethoven we must consider the connexion between sonata movements in a last new light.

Historical views of art are apt to be too exclusively progressive and to regard higher and lower degrees of organization in an art-form as differing relatively, as a kind of “artistic” progress. But in trying to prove that the megalithism could not survive under present conditions, we must be careful of arguing that it never existed; nor must we cite the fact that man is a higher organism in order to argue that a jelly-fish is neither organic nor alive. Organization in art, as elsewhere, may be alive and healthy in its lowest forms. The uniformity of key in the suite forms is low organization; but it is not inorganic until a mild seeker after novelty, like A. G. Muffat, tries to introduce more keys than it will hold. The interdependence of movements in Haydn and Mozart is not such high organization as the ideal form of the future, in which there is no more breaking up of large instrumental works into separate movements at all; but neither is it a mere survival from the decorative contrasts of the suite. Evolutionists must not forget that in art, as in nature, the survival of the fit means the adaptability to environment. And the immortal works of art bring their proper environment with them into later ages.

The large instrumental forms have, until recent times, remained grouped into sonata movements, because their expression is so concentrated and their motion so swift that they cannot, within the limits of a single design, give the mind time to dwell on the larger contrasts they themselves imply. Thus, in the "Sonata Appassionata," the contrast between the first subject and the main theme of the second is magnificent; but that calm second theme lasts just the third part of a minute before it breaks off. Now, though the third part of a minute bears about the same proportion to the whole design as five hundred lines does to the design of Paradise Lost; though, moreover, this theme recurs three times later on, once in an exact recapitulation, and twice transformed in terribly tragic climaxes; yet the mind refuses to be whirled in less than ten minutes through a musical system which Shakespearean power without opportunity for repose in a larger scheme of sonata, Op. 106, and the 9th symphony) where its whole point is that of a surprise. Yet the treatment by each movement of its own thematic material is so complete that there is little or no scope for one movement to make use of the themes of another. Such instances as may be suspected in Beethoven’s later works (for example, the similarity of opening themes in various movements of the sonatas, Op. 106 and Op. 110) are too subtle to be felt more than subconsciously; while the device of clearly quoting an earlier movement occurs only in three intensely dramatic situations (the introductions to the finales in Op. 101, the violent sonata, Op. 106, and the 9th symphony) where its whole point is that of a surprise.

5. The Sonata since Beethoven.—It is unlikely that really vital sonata work will ever be based on a kind of Wagnerian Leitmotif system, until the whole character of instrumental form shall have attained the state of things in which the movements are not separated at all. There has been no ambitious or “progressive” composer since Beethoven who has not, almost as a matter of etiquette, introduced the ghosts of his earlier movements into his finale, and defended the procedure as the legitimate consequence of Beethoven’s Op. 106, but while there is no a priori reason for condemning such devices, they illustrate no principle, new or old. The nearest approach to such principle is furnished once by Schumann, who always ingeniously adapts the outward forms of the sonata to his own peculiar style of epigrammatic and antithetic expression, discarding as beyond his scope the finer aspects of freedom and continuity of rhythm, and constructing works which bear much the same relation to the classical sonata as an elaborate mosaic bears to a casel-picture. Dealing thus with a looser and more artificial type of organization, Schumann was able in his D minor symphony to work in which Movements are thermatically connected to an extent which in more highly organized works would appear like poverty of invention, but which here furnishes a rich source of interest. Many other experiments have been tried since Beethoven, by composers whose easy mastery is that of the artist who, from long practice in putting material into a ready-made form, becomes interested in the construction of new ready-made forms into which he can continue to put the same material. A sense of beauty is not a thing to be despised, even in pseudo-classical art; and neither the many beautiful, if mannered, works of Spohr, which disguise once stereotyped form in a bewildering variety of instrumental

1 In Op. 106 the first two notes of the slow movement were an afterthought added (as Beethoven told his publisher) for the purpose of producing such a connexion.
and literary externals, nor the far more important and essentially varied works of Mendelssohn deserve the contempt which has been the modern correction for their high position in their day. But we must not forget that the subject of sonata forms is no mere province, but covers the whole of classical instrumental music; and we must here pay attention only to the broadest essentials of its central classics, mentioning what diverges from them only in order to illustrate them. Schubert's tendencies are highly interesting and instructive, but, as far as they are carried up, they are but a fragment of what is said of them in the articles on Music and Schubert.

The last great master of the sonata style is Brahms. A larger scale and more dramatic scope than Beethoven's seems unattainable within the limits of any music identifiable with the classical forms; and the new developments of Brahms lie too deep for more than a bare suggestion of their scope here. Much of the light that can as yet be shed upon them will come through the study of Counterspan and Contrapuntal Forms (q.v.). Outwardly we may see a further evolution of the coherence of the key-system of works as wholes; and we may especially notice how Brahms's modern use of key-relationships makes him carry on the development of a first movement rather in a single remote key (or group of keys) than in an incessant flow of modulations which, unless worked out on an enormous scale (as in the 2nd and 4th symphonies), will no longer present vivid enough colours to contrast with those of the exposition. Beethoven's last works already show this tendency to confuse the development to one region of key. Another point, fairly easy of analysis, is Brahms's unlimited new resources in the transformation of themes. Illustrations of this, as of older principles of thematic development, may be found in musical type in the article MELODY (examples 8–16). But no mere formal analysis or argument will go further to explain the greatness of Brahms than to explain that of Beethoven, Haydn or Mozart. Yet by that outward sign of dramatic mastery in the true sonata style, that variety of rhythmic motion which we have taken as our criterion, Brahms has not only shown in every work his kinship with Haydn, Mozart and Beethoven, but in one particular work he has given us documentary evidence of his faith in it. In his last years he revised, or rather recomposed, his first piece of chamber music, the trio in B major, Op. 8. The new masterly differences from the old, not only as a rhythmic expression, but also in the simple fact that it moves literally four times as fast. Such rapidity is not shown by any external display of energy; indeed there is incomparably more repose in the new version than in the old. But the comparison of the two clearly demonstrates that the true sonata style is, now, as at the outset, primarily a matter of swift action and rhythmic variety; and nothing more certainly indicates the difference between the true style and the lifecessness of decadence or academicism than this sense of motion and proportion.

In so far as the tendencies of modern instrumental music represent an artistic ideal which is foreign to that of the sonata without being false, they represent a different type of motion, wider in its sweep, and consequently slower in its steps. The forms such a motion will produce may owe much to the sonata when they are realized, but they will certainly be beyond recognition different. In all probability they constitute the almost unconscious aims of the writers of symphonic poems (q.v.) from Liszt onwards, just as the classical sonata constituted the half-conscious aim of more than one great writer of 18th-century programme-music. But the growing importance and maturity of the symphonic poem does not continue the continuous development of the sonata forms, nor has it so far realized sufficient consistency and independence of style to take as high a place in a sound artistic consciousness. The wider sweep of what we may conveniently call "ultra-symphonic" rhythm owes its origin to Wagner's life-work, which consisted in evolving it as the only musical medium by which opera could be emancipated from the necessity of keeping step with instrumental music. Small wonder, then, that the new art of our time is as yet, like that of Haydn's youth, stage-struck; and that all our popular criteria suffer from the same obsession. One thing is certain, that there is more artistic value and vitality in a symphonic poem which, whatever its defects of taste, moves at the new pace and embodies, however imperfectly, such forms as that pace is fit for, than in any number of works in which the sonata form appears as a clumsy mould for ideas that belong to a different mode of thought. If from the beginnings exemplified by the symphonic poems of the present day a new art-form arises in pure instrumental music that shall stand to the classical sonata as a classical sonata stands to the suite, then we may expect a new epoch no less glorious than that which seems to have closed with Brahms. Until this aim is realized the sonata forms will represent the highest and purest ideal of an art-form that music, if not all art, has ever realized.

SONCINO—SONE

SONCINO, a town of Lombardy, Italy, in the province of Cremone, 11 m. E. of Crema by steam tramway, 282 ft. above sea-level. Pop. (1901), 6159 (town); 8136 (commune). It contains a handsome castle built in 1469–1475 for Galeazzo Maria Sforza by Benedetto Terrini (cf. L. Beltrami, Il Castello di Soncino, Milan, 1890). The town was the seat of a Hebrew printing-press founded in 1472, but suppressed in 1597, when the Jews were expelled from the duchy of Milan.

SONDERBURG, a seaport and seaside resort of Germany, in the Prussian province of Schleswig-Holstein, on the S.W. coast of the island of Alsen, of which it is the chief town, and 17 m. by steamboat N.E. from Flensburg. Pop. (1905), 7047. It is connected with the mainland by a pontoon bridge, and has a castle, now used as barracks, in the beautiful chapel of which many members of the Sonderburg-Augusten line lie buried; a Lutheran church and a town hall. There is an excellent harbour, and a considerable shipping trade is done. The town, which existed in the middle of the 13th century, was burnt down in 1864 during the assault by the Prussians upon the Döppel trenches.

SONDERSHAUSEN, a town of Germany, capital of the principality of Schwarzburg-Sondershausen, situated in a plain 37 m. by rail N. of Erfurt. Pop. (1905), 7383. It possesses a castle, with natural history and antiquarian collections, and a parish church (restored 1891), with the mausoleum (1892) of the reigning princes. There are manufactures of woolens and pins.

SONDROIO, a town of Lombardy, Italy, capital of the province of Sondrio, in the Valtellina, 1140 ft. above sea-level, on the river Adda, 26 m. E. of Lake Como and 82 m. by rail N.E. of Milan. Pop. (1901), 4425 (town); 7707 (commune). The Valtellina, of which Sondrio is the capital, produces a considerable quantity of red wine. Sondrio also has silk-work. Above the town to the north rise the snow-capped peaks of the Bernina group. The railway goes on to Tirano, 16 m. farther east, from which diverge the Bernina and Stelvio roads.

SONE, or Son, a river of central India which has been identified with the Eranoboas of the Greek geographers. With the exception of the Jumna it is the chief tributary of the Ganges on its right bank. It rises in the Amarkantak highlands about 3500 ft. above sea-level, the Nerudda and Mahanadi also having their sources in the same table-land. From this point it flows north-west through an intricate mass of hills, until it strikes the Kaimur range, which constitutes the southern wall of the Gangetic plain. Here it turns east and continues in that direction until it falls into the Ganges about 10 m. above Patna, after a fall of 465 ft. Its upper waters drain about 350 m. of wild hilly country, which has been imperfectly explored; while in its lower section of 160 m. it traverses the British districts of Mirzapur, Shahabad, Gaya and Patna. The Sone canals, fed by the river, form a great system of irrigation in the province of Behar. The headworks are situated at Dehri about 25 m. below the point where the river leaves the hilly ground. The weir across the Sone at this point is believed to be the longest constructed in a single unbroken piece of masonry, the length between abutments being 12,409 ft. A main canal is taken off on either bank of the river, and each of these is divided into branches,

the
of determining the intervening sounds. It has been generally assumed that the fall of a fourth is the interval earliest arrived at by the instinct of the Indo-European race—and that intervening sounds were added which resulted eventually in the three possible forms of the diatonic tetrachord, the earliest being that which is characteristic of the ancient Dorian mode or scale (the basis of the Greek musical system) in which two tetrachords, having the semitone between the lowest note and the next above it, are superimposed (see Bourgault Ducoudray, Introduction to 30 Chansons de Grèce et d'Orient).

It must, however, be remembered that the popular instinct knows nothing about tetrachords or scales, which are abstractions, and only creates melodies, or at least successions of sounds, which are the outward expression of inward feelings. The Greek theorists therefore, in recording certain modes as being in use in their day, were in effect merely stating results arrived at by analysing popular melodies—and from the persistence with which the Greeks, and following them, most of the musical historians of Europe, have insisted upon a tetrachordal basis for the art of music it may be assumed that in these melodies a basis of four diatonic notes was a conspicuous feature.

It is a feature which marks a considerable number of folk-songs heard in Greece at the present day, and also of many folk-songs which are not Greek, the Breton, for example (see Bourgault Ducoudray, Chansons de Basse-Bretagne). The interval of a fourth is nearly always prominent too in the music of savages. If it is natural to connect these facts with the drop of a fourth, characteristic of the speaking voice, it is dangerous to assume an exclusively "tetrachordal period" of primitive song, at any rate till it can be shown that melodies based on other principles did not exist side by side with those that are tetrachordal. From the rise of a fifth and the fall of a fourth, the octave, which results from combining these intervals, may well have become familiar at a very early epoch. Indeed a prolonged howl beginning on a high note and descending a full octave in semitones—or notes approximately resembling semitones—is recorded both of the Caribs and of the natives of Australia, so that familiarity with the octave need not presuppose an advanced stage of musical development.

To pass from the sphere of mere speculation nearer to the domain of history, it may be asserted with confidence that the oldest form of song or chant which can be established is found in certain recitation formulae. There is a natural, will be found to be derived from the rise and fall of the voice in speech. It is therefore not surprising that O. Fleischer (Sammelblüte der internationalen Musik-Gesellschaft, Jan.-Mar. 1902) is able to trace practically identical formulae in the traditional methods of reciting the Vedas, the Koran, the Jewish and Christian liturgies. The simplest form consists of four notes (a diatonic tetrachord), a reciting note, preceded by two notes rising to it, and followed by a fall, or cadence, for the close, the voice rising above the reciting note in order to emphasize important words, or according to the nature of the sentence. An extended form is both natural and common.

The influence of these and similar formulae upon popular melodies can be illustrated by countless examples (for which the reader is referred to I.M.G.). As characteristic as any is the melody of the Christian hymn which begins

\[
\text{Te lu-cis an-te ter-mi-num,}
\]

and concludes

\[
\text{Sis praes-ul et cuso-di-a.}
\]

Another is the Hungarian folk-song: Nem Szoktám.

Many French songs have been collected in recent years, of which the following formula, or variations of it, form an essential feature:

This corresponds closely with the third example given above. That the melodies in question are of great antiquity may be inferred from the fact that they are almost confined to the oldest class of folk-song, that which celebrates May Day and the beginning of spring. M. Tiersot (La Chanson populaire en France, Paris, 1889) plausibly finds in them a survival of a melodic fragment, which may have belonged to pagan hymns in honour of spring, having his supposition upon the fact that the phrase in question occurs in the melody of the Easter hymn "O Filii et Filiae." The medieval Church, acting on principles familiar in all ages, may well have helped to merge a pagan in a Christian festival by adopting, not merely old rites and observances, but the actual melody with which these had for ages been associated. A similar survival in French folk-song is that of the melody of the Tonus peregrinus, the chant used for the psalm "When Israel came out of Egypt" (mentioned in the 9th century by Aurelian Réomé as being very old). Its appearance, like that of the Easter hymn, in songs, which on other grounds can be proved to be of great antiquity, points to the probability of its being of popular origin. It also bears equally strong marks of being derived from a recitation formula, as indeed its appropriation for chanting a psalm sufficiently indicates.

Endeavours to detach other primitive formulae from the popular melodies in which they are enshrined form a branch of folklore now being actively pursued. It may be hoped that "comparative melodology"—if the term may be coined—will do for this department of musical knowledge what the science of comparative philology has done for language. Oscar Fleischer (I.M.G. i. 1) has endeavoured to trace the history in Europe of the primitive phrases belonging to the melody of "Les Série" (or Unus est Deus) as given by De Villemarqué in Baraz-Breiz.
SONG

No. 1, in the musical appendix, as also of the opening phrase in the old Christian hymn, "Conditor alme siderum" (attributed to Bishop Ambrose):

![Melodic notation]

The phrase here belongs to a melody in the Phrygian mode, but when it is used in major melodies its characteristic notes are those of the common chord, with a rise to the sixth at the point of climax, corresponding to the rise in the recitation formula given above.

By what processes the notes of the common chord became universally established it is not possible to determine, but it may be said in a general way that the reference to a given tonic was felt in all ages to be a necessary condition even of the simplest melody, and that, as the melodic instinct grew, an almost equal necessity was found for a point of contrast, and that this point of contrast became with most nations of Aryan origin the fifth note above the tonic, at any rate in the more popular scales. Combarieu (La Musique, p. 121) observes that we owe the use of the octave, the fifth and the fourth to the South and East, but that the importance of the third in our modern musical system is due to the instinctive genius of the West and North, i.e. to England and Scandinavia (see also Hugo Riemann, Geschichte der Musiktheorie, Leipzig, 1898, and Woodridge, Oxford History of Music, i. 161-162, where the well-known quotation from Giralda Cambriensis, or Gerald Barry, of the 12th century, establishing the fact of part-singing in England, is given). If, as has been shown, the origin of many melodies can be traced to formulae originally used for chanting or reciting, it must not be forgotten that formulae thus derived assume very different characters under the influence of more decided rhythms than that of speech. To accompany bodily movements (which by a natural law become rhythmic when often repeated) with music, vocal or instrumental, is an almost universal human instinct, whether to alleviate the burden or the monotony of labour, as in rowing, sawing, spinning, hammering and a score of other pursuits, or to promote pleasure and excitement, as in the dance.

It is unsafe to infer, as some have done, from the custom, known in all ages, of dancing and singing at the same time, that song arose as a mere accessory to the dance. It is more probable that the dance has its origin in the mimetic actions, which are the natural accompaniment of rudimentary song. At the same time, no one will deny that races with ballads of their own early made use of them for the dance, and that, especially on the rhythmical side, melody owes to the dance an incalculable debt. It may be assumed then that upon some such basis as has been roughly indicated the different nations of the world have developed each their own musical phraseology, emanating from and answering to their several needs and temperaments and that the short melodic phrases, out of which folk-tunes are made, have their roots in a past as distant as that in which the elements of language were formed, and that the popular instinct which through countless ages has diversified those forms and arranged them into melodies, whose constructions are mostly susceptible to analysis, is the same instinct as that which has given to language its grammar and its syntax.

In proceeding now to the actual history of song in Europe, it must be remembered that it is inseparably connected with poetry. Melody till within comparatively recent times continued to fulfill its original function of enhancing the value and expressiveness of language. For poetry of the epic kind with the long lines common to early European peoples, some such forms of chanting as have been indicated must have sufficed.

The melody, as we understand it, with compact form and balanced phrases, could only have existed if and when the same qualities appeared in popular poetry. This was probably the case long before the taste for long epic narratives began to disappear in favour of more concise forms of ballad and of lyric. The stanza form must have been generally familiar in the early middle ages from the Latin hymns of the Church, and these hymns themselves are likely to have been formed, in part at any rate, on models which were already known and popular. So we have that definite indication that in the early middle ages two sorts of popular poetry existed—the historical ballads (descendants of those alluded to by Tacitus in his Germania as characteristic of the Germans, and as constituting their only historical records), and popular songs of a character which caused them to be described as cantica nefarior as sung by knightly folk, both men and women; the Council of Cluny denounced the women, who seem to have been the chief offenders, with excommunication; and the desire for the better class of song is attested by the fact that he ordered a collection of them to be made for his own use, said of the other "cantica turpe et luxuriosum circa ecclesiays agere omnino, quod et ubiquitamund est." Beyond the fact of their existence we know nothing of these songs of the early middle ages. Their influence on the popular mind was vigorously resisted, as we have seen, by the Church, and for many centuries efforts were made to supplant them by songs, the subjects of which were taken from the Gospel narratives and the lives of the saints, both folk-songs and church song strove together for popularity. Doubtless the church song borrowed musical elements from its rival; nor was the folk-song uninfluenced in its turn by the traditional music of the Church.

In considering this latter music, it is important to distinguish between the melodies adapted to the prose portions of the ritual without definite rhythm, and those of the hymns, where the metre of the Latin verses and their stanza form necessitated a corresponding rhythm and musical form. Rhythm in music, which has its origin and counterpart in the regular bodily movements involved in various departments of labour and in the dance, must, as has already been said, have always been an essential feature of popular melody, and it is reasonable to conclude from its absence in the plain-song, and indeed for many centuries in the compositions of musicians, which had the plain-song for their basis, that these hymns, which represented the popular part of the Church services, were also representative of the popular tastes of the time. In all ages the Church has drawn largely from popular song for the melodies of its hymns. It is moreover in the highest degree improbable that the Church should have been able to evolve out of its inner consciousness, without pre-existing models, a melody—to take a single instance—like that of "Conditor alme siderum"—the survival of which in innumerable European folk-songs has already been alluded to.

Numerous additions to the store of plain-song melodies were made by the monastic composers of the middle ages; the most notable is that of the Dies Irae, of which the words are attributed to Thomas de Celano (d. 1256). Reference should also be made to the music of the liturgical dramas or mysteries, popular in medieval times: The Lamentation of Rachel, The Wise and Foolish Virgins and The Prophecy of Christ, are given, both text and music, in Coussemaker's L'Histoire de la Musique de l'Eglise, and were probably intended for cultivated rather than popular audiences. The same is probably true of the secular songs quoted in the same work. These have a special interest as being the earliest specimens of song which have come down to us in Christian times. The best known is the "Complaint," on the death of Charlemagne (quoted in many histories), the dignified, if somewhat dreary, melody of which revolves mostly on the first three notes of a major scale, once rising to the fourth (thus recalling the old recitation formula). Rhythm is practically

---

1 For the growth of the refrain from communal dancing and singing, see C. J. Sharp, English Folk-Songs, p. 93. Nor should the association of dancing with all primitive religious ceremonies be forgotten—see K. J. Freeman, Schools of Hellas (1907).
The oldest collection of folk-songs in existence; for the original compositions which Maitre Adam has bequeathed to posterity preclude us from believing that he could have originated the theory which is contained in that play, of which Robin m’aime is generally familiar, and is still to be heard on the lips of peasants in the north of France (see Tieros, p. 424, n.). If M. Tieros’s view is correct, the melodies in Robin et Marion may be taken to represent the popular style of an epoch considerably anterior to the date of the play itself (though allowance must be made for the correcting hand of a professional musician) which is our excuse for introducing them at this place.

Before speaking of the songs of troubadours, trouvères and minnesingers, allusion must be made to a class of men who played a part the importance of which both in the social and political life of the middle ages is attested by innumerable chronicles and poems, viz. the minstrels—the chief depositories of the musical and poetical traditions of the several countries to which they belonged. They varied greatly in rank. Some were attached to the retinue of kings and nobles, whilst others catered for the ear of the peasantry (eventually to be classed with jugglers, acrobats, bearers and the like, sharing the unenviable reputation which attached to these representatives of popular medieval amusements). That these latter were also welcome at the halls of the great, is an established fact, which may serve as a reminder that in feudal times the distinction that now exists, between the music of the cultivated classes and the peasantry was but slight. The style of the church music was as universally familiar as the style of the folk-song. For musicians, both of high and low degree, no other models existed. That fact is patently clear when the songs of the troubadours, trouvères and minnesingers are studied. Those minstrels continued the traditions of the better class of their predecessors, with a style evolved, elaborated and refined, whose form folk-songs and church-songs they in fact assimilated, and created a mongrel product without real vitality—a product that left practically no mark upon the subsequent development of the art. The astonishing skill which they exhibited in adapting the language of poetry to the most complicated metrical forms deserted them when they touched the question of musical form and of melody. Indeed their music, except in rare instances, was an adornment which the poetry could have dispensed with, and may be regarded in the main simply as a concession to the inmemorial custom of treating music and poetry as inseparable arts.

The real importance of these courtly minstrels in the history of song consists in their having firmly established the rhyming stanza as the vehicle for the expression of lyrical feeling, for it was the rhyming stanza a corresponding compact and symmetrical melodic form, to which the song. It was, however, reserved for the popular instinct, and not for trouvères and minnesingers, to develop this form (it is probable too that at least at the stanza forms employed belonged first to popular poetry and were afterwards developed and elaborated by these musicians of the great houses). The scheme upon which the rhyming stanza was usually based was one in which two similar parts (called by the German Meistersingers, Stollen or props, and constituting the Aufgesang or opening song) were followed by an independent third part, the length of which was not prescribed (called Abgesang or concluding song). The complete stanza was called Lied and was knit together by different schemes of rhyme. For the first part the trouvères and Meistersingers were content with some simple phrase, often borrowed direct from the folk-song, repeating it, as was natural, for the exactly similar second part; then for the third the style was apt to change towards the ecclesiastical and to wander aimlessly on to an unconvincing conclusion. The popular instinct was finer, for we find in innumerable folk-songs, belonging to the 14th and 15th centuries, that the greater length of the song was seized upon as an opportunity, not merely for introducing fresh material but for the repetition of the phrase attached to the two Stollen, but also for a return to that phrase.
or some reminiscence or variation of it, by way of conclusion, thus producing a compact form, answering to the natural requirements of the artistic sense. Thus the favourite scheme of modulation in the troubadours, which may be represented as AAB, had developed in the folk-song into the scheme AABA—and this scheme has served for thousands of popular melodies throughout Europe. In some rare cases the contrasting portion might be conceived as implying modulation into the key of the dominant, thus foreshadowing the form of the first movement in modern sonatas and symphonies. But the present writer is sceptical, from the evidence afforded by folk-song melodies recently collected, of an instinct for modulation among a peasantry unfamiliar with harmonic music. Be that as it may, the courtly minstrels both of France and Germany rendered a real service to the popular art, for they were in the vanguard of the popular verdict in favour of the major scale or Ionian mode, and in so doing prepared the way for modern harmony, which is based upon a particular relationship of contrast between the notes composing the chord of the tonic and those composing the chords of the dominant and the subdominant—a relationship inherent in no other scale of the Gregorian system but the Ionian. On it the secret of musical form in the modern sense depends, for it brings with it the power of modulation (unknown to medieval times), i.e., the power of treating the same note as belonging to different tone centres (G, for instance, as the dominant of the scale of C, and also as the subdominant of F), and the further power, derived from the chord of the dominant seventh, of proceeding from one tone centre to another. As long then as musicians held the Ionian scale at arm's length, progress in the modern direction was impossible. They did indeed arrive eventually at the goal, partly through the practice of using popular melodies as the foundation, or canto fermo, of masses and motets, and of arranging the melodies themselves for choirs of voices, and also through the increasing need, as the art of part-writing became more elaborate and better understood, of modifying the strict character of the modes by the introduction of accidentals, till, as Sir Hubert Parry remarks, "after centuries of gradual and cautious progress they ultimately completed a scale which they had known all along, but bad rather looked down upon as an inferior specimen of its kind." The melodic instinct, thus developing consciously in the minds of trained musicians, and unconsciously in the makers of folk-songs, arrived eventually at the same result. But the major scale once firmly established, the trained musician based upon it a new art of harmony; further, he modified existing minor scales for harmonic purposes, leaving the old traditional scales as the almost exclusive possession of the folk-song (which has cherished and preserved them through the centuries up to our own day) and working out the problem of musical composition, and of melody itself, on a new foundation.

The fall of the Hohenstaufen dynasty, and the troublous times that ensued in Europe, involved the removal of the patronage to which the higher kinds of minstrelsy owed their position and their influence. Song passed with the close of the age of chivalry from the noble to the burgher class. The Minnesingers were succeeded by the Meiêlersingers, the first gild of whom is said to have been established in 1311 by Heinrich von Meissen (popularly known as the poet of the Minnesingers) at Mainz. Minnesingers was treated more in the spirit of a trade than an art, and subjected to many absurd and precipitate regulations. In Wagner's famous opera is given a very accurate and faithful picture of their methods and ideals. Their importance in the history of song consists not so much in actual work achieved as in the enthusiasm widely spread through their means in the class from which most of the great German composers were eventually to spring.

The real interest for the historian of song centres during this period not in the attempts of minstrels and burgher gilds to improve upon the folk-song, but in the folk-song itself. Those who have studied the large collection of medieval melodies contained in Böhme's Alteutsches Liederbuch for Germany, and in Duyse's Hei oude Nederlandsche Lied for the Netherlands, will on other grounds than those mentioned above be ready to confirm this judgment. It is not too much to say that they contain many of the noblest melodies which the world possesses. "Hesitation is not suitable to the line of a minstrel, and knit together in all their parts with rare and unconscious art, on principles of structure which are carefully analysed in the chapter on folk-song in Sir Hubert Parry's The Art of Music. To the examples there quoted may be added the wonderful Tagelied ("Der Dag wil nit verborgen sin"), Ik sek adieu, Lieblich hab sich gesellet, Abschied von Innspruck (of which both Bach and Mozart are reported to have said that they rather would have been the author than of any of their own compositions), and "Entlautet ist der Walde" (which, like so many of the popular songs of the 14th and 15th centuries, was utilized by the Reformers for one of their finest hymns). A characteristic feature of many of these songs, both German and Dutch, is the melisma, or vocal flourish, of the concluding phrase, derived, if German historians are to be trusted, from the vocalization on the last syllable of the word Alleluia, which in the early Church represented the congregational portion of its services and which afterwards developed into the sequences, so popular in the middle ages.

A similar feature is not uncommon in French melodies of the same period (see L'Ameure de mo, Vrai D jean d' aum, and Rencres, Picard, in Chansons du 15e siècle, by Gaston Paris and Gevaert, Paris, 1879). If the charming English song "The Nightingale" (Medieval and Plainsong Society) is of popular origin, it may serve as an indication that these melismata were also common in England (cf. also "Ah! the sights that come from my heart," which belongs to the reign of Henry VIII.). It is in the highest degree unfortunate that no collections were made of English popular songs of the middle ages: everything points to the fact that quantities of them existed. The importance of song in the social life of every class is attested by all the chroniclers and poets. An age that produced "Sumer is ic cnin" (1230) must have been prolific of melody. It is impossible to regard it as an isolated phenomenon. The beauty of songs by early composers, and of others, which are possibly of popular origin, met with in the reigns of Henry VII., Henry VIII., Edward VI. and Elizabeth (see Wooldridge's edition of Chappell's Popular Music of the Olden Time) argue a great and healthy activity in the preceding centuries. It is sufficient to mention Morley's "It was a lover and his lass" and "O Mistress mine," or "The Three Ravens," which though it first appeared in print in 1611 is undoubtedly a folk-song belonging to an earlier epoch (for versions still extant see Kidson's Traditional Times). The same is probably true of "A poor soul sat sighing" and many others. It is to be remarked, however, that printed versions of popular songs can seldom be relied upon as faithfully representing their original form, or even the form in which they were sung at a particular epoch. Editors have seldom resisted the temptation of tampering with popular airs, if by so doing they can render them more attractive to polite tastes. Within recent years, however, the collection and publication of folk-songs has been undertaken in a different spirit—and it is possible in most countries to study the folk-songs in versions which have been taken direct from the lips of the peasantry and are presented without editorial alterations. The question as to the propriety of such alterations, or the larger question of what is suitable in the way of
instrumental accompaniment, need not be discussed here more
than to point out that the strictly scientific point of view
—which seeks to understand the folk-song in its native
simplicity—should not be mixed up with that of the artist
who aims at adding to the world's store of beautiful music.
It is to be deplored that the English composers of the 15th
and 16th centuries did not follow the example of German,
Dutch and French, who utilized popular melodies as the
foundation or canto fermo of their masses and motets (one
example only is known, "O Westron Wynde") and also arrange
them in parts for music-loving circles (to a limited extent this
appears to have been done in England, e.g. the Freemen's
Songs in Deuteronomel). But in England, as in other European
countries, survivals of medieval melodies are still to be found
among the peasantry in quantities which vary according to
the district to which a given musician may happen to have
been invited. These melodies were of survival, not invention,
and had been passed on by eye and ear from generation to
generation. They are a product of the peasantry, not of
art, since they are based on empirical rules of composition
which have been evolved by the peasantry itself from
the natural laws of transformation of its own folk-melodies
as it has worked them out and adapted them to its own
needs; music of this kind has never been the property of
the rich and the learned.

The folk-song is essentially a song, not primarily a
melody; this distinction is important and has often been
missed. A folk-song is a whole, an entity, consisting of
melody, text, rhythm, and vocal style, and cannot be
analyzed as a simple combination of these elements
nor can its history be traced. It is the product of generations
of singing and is thus not subject to the laws of the
composer's art. A folk-song is a living thing, growing
and changing as the circumstances of life change. It has
no beginning or end but is part of the life of the people
from whom it is sung. It is a manifestation of the
people's joy and sorrow, hope and despair, love and
hatred. It is a symbol of their culture and their way of
life. It is a reflection of their thoughts and feelings.

The history of the art-song begins with the learned
song, the song of the troubadours and trobadores of the
12th century. This was a song for the court, for the
aristocracy, a song of love and beauty. It was
written in a stylized language, and the melodies were
composed by professional musicians. The art-song was
a reflection of the culture of the time, and it was
shaped by the tastes and values of the people who
sang it. It was a song for the rich, and it was not
available to the masses.

The folk-song, on the other hand, is a song for all
people, for the masses. It is a song of the common
people, of the peasants and the farm workers, of
the fishermen and the sailors. It is a song of labor
and toil, of joy and sorrow, of hope and despair.
It is a song of the life of the people, and it is
sung by the people themselves. It is a song that
reflects the culture of the people, and it is shaped
by the tastes and values of the people who
sang it. It is a song for the people, and it is
available to all people.

The folk-song is a simple song, and the art-song is
a complex song. The folk-song is a song of
simplicity, and the art-song is a song of
complexity. The folk-song is a song of
freedom, and the art-song is a song of
constraint. The folk-song is a song of
the people, and the art-song is a song of
the aristocracy.

The folk-song is a song of the past, and the art-song is
a song of the present. The folk-song is a song of
the old, and the art-song is a song of
the new. The folk-song is a song of
the traditional, and the art-song is
a song of the modern. The folk-song is
a song of the common, and the art-song is
a song of the rare. The folk-song is
a song of the popular, and the art-song is
a song of the elite. The folk-song is
a song of the common, and the art-song
is a song of the elite.

The folk-song is a song of the past, and the art-song is
a song of the present. The folk-song is a song of
the old, and the art-song is a song of
the new. The folk-song is a song of
the traditional, and the art-song is
a song of the modern. The folk-song is
a song of the common, and the art-song is
a song of the rare. The folk-song is
a song of the popular, and the art-song is
a song of the elite. The folk-song is
a song of the common, and the art-song
is a song of the elite.
SONG

to break away from polyphonic traditions. Le Roy's *Air de Cour*, published in 1571, may be cited in proof of this statement. Of these airs "Je suis amour" is somewhat in the declamatory recitative style of Caccini's *Nuove musiche* (see Sammelbände, *Int. Musik-Gesellschaft*, article "Air de Cour de Adrien le Roy," by Janet Dodge). Generally speaking, it may be said of early French songs that they were longer in shaking off the influence of the past than the songs of the Italians, many tricks of expression and embellishment were borrowed from the Italians, and used in a manner that not only suited the voice, but was also a peculiar expression of the deep feeling and passion which the airs and songs contained. But it may be said that they were never so much misused in Italy; The *Air de l'Amour* of Lawes (from Shakespeare's *Hamlet*), and the motets by Rosseter, were published in 1500, 1506, and 1512, in the second of which appears the famous "Flow my tears" (Lachrymae) for two voices, but almost equally effective as a solo, and doubtless often used as such. It is published in vol. vii. of *Estampes* (Breitkopf & Härtel, London), which also contains a valuable monograph on English lutenists and lute music by Miss Janet Dodge. Dowland's few solo-songs are unimportant.

Of emotional situations was more natural to them and to their successors than a treatment in which points are emphasized in detail. It was moreover inevitable in these early developments of musical style, in which melody had to play the leading part, that such sacrifices as were necessary in 'balancing the rival claims of expression and form should be in favour of the latter rather than the former. But the formal perfection of melody was not the only problem which 17th-century Italian composers had to face. The whole question of instrumental accompaniment was to be worked out and capacities of instruments, including the voice itself, had to be explored; the reconciliation of the new art of harmony with the old art of counterpoint to be effected. It speaks volumes for the innate musical sense and technical skill of the early Italian composers that the initial stage of tentative effort passed so quickly, and that at the close of the 17th century we are conscious of breathing an atmosphere not of experimental work, but of mature art. Alessandro Scarlatti (1659-1725) sums up the period for Italy. That much of his work is dry, a mere exhibition of consummate technical skill without inspiration, is not surprising when the quantity of it is realized, and also the invariable conditions under which operatic composers had to work, but the best of it is singularly noble in conception and perfect in design. The same is true of the best work of Legrenzi, Stradella, Caldara, Leonardo Leo, Durante, work which was of incalculable importance for the development of musical, and particularly of vocal, art, and which will always, for minds attuned to its atmosphere of classical intellectuality, severity and self-restraint, possess an abiding charm: but comparatively few specimens have retained the affections of the world at large. Carissimi's *Vittoria*, Scarlatti's *O Cesare!* and *Le Violette* are the most notable exceptions ("Pietà Signore" is not included, as no one now attributes it to Stradella).

The almost universal preference of the Italians in the 17th and 18th centuries for the aria in *da capo* form involved serious sacrifices on the dramatic and emotional side: for although this form was but an elaboration of the folk-song type, *ABA*, yet it involved, as the folk-song type did not, the repetition note merely of the melody of the opening part, but of the words attached to it. It is this double repetition which from the point of view of dramatic sincerity forms so disturbing an element. But composers, as has been remarked, were too much occupied with exploring the formal possibilities of melody to establish a really intimate connexion between music and text (Monteverde being a notable exception), a detailed interpretation of which lay outside their scheme of song. Elaboration of melody soon came to involve much repetition of words, and this was not felt as an absurdity so long as the music was broadly in accord with the atmosphere or situation required. A few lines of poetry were thought sufficient for a fully developed aria. Exceptions are however to be found in what is known as the *recitativo asilo*—of which remarkably fine specimens appear in some of Scarlatti's cantatas—and in occasional songs in slighter form than the tyrannous *da capo* aria, such as Caldara's "Come raggio di sol!"—which foreshadows with its dignified and expressive harmonies the Schubertian treatment of song.

Before Scarlatti's death in 1725 symptoms of decline had appeared. He was himself often compelled to sacrifice his finer instincts to the popular demand for mere vocal display. A race of singers, who were *virtuosi* rather than artists, dominated the taste of the public, and forced composers to furnish opportunities in each role for a full display of their powers. An opera was expected to provide for each favourite five kinds of aria! (aria cantabile, aria di portamento, aria di mezzo carattere, aria parlante and aria d'agilità). It was not long before easier and more obvious types of melody, expressing easier and more obvious feelings, became the fashion. The varied forms of accompaniment, in which a good contrapuntal bass had been a conspicuous feature, were wasted upon a public which came to hear vocalists, not music; and stereotyped figures, of the kind which second-rate art after the first half of the 18th century has made too familiar, took the place of sound contrapuntal workmanship,
till the Italian school, which had stood as a model for the world, became identified with all that was trivial, insipid, conventional, melodramatic. Not that the Italian tendency in the direction of mere tunefulness was in itself either unhealthy or unworthy. It was indeed a necessary reaction from the severe earlier style, as soon as that style began to lose its earnestness and sincerity, and to pass into cold and calculating formalism. But the spirit of shallowness and frivolity which accompanied the reaction involved the transference of musical supremacy from Germany to Italy, the only country, which, while accepting what was necessary to it of Italian influences, steadily remained true to its own ideals.

Before speaking of German song, it is necessary to glance at what was being done outside of Italy in the 17th century. Reference has already been made to the French as pioneers in establishing solo song to lute accompaniment, which here, as in Italy, originated in adaptations of polyphonic compositions. But in France from the first the main influence was derived from popular sources, the native folk-song and the vaudeville, the ditties of country and of town. In both that union of grace, simplicity and charm, characteristic of the French nation, tended to produce an art of dainty unpretentious attractiveness, in strong contrast to the serious and elaborate Italian work. It preserved these characteristics in spite of the artificial atmosphere of the French court, in which it mainly flourished up to the time of the Revolution, in spite too of the somewhat different influences which might have been expected to affect it, derived from opera, the mania for which did not, as in Italy, kill the smaller branch of vocal music. Brunettes, musettes, minuets, vaudevilles, barcarolles, as the airs de cour were styled according to the nature of the poetry to which they were attached, may be found in Weckerlin's *Échos du temps passé*, but the reader must beware of judging the real character of these songs from that which they assume under the hands of the modern arranger.

With the latter part of the 18th century came in the languid and sentimental romance, in which the weaker phases of Italian melody are felt as an enervating influence. The romance became after the Revolution the most popular form of polite song, leading by degrees to that purely melodious type of which Gounod may be considered the best representative, and which other composers, such as Godard, Massenet, Widor, have been for the most part content to follow and develop, leaving to more adventurous spirits the excitement of exploring less obviously accessible regions.

In England, as in France and Italy, the beginning of the 17th century brought into existence solo song. Its beginnings have already been alluded to in speaking of the songs of Rosseter, Jones, Campion and Dowland. The work of H. Lawes, and his contemporaries, William Lawes, Coleman and Wilson, was equally unpretentious and simple. A gem here and there, such as "Gather ye Rosebuds" (W. Lawes), is the student's reward for a mass of uninspired, though not ungraceful, work in which is to be noted an attempt to come to closer quarters with poetry, by following as closely as they could the rhythmical outlines of non-musical speech: they listened to their poet friends reciting their own verses and then tried to produce artificially exact imitations in musical notes." (Ernest Walker, *History of Music in England*, p. 130), producing what was neither good melody nor good declamation. Such tentative work, in spite of Milton's sonnet to H. Lawes, could only have a palliamento especially with a Purcell so near at hand. As to the world the difference between talent and genius, between amateurish effort and the realized conceptions of a master of his craft. Songs like "Let the dreadful Engines" and "Mad Bess of Bedlam" reach a level of dramatic intensity and declamatory power, which is not surpassed by the best work of contemporary Italian composers. "I attempt from love's sickness to fly" is so familiar in its quiet beauty that we are apt to forget that melodies so perfectly proportioned were quite new to English art (though Dr Blow's "The Self-banished!" deserves fully to stand with it side by side). Monteverde's "Lament of Ariadne" has already been alluded to. It is interesting to contrast its emotional force, obtained by daring defiance of rule, with the equally intense, but more sublime pathos of Purcell's "Lament of Dido," in which song a ground bass is used throughout. The "Elegy on the death of Mr John Playford" (quoted in full by Dr Walker, p. 176 of his history) exhibits the same feature and the same mastery of treatment. The "Morning Hymn" is scarcely less remarkable, and has likewise a ground bass. Purcell died in 1695; Bach and Handel were then but ten years old, and Scarlatti had still thirty years to live—facts of which the significance may be left to speak for itself.

It is among the ironies of musical history that so great a beginning was not followed up. There are echoes of Purcell in the generation that succeeded him, in Croft, Greene, Boyce and Arne: but they quickly died away. The genius of Handel first and of Mendelssohn later seem to have prevented Englishmen from thinking musically for themselves. At least this is the orthodox explanation: but it should be borne in mind that a list of English composers, who have been willing to sacrifice ease and prosperity to a life of devotion to artistic ideals, would be exceedingly difficult to draw up and would certainly not include many of the best-known names. From the death of Purcell to the Victorian era there is no consistent development of artistic song that is worth recording in detail. The only songs that have survived are of the melodious order; of these Arne contributes several that are still acceptable for an air of freshness and gracefulness which marks them as his own. "Where the Bee sucks" and "Blow, blow, thou Winter Wind" are typical of his style at its best, as "The Soldier tired" and "War's Alarms" is typical of it at its worst. Song writers that followed him, Shield, Hook, Dibdin, Storace, Horn, Linley (the elder) and Bishop, were all prolific melodists, who have each left a certain number of popular songs by which their names are remembered, and which are still pleasant enough to be heard occasionally; but there is no attempt to advance in any new direction, no hint that song could have any other mission than to gratify the public taste for tuneful melodies allied to whatever poetry—pastoral, bacchanalian, patriotic or sentimental—lay readiest to hand.

The musical genius of Germany, which has created for the world the highest forms as yet known of symphony, oratorio, and opera, is not less remarkable as the originator of the Lied—the term by which are most easily conveyed the modern conceptions of ideal song. Germany is moreover the only country in which in orderly and progressive development the art of song may be traced from the simple medieval Volkslied to the elaborate productions of Schubert, Schumann and Brahms. If Germany is united to the rest of Europe in her debt to Italy, still her final conceptions of song belong to herself alone. And these conceptions have more profoundly influenced the rest of Europe than any Italian conception ever influenced Germany. When the rest of Europe was content with the vapid outpourings of Italian and pseudo-Italian puerilities, an acute observer could have read the signs in Germany, from which the advent of a Schubert might have been foretold. The student therefore is more profitably employed in studying the phases of song-development in Germany than in any other country. German ideals and German methods of technique have permeated the best modern song-work of countries differing as widely in idiom as Russia, Norway, France and Spain.

It is not necessary to dwell, except in very general terms, upon German song of the 17th century. There had been no development corresponding with that which produced the airs de cour of France and the aires de England. The very literature necessary for such development was wanting. Indeed German art was too profoundly affected by the spirit which produced the Reformation to develop freely in secular directions. Even in the domain of the Volkslied the sacred songs can scarcely have been less numerous than the secular; and at the Reformation adaptations of secular airs to sacred words constituted
borrowings on a very large scale. In the 17th century the work of the Italian monodists was bound eventually to stimulate German composers to make songs, but their main interest lay in larger choral-instrumental works, in which solo songs naturally appear, not in song as an independent branch of art. A good general view of such isolated songs as appeared can be obtained from Reimann’s collections Das deutsche geistliche Lied and Das deutsche Lied (Simrock). In spite of some stiffness and awkwardness, these 17th-century songs exhibit a loftiness of aim, a touching earnestness and sincerity, which mark them off as quite distinct from any work done elsewhere at the same time. On the other hand there is not that sure grasp of their material, nor the melodic and declamatory power, which make Purcell in England stand out pre-eminently as the greatest song composer of the 17th century. The treatment of the aria by Bach and Handel is discussed in separate articles (see ARIA; BACH; HANDEL), which render unnecessary any further comment here.

Nor need we pause to consider the vastly inferior work of lesser composers such as Telemann, Marpurg and Agricola, most of which is confined to opera, oratorio and cantata. Our concern is rather with the smaller lyrical forms, and to these the absence of suitable poetry virtually amounts to a barrier.

It was not till the middle of the 18th century that the reform in German poetry associated with the name of Martin Opitz (who translated Rinuccini’s text of Daunz, J. Perl’s first opera, for Heinrich Schlütz) bore real fruit. At the outset it is necessary to make a broad distinction between the more distinctly popular form of song, known as the Volkstümliches Lied, in which the same music served for each stanza of a poem (as in the Volkslied itself, on which the Volks-
tümliches Lied was modelled), and the Kunstlied, or, to adopt the more descriptive term, the durch-componirtes Lied, in which the music forms a running commentary on a poem, without respect to its form—or, if stanza form is preserved, varying the music in some stanzas or in all in accordance with their poetical significance.

Generally speaking the former aims at a wider audience than the Kunstlied, the appreciation of which, when it is worth appreciating, involves some degree of culture and intelligence, inasmuch as it aims as a rule at interpreting more complex and difficult kinds of poetry. In the 18th century the simpler Volkstümliches Lied in strophic form was most in favour, and those who care to trace its history in the hands of popular composers like J. A. Hiller, J. A. F. Schulz, Reichhardt, Berger and Zelter, can easily do so by consulting Hartel’s Liederlexicon (Leipzig, 1867) and a number of similar publications. Side by side with the outpouring of somewhat obvious and sentimental melodiousness, which such volumes reveal, it must be remembered that the attention of greater men to instrumental composition, the growing power to compose for key instruments (which began to replace the lute in the middle of the 17th century), and the mechanical improvements, through which spinet, clavichord and harpsichord were advancing toward the modern pianoforte, were preparing the way for the modern Lied, in which the pianoforte accompaniment was to play an increasingly important part. C. P. E. Bach (cir. 1788), alone of his time, did not give serious attention to lyrical song, selecting the best poetry he could get hold of, and aspiring to something beyond merely tuneful melody. The real outburst of song had to wait for the inspiration which came with Goethe and Schiller.

It is unfortunate that Haydn and Mozart, pre-eminently endowed with every gift that makes for perfect song except that of literary discernment, should have left us so little of real value. There is indeed much to admire in some of Haydn’s canzonets, of which “My Mother bids me bind my Hair” fully deserves its continued popularity, while Mozart’s “Schlaf mein Prinzenchen”—if it is Mozart’s—and a few others, like these in simple strophic form, are isolated treasures which we could not afford to lose. But in only two songs by Mozart, “Abendempfindung” and “Das Veilchen,” is the goal, to which the art was to advance, clearly discerned and in the latter case perfectly attained. Both are durch-componirt, that is, they follow the words in detail; in both the general spirit, as well as each isolated point of beauty in the verses, is seized and portrayed with unerring insight. “Abendempfindung” is indeed seriously marred by some carelessness in accentuation (worse examples may be seen in “An Chloe”) and by annoying repetition of words, due to the development of the melody into a formal and effective climax. In the process the balance of the poem is destroyed, and the atmosphere of suffused warmth and tenderness, which pervades the rest of the song, is almost lost. The lyrical mood passes into one in which the operatic aria is suggested on the one hand, and on the other the formality of instrumental methods of developing melody. Not till Schubert were these traditions, fatal to the pure lyric, finally overthrown, and the conditions of true union between music and poetry perfectly realized. In “Das Veilchen” however, where Mozart touched a poem that was worthy of his genius and appealed to his extra-ordinarily fine dramatic instinct, he produced a masterpiece—rightly regarded as the first perfect specimen of the durch-
componirtes Lied. Every incident in the flower’s story is minutely followed, with a detailed pictorial and dramatic treatment (involving several changes of key, contrasts between madness and reason, the declamatory or recitative passages which was quite new to the art. The accompaniment too takes its full share, illustrating each incident with exquisite fancy, delicacy and discretion—and all with no violence done to the form of the poem.

With Beethoven song was suddenly exalted to a place among the highest branches of composition. Taken in hand with the utmost seriousness by the greatest musician of the age and associated by him for the most part with lyrical poetry of a high order, it could at last raise its head, and, freed from the conventional formalities of the salon, look a larger world confidently in the face. It cannot, however, be admitted that Beet-
hoven, in spite of several noble songs, was an ideal song compos-
er. His genius moved more easily in the field of abstract music. The forms of poetry were to him rather a hindrance than a help. His tendency is to press into his melodies more meaning than the words will bear. The very qualities in fact which make his instrumental melodies so inspiring tell against his songs. Though his stronger critical instinct kept him as a rule from the false accentuation which marred some of the work of Haydn and Mozart, and the exciting and stirring declamatory or recitative passages which was quite new to the art. The accompaniment too takes its full share, illustrating each incident with exquisite fancy, delicacy and discretion—and all with no violence done to the form of the poem.

provide both a background and a commentary to the central personages. The tentative and uninspired work of Zelter, Reichardt, Schulz and others, when they attempted anything beyond a merely tuneful melody in the strophic form, may be passed over, but a word is due to J. R. Zumsteeg, because in spite of the sometimes childish simplicity of his work he yet, in the kind of use which he made of modulation as a means of lyrical expression, anticipated, more than any other composer of songs, one of the chief features of the greatest song writer of all ages, Franz Schubert. Schubert’s “Erkönig” was written a few months before Beethoven’s “Liederkreis,” “Gretchen am Spinnrade” about a year before the “Erkönig.” He was eighteen when he composed the latter, in 1814. Lyrical song, divorced from all hindering elements and associations, whether of salon or theatre, was here at the threshold of his short career in almost full maturity and plenitude of power. It is sufficiently remarkable that a lad with so little education should have composed such music: it is more astonishing still that he should have penetrated with such unerring insight into the innermost secrets of the best poetry. Two of the necessary qualifications for a great song composer were thus at last united. Schubert possessed the third—a knowledge of the human voice, partly intuitive, partly the result of his experience as a chorister boy. The beauty of his melodies is scarcely more striking than the gratefulness of their purely vocal qualities. The technique of singing had indeed been understood for nearly two centuries; but Schubert was the first to divine fully its emotional range, and to dissociate it in lyrical work from all traditions of the schools. From the beginning to the end of his career he never penned a note or a phrase because it was vocally effective. What he wrote for the voice to sing was there because for him the poetry could not have it otherwise. This was inherent in his method of working, in which he relied implicitly upon his musical inspiration for a response, usually instantaneous, to the inordinate receptivity of his mind to the impressions of poetry. To read through a poem was for him not only to seize its innermost significance, and every salient point of language or of form, but also to visualize the scheme by which both the whole and the parts could be translated and glorified through the medium of music. As the singer Vogl, the first of his profession to appreciate him, remarked, “He composed in a state of clairvoyance.” The modulations in “Wohin” illustrate the subtle atmosphere effects he loved to produce by sudden contrasts between major and minor harmonies. More familiar instances occur in “Gute Nacht,” “Die Rose,” “Rosamunde.” Secondly, his inexhaustible fertility in devising forms of accompaniment, which serve to illustrate the pictorial or emotional background of a poem; we have the galloping horses (and the horn) in “Die Post,” the spinning wheel in “Gretchen,” murmuring brooks in many songs from “Die Schöne Müllerin” and in “Liebesbotschaft,” the indication of an emotional mood in “Die Stadt” or “Litanei.” Occasionally, it is true, the persistence of a particular figure and rhythm induces monotony, as in “Ave, Maris!” or “Normans Gesang,” but generally Schubert has plenty of means at his command to prevent it, such as the presence of an appropriate subsidiary figure making its appearance at intervals, as in “Halt,” “Der Einsame,” or some enchanting ritornello, by which a phrase of the vocal melody is echoed in the accompaniment, as in “Liebesbotschaft,” “An Sylvia,” “Ständchen” and “Fischerweise.” Thirdly, the sudden entrances of declamatory passages, as in “Der Neugierer,” “Am Feierabend,” in “Gretchen,” at the famous “Ach sein Kuss,” and in “Erkönig” at “Mein Vater, mein Vater.” Fourthly, the realistic touches by which suggestions in a poem are incorporated into the accompaniment, such as the cow crowing in “Frülingstraum,” the convenant bell in “Die Junge Nonne,” the nightingale’s song in “Ganymed” or the falling tears in “Ihr Bild.” Finally should be noted the extreme rarity of any slips in the matter of the just accentuation of syllables, and this is especially remarkable in a song writer who relies so much upon pure melody as Schubert, to preserve a perfect modulatory balance of his modulations. Of the least conflicting efforts. A song of his is mere ornamentation and a fine and subtle gift. The poet’s text presents far more difficult problems than the declamatory style. Yet Schubert is as successful in “Liebesbotschaft” as in “Prometheus.” Purists may be disturbed by the repetitions of words involved in the magnificent “Dithyrambe”—but Schubert cannot be expected to betray a sensibility which is really post-Wagnerian. Nor is it just to a composer of over 600 songs to fasten for critical purposes on those which do not represent him at his best. His best level is so often attained as to make attacks on points which he has missed—as in some of the songs from Wilhelm Meister—somehow slip out of the mark. It is usually the work of enthusiasts who wish to exalt others at Schubert’s expense. For further details the reader is referred to the brilliant essay on Song with which Mr. Hadow concludes vol. v. of the Oxford History of Music. It must suffice here to point out in a general way that in wideness of scope and aim, in intensity of expression Schubert produced the same transformation in the lyrical field that Beethoven had produced in the larger forms of sonata, string quartet and symphony. Beethoven’s work was necessary before Schubert could rise, but Schubert’s conceptions and methods remained his own, and not the least violent, the most difficult to pass through. Beethoven’s was a process of introduction and did not destroy the difficulties involved in setting long ballads to music. To preserve homogeneity in a form in which simple narration presents perpetually shifting changes of action, of picture, of mood, is a problem which Schubert himself only once triumphantly solved. Weber contributed nothing to song, except in his operas, of permanent value, beyond a few strophic songs of a popular nature. He disqualified himself for higher work by that singular preference for vivid and trivial verse which so often led Haydn and Mozart astray. Mendelssohn’s literary tastes took him to the best poetry, but he made but little attempt to penetrate beyond its superficial and obvious import. His own lovely personality is far more clearly revealed in his songs than the spirit of his poets. Differences of literary style affected the style of his music perhaps less than that of any other distinguished composer. He attained his highest level in “Auf Flügeln des Gesanges,” the first of the two songs to Zuleika, and Nachtdicht. It is noteworthy that there is no trace of Schubert’s influence. Had Schubert not lived, Mendelssohn’s songs would have been just the same. Hence in spite of graceful and flowing melodies, elegant but simple in form, and instinct with that polished and charming manner which endeared both himself and his works to his own generation, his songs have exercised no permanent influence upon the art. Their immediate influence, it is true, was enormous: it is felt occasionally in Schumann, only too often in Robert Franz, and a host of lesser composers in many countries besides his own, such as Gade, Lindblad, Sternadale Bennett, and others who need not be specified.
Of far greater importance is the work of Robert Schumann, whose polyphonic methods of technique and peculiarly epigrammatic style enabled him to treat complex phases of thought and feeling which had hardly become prominent in Schubert's time with quite extraordinary success. Both by temperament and by choice he is identified with the so-called romantic movement, a movement in which both poetry and music have tended more and more to become rather a personal revelation than "a criticism of life." Thus with Schubert the note of universality, the abiding mark of the classical composers, is stronger than the impress of his own personality. With Schumann the reverse is the case. If the romantic movement gave a new impetus of vast importance both to music and literature, yet it had its weaker side in extremes of sensibility, which were not always equivalent to strength of feeling. Mendelssohn's songs admittedly err on the side of pure sentimentality—Schumann, with Liszt, Jensen and Franz, frequently betrays the same weakness, but his best work, his settings to Heine (especially the Dichterliebe), the Eichendorff "Liederkreis," Chamisso's "Frauenliebe u. Leben" (with some reservations), besides a fair number of other songs, such as "Widmung," "Der Nussbaum," "Ihre Stimme," and his one completely successful ballad, "Die beiden Grenadiere," are strong in feeling and full of poetic and imaginary qualities of the very highest order. Most of the poetry called for newer methods of treatment. These Schumann, instinctively, if not always successfully, first, by a closer attention to the minutiae of declamation than had hitherto been attempted—and herein syncopation and suspension furnished possibilities unsuspected even by Schubert—secondly by increasing the rôle of the pianoforte accompaniment—and in this he was helped on the one hand by novel methods of technique, of which himself and Chopin were the originators, and on the other by his loving study of Bach, which imparted a polyphonic treatment, quite new to song. In nearly all Schubert's songs, and in quite all of Mendelssohn's, there is a tendency of late in the verse to turn sentiment and supersonality. In Schumann it not infrequently becomes the secondary factor, the main rôle of lyric interpreter passing to the accompaniment, as in "Es ist ein Flöten u. Geigen" or "Räuselten." He also gave quite a new prominence to the opening and closing instrumental symphonies, which become in his hands no merely formal introduction or conclusion but an integral part of the whole conception and fabric of the Lied. This may be illustrated by many numbers of the Dichterliebe, but most remarkable is the final page, in which the pianoforte, after the new has stopped, sums up the whole tenour of the cycle. This feature has been seized upon by many subsequent composers, but by few with Schumann's rare insight and judgment. In Franz, for instance, the concluding symphony is often introduced without necessity, and becomes a mere irritating mannerism. In Brahms however it is developed, both at the opening and close of many songs, to an importance and pregnancy of meaning which no other composer has attained.

A third point in Schumann's method is his fondness for short interrupted phrases (often repeated at different levels) in place of the developed Schubertian melodies; it is alluded to here because he is more frequently described by his softer qualities than is Liszt, and often too often, as in the case of Franz, without Schumann's tact. On many grounds, then, Schumann may be regarded as having widely extended the conception of the Lied; his example has encouraged later composers to regard no lyric poetry as too subtle for musical treatment. Unfortunately in presenting complexity of mood Schumann was not invariably careful to preserve structural solidity. Many later composers have followed the occasional looseness of design which is his fault, without approaching the beauty of spirit, in which he stands alone.

A bold experimenter in song was Franz Liszt, whose erudite genius, with its irresistible bent towards the theatrical and melodramatic, was never at home within the limits of a short lyric. It is true that there is sincerity of feeling, if not of the deepest kind, in "Es muss ein Wunderbares sein" and "Über allen Gipfeln"; but concentrated emotion, which involves for its expression highly organized form, was alien to Liszt's genius, which is more truly represented in songs like "Die Lorelei," "Kennst du das Land," "Am Rhein"—in which are presented a series of pictures loosely connected, giving the impression of clever extemporizations on paper. It is not sufficiently recognized that such work is far easier to produce than a successful strophic song, even of the simplest kind, because the composer ignores the fact that a formal lyric implies formal music, and that the most formal poetry is often the most emotional. Critics, who measure the advance of song by the increase in number of those that are durchkomponiert, and the decreasing output of those which have the same music to each stanza, are in danger of forgetting the best qualities both of music and of poetry. Formless music never interpreted a finely formed poem, and unless the durchkomponierte Lied has more form instead of less than the strophic song, it is artistically valueless.

The popularity therefore of "Die Lorelei" is not so much a tribute to Liszt's genius as an example of the extent to which gifted singers and undiscerning critics can mislead the public. Mere scene painting, however vivid, however atmospheric—and these qualities may be conceded to Liszt and to others who have followed his example—takes its place upon the lower planes of art.

The admiration expressed by Liszt and Wagner for the songs of Robert Franz, and the cordial welcome extended by Schumann to those characters, render his songs an important contribution to the strophic song, even of the simplest kind, because the composer ignores the fact that a formal lyric implies formal music, and that the most formal poetry is often the most emotional. Critics, who measure the advance of song by the increase in number of those that are durchkomponiert, and the decreasing output of those which have the same music to each stanza, are in danger of forgetting the best qualities both of music and of poetry. Formless music never interpreted a finely formed poem, and unless the durchkomponierte Lied has more form instead of less than the strophic song, it is artistically valueless.

at his best, and point to Corneius as one of the most beautiful and original spirits of the 19th century.

In the song-work of the 19th century, though Schubert remains the rock upon which it has been built, Brahms represents the most directly inspiring influence, even when, as in the case of Adolph Jensen (whose spontaneously melodic and graceful, if not very deep, songs deserve mention), there are importations from such widely divergent sources as those of Mendelssohn and Wagner.

The application of the principles of Wagnerian music-drama to lyrical work, allied, as was natural, with the exaggerations and unconventionality of Liszt and Berlioz, was sooner or later bound to come, bound also for a time to issue in confusion; to rescue song from which was the work of two men of genius, who, though approaching the task from standpoints removed by the wide distance of pole to pole, may be considered as placing the crown of final achievement upon the aspirations of 19th-century song—Hugo Wolf and Johannes Brahms.

Wolf exhibits an entirely unconventional and original style. He is as untroubled by tradition as Schubert, whom he resembles not often, as in "Fussreise," and "Der Gärtner," in pure melodiousness, but in the intensity of his power to penetrate to the very heart of poetry. To him may also be most fitly applied the epithet "clairvoyant." He is the first who published songs for voice and pianoforte, not songs with pianoforte accompaniment, thus finally asserting the identity of singer and accompanist in true lyrical interpretation.

The unerring sagacity of Brahms discerned that the possibilities of song on the lines set by Schubert were far from being exhausted: his practical mind preferred to develop those possibilities rather than to seek after strange and novel methods, conforming thus in song to his practice in other branches of composition. A broad melodic outline is for him an essential feature: equally essential is a fine contrapuntal bass. In form the majority of his songs follow the orthodox A B A pattern, the central portion being so organized as to offer, with the least possible change of mood and key, a heightening contrast with the opening portion by means of new treatment and new tonalities, and at the same time to justify itself by producing the mood in which the return to the opening portion is felt as a logical necessity. Chromatic effects in Brahms's scheme of melody are rarely introduced till the middle section, the opening being almost invariably diatonic. It must however be admitted that Brahms's formal perfection involves occasionally an awkward handling of words, and that in a few instances (see Magelone-lieder, Nos. 3 and 6), they are frankly sacrificed to that formal development of his material which has been criticized in the cases of Mozart and Beethoven. No portion of his songs deserves closer study than the few bars of instrumental prelude and conclusion, in which is enshrined the very essence of his conception of a poem. It may almost be said that, since Schumann set the example, the first and the last word has passed from the voice to the instrument. Accompanist, like singer, must understand poetry as well as music: but with no composer is his responsibility greater than with Brahms.

Complete mastery in close organization of form was allied in Brahms not only with the warmth and tenderness of romance, but with the imaginativeness and profoundness of thought. Concentration of style, and of thought have nowhere in the whole history of song been combined on a plane so high as that which is reached, with all perfection of melodic and harmonic beauty, in "Schwermut," "Der Tod das ist die kühle Nacht," "Mit vierzig Jahren," "Am Kirchhof," "O wüsset ich doch den Weg zurück," and the "Vier ernste Gesänge," which closed the list of his 197 songs. The alliance to song of so dangerous a companion as philosophy, or at any rate of thoughts which are philosophical rather than lyrical, proved no obstacle to Brahms's equal success in the realm of romance. This side of his genius may be illustrated by numerous songs from the Magelone cycle (notably "Wie froh und frisch" and "Ruhe, süßes, Liebchen") and by others, of which "Liebestreu," "Die Mainacht," "Feldeinsamkeit," "Wie rafft' ich mich auf in der Nacht," "Minnelied" and "Wir wandelten" are a few examples picked at random.

It has already been indicated that Brahms was a deep student of Schubert. If he had not Schubert's absolute spontaneity of melody, he restored it to its Schubertian place of supreme importance. In spite of all the tendencies of his age he never shirked that supreme test of a composer, the power to originate and organize melody: but it is melody often of a type so severe in its outline and proportions as to repel those hearers who are unable to attain to his level of thought and feeling. All more prettiness and elegance are as alien to his nature as even the slightest approach to sentimental weakness on the one hand, or to realistic scene-painting on the other, so that for the world at large his popularity is jeopardized by an attitude which is felt to be unconvincing and uncongenial, but that he yet had time to reconcile itself to the union of modern lyrical poetry with a style whose elaborate contrapuntal texture differs as much from the delicate polyphony of Schumann as that in its turn differed from the broad harmonic system of Schubert.

But that Brahms was never difficult without reason, or elaborate when he might have been simple, appears plainly from the preference he felt for his lighter songs in the Volksstimlich style and form, rather than for those which were durchkomponirt. He was strongly influenced by the Volkslieder of his country, the words of which he loved to repeat to himself, as they suggested ideas even for his instrumental compositions. His arrangements of Volkslieder mark an epoch in that field of work.

In the history of song Brahms's name is likely to stand for the closing of a chapter. It is difficult to conceive of more complete work on lines that are essentially classical. The soundest traditions find in him their justification and their consummation. He has enshrined the best thought and the noblest feeling of his age in forms where elaboration and complexity of detail serve essential purposes of interpretation, and are never used as a brilliant artifice to conceal foundations which are insecure. It is not proposed to discuss the work and tendencies of contemporary German composers—of whom Felix Weingartner (b. 1863), Max Reger (b. 1873) and Richard Strauss have attracted the largest share of attention. The above summary, though necessarily incomplete and confined only to the most conspicuous names, may yet provide some points of view from which the songs of other countries than Germany may be regarded, especially those in which German conceptions and German methods of technique have been dominant factors. Actual settings of German lyrics figure largely in the works of many non-German composers, and these it is hard to judge except by German standards. But, strongly as German influence has been felt in Russia, for instance, in Norway and in Finland, yet the last half century has seen the rise of more distinctly national schools of song in all these countries, and to this result the cult of the folk-song has very largely contributed. Glinka, Rimsky-Korsakov, Borodin, Balakirev, César Cui (b. 1835), and Moussorgsky in Russia, Nordraak (1842—1866) and Grieg in Norway, Sibelius (b. 1865) in Finland, are conspicuous names in this connexion.

The Latin countries have, as is natural, been but little subject to German influences; yet France alone seems to be working her way towards a solution of artistic problems which has interest for those who live beyond her borders and which bears emphatically her own hallmark. The melodious style of Gounod, which has so powerfully affected composers like Massenet, Godard and Widor, has

1 Their value may be tested by comparing them with the small volume containing arrangements by R. Franz, which are sympathetic, though without inspiration, with those of Tapper, which are models of what such things ought not to be, and with the dull, uninspiring work of A. Saran. Many of Reimann's arrangements, however, deserve cordial recognition as both sympathetic and scholarly. One fact emerges clearly from the study of folk-songs, arrangements in Germany and elsewhere, that success depends upon qualities which are as rare as, and are seldom dissociated from, the power of original composition. Only a great composer can be a great arranger.
begun to yield during the last quarter of a century to tendencies which correspond closely with those of the impressionist movements in French literature and painting. The deeper side of the movement, in which a strong element of mysticism plays an important part, is found in the best songs of César Franck, Fauré and Bruneau, a notable group of composers, whose occasional extravagances are atoned for by original impressions of nature in her more unusual moods, and by much that arrests attention both in thought and style. The songs of Duparc (1848-1933) and Vincent d'Indy likewise receive repair study. Nothing can be clearer than that traditional methods were inadequate, if modern French poetry was to find interpretation in the sister sphere of music; but how far the work of composers such as those named is likely to be regarded as final, it is premature to ask. The world had hardly had time to feel at home with them before it was called upon to face what it is difficult not to regard as representing the extreme limits of impressionistic style in Debussy. We are still too much accustomed to melody and rhythm, to harmonies that have some intelligible principle in their successions, to judge securely of music which is neither melodious nor rhythmical nor in the accepted sense harmonious. We are still too much accustomed to music regulated by analysable laws to feel at ease with music that seems, at any rate at present, to acknowledge none. Whether the work of Debussy is the beginning of a new epoch the future alone can decide, but it is permissible to feel apprehensive of an art which is based upon impressions rather than upon convictions; and the value of impressions is apt to be measured more by the degree in which they are fugitive, elusive, evanescent, or merely peculiar to the composer's temperament, than by the relation which they bear to permanent elements in nature or humanity. Hence in the modern school of song-writers, which finds its culmination in Debussy, the quality of unselfconsciousness is the one which seems most difficult for them to attain. In French art we are too often reminded how close the sublime is to the ridiculous, the dramatic to the theatrical, pathos to bathos, truth to paradox. Even in the quieter pictures we are conscious of a forced atmosphere, an unnatural calm, not the abiding peace of a landscape by Corot or Millet. Lastly, the opinion of Bruneau (La Musique francaise, p. 233) that prose will in time supplant poetry in drama and song is, at least to those to whom form is still an essential from humanity, a disquieting omen for the future. The best qualities of the French nation, its unaffected gaiety, its sincerity, grace, humour, pathos, tenderness, are far more touchingly and truthfully revealed in the simple melodies of the country-side—or in the less pretentious songs (of which Bruneau and Massenet have given examples, as well as many others) formed upon their model.

Modern English Song.

A more valid one is to be found in the absence, until its two closing decades, of great names to which can be attached the history of any orderly development, of any well-conceived and definite ideals. The authors of the very limited number of good songs are too often the authors of others in larger quantities which are bad, and that not in every case owing to failure of inspiration but to a lowering of ideals in order to gratify the tastes of an unintelligent public on the one hand, and the demands of exacting publishers on the other. That a healthier art might have arisen is indicated by the presence of such songs as Hatton's "To Anthea," Loder's unexpectedly fine setting of "The Brooklet" (the world's most ancient ballad) in its original German version as "Wahn"), Sullivan's fresh and original settings of several Shakespearian lyrics, and of Tennyson's unsurpassed cycle of versés entitled "The Songs of the Wrens," and "Clay" I'll sing thee songs of Araby." The name of Sternstde Bennett stands out as that of a composer who remained steadfastly true to his ideals. His output was indeed a small one, and covered a somewhat limited range of style and feeling: but the thought, like the workmanship, is always of delicate and beautiful quality. Though Mendelssohn's influence is apparent he has a touch which is all his own. "To Chloe in sickness," "Forget-me-not," "Gentle Zephyr" and "Sing, Maiden, sing," have certainly not yet lost their charm. Sternstde Bennett marks the beginning of higher ideals in English song—but it is only within the last twenty-five years that we have begun to see their realization, owing to the training of many English musicians in German schools and to the increasing familiarity of the musical public with the best German Lieder. The lead has been given by Parry, who has been followed by many, such as Parry himself, who have published large numbers of songs in great variety of styles, and with uniform seriousness of aim and treatment. Parry's delightfully fresh early work is represented at its best in "A Spring Song," "A Contrast," and "Why does azur deck the skies?" The transition to a later manner is marked by the four anacreontic odes; and several small volumes of lyrics have since made their appearance. If some of these miss the true lyrical note, of which absolute spontaneity is an essential condition, yet a lofty level of thought and workmanship is always manifest, rising to highest inspiration perhaps in "When we two parted," "Through the ivy gate," and "I'm weaving Sweet Violets." Stanford has essayed songs in many styles, suited to poems drawn from many periods, but he is most himself and most successful in Keats's weird and dramatic ballad "La Belle dame sans merci," in Browning's cavalier songs, in the cycle of sea songs (H. Newbolt) and above all in the Irish idyll (Moira O'Neill)—where in six pieces of rarest beauty the composer has revealed different phases of Irish feeling, pathos and humour with a poetical and imaginative power unequalled in British art. It is hard to imagine a more perfect alliance between the poetry and the music, a poetic interpretation of the new song down to the minutest detail of declamation, than is found here. As an arranger of Irish melodies—of which four volumes have been published—Stanford has also shown himself a complete master. Cowen, Mackenzie and Elgar have contributed few songs worthy of reputations gained in larger forms of composition. Of the work done and being done by younger composers much might be said. There is activity in many directions; a cycle of songs by Arthur Somervell from Tennyson's Maud is an artistic work of very real value, beautiful and original as music, and forming a highly interesting commentary upon the poet. R. Vaughan Williams, in the more difficult task of setting six sonnets from Rossetti's House of Life and in three of Stevenson's Songs of Travel, has displayed imaginative qualities of a remarkable order. Not less original is the highly finished and poetical work of H. Walford Davies. Somewhat different in style and thought, but instinct with true lyrical tenderness and charm, are the songs of Roger Quiller, drawn mainly from the Elizabethan period, and the poems of Herrick. Various songs by Maude V. White, W. H. Hadow, Hamilton Harty, Harold Darke, Ernest Walker, Donald Tovey, William Wallace and others give evidence, with the work already cited, of a revolution in the treatment and conception of song in England, which is full of promise for the future. Its fulfilment however is likely to depend upon a change in the prevailing conditions, under which professional vocalists have a financial interest in popularizing inferior productions. Good songs, apart from the initial difficulty of finding a publisher, are thus penalized from the start, whilst the larger and less instructed portion of the public, which forms its taste upon what the singers of the day provide, remains ignorant of precisely those works which are most necessary for its enlightenment.

BIBLIOGRAPHY.—In Grove's Dictionary of Music and Musicians (new ed.) Mrs E. Woodhouse's article on "Song" (vol. iv.) gives a practically exhaustive bibliography of the whole subject of song and folk-song, country by country; her account is quite unique, and indispensable to the student. The following list is mainly of books which the present writer has found most valuable: Sir Hubert Parry, Art of Music (London, 1897); Oxford History of Music (1901-1905), esp. vol. iii.; "The Seventeenth Century" by Sir Hubert Parry, vol. iv.; "The Age of Bach and Handel" by J. A. Fuller-Maitland, vol. v.; "Romantic Period" by W. H. Hadow; "The Romantic Period" by E. Dannreuther; Cambrier, La Musique, ses lois et son evolution (Paris, 1907); Ambros, Geschichte der Musik (1862-1882); Coussemaeker, Histoire de l'harmonie au moyen...
The Song of Birds

The characteristic modulated voice of birds is the outstanding example of natural "song" in the animal world. The essential requirements of a vocal organ, the pressure of vibratory membranes, the tract which we call the syrinx, but how these membranes act in particular, and how their tension is modified by the numerous syringal muscles, we do not know. The voice of birds is produced entirely by the syrinx; the larynx no doubt modifies it, but the tongue seems to play no part in it. The "loosening of the tongue" by cutting its frenum, in order to assist a bird in talking &c., is an absolutely silly operation. The possession of the most elaborate syrinx is not enough to enable a bird to sing. In this respect they are like ourselves: special mental faculties are required to control the apparatus. Anatomically the raven has the same elaborate syrinx as the thrush or the nightingale, and yet the raven cannot "sing" although it can modulate its voice and can even learn to talk. As a rule the faculty of singing is restricted to the males, although the females possess the same organs; moreover, birds vary individually. Some learn to sing marvellously well, while others remain tyros in spite of the best education. But given all the necessary mental faculties, birds sing only when they are in such a healthy condition that there is a surplus of energy. This, of course, is greatest during the time of propagation, when much of the surplus of the general metabolism comes out—use homely words—in untwisted functions, such as dancing, posing, spreading of feathers and giving voice. Every one of these muscular exertions is a spasm, releasing some energy, and—again in homely parlance—relieving the mind. In many cases these antics and other manifestations become rhythmical, and music consists of rhythmical sounds. Of course birds, like other creatures, are to a certain extent reflex machines, and they often sing because they cannot help it, just as male frogs continue to croak long after the pairing season, and not necessarily because they or their mates appreciate those sounds. But birds stand mentally on a different footing from their human brethren. They have no reason to sing their song, except for the cases they enjoy, and therefore sing their song. Many a tame bird, a canary, starling, magpie, will repeat its keeper with its song, out of season, for any kindness shown to it, or for its mere presence.

If we regard any sound made by a bird under the all-powerful influence of love or lust as its "song," then probably every bird is possessed of this faculty, but in the ordinary acceptance of the term very few, besides the oscines, can sing, and even this group contains many which, like the ravens and the crows, are decidedly not songsters. On the other hand, it seems unfair not to call the charming series of notes of the dove its song.

D. Bartronn in a very remarkable paper ("Experiments and Observations on the Singing of Birds," Phil. Trans., 1773, pp. 249-291) defines a bird's song "to be a succession of three or more different notes, which are continued without interruption during the same interval with a musical bar of four crotchets in an adagio movement, or whilst a pendulum swings four seconds." The late A. Newton (Encyc. Brit., 9th ed., iii. 775) see also Dict. Birds, s.v. "Song," pp. 892-894), taking a much wider view of "song," proceeds as follows:

"It seems impossible to draw any but an arbitrary line between the deep booming of the emu, the harsh cry of the guillemot (which, when proceeding from a hundred or a thousand throats, strikes the distant ear in a confused murmur like the roar of a tumultuous crowd), the plaintive wall of the plover, the melodious whistle of the wigeon, 'the cock's shrill clarion,' the scream of the eagle, the hoot of the owl, the solemn chime of the bell bird, the whip-cracking of the manakin, the chaffinch's joyous burst, or the hoarse croak of the raven, on the one hand, and the bleating of the snipe or the drumming of the ruffled grouse, on the other. Innumerable are the forms which such utterances take. In many birds the sounds are due to a combination of vocal and instrumental powers, or, as in the cases last mentioned, to the latter only. But, however produced—and of the machinery whereby they are accomplished there is no room here to speak—have all the same cause and the same effect. The former has been already indicated, and the latter is its consummation. Almost coincidentally with the hatch- ing of the nightingale's brood the song of the sire is hushed, and the notes to which we have for weeks hearded with rapt admiration are changed to a guttural croak, expressive of alarm and anxiety, inspiring a sentiment of the most opposite character. No greater contrast can be imagined, and no instance can be cited which more completely points out the purpose which 'song' fulfils in the economy of the bird, for if the nightingale's nest at this early time be destroyed or its contents removed, the cock speedily recovers his voice, and his favourite haunts again resound to his bewitching strains. For them his mate is content again to undergo the wearisome round of nest-building and incubation. But should some days clapse before disaster befalls their callow care, his constitution undergoes a change and no second attempt to rear a family is made.

It would seem as though a mild temperature, and the abundance of food by which it is generally accompanied, prompt the physiological alteration which inspires the males of most birds to indulge in the 'song' peculiar to them. Thus after the annual moult is accomplished, and this is believed to be the most critical epoch in the life of any bird, cock thrushes, skylarks, and others begin to sing, not indeed with the jubilant voice of spring but in an uncertain cadence which is quickly silenced by the super- vention of cold weather. Yet some birds we have which, except during the season of moult, hard frost, and time of snow, sing almost all the year round. Of these the redbreast and the wren are familiar examples, and the chaffinch repeats its two-noted cry, almost to weariness, during the whole period of its residence in this country.

"Akin to the 'song of birds,' and undoubtedly proceeding from the same cause, are the peculiar gestures which the males of many perform under the influence of the approaching season of pairing, but these again are far too numerous here to describe with particularity. It must suffice to mention a few cases. That the drake, during his courtship, will hold his head so that the crotchets and some of his allies mount aloft and wildly execute unlooked-for evolutions almost in the clouds. The woodcock and many of the goatsuckers beat evening after evening the same aerial path with its sudden and sharp turnings. The ring-dove rises above the neighbouring trees and then with motionless wings slides down to the leafy retreat they afford. The capercally and blackcock, perched on a commanding eminence, throw themselves into postures that defy the skill of the caricaturist—other species of the grouse-trIBE assume
SONGHOI—SONNET

the strangest attitudes and run in circles till the turf is worn bare. The peacock in pride spreads his train so as to show how nearly akin are the majestic and the ludicrous. The bowerbird, not content with its own splendour, builds an arcade, decked with bright feathers and shining shells, through and around which he parades with his gay companions. The larks and pipits never deliver their song so well as when seeking the upper air. Rocks were one after the other to a height and an altitude along their backs. If in the Sudan an unexpected many yards towards the ground, while the solemn raven does not scorn a similar feat, and, with the tenderness of croaks, glides supinely alongside or in front of his mate."

SONGHOI, SONNTHAL, SORHAT, &c., a great negroid race inhabiting a large tract of country on both banks of the middle Niger. They formed a distinct state from the 8th to the 16th century, being at one period masters of Timbuktu (q.v.) and the most powerful nation in the western Sudan. The origin of this people, who are said still to number some two millions, though their national independence is lost, has been a source of much dispute. Heinrich Barth, who has given the fullest account of them, reckoned them as aborigines of the Niger valley; but he also tried to connect them with the Egyptians. The people themselves declare their original home to have been to the eastward, but it seems unlikely that they or their culture are to be connected at all with the Nile valley. According to the Tarikh el Sudan, a 17th century history of the Sudan written by Abderrahman Sadi of Timbuktu, the first king of the Songhoi was called Diallanam (Arabic Dia al-im al-jemen, "he is content from Yemen"), and the account given in this Arabic manuscript leaves little doubt that he was an Arab adventurer who, as has been frequently the case, became chief of a negro people and led them westward. The Songhoi emigration must have begun towards the middle of the 7th century, for Jenné, their chief city, was founded one hundred and fifty years after the Hejira (about a.d. 765), and it represents the extreme western point in their progress. From a hundred to a hundred and twenty years would be about the time which must be allowed for the years of wandering and those of settlement and occupation in the Songhoi countries. In the north they have mixed with the Ruma "Moors," and in the south with the Fula. The Songhoi, then, are probably Sudanese negroes much mixed with Berber and even Arab blood, who settled among and crossed with the natives of the Niger valley, over whom they long ruled.

In their physique they bear out this theory. Although often as black as the typical West African, their faces are frequently more refined than those of pure negroes. The nose of the Songhoi is straight and long, pointed rather than flat; the lips are comparatively thin, and in profile and jaw 'projection they are easily distinguishable from the well-known nigrice type. They are tall, well-made and slim. In character, too, they are a contrast to the merry light-heartedness of the true negro. Barth says that of all races he met in negroland they were the most morose, unfriendly and churlish. The Songhoi language, which, owing to its widespread use, is, with Hausa, called Kalam al Sudan ("language of the Sudan") by the Arabs, is often known as Kisur. According to Friedrich Müller it resembles in structure none of the neighbouring tongues, though its vocabulary shows Arab influence. Keane states that the language "has not the remotest connexion with any form of speech known to have been at any time current in the Nile valley."
a prescribed sequence and then satisfying that expectation—which entitles a form of fourteen verses to be called a sonnet.

Hence the sonnet of Petrarch and the sonnet of S. Waddington and several other critics have attributed to Fra Guittono the honour of having invented the form. But J. A. Symonds has reminded us that the sonnet beginning Però ch’amo, attributed to Pier delle Vigne, secretary of state in the Sicilian court of Frederick, has claims which no student of early Italian poetry can ignore. As regards English sonnets, whether the Petrarchan and the Shakespearean are really the best of all possible forms we need not inquire. But, inasmuch as they have become so vital and so dominant over other sonnet forms that whenever we begin to read the first verse of an English sonnet we expect to find one or other of these recognized rhyme-arrangements, any departure from these two arrangements, even though the result be a magnificent poem as Shelley’s “Ozymandias,” disappoints the expectation, baffles the ear, and brings with it that sense of the fragmentary and the inchoate to which we have before alluded. If, however, some writer should arise with sufficient originality of metrical endowment and sufficient poetic power to do what Keats, in a famous experiment of his, tried to do and failed—impress the public ear with a new sonnet structure, impress the public ear so powerfully that a new kind of expectation is created the moment the first verse of a sonnet is recited—then there will be three kinds of English sonnets instead of two.

With regard to the Petrarchan sonnet, all critics are perhaps now agreed that, while the form of the octave is variable, the form of the sestet is absolutely free, save that the emotions should govern the arrangement of the verses. But as regards the division between octave and sestet, Mark Pattison says, with great boldness, but perhaps with truth, that by blending the sonnet forms he has arrived at the perfect form of the Petrarchan scheme. Another critic, however, Hall Caine, contends that by making “octave flow into sestet without break of music or thought” Milton consciously or unconsciously invented a new form of sonnet; that is to say, Milton, in his use of the Petrarchan octave and sestet for the embodiment of intellectual substance incapable of that partial disintegration which Petrarch himself always or mostly sought, invented a species of sonnet which is English in impetus, but Italian, or partially Italian, in structure. Hence this critic, like William Sharp, divides all English sonnets into four groups: (1) sonnets of Shakespearean structure; (2) sonnets of octave and sestet of Miltonic structure; (3) sonnets of contemporary structure, i.e., all sonnets on the Petrarchan model in which the metrical and intellectual “wave of flow and ebb” (as originally formulated by the present writer in a sonnet on the sonnet, which has appeared in most of the recent anthologies) is strictly observed, and in which, while the rhyme-arrangement of the octave is invariably, that of the sestet is free; (4) sonnets of miscellaneous structure.

With regard to what is called the contemporary form—a Petrarchan arrangement with the sestet divided very sharply from the octave—the crowning difficulty and the crowning triumph of the sonnet writer has always been to handle the rhythm of the prescribed structure so as to make it seem in each individual sonnet the inevitable and natural rhythm demanded by the emotion which gives the individual sonnet birth, and this can perhaps only be achieved when the richness and apparent complexity of the rhyme-arrangement is balanced by that perfect lucidity and simplicity of syntax which is the special quest of the “sonnet of flow and ebb.”

The wave theory has found acceptance with such students of the sonnet as Rossetti and Mark Pattison, J. A. Symonds, Hall Caine, and William Sharp. Symonds, indeed, seems to hint that the very name given by the Italians to the two tercets, the volta or turn, indicates the metrical meaning of the form. “The striking metaphorical symbol,” says he, “drawn from the observation of the swelling and declining wave can even in some examples be applied to sonnets on the Shakespearean model; for, as a wave may fall gradually or abruptly, so the sonnet may sink with stately volume or with precipitate subsidence to its close. Rossetti furnishes incomparable examples of the former and more desirable conclusion; Sydney Dobell, in ‘Home in War Time,’ yields an extreme specimen of the latter.” And now as to the Shakespearean sonnet. Some very acute critics have spoken as if this form were merely a lawless successions of three quatrains clinched by a couplet, and as if the number of the quatrains might just as well have been two or four as the present prescribed number of three. If this were so, it would unquestionably be a serious impecachment of the Shakespearean sonnet, for, save in the poetry of ingenuity, no metrical arrangement is otherwise than bad unless it be the result of a deep metrical necessity.

If the prescriptive arrangement of three quatrains clinched by a couplet is not a metrical necessity, if it is not demanded in order to prevent the couplet from losing its power, such an arrangement is idle and worse than idle; just as in the case of the Petrarchan sonnet, if it can be shown that the solid unity of the outflowing wave can be maintained as completely upon three rhymes as upon two, then the restriction of the octave to two rhymes is simple pedantry. But he who would test the metrical necessity of the arrangement in the Shakespearean sonnet has only to make the experiment of writing a poem of two quatrains with a couplet, and then another poem of four quatrains with a couplet, in order to see how inevitable is the metrical necessity of the Shakespearean number and arrangement for the achievement of the metrical effect which Shakespeare, Drayton and others sought. While in the poem of two quatrains the expected couplet has the sharp epigrammatic effect of the couplet in ordinary stanzas (such as that of otello rime,
and as that of the "Venus and Adonis" stanza, destroying that pensive sweetness which is the characteristic of the Shakespearean sonnet, the poem of four quatrains is just sufficiently long for the expected pleasure of the couplet to be dispersed and wasted.

The quest of the Shakespearean sonnet is not, like that of the sonnet of octave and sestet, sonority, and, so to speak, metrical counterpoint, but sweetness; and the sweetest of all possible arrangements in English versification is a succession of decasyllabic quatrains in alternate rhymes knit together and clinched by a couplet—a couplet coming not so far from the initial verse as to lose its binding power, and yet not so near the initial verse that the ring of epigram disturbs the "linked sweetness long drawn out" of this movement, but sufficiently near to shed its influence over the poem back to the initial verse.

A chief part of the pleasure of the Shakespearean sonnet is the expectation of the climactic rest of the couplet at the end (just as a chief part of the pleasure of the sonnet of octave and sestet is the expectation of the answering ebb of the sestet when the close of the octave has been reached); and this expectation is gratified too early if it comes after two quatrains, while if it comes after a greater number of quatrains than three it is dispersed and wasted altogether.

The Spanish sonnet is a regular Petrarcan octave with a sestet of three rhymes beginning with a couplet. The Spanish sonnet is also based on the pure Italian type, and is extremely graceful and airy. The same may be said of the Portuguese sonnet—a form of which the illustrious Camoens has left nearly three hundred examples.

SONNINO, SIDNEY, BARON (1847— ), Italian statesman and financier, was born at Florence on the 11th of March 1847. Entering the diplomatic service at an early age, he was appointed successively to the legations of Madrid, Vienna, Berlin and Versailles, but in 1871 returned to Italy, to devote himself to political and social studies. On his own initiative he conducted exhaustive inquiries into the conditions of the Sicilian peasants and of the Tuscan métayers, and in 1877 published in co-operation with Signor Leopoldo Franchetti a masterly work on Sicily (La Sicilia, Florence, 1877). In 1878 he founded a weekly economic review, Il Sonnino, which four years later he converted into a political daily journal. Elected deputy in 1886, he distinguished himself by trenchant criticism of Magliani's finance, and, upon the fall of Magliani was for some months, in 1889, under-secretary of state for the treasury. In view of the severe monetary crisis of 1893 he was entrusted by Crispi with the portfolio of finance (December 1893), and in spite of determined opposition dealt energetically and successfully with the deficit of more than £6,000,000 then existing in the exchequer. By abolishing the illusory pensions fund, by applying and amending the Bank Laws, effecting economies, and increasing taxation upon corn, incomes from consolidated stock, salt and matches, he averted national bankruptcy, and placed Italian finance upon a sounder basis than at any time since the fall of the Right. Though averse from the policy of unlimited colonial expansion, he provided by a loan for the cost of the Abyssinian War in which the tactics of General Baratieri had involved the Crispi cabinet, but fell with Crispi after the disaster at Adowa (March 1896). Assuming then the leadership of the constitutional opposition, he combated the alliance between the Di Rudini cabinet and the subversive parties, criticized the financial schemes of the treasury minister, Luzatti, and revealed the "phantasie" finance of the first Pelloux administration as likely to endanger financial stability. After the modification of the Pelloux cabinet (May 1890) he became leader of the ministerial majority, and bore the brunt of the struggle against Socialist obstruction in connexion with the Public Safety Bill. Upon the formation of the Zanardelli cabinet (Feb. 1901) he once more became leader of the constitutional opposition, and in the autumn of the year founded a daily organ, Il Giornale d'Italia, the better to propagate moderate Liberal ideas. Although highly esteemed for his integrity and genuine ability, it was not until February 1906 that he was called upon to form a ministry, on the fall of the Forni cabinet. He immediately set about introducing certain urgent reforms, suppressed all subsidies to the press, and declared his intention of governing according to law and justice. In May, however, an adverse vote of the Chamber on a purely technical matter led to his resignation.

SCHILTZ, a northern state of Mexico, bounded 1812 by the United States, E. by Chihuahua, S. by Sinaloa and W. by the Gulf of California. It is the second largest state in the republic, having an area of 76,000 sq. m. Pop. (1900), 221,682, a large part being Indian. The surface of the state is much broken by the Sierra Madre Occidental, which extends through it from north to south and covers its entire width with parallel ranges, enclosing fertile valleys. Four important rivers traverse the state from east to west with courses of 145 to 300 m. and discharge into the Gulf of California, viz.: the Altar, or Asunción, Sonora, Yaqui and Mayo. The longest is the Yaqui, which has its source on the eastern side of the Sierra Tarahumare in Chihuahua and breaks through several ranges of the Sierra Madre before reaching the gulf near Guaymas. The smaller tributaries of these rivers of Sonora are often only dry canyons in the dry season. Agriculture has been developed only to a limited extent in Sonora, because of its aridity, lack of irrigation facilities, lack of railways and roads, and the unsettled state of the country. The soil of the sierra valleys is fertile, and when it is irrigated forage and cereal crops may be grown in abundance. Sugar-cane, tobacco, maguey, cotton, in small quantities, and fruits are also produced. There are excellent pastoral lands, especially in the upland districts, which are an important and profitable industry. Land is held in large estates, some of them upwards of 100 sq. m. in area. The mineral resources include silver, gold, copper, lead, tin, iron and coal, and mining is the chief industry. The lack of transportation facilities has been partly relieved by the construction of a branch of the Southern Pacific (American) from Nogales southward to Guaymas and the Sinaloa frontier, from which it has been extended to Mazatlán. Guaymas is the only port of importance on the coast, but it has a large trade and is visited by the steamers of several lines. The capital of the state (since 1882) is Hermosillo (pop. 1900, 7,518), on the Sonora river, 116 m. north of Guaymas, with which it is connected by rail. It suffered severely in 1866 from the savage struggle between Imperialists and Republicans, and in subsequent partisan warfare. Other important towns are Alamos (pop. 1895, 6737), 132 m. E.S.E. of Guaymas, Mocetzuma, 90 m. north of Hermosillo, and Ures, the old capital of Sonora and seat of a bishopric, 33 m. north-east of Hermosillo.

The first Jesuit mission in Sonora, founded among the Mayos in 1613, seems to have been the first permanent settlement in the state, although Coronado passed through it and its coast had been visited by early navigators. The Mayos, guerrilla-like tribes, prevened its rapid settlement. Ures was founded in 1636, and Arizpe in 1648. Near the end of the century Sonora and Sinaloa were divided into two districts, in 1767 the Jesuit missions were secularized, in 1779 the government of the province was definitely organized by Caballero de Croix, and in 1783 Arizpe became the provincial capital. The bishopric of Sonora was created in 1781 with Arizpe as its seat. Up to this time the history of the province is little else than a record of savage warfare with the Apaches, Seris, Yaquis and other tribes. The development of rich gold and silver mines brought in more Spanish settlers, and then the record changes to one of partnership warfare, which continued down to the administration of President Porfirio Díaz.

SONPUR, a feudatory state of India, in the Orissa division of Bengal, to which it was transferred from the Central Provinces
in 1905. Arca, 906 sq. m. Pop. (1901), 169,877, showing a decrease of 13% in the decade, due to the results of famine. Estimated revenue £8,000, tribute £500. The chief is a Rajput of the Patna line. Rice and timber are exported, and iron ore is said to abound. The town of Sonpur is on the Mahanadi river just above the point where it enters Orissa. Pop. (1901), 888.

SONSONATE, the capita! of the department of Sonsonate, Salvador; on the river Sonsonapa and the railway from San Salvador to the Pacific port of Acacuta, 131 m. south Pop. (1905), about 17,000. Sonsonate is the centre of a rich agricultural district, and one of the busiest manufacturing towns in the republic. It produces cotton cloth, pottery, mats and baskets, boots and shoes, sugar, starch, cigars and spirits. Through Acacuta it exports coffee and sugar, and imports grain for distribution to all parts of the interior.

SOOT (O. Eng. sot, cf. Icel. sór, Dan. sad; possibly from root sot, to sit), the black substance produced in the process of the combustion of fuel and deposited in finely granulated particles on the interior of chimneys or pipes through which the smoke passes. Soot is a natural nitrogenous manure (q.v.), and its value depends on the ammonia salts contained in it.

SOPHIA (1630-1714), electress of Hanover, twelfth child of Frederick V, elector palatine of the Rhine, by his wife Elizabeth, a daughter of the English king James I, was born at the Hague on the 14th of October 1630. Residing after 1659 at Heidelberg with her brother, the restored elector palatine, Charles Louis, she betrothed to George William afterwards duke of Lüneburg-Celle; but in 1658 she married his younger brother, Ernest Augustus, who became elector of Brunswick-Lüneburg, or Hanover, in 1662. Her married life was not a happy one. Her husband was unfaithful; three of her six sons fell in battle; and other family troubles included an abiding hostility between her and Sophia Dorothea, the wife of her eldest son, George Louis. Sophia became a widow in 1668, but before then her name had been mentioned in connexion with the English throne. When considering the Bill of Rights in 1689 the House of Commons refused to place her in the succession, and the matter rested until 1700 when the state of affairs in England was more serious. William III. was ill and childless; William, duke of Gloucester, the only surviving child of the princess Anne, had just died. The strong Protestant feeling in the country, the danger of a Catholic succession, and the fact that her husband, made it imperative to exclude all Roman Catholics from the throne, and the electress was the nearest heir who was a Protestant. Accordingly by the Act of Settlement of 1701 the English Crown, in default of issue from either William or Anne, was settled upon “the most excellent princess Sophia, electress and duchess-dowager of Hanover” and “the heirs of her body, being Protestant.” Sophia watched affairs in England during the reign of Anne with great interest, although her son, the elector George Louis, objected to any interference in that country, and Anne disregarded all mention of her successor. An angry letter from Anne possibly hastened Sophia’s death, which took place at Herrenhausen on the 8th of June 1714; less than two months later her son, George Louis, became king of Great Britain and Ireland as George I. on the death of Anne. Sophia, who corresponded with Leibnitz, was a strong woman both mentally and physically, and possessed wide and cultured tastes.

SOPHIA ALEKSYEVNA (1657-1704), tsarevna and regent of Russia, was the third daughter of Tsar Alexis and Maria Miloslavskaya. Educated on semi-eclesiastical lines by the learned monk of Kiev, Polotsky, she emancipated herself betimes from the traditional tyranny of the tsar, or women’s quarters. Setting aside court etiquette, she had nursed her brother Tsar Theodore III. in his last illness, and publicly appeared at his obsequies, though it was usual only for the widow of the deceased and his successor to the throne to attend that ceremony. Three days after little Peter, then in his fourth year, had been raised to the throne, she won over the streltsy, and the new musketeers, who at her instigation burst into the Kremlin, murdering everyone they met, including Artamon Matvyeev, Peter’s chief supporter, and Ivan Narushkin, the brother of the tsaritsa-regent Natalia, Peter’s mother (May 15-17, 1682). When the rebellion was over there was found to be no government. Everyone was panic-stricken and in hiding except Sophia, and to her, as the only visible representative of authority, the court naturally turned for orders. She took it upon herself to pay off and pacify the streltsy, and secretly worked upon them to present (May 29) a petition to the council of state to the effect that her half-brother Ivan should be declared senior tsar, while Peter was degraded into the junior tsar. As Ivan was hopelessly infirm and half idiotic, it is plain that the absurd duumvirate was but a stepping-stone to the ambition of Sophia, who thus became the actual ruler of Russia. The streltsy were not only pardoned for their atrocities, but petted. A general amnesty in the most absolute terms was granted to them, and at their special request a triumphal column was erected in the Red Square of the Kremlin, to commemorate their cowardly massacre of the partisans of Peter. When, however, instigated by their leader Prince Ivan Khovansky, who is suspected to have been aiming at the throne himself, and supported by the reactionary elements of the population, conspicuous among whom were the raz Kokinoks or dissenters, they proceeded on the 3th of July to the great reception-hall of the palace in the Kremlin to present a petition against all novelties, Sophia boldly faced them. Supported by her aunts and the patriarch, and secretly assured of the support of the orthodox half of the streltsy, she forbade all discussion and browbeat the rebels into submission. A later attempt on the part of Khovansky to overthrow her was anticipated and severely punished. By the 6th of November Sophia’s triumph was complete. The conduct of foreign affairs she committed to her cousin, Prince Vasili Dolgoruky. The inexhaustible, crafty and experienced clerk of the council, Theodore Shaklovity, looked after domestic affairs and the treasury. Sophia’s fondness for Golitsines induced her to magnify his barely successful campaigns in the Crimea into brilliant triumphs which she richly rewarded, thus disgusting everyone who had the honour of the nation at heart. Most of the malcontents rested their hopes for the future on the young tsar Peter, who was the first to benefit by his sister’s growing unpopularity. Sophia was shrewd enough to recognize that her position was becoming very insecure. When Peter reached man’s estate she would only be in the way, and she was not the sort of woman who is easily thrust aside. She had crowned her little brothers in order that she might reign in their names. She had added her name to theirs in state documents, boldly subscribing herself “Sovereign Princess of all Russia.” She had officially informed the doge of Venice that she was the co-regent of the tsars. And now the terrible term of her usurped authority was approaching. In her extremity she took council of Shaklovity, and it was agreed (1687) between them that the streltsy should be employed to dethrone Peter. The streltsy, however, received the whole project so coldly that it had to be abandoned. A second conspiracy to seize him in his bed (August 1686) was betrayed to Peter, and he fled to the fortress-monastery of Troitsa. Here all his friends rallied round him, including the bulk of the magnates, half the streltsy, and all the foreign mercenaries. From the 12th of August to the 7th of September Sophia endeavoured to set up a rival camp in the Kremlin; but all her professed adherents gradually stole away from her. She was compelled to retire within the Novo-Dyeryichy monastery, but without

taking the veil. Nine years later (1698), on suspicion of being concerned in the rebellion of the strydelcy, she was shorn a nun and imprisoned for life under military supervision. As “Sister Susannah” she disappeared from history. Russian historians are still divided in their opinion concerning this extraordinary woman. While some of them paint her in the darkest colours as an unprincipled adventuress, the representative of a new Byzantinism, others simply regard her as the victim of circumstances. Others, more indulgent still, acclaim her of all blame; and a few, impressed by her indomitable energy and ability, evade a decision altogether by simply describing her as a prodigy.

SOPHIA DOROTHEA (1666–1726), wife of George Louis, elector of Hanover (George I. of England), only child of George William, duke of Brunswick-Lüneburg, by a Huguenot lady named Eleonore d’Olbreuse (1649–1732), was born on the 15th of September 1666. George William had undertaken to remain unmarried, but his desire to improve the status of his mistresses (whom in spite of his promise he married in 1676) and of his daughter greatly alarmed his relatives, as these proceedings threatened to hinder the contemplated union of the Lüneburg territories. However, in 1682, this difficulty was bridged over by the marriage of Sophia Dorothea with her cousin George Louis, son of Duke Ernest Augustus, who became elector of Hanover in 1691. This union was a very unhappy one. The relatives of George Louis, especially his mother, the Electress Sophia, hated and despised his wife, and this feeling was soon shared by the prince himself. It was under these circumstances that Sophia Dorothea made the acquaintance of Count Philipp Christoph von Königsmark (q. v.), with whom her name is inseparably associated. Königsmark assisted her in one or two futile attempts to escape from Hanover, and rightly or wrongly was regarded as her lover. In 1694 the count was assassinated, and the princess was divorced and imprisoned at Ahlden, remaining in captivity until her death on the 23rd of November 1726. She is sometimes referred to as the “princess of Ahlden.” Her two children were the English king, George II., and Sophia Dorothea, wife of Frederick William I. of Prussia, and mother of Frederick the Great.

Sophia’s infidelity to her husband is not absolutely proved, as it is probable that the letters which purport to have passed between Königsmark and herself are forgeries.

SOPHISTS (from Gr. σωφισταὶ, literally, man of wisdom), the title given by the Greeks about the middle of the 3rd century BC to certain teachers in Greece, who were not content with maintaining the habits and drawing themselves from philosophers on the one hand and from artists and craftsmen on the other, claimed to prepare their pupils, not for any particular study or profession, but for civic life. For nearly a hundred years the sophists held almost a monopoly of general or liberal education. Yet, within the limits of the profession, there was considerable diversity both of theory and of practice. Four principal varieties are distinguishable, and may be described as the sophists of culture, of rhetoric, of politics, and of “eristic,” i.e., disputation. Each of these predominated in its turn, though not to the exclusion of others, the sophists of culture beginning about 447, and leading to the sophists of eristic, and the sophistry of rhetoric taking root in central Greece about 427, and merging in the sophistry of politics. Further, since Socrates and the Socrates were educators, they too might be, and in general were, regarded as sophists; but, as they conceived truth—so far as it was attainable—rather than success in life, in the law court, in the assembly, or in the debate, to the be the right end of intellectual effort, they were at variance with their rivals, and are commonly ranked by historians, not with the sophists, who confessedly despised of knowledge, but with the philosophers, who, however unavailingly, continued to seek it. With the establishment of the great philosophical schools—first, of the Academy, next of the Lyceum—the sophists took the place of the sophists as the educators of Greece.

The sophistical movement was then, primarily, an attempt to provide a general or liberal education which should supplement the formal education in reading, writing, gymnastic and music. But, as the sophists of the first generation found that their instruments grammar, style, literature and oratory, while those of the second and third developments were professed rhetoricians, sophistry exercised an important influence upon literature. Then again, as the movement, taking its rise in the philosophic agnosticism which grew out of the early physical systems, was itself persistently sceptical, sophistry may be regarded as an interlude in the history of philosophy. Finally, the practice of rhetoric and eristic, which presently became prominent in sophistical teaching, had, or at any rate seemed to have, a mischievous effect upon conduct; and the debate of seeking, whether in exposition or in debate, not true but victory—which charge was impressively urged against the sophists by Pluto—grew into an accusation of holding and teaching immoral and unsocial doctrines, and in our own day has been the subject of eager controversy.

1. Genesis and Development of Sophistry.—Sophistry arose out of a crisis in philosophy. The earlier Ionian physicists, Thales, Anaximander and Anaximenes, in their attempts to trace the Multiplicity of things to a single material element, had been troubled by the sceptical objections of the Ionian philosophers. Thus they, despite their air of doctrine, brought forth the Electress Sophia, hated and despised his wife, and this feeling was soon shared by the prince himself. It was under these circumstances that Sophia Dorothea made the acquaintance of Count Philipp Christoph von Königsmark (q.v.), with whom her name is inseparably associated. Königsmark assisted her in one or two futile attempts to escape from Hanover, and rightly or wrongly was regarded as her lover. In 1694 the count was assassinated, and the princess was divorced and imprisoned at Ahlden, remaining in captivity until her death on the 23rd of November 1726. She is sometimes referred to as the “princess of Ahlden.” Her two children were the English king, George II., and Sophia Dorothea, wife of Frederick William I. of Prussia, and mother of Frederick the Great. Sophia’s infidelity to her husband is not absolutely proved, as it is probable that the letters which purport to have passed between Königsmark and herself are forgeries.

SOPHISTS (from Gr. σωφισταὶ, literally, man of wisdom), the title given by the Greeks about the middle of the 3rd century BC to certain teachers in Greece, who were not content with maintaining the habits and drawing themselves from philosophers on the one hand and from artists and craftsmen on the other, claimed to prepare their pupils, not for any particular study or profession, but for civic life. For nearly a hundred years the sophists held almost a monopoly of general or liberal education. Yet, within the limits of the profession, there was considerable diversity both of theory and of practice. Further, since Socrates and the Socrates were educators, they too might
Sophists

(a) that nothing is, (b) that, if anything is, it cannot be known, (c) that, if anything is and can be known, it cannot be expressed in speech; and the summaries which have been preserved by Sextus Empiricus (Adv. Math. vii. 65-87) and by the author of the De Melissae, &c. (chs. 5, 6), show that, in defending these propositions, Gorgias indulged himself in the arguments which Zeno had used to discredit the popular belief in the existence of the Many; in other words, that Gorgias turned the destructive logic of Zeno against the constructive ontology of Parmenides, thereby not only reducing Ekelacic to nothingness, but also, until such time as a better logic than that of Zeno should be provided, precluding all philosophical inquiry whatsoever. Thus, whereas the representatives of the three successions had continued to regard themselves as philosophers or seekers after truth, Protagoras and Gorgias, plainly acknowledging their defeat, withdrew from the ungrateful struggle.

Many of the pupils which the earlier thinkers had obtained, the extinction of philosophy just at the time when the liberal arts became more technical and consequently less available as employments of leisure, threatened to leave a blank in Hellenic life. Accordingly, Protagoras, while with the one hand he put away philosophy, with the other offered a substitute. Emphasizing the function of the teacher, which, with the philosophers had been subordinate, and proclaiming the right end of intellectual endeavour to be, not "truth" (διδασκαλία) or "wisdom (σοφία), which was unattainable, but "virtue (μόρφωσις)" or "excellence (δόξη)"), he sought to communicate, not a theory of the universe, but an aptitude for civic life. "The lesson which I have to teach," Plato makes him say (Prot. 318 E), "is prudence or good counsel, both in respect of domestic matters that the man may manage his household aright, and in respect of public affairs, that he may be thoroughly qualified to take part, both by deed and by word, in the business of the state. In other words, I profess to make men good citizens." As instruments of education Protagoras used grammar, style, poetry and oratory. Thus, whereas hitherto the young Greek, having completed his elementary training in the schools of the γραμματεία, the ταγματική, and the σημαδορία, was left to prepare himself for his life's work as best he might, by philosophical speculation, by artistic practice, or otherwise, one who passed from the elementary schools to the lecture-room of Protagoras received from him a "higher education." The programme was exclusively literary, but for the moment it enabled Protagoras to satisfy the demand which he had discovered and evoked. Wherever he went, his lecture-room was crowded with admiring pupils, whose homage filled his purse and enhanced his reputation.

After Protagoras the most prominent of the literary sophists was Proclus of Ceos. Establishing himself at Athens, he taught "virtue" or "excellence," in the sense attached to the word by Protagoras, partly by means of literary subjects, partly in discourses upon practical ethics. It is plain that Proclus was an affected pedant; yet his simple conventional morality found favour, and Plato (Rep. 600 C) couples him with Protagoras in his testimony to the popularity of the sophists and their teaching.

At Athens, the centre of the intellectual life of Greece, there was soon to be found a host of sophists; some of them strangers, others citizens; some of them bred under Protagoras and Proclus, others self-taught. In the teaching of the sophists of this younger generation two points are observable. First, their independence of philosophy and the arts being assured, though they continued to regard "civic excellence" as their aim, it was no longer necessary for them to make the assertion of its claims a principal element in their exposition. Secondly, for the sake of novelty they extended their range, including scientific and technical subjects, but handling them, and teaching their pupils to handle them, in a popular way. In this stage of sophistry then, the sophist, though not a specialist, trenched upon the provinces of specialists; and accordingly Plato (Prot. 318 E) makes Protagoras pointedly refer to sophists who, "when young men have made their escape from the arts, plunge them once more into technical study, and teach them such subjects as arithmetic, astronomy, geometry and music." The sophist of whom the Platonic Protagoras is here thinking was Hippias of Elis, who gave popular lectures, not only upon the four subjects just mentioned, but also upon grammar, mythology, family history, archaeology, Homerology and the education of youth. In this polymath we see at once the degradation of the sophistry of culture and the link which connects Protagoras and Proclus with the eristici, who at a later period taught, not, like Hippias, all branches of learning, but a universally applicable method of disputation.

Meanwhile, Gorgias of Leontini, who, as has been seen, had rejected the philosophy of western Greece, gave to sophistry a new direction by bringing to the mother country the technical study of rhetoric—especially forensic rhetoric (Plato, Gorg. 454 B; cf. Aristotle, Rhet. 1354, b 26)—which study had been cultivated in Sicily by Gorgias and for nearly forty years before. Gorgias was already advanced in years and rich in honours when, in 427, he visited Athens as the head of an embassy sent to solicit aid against Syracuse. Received with acclamation, he spent the rest of his long life in central Greece, winning applause by the display of his oratorical gifts and acquiring wealth by the teaching of rhetoric. There is no evidence to show that at any period of his life he called himself a sophist; and, as Plato (Gorg. 449 A) makes him describe himself as a μητροπολιτής, it is reasonable to suppose that he preferred that title. That he should do so was only natural, since his position as presiding over the subject of rhetoric was established for him. Gorgias makes his first appearance in the character of a sophist, thus, as Protagoras, Proclus and the rest of the sophists of culture, the arts, for which oratory formed only a part, whilst Gorgias made no pretence of teaching "civic excellence" (Plato, Meno, 95 C), and found a substitute for philosophy, not in literature generally, but in the professional study of rhetoric alone, it would have been convenient if the distinction between sophistry and rhetoric had been maintained. But though, as will be seen hereafter, these two sorts of education were sometimes distinguished, Gorgias and those who succeeded him as teachers of rhetoric, such as Thrasymachus of Chalcodon and Polus of Agrigentum, were commonly called by the title which Protagoras had assumed and brought into familiar use.

Rhetorical sophistry, as taught by Gorgias with special reference to the requirements of the law courts, led by an easy transition to political sophistry. During the century which had elapsed since the expulsion of the Peisistratids and the establishment of the democracy, the Athenian constitution had developed with a rapidity which produced an oligarchical reaction, and the discussion of constitutional principles and precedents, always familiar to the citizen of Athens, was thus abnormally stimulated. The Peloponnesian War, too, not only added a deeper interest in the arts, but also gave rise to ordinary questions of policy, but also caused the relations of dissentient parties, of allied and belligerent states, of citizens and aliens, of bond and free, of Greeks and barbarians, to be eagerly debated in the light of present experience. It was only natural then that some of those who professed to prepare young Athenians for public life should give to their teaching a distinctly political direction; and accordingly we find Isocrates recognizing teachers of politics, and discriminating them at once from those earlier sophists who gave popular instruction in the arts and from the contemporary eristici. To this class, that of the political sophists, may be assigned Lycophron, Alcidamas and Isocrates himself. For, though that celebrated personage would have liked to be called, not "sophist", but "political philosopher," and tried to fasten the name of "sophist" upon his opponents the Socratics, it is clear from his own statement that he was commonly ranked with the sophists, and that he had no claim, except on the score of superior popularity and success, to be dissociated from the other teachers of political rhetoric. It is true that he was not a political sophist of the vulgar type, that as a theorist he was honest and patriotic, and that, in addition to his fame as a teacher, he
had a distinct reputation as a man of letters; but he was a professor of political rhetoric, and, as such, in the phrasology of the day, a sophist. He had already reached the height of his fame when Plato opened a rival school at the Academy; and, pointedly attacked him in the Gorgias, the Phaedrus and the Republic. Thenceforward, there was a perpetual controversy between the rhetorician and the philosopher, and the struggle of educational systems continued until, in the next generation, the philosophers were left in possession of the field.

While the sophistry of rhetoric led to the sophistry of politics, the sophistry of culture led to the sophistry of disputation. It has been seen that the range of subjects recognized by Protagoras and Prodicus gradually extended itself, until Hippias professed himself a teacher of all branches of learning, including in his list subjects taught by artists and professional men, but handling them from a popular or non-professional point of view. The successors of the polymath claimed to possess and to communicate, not the knowledge of all branches of learning, but an aptitude for dealing with all subjects, which aptitude should make the knowledge of any subject superfluous. In other words, they cultivated skill in disputation. Now skill in disputation is plainly a valuable accomplishment; and, as the Aristotelian logic grew out of the regulated discussions of the eristics and their pupils, the disputation sophistry of the 4th century deserves more attention and more respect than it usually receives from historians of Greek thought. But when men set themselves to cultivate skill in disputation, regardless of the matter discussed, not as a serious issue, but as a thesis upon which to practise their powers of controversy, they learn to pursue, not truth, but victory; and, their criterion of excellence having been thus perverted, they presently prefer ingenious fallacy to solid reasoning and the applause of bystanders to the consciousness of honest effort. Indeed, the sophists generally had a special predisposition to error of this sort, not only because sophistry was from the beginning a substitute for the pursuit of truth, but also because the successful professor, travelling from city to city, or settling abroad, could take no part in public affairs, and thus was not at every step reminded of the importance of the "material" element of exposition and reasoning. Paradox, however, soon becomes stale, and fallacy wearsome. Hence, despite its original popularity, eristical sophistry could not hold its ground. The man of the world who had cultivated it in his youth regarded it in riper years as a foolish pedantry, or at best as a propaedeutic exercise; while the serious student, necessarily preferring that form of disputation which recognized truth as the end of this, as of other intellectual processes, bestowed himself to one or other of the philosophies of the revival.

In order to complete this sketch of the development of sophistry in the latter half of the 5th century and the earlier half of the 4th, it is necessary next to take account of Socrates and the Sophists. A foe to philosophy and a renegade from art, Socrates took his departure from the same point as Protagoras, and moved in the same direction, that of the education of youth. Finding in the cultivation of "virtue" or "excellence" a substitute for the pursuit of scientific truth, and in disputation the sole means by which "virtue" or "excellence" could be attained, he resembled at once the sophists of culture and the rhetoricians of the 5th century. But when, in an effort to "excellence" which he sought was that of the man rather than that of the official, while the disputation which he practised had for its aim, not victory, but the elimination of error, the differences which separated him from the sophists of culture and the sophists of eristic were only less considerable than the resemblances which he bore to both; and further, though his whole time and attention were bestowed upon the education of young Athenians, his theory of the relations of teacher and pupil differed from that of the recognized professors of education, inasmuch as the taking of fees seemed to him to entail a base surrender of the teacher's independence. The principal characteristics of Socrates' theory of education were accepted, mutatis mutandis, by the leading Sophists. With these resemblances to the contemporary professors of education, and with these differences, were Socrates and the Socratic sophists or not? To this question there is no simple answer, yes or no. It is certain that Socrates' contemporaries regarded him as a sophist; and it was only reasonable that they should so regard him, because in opposition to the physicists of the past and the artists of the present he asserted the claims of higher education. But, though according to the phrasology of the time he was a sophist, he was not a typical sophist—his principle that, while scientific truth is unattainable by man, right opinion is the only basis of right action, clearly differentiating him from all the other professors of "virtue." Again, as the Socratic—Plato himself, when he established himself at the Academy, being no exception—were, like their master, educators rather than philosophers, and in their teaching lied special stress upon discussion, they, too, were doubtless regarded as sophists, not by Isocrates only, but by their contemporaries in general; and whether we regard that the disputational tendencies of the Megarian school made it all the more difficult for Plato and others to secure a proper appreciation of the difference between dialectic, or discussion with a view to the discovery of truth, and eristic, or discussion with a view to victory. Changing circumstances, however, carry with them changes in the meaning and application of words. Whereas, so long as philosophy was in abeyance Socrates and the Sophists were regarded as sophists of an abnormal sort, as soon as philosophy revived it was dimly conceived that, in so far as Socrates and the Sophists disdained from sophistry, they preserved the philosophical tendencies. This being so, it was found convenient to revise the terminology of the past, and to include in the philosophical succession those who, though not philosophers, had cherished the sacred spark. As for Socrates, he ranked himself neither with the philosophers, who professed to know, nor with the sophists, who professed to teach; and, if he sometimes described himself as a φιλόσοφος he was careful to indicate that he pretended to no other knowledge than that of his own limitations.

It would seem then, (1) that popular nomenclature included under the term "sophists" all teachers of philosophy, whether professors, or like Socrates, amateurs—who communicated, not artistic skill, nor philosophical theory, but a general or liberal education; (2) that, of those who were commonly accounted sophists, some professed culture, some forensic rhetoric, some political rhetoric, some eristic, some (i.e. the Socrates) dialectic; (3) that the differences between the different groups of sophists were not inconsiderable, and that in particular the teaching of the rhetoricians was distinct in origin, and, in so far as its aim was success in a special walk of life, distinct in character, from the more general teaching of the sophists of culture, the eristics, and the dialecticians, while the teaching of the dialecticians was discriminated from that of the rest, in so far as the aim of the dialecticians was truth, or at least the bettering of opinion; and, consequently, (4) that, in awarding praise and blame to sophistry and its representatives, the distinctive characteristics of the groups above enumerated must be studiously kept in view.

Lapse of time and change of circumstances brought with them not merely changes in the subjects taught, but also changes in the popular estimate of sophistry and sophists. The first under the term "sophists" all teachers who practised an enthusiastic and admiring interest. The sophist seemed to his youthful hearers to open a new field of intellectual activity and thereby to add a fresh zest to existence. But in proportion to the fascination which he exercised upon the young was the distrust which he inspired in their less pliable elders. Not only were they dismayed by the novelty of the sophistical teaching, but also they vaguely perceived that it was subversive of authority, of the authority of the parent over the child as well as of the authority of the state over the citizen. Of the two conflicting sentiments, the favour of the young, gaining as years passed away, naturally prevailed; sophistry ceased to be novel, and attendance in the lecture-rooms of the sophists came to be thought not less necessary for the youth than attendance in the elementary schools for the boy. The lively enthusiasm
and the furious opposition which greeted Protagoras had now burnt themselves out, and before long the sophist was treated by the man of the world as a harmless, necessary pedagogue.

That sophistry must be studied in its historical development was clearly seen by Plato, whose dialogue called the 'Sophist' contains a eulogy of the practice of teaching. The subject which is discussed in that dialogue and its successor, the 'Statesman', being the question: Are sophist, statesman, and teacher different branches of the same art? In his answer to the question, the protagonist seeks a definition of the term 'sophist' by means of a series of divisions or dichotomies. In this way he is led to regard the sophist successively—(1) as a practitioner of that branch of mercenary public instruction which since the time of Socrates has in its practice and exacts payment in the shape of a fee, in opposition to the flatterer who offers pleasure, asking for sustenance in return; (2) as a practitioner of that branch of mental trading which purveys discourse and lessons about the arts; (3) and (4) as a practitioner of those branches of mental trading, retail and wholesale, which purvey discourses and lessons about 'virtue' within a city, in opposition to the artists who similarly purvey discourses and lessons about the arts; (5) as a practitioner of that branch of eristic which brings to the professor pecuniary remuneration being a consideration, when and dealing with justice, injustice and other abstractions, and antilogic being that form of disputation which uses question and answer in private, in opposition to forensic, which uses continuous discourse in public, and the forensic branch of eristic which purges away the vain conceit of wisdom by means of cross-examination, in opposition to the traditional method of reproof or admonition. These definitions being thus various, the Eleatic nobleman of the fifth century, Polyclitus, fits into a second stage or phase of eristic, in opposition to the sophists, who represent him as an unattentive sophist, who is in a position to define the sophist (7) as a conscious impostor who, in private, by discontinuous discourse, compels his interlocutor to contradict himself, in opposition to the διαλεκτικος, who is a practitioner of discourses and lessons on a common basis. It is clear that the final definition is preferred, not because of any intrinsic superiority, but because it has a direct bearing upon the question: Are sophist, statesman and philosopher identical or different? If we express it in the form of two opposite stages or forms of sophistry as conceived from different points of view. Thus the first and second definitions represent the founders of the sophistry of culture, Protagoras and Proclus, from the respective points of view of the older Athenians, who disliked the new culture, and the younger Athenians, who admired it; the third and fourth definitions represent imitators to whom the name of Protagoras was not applicable; the fifth definition represents and earlier eristics, contemporaries of Socrates, whom it was necessary to distinguish from the teachers of forensic oratory; the sixth is framed to meet the anomalous case of Socrates, in whom many saw a sophist; and the seventh definition gives through the mouth of Plato, which was an unfortunate; and the seventh and final definition, having in view eristical sophistry fully developed, distinguishes it from διαλεκτικος, i.e. understanding that the fundamental principles of the art of sophistry and διαλεκτικος may be discriminated, they are nevertheless near akin, the one being the ape of philosophy, the other the ape of statesmanship. In short, Plato traces the changes which, in less than a century, had taken place in the aims and methods of sophistical teaching, partly through changes in the practice of the sophists, partly through changes in their surroundings and in public opinion, so as to show by a familiar instance that general terms which do not describe natural kinds cannot have a stable connotation.

Now it is easy to see that in this careful statement Plato recognizes three periods. The first four definitions represent the period of Protagoras, Prodikos, and their immediate successors, when the object sought was 'virtue', 'excellence', 'culture', and the means to it was literature. The fifth and sixth definitions represent the close of the 5th century, when sophistry handled eristicaly, and perhaps, through the medium of a dialectic mode of teaching, propositions of justice, injustice and the like, διαδικαιος or forensic rhetoric being its proximate rival. The seventh definition represents the first half of the 4th century, when sophistry was in a wider field, having for its rival, not forensics, but the other assembly. Plato's classification of educational theories is then substantially the classification adopted in this article, though wherever we do not agree with the writer, and with popular and the educational theories mentioned are included under the head of sophistry, Plato allows to rhetoric, forensic and political, an independent position, and hints that there are grounds for denying the title of 'sophistry' to these. Thus when we come to consider, with the changing nature of the sophists and their aims, we find that the two important facts—(1) that contemporary with the dialectic of Socrates there was an eristic, and (2) that this eristic was mainly applied to rhetorical questions. Finally, we may be sure that, if Plato was thus careful to show that the aims and means of the sophists, development, he could never have fallen into the modern error of bestowing upon those whom the Greeks called sophists either indiscriminate censure or indiscriminate laudation.

2. Relations of Sophistry to Education, Literature and Philosophy.—If then the sophists, from Protagoras to Isocrates, were before everything educators, it becomes necessary to inquire whether their labours marked or promoted an advance in educational theory and method. At the beginning of the 5th century, every young Greek of the better sort already received rudimentary instruction, not only in music and gymnastics, but also in reading and writing. Further, in the colonies, and especially the colonies of the West, philosophy and art had done something for higher education. Thus in Italy the Pythagorean school was, in the fullest sense of the term, an educational institution; and in Sicily the rhetorical teaching of Corax and Tisias was presumably educational in its effect upon the teaching of the Gorgias. But in central Greece, where, at any rate, down to the Persian Wars, politics, domestic and foreign, were all-engrossing, and left the citizen little leisure for self-cultivation, the need of a higher education had hardly made itself felt. The overthrow of the Persian invaders changed all this. Henceforward the best of Greek art, philosophy, and literature gravitated to Athens, and with their concentration and consequent development came a general and growing demand for teaching. As has been seen, it was just at this period that philosophy and art ceased to be available for educational purposes, and the unification of the literary sophists was popular precisely because they offered advanced teaching. This was not a purely philosophical nor artistic. Their recognition of the demand and their attempt to satisfy it are no small claims to distinction. That, whereas before the time of Protagoras there was little higher education in the colonies and less in central Greece, after his time attendance in the lecture-rooms of the sophists was the customary sequel to attendance in the elementary schools, is a fact which speaks for itself.

But this is not all. The education provided by the sophists of Plato's day is positively meritorious. When Protagoras included in his course grammatic, story, interpretation of the poets and oratory, supplementing his own continuous expositions by disputations in which he and his pupils took part, he showed a not inadequate appreciation of the requisites of a literary education; and it may be conjectured that his comprehensive programme, which Prodikos and others extended, had something to do with the development of that versatility which was the most notable element in the Athenian character.

There is less to be said for the teachers of rhetoric, politics and eristic, who, in limiting themselves each to a single subject—philosophy, poetry, oratory—were preparing prosaic forensic rhetoricians to one branch of oratory, the politicians or the political orators, the eristic to—disputation—ceased to be educators and became instructors. Nevertheless, rhetoric and disputation, though at the present day strangely neglected in English schools and universities, are, within their limits, valuable instruments; and, as specialization in teaching does not necessarily imply specialization in learning, many of those who attended the lectures and the classes of a rhetorician or an eristic sought and found other instruction elsewhere. It would seem then that even in its decline sophistry had its educational use. But in any case the title may be claimed by the sophists, who in the course of a century they discovered and turned to account most of the instruments of literary education.

With these considerable merits, normal sophistry had one defect, its indifference to truth. Despairing of philosophy—that is to say, of physical science—the sophists were prepared to go all lengths in scepticism. Accordingly the epidioic sophists in exposition, and the argumentative sophists in debate, one and all, studied, not matter but style, not accuracy but effect, not proof but persuasion. In short, in their hostility to science they refused to handle literature in a scientific spirit. That this defect was serious is well appreciated even by those who frequented and admired the lectures of the earlier sophists; that it was fatal was clearly seen by Socrates, who, himself commonly regarded as a sophist, emphatically reprehended,
not only the taking of fees, which was after a mere incident, objectionable because it seemed to include independence of thought, but also the fundamental disregard of truth which infected every part and every phase of sophistical teaching. To these contemporary censure the modern critic cannot refuse his assent.

To literature and to oratory the sophists rendered good service. Themselves of necessity stylists, because their professional success largely depended upon skilful and effective exposition, the sophists both of culture and of rhetoric were especially the teachers of the rules of grammar and the principles of written and spoken discourse. Thus, by example as well as by precept, they not only taught their hearers to value literary and oratorical excellence, but also taught the lead in fashioning the style of their time. Their influence in these respects was weighty and important. Whereas, when sophistry began, prose composition was hardly practised in central Greece, the sophists were still the leaders in literature and oratory when Plato wrote the Republic, and they had hardly lost their position when Demostenes delivered the Philippics. In fact, it is not too much to say that it was the sophists who provided those great masters with their consummate instrument, and it detracts but little from the merit of the makers if they were themselves unable to draw from their followers the same results.

The relation of sophistry to philosophy was throughout one of pronounced hostility. From the days of Protagoras, when this hostility was triumphant and contemptuous, to the days of Isocrates, when it was jealous and bitter, the sophists were declared and consistent sceptics. But, although Protagoras and Gorgias had examined the teaching of their predecessors so far as to satisfy themselves of its futility and to draw the sceptical inference, their study of the great problem of the day was preliminary to their sophistry rather than a part of it; and as the overthrow of philosophy was complete and the attractions of sophistry were all-powerful, the question "What is knowledge?" ceased for a time to claim or to receive attention. There is, then, no such thing as a "sophistical theory of knowledge." Similarly, the recognition of a "sophistical ethic" is, to say the least, misleading. It may have been that the sophists' preference of seeming to reality, of success to truth, had a mischievous effect upon the morality of the time; but it is clear that they had no common theory of ethics, and there is no warrant for the assumption that a sophist, as such, specially interested himself in ethical questions. In ethical questions they expressed "excellence" or "virtue" to be the end of education, he neither expressed nor implied a theory of morality. Proclus in his platitudes reflected the customary morality of the time. Gorgias said plainly that he did not teach "virtue." If Hippias, Polus and Thrasymachus defied conventional morality, they did so independently of one another, and in this, as in other matters, they were disputants maintaining paradoxical theses, rather than thinkers announcing heretical convictions. The morality of Isocrates bore a certain resemblance to that of Socrates. In short, the attitude of the sophists towards inquiry in general overthrew them, collectively and individually, from and attachment to any particular theory. Yet among the so-called sophists there were two who had philosophical leanings, as appears in their willingness to be called by the title of philosopher. First, Socrates, whilst he conceived that the physicists had mistaken the field of inquiry, absolute truth being unattainable, maintained, as has been seen, that one opinion was better than another, and that consistency of opinion, resulting in consistency of action, was the end which the human intellect properly proposes to itself. Hence, though an agnostic, he was not unwilling to be called a philosopher, in so far as he pursued such truth as was attainable by man. Secondly, when sophistry had begun to fall into contempt, the political rhetorician Isocrates claimed for himself the time-honoured designation of philosopher, "herein," says Plato, "resembling some tinker, bald-pated and short of stature, who, having made money, knocks off his chains, goes to the bath, buys a new suit, and then takes advantage of the poverty and desolation of his master's daughter to urge upon her his odious address" (Rep. vi. 405 E). It will be seen, however, that neither Socrates nor Isocrates was philosopher in any strict sense of the word, the speculative aims of physicists and metaphysicians being foreign to the practical theories both of the one and of the other.

As for the classification of sophistical methods, so for their criticism, the testimony of Plato is all-important. It may be conjectured that, when called upon to defend his name from the charge of false teaching, Plato gave himself to the study of contemporary methods of education and to the elaboration of an educational system of his own, and that it was in this way that he came to the conclusion that his mathematical philosophies, as they are termed, detract from the dignity of the name of sophistry. Further, when, he established himself at the Academy, his first care was to draw up a scheme of education, including arithmetic, geometry (plane and solid), astronomy, harmonies and dialectic, and it was not until after he had arranged in this programme that he devoted himself to the special functions of professor of philosophy. However this may be, we find amongst his writings—in intermediate, as it would seem, between the Sophistic conversations of his first period of literary activity and the metaphysical disquisitions of a later time—a series of dialogues which, however varied their ostensible subjects, agree in having a direct bearing upon education. Thus the Protagoras brings the educational theory of Protagoras and the sophists of culture face to face with the educational theory of Socrates, so as to expose the limitations of both; the Gorgias deals with the moral aspect of the teaching of Gorgias himself; the Hippias deals with the sophistical theories of Isocrates, and the intellectual aspect of their respective theories of education is handled in the Phaedrus; the Meno on the one hand exhibits the strength and the weakness of the teaching of Socrates, and, on the other brings into view the makeshift method of those who, despising systematic teaching, regarded the practical politician as the true educator; the Theaetetus has for its subject the methods of inquiry in mathematics and its discussion of the current theories of education, Plato proceeds in the Republic to develop an original scheme. Plato's criticisms of the sophists are then, in the opinion of the present writer, no mere obiter dicta, introduced for purposes of literary adornment or dramatic effect, but rather the expressions of profound and reasoned conviction, and, as such, entitled at any rate to respect. For the details of Plato's critique the reader should go not to the summaries of commentators, but to the dialogue itself. Perhaps it is sufficient to say that, while Plato accounts no education satisfactory which has not knowledge for its basis, he emphatically prefers the scepticism of Socrates, which, despairing of knowledge, seeks right opinion, to the scepticism of the sophists, which, despairing of knowledge, abandons the attempt to better existing beliefs.

3. The Theory of Grote.—The post-Platonic historians and critics, who, while they knew the earlier sophistry only through tradition, were eyewitnesses of the sophistry of the decadence, have been either silent or ambiguous. When we compare with them the statements of Grote, who, though perhaps overlooking the differences which separated the humanists from the eristics, and both of these from the rhetoricians, and taking no account of Socrates, whom they regarded as a philosopher, they forgot the services which Protagoras and Cercidas, Gorgias and Isocrates had rendered to education and to literature, and included the whole profession in an indiscriminate and contemptuous censure. This prejudice, establishing itself in familiar speech, has descended from antiquity to modern times, colouring, when it does not distort, the narratives of biographers and the criticisms of commentators. "The sophists," says Grote, "are spoken of as a new class of men, or sometimes in dialectics which implies a new doctrinal sect or school, as if they then sprang up in Greece for the first time—ostentatious impostors, flattering and duping the rich youth for their own personal gain, undermining the morality of Athens, public and private, and encouraging their pupils to the unscrupulous prosecution of ambition and cupidity. They are even affirmed to have succeeded in corrupting the general morality, so that Athens had become miserably degenerated and vicious in the latter years of the Peloponnesian War, and was redeemed from the pernicious influence of the sophistics by the virtuous example of the last of the five Great Statesmen, Aristeides;" and, although amongst the pre-Gromatic scholars there were some who saw as clearly as Grote himself that "the sophists are a much-calumniated race" (G. H. Lewes), it is certain that historians of philosophy, and editors of Plato, especially the "acumen plumbeum Stallbaumi," had given ample occasion for the energetic protest contained in the famous sixty-seventh chapter of Grote's History of Greece. Amongst the many merits of that
SOPHISTS

admirable scholar, it is one of the greatest that he has laid “the
fiend called die Sophists,” that is to say, the theory that
 sophistry was an organized conspiracy against law and morals.
Nevertheless, in this matter he is always an advocate; and it
may be thought that, while he successfully disposes of the
current slander, his description of his clients needs correction
in some important particulars. Hence the following paragraphs,
while they will resume and affirm his principal results, will
qualify and impugn some of his positions.

In so far as he is critical, Grote leaves little to be desired.
That the persons styled sophists “were not a sect or school,
with common doctrines or method,” is clear. Common doctrine,
that is to say, common doctrine of a positive sort, they could
not have, because, being sceptics, they had nothing which could
be called positive doctrine; while there was a period when even
their scepticism was in no wise distinctive, because they shared
it with all or nearly all their contemporaries. Neither were
they united by a common educational method, the end and the
instruments of education being diversely conceived by Pro-
tagoras, Gorgias and Isocrates, to say nothing of the wider
differences which separate these three from the eristics, and all
these abnormal types from the abnormal type represented by
Socrates.

Again, it is certain that the theoretical and practical morality
of the sophists, regarded as a class, was “neither above nor
below the standard of the age.” The taking of fees, the pride
of professional success, and the teaching of rhetoric are no proofs
either of conscious charlatanism or of ingrained depravity.
Indeed, we have evidence of sound, if conventional, principle
in Prodicus’s apologue of the “Choice of Heracles,” and of
honourable, though eccentric, practice in the story of Pro-
tagoras’s treatment of defaulting pupils. But, above all, it is
admittedly certain that detection from the ordinary standard
of morality would have precluded the success which the sophists
unquestionably sought and won. In fact, public opinion made
the morality of the sophists, rather than the sophists the morality
of public opinion. Hence, even if we demur to the judgment
of Grote that “Athens at the close of the Peloponnesian War
was not more corrupt than Athens in the days of Miltiades
and Aristeides,” we shall not “consider the sophists as the
corrupters of Athenian morality,” but rather with Plato lay
the blame upon society itself, which, “in popular meetings,
laws, and councils of the statesmen and generals they
uproarious censure and clamorous applause” (Rep. vi. 492),
educates young and old, and fashions them according to its
pleasure.

Nor can we regard “Plato and his followers as the authorized
teachers of the Greek nation and the sophists as the dissenters.”
On the contrary, the sophists were in quiet possession of the
field when Plato, returning to Athens, opened the rival school
of the Academy; and, while their teaching in all respects accom-
modated itself to current opinion, his, in many matters, ran
directly counter to.

But if thus far Grote’s protest against prevalent assumptions
carries an immediate and unhesitating conviction, it may be
doubted whether his positive statement can be accounted
final. “The appearance of the sophists,” he says, “was no
new fact... The paid teachers—whom modern writers set
down as the sophists, and denounce as the modern pestilence
of their age—were not distinguished in any marked or generic
way from their predecessors.” Now it is true that before 447
B.C., besides the teachers of writing, gymnastics and music, to
whom the young Greek resorted for elementary instruction,
there were artists and artisans who not only practised their
crafts, but also communicated them to apprentices and pupils,
and that accordingly the Platonic Protagoras recognizes in the
gymnast Iccus, the physician Herodicus, and the musicians
Agathocles and Pythocides, forerunners of the sophists. But
the forerunners of the sophists are not to be confounded with
the sophists themselves, and the difference between them is
not far to seek. Though some of those who resorted to the
gymnasts, physicians and musicians derived from them such
substitute for “higher education” as was before 447 generally
obtainable, it was only incidentally that professional men
and artists communicated anything which could be called
by that name. Contrariwise, the sophists were always and
especially professors of the higher education; and, although
in process of time specialization assimilated sophistry to the
arts, at the outset at any rate, its declared aim—the cultivation
of the civic character—sufficiently distinguished sophistical
education both from professional instruction and from artistic
training. It is true too that in some of the colonies philosophy
had busied itself with higher education; but here again the
forerunners of the sophists are easily distinguished from
the sophists, since the sophists condemned not only the scientific
speculations of their predecessors, but also their philosophical
aims, and offered to the Greek world a new employment for
leisure, a new intellectual ambition.

Nor is it altogether correct to say that “the persons styled
sophists had no principles common to them all and distinguishing
them from others.” Various as were the phases through which
sophistry passed between the middle of the 5th century and the
middle of the 4th, the sophists—Socrates himself being no
exception—lived in a non-philosophical spirit, and doctrine
is a common characteristic; and, if in the interval, philosophical
speculation was temporarily suspended, scepticism ceased
for the time to be peculiar, at the outset, when Protagoras and
Gorgias broke with the philosophers, and in the sequel, when
Plato raised the cry of “back to Parmenides,” this common
characteristic was distinctive.

Further, it may be doubted whether Grote is sufficiently care-
ful to distinguish between the charges brought against the
sophists personally and the criticism of their educational methods.
When the sophists are represented as conscious impostors who
“stood inedited and demented and arrogant sophistry,”
we are not warranted to pronounce his “moral character,” he has, as has been seen, an easy and complete
reply. But the question still remains—Was the education
provided by Protagoras, by Gorgias, by Isocrates, by the eristics
and by Socrates, good, bad or indifferent? And, though
the modern critic will not be prepared with Plato to deny the name
of education to all teaching which is not based upon an ontology,
it may nevertheless be thought that normal sophistry—as
opposed to the sophistry of Socrates—was in various degrees
unsatisfactory, in so far as it tacitly or confessedly ignored the
“civic virtue” and took refuge in rationalism by reasoning.

And if Grote overlooks important agreements he seems also
to understate important differences. Regarding Protagoras,
Gorgias and Isocrates as types of one and the same sophistry
(pp. 487, 493, 495, 499, 544, 2nd ed.), and neglecting as
slander or exaggeration all the evidence in regard to the sophistry
of eristic (p. 540), he conceives that the sophists undertook “to
educate young men so as to make them better qualified for
statesmen or ministers,” and that “which stood most
prominent in the teaching of Gorgias and the other sophists was,
that they cultivated and improved the powers of public speaking
in their pupils.” Excellent as a statement of the aim associated
with Isocrates, and tolerable as a statement of the aims of Gorgias,
these phrases are inexact if applied to Protagoras, who, making
“civic virtue” his aim, regarded statesmanship and administra-
tion as parts of “civic virtue,” and consequently assigned to
oratory no more than a subordinate place in his programme,
while to the eristics—whose existence is attested not only by
Plato, but also by Isocrates and Aristotle—and to Socrates—
whom Grote himself accounts a sophist—the description is
plainly and palpably inappropriate.

Grote’s note about the eristical sophists is perhaps the least
satisfactory part of his exposition. That “there were in Athens
persons who abused the dialectical exercise for frivolous puzzles” he
admits, but “to treat Euthydemos and Dionysodorus as
Waples’s ‘Sophists’ is, he continues, ‘altogether un-
warrantable.’ It would seem, then, that, while he regards rhetoric
as the function of normal sophistry, taking indifferently as
his types Protagoras, Gorgias and Isocrates, he accounts Euthydemos
and Dionysodorus (together with Socrates) as sophists, but as
sophists of an abnormal sort, who may therefore be neglected. Now
this view is inconsistent with the evidence of Plato, who, in the
SOPHOCLES

Sophocles, in his final and operative definition, gives prominence to the esthetic element, and quaintly assigns the mark of sophistry not indeed of the sophistry of the 5th century, but of the sophistry of the 4th. It must be presumed, then, that, in virtue of his being a modern student of the Platonic testimony, Grote in this matter leaves the Sophists out of consideration. There is another theory of the significance of Plato's allusions to eristical sophistry, that of Professor H. Sidgwick, whose brilliant defence of Gorgias, in 1876, was a stepping stone to the original lectures. Giving a hearty general assent to Grote's theory, Sidgwick nevertheless introduces qualifications similar to some of those which are suggested in this article. In particular he allows that "there was at Athens, as at Athens and Periclean Athens as a whole, no
prevent any arbour for their historical reputation," that the sophists generally "had in their lifetime more success than they realized," and that "a fantasiaism to their teaching which developed the genius of the Sophists, which led them to alter their anxiety to do justice to the Sophist, Grote laid more stress than is at all necessary on the partisanship of Plato." Now this last admission precludes Sidgwick from neglecting, as Grote had done, the evidence of the Euthydemus. Pointing out that the sophists of that dialogue "profess a ερήτηρι ενίπατον κριτήρια by means of dialogue," that they challenge the interlocutor ἀνώνυμος λόγος, that their examples are drawn from commerce and vulgar trades, that "they maintain positions that we know to have been held by Megarians and Cynics," he infers that "what we must stress, next to the eristical, is neither more nor less than a caricature of the Megarian views," and finds a ground that "the whole conception of Socrates and his effect on his contemporaries, as all authorities combine to represent it, represents him as an elaborate exhibition." It was possible, then, that no one before had systematically attempted to show men their utterance of which they believed themselves to know," he is "disposed to think that the art of disputation which is ascribed to sophistry was simply a refinement of the Anaxagorean (and, as analysed by Aristotle in the Περι σωφρικῶν διάλεξων) originated entirely with Socrates, and that he is altogether responsible for the form at least of this second species of sophistic." To this theory the present writer is unable to subscribe, that Plato was not careful to distinguish the Megarians and the Cynics from the eristical sophists, and that the disputants of the 4th century affected some of the eristics to the same extent as the eristics of the 5th, he unwillingly concedes. But he cannot allow either that the Megarians and the Cynics were the only eristics, or that eristical sophistry began with Socrates. Plainly this is not the place for a full examination of the question; yet it may be remarked—(1) that the previous history of the sophists of the Euthydemus, who had been professors of tactics (Xenophon, Mem. iii. i, 1), swordsmanship, and forensic argumentation, implies that they came to eristic from the sophistry of Socrates, but from that of the later humanists, poets, and orators; polyaths of the type of Hippias; (2) that the fifth and sixth definitions of the Sophists, in which "that branch of eristic which belongs to the modern group," is opposed to, the "patience-trying, pugnitive elenchus" of Socrates, indicate that contemporary with Socrates there were eristics whose aims were not his; (3) that, whereas the sophist of the final definition "dispute in the presence of one's hearers," is opposed to, the metaphysical, legal, political, technical, in effect, in all things, we have no ground for supposing that the Megarians and the Cynics used their eristic for any purpose except the defence of their logical hypotheses.

Nor is it possible to accept the statements that "the splendid genius, the lasting influence, and the reiterated polemics of Plato have stamped the name sophist upon the men against whom he wrote as if it were their recognized, legitimate and peculiar designation," and that "Plato not only stole the name out of general circulation, in order to fasten it specially upon his opponents the paid teachers, but also connected with it express disapprobation," which he opposed to, the "patience-trying, pugnitive elenchus" of Socrates, that to say, Grote supposes that for at least eight and forty years, from 447 to 399, the paid professors had no professional title; that, this period having elapsed, a youthful opponent succeeded in fastening an uncomplimentary title not only upon the contemporary teachers, but also, retrospectively, upon their predecessors; and that, artfully enhancing the indignity of the title affixed, he thus obscured, perverted and effaced the records and the memories of the past. Manifestly all three propositions are absolutely improbable. In the nomenclature of Plato's contemporaries Protagoras, Gorgias, Socrates, Dionysodorus and Isocrates were all of them sophists, Plato himself, in his careful investigation summarized above, limits the meaning of the term so that it shall include the humanists and the eristics only. Now, if his use of the term was stricter than the customary use, he can hardly be held answerable for the latter.

Nor is Grote altogether just in his account of Plato's attitude towards the several sophists, or altogether judicious in his appreciation of Plato's testimony. However contemptuous in his portraiture of Hippias and Dionysodorus, however severe in his polemic against Isocrates, Plato regards Protagoras with admiration and Gorgias with respect. While he emphasizes in the later sophists the consequences of the fundamental error of sophistry—its indifference to truth—he does honour to the genius and the originality of the leaders of the movement. Indeed, the author of this article finds in the writings of Plato a grave and discriminating study of the several forms of sophistry, and no trace whatsoever of that blind hostility which should warn us in neglecting his clear and precise evidence.

In a word, the present writer agrees with Grote that the sophists were not a sect or school with common doctrine or method; that their theoretical and practical morality was neither above nor below that of their age, being, in fact, determined by it; and that Plato and his followers are not to be regarded as the authorized teachers of the Greek nation, nor the sophists as the dissenters, but vice versa. At the same time, in opposition to Grote, he maintains that the appearance of the sophists marked a new departure, in so far as they were the first professors of education as such; that they agreed in the rejection of "philosophy"; that, although the Thurii, with the sophists, gave way to criticism, inasmuch as, with the exception of Socrates, they attached too much importance to the form, too little to the matter, of their discourses and arguments; that humanism, rhetoric, political and disputation were characteristic not of all sophists collectively, but of sections of the profession; that Plato was not the first to give a special meaning to the term "sophist" and to affix it upon the professors of education; and, finally, that Plato's evidence is in all essentials trustworthy.

SOPHOCLES (495-406 B.C.). Greek tragic poet, was born at Colonus in the neighbourhood of Athens. His father's name was Sophillus; and the family burial-place is said to have been about a mile and a half from the city on the Decelian Way. The date assigned for the poet's birth is in accordance with the tale that young Sophocles, then a pupil of the musician Lamprus, was chosen to lead the chorus of boys in the celebration of the victory of Salamis (480 B.C.). The time of his death is fixed by the allusions to it in the Frogs of Aristophanes and in the Muses, a lost play of Phrynichus, the comic poet, which were both produced in the first or second year of the war. And the legend which implies that Lyssander allowed him funeral honours is one of those which, like the story of Alexander and Pindar's house at Thebes, we can at least wish to be founded on fact, though we should probably substitute Agis for Lyssander. Apart from tragic victories, the event of Sophocles' life most fully authenticated is his appointment at the age of fifty-five as one of the generals who served with Pericles in the Samian War (440-439 B.C.). Conjecture has been rife as to the possibility of his here improving acquaintance with Herodotus, whom he probably met some years earlier at Athens. But the distich quoted by Plutarch

"Dieβκου 'Προέδρου ταῖς Σωφόκλης ἀπὸ τῶν Περί ἢν ἔχει συγκεκριμένα—

is a slight ground on which to reject the stronger tradition according to which Herodotus was ere this established at Thurii;
and the coincidences in their writings may be accounted for by their having drawn from a common source. The fact of Sophocles'

generalship is the less surprising if taken in connexion with the

interesting remark of his biographer (whose Life, though absent

from the earliest MS. through some mischance, bears marks of an

Alexandrian origin) that he took his full share of civic duties, and

even served on foreign embassies. The large acquaintance-

ship which this implies, not only in Athens, but in Ionic cities

generally, is a point of main importance in considering the

opportunities of information at his command. And, if we credit

this assertion (as we are the more at liberty to doubt the other state-

ment, though it is not incredible, that his appointment as general

was due to the political wisdom of his Antigone).

The testimony borne by Aristophanes in the Frogs to the

amiability of his poet's temper (ὅροι ἐπικρατεῖ μεν τὴν ἐπικρατεῖ ἐπικρατεῖ ἐπικρατεῖ)

agrees with the record of his biographer that he was universally

beloved. And the anecdote recorded by Cephalus in Plato's Repub-

lic, that Sophocles welcomed the release from the passions which

is brought by age, accords with the spirit of his famous Ode to Love in the Antigone. The Sophocles who, according to

the chorus here quoted, was more beloved than any other poet for the Four

Hundred that it was the better of two bad alternatives (probably

the same who was one of the poets), may or may not have been the

poet. Other gossiping stories are hardly worth repeating—

as that Pericles rebuked his love of pleasure and thought him a

bad general, though a good poet; that he humorously boasted of his own "generalship" in affairs of love; or that he said of

Aeschylus that he was often right without knowing it, and that

Euripides represented men as they are, not as they ought to be. (This last anecdote has the authority of Aristotle.) Such

titlives rather reflect contemporary or subsequent impressions of a superfluous kind than tell us anything about the man or

the dramatist. The gibe of Aristophanes (Pax 650 seq.), that

Sophocles in his old age was become a very Simonides in his

love for gain, may turn on some perversion of fact, without being altogether fair to either poet. It is certainly irreconcilable with the remark (Vit. anon.) that in spite of pressing invitations he refused to leave Athens for kings' courts. And the story of

his indictment by his son Lophon for incompetence to manage his

affairs—to which Cicero has given some weight by quoting it in the De

senectute—appears to be really traceable to Satyrus (fl. c. 300 B.C.), the same author who gave publicity to the most

ridiculous of the various absurd accounts of the poet's death, that

his breath failed him for want of a pause in reading some passage of the Antigone. Satyrus is at least the sole authority for the defence of the aged poet, who, after reciting passages from the Oed. Col., is supposed to have said to his accusers, "If I am Sophocles I am no dotard, and if I dote I am not Sophocles." On the other hand, we need not the testimony of biographers to assure us that he was devoted to Athens and renowned for

pity. He is said to have been priest of the hero Aion, and himself to have received divine honours after death.

The duty of managing the actors as well as of training the

chorus belonged to the author as well known. But did Aeschylus act in his own plays? This certainly is implied in the

tradition that Sophocles, because of the weakness of his voice, was the first poet who desisted from doing so. In his

Thymyrras, however, he is said to have performed on the lyre to

admiration, and in his Nausicaa (perhaps as corypheus) to

have played gracefully the game of ball. Various minor

improvements in decoration and stage carpentry are attributed to

him—whether truly or not who can tell? It is more interesting,

if true, that he wrote his plays having certain actors in his

eye: that he introduced satyric interludes of a satirical character; and that he was the first to introduce three actors on the

stage. It is asserted on the authority of Athenoxenus that

Sophocles was also the first to employ Phrygian melodies.

And it is easy to believe that Aj. 605 seq., Trach. 205 seq., were

sung to Phrygian music, though there are strains in Aeschylus

(e.g. Choeph. 152 seq., 425 seq.) which it is hard to distinguish essentially from these. Ancient critics had also noted his

familiarity with Homer, especially with the Odyssey, his power

of selection and of extracting an exquisite grace from all he

touched (whence he was named the "Attic Bee"), his mingled

felicity and boldness, and, above all, his subtle delineation of

human nature and feeling. They observed that the balanced

proportions and fine articulation of his work are such that in a

single half line or phrase he often conveys the impression of an

total character. Nor is this verdict of antiquity likely to be

reversed by modern criticism.

His minor poems, elegies, paeneus, &c., have all perished;

and of his hundred and odd dramas only seven remain. These

all belong to the period of his maturity (he had no decline); and

not only the titles but some scanty fragments of more than

ninety others have been preserved. Several of these were, of

course, satyric dramas. And this recalls a point of some

importance, which has been urged on the authority of Suidas, who

says that "Sophocles began the practice of putting play against

play, instead of the tetralogy." If it were meant that Sophocles
did not exhibit tetralogies, this statement would have simply to be rejected. For the word of Suidas (A.D. 950) has no weight against quotations from the lists of tragic victories (ἰδιαρὰν, 

\textit{ididaraion}, i.e. a quartet, and also in the list of dramatists) to the effect that he asserted on the authority of the \textit{ididaraion} that the Bacchae of Euripides, certainly as late as any play of Sophocles, was one of a trilogy or tetralogy. And if the custom was thus

maintained for so long it was clearly impossible for any single competitor to break through it. But it seems probable that

the trilogy had ceased to be the continuous development of one legend or cycle of legends—presenting Thibes or Pelops' line "—If, indeed, it ever was so exclusively; and if a Sophoclean

tetralogy was still linked together by some subtle bond of tragic thought or feeling, this would not affect the criticism of each

play considered as an artistic whole. At the same time it appears

that the satyrical drama lost its grosser features and became more or less assimilated to the milder form of tragedy. And these

changes, or something like them, may have given rise to the

statement in Suidas.

The small number of tragic victories attributed to Sophocles, in proportion to the number of his plays, is only intelligible on the supposition that the dramas were presented in groups.

If the dictum of Sophocles sometimes reminds his readers of the

Odyssey, the subjects of his plays were more frequently chosen from those later epics which subsequently came to be

embodyed in the epic cycle—such as the \textit{Aithiopikai}, the Little

Hliad, the \textit{Iliopseis}, the \textit{Cypria}, the \textit{Nosti}, the \textit{Teleogonia} (all

revolving round the tale of Troy), the \textit{Thebaiai}, the \textit{Olympos}

\textit{Olympos}, and others, including probably, though there is no

mention of such a thing, some early version of the Argonautic

story. In one or other of these heroic poems the legends of all

the great cities of Hellas were by this time embodied; and

though there must also have been a cloud of oral tradition floating over many a sacred spot, Sophocles does not seem, unless in his \textit{Oedipus Coloneus}, to have directly drawn from this. He

was content to quarry from the epic rhapsodies the materials

for his more concentrated art, much as Shakespeare made use

of Hollingshed or Plutarch, or as the subjects of Tennyson's

\textit{Idylls of the King} were taken from Sir Thomas Malory. As

Sophocles has been accused of narrowing the range of tragic

sympathy from Hellas to Athens, it deserves mention here that,

of some hundred subjects of plays attributed to him, fifteen only

are connected with Attica, while exactly the same number

belong to the tale of Argos, twelve are Argonautic, and thirty

Trojan. Even Corinthian heroes (Bellerophon, Polydivus) are

not left out. It seems probable on the whole that, within the

range of his art defined by convention, Sophocles was guided simply by his instinctive perception of the tragic capabilities of a particular fase.

To say that subsidiary or collateral motives were never present to Sophocles in the selection of a subject would, however, be

beyond the mark. His first drama, the \textit{Triptolemus}, must have

been full of local colouring; the \textit{Ajax} appealed powerfully to

the national pride; and in the \textit{Oedipus Coloneus} some faint echoes even of oligarchical partisanship may be possibly discerned

\textbf{SOPHOCLES}
SOPHOCLES

The result of this method is the union, in the highest degree, of simplicity with complexity, of largeness of design with absolute finish, of grandeur with harmony. Superfluities are thrown off while there is no loss of the pathos, and tragedy is not weakened by elements of irony. Not only what is said, but what is left unsaid, is felt by the audience, and is an essential part of the dramatic effect. This is what has been termed the "exit," and is a feature of all Sophoclean drama.

Sophocles is often praised for skilful construction. But the secret of his skill depends in large measure on the profound way in which the central situation in each of his fables has been conceived and felt. Concentration is the distinguishing note of tragedy, and it is by greater concentration that Sophocles is distinguished from other tragic poets. In the Septem contra Thebas or the Prometheus of Aeschylus there is still somewhat of epic enlargement and breadth; in the Hecuba and other dramas of Euripides separate scenes have an idyllic beauty and tenderness which affect us more than the progress of the action as a whole, a defect which the poet sometimes tries to compensate by some novel denouement or catastrophe. But in following a Sophoclean tragedy we are carried steadily and swiftly onward, looking neither to the right nor to the left; the more elaborately any scene or single speech is wrought the more does it contribute to enhance the main emotion, and if there is a deliberate pause it is felt either as a welcome breathing space or as the calm of brooding expectancy.

The Antigone certainly belongs to the Periclean epoch, and while Creon's large professions (lines 175–190) have been supposed to reflect the policy of the Athenian statesman, the heroine's grand appeal to the unwritten laws may have been suggested by words which an Attic orator afterwards quoted as having been spoken by Pericles himself: "They say that the man who has destroyed his own countrymen for the right of his own individual rights, is worthy of admiration, and even of the Eumolpidae in their instructions—laws which no man ever yet had power to abrogate, or dared to contradict, nor do the Eumolpidae themselves know who enacted them, for they believe that whose violates them must pay the penalty not only to man, but to the gods." [Lyssias contra Andocidem, § x. p. 104.]

Modern readers have thought it strange that Creon when convinced goes to bury Polyneices before attempting to release Antigone. It is obvious how this was necessary to the catastrophe, but it is also true to character, for Creon is not moved by compunction for the maiden nor by anxiety on Haemon's account, but by the fear of retribution coming on himself and the state, because of the sacred law of sepulture which he has defied. Antigone is the martyr of natural affection and of the religion of the family. But, as Käbel pointed out, she is also the high-born Cadmean maiden, whose defiance of the oppressor is accentuated by the pride of race. She despises Creon as an upstart, who has done outrage not only to eternal ordinance, but to the rights of the royal house.

The modern admiration of the poet, which still bears some traces of Aeschylean influence, and may be even earlier than the Antigone. But it strikes the peculiarly Sophoclean note, that the great and noble spirit, although through its own or others' errors it may be overclouded for a time and rejected by contemporaries amongst mankind, is notwithstanding accepted by the gods and shall be held in lasting veneration. The construction of the Ajax has been adversely criticized, but without sufficient reason. If it has not the concentration of the Antigone, or of the Oedipus Tyrannus, it has a continuous movement which culminates in the hero's suicide, and develops a fine depth of pathetic emotion in the sequel.

In the King Oedipus the poet attains to the supreme height of dramatic concentration and tragic intensity. The drama seems to have been produced soon after the outbreak of the Peloponnesian War, but certainly not in the year of the plague— else Sophocles, like his predecessor Phrynichus, might be said to have reminded his countrymen too poignantly of their home troubles. "The unwritten laws..." are now a theme for the chorus. The worship of the Delphic Apollo is associated with a profound sense of the value and sacredness of domestic purity, and in the command to drive out pollution there is possibly an implied reference to the expulsion of the Alcmaeonidae.

The Electra, a less powerful drama, is shown by the metrical indications to be somewhat later than the Oedipus Rex. The harshness of the vendetta is not relieved as in Aeschylus by long-drawn invocations of the dead, nor, as in Euripides, is it made a subject of casuistry. Electra's heroic impulse, the offspring

(see below). But, even where they existed, such motives were collateral and subsidiary; they were never primary. All else was subordinated to the dramatic, or, in other words, the purely human, interest of the fable. This central interest is even more dominant and pervading in Sophocles than the otherwise supreme influence of religious and ethical ideas. The idea of destiny, for example, was of course inseparable from Greek tragedy. Its prevalence was one of the conditions which presided over the art from its birth, and, unlike Aeschylus, who wrestles with gods, Sophocles simply accepts it, both as a datum of tradition and a fact of life. But in the free handling of Sophocles even fate and providence are admissible to tragic art. They are instruments through which sympathetic emotion is awakened, deepened, and concentrated, when, as in the Oedipus Tyrannus and unvaried laws was holier yet, for it was not the creation of any former age, but rose and culminated with the Sophoclean drama, still to the poet and his Periclean audience this was no abstract notion, but was inseparable from their impassioned contemplation of the life of man—so great and yet so helpless, aiming so high and falling down so far, a plaything of the gods and yet essentially divine. This lofty vision subdued with the serenity of awe the terror and pity of the scene, but from neither could it take a single tremor or a single tear. Emotion was the element of the Sophoclean tragedy, the other moved, albeit an emotion that was curbed to a serene stillness through its very depth and intensity.

The final estimate of Sophoclean tragedy must largely depend upon the mode in which his treatment of destiny is conceived. That Aeschylus had risen on the wings of faith to a height of prophetic vision, from whence he saw the triumph of equity and the defeat of wrong as an eternal process moving on toward one divine event—that he realized sin, retribution, responsibility as no other ancient did—may be gladly conceded. But it has been argued that because Sophocles is saddened by glancing down upon his world life—because in the fatalism of the old fable he finds the reflection of a truth—he in so far takes a step backward as a tragic artist. This remark is not altogether just. His value for what is highest in man is none the less because he strips it of earthly rewards, nor is his reverence for eternal law less deep because he knows that its workings are sometimes pitiless. Nor, once more, does he disbelieve in Providence, because experience has shown him that the end towards which the supreme powers lead forth mankind is still unseen. Not only the utter devotion of Antigone, but the lacerated innocence of the Trojan, and the therapy of the old man, that the heroism that he has been told to expect from the essential nobility of Ajax, leave an impression on the heart, which is ineffaceable, and must elevate and purify while it remains. In one respect, however, it must be admitted that Sophocles is not before his age. There is an element of unrelieved vindictiveness, not merely inherent in the fables, but inseparable from the poet's handling of some themes, which is only too consistent with the temper of the "tartan city." Aeschylus represents this with equal dramatic vividness, but he associates it not with heroism, but with crime.

Sophocles is often praised for skilful construction. But the secret of his skill depends in large measure on the profound way in which the central situation in each of his fables has been conceived and felt. Concentration is the distinguishing note of tragedy, and it is by greater concentration that Sophocles is distinguished from other tragic poets. In the Septem contra Thebas or the Prometheus of Aeschylus there is still somewhat of epic enlargement and breadth; in the Hecuba and other dramas of Euripides separate scenes have an idyllic beauty and tenderness which affect us more than the progress of the action as a whole, a defect which the poet sometimes tries to compensate by some novel denouement or catastrophe. But in following a Sophoclean tragedy we are carried steadily and swiftly onward, looking neither to the right nor to the left; the more elaborately any scene or single speech is wrought the more does it contribute to enhance the main emotion, and if there is a deliberate pause it is felt either as a welcome breathing space or as the calm of brooding expectancy.
SOPHOCLES

of filial love, through long endurance hardened into a "fixed idea," is irresistible, and Orestes, supported by Pylades, goes directly to his aim in obedience to Apollo. But nothing can exceed the tenderness of the recognition scene—lines 1008-1321, and the description of the falsely reported chariot race (681-763) is full of spirit.

In the Trachinian Maidens there is a transition towards that milder pathos which Sophocles is said to have finally approved (ἔστιν τις ρνοθῶν ἡ ἡμεῖς). The fate of Deianira is tragic in the arch of ruin and of Monticellus in her rival, Iole; there are modern touches reminding one of Shakespeare. The play may have been produced at a time not far removed from the peace of Nicia; and if this were so Deianira's prayer that her descendants may never undergo captivity—lines 303-305—might remind Athenian matrons of the captive Heraclids from Pylos, descendants through Hyllus of Deianira herself. The "modern" note is even more conspicuous in the Philoctetes, where the inward conflict in the mind of Neoptolemus, between ambition and friendship, is delineated with equal subtlety and force, and the contrast of the ingenuous youth with the aged solitary, in whom just resentment has been subordinated to a sublime sense of great depth of psychological insight. The tragic catastrophe of the Oedipus Tyrannus and the Trachiniae is absent here. The contending interests are reconciled by the intervention of the deified Heracles. But even more clearly than in the Ajax the heroic sufferer, rejected by men, is accepted by the gods and destined to triumph in the end. The Philoctetes is known to have been produced in the year 408 b.c., when Sophocles was 87 years old. The Oedipus Colonos is said to have been brought out after the death of Sophocles by his grandson in the amphitheatre of Micon. 402 b.c. a notable and impressive and thoughtful play, with the gods the principal sufferers, with the hero not overcome by them, but with the heroes and goddesses, powerful and voluntary and necessary. The question naturally arises, why a work of such surpassing merit should not have appeared in the lifetime of the poet. The answer is conjectural, but acquires some probability when several facts are taken into one view. It is surely remarkable that in a drama which obviously appeals to Athenian patriotism, local sanctities should obtain prominence to the exclusion of the corresponding national shrines on the Acropolis. It has been thought that the aged poet felt a peculiar satisfaction in celebrating the beauty and sacredness of his native district. This may well have been so, but it could hardly supply a sufficient motive for production. Perhaps the isolation of Athens, the war with the Aetolians, and the Dionysiac theatre. But there was a crisis in Athenian politics when "Colonus of the Knights" acquired a national significance. Those who organized the constitution of the Four Hundred made the precinct of Poseidon at Colonos the place of meeting, and probably sacrificed at the very altar which is consecrated by Theseus in this play. There must have been some reason for this. May it not have been that the occupants of the whole region, including the Academy, belonged mostly to the oligarchic faction? May not those who honoured Colonus by frequenting it—lines 62 and 63—have belonged to the order of knighthood? The name Colonos Hippipus (or ταύτης) would then have an appropriate meaning, and the equestrian statue of the eponymous hero (line 59) would be symbolic. In times of political agitation Colonus would then be regarded like St Germain, as the aristocratic quarter, while the Peiraeus was that of the extreme democracy, a sort of Faubourg St Antoine. It was there that the counter-movement reached its culmination. If so much be granted, is it not possible that this play, so deeply tinged with oligarchic influence, may have been thought too dangerous, and consequently withheld from production until after the amnesty, when the name of Sophocles was universally beloved, and this work of his old age could be prudently made public by his descendant? The knights in Aristophanes (424 b.c.) make their special appeal to Poseidon of the chariot race and to the Athene of victory. The Coloniates celebrate the sons of Theseus as worshippers of Athene Hippia, and of Poseidon. Theseus in Euripides (Supplices) is the first citizen of a republic. In this drama he is the king whose word is law, and he is warned by Oedipus to avoid the madness of revolutionary change (lines 1356-1538). The tragic story of Oedipus is resumed, but in a later and deeper strain of truthful emotion. Once more the noble spirit, rejected by man, is accepted by the gods. The eternal laws have been vindicated. Their decrees are irreversible, but the involuntary unconscious criminal is not finally condemned. He has no more hope in this world, but is in mysterious communion with unseen powers. The sufferer is now a holy person and an author of blessing. An approach is even made to the New Testament doctrine of the sacredness of sorrow.

Whatever may have been the nature of a Sophoclean tetralogy, the practice which at one time prevailed of describing the Oedipus Rex, Oedipus Colonus and Antigone as "the Theban trilogy" was manifestly erroneous and misleading. The three plays belong to different periods in the life-work of the poet, and the Antigone is the earliest of the three.

The spectator of a Sophoclean tragedy was invited to witness the supreme crisis of an individual destiny, and was possessed at the outset with the circumstances of the decisive moment. Except in the Trachiniae, where the retrospective soliloquy of Deianira is intended to emphasize her lonely position, the exposition is effected through a brief dialogue, in which the protagonist may or may not take part. In the Oedipus Tyrannus the king's entrance and his colloquy with the aged priest introduce the audience at once to the action and to the chief person. In the Ajax and Philoctetes the entrance or discovery of the hero is made more impressive by being delayed. Immediately after the prologus the chorus enter, numbering fifteen, either chanting in procession as in the Antigone and Oedipus Tyrannus, or dispersely as in the Oedipus Colonus and Philoctetes, or, thirdly, as in the Electra, where, after entering silently during the monody of the heroine, and taking up their position in the orchestra, they address her one by one. With a remarkable exception, to be noted presently, the chorus, having once entered, remain to the end. They always stand in some carefully adjusted relation to the principal figure. The elders of Thebes, whose age and coldness throw into relief the fervour and the desolation of Antigone, are the very men to realize the calamity of Oedipus, and, while horror-stricken, to lament his fall. The rude Salaminian mariners are loyal to Ajax, but cannot enter into his grief. The Trachinian maidens would gladly support Deianira, but are too young and inexperienced for the task. The noble Argive women can sympathize with the sorrows of Electra, but no sympathy can soothe her distress.

The parodos of the chorus is followed by the first scene or episoicon, with which the action may be said to begin. For in the course of this the spectator's interest is strongly roused by some new circumstance involving an unforeseen complication—the awakening of Ajax (Ajax), the burial of Polynices (Ant.), the dream of Clytaemnestra (El.), the dark utterance of Teiresias (Od. Tyr.), the arrival of Lichas and Iole (Track.), the report of Iphigenia announcing Creon's coming (Oed. Col.), the sudden entreaty of Philoctetes crossed by the entrance of the pretended mariner (Phil.). The action from this point onwards is like a steadily flowing stream into which a swift and turbulent tributary has suddenly fallen, and the interest advances with rapid and continuous climax until the culmination is reached and the catastrophe is certain. The manner in which this is done, through the interweaving of dialogue and narration with the various lyrical portions, is very different in different dramas, one of the principal charms of Sophocles being his power of ingenious variation in the employment of his resources. Not less admirable is the strength with which he sustains the interest after the peripeteia 1 whether, as in the Antigone, by heaping sorrow upon sorrow, or, as in the first Oedipus, by passing from horror to tenderness and unlocking the fountain of tears. The extreme point of boldness in arrangement is reached in the Ajax, where the chorus and Tecmmessa, having been warned of the impending

1 A tragic action has five stages, whence the five acts of the modern drama: the start, the rise, the height, the change, the close...
danger, depart severally in quest of the vanished hero, and thus leave not only the stage but the orchestra vacant for the soliloquy that precedes his suicide.

No such general description as has been here attempted can give even a remote impression of the march of Sophoclean tragedy—by what subtle yet firm and strongly marked gradations the plot is unfolded; how stroke after stroke contributes to the harmonious totality of feeling; what vivid interplay, on the stage, in the orchestra, and between both, builds up the majestic, ever-moving spectacle. Examine, for example, the opening scene or πρόλογος of the Οἰδίπους Τυραννύς. Its function is merely to propound the situation; yet it is in itself a miniature drama. First there is the silent spectacle of the eager throng of suppliants at the palace gate—young children, youths and aged priests. To them the king appears, with royal condescension and true public zeal. The priest expresses their heartfelt loyalty, describes the distress of Thebes, and, extolling Oedipus’s past services, implores him to exercise his consummate wisdom for the relief of his people. The king’s reply unveils yet further his incessant watchfulness and anxious care for his subjects. And he discloses a new object to their expectancy and hope. Creon, a royal person, had been sent to Delphi, and should ere then have returned with the response of Apollo. At this all hearts are trembling in suspense, when Creon is seen approaching. He is wreathed with Apollo’s laurel; he looks cheerfully. What has Phoebus said? Another moment of suspense is interposed. Then the oracle is repeated—so thrilling to the spectator who understands the haste, the urgency of the hour, and the hope and dread to all the persons of the drama: “It is for the blood of Laius—his murderers are harboured in the land of Thebes. The country must be purged.” That is the culminating point of the little tragedy. While Oedipus asks for information, while in gaiety of heart he undertakes the search, while he bides the folk of Cadmus to be summoned thither, the spectators have just time to take in the full significance of what has passed, which every word that is uttered sends further home. All this in 150 lines!

Or, once more, consider the employment of narrative by this great poet. The Τυραννύς might be again adduced, but let us turn instead to the Αντιγόνη and the Τραχινίαι. The speech of the messenger in the Αντιγόνη, the speeches of Hyllus and the Nurse in the Τραχινίαι, occur at the supreme crisis of the two dramas. Yet there is no sense of any retardation in the action by the report of what has been happening elsewhere. Much rather the audience are carried breathlessly along, while each speaker brings before their mental vision the scene of which he had himself been part. It is a drama within the drama, an action rising from its starting-point in rapid climax, swift, full, concentrated, that have wave and tone and is his language born of expectation. Nor is this all. The narrative of the messenger is overheard by Eurydice, that of Hyllus is heard by Deianira, that of Nurse by the chorus of Maidens. And in each case a poignancy of tragic significance is added by this circumstance, while the speech of the Messenger in the Αντιγόνη, and that of Hyllus in a yet higher degree, bind together in one the twofold interest of an action which might otherwise seem in danger of distracting the spectator’s sympathies.

So profound is the contrivance, or, to speak more accurately, such is the strength of central feeling and conception, which secures the grace and utility in complexity to the Sophoclean drama.

The proportion of the lyrics to the level discourse is considerably less on the average in Sophocles than in Aeschylus, as might be expected from the development of the purely dramatic element, and the consequent subordination of the chorus to the protagonist. In the seven extant plays the lyrical portion ranges from one-fifth to nearly one-third, being highest in the Αντιγόνη and lowest in the Οἰδίπους Τυραννύς. The distribution of the lyrical parts is still more widely diversified. In the Πελεκτος, for instance, the chorus has less to do than in the Οἰδίπους Τυραννύς, although in the former the lyrics constitute one-fourth, and in the latter only one-fifth of the whole. But then the part of Electra is favourable to lyrical outbursts, whereas it is only after the tragic change that Oedipus can appropriately pass from the stately senarius to the broken language of the dochmiae and the “lamenting” anapaest.

The protagonists of the Αἴξα and the Φιλίκεια had also large opportunities for vocal display, with the help of Musurus in 1818.

The union of strict symmetry with freedom and variety, which is throughout characteristic of the work of Sophocles, is especially noticeable in his handling of the tragic metres. In the iambics of his dialogue, as compared with those of Aeschylus, there is an advance which may be compared with the transition from "Marlowe’s mighty line" to the subler harmonies of Shakespeare. Felicitous pauses, the linking on of line to line, triasyllabic feet introduced for special effects, alliteration both hard and soft, length of speeches artfully suited to character and situation, and the expressiveness of language: these are some of the points which occur most readily in thinking of his senarii. A minute speciality may be noted as illustrative of his manner in this respect. Where a line is broken by a pause towards the end and the latter phrase runs on into the following line, elision sometimes takes place between the lines, e.g. (Οἰδ. Τυρ., 332–333):—

This is called συναφεία, and is peculiar to Sophocles.

He differentiates more than Aeschylus does between the marrow, or oblong, and the shorter, the κοιμάτια, and in the choral odes. The dochmius, crotic, and free anapaest are employed chiefly in the κοιμάτια. In the stasima he has greatly developed the use of logaoedic and particularly of glyconic rhythms, and far less frequently than his predecessor indulges in long continuous runs of dactylos or trochees. The light trochaic line ἄνδρος—, so frequent in Aeschylus, is comparatively rare in Sophocles. If, from the very severity with which the choral element is subordinated to the purely dramatic, his lyrics have neither the magnificent sweep of Aeschylus, nor the lip-plunging meditations. Even sides, they have a concinnity and point, a directness of aim, and a truth of dramatic keeping, more perfect than is to be found in either. And even in grandeur it would be hard to find many passages to bear comparison with the second stasimon, or central ode, either of the Αντιγόνη (εἴσοδος έναίδιαμερος οίνοι κακών) or the first Οἰδίπους (εἴ μοι ξυνιή φερόμενο). Nor does anything in Euripides equal in grace and sweetness the famous eulogy on Colonus (the poet’s birthplace) in the Οἰδίπους Κολονεύον.

BIBLIOGRAPHY.—Sophocles was edited (probably from the Venetian MS.) by Wurnberg in 1798, and by Musurus in 1800. The June issue in which the text of Aldus was slightly modified with the help of Florentine MSS. was published in 1522, 1547, respectively. An edition of the Scholia, very nearly correct, is one of those on the market of the Medici or chief Laurentian MS. (La or L) has previously appeared at Rome in 1518. The first great modification of the text was due to Turnebus, who had access to the Parisian MSS.; but he was not fortunate in his selection. The earliest editors had been aware that the traditional arrangement of the metres was faulty, but little way had been made towards a readjustment. Now it so happens that the Parisian MS. T, which contains the recension of Trenniosis, an early 14th-century scholar, contains also the metrical views of the same editor; and, having found (as he erroneously supposed) a sound authority, Trenniosis (1552) blindly adopted it, and was followed in this by H. Stephanus (1568), and by Canis in Holland (1570), who was the first to recognize the arrangement of the odes in strophe and antistrope. The error was to a large extent corrected by Brunk (1786), who rightly preferred Par. A (271), a 13th-century MS., belonging to the same family with Ven. 467, which Aldus had mainly followed. Thus after nearly three centuries the text returned (though with conjectural variations) into the former channel. Musgrave’s MSS., published in 1800, and Gilbert Wakefield had published a selection shortly before. Erfurdt in Germany then took up the succession, and his edition formed the basis of Hermann’s, whose psychological method set the authorities of vocal declamation in order. Passow and Wunder. A new era commenced with Peter Elmsley’s collation of the Laurentian MS. (made in 1818, but only published in full after his death). His transcription of the Scholia still exists in the Bodleian Library. The most important German commentaries
SOPHOMORY—SOPHOMORY

since Herennius had been one of those of Scheidenewin, G. Wolff and Wecklein. L. Campbell's edition of the plays and fragments (1871-1881) was quickly followed by Jebb's edition of the seven plays (1881-1896). Editions of one or more dramas most worth comparing are those of O. Jahn, D. Ahrens, and F. Schmitt, of Sophocles, Böckh's Antigone, Lobbeck's Ajax, J. W. Donaldson's Antigone, O. Jahn's Electra and J. William White's Oed. Tyr. A monograph on the Antigone by Kalbel is also well worth mentioning, as are those by Kiernan, D. A. Porter, D. La Plante, L. Campbell, Whitlaw; in prose by R. C. Jebb. The chief German translations are those of Solger (1824), Donner (1839), Hartung (1853) and Thudichum. The French prose translation by Leconte de Lisle, and the Italian in verse by Bellotti deserve special mention. The Antigone was produced at Berlin with Mendelssohn's music in 1841 and the Oedipus Coloneus in 1845. They have been reproduced in English several times—the Antigone notably with Helen Faust (Lady Martin) in the title-role in 1845. The Oedipe Re (trans. La Croix) and the Antigone (trans. Vacquerie) have been frequently performed in Paris. A performance of the Oedipus Tyrannus in Greek at Harvard University, U.S.A. (1890), was remarkably successful. Of dissertations immediately devoted to Sophocles those of Lessing, Patin, Dronke and Evelyn Abbott (in Hellenica) are especially noteworthy. (L. C.)

SOPHOMORAE, the name in American universities (corresponding to "sophister" at Cambridge, England, and Trinity College, Dublin) for a student who has completed his first year of academic studies. It is a corruption of the earlier "sophister", a somewhat degraded designation for one who was a wise but foolish, alluding to the air of wisdom assumed by students after their freshman's year was concluded. The earlier word "sophomore" (cf. "Laws of Yale Coll., 1774," in Hall's College Words) represents "sophismer," a double of "sophister," and means an arguer or debater (cf. the Cambridge use of "wangler"), and is formed from the Greek σοφισμα, sophism, an ingenious or captious argument.

SOPHON, of Syracuse, writer of mimes, flourished about 430 B.C. He was the author of prose dialogues in the Doric dialect, containing both male and female characters, some scenes of which were used in the plays. They prefixed an eulogy of the daily life of the Sicilian Greeks. Although in prose, they were regarded as poems; in any case they were not intended for stage representation. They were written in pithy and popular language, full of proverbs and colloquialisms. Plato is said to have introduced them into Athens and to have made use of them in his dialogues; according to Suidas, they were Plato's constant companions, and he even slept with them under his pillow. Some idea of their general character may be gathered from the 2nd and 15th idylls of Theocritus, which are said to have been imitated from the "Asyndetic Sophon," a pseudonym of Sophocles. Their influence is also to be traced in the satires of Persius. The fragments will be found in H. L. Ahrens's De graecae linguae dialectis (1843), ii. (app.). Latest edition by C. J. Botzon (1867); see also his De Sophone et Xenarcho mimographis (1856).

SOPHONIUS, Greek "sophist" and theological writer, was born at Damascus. For many years he was a monk in the monastery of the Theodosius, near Jerusalem, removed to Alexandria, whence he was driven out by the advance of the Persians, and finally settled in Palestine, where he became (634) successor of Modestus in the patriarchate of Jerusalem. After his elevation he showed himself a staunch supporter of orthodox principles and one of the most determined opponents of the Monothelites. In 656, when Jerusalem surrendered to the Arabs under Omar, he succeeded in obtaining important concessions for the Christians in the exercise of their worship. He did not long survive the capture of the city, and after his death the see remained unfilled for 29 years. Sophonius was a prolific writer, both in prose and verse, in various departments of literature. His chief work is a long account of the Egyptian saints and martyrs Cyrenus and John, and of the miraculous cures effected by them, valuable for its information concerning the topography of Egypt. The Life of Mary of Egypt, who abandoned immorality for a life of the strictest penance in Palestine for 48 years, is generally attributed to him. He was also the author of anacreontic odes, hymns, and epigrams.

Works in J. P. Migne, Patrologia graeca, lxxxvii, and in Fabricius, Bibliotheca graeca, ix. 162; see also L. de St Aignan, Vie de Sophonius (Orleans, 1884); C. Krumbacher, Geschichte der byzantinischen Literatur (1897); and for Sophonius and Omar, Gilchrist, 51.

SOPRANO (a variant of Ital. soprano, supreme, sovereign, Late Lat. superans, from super, above), the term applied in music to the highest natural range of the human voice, and often restricted to that range in the female voice, "treble" being used of a boy's voice. Male sopranos, either natural or artificially produced, as formerly in the castrati of the papal choirs (see EUNUCH), are also found. The female voice whose range is intermediate between that of a soprano or a contralto is termed "mezzo-soprano."

SOPRON (Ger. Oedenburg; Med. Lat. Superonium), a town of Hungary, capital of the county of the same name, 140 m. W. of Budapest by rail. Pop. (1900), 50,628, about 60% Germans. It lies in an extensive valley enclosed on all sides by the outskirts of the Rassaili mountains, a group belonging to the eastern outliers of the Alps. In the principal square are the Benedictine church, built at the end of the 13th century and restored in the 15th century, and the town hall, completed in 1894. The Dominican church, built in 1674; the church of St Michael, in the Gothic style, completed in 1848, the most interesting church in the town; and the old tower, 200 ft. high, are all worth notice. Sopron has a thriving industry in sugar, soap, vinegar, bell-found ing and machinery, and it carries on an active trade in cereals, fruit and wine. Large cattle markets are also held here. Within the county a good quality of wine is produced, especially near the little town of Rusz (pop. 1608) and at the village of Balf (Ger., Wolfs) on the shores of the Neusiedler lake. In the neighbourhood of Sopron is the Brennberg, with extensive coal-mines. Sopron was a Roman colony under the name of Scarcabanitia. It was afterwards occupied by German settlers and became a royal free town in the 11th century. Matthias Corvinus granted the town special privileges in 1464. An important Diet of Hungarian Protestants took place here in 1681.

About 12 m. north, at the foot of the Leitha mountains, lies the town of Kismarton (Ger. Esterstadt; pop. 2951), which contains a magnificent castle of the Esterhazy family, built in 1683 and enlarged in 1805. About 10 m. north-west lies Nagymarton (Ger. Gross Kismarte, pop. 6000), the seat of the Esterhazy family, and 12 m. north-west lies Nagycsoros, a town of nobles, with the castle of the Esterhazy family.

SORA, a city of Campania, Italy, in the province of Caserta, 77 m. N. by W. of that town on the railway between Roccasera and Avezzano, 920 ft. above sea-level. Pop. (1901), 6,050 (town); 16,022 (commune). It is built in a plain on the banks of the Liris. This part of the valley is the seat of some important manufactures, especially of paper-mills. The original cathedral, consecrated by Pope Adrian IV. in 1155, was destroyed by pop. earthquakes and not far from the former site of the town (1768 ft.) which guards the Liris valley and the entrance to the Abruzzi are remains of polygonal walls; here, possibly, was the citadel of the original Volscan town. There are also remains of medieval fortifications. In the town itself there are no remains of antiquity nor buildings of interest. The district around Sora is famous for the costumes of its peasants.

Sora, an ancient Volscan town, was thrice captured by the Romans, in 345, 314 and 305 B.C., before they managed, in Egypt, by means of a colony so strong, to confirm its annexation. In 269 it was one of the colonies which refused further contributions to the war against Hannibal. By the lex Julia it became a municipium, but under Augustus it was colonized by soldiers of the legio IV. Sorana, which had been mainly enrolled there. It belonged technically to Latiurn Adiectum. The castle of Sorella, built on the rocky height above the town,
was in the middle ages a stronghold of some note. Charles I. of Anjou made Sora a duchy for the Cantemel; it was afterwards seized by Pius II., but, being restored to the Cantemel by Sixtus IV., it ultimately passed to the Della Rovere of Urbino. Against Caesar Borgia the city was heroically defended by Giovanni di Montefeltro. It was purchased by Gregory XIII. for 11,000 ducats and bestowed on the Buoncompagni, the ancestors of the line of Buoncompagni-Ludovisi. In ancient times Sora was the birthplace of the Decii, Attilius Regulus, and Lucius Mummius; and among its later celebrities is Cardinal Barea.

SORACTE, a mountain in the province of Rome, Italy. It is a narrow, isolated limestone ridge, some 5 m. S.E. of Civita Castellana, and 31 m. in length. The highest summit is 2267 ft. above sea-level; just below it is a monastery removed there from the summit in 1835; it was originally founded about 748 by Car-Iom, son of Charles Martel (the altar has, indeed, fragments of sculptures of this period), and until modern times was occupied by Trinitarian monks. On the actual summit is a church. Owing to the isolated position of the mountain the view from the summit is said to be the finest in Italy, and as it is occupied by a monastery, there is a picturesque summits and cloisters on the sides. In the landscape, being visible from Rome itself. It is thus mentioned by Horace ("vides ut alta stet nivea candidum Soracte") Carm. i. 9), and Virgil, who mentions Apollo as its guardian deity, though no traces of his temple exist; and in reality it was sacred to Dias Pater and the gods of the lower world. At the bottom of the mountain on the east is a disused limestone quarry. The village of S. Oreste at the south-east end of the ridge owes its name to a corruption of the ancient name. In the communal palace is a fine procession cross of the 12th century, in the Byzantine style (see Römische Quartalschrift, 1906, 209—Archäologie).

SORANUS, Greek physician, born at Ephesus, lived during the reigns of Trajan and Hadrian (A.D. 98-138). According to Suidas, he practised in Alexandria and subsequently in Rome. He was the chief representative of the school of physicians known as "methodists." Two treatises by him are extant: On Fractures (in J. L. Ideler, Physiologie et medecine minores. i. 1841) and On Diseases of Women (first published in 1838, later by V. Rose, in 1882, with a 6th-century Latin translation by Moschus, a physician of the same school). Of his most important work (On Acute and Chronic Dis. and Solyte) a few fragments remain, but we possess a complete Latin translation by Caesius Aurelianus (5th century). The Life of Hippocrates (in Ideler) probably formed one of the collection of medical biographies by Soranus referred to by Suidas, and is valuable as the only authority for the life of the great physician, with the exception of articles in Suidas and Stephanus of Byzantium (s.v. Kös). The Introduction to the Science of Medicine (V. Rose, Anecdota graeca, ii. 1870) is considered spurious.

See article by J. Hahn, in Dechambre's Dictionnaire encyclopédique des sciences médicales, 3rd series, tom. 10; W. Christ, Geschichte der griechischen Literatur (1898); J. Iberg, Die Überlieferung der Gynaekologie des Soranos von Ephesos (Leipzig, 1910).

SORANUS, BAREA, Roman senator, lived in the reign of Nero. His gentle name was possibly Servilia. In 52 he was consul suffectus, and (perhaps in 61) proconsul of Asia. The upright and considerable manner in which he treated the provincials won him their affection, but at the same time brought upon him the hatred of Nero, who felt specially aggrieved because Soranus had refused to punish a city which had defended the statues of its gods against the Imperial commissioners. Soranus was accused of insurrection with Rubellius Plautus (another object of Nero's hatred), and of endeavouring to obtain the good will of the provincials by reasonable intrigues. One of the chief witnesses against him was Egnatius Celer of Berytus, his client and former tutor. Soranus was condemned to death (in 65 or 66), and committed suicide. His daughter Servilia, who was charged with having consulted the sorcerers, professedly in regard to her father's fate, but in reality with evil designs against the emperor, was involved in his downfall. The accuser, who was condemned to death in the reign of Vespasian for his conduct on this occasion, is a standing example of ingratitude and treachery.

Tacitus, Annals, xvi. 30, 32; Hist. iv. 10; Juvenal iii. 116; Dio Cassius xii. 26.

SORAU, a town of Germany, in the Prussian province of Brandenburg, on the Sorebach, 54 m. S.E. of Frankfort-on-Oder by rail, and at the junction of lines to Cottbus and Görlitz. Pop. (1923), 16.410. One of the oldest towns in Lower Lusatia, Sorau contains a number of ancient buildings, among which the most prominent church, the Chapel of St. John, was erected in 1260, and the old palace of 1207 (now a prison). The new palace, erected in 1711 by Count Erdmann II. of Promnitz, is utilized for government offices. The varied manufactures of the town comprise cloth, linen, wax candles, starch, glass and porcelain.

Sorau is said to have existed in 840, and to have belonged to the abbey of Fulda till the 12th century. It received civic rights in 1250. With the surrounding district, known as the barony of Sorau, it became the seat of successive noble families; and in 1400 it was united with the barony of Tribel. The 18th century was a period of conflict, when a number of baronies from Frederick of Bohemia in 1556, sold them in 1765 to the elector of Saxony for an annuity of 12,000 thalers (£1,800). In 1815 Saxony ceded them to Prussia.

See Worbs, Geschichte der Herrschaft Sorau und Tribel (Sorau, 1826).

SORBONNE, the name given originally to the college founded by Robert de Sorbon in Paris; hence applied afterwards popularly to the theological faculty, and so to the institution which is now the seat of the Académie de that city (see UNIVERSITIES). The Sorbonne owes its origin and its name to Robert of Sorbon, near the church of St. Denis (1201–1274), who, after the death of St. Louis in 1260, laid the foundations of the building, which was consecrated in 1263 and 1268. Destined originally for poor students (and called domus magistrorum populi, "most poor house of masters"), the Sorbonne soon became a meeting-place for all the students of the university of Paris, who resorted thither to hear the lectures of the most learned theologians of the period—Guillaume de Saint Amour, Eudes de Douai, Laurent l'Anglais, Pierre d'Ailly. At the close of the century it was organized into a full faculty of theology, and under that title its degrees, and the severity of its examinations gave an exceptional value to its diplomas. The so-called "these sorbonique," instituted towards the beginning of the 14th century, became the type of its order by the length and difficulty of its tests. Ultimately the professors of the Sorbonne came to be restored not only for lectures and examinations, but also for dogmatic decisions and judgments in canon law; the clergy of France and of the whole Catholic world had recourse to them in difficult cases, and the Curia Romana itself more than once submitted to them. The faculty of Sorbonne was the closest rival of that of Paris, and secured to itself the title of "Concilium in Gallia subsistent." To the Sorbonne belongs the glory of having introduced printing into France in 1469: within its precincts it assigned quarters for Ulric Gering and two companions in which to set up their presses. The Sorbonne took a leading part in the religious discussions which agitated France during the 16th and 18th centuries, and its influence thus inevitably extended to political questions. During the insanity of Charles V. it helped to bring about the abdication of Jean Sans-Peur for the assassination of the duke of Orleans.
SORBS—SORDINO

Shortly afterwards it demanded and supported the condemnation of Joan of Arc; during the Reformation it was the animating spirit of all the persecutions directed against Protestants and unbelievers: without having advised the massacre of St. Bartholomew, it did not hesitate to justify it, and it inflamed the League by its vigorous and irresistible press; it divided the Lords of Navarre, hesitating to recognize the latter even after his abjuration. From this point dates the beginning of its decadence, and when Richelieu in 1626 ordered the reconstruction of its church and buildings the following prophetic couplet was circulated—

"Instaunata ruet jamjam Sorbona. Caduca
Dum fuit, inconcussa stetit; renovata peribit."

The declaration of the clergy in 1628, which it subscribed, proved fatal to its authority with the Curia Romana; it revived for a short time under Louis XIV. during the struggle against Jansenism, but this was its last exploit; it was suppressed like the old universities in 1792.

When the university of France was organized in 1808 the Sorbonne became the seat of the académie of Paris; and between 1816 and 1821 the faculties of theology (since disappeared), science and literature were installed there. The university library was transferred to the Sorbonne in 1823. In 1868, it was the École des Hautes Études, and in 1897 the École des Chartes also found its home at the Sorbonne.

In 1852 the Sorbonne was made the property of the city of Paris; a reconstruction of the buildings, projected by Napoleon III., was begun in 1853, and completed in 1858. The old church containing the tomb of Richelieu was retained on account of its artistic merit. This new Sorbonne is one of the finest university edifices in the world, and has developed into the chief French centre of learning.

See A. Franklin, La Sorbonne (1875); Denille, Documents relatifs à la fondation de l'université de Paris (1883); J. A. Randolph, History of the Sorbonne.

SORBS, the tribal name of the Slavonic people, whom the Germans call Wendish, in Lusatia (Lausitz); they call themselves Sorbs or Lužišťane. Their country includes the western extremity of the kingdom of Saxony and parts of the districts of Hoyerswerda, Muskau, Kottbus, Kalau, Spremberg and Sorau in Prussia; they are now surrounded on all sides by Germans, but they formerly had them as neighbours only on the west along the Fulda, while on the north towards Köpenick they marched with the Lutici, on the east with the Poles and Silesians along the Quiss and Bobr, and on the south were separated from the Bohemians by the mountains that now make the Austrian frontier. The Sorbs first appeared in central Europe in the reign of Henry the Lion, by whose favour and protection they became established in Lusatia. They are in all about 180,000 in number; 50,000 Low Sorbs and 40,000 of the 100,000 High Sorbs are in Prussia, and 60,000 High Sorbs in Saxony. These have gained definite rights for their language in school and administration, so that Bautzen (Budyšín), their capital, is the intellectual centre not only for Saxon subjects, but for all High Sorbs and to a great extent for Low Sorbs. The first monuments of both dialects belong to the Reformation period, these being translations of Luther's Catechism by Varüchisch and Möller. Some Sorbs are Protestants, though the Saxon Sorbs are mostly Roman Catholics. Early in the 16th century the High Sorbs had a revival under the leadership of F. A. Klin, a lawyer and politician; A. Seidler, a considerable poet, and S. E. Smoler, an ethnographer and publicist. More recent writers are J. Čišinský and J. Radyserb. A Macia or Literary and Linguistic Society was founded in 1847, and publishes a Casopis or Periodical. Meanwhile Low Sorb has remained most unvitiated owing to the pressure of the Prussian administration.

The two dialects stand between Polish and Čech; they have lost the nasal vowels, have the accent on the first syllable, and make ğ into ě, ď into ďě, like Čech, but they retain ă and y and, like Polish, have d for Čech g. High Sorb has ďě, Low the original ě. They have kept the old aorist and dual. Sorb is usually printed in German blackletter variously adapted; the Macia publishes some books spelt after the Čech system.

SORBY, HENRY CLIFTON (1826-1908), English microscopist and geologist, was born at Woodbourne near Sheffield on the 10th of May 1826. He early developed an interest in natural science, and one of his first papers related to the excavation of valleys in Yorkshire. He subsequently dealt with the physical geography of former geological periods, with the wave-structure in certain stratified rocks, and the origin of slaty cleavage. He took up the study of rocks and minerals under the microscope, and published an important memoir on The Microscopical Structure of Crystals in 1853 (Quart. Journ. Geol. Soc.). In England he was one of the pioneers in petrography; he was awarded the Wollaston medal by the Geological Society of London in 1869, and when president of the society he published in his addresses the results of original researches on the structure and origin of limestones, and of the non-calcareous stratified rocks (1879-1880). He had previously been president of the Royal Microscopical Society. He wrote on the construction and use of the micro-spectroscope in the study of animal and vegetable colouring matter, and in later essays he dealt with such varied subjects as the microscopical structure of iron and steel, and the temperature of the water in estuaries.

SORERY, magic, enchantment, witchcraft; the use of supposed supernatural powers by the agency of evil spirits called forth by spells, incantations, &c., on the part of the magician, sorcerer or witch. The word meant originally divination by means of the casting or drawing of lots, and is derived from the O. Fr. sorcere, sorcer, a sorcerer, Med. Lat. sortiarius, one who practises divination by lots, sortes (see MAGIC, DIVINATION AND WITCHCRAFT).

SORDINO, a 13th-century Italian troubadour, born at Mantua, who is praised by Dante in the De vulgari eloquio, and in the Purgatorio made the type of patriotic pride. He is also the hero of a well-known poem by Robert Browning. The real Sordello, so far as we have authentic facts about his life, hardly seems to justify these idealizations, though he was the most famous of the Italian troubadours. About 1220 he appears at Florence in a tavern brawl; and in 1226, while at the court of Richard of Bonifazio at Verona, he abducts his master's wife, Curizza, at the instigation of her brother, Ezze- lino da Romano. The scandal resulted in his flight (1229) to Provence, where he seems to have been for some time. He entered the service of Charles of Anjou, and probably accompanied him (1265) on his Naples expedition; in 1266 he was a prisoner in Naples. The last documentary mention of him is in 1269, and he is supposed to have died in Provence. His didactic poem, L'Enseñamens d'onor, and his love songs and satirical pieces have little in common with Dante's presentation, but the invective against negligent princes which Dante puts into his mouth in the 7th canto of the Purgatorio, he originally paralleled in his Serenarz (1237) on the death of his patron Blacatz, where he invites the princes of Christendom to feed on the heart of the hero.

For Sordello's life and works see the edition of Cesare de Lollis (Halle, 1896); for Browning's poem see Stopford Brooke's "Browning (1902)."

SORDINO, SORDONI, SORDUN. Italian terms somewhat promiscuously applied by various writers (1) to contrivances for producing or muting wind, string and percussion instruments (Sordino); (2) to a family of obsolete wind instruments blown by means of a double reed (Sordoni or Sordun); (3) to a stringed instrument. To these must also be added the Sordellina or
Sorel, a kind of musette invented (see BAGPIPE) in Naples in the 17th century, and evidently named after its inventor. The term sordoni are comprised the dampers used with stringed instruments, such as the violin, and the dampers of keyboard instruments, all well known, and described with the instruments themselves. As a certain amount of misconception exists among certain non-musicians concerning the place of origin, it is well to clear up this particular point.

If the sordino used early in the 17th century had had this effect of raising the pitch, the fact would have been stated by such writers as Merseenne and Praetorius; it would, moreover, have rendered the mute useless with instruments on which no sort of compensation was possible. H. Domnich and J. Fröhlich, however, describe the sordino which leaves the pitch unaffected: it consisted of a hollow conical mouthpiece of say 9 cm. bore, the surface of the apex to allow the air to pass through and escape through a hole in the base. The bore of the instrument thus continued through the cone of the mute was the essential point, and the proportions to be maintained. Measurements published in the last century do not, however, dispel that doubt, of importance. Domnich expressly states that it was when Hampel substituted a plug of cotton-wood (therefore solid and providing a central passage for the escaping air) to the bore of the mute, that he discovered the sordino. Domnich's evidence is of value, for his father was a horn-player contemporary with Hampel, and he himself was the intimate friend and colleague of Michael Domnich, Celebrated German horn-player of the 18th century. In this particular instance the pitch of the instruments lies within a semi-tone of that of the contra-bass and bass of Praetorius.

SOREL, AGNES (c. 1422–1450), mistress of King Charles VII. of France, was born of a family of the lesser nobility at Fromenteau in Touraine. While still a girl she was attached to the household of Isabel of Sicily, wife of Charles, Duke of Anjou, the brother-in-law of Charles VII. From 1444 until her death in 1450 she was the acknowledged mistress of the king, the first woman to hold that semi-official position which was to be of so great importance in the subsequent history of the old régime. Her ascendency dated from the festivals at Nancy in 1444, the first brilliant court of Charles VII. Here her great beauty captivated the king, whose love for her remained constant until her death. She gave her wealth, castles and lands, and secured for her the state and distinction of a queen. This first public recognition of his mistress by a king of France scandalized the French Church, and when the Duke of Burgundy died in 1467, the sudden death from dysentery, shortly after the birth of her fourth child, was accordingly attributed to poison. Burgundian historians even openly accused the Dauphin, afterwards Louis XI., of her death, and later the enemies of Jacques Coeur, in their search for crimes to be brought against him, used this rumour to charge him with the one crime most likely to turn the ring against him. Her heart was buried in the abbey of Jumièges, her body in the collegiate church of Loches. Contemporary writers all bear witness to her extraordinary beauty, but no genuine portraits of her have come down to us.

Legend has made an entirely different character of this first official mistress of the French kings. The date of her birth was placed at about 1409, her liaison with the king dated from 1433. Then, so the story ran, she drew him from his indolence, continuing the work of Joan of Arc, both by benving the king to warlike enterprises—she did apparently induce him to take part personally in the conquest of Normandy—and by surrounding him with that band of wise advisers who really administered France during her ascendancy. Recent investigation has dispelled this romantic story showing that Charles VII. had not met her until ten years later than in the legend. Instead of being his sole good angel, she seems rather to have demoralized the king, who, hitherto chaste, henceforth gave himself up to courtesans. Yet she favoured the best advisers of the king, and at least in this deserved the gratitude of the realm. Pierre de Brézé seems especially to have used Agnes to gain his ascendancy over the king.

SOREL, ALBERT (1842–1906), French historian, was born at Honfleur on the 13th of August 1842. He was of a characteristically Norman type, and remained all his life a lover of his native province and its glories. His father, a rich manufacturer, would have liked him to succeed to the business, but his literary vocation prevailed. He went to live in Paris, where he studied law, and after a prolonged stay in Germany entered the Foreign Office (1866). He had strongly-developed literary and artistic tastes, was an enthusiastic musician, even composing a little, and wrote both verses and novels, which appeared a little later (La Grande Fédération, 1878–1879, in 4 vols.; La Duette en action, 1875); but he did not go much into society. He was anxious to know and understand present as well as past events, but he was above all things a student. In 1870 he was chosen as secretary by M. de Chauliard, who had been sent to Tours as a delegate in charge of the diplomatic side of the problem of national defence; in these affairs he proved himself a most valuable collaborator;
he was unremitting in his labours, full of finesse, good temper and excellent judgment, and at the same time so discreet that we can only guess at the part he played in these terrible crises. After the war, when Boutmy founded the *École libre des sciences politiques*, Sorel was appointed to teach diplomatic history (1872), a duty which he performed with striking success. Some of his courses have formed books: *Le Traité de Paris du 20 novembre 1871* (1873); *Histoire diplomatique de la guerre franco-allemande* (1875); we may also add the *Précis du droit des gens* which he published (1877) in collaboration with his colleague Théodore Funck-Brentano. In 1875 Sorel left the Foreign Office and became general secretary to the newly-created office of the *Présidence du sénat*. Here again, in a congenial position where, without heavy responsibilities, he could observe and review affairs, he performed valuable service, especially under the presidency of the duc d'Audiffred Pasquier, who was glad to avail himself of his advice in the most serious crises of internal politics. His duties led him, however, sufficient leisure to enable him to accomplish the great work of his life, *L'Europe et la révolution française*. His object was to do over again the work already done by Sybel, but from a less restricted point of view and with a clearer and more calm understanding of the chessboard of Europe. He spent almost thirty years in the preparation and composition of the eight volumes of this history (vol. i., 1885; vol. viii., 1904). For he was not merely a conscientious scholar; the analysis of the documents, mostly unpublished, on French diplomacy during the first years of the Revolution, which he published in the *Revue historique* (vol. v.–vii., x.–xii.), shows what scrupulous care he read the innumerable despatches which passed in his hands, and the light which his notice shed on all things, an artist. He drew men from the point of view of a psychologist as much as of a historian, observing them in their surroundings and being interested in showing how greatly they are slaves to the fatality of history. It was this fatality which led the rashest of the Conventionals to resume the tradition of the Ancien Régime, and caused the revolutionary propaganda to end in a system of alliances and annexations which carried on the work of Louis XIV. This view is certainly suggestive, but incomplete; it is largely true when applied to the men of the Revolution, inexperienced or mediocre as they were, and incompetent to develop the enormous enterprises of Napoleon I. In the earlier volumes we are readily dominated by the grandeur and relentless logic of the drama which the author unfolds before our eyes; in the latter ones we begin to make some reservations; but on the whole the work is so complete and so powerfully constructed that it commands our admiration. Side by side with this great general work, Sorel undertook various detailed studies more or less directly bearing on his subject. In *La Question d' Orient au XVIIe siècle, les origines de la triple alliance* (1879), he shows how the partition of Poland on the one hand reversed the traditional policy of France in eastern Europe, and on the other hand contributed towards the salvation of republican France in 1793. In the *Grands écrivains* series he was responsible for *Montesquieu* (1887) and *Mme de Staël* (1881); the portrait which he draws of Montesquiou is all the more vivid for the intellectual affinities which existed between him and the author of the *Lettres persanes* and the *Esprit des lois*. Later, in *Bonaparte et Hoche en 1797*, he produced a critical comparison which is one of his most finished works (1890); and in the *Recueil des instructions données aux ambassadeurs* he prepared vol. i. dealing with Austria (1884). Most of the articles which he contributed to the *Temps* newspaper have been collected into volumes: *Essais d'histoire et de critique* (1883), *Lectures historiques* (1894), *Nouveaux essais d'histoire et de critique* (1898), *Études de littérature et d'histoire* (1901); in these are to be found a great deal of information and of ideas not only about political men of the last two centuries, but also about certain literary men and artists of Normandy. Honours came to him in abundance, as an eminent writer and not as a public official. He was elected a member of the Académie des sciences morales et politiques (December 18, 1880) on the death of Fustel de Coulanges, and of the Académie française (1894) on the death of Taine. His speeches on his two illustrious predecessors show how keenly sensible he was of beauty, and how unbiased was his judgment, even in the case of those whom he most esteemed and loved. He had just obtained the great Prix Osiris of a hundred thousand francs, conferred for the first time by the Institut de France, when he was stricken with his last illness and died at Paris on the 29th of June 1906.

**SOREL, CHARLES, SIEUR DE SOUVIGNY** (1597–1674), French novelist and miscellaneous writer, was born in Paris about 1597. Very little is known of his life except that in 1615 he was historiographer of France. He wrote on science, history and religion, but is only remembered by his novels. He tried to destroy the vogue of the pastoral romance by writing a novel of adventure, the *Histoire comique de Fransoin* (1622). The episodical adventures of Fransoin found many readers, who nevertheless reserved their admiration for the *Astrée* it was intended to ridicule. Sorel decided to make his intention unmistakable, and in *Le Berger extravagant* (3 vols., 1627) he wrote a burlesque, in which a Parisian shop-boy, his head turned by sentiment, chooses an unprepossessing mistress and starts life as a shepherd with a dozen sheep on the banks of the Seine. Sorel did not succeed in founding the novel of character, and what he accomplished was more in the direction of farce, but he struck a shrewd blow at romance. Among his other works are *Polyandre* (1648) and *La Connaissance des bons livres* (1673). He died in Paris on the 8th of March 1674.

**SOREL, a town and port of entry of Quebec, Canada, capital of Richelieu county, 42 m. N.E. of Montreal, at the confluence of the Richelieu and St Lawrence rivers. Pop. (1901), 7057. It is on the Grand Trunk and the Quebec Southern railways, and is a port of call for the Montreal and Quebec river steamers. It contains iron and leather manufactories, and shipbuilding is carried on. It occupies the site of a fort built in 1665 by A. de Tracy to guard the route by way of the Richelieu to Lake Champlain and the Hudson, and is named after the first commandant of the garrison.**

**SORGHUM, a genus of grasses belonging to the tribe Andropogoneae, and including one of the most important tropical grains, *Sorghum vulgare*, great millet, Indian millet or Guinea corn. In India it is known as *jawari* (Hindustani), *jawari* (Bengali), *cholam* (Tamil), and *jonna* (Telugu), and in the West Indies as Negro or Guinea Corn. It is a strong grass, growing to a height of from 4 to 8 ft.; the leaves are sheathing, solitary, and about 2 ft. broad and 2 ft. in length; the panicles are contracted and dense, and the grains, which are enclosed in husks and protected by awns, are round, hard, smooth, shining, brownish-red, and somewhat larger than mustard seeds. The plant is cultivated in various parts of India and other countries of Asia, in the United States, and in the south of Europe. Its curms and leaves affixed excellent fodder for cattle and the grain, of which the yield in favourable situations is upwards of a hundredfold, is used for the same purposes as maize, rice, corn and other cereals.**

Speaking of its cultivation, Eduard Hackel (in his article on "Grasses" in *Die natürlichen Pflanzenfamilien*) says the culture of Sorghum probably had its origin in Africa, where a variety...
known as durra is now cultivated over the entire continent, and has become the most important cereal; the natives also chew the stem, which contains sugar. In Europe it is raised less for bread than for mechanical purposes; the panicles are made into the so-called rice-brooms and into brushes. In Germany it is occasionally raised for green fodder. From the fruit the Kaffirs make an alcoholic drink, Tialva, and the negroes one known as Merisa. Allied species are S. bicolor, much valued in India as a forage-plant, and S. saccharatum, commonly called sorghum or Chinese sugar-cane, which is extensively cultivated in China, North India and Africa. The latter species is grown in America chiefly for the manufacture of molasses from its juice, and in France as a source of alcohol.

A full account of the cultivation and use of the species in India will be found in Sir G. Watt’s Dictionary of the Economic Products of India (1893).

SORIA, a province of Spain, formed in 1833 of districts belonging to Old Castile, and bounded on the N. by Logroño, E. by Saragossa, S. by Guadalajara and W. by Segovia and Burgos. Pop. (1900), 150,662; area, 3983 sq. m. Soria is a bleak and lofty region, bounded on three sides by mountains. A range of sierras culminating in the peaks of Urbion (7385 ft.) and Cebronedora (7135 ft.) on the north, and the great Sierra de Monzón (7097 ft.) on the east, separate the valley of the Ónigo (Douro) from that of the Ebro, while on the south it is divided from the valley of the Távora by a continuation of the Sierra Guadarrama. Almost the whole of the province belongs to the region watered by the Duero and its affluents. This river rises among the southern slopes of Urbion and traverses the province in a circuitous course, first to the south and then to the west. The other rivers are mostly affluents of the Duero, but a few of the tributaries of the Ebro have their sources within the limits of the province. The soil is not remarkable for fertility; a large proportion of the area being occupied with barren mountains, which take up 2070 sq. m. The population of the province is very few for its great area. There are, however, in some places extensive forests of pine, oak and beech; while in others there are large tracts of pasture land, on which numbers of cattle, sheep and swine are reared. Grain and vegetables are raised, but neither of very good quality nor in sufficient quantities to supply the wants of the population. The climate is cold and dry, and the scenery grand, but austere. Most of the people are employed in farming and rearing cattle; but the cutting and sawing of timber and the preparation of charcoal also occupy a considerable number. There is a great want of roads; and on the east, separate the valley of the Tiéno river, commerce is consequently very limited. Fine wool was formerly produced; but the only important articles of trade at present are timber, salt, asphalt, leather and cheese, which are sent to Madrid and Aragon. Salt and asphalt are the only minerals worked, though others are known to exist. The capital, Soria, is described below. The only other town with more than 3500 inhabitants is ElBurgo de Osma (3500), an episcopal see. Between 1887 and 1900 the population decreased by nearly 7000; its density in the last-named year was 37.7 per sq. m., or lower than that of any other Spanish province except La Rioja (37.0). The principal depopulation part of the district is due to the stagnation of industry, and the attraction of emigrants to large towns outside the province.

SORIA, the capital of the Spanish province of Soria; on the right bank of the river Duero (Douro), 155 m. N.E. of Madrid by the Madrid-Alcunza-Soria railway. Pop. (1900), 7151. Soria has a provincial institute, schools for teachers of both sexes, many primary schools, savings banks, two hospitals, barracks, a theatre and a bull-ring. The churches of Santo Domingo and San Nicolás, the cloisters of the convent of San Juan, and several other ecclesiastical buildings are fine specimens of Romanesque work of the 12th and 13th centuries. Near the Duero are the ruins of the old citadel, and in many places the remains of the 13th century walls of the city are yet standing. The more modern streets are clean and well paved. The bridge across the Duero is a massive structure which formerly had a tower in the centre. The population is chiefly agricultural; but there are also flour mills, tanneries, potteries, &c., and some trade in timber, wool and fruit is carried on. The Iberian and Castilian city of Numantia, captured in 133 B.C. by the Romans, after a long and heroic resistance, was set on fire by them. On, a hill overlooking the confluence of the small river Tera with the Duero.

SOROKI, a town of south Russia, in the government of Bessarabia, 81 m. N.N.W. of Kishinev, in a narrow ravine on the right bank of the Dniester. Pop. (1900), 25,523, half of whom were Jews. It is an important river port for the export of corn, wool, fruit, wine and cattle. Formerly it was the old Genoese colony of Olchonlia, and has still the ruins of a 13th-century Genoese castle. In the 15th century the Moldavians erected here a fort, which the Poles took in 1708. After the battle of Parnawa Peter the Great captured the place in 1711, but it was returned to the Turks, and was only definitely annexed to Russia in 1812. (M. H. S.)

SOROLLA Y BASTIDA, JOAQUIN (1863- ), Spanish painter, was born in Valencia, and received his art education first in his native town and under F. Pradilla, and then in Italy and Paris. His first striking success he achieved with “Another Margaret,” which was awarded a gold medal in Madrid and was bought for the St Louis Gallery. He soon rose to general fame and became the acknowledged head of the modern Spanish school of painting. A few years before his death, which occurred at Guadarrama, he was much admired at the Paris Salon and was acquired by the state for the Luxembourg Museum. His visit at the Paris Universal Exposition of 1900 won him a medal of honour and his nomination as Knight of the Legion of Honour. A special exhibition of his works—figure subjects, landscapes and portraits—at the Georges Petit Gallery in Paris in 1906 eclipsed all his earlier successes and led to his appointment as Officer of the Legion of Honour. He is represented at the Berlin National Gallery, at the Venice and Madrid Museums, and in many private collections in Europe and America, especially in Buenos Aires. He has painted portraits of Alfredo Zuloaga, Peter the Great, Eugénie of Spain, and a magnificent portrait group of the family of Don Aureliano de Beruete. Three of his works were shown in London at the Spanish Exhibition, Guildhall, 1901.

SORREL, Rumex acetosa, a member of the natural order Polygonaceae, a hardy perennial, native to Britain and found throughout the north temperate zone. The leaves are used in soups, salads and souces. Sorrel grows freely in any good garden soil, and is increased by dividing the roots during the early part of spring. They should be planted in rows 15 to 18 in. apart. The leaves, when fully grown, are gathered singly. The common garden sorrel is much superior to the wild plant; but the Belleville, which is the kind generally cultivated near Paris, is still better, its leaves being larger and not so acid. The Blistered-leaved, which has large leaves with a blistered surface, has the advantage of being slow in running to seed. French Sorrel (Rumex scutatus) is a hardy perennial, distributed through Europe but not native in Britain, with densely-branched trailing stems. The leaves are roundish, heart-shaped and glaucous; they are more acid than those of the common sorrel.

SORRENTO, ane. Surrentium, q.v.), a city of Campania, Italy, in the province of Naples, 10 m. by electric tramway (along the highroad) S.W. from Castellamare di Stabia, and served also by steamer from Naples (16 m.). Pop. (1901), 6849 (town); 8832 (commune). It stands on cliffs about 160 ft. above sea-level on the north side of the peninsula that separates the Bay of Naples from the Bay of Salerno. Sorrento contains only a few ancient remains, and its present prosperity depends mainly on its reputation as a place of resort both in winter and in summer, its northerly aspect rendering it comparatively cool. Its climate is delightful and healthy, and it is situated amid picturesque coastal scenery. The chief local industries are the inlaying of wood, silk and lace-making and straw-plaiting, and the growing of oranges and lemons. In ancient times the Surrentine wines had a great repute.

In 1558 the corsair Pialy attacked the town and carried off two thousand prisoners. It was at Sorrento that Bernardo Tasso wrote his Amadigi; and Torquato Tasso, to whom a marble
SOSIGENES. Greek astronomer and mathematician, probably of Alexandria, flourished in the 1st century B.C. According to Pliny (Nat. Hist. xlviii. 23), he was employed by Julius Caesar in the reform of the Roman calendar (46 B.C.), and wrote three treatises, of which a conscientiously correct version from fragments of Pliny (ii. 8) it is inferred that Sosigenes maintained the doctrine of the motion of Mercury round the sun, which is referred to by his contemporary Ciceron, and was also held by the Egyptians.

The astronomer is to be distinguished from the Peripatetic philosopher of the same name, who lived at the end of the 2nd century A.D. and wrote a commentary on Aristotle's De caelo (the subject is fully discussed by T. H. Martin, "Sur deux Sophêmes," in Annales de la fac. des lettres de Bordeaux, i. 1879).

SOSTHES (c. 280 B.C.), Greek tragic poet, of Alexandria Troas, a member of the Alexandrian "pleiad." He must have resided at some time in Athens, since Diogenes Laërtius tells us (vii. 5, 4) that he attacked the Stoic Cleants in the stage, and was hissed off by the audience. As Suidas also calls him a Syracusan, it is conjectured that he belonged to the literary circle of the court of Hiero II. According to an epitaph of Stobaeus, which is extant in the Greek Anthology (Anth. Pal. vii. 707) he restored the satyrical drama in its original form. A considerable fragment is extant of his pastoral play Daphnis or Lytyerses, in which the Sicilian shepherd, in search of his love Pimplea, is brought into connexion with the Phrygian reaper, son of Midas, who slew all who unsuccessfully competed with him in reaping his corn. Heracles came to the aid of Daphnis and slew Lytyerses.

See O. Crusius s.v. Lytyerses in Roscher's Lexikon der griechischen und römischen Mythologie. The fragment of twenty-four lines in Nauck's Tragicorum Graecorum Fragmenta apparently contains the beginning of the drama. Two lines from the Athlithus (probably the traditional first king of Elis, father of Endymion) are quoted by Stobaeus (Flor. iv. 55). See also S. Jones, "The Fragments of Stobaeus," in the Rev. of reviews, vol. xxxi, 1882.

SOTADES, Greek satirist, of Maronea in Thrace (or of Crete), chief representative of the writers of coarse satirical poems, called κώμαδοι, composed in the Ionic dialect and in a metre named after him "sotadic." He lived in Alexandria during the reign of Ptolemy II. Philadelphus (282-247 B.C.). For a violent attack on the king, on the occasion of his marriage to his own sister Arsinoë, Sotades was imprisoned, but escaped to the island of Cy caurus, where he was afterwards captured by Ptole- cius, Ptolemy's admiral, shut up in a leaden chest, and thrown into the sea (Athenaeus xiv. p. 620; Plutarch, De educatione perier. c. 118, 2). See also Stobaeus (Fragmenta, iv. 52). See also Stobaeus (Fragmenta, iv. 52). See also Stobaeus (Fragmenta, iv. 52).

Only a few genuine fragments of Sotades have been preserved (see J. G. Hermann, Elementa doctrinae metricae, 1816); those in Stobaeus are generally considered spurious. Ennius translated some of this kind of poems, included in his book of satires, under the name of Sota.

SOTER, pope from about 167 to 174. He wrote to the Church of Corinth and sent it aid. His letter is mentioned in the reply given by Dionysius, bishop of Corinth, and Harnack thinks it can be identified with the second so-called epistle of Clement to the Corinthians.

SOTHEBY, WILLIAM (1757-1833), English author, was born in London on the 9th of November 1757. He was educated at Harrow, and subsequently procured a commission in a cavalry regiment. In 1780 he retired from the army on his marriage and devoted himself to literature, becoming a prominent member of the London literary society. His ample means enabled him to play the part of patron to many struggling authors, and his friends included Scott, Byron, Wordsworth, Coleridge, Southey, Hallam and Tom Moore. He himself soon acquired a considerable reputation as a translator, his verse translation of Virgil's Georgics (1800) being specially praised by contemporary critics, while in later life he published translations of the Iliad and Odyssey. He also wrote several historical tragedies for the stage, of which one acted, and some poems. He died on the 30th of December 1833.

SOTHERN, EDWARD MOKE (1856-1881), English actor, was born in Liverpool on the 1st of April 1826, the son of a merchant. He began acting as an amateur, and in 1859 drifted into a professional engagement with a dramatic company at St Heliers in Jersey, where he appeared as Claude Melnotte in Bulwer Lytton's Lady of Lyons. Between then and 1858 he played in various companies without particular success, in Birmingham and in America, where he went in 1852. On the 12th of May 1858 Tom Taylor's Our American Cousin, a play of no special merit, was brought out in New York, with Southem in the small part of Lord Dundreary, a caricature of an English nobleman. He gradually worked up the humour of this part so that it became the central figure of the play. In 1861, when it was produced at the Haymarket Theatre, in London, he made such a hit that the piece ran for nearly five hundred nights: "Dundreary whiskers" became the fashion, and Dundreary this, that or the other made its appearance on every side. At various times Sothern revived the character, which retained its popularity in spite of all the extravagances to which it developed its amusing features; and his name will always be famous in connexion with this rôle. In T. W. Robertson's David Garrick (1864) he again had a great success, his acting in the title-part, was more treated, but less celebrated, than the comic one. His popularity also sprang from his interpretation of Sam Slingshy in Oxenford's Brother Sam (1865). Sothern was a born comedian, and off the stage had a passion for practical joking that amounted almost to a mania. His house in Kensington was a resort for people of fashion, and he was as much a favourite in America as in the United Kingdom. He died in London on the 21st of January 1881.

Sothern had three sons, all actors, the second of them, EDWARD H. SOTHERN (b. 1859), being prominent on the American stage.

SOTHIC PERIOD, in ancient Egyptian chronology, the period in which the year of 365 days circled in succession through all the seasons. The tropical year, determined as it was in Egypt by the heliacal rising of Sirius (Sothis), was almost exactly the Julian year of precisely 365.25 days (differing from the true solar year, which was 11 minutes less than this). The sothic period was thus 1461 years.

See EGYPT, ANCIENT, § F. "Chronology."

SOTO, JERONIMO [FERNANDO, OR HERNANDO] DE (1492-1542), Spanish captain and explorer, often, though wrongly, called the discoverer of the Mississippi (first sighted by Alonso de Pineda in 1510), was born at Córdoba, in Granada, of an impoverished family of good position, and was embarked on the favour of Pedro de Ávila for the means of pursuing his studies at the university. In 1519 he accompanied Ávila on his second expedition to Darien. In 1528 he explored the coast of Guatemala and Yucatan, and in 1532 he led 300 volunteers to reinforce Pizarro in Peru. He played a prominent part in the conquest of the Incas' kingdom (helping to seize and guard the person of Atahuallpa, discovering a pass through the mountains to Cuzco, &c.), and returned to Spain with a fortune of 180,000 ducats, which enabled him to marry the daughter of his old patron Ávila, and to maintain the state of a nobleman. Excited by the reports of Alvaro Nuñez (Cabeza de Vaca) and others as to the wealth of Florida (a term then commonly used in a much wider extension than subsequently), he sold great part of his property, gathered a force of 620 foot and 123 horse, armed four ships, and obtained from Charles V. a commission as "adelantado of the Lands of Florida" and governor of Cuba. Sailing from San Lucar in April 1538, he first went to Havana, his advanced base of operations; starting thence on the 12th of May 1539 he landed in the same month in Santo Bautista, on the west coast of the present state of Florida. For nearly four years he led his men in fruitless search of gold hither and thither over the south-east of the North
American continent. His exact route is often doubtful; but it seems to have passed north into Georgia as far as 35° N., then south to the neighbourhood of Mobile, and finally north-west towards the Mississippi. This river was reached early in 1541, and the following winter was spent on the Ouachita, in modern Arkansas and Louisiana, west of the Mississippi. As they were returning in 1542 along the Mississippi, De Soto died (either in May or June; the 25th of June is perhaps the true date), and his body was sunk in its waters. Failing in an attempt to push westwards again, De Soto’s men, under Luis Moscoso de Larvardo, descended the Mississippi to the sea in nineteen days from a point close to the junction of the Arkansas and the great river, and thence coasted along the Gulf of Mexico to Panuco.

Of this unfortunate expedition three very different narratives are extant, of seemingly independent origin. The first was published in 1557 at Evora, and professes to be the work of a Portuguese gentleman of Elvas, who had accompanied the expedition: Relatam perdeida dos trabalhos do governador d’or Fereduo d’Soulou & certos fidalgos portugueses passaram no desbrimate da Provincia do Florida. Agora semaesta feita por ha fidalo Delsas, An English translation was published by Halkytt in 1609 (reprinted from the 1611 edition by the Hakluyt Society [London, 1851]), and another by an anonymous translator in 1686, the latter being based on a French version by Citiri de la Guette [Paris, 1548]. The second narrative is the famous history of Florida by the Inca, Garcilasso de la Vega, who obtained his information from a Spanish cavalier engaged in the enterprise; it was completed in 1551, first appeared at Lisbon in 1555 under the title of La Florida Mattaca, and has since passed through many editions in various languages.

The third is a report presented to Charles V. of Spain in his Council of the Indies in 1544, by Luis Hernandez de Bledma, who had accompanied De Soto’s expedition. It is in the form of a translation of the words of Ternaux-Comans’ “Recueil de pieces sur la Floride” in the Historical Collections of Louisiana [Philadelphia, 1850] and in W. B. Rye’s reprint for the Hakluyt Society of Hakluyt’s translation of the Portuguese narrative (The Discovery and Conquest of Terra Florida, London, 1851). See also Bancroft’s History of the United States, vol. 1; J. H. Muir’s Inca Empire and the Bernal Diaz del Castillo’s Relacion de las cosas de Nueva Espana (Baltimore, 1829); Albert Gallatin, “Synopsis of the Indian Tribes” in Americae antiquae (Baltimore, 1836); E. G. Bourne (ed.), Narratives of the Career of Hernando de Soto in the Conquest of Florida (2 vols., New York, 1852); J. W. Moore, History of the Discovery and Settlement of the Valley of the Mississippi (New York, 1846, 2 vols.).

SOU (O. Fr. sol, Lat. solidus, sc. nummum), the name of the bronze 5-centime French coin, corresponding to the English “halfpenny.” It is still colloquially used in France in reckoning, and the franc, 2 and 5-franc pieces are known as pièce de vingt, pièce de dix and pièce de cinq. The word solidus was a silver coin, first struck c. A.D. 312 by Constantine to take the place of a aureus. In the Eastern Empire this gold coin was the standard down to 1453, and, as the “bezant,” circulated from Portugal to the Indies. In the West after Pippin gold coinage ceased and the solidus in silver became the standard, one pound of silver making 22 sols (soli) and 244 deniers (denarii). Under Charlemagne one pound of silver = 20 sols = 244 deniers. The livre (libra), the sol and the denier formed the universal money of account throughout France until the Revolution; and the latter left their mark on the English money symbols £ t.s. d., for pounds, shillings and pence.

SOUBISE, BENJAMIN DE ROHAN, DUC DE (? 1580-1642), Huguenot leader, younger brother of Henri de Rohan, inherited his title through his mother Catherine de Parthenay. He served his apprenticeship as a soldier under Prince Maurice of Orange-Nassau in the Low Countries. In the religious wars from 1621 onwards his elder brother chiefly commanded on land and in the south, Soubise in the west and along the sea-coast. His exploits in the conflict have been sympathetically related by his brother, who if he was not quite an impartial witness, was one of the best military observers of his time. Soubise’s chief exploit was a singularly bold and well-conducted attack (in 1625) on the Royalist fleet in the river Blavet (which included the cutting of a boom in the face of superior numbers) and the occupation of Olérion. He commanded at Rochelle during the famous siege, and (if we may believe his brother) the failure of the defence and of the English attack on Rhé was mainly due to the alternate obstinacy of the townsfolk and the English commanders in refusing to listen to Soubise’s advice. When surrender became inevitable he fled to England, which he had previously visited in quest of succour. He died in 1642 in London. The Soubise title afterwards served as the chief second designation (not for heirs apparent, but for the chief collateral branch for the time being) of the house of Rohan-Chabot.

The name Soubise appears again in the military history of France in the person of CHARLES DE ROHAN, PRINCE DE SOUBISE (1715-1787), peer and marshal of France, the grandson of the princesse de Soubise, who is known to history as one of the mistresses of Louis XIV. He accompanied Louis XV. in the campaign of 1745, and obtained high military rank, which he owed more to his courtiers than to his generalship. Soon after the beginning of the Seven Years’ War, through the influence of Mme de Pompadour, he was put in command of a corps of 24,000 men, and in November 1757 he sustained the crushing defeat of Rossbach. He was more fortunate, however, in his later military career, and continued in the service until the general peace of 1763, after which he lived the life of an ordinary courtier and man of fashion in Paris, dying on the 4th of July 1787.

SOUTH, JOSEPH, COUNT (1760-1837), French soldier, was born at Lhurersac on the 30th of April 1760, and served in the French army as a private from 1782 to 1790. In 1792, having shown himself active in the cause of the Revolution, he was elected commandant of a volunteer battalion, and by 1793 he had risen to the rank of general of division. He served with credit under Pichegru in Holland (1793), but in 1799 fell into disgrace on suspicion of being concerned in Royalist intrigues. He was reinstated in 1800 and served under Moreau in the Danube campaign of that year. During the Consulate he appears to have been involved in conspiracies, and along with his old commanders Moreau and Pichegru was disgraced for alleged participation in that of Georges Cadoudal. He regained his rank, however, in 1809, took a notable part in Gouvion St. Cyr’s operations in Catalonia, and won the title of count by his conduct at the action of Vich, in which he was wounded. In 1812 Marshal Masséna, in declining the command of Marmont’s army which had just been defeated at Salamanca, recommended Soubise for the post. The latter was thus lifted against Wellington, and by his skillful manoeuvres drove the English general back from Burgos and regained the ground lost at Salamanca. In 1813 he distinguished himself again at Lützen and at Leipzig (when he was wounded). At the fall of the First Empire he deserted the emperor, and having suffered for the Royalist cause was well received by Louis XVIII., who gave him high commands. These Souham lost at the return of Napoleon and regained after the Second Restoration. He retired in 1832, and died on the 28th of April 1837.

SOULLAY, JOSEPHIN [JOSEPH MAKIE] (1815-1891), French poet, son of a Lyons merchant of Genoese origin (Solaril), was born on the 23rd of February 1815. He entered a line regiment when he was sixteen, serving for five years. He was chef de bureau in the prefecture of the Rhône from 1845 to 1867, and in 1868 he became librarian to the Palais des arts in his native town. He died at Lyons on the 28th of March 1891. His works include À travers champs (1837); Les Cinq cordes du luth (1838); Les Éphéméres (two series, 1846 and 1857); Sonnets humoristiques (1862); Les Figulines (1862); Pendant l’invansion (1871); Les Rimes trompées (1877); Jeux divins (1882), and two comedies. His Oeuvres poétiques were collected in three volumes (1875-1883). “His Sonnets humoristiques attracted great attention, and charmed their readers by the mixture of gaiety and tragedy which his countryman, his friend, and his patron, had put into his art, especially in the sonnet, won him the title of the “Benvenuto of rhyme.””

See also Paul Mariéton, Souilly and la Pléiade lyonnaise (1884).

SOULT, NICOLAS JEAN DE DIEU, Duke of Dalmatia (1769-1851), marshal of France, was born at Saint-Amans-la-Bastide (now in department of the Tarn) on the 29th of March 1769, and was the son of a country notary at that place. He was fairly well educated, and intended for the bar, but his father’s death when
he was still a boy made it necessary for him to seek his fortune, and he enlisted as a private in the French infantry in 1785. His superior education ensured his promotion to the rank of sergeant after six years' service, and in July 1791 he became instructor to the first battalion of volunteers of the Bas-Rhin. He served with his battalion in 1792. By 1794 he was adjutant-general (with the rank of chef de bataille). After the battle of Fleurus, in which he greatly distinguished himself for coolness, he was promoted general of brigade by the representatives on mission. For the next five years he was constantly employed in Germany under Jourdan, Moreau, Kléber and Lefebvre, and in 1799 he was promoted general of division and ordered to proceed to Switzerland. It was at this time that he laid the foundations of his military fame, and he particularly distinguished himself in Masséna's great Swiss campaign, and especially at the battle of Zürich. He accompanied Masséna to Genoa, and acted as his principal lieutenant throughout the protracted siege of that city, during which he operated with a detached force without the walls, and after many successful actions he was wounded and taken prisoner at Monte Cettro on the 13th of April 1800. The victory of Marengo restoring his freedom, he received the command of the southern part of the kingdom of Naples, and in 1802 he was appointed one of the four generals commanding the consular guard. Though he was one of those generals who had served under Moreau, and who therefore, as a rule, disdained and despised Napoleon, Soult had the wisdom to show his devotion to the ruling power; in consequence he was in August 1803 appointed to the command-in-chief of the camp of Boulogne, and in 1807 became one of the field marshals of France. He commanded a corps in the advance on Ulm, and at Austerlitz (q.v.) he led the decisive attack on the allied centre. He played a great part in all the famous battles of the Grande Armée, except the battle of Friedland (on the day of which he chose his way into Königsberg), and after the conclusion of the peace of Tilsit he returned to France and was created (1808) duke of Dalmatia. In the following year he was appointed to the command of the II. corps of the army with which Napoleon intended to conquer Spain, and after winning the battle of Gamonal he was detailed by the emperor to pursue Sir John Moore, whom he only caught up at Corunna.

For the next four years Soult remained in Spain, and his military history is that of the Peninsular War (q.v.). In 1809, after his defeat by Sir John Moore, he invaded Portugal and took Oporto, but, busying himself with the political settlement of his conquests in the French interests and, as he hoped, for his own ultimate benefit as a possible candidate for the throne, he neglected to advance upon Lisbon, and was eventually dislodged from Oporto by Sir Arthur Wellesley, making a painful and almost disastrous retreat over the mountains. After the battle of Talavera he was made chief of staff of the French troops in Spain with extended powers, and on the 10th of November 1809 won the great victory of Ocaña. In 1810 he invaded Andalusia, which he speedily reduced, with the exception of Cadiz. In 1811 he marched north into Estremadura, and took Badajoz, and when the Anglo-Portuguese army laid siege to it he marched to its rescue, and fought the famous battle of Albuera (May 16). In 1812, however, he was obliged, after Wellington's great victory of Salamanca, to evacuate Andalusia, and was soon after recalled from Spain at the request of Joseph Bonaparte, with whom, as with the other marshals, he had always disagreed. In March 1813 he assumed the command of the IV. corps of the Grande Armée and commanded the centre at Lützen and Bautzen, but he was soon sent, with unlimited powers, to the south of France to repair the damage done by the great defeat of Vittoria. His campaign there is the finest proof of his genius as a general, although he was repeatedly defeated by the English under Wellington, for his soldiers were but raw conscripts, while those of Wellington were the veterans of many campaigns. Such was the military career of Marshal Soult. His political career was by no means so creditable, and it has been said of him that he had character only in front of the enemy. After the first abdication of Napoleon he declared himself a Royalist, received the order of St Louis, and acted as minister for war from the 3rd of December 1814 to the 11th of March 1815. When Napoleon returned from Elba Soult at once declared himself a Bonapartist, was made a peer of France and acted as major-general (chief of staff) to the emperor in the campaign of Waterloo, in which rôle he distinguished himself far less than he had done as commander of an over-matched army. At the Second Restoration he was exiled, but not for long, for in 1819 he was recalled and in 1820 again made a marshal of France. He once more tried to show himself a fervent Royalist and was made a peer in 1827. After the revolution of 1830 he made out that he was a partisan of Louis Philippe, who welcomed his adhesion and revived for him the title of marshal-general. He served as minister for war from 1830 to 1834, as ambassador extraordinary to London for the coronation of Queen Victoria in 1838, and again as minister for war from 1840 to 1844. In 1848, when Louis Philippe was overthrown, Soult again declared himself a republican. He died at his castle of Sourdberg, near his birthplace, on the 26th of November 1851. Soult himself wrote, but little. He published a memoir justifying his adhesion to Napoleon during the Hundred Days, and his notes and journals were arranged by his son Napoleon Hector (1801-1857), who published the first part (Mémoires du maréchal-général Soul) in 1854. Le Noble's Mémoires sur les opérations des Français en Galicie are supposed to have been written from Soult papers.

See A. Sellié, Vie politique du maréchal Soul (Paris, 1834); A. de C.-E. Le Maréchal Soul (Paris, 1849); A. Combiez, Histoire anecdote du maréchal Soul (Castres, 1860).

SOUMET, ALEXANDRE (1788-1845), French poet, was born on the 8th of February 1788 at Castelnau-d'audary, department of Aude. His father wished him to enter the army, but an early-developed love of poetry turned the boy's ambition in other directions. He was an admirer of Klopstock and Schiller, then little known in France, and reproached Mme de Staël with lack of enthusiasm for her subject in De l'Allemagne. Soumet came to Paris in 1819, and some poems in honour of Napoleon secured his nomination as auditor of the Conseil d'Etat. His well-known elegy La Paure fille appeared in 1814, and two successful tragedies produced in 1822, Clytemnestre and Soult, secured his admission to the Academy in 1824. Jeanne d'Arc (1825) aroused great enthusiasm, and was the best of his plays. Among his other pieces Élisabeth de France (1828), a weak imitation of Schiller's Don Carlos, may be noted, but Soumet's real bent was towards epic poetry. His most considerable work is a poem inspired by Klopstock, La Divine épopee, which describes the descent of Christ into Hades. Under Louis XVIII. he became librarian of Saint-Cloud, and subsequently was transferred to Rambouillet and to Compiègne. He died on the 30th of March 1845, leaving an unfinished epic on Jeanne d'Arc. His daughter Gabrielle (Mme Beauvain d'Altenheim) had collaborated with him in some of his later works.

SOUND, a subjectively the sense impression of the organ of

1 "Sound" is an interesting example of the numerous homonymous words in the English language. In the sense in which it is treated in this article it appears in Middle English as sound, and comes through Fr. son from Lat. sonus; the d is a mere addition, as in 'a word of a musical term' (inner, homeward bound) for the earlier 'boun,' to make ready. In the adjectival meaning, healthy, perfect, complete, chiefly used of a deep undisrupted sleep, or of a well-based argument or doctrine, or of a person who has a mind free from sin or sinfulness, or of the senses, is used in O. Eng. sound, and also in Ger. gesund, Du. gezond. It is probably cognate with the Lat. sonus, whence the Eng. sane, insanity, sanitation, &c. Lastly, there is a group of words which are usually declined to treat as being all forms of the word which in O. Eng. is sund, meaning "swimming." These words are for (1) the swim-bladder of a fish; (2) a narrow stretch of water between an inland sea and the sea by which it is connected; and the Lolland, Ægden, &c. Sound, This, below; (3) to test or measure the depth of anything, particularly the depth of water in lakes or seas (see SOUNDING, below). As a substantive the term is used of a surgical instrument for the introduction of a wound, a term also used by surgeons. In all these senses the word has frequently been referred to Lat. sub unda, under the water; and Fr. sombre, gloomy, possibly from sub umbra, beneath the shade, is given as a parallel.
hearing, and objectively the vibratory motion which produces the sensation of sound. The physiological and psychical aspects of sound are treated in the article Hearing. In this article, which covers the science of Acoustics, we shall consider only the physical aspect of sound, that is, the physical phenomena outside ourselves which excite our sense of hearing. We shall discuss the disturbance which is propagated from the source to the ear, and which produces sound, and the modes in which various sources vibrate and give rise to the disturbance.

Sound is due to Vibrations.—We may easily satisfy ourselves that, in every instance in which the sensation of sound is excited, the body whence the sound proceeds must have been thrown, by a blow or other means, into a state of agitation or tremor, implying the existence of a vibratory motion, or motion to and fro, of the particles of which it consists.

Thus, if a common glass-jar be struck so as to yield an audible sound, the existence of a motion of this kind may be felt by the finger lightly applied to the edge of the glass; and, on increasing the pressure so as to destroy this motion the sound forthwith ceases. Small pieces of cork put in the jar will be found to dance about during the continuance of the sound; water or spirits of wine poured into the glass will, under the same circumstances, exhibit a ruffled surface. The experiment is usually performed, in a more striking manner, with a bell-jar and a number of small light wooden balls suspended by silk strings to a fixed frame above the jar, so as to be just in contact with the widest part of the glass. On drawing a violin bow across the edge, the pendulums are thrown off to a considerable distance, and falling back are again repelled, and so on.

It is also in many cases possible to follow with the eye the motions of the particles of the sounding body, as, for instance, in the case of a violin string or any string fixed at both ends, when the string will appear through the persistence of visual sensation to occupy at once all the positions which it successively assumes during the continuance of a motion

Sound takes Time to Travel.—If we watch a man breaking stones by the roadside some distance away, we can see the hammer fall before we hear the blow. We see the steam issuing from the whistle of a distant engine long before we hear the sound. We see lightning before we hear the thunder which spreads out from the flash, and the more distant the flash the longer the interval between the two. The well-known rule of a mile for every five seconds between flash and peal gives a fair estimate of the distance of the lightning.

Sound needs a Material Medium to Travel Through.—In order that the ear may be affected by a sounding body there must be continuous matter reaching all the way from the body to the ear. This can be shown by suspending an electric bell in the receiver of an air-pump, the wires conveying the current passing through an air-tight cork closing the hole at the top of the receiver. These wires form a material channel from the bell to the outside air, but if they are fine the sound which they carry is hardly appreciable. If while the air within the receiver is at atmospheric pressure the bell is set ringing continuously, the sound is very audible. But as the air is withdrawn by the pump the sound decreases, and when the exhaustion is high the bell is hardly audible at all.

Usually air is the medium through which sound travels, but it can travel through solids or liquids. Thus in the air-pump experiment, before exhaustion it travels through the glass of the receiver and the base plate. We may easily realise its transmission through a solid by putting the ear against a table and scratching the wood at some distance, and through a liquid by keeping both ears under water in a bath and tapping the side of the bath.

Sound is a Disturbance of the Wave Kind.—As sound arises in general from vibrating bodies, as it takes time to travel, and as the medium which carries it does not on the whole travel forward, but subsides into its original position when the sound has passed, we are forced to conclude that the disturbance is of the wave kind. We can at once gather some idea of the nature of sound waves in air by considering how they are produced by a bell.

Let AB (fig. 1) be a small portion of a bell which vibrates to and fro from CD to EF and back. As AB moves from CD to EF it pushes forward the layer of air in contact with it. That layer presses against and pushes forward the next layer and so on. Thus a push or a compression of the air is transmitted onwards in the direction Ox. As AB returns from EF towards CD the layer of air next to it follows it as if it were pulled back by AB. Really, of course, it is pressed into the space made for it by the rest of the air, and flowing into this space it is extended. It makes room for the next layer of air to move back and to be extended and so on, and an extension of the air is transmitted onwards following the compression which has already gone out. As AB again moves from CD towards EF another compression or push is sent out, as it returns from EF towards CD another extension or pull, and so on. Thus waves are propagated along Ox, each wave consisting of one push and one pull, one wave emanating from each complete vibration to and fro of the source AB.

Crov's Disk.—We may obtain an excellent representation of the motion of the layers of air in a train of sound waves by means of a device due to Crova and known as "Crov's disk." A small circle, say 2 or 3 mm. radius, is drawn on a card as in fig. 2, and round this circle equidistant points, say 8 or 12, are taken. From these points as centres, circles are drawn in succession, each with radius greater than the last by a fixed amount, say 4 or 8 mm. In the figure the radius of the inner circle is 3 mm. and the radii of the circles drawn round it are 12, 16, 20, &c. If the figure thus drawn is spun round its centre in the right direction in its own plane waves appear to travel out from the centre along any radius. If a second card with a narrow slit in it is held in front of the first, the slit running from the centre outwards; the wave motion is still more evident. If the figure be photographed as a lantern slide which is mounted so as to turn round, the wave motion is excellently shown on the screen, the compressions and extensions being represented by the crowding in and opening out of the lines.

Another illustration is afforded by a long spiral of wire with coils, say 2 in. in diameter and 1 in. apart. It may be hung up by threads so as to lie horizontally. If one end is sharply pressed in, a compression can be seen running along the spring.

The Disturbance in Sound Waves is Longitudinal.—The motion of a particle of air is, as represented in these illustrations, to and fro in the direction of propagation, i.e. the disturbance
is "longitudinal." There is no "transverse" disturbance, that is, there is in air no motion across the line of propagation, for such motion could only be propagated from one layer to the next by the "viscous" resistance to relative motion, and would die away at a very short distance from the source. But transverse disturbances may be propagated as waves in solids. For instance, if a rope be fixed at one end and held in the other end, a transverse jerk by the hand will travel as a transverse wave along the rope. In liquids sound waves are longitudinal as they are in air. But the waves on the surface of a liquid, which are not of the sound kind, are both longitudinal and transverse, the compound nature being easily seen in watching the motion of a floating particle.

**Displacement Diagram.**—We can represent waves of longitudinal displacement by a curve, and this enables us to draw very important conclusions. The travelling may be represented by pushing on the displacement curve. At the point where a wave first begins to be displaced, it is displaced at L. At the right or forwards, at a given instant. Draw LP upward and some convenient multiple of LI. Let the particle which was at M originally be at N at the given instant, being displaced to the left or backwards. Draw MQ downward the same multiple of MM. Let N be displaced forward to N. Draw NR the same multiple of MN and upwards. If this is done for every point we obtain a continuous curve APBQCRD, which represents the displacement at every point at the given instant, though by a length at right angles to the actual displacement and on an arbitrary scale. At the points ABCD there is no displacement, and the line AD through these points is called the axis. Forward displacement is represented by height above the axis, backward displacement by depth below it. In ordinary sound waves the displacement is very minute, perhaps of the order 10⁻³ cm., so that we may multiply it perhaps by 100,000 in forming the displacement curve.

**Wave Length and Frequency.**—If the waves are continuous and each of the same shape they form a "train," and the displacement curve repeats itself. The shortest distance in which this repetition occurs is called the wave-length. It is usually denoted by \( \lambda \). In fig. 3, AC = \( \lambda \). If the source makes \( n \) vibrations in one second it is said to have "frequency." It sends out \( n \) waves in each second. If each wave travels out from the source with velocity \( U \) the \( n \) waves emitted in one second must occupy a length \( U \) and therefore \( U = n \lambda \).

**Distribution of Compression and Extension in a Wave.**—Let fig. 4 be the displacement diagram of a wave travelling from left to right. Let the wave AQBTC (fig. 5) travel to A'QB'TC' in a very short time. In that short time the displacement at H decreases from HP to HP' or by \( \frac{1}{2} \). The motion of the particle is therefore backwards towards A. At J the displacement remains the same, or the particle is not moving. At K it increases by \( \frac{1}{2} \) forwards, or the motion is forwards towards B. At L the displacement backwards decreases, or the motion is forwards towards A. At M, as at J, there is no change, and at N it is easily seen that the motion is backwards. The distribution of velocity then is represented by the dotted curve and is forward when the curve above the axis and downwards when it is below.

Comparing figs. 4 and 5 it is seen that the velocity is forward in compression and backward in extension.

**The Relations between Displacement, Compression and Velocity.**—The relations shown by figs. 4 and 5, and in a general manner may easily be put into exact form. Let \( Ox \) (fig. 6) be the direction of travel, and let \( x \) be the distance of any point \( M \) from a fixed point 0. Let \( ON = x + dx \). Let \( MP = y \) represent the forward displacement of the particle originally at M, and \( NQ = y + dy \) that of the particle originally at N. The layer of air originally of thickness \( dx \) has thickness \( dx + dy \), since N is displaced forwards \( dy \) more than M. The volume \( dx \), then, has increased to \( dx + dy \) or volume \( i \) has increased to \( i + dy/dx \) and the increase of volume is \( dy/dx \).

Let \( E \) be the bulk modulus of elasticity, defined as increase of pressure \( + \) decrease of volume per unit volume where the pressure increase is so small that this ratio is constant, \( \omega \) the small increase of pressure, and \( -dy/dx \) the volume decrease, then

\[
\frac{E}{\omega \cdot dx} = -dy/dx
\]

(1)

This gives the relation between pressure excess and displacement. To find the relation of the velocity to displacement and pressure we shall express the fact that the wave travels on carrying all its conditions with it, so that the distribution now at M will arrive at N while the wave travels over MN. Let U be the velocity of the wave and let \( u \) be the velocity of the particle originally at N. Let \( MN = dx \) and \( u = dy/dx \). In the time \( dx \) which the wave takes to travel over MN the particle displacement at N changes by \( QR \) and \( QR = -adt \), so that \( QR/MN = -u/U \). But \( QR/MN = dy/dx \). Then

\[
u = \frac{U}{U} = -dy/dx
\]

(2)

This gives the velocity of any particle in terms of the displacement. Equating (1) and (2)

\[
u = \frac{U}{U} = E
\]

(3)

which gives the particle velocity in terms of the pressure excess.

Generally, if any condition \( \phi \) in the wave is carried forward unchanged with velocity \( U \), the change of \( \phi \) at a given point in time \( dx \) is equal to the change of \( \phi \) as we go back along the curve a distance \( dx = U dt \) at the beginning of \( dt \).

Then

\[
\frac{\phi}{dx} = \frac{U}{U} \frac{\phi}{U}
\]

The **Characteristics of Sound Waves Corresponding to Loudness, Pitch and Quality.**—Sounds differ from each other only in the three respects of loudness, pitch and quality.

The **Loudness** of the sound brought by a train of waves of given wave-length depends on the extent of the tension and the excitation of the air particles. It is obvious if we consider that the greater the vibration of the source the greater is the excitation of the air in the issuing waves, and the louder is the sound heard. Half the total excitation is called the amplitude. Thus in fig. 4 QJ is the amplitude. Methods of measuring the amplitude in sound waves in air have been devised and will be described later. We may say here that the energy or the intensity of the sound of given wave-length is proportional to the square of the amplitude.

The **Pitch of a sound**, the note which we assign to it, depends on the number of waves received by the ear per second. This is generally equal to the number of waves issuing from the source per second, and therefore equal to its frequency of vibration. Experiments, which will be described most conveniently when
we discuss methods of determining the frequencies of sources, prove conclusively that for a given note the frequency is the same whatever the source of that note, and that the ratio of the frequencies of two notes forming a given musical interval is the same in whatever part of the musical range the two notes are situated. Here it is sufficient to say that the frequencies of a note sounded on one instrument from the same note on another instrument, depends neither on amplitude nor on frequency or wave-length. We can only conclude that it depends on wave form, a conclusion fully borne out by investigation. The displacement curve of the waves from a tuning-fork on its resonance box, or from the human voice sounding oo, are nearly smooth and symmetrical, as in fig. 7a. That for the air waves from a violin are probably nearly as in fig. 7b.

**Calculation of the Velocity of Sound Waves in Air.**—The velocity with which waves of longitudinal disturbance travel in air or in any other fluid may be calculated from the resistance to compression and extension and the density of the fluid. It is convenient to give this calculation before proceeding to describe the experimental determination of the velocity in air, in other gases and in water, since the calculation serves to some extent as a guide in conducting and interpreting the observations.

The waves from a source surrounded by a uniform medium at rest spread out as spheres with the source as centre. If we take one of these spheres a distance from the source very great as compared with a single wave-length, and draw a radius to a point on the sphere, then for some little way round that point the sphere may be regarded as a plane perpendicular to the radius or the line of propagation. Every particle in the plane will have the same displacement and the same velocity, and these will be perpendicular to the plane and parallel to the line of propagation. The waves for some little distance on each side of the plane will be practically of the same size. In fact, we may neglect the divergence, and may regard them as "plane waves."

We shall investigate the velocity of such plane waves by a method which is only a slight modification of a method given by W. J. M. Rankine (Phil. Trans., 1870, p. 277).

Whatever the form of a wave, we could always force it to travel along a form unchanged, and with any velocity we chose, if we could apply any "external" force we liked to each particle, in addition to the "internal" force called into play by the compressions or extensions. For instance, if we have a wave with displacement curve of form ABC (fig. 8), and we require it to travel on in time dt to A'B'C', where AA' = Udt, the displacement of the particle originally at M must change from PM to P'M or by P'. This change can always be effected if we can apply whatever force may be needed to produce it.

We shall investigate the external force needed to make a train of plane waves travel on unchanged in form with velocity U.

We shall regard the external force as applied in the form of a pressure X per square centimetre parallel to the line of propagation and varied from point to point as required in order to make the disturbance travel on unchanged in form with the specified velocity U. In addition there will be the internal force due to the change in volume, and consequent change in pressure, from point to point.

Suppose that the whole of the medium is moved backwards in space along the line of propagation so that the undisturbed portions travel with the velocity U. The disturbance, or the train of waves, is then fixed in space, though fresh matter continually enters the disturbed region at one end, undergoes the disturbance, and then leaves it at the other end.

**Let A (fig. 9) be a point fixed in space in the disturbed region, B a fixed point where the medium is not yet disturbed, the medium moving through A and B from right to left. Since the condition of the medium between A and B remains constant, even though the matter is continually changing, the momentum possessed by the matter between A and B is constant. Therefore the momentum entering through a square centimetre at B per second is equal to the momentum leaving through a square centimetre at A. Now the transfer of momentum across a surface occurs in two ways, firstly by the carriage of moving matter through the surface, and secondly by the force acting between the matter on one side of the surface and the matter on the other side. U cubic centimetres per second move in at A (since the mass moving in through a square centimetre is \( \rho U \)). But it has velocity U, and therefore momentum \( \rho U^2 \) is carried in. In addition there is a pressure between the layers of the medium, and if this pressure in the undisturbed parts of the medium is \( P \), momentum per second is being transferred from right to left across each square centimetre. Hence the matter moving in is receiving on this account \( \rho U^2 \) per second from the matter to the right of it. The total momentum moving in at B is therefore \( P + \rho U^2 \). Now consider the momentum leaving at A. If the velocity of a particle at A relative to the undisturbed parts is \( u \) from left to right, the velocity of the matter moving out at A is \( U - u \), and the momentum carried out by the moving matter is \( \rho(U-u)^2 \). But the matter to the right of A is also receiving momentum from the matter to the left of it at the rate indicated by the force across A. Let the excess of pressure due to change of volume be \( \dot{\rho} \), so that the total "internal" pressure is \( P + \dot{\rho} \). There is also the "external" applied pressure \( X \), and the total momentum per second is

\[
X + P + \dot{\rho} + \rho(U-u)^2
\]

Equating this to the momentum entering at B and subtracting \( P \) from each

\[
X + \dot{\rho} + \rho(U-u)^2 = \rho U^2
\]

If \( y \) is the displacement at A, and \( E \) is the elasticity, substituting for \( \dot{\rho} \) and \( u \) from (2) and (3) we get

\[
X = E\frac{\partial^2 X}{\partial t^2} + \rho U^2 (1 + \frac{\partial^2}{\partial x^2}) = \rho U^2
\]

But since the volume \( dx \) with density \( \rho \) has become volume \( dx + dy \) with density \( \rho 
\]

\[
\rho (1 + \frac{\partial}{\partial x}) = \rho
\]

Then

\[
X = E\frac{\partial^2 X}{\partial t^2} + \rho U^2 (1 + \frac{\partial^2}{\partial x^2}) = \rho U^2
\]

or

\[
X = (E-\rho U^2)dy/dx
\]

If we then apply a pressure \( X \) given by (5) at every point, and move the medium with any uniform velocity \( U \), the disturbance remains fixed in space. Or if we now keep the undisturbed parts of the medium fixed, the disturbance travels on with velocity \( U \) if we apply the pressure \( X \) at every point of the disturbance. If the velocity \( U \) is so chosen that \( E-\rho U^2 = 0 \), then \( X = 0 \), or the wave travels on through the action of the internal forces only, unchanged in form and unchanged in velocity.

\[
U = \sqrt{E/\rho}
\]

The pressure \( X \) is introduced in order to show that a wave can be propagated unchanged in form. If we omitted it we should have to assume this, and equation (6) would give us the velocity of propagation if the assumption were justified. But a priori we are hardly justified in assuming that waves can be propagated at all, and certainly not justified in assuming that they go on unchanged by the action of the internal forces alone. If, however, we put on external forces of the required kind \( X \) it is obvious that a wave can be propagated with any velocity, and our investigation shows that when \( U \) has the value in (6) then and only then \( X \) is zero everywhere, and the wave will be propagated with that velocity without set going.

It may be noted that the elasticity \( E \) is only constant for small volume changes or for small values of \( dy/dx \).

Since by definition \( E = \frac{\partial P}{\partial \rho} \), \( \rho \) and \( dp/d\rho \) equation (6) becomes

\[
U = \sqrt{\frac{E}{\rho}}
\]

The value \( U = \sqrt{E/\rho} \) was first virtually obtained by Newton (Principia, bk. ii, § 8, props. 48-49). He supposed that in air Boyle's law holds in the extensions and compressions, or that \( \frac{E}{\rho} \), whence \( dp/d\rho = k \rho/p \). His value of the speed of air in therefore

\[
U = \sqrt{\frac{E}{\rho}}
\]

(=20 ft./sec.)

At the standard pressure of 76 cm. of mercury or 1,014,000 dynes / sq. cm., the density of dry air at \( 0^\circ \)C., being taken as 0.001293, we get for the velocity in dry air at \( 0^\circ \)C.

\[
U = \frac{28,000}{920} = \text{about 30 ft./sec.}
\]
approximately. Newton found 979 ft./sec. But, as we shall see, all the determinations have a value in the neighbourhood of 33,000 cm./sec., or about 1080 ft./sec. This discrepancy was not explained till 1816, when Laplace (Ann. de chimie, 1816, vol. iii.) pointed out that the compressions and extensions in sound waves in air alter, so rapidly that there is no time for the temperature inequalities produced by them to spread. That is to say, instead of using Boyle's law, which supposes that the pressure changes so exceedingly slowly that conduction keeps the temperature constant, we must use the adiabatic relation and

\[ \frac{dp}{dV} = \gamma p, \]

and

\[ U = \sqrt{(\gamma p/V)}. \]  

[ Laplace's formula.]

If we take \( \gamma = 1.4 \), we obtain approximately for the velocity in dry air at a.\( \cdot^\circ \)C.

\[ U_0 = 33.150 \text{ cm./sec.}, \]

which is closely in accordance with observation. Indeed Sir G. G. Stokes (Math. and Phys. Papers, iii. 142) showed that a very small pressure from the adiabatic condition would lead to a stifling of the sound quite out of accord with observation. If we put \( p = \kappa p_0 (1 + a) \) in (8) we get the velocity in a gas at a \( ^\circ \)C.

\[ U_0 = \sqrt{\gamma p_0 (1 + a)}. \]

At a.\( \cdot^\circ \)C, we have \( U_0 = \sqrt{\gamma p_0} \), and hence

\[ U_1 = U_0 (1 + a) = U_0 (1 + 0.00184) \]  

(for small values of \( a \)).

(g) The velocity then should be independent of the barometric pressure, a result confirmed by observation.

For two different gases with the same value of \( \gamma \), but with densities at the same pressure and temperature respectively \( n \) and \( n_1 \), we should have

\[ \frac{U_1}{U_2} = \sqrt{\frac{n_1}{n_2}}, \]  

(10)

another result confirmed by observation.

Alteration of Form of the Waves when Pressure Changes are Considerable.—When the value of \( dy/dz \) is not very small \( E \) is no longer constant, but is rather greater in compression and rather less in extension than \( \gamma P \). This can be seen by considering that the relation between \( p \) and \( \rho \) is given by a curve and not by a straight line. The consequence is that the compression travels rather faster, and the extension rather slower, than at the speed found above.

We may get some idea of the effect by supposing that for a short time the change can be neglected. In the momentum equation (4) we may now omit \( X \) and it becomes

\[ \omega p (U - u) = \rho U^3. \]

Let us seek a more exact value for \( \omega \). If \( p \) changes to \( p + \delta p \), let \( V \) change to \( V + \delta V \) then (P + \delta P)(V + \delta V) = PV,

whence

\[ \omega \delta p = \frac{\delta V}{V} \]

We have \( U - u = (U_1 - u)/U_1 \), so \( U_1 = U - u/\sqrt{\rho} \), hence

\[ \rho = \rho_0 \]  

and so on (11).

Substituting in the momentum equation, we obtain

\[ \frac{\rho U}{\sqrt{\gamma}} \left( 1 + \frac{\gamma + 1}{2} \right) \rho U^3 = 4 \rho U, \]

whence

\[ U = \frac{2}{\gamma + 1} \left( \frac{\gamma + 1}{2} \right) \rho U. \]

Thus, for changes in the wave form, we have

\[ U = \frac{2}{\gamma + 1} \left( \frac{\gamma + 1}{2} \right) \rho U. \]

This investigation is obviously not exact, for it assumes that the form is unchanged, i.e., that the momentum issuing from (A fig. 9) is equal to that entering at B, an assumption no longer tenable when the form changes. But for very small times the assumption may perhaps be made, and the result at least shows the way in which the velocity is affected by the addition of a small term on and changing sign with \( u \). It implies that the different parts of a wave move on at different rates, so that its form must change.

As we obtained the result on the supposition of unchanged form, we can of course only apply it for such short lengths and such short times that the part dealt with does not appreciably alter. We see at once that, where \( \rho = \rho_0 \), the velocity has its " normal " value, while where \( \rho = 0 \), it is zero, and it is least in the case of the short waves, when \( \rho = 0 \). The velocity in this case is zero, and it is least in the case of the short waves, when \( \rho = 0 \). The velocity in this case is zero.

Like the breaking of a water-wave when the crest gains on the next trough. In ordinary sound-waves the effect of the particle velocity in affecting the velocity of transmission must be very small.
We may find here the value of this when we have a train of waves in which the displacement is represented by a sine curve of amplitude $a$, viz. $y = a \sin \left( \frac{2\pi}{\lambda} (x - U) \right)$. For a discussion of this type of wave, see below.

We have

$$u = \frac{dy}{dt} = \frac{2\pi}{\lambda} a \cos \left( \frac{2\pi}{\lambda} (x - U) \right),$$

and

$$\int_0^a \rho u^2 dx = \rho a^2 \sum_{n=1}^{\infty} \cos \left( \frac{2\pi n}{\lambda} (x - U) \right) dx = 2 \rho a^2 U^2 / \lambda^2.$$  

(12)

The energy per cubic centimetre on the average is

$$2 \rho a^2 U^2 / \lambda^2.$$  

(13)

and the energy passing per second through 1 sq. cm. perpendicular to the line of propagation is

$$2 \rho a^2 U^2 / \lambda^2.$$  

(14)

### The Pressure of Sound Waves

Sound waves, like light waves, exercise a small pressure against any surface upon which they impinge. The existence of this pressure has been demonstrated experimentally by W. Altmann (Ann. der Physik, 1903, 11, p. 405). A small circular disk at one end of a torsion arm formed part of a solid wall, but was free to move through a hole in the wall slightly larger than the disk. When intense sound waves impinged on the wall, the disk moved back through the hole, and by an amount showing a pressure of the order given by the following investigation:

Suppose that a train of waves is incident normally on the surface $S$ (fig. 11), and that they are absorbed there without reflection. Let $ABCD$ be a column of air 1 sq. cm. cross-section. The pressure on $CD$ is equal to the momentum which it receives per second. On the whole the air within $ABCD$ neither gains nor loses momentum, so that on the whole it receives as much through $AB$ as it gives up to $CD$. If $P$ is the undisturbed pressure and $P + \Delta P$ is the pressure at $AB$, the momentum entering through $AB$ per second is $\int_0^a (P + \rho u^2) dU$. But $\int_0^a P dU = P$ is the normal pressure, and as we only wish to find the excess we may leave this out of account.

The excess pressure on $CD$ is therefore $\int_0^a (\rho + \rho u^2) dU$. But the values of $\rho + \rho u^2$ which occur successively during the second at $AB$ exist simultaneously at the beginning of the second over the distance $U$ behind $AB$. Or if the conditions along this distance $U$ could be maintained constant, and we could travel back along it uniformly in time, we should have the same conditions as at the condition actually arriving at $AB$ and at the same intervals. If then $dt$ is an element of the path, putting $dt = dU/U$, we have the average excess of pressure

$$p = \int_0^a (\rho + \rho u^2) dU = \int_0^a (\rho + \rho u^2) dU.$$  

Here $dU$ is an actual length in the disturbance. We have $\omega$ and $u$ expressed in terms of the original length $d$ and the displacement $dy$ so that we must put $dU = dx + dy = (1 + dy/dx)dx$, and

$$p = \frac{1}{U} \int_0^a (\rho + \rho u^2) (1 + dy/dx) dx.$$  

We have already found that if $V$ changes to $V - v$

$$\omega' = \frac{\rho u}{\rho + \rho u^2} = \frac{\rho u}{\rho + \rho u^2}$$

Here $dV = -dy/dx$. We also have $\rho u^2 = \rho u^2 (1 + dy/dx)$. Substituting these values and neglecting powers of $dy/dx$ above the second we get

$$p = \frac{1}{U} \int_0^a \rho u (1 + dy/dx) dx.$$  

But $\int_0^a dy/dx = \infty$ since the sum of the displacements $= \infty$. Then putting $(dy/dx) = (u/U)^2$, we have

$$p = \frac{\rho u}{2} \frac{1}{U} \int_0^a \rho u dx = \frac{\rho u^2}{2} \frac{1}{U} \frac{1}{U} \frac{1}{U}.$$  

(15)

A result first published by Lord Rayleigh (Phil. Mag., 1905, 10, p. 354).

If the train of waves is reflected, the value of $p$ at AB will be the sum of the values for the two trains, and will, on the average, be doubled. The pressure on CD will therefore be doubled. But the energy will also be doubled, so that (15) still gives the average excess of pressure.

---

**Experimental Determinations of the Velocity of Sound**

An obvious method of determining the velocity of sound in air consists in starting some sound, say by firing a gun, and stationing an observer at some measured distance from the gun. The observer measures by a clock or chronometer the time elapsing between the receipt of the flash, which passes practically instantaneously, and the receipt of the report. The distance divided by the time gives the velocity of the sound. The velocity thus obtained will be affected by the wind. For instance, William Derham (Phil. Trans., 1705) made a series of observations, noting the time taken by the report of a cannon fired on Blackheath to travel across the Thames to Upminster Church in Essex, 12 ½ m. away. He found that the time varied between 553 seconds when the wind was blowing most strongly with the sound, to 63 seconds when it was most strongly against the sound. The value for still air he estimated at 1142 ft. per second. He made no correction for temperature or humidity. But when the wind is steady its effect may be eliminated by "reciprocal" observations, that is, by observations of the time of passage of sound in each direction over the measured distance.

Let $D$ be the distance, $U$ the velocity of sound in still air, and $W$ the velocity of the wind, supposed for simplicity to blow directly from one station to the other. Let $T_1$ and $T_2$ be the observed times of passage in the two directions. We have $U + w = D/T_1$ and $U - w = D/T_2$. Adding and dividing by 2

$$U = \frac{D}{2} \left( \frac{1}{T_1} + \frac{1}{T_2} \right).$$

If $T_1$ and $T_2$ are nearly equal, and if $T = (T_1T_2)/T_1T_2$, this is very nearly $U = D/T$.

The reciprocal method was adopted in 1738 by a commission of the French Academy (Mémoires de l'académie des sciences, 1738). Cannons were fired at half-hour intervals, alternately at Montmartre and Montlhéry, 17 or 18 m. apart. There were also two intermediate stations at which observations were made. The times were measured by pendulum clocks. The result obtained at a temperature of 6°C. was, when converted to metres, $U = 337$ metres/second.

The theoretical investigation given above shows that if $U$ is the velocity in air at °C. then the velocity $U_0$ at °C. in the same air is independent of the barometric pressure and that $U_0 = U/(1 + \alpha \cos 4\phi)$, whence $U_0 = 332$ met./sec.

In 1825 a commission of the Bureau des Longitudes made a series of experiments between Montlhéry and Villejuliet, 11 m. apart. Cannons were fired at the two stations at intervals of five minutes. Chronometers were used for timing, and the result at 15°C. was $U = 1409$ met./sec., whence $U_0 = 330$ met./sec. (J. J. Arago, Comptes rendus, 1825).

When the measurement of a time interval depends on an observer, his "personal equation" comes in to affect the estimation of the quantity. This is the interval between the arrival of an event and his perception that it has arrived, or it may be the interval between arrival and his record of the arrival. This personal equation is different for different observers. It may differ even by a considerable fraction of a second. It is different, too, for different senses with the same observer, and different even for the same sense when the external stimuli differ in intensity. When the interval between a flash and a report is measured, the personal equations for the two arrivals are, in all probability, different, that for the flash being most likely less than that for the sound. In a long series of experiments carried out by V. Regnault in the years 1862 to 1866 on the velocity of sound in open air, in air in pipes and in various other gases in pipes, he sought to eliminate personal equation by dispensing with the human element in the observations, using electric receivers as observers. A short account of these experiments is given in Phil. Mag., 1868, 35, p. 161, and the full account, which serves as an excellent example of the extraordinary care and ingenuity of Regnault's work, is given in the Mémoires de l'académie des sciences, 1868, xxxvii. On page 459 of the Mémoire will be found a list of previous careful experiments on the velocity of sound.

In the open-air experiments the receiver consisted of a large
SOUND

Correcting the velocity obtained in the 0.7 m. tube by Kirchhoff’s formula, Violle and Vautier found for the velocity in open air at $0^\circ$ C.:

$$U_0 = 331.10 \text{ m/sec.}$$

with a probable error estimated at $\pm 0.10$ metre.

It is obvious from the various experiments that the velocity of sound in dry air at $0^\circ$ C. is not yet known with very great accuracy. At present we cannot assign a more exact value than

$$U_0 = 331 \text{ m/sec. per second.}$$

Violle and Vautier made some later experiments on the propagation of musical sounds in a tunnel 3 metres in diameter (Ann. chim. phys., 1895, vol. 5). They found that the velocity of propagation of different musical sounds was the same. Some curious effects were observed in the formation of harmonics in the rear of the primary tone used. These have yet to find an explanation.

**Velocity of Sound in Water.**—The velocity in water was measured by J. D. Colladon and J. K. F. Sturm (Ann. chim. phys., 1827 (8), 36, p. 236) in the water of Lake Geneva. A bell under water was struck, and at the same instant some gunpowder was flashed in air above the bell. At a station more than 13 kilometres away a sort of big ear-trumpet, closed by a membrane, was placed with the membrane under water, the tube rising above the surface. An observer with his ear to the tube noted the interval between the arrival of flash and sound. The velocity deduced at $8^\circ$ C. was $U = 1435 \text{ m/sec.}$, agreeing very closely with the value calculated from the formula $U = \frac{E}{p}$.

Experiments on the velocity of sound in iron have been made on lengths of iron piping by J. B. Biot, and on telegraph wires by Wertheim and Brequet. The experiments were not satisfactory, and it is sufficient to say that the results accorded roughly with the value given by theory.

**Reflection of Sound.**

When a wave of sound meets a surface separating two media it is in part reflected, travelling back from the surface into the first medium again with the velocity with which it approached. Echo is a familiar example of this. The laws of reflection of sound are identical with those of the reflection of light, viz. (1) the planes of incidence and reflection are coincident, and (2) the angles of incidence and reflection are equal. Experiments may be made with plane and curved mirrors to verify these laws, but it is necessary to use short waves, in order to diminish diffraction effects. For instance, a ticking watch may be put at the focus of a large concave metallic mirror, which sends a parallel “beam” of sound to a second concave mirror facing the first. If an ear-trumpet is placed at the position diametrically opposite to that occupied by the whisperer, and the ticking may be heard easily, though it is quite inaudible by direct waves. Or it may be revealed by placing a sensitive flame of the kind described below with its nozzle at the focus. The flame jumps down at every tick.

Examples of reflection of sound in buildings are only too frequent. In large halls the words of a speaker are echoed or reflected from flat walls or roof or floor; and these reflected sounds follow the direct sounds at such an interval that syllables and words overlap, to the confusion of the speech and the annoyance of the audience.

Some curious examples of echo are given in Herschel’s article on “Sound” in the Encyclopaedia Metropolitana, but it appears that he is in error in one case. He states that in the whispering gallery in St. Paul’s, London, “the faintest sound is faithfully conveyed from one side to the other of the dome but is not heard at any intermediate point.” In some domes, for instance in a dome at the university of Birmingham, a sound from one end of a diameter is heard very much more loudly quite close to the other end of the diameter than elsewhere, but in St. Paul’s Lord Rayleigh found that “the abnormal loudness with which a whisper is heard is due to a position diametrically opposite to that occupied by the whisperer, and therefore, it would appear, does not depend materially upon the symmetry.

CONSEQUENCES OF THE DISCOVERY

If the velocity of sound is $U$, and $P$ the mean excess of pressure above the normal, according to von Helmholz and Kirchhoff the velocity in a tube should be less than that in free air by a quantity depending on the diameter of the tube, the frequency of the note used, and the viscosity of the gas (Rayleigh, Sound, vol. ii. §§ 347-8).

\[ \text{SOUND} \]

\[ \text{Reflection} \]

\[ \text{Velocity of Sound in Air and other Gases in Pipes.} \]

\[ \text{Velocity of Sound in Water.} \]

\[ \text{Reflection of Sound.} \]
of the dome. The whisper seems to creep round the gallery horizontally, not necessarily along the shorter arc, but rather along that arc towards which the whisperer faces. This is a consequence of the very unequal audibility of a whisper in front and behind the speaker, a phenomenon which may easily be observed in the open air” (Sound, ii. § 287).

Let fig. 12 represent a horizontal section of the dome through the source P. Let OPA be the radius through P. Let PQ represent a ray of sound making the angle $\theta$ with the tangent at A. Let $\text{ON} = \text{OP} \cos \theta$ be the perpendicular on PQ. Then the reflected ray QR and the ray reflected at R, and so on, will all touch the circle drawn with ON as radius. A ray making an angle less than $\theta$ with the tangent will, with its reflections, touch a larger circle.

Hence all rays between $\pm \theta$ will be confined in the space between the outer dome and a circle of radius $\text{OP} \cos \theta$, and the weakening of intensity will be chiefly due to vertical spreading.

Rayleigh points out that this clinging of the sound to the surface of a concave wall does not depend on the exactness of the spherical form. He suggests that the propagation of earthquake disturbances is probably affected by the curvature of the surface of the globe, which may act like a reflecting mirror.

In some cases of echo, when the original sound is a compound musical note, the octave of the fundamental tone is reflected much more strongly than that tone itself. This is explained by Rayleigh (Sound, ii. § 296) as a consequence of the irregularities of the reflecting surface. The irregularities send back a scattered reflection of the different incident trains, and this scattered reflection becomes more copious the shorter the wave-length. Hence the octave, though comparatively feeble in the incident train, may predominate in the scattered reflection constituting the echo.

**Refraction of Sound.**

When a wave of sound travelling through one medium meets a second medium of a different kind, the vibrations of its own particles are communicated to the particles of the new medium, so that a wave is excited in the latter, and is propagated through it with a velocity dependent on the density and elasticity of the second medium, and therefore differing in general from the previous velocity. The direction, too, in which the new wave travels is different from the previous one. This change of direction is termed **refraction**, and takes place according to the same laws as does the refraction of light, viz. (1) The new direction or refracted ray lies always in the **plane of incidence**, or plane which contains the incident ray (i.e. the direction of the wave in the first medium), and the normal to the surface separating the two media, at the point in which the incident ray meets it; (2) The **sine** of the angle between the normal and the incident ray bears to the **sine** of the angle between the normal and the refracted ray a ratio which is constant for the same pair of media. As with light the ratio involved in the second law is always equal to the ratio of the velocity of the wave in the first medium to the velocity of the wave in the second; in other words, the sines of the angles in question are directly proportional to the velocities.

Hence sound rays, in passing from one medium into another, are bent towards the normal, or the reverse, according as the velocity of propagation in the former exceeds or falls short of that in the latter. Thus, for instance, sound is refracted **towards** the perpendicular when passing into air from water, or into carbonic acid gas from air; the converse is the case when the passage takes place in the opposite way.

It further follows, as in the analogous case of light, that there is a certain angle termed the **critical angle**, whose sine is found by dividing the less by the greater velocity, such that all rays of sound meeting the surface separating two different bodies will not pass onward, but suffer total reflection back into the first body, if the velocity in that body is less than that in the other body, and if the angle of incidence exceeds the limiting angle.

The velocities in air and water being respectively 1090 and 4700 ft. the limiting angle for these media may be easily shown to be slightly above 15°. Hence, rays of sound proceeding from a distant source, and therefore nearly parallel to each other, and to PO (fig. 13), the angle POM being greater than 15°, will not pass into the water at all, but suffer total reflection. Under such circumstances, the report of a gun, however powerful, should be inaudible by an ear placed in the water.

**Stokes Lens.**—As fig. 14 is curved into a focus by a convex glass lens (for which the velocity of light is less than for the air), so sound ought to be made to converge by passing through a convex lens formed of carbonic acid gas. On the other hand, to produce convergence with water or hydrogen gas, in both which the velocity of sound exceeds its rate in air, the lens ought to be concave. These results have been confirmed experimentally by K. F. J. Sondhaus (Pogg. Ann., 1852, 85, p. 373). He has used a collodion lens filled with carbonic acid. He found its focal length and hence the refractive index of the gas. C. Hajech (Ann. chim. phys., 1858, (iii), vol. 54) also measured the refractive indices of various gases, using a prism containing the gas to be experimented on, and he found that the deviation by the prism agreed very closely with the theoretical values of sound in the gas and in air.

Osborne Reynolds (Proc. Roy. Soc., 1874, 22, p. 531) first pointed out that refraction would result from a variation in the temperature of the air at different heights. The velocity of sound in air is independent of the pressure, but varies with the temperature, its value at $T \, ^\circ C$. being as we have seen

$$U = U_0(1 + \frac{\alpha}{100})$$

where $U_0$ is the velocity at $0 \, ^\circ C$, and $\alpha$ is the coefficient of expansion $\cdot0365$. Now if the temperature is higher overhead than at the surface, the velocity overhead is greater. If a wave front is in a given position, as at 1 (fig. 14), at a given instant the upper part, moving faster, gains on the lower, and the front tends to swing round as shown by the successive positions in a 2, 3 and 4; that is, the sound tends to come down to the surface. This is well illustrated by the remarkable horizontal carriage of sound on a still clear frosty morning, when the surface layers of air are decidedly colder than those above.

At sunset, too, after a warm day, if the air is still, the cooling of the earth by radiation cools the lower layers, and sound carries excellently over a level surface. But usually the lower layers are warmer than the upper layers, and the velocity below is greater than the velocity above. Consequently a wave front such as at 1 tends to turn upwards as shown in the successive positions 2, 3 and 4. Sound is then spread outwards, being carried along the level, but may still reach an elevated observer. On a hot summer's day the temperature of the surface layers may be much higher than that of the higher layers, and the effect on the horizontal carriage of sound may be very marked.

It is well known that sound travels far better with the wind than against it. Stokes showed that this effect is one of refraction, due to variation of velocity of the air from the surface upwards (Brit. Assoc. Rep., 1857, p. 22). It is, of course, a matter of common observation that the wind increases in velocity from the surface upwards. An excellent illustration of this increase was pointed out by F. Oehler in the shape of old clouds; their upper portions always appear dragged forward and they lean over, as if they were, in the
direction in which the wind is going. The same kind of thing happens with sound-wave fronts when travelling with the wind.

The velocity of any part of a wave front relative to the ground will be the normal velocity of sound + the velocity of the wind at that point. Since the velocity increases as we go upwards the front tends to swing round and travel downwards, as shown in the successive positions 1, 2, 3, and 4, in fig. 14, where we must suppose the wind to be blowing from left to right. But if the wind is against the sound the velocity of a point of the wave front is the normal velocity—the wind velocity at the point, and so decreases as we rise. Then the front tends to swing round and travel upwards as shown in the successive positions 5, 6, 7, and 8, in fig. 14, where the wind is travelling from right to left. In the first case the waves are more likely to reach and be perceived by an observer level with the source, while in the second case they may go over his head and not be heard at all.

Diffraction of Sound Waves.

Many of the well-known phenomena of optical diffraction may be imitated with sound waves, especially if the waves be short. Lord Rayleigh (Scientific Papers, iii. 24) has given various examples, and we refer the reader to his account.

We shall only consider one interesting case of sound diffraction which may be easily observed. When we are walking past a fence formed by equally-spaced vertical rails or overlapping boards, we may often note that each footstep is followed by a musical ring. A sharp clap of the hands may also produce the effect. A short impulsive wave travels towards the fence, and each rail as it reaches the wave becomes the centre of a new secondary wave sent out all round, or at any rate on the front side of the fence.

\[ F \quad E \quad D \quad C \quad B \quad A \quad S \]

\[ \text{FIG. 15.} \]

Let S (fig. 15) be the source very nearly in the line of the rails ABCDEF. At the instant that the original wave reaches F the wave from E has travelled to a circle of radius very nearly equal to EF—not quite, as S is not quite in the plane of the rails. The wave from D has travelled to a circle of radius nearly equal to DF, that from C to a circle of radius nearly CE, and so on. At these "secondary waves" return to S their distance apart is nearly equal to twice the distance between the rails, and the observer then hears a note of wave-length nearly 2EF. But if an observer is stationed at S' the waves will be about half as far apart and will reach him with nearly twice the frequency, so that he hears a note about an octave higher. As he travels further round the frequency increases still more. The rattle in fact do for sound what a diffraction grating does for light.

Frequency and Pitch.

Sounds may be divided into noises and musical notes. A mere noise is an irregular disturbance. If we study the source producing it we find that there is no regularity of vibration. A musical note always arises from a source which has some regularity of vibration, and which sends equally-spaced waves into the air. A given note has always the same frequency, that is to say, the ear receives the same number of waves per second whatever the source by which the note is produced. Various instruments have been devised for simulating any desired pitch, and which are provided with methods of counting the frequency of vibration. The results obtained fully confirm the general law that "pitch," or the position of the note in the musical scale, depends solely on its frequency. We shall now describe some of the methods of determining frequency.

Savart's toothed wheel apparatus, named after Félix Savart (1791-1841), a French physicist and surgeon, consists of a brass wheel, whose edge is divided into a number of equal projecting teeth distributed uniformly over the circumference, and which is capable of rapid rotation about an axis perpendicular to its plane and passing through its centre, by means of a series of multiplying wheels, the last of which is turned round by the hand. The toothed wheel is then set in motion when the observer is seated in any part of the room. A piece of common notepaper is held against the teeth, when a note will be heard arising from the rapidly succeeding displacements of the air in its vicinity. The pitch of this note will rise as the rate of rotation increases, and becomes steadily maintained uniform. It may thus be brought into union with any sound of which it may be required to determine the corresponding number of vibrations per second, as, for instance, the note A, through various other notes of the scale which is designated by a small circle placed between the second and third lines of the G clef, which A is the note of the tuning-fork usually employed for this purpose. A Concert-piano contains a set of these, as given by a piano. Now, suppose that the note produced with Savart's wheel is in unison with A, when the experimenter turns round the first wheel at the rate of 60 turns per minute or one per second, and that the circumferences of the various multiplying wheels are such that the rate of revolution of the toothed wheel is thereby increased 44 times, then the last wheel will perform 44 revolutions in a second, and hence, if the number of its teeth be 36, the number of taps imparted to the card every second will amount to 44×36 or 3520. This, therefore, is the number of vibrations corresponding to the note A. If we divide this by 2 or 8, we obtain 440 as the number of vibrations answering to the note E or C. If, for the single toothed wheel, be substituted a set of four with the same number of teeth, the teeth are in the ratios 4:5:6:8; and if the card be rapidly passed along their edges, we shall hear distinctly produced the fundamental note of each chord that is shown with the instrument. If we multiply the intervals C, E, G, and C, by 1, 1, 2 respectively. Neither this instrument nor the next to be described is now used for exact work; they merely serve as illustrations of the law of pitch.

The siren of L. F. W. A. Seebeck (1805-1849) is the simplest form of apparatus thus designated, and consists of a large circular disk mounted on a central axis, about which it may be made to rotate with moderate rapidity. This disk is perforated with small round holes arranged in circles about the centre of the disk. In the first series of circles, reckoning from the centre the openings are so made as to divide the circumference into 24 equal parts, and some are circular, while others are ellipses, the axes of which are parallel to the radius. In the second series of circles of which the diameters of the ellipses are 18 times their focal length. The second series consists of circles each of which is composed of two sets of perforations, in the first set the centres of the ellipses are at 4:5, in the next at 2:3, then at 2:3, 3:5, 4:7. In the outer series a circle is divided by perforations into four sets, the number of such parts being as 3:4:5:6, followed by others which we need not here refer to.

The disk being started, then by means of a tube held at one end between the lips, and applied near to the disk at the other, or more particularly in a common receptacle for holding a blust, is moved in a circle or a circle of a second order, almost parallel to the disk which contains any one of the above circles. The current being alternately transmitted and shut off, as a hole passes on and off the aperture of the tube or bellows, causes a vibratory motion of the air, and these vibrations are made audible, by the air passing through that a perforation passes the mouth of the tube. Hence the note produced with any given circle of holes rises in pitch as the disk revolves more rapidly; and if, the revolution of the disk being kept as nearly as possible the same, we pass in succession to the circle of the first series, a series of notes is heard, which, if the lowest be denoted by C, form the sequence C, C, G, B, G, C, &c. In like manner, the first circle in which we have two sets of holes dividing the circumference, the one into say 8 parts, and the other into 10, or in ratio 4:5, the note produced is a compound one, such as would be obtained by striking on the piano two notes separated by the interval of a major third. Similar results are obtainable by means of the remaining perforations.

A still simpler form of siren may be constituted with a good spinning-top, a perforated card disk, and a tube for blowing with. The method of Cagniard de la Tour is followed as the preceding. It consists of a cylindrical chest of brass, the base of which is pierced at its centre with an opening through which a cylinder is formed of a plate perforated near its edge by a number of holes, which are distributed in a circle on a common plane, and which are cut obliquely through the thickness of the plate. Immediately above this fixed plate, and almost in contact with it, is another of the same dimensions, and furnished with the number of holes, n, of openings similarly placed, but passing obliquely through in an opposite direction to those in the fixed plate, the one set being inclined to the left, the other to the right. The second plate is made to rotate about an axis perpendicular to its plane and passing through its centre. Now, let the movable plate be at any time in a position such that its holes are immediately above those in the fixed plate, and let the bellows by which air is forced into the cylinder (air, for simplicity, being
supposed to be the fluid employed) be put in action; then the air in its passage will strike the side of each opening in the movable plate in an oblique direction (as shown in fig. 16), and will therefore urge the latter to raise to one of the positions shown in the figure. For each division of a revolution, the two sets of perforations will again coincide, the lateral impulse of the air will be zero, and hence the velocity of rotation increased. This will go on continually as long as air is supplied to the cylinder, and the velocity of rotation of the upper plate will be accelerated up to a certain maximum, at which it may be maintained by keeping the force of the current constant.

Now, it is evident that each coincidence of the perforations in the two plates is followed by a non-coincidence, during which the air-current is shut off, and that consequently during each revolution of the upper plate, there occur alternate passages and intercessions of the current. Hence arises the same number, of successive impul-

ses of the external air immediately in contact with one face of the plate, which is thus thrown into a state of vibration at the rate of \( n \) for every revolution of the plate. The result is a note whose pitch rises as the velocity of rotation increases, and becomes steady when that velocity reaches its constant value. If, then, we can determine the number \( m \) of revolutions performed by the plate in every second, we shall have at once the number of vibrations per second corresponding to the audible note by multiplying \( m \) by \( n \).

For this purpose the axis of the main cylinder is furnished with a screw working into a toothed wheel, and driving it round, during each revolution of the plate, through a space equal to the interval between two teeth. An index representing each tooth par
takes of this motion, and points successively to the divisions of a graduated dial. On the completion of each revolution of this toothed wheel (which, if the number of its teeth be 100, will comprise 100 revolutions of the moving plate), the index is released, and a projection on the dial is brought to catch a tooth of another toothed wheel and turns it round, and with it a corresponding index which thus records the number of turns of the first toothed wheel. As an example of the applica-
tion of this siren, suppose that the number of revolutions of the plate, as shown by the indices, amounts to 5400 in a minute, that is, to 90 per second, then the number of vibrations per second of the note heard amounts to 900, or (if number of holes in each plate = 8) to 720.

H. N. Dove (1803-1879) produced a modification of the siren by which the relations of different musical notes may be more readily ascertained. In this modification, the two plates, and move-

FIG. 16.

sponding to those in the plates, and which may be pressed round by projecting pins, so as to admit the air-current through any one or more of the series of perforations in the fixed plate. Thus may be obtained, either separately or in various combinations, the four notes whose vibrations are in the ratios of the above numbers, and which therefore form the fundamental chord (CEGC). The inventor has given to this instrument the name of the many-voiced siren.

Helmholtz (Sensations of Tone, ch. viii.) further adapted the siren for more extensive use, by the addition to Dove’s instrument of a mirror and moving retinal rings, both the movable plates being driven by the same current and revolving about a common axis. The invention is a figure of this instrument (fig. 17). Hedgehog Methods.—The relation between the pitch of a note and the period of the corresponding vibrations has also been studied by graphic methods. Thus, if an elastic metal strip or trapezoidal plate is fixed by a pin to a fork, and if the fork, while in vibration, is moved rapidly over a glass plate placed with lamp-black on it, the attached stylus touching the plate lightly, a wavy line will be traced on the plate answering to the fork at the period of the fork. The same result will be obtained with a stationary fork and a glass plate moved under it, and the plate moving through a given distance can be ascertained when the number of complete undulations exhibited on the plate for that distance, which is evidently the number of vibrations of the fork in that time, is reckoned, we shall have determined the numerical vibration-value of the note yielded by the fork. Or, if the same plate be moved in contact with two tuning-forks, we shall, by comparing the number of sinuosities in the one trace with that in the other, be enabled to assign the ratio of the corresponding numbers of vibrations per second. If vibrations per second are higher than the other, it will give double the number of waves in the same distance. The motion of the plate may be simply carried on by dropping it on two forked grooves, the tuning-forks being properly fixed to a frame above.

Greater accuracy may be attained with a revolving-drum chronograph first devised by Thomas Young (Lect. on Nat. Phil., 1807). Koenig’s revolving drum, to which a red or other color is given by lamp-black, or, better still, a metallic cylinder, round which a blackened sheet of paper is wrapped. The cylinder is mounted on an axis and turned round, while the stylus, which is fixed to the drum and traces therefore a wavy circle, which, on taking off the paper and flattening it, becomes a wavy straight line. The superiority of this arrangement is well seen in the fact that the number of revolutions of the cylinder in a given time may be ascertained. In R. Koenig’s arrangement (Quelques expériences d’acoustique, p. 1) the axis of the cylinder is fashioned as a fork, which works in fixed nuts at the ends, causing a sliding, as well as a rotatory motion of the cylinder. The lines traced out by the vibrating pointer are thus prevented from overlapping when more than one turn is given to the cylinder. In the phonoautographic method employed by L. S. Schuster, the paper is drawn through a revolving drum, whatever may be made to record its trace on the paper by means of a large parabolic cavity resembling a speaking-trumpet, which is fixed to the drum, and the intensity of the sound is registered by a pointer at the back of the drum. The sound is recorded by a current of air passing through a small hole in a metal plate and emerging from a narrow slit. The current is made to pass through a suitable solution of a coloring matter, and causes a colored line on the revolving drum, which may be drawn or turned as desired. The integral or herbal numbers (developed) of the vibrations may be ascertained in this case by means of a pointer which may be so regulated as to register an integral number of vibrations per second by means of a fixed scale. One of its principal advantages is that it may be turned very fast, so that in a very short time, the number of vibrations from 1/1000 to 1000 per second may be obtained. The drum is divided into minutes, each minute being divided into 60 equal parts, each part into 60 equal parts, each part into 60 equal parts, each part into 60 equal parts, each part into 60 equal parts.

Lissajous Figures.—A mode of exhibiting the ratio of the frequen-
cies of two forks was devised by Jules Antoine Lissajous (1822-
1880). Two forks, fixed in a common fork, are so arranged that the two forks are fixed so that one vibrates in a vertical, and the other in a horizontal, plane, and they are so placed that a converging beam of light received on one mirror is reflected to the other and then to a point on a screen. If the first fork alone vibrates, the point on the screen appears lengthened out into a vertical line through the changes in inclination of the first mirror, while if the second fork alone vibrates, the point appears lengthened out into a horizontal line. If both vibrate, the point describes a curve which appears continuous through the persistence of the retinal impression. Lissajous also obtained the figures by aid of the vibra-
tion microscope, which is a simple modification of a microscope, in which a mirror, the objective of a microscope is attached to one prong of the first fork and the eyepiece of the microscope is fixed behind the fork. Instead of a mirror, the empty space, or the objective, being fixed on a point on one prong, and the microscope is focused on this. If both forks vibrate, an observer looking through the microscope sees the bright point describing Lissajous figures. If the two forks have the same frequency, it is easily seen that the figure will be an ellipse (including as limiting cases, depending on relative amplitude and phase, a circle and a straight line). If the forks are not of exactly the same frequency the ellipse will slowly revolve, and its rate of revolution the ratio of the frequencies may be determined (Rayleigh, Sound, i. § 33). If one is the octave of the other a figure of 8 may be described, and so on. Fig. 18 shows curves given by interferometer and a circular or straight line. Koenig devised a clock in which a fork of frequency 64 takes the place of the pendulum. The motion of the fork is maintained by the clock acting through an escapement, and the dial registers both the number of vibrations of the fork and the seconds, minutes and hours. Instead of a circular or straight line, the total number of vibrations of the fork in any time may be accurately determined. One prong of the fork carries a micro-
scope objective, part of a vibration microscope, of which the eyepiece is fixed at the back of the clock and the Lissajous figure is given by the mirror of the microscope.
If the wheel has very little work to do it may not be necessary to apply driving power, and uniform rotation may be maintained by the electro-magnet. In an experiment described by Rayleigh such a wheel provided with four armatures was used to determine the exact frequency of a driving fork known to have a frequency nearer than 8 revolutions per second. There was one opening in its disk, and through this was viewed the pendulum of a clock beating seconds. On the pendulum was fixed an illuminated silver bead which appeared as a bright point of light when seen for an instant. Suppose now that one looks from a fixed point at the bead through the hole in the phonic wheel, he will see the bead as 8 bright points flashing out in each beat, and in succession at intervals of ½ second. Let us suppose that he notes the positions of each of these points to each other in the beat of the pendulum one way. If the fork makes exactly 32 vibrations and the wheel 8 revolutions in one pendulum beat, then the positions will be the same, and every second in a complete pendulum vibration, he will see the two positions looked at flash out in succession at an interval of ½ second. But if the fork has, say, rather greater frequency, the hole in the wheel comes round at the end of the two seconds before the bead has quite come into position, and the two flashes appear gradually to move back in the opposite way to the pendulum. Suppose that in N beats of the clock the flashes have moved exactly one place back. Then the first flash in the new position is viewed by the Nth passage of the opening, and the second flash in the original position of the first is viewed when the pendulum has made exactly N beats by the (8 N + 1)th passages of the hole. Then the wheel makes 8 N + 1 revolutions in N clock beats and the fork makes 32 N + 4 vibrations in the same time. If the clock is going exactly right, this gives a frequency for the fork of 32 + 4/N. If the fork has rather less frequency than 32 then the flashes appear to move forward and the frequency will be 32–4/N. In Rayleigh’s experiment the 32 fork was made to drive electrically one frequency about 125, and somewhat as with the phonic wheel, the frequency was controlled so as to be exactly four times that of the 32 fork. A standard 128 fork could then be compared either electrically or by beats with the electrically driven fork.

Scheibler’s Tonometer.—When two tones are sounded together with frequencies not very different, “beats” or swellings-out of the sound are heard of frequency equal to the difference of frequencies of the two tones (see below). Johann Heinrich Scheibler (1777–1859) tuned two forks to an exact octave, and then a number of others dividing the octave into such small steps that the beats between each and the next could be counted easily. Let the forks be numbered 0, 1, 2, . . . N. If the frequency of a beat of that of No. 1 makes m1 beats with No. 0, then No. 2 makes m2 beats with No. 1, and so on, then the frequencies are

$$n, n + m_1, n + m_1 + m_2, \ldots, n + m_1 + m_2 + \ldots + m_N$$.

and it follows that when n is known, the frequency of every fork in the range may be determined.

Any other fork within this octave can then have its frequency determined by finding the two between which it lies. Suppose, for instance, it makes 3 beats with No. 10. It might have frequency either 3 above or below that of No. 10. But if it lies above No. 10 it will beat less often with No. 11 than with No. 9; if below No. 10 it will beat more often with No. 11 than with No. 9. It lies between No. 10 and No. 11 if its frequency is that of No. 10 + 3.

Meniscometric Flames.—This is a device due to Koenig (Phil. Mag., 1873, 45) and represented diagrammatically in fig. 19. It is a flame

from a pinhole burner, fed through a cavity C, one side of which is closed by a membrane m; on the other side of the membrane is a loud-speaker C, with which another microphone is arranged. The sound, as for instance, a Helmholtz resonator excited by a fork of the same frequency. The membrane vibrates, and alternately checks and increases the gas supply, and the flame jumps up and down with the frequency of the source. It then appears elongated. To show its intermittent character its reflection is viewed in a revolving mirror. For this purpose four vertical mirrors are arranged round the vertical sides of a cube which is rapidly revolved about one horizontal axis. The path of the beam appears to be broken, and several notes are present the flame is jagged by each. Interesting results are obtained by singing the different vowels into a funnel substituted for the resonator in the figure.
If two such flames are placed one under the other they may be excited by different sources, and the ratio of the frequencies may be approximately determined by counting the number of teeth in each in the same plane.

The Diatonic Scale.

It is not necessary here to deal generally with the various musical scales. We shall treat only of the diatonic scale, which is the basis of European music, and is approximated to as closely as is consistent with convenience of construction in key-board instruments, such as the piano, where the eight white notes beginning with C and ending with C an octave higher may be taken as representing the scale with C as the key-note.

Experiments in frequency show that two notes forming a definite musical interval, have their frequencies always in the same ratio wherever in the musical scale the two notes are situated. In the scale of C the intervals from the key-note, the frequency ratios with the key-note, the successive frequency ratios and the successive intervals are as follows:—

<table>
<thead>
<tr>
<th>Note</th>
<th>Interval with C</th>
<th>Frequency</th>
<th>Successive frequency ratios</th>
<th>Successive intervals</th>
</tr>
</thead>
<tbody>

If we pass through two intervals in succession, as, for instance, if we ascend through a fourth from C to F and then through a third from F to A, the frequency ratio of A to C is 3/2, which is the product of the ratios for a fourth 4/3 and a third 2/3. That is, if we add intervals we must multiply frequency ratios to obtain the frequency ratio for the interval which is the sum of the two.

The frequency ratios in the diatonic scale are all expressible either as fractions, with 1, 2, 3 or 5 as numerator and denominator, or as products of such fractions; and it may be shown that for a given note the numerator and denominator are smaller than any other numbers which would give us a note in the immediate neighborhood.

Thus the second 4/3 = 4/3 x 3/4, and we may regard it as an ascent through two fifths in succession and then a descent through an octave. The third 4/3 = 4/3 x 3/4 or ascent through an interval 4/3 which has no special name, and a descent through two octaves, and so on.

Now suppose we take G as the key-note and form its diatonic scale. If we write down the eight notes from G to G in the key of C, their frequency ratios to C, the frequency ratios required by the diatonic scale for G, we get the frequency ratios required in the last line:

<table>
<thead>
<tr>
<th>Note</th>

We see that all but two notes coincide with notes on the scale of C. But instead of A = 5/4 we have 1/2, and instead of f = 4/3 we have 1. The interval between 4/3 and 4/3 = 4/3 + 4/3 = 8/3 is termed a "comma," and is so small that the same note on an instrument may serve for both. But the interval between 4/3 and 4/3 = 4/3 + 4/3 = 8/3 is quite perceptible, and on the piano, for instance, a separate string must be provided above f. This note is f sharp, and the interval 8/3 is termed a sharp.

Taking the successive key-notes D, A, E, B, it is found that besides small and negligible differences, each introduces a new sharp, and so we get the five sharps, C, D, F, G, A, represented nearly by the black keys.

If we start with F as key-note, besides a small difference at d, we have as the fourth from it 4/3 x 4/3 = 4/3, making with B = 4/3 an interval 4/3, and requiring a new note, B flat. This does not coincide with A sharp which is the octave below the seventh from B or 8/3 x 4/3 = 8/3. It makes with

it an interval = 8/3 + 4/3 = 12/3 = 4/1, rather less than a comma; so that the same string in the piano may serve for both. If we take the new note, C sharp, another note, E flat, is required. E flat as key-note introduces another flat, and so on, each flat not quite coinciding with a sharp but at a very small interval from it.

It is evident that for exact diatonic scales for even a limited number of key-notes, key-board instruments would have to be provided with a great number of separate strings or pipes, and the corresponding keys would be required. The construction would be complicated and the playing exceedingly difficult.

The same string or pipe and the same key have therefore to be used, and there must be slightly different notes. A compromise has to be made, and this has led to a scale as to the compromise as little unsatisfactory as possible. At present twelve notes are used in the octave, and these are arranged at equal intervals 12. This is termed the equal temperament scale, and it is obviously only an approach to the diatonic scale.

Helmholtz's Notation.—In works on sound it is usual to adopt Helmhotz's notation, in which the octave from bass to middle C is written c e g a b c'. The octave above is c' d' f' g' a b c". The next octave above has two accents, and each succeeding octave another accent. The octave below bass C is written C D E F G A B C, and the next octave below is C D E F G A B C, and each preceding octave has another accent as suffix.

The standard frequency for laboratory work is c' = 128, so that middle c" = 256 and treble c" = 512.

The standard for musical instruments has varied (see PITCH, MUSICAL). Here it is sufficient to say that the French standard is a' = 435 with c' practically 522, and that in England the pitch is somewhat higher.

The French notation is as under:

<table>
<thead>
<tr>
<th>Note</th>
<th>Frequency</th>
</tr>
</thead>
<tbody>
<tr>
<td>C</td>
<td>D E F G A B C</td>
</tr>
<tr>
<td>Ut</td>
<td>Re Mi Fa Sol La Si Ut</td>
</tr>
</tbody>
</table>

The next higher octave has the suffix 2, the next higher the suffix 3, and so on. French forks are marked with double the true frequency, so that the fork is marked 435. 

Limiting Frequencies for Musical Sounds.—Until the vibrations of a source have a frequency in the neighbourhood of 30 per second the ear can hear the separate impulses, if strong enough, but does not hear a note. It is not easy to determine the exact point at which the impulses fuse into a continuous tone, for higher tones are usually present with the deepest of which the frequency is being counted, and these may be mistaken for it. Helmhotz's (Sensations of Tone, p. 141) limit of hearing is 5000 vibrations per second, and thus the higher tones were several octaves above the fundamental, and so not likely to be mistaken for it; he found that with 37 vibrations per second a very weak tone was heard, and that there was scarcely anything audible left. A determinate musical pitch is not perceived, he says, till about 40 vibrations per second. At the other end of the scale with increasing frequency there is another limiting frequency beyond which the ear cannot hear, beyond which no sound is heard. But this limit varies greatly with different individuals and with age for the same individual. Persons who when young could hear the squeaks of bats may be quite deaf to them when older. Koening constructed a series of bars forming a harmonicon, the frequency of each bar being calculable, and he found the limit to be between 16000 and 24000.

The Number of Vibrations needed to give the Perception of Pitch.—Experiments have been made on this subject by various workers, the most extensive by W. Kohlrausch (Wied. Ann., 1880, x. i.). He allowed a limited number of teeth on the arc of a circle to strike against a steel plate with nine teeth it was fairly determinate; and even with two teeth it could be assigned with no great error. His remarkable result that two waves give some sense of pitch, in fact a tone with wavelength short enough to the interval between the waves, has been confirmed by other observers.

Alteration of Pitch with Motion of Source or Hearer: Doppler's Principle.—A very notable alteration of pitch by motion occurs when a whistling locomotive moves rapidly past an observer. As it passes, the pitch of the whistle falls quite appreciably. The explanation is simple. The engine follows up any sound wave that it has produced, and so crowds up the succeeding waves into a less distance than if it remained at rest. It draws off from any wave it has sent backward and so spreads the succeeding waves over a longer distance than if it had remained at rest. Hence the frequency of the waves must be altered. Since U = c + λ where U is the velocity of sound, λ the wave-length, and n the frequency, it follows that the forward frequency is greater than the backward frequency.

The more general case of motion of source, medium and receiver
The maximum pressure excess is the amplitude of \( a = E a U / (E/U) dy/dt \). It is

\[
\Delta a = (E/U) 2\pi U \alpha = 2\pi \alpha U a.
\]

(20)

We have already found the energy density in the train and the energy stream in equations (13) and (14).

The chief experimental basis for supposing that a train of longitudinal waves with displacement curve of this kind arouses the sensation of a pure tone is that the more nearly a source is made to vibrate with a single simple harmonic motion, and therefore, the more nearly it sends out waves which are those of a harmonic train, the more nearly does the note heard approximate to a single pure tone.

Any periodic curve may be resolved into sine or harmonic curves by Fourier's theorem.

Suppose that any periodic sound disturbance, consisting of plane waves, is being propagated in the direction ABCD (fig. 22). Let it be represented by a displacement curve AHBKC. Its periodicity implies that after a certain distance the displacement curve exactly repeats itself. Let AC be the shortest distance after which the repetition occurs, so that CLDM is merely AHBKC moved on a distance AC. Then AC = \( \lambda \) is the wave-length or period of the curve. Let ABCD be drawn at such level that the areas above and below it are equal; then ABCD is the axis of the curve. Since the curve represents a longitudinal disturbance in air it is always continuous, at a finite distance from the axis, and with only one ordinate for each abscissa.

Fourier's theorem asserts that such a curve may be built up by the superposition, or addition of ordinates, of a series of sine curves, one of length \( \lambda \) in one wave-length, \( \lambda/2 \) in another, and so on. The ordinates of the original curve of function \( f(x) \) are alternates of the ordinates of the sine functions of the angles \( \pi x / \lambda \), \( 2\pi x / \lambda \), \( 3\pi x / \lambda \), etc., that is, the ordinates \( f(x) \), \( f(\pi x / \lambda) \), \( f(2\pi x / \lambda) \), etc., are suitably adjusted, and the proof of the theorem gives rules for finding these quantities when the original curve is known. We may therefore put

\[
y = a \sin \frac{2\pi x}{\lambda} + b \sin \frac{4\pi x}{\lambda} + c \sin \frac{6\pi x}{\lambda} + \cdots. \tag{21}
\]

where the terms may be infinite in number, but always have wave-lengths submultiples of the original or fundamental wave-length \( \lambda \). Only one such resolution of a given harmonic curve is possible. In the present case there is one of the constituents repeats itself not only after a distance equal to its own wave-length \( \lambda n \), but evidently also after a distance equal to the fundamental wave-length \( \lambda \). The successive terms of (21) are called the harmonics of the first term.

It follows from this that any periodic disturbance in air can be resolved into a definite series of simple harmonic disturbances of wave-lengths equal to the original wave-length and its successive submultiples, and each of these would separately give the sensation of a pure tone. If the series were complete we should have terms which separately would correspond to the fundamental, its octave, its quarter, its half and so on, and the amplitude and ordinates of each of these would separately give the sensation of a pure tone. If the series were complete, we should have terms which separately would correspond to the fundamental, its octave, its quarter, its half and so on, and the amplitude and ordinates of each of these would separately give the sensation of a pure tone. If the series were complete, we should have terms which separately would correspond to the fundamental, its octave, its quarter, its half and so on, and the amplitude and ordinates of each of these would separately give the sensation of a pure tone.

Fourier's theorem can also be usefully applied to the disturbance of a source of sound under certain conditions. The nature of these conditions will be best realized by considering the case of a stretched string. It is shown below how the vibrations of a string may be deduced from stationary waves. Let us suppose that a membrane AB is displaced into the form AHBK (fig. 23) and then let go. Let

\[
y \approx \text{sine} \frac{2\pi x}{\lambda} + \text{sine} \frac{4\pi x}{\lambda} + \text{sine} \frac{6\pi x}{\lambda} + \cdots.
\]

The tension + mass per unit length of each half of the train represented in fig. 25. For the superposition of these trains will give a stationary wave between A

\[
\text{FIG. 22.}
\]

and B.

\[
\text{FIG. 23.}
\]

\[
\text{FIG. 24.}
\]
and B. Now we may resolve these trains by Fourier's theorem into harmonics of wave-lengths $\lambda$, $2\lambda$, $3\lambda$, &c., where $\lambda = 2AB$ and the conditions as to the values of $\gamma$ can be shown to require that the harmonics shall all have nodes, coinciding with the nodes of the fundamental curve. Thus the same for all disturbances they all travel at the same speed, and the two trains will always remain of the same form. If then we resolve AHBK into harmonics by Fourier's theorem, we may follow the motion of the separate harmonics by their superposition will give the form of the string at any instant. Further, the same harmonics with the same amplitude will always be present.

We see, then, that the conditions for the application of Fourier's theorem are equivalent to saying that all disturbances will travel along the system with the same velocity. In many vibrating systems this does not hold, and then Fourier's theorem is no longer an appropriate resolution. But when the frequency is such that the vibrations can be disposed into waves, each of the same natural frequency, and to be set into vibration when the ear receives a train of waves of that frequency. The vibration in some way arouses a sensation of the corresponding tone. But the resonator will be appreciably though less affected by waves of frequency differing slightly from its own. Thus Helmholz from certain observations (Sound, ii. § 388) thought that if the frequency of the periodic sound wave was $\lambda$, and the frequency of the periodic sound wave was taken as $\lambda$, then its response to an equal loud tone a semitone different may be taken as about $\lambda$. According to this theory, then, when a pure tone is received the auditory apparatus corresponding to that tone is most excited, but the apparatus on each side of it is also excited, though by a rapidly diminishing amount, as the interval increases. If the sensations corresponding to these neighboring elements are thus aroused, we have no such perception as a pure tone, and what we regard as a pure tone is the mean of a group of sensations. The sensitiveness of the ear in judging of a given tone must then correspond to the accuracy with which it can judge of the mean.

Measurements of Intensity of Sound or Loudness. Various devices have been successfully employed for measuring sounds but the ear is not intended to the hearing of partially deaf people. But the converse, the measurement of the loudness of a sound not produced at our will, is by no means so easy. If we compare the problem with that of measuring the illumination due to a source of light, we see at once how different it is. In sound sensation we have nothing corresponding to white light. A noise such as the roar due to traffic in a town may correspond physically in that it could probably be resolved into a nearly continuous series of wave-lengths, but psychologically it is of no interest. We do not use such noise, but rather seek to avoid it. In this connection the ear, as we have seen, is the keystone and if we did it might be difficult to fix on any unit of noisefulness. Probably we should be driven to a purely physical unit, the stream of energy proceeding in any direction, and if the noise were great enough we might measure it possibly by the pressure against a surface.

The intensity of the stream of energy passing per second through a square centimetre when a given pure tone is sounded is more definite and can be measured. There are two practical methods. In the one, the energy of the vibration of the source is measured, and the rate at which energy decreases as the sound travels through the air is determined, and the energy of the stream at any distance is known. In the other, the waves produce a measurable effect on a vibrating system of the same frequency, and the amplitude in the waves can be deduced.

The first may be illustrated by Lord Rayleigh's experiments to determine the amplitude of vibration in waves only just audible (Sound, ii. § 384). He used two kinds of experiments, but it will be sufficient here to indicate the second. A fork of frequency 256 was used as the source. The energy of this fork with a given amplitude of vibration could be calculated from its dimensions and elasticity, and the energy that the ear receives is the energy that it can do work on. This energy was observed by measuring with a microscope the line into which the image of a starch grain on the prong was drawn by the vibration. The rate of loss of energy from the fork by the ear was thus determined. The rate of loss for each experiment was determined (1) when the fork was vibrating alone, and (2) when a resonator was placed with its mouth under the free ends of the fork. The difference in loss in the two cases measured the energy given up to and sent out by the resonator as sound. The amplitude of the fork was observed when the sound just ceased to be audible at 27.4 metres away, and the rate of energy entering the resonator was calculated. If the energy that the ear can do work on is known, then the energy of the waves to which the ear is sensitive can be calculated. Assuming this energy to be propagated in hemispherical waves, it is easy to find the quantity per second going through 1 sq. cm. at the distance of the listener, and thence to find the intensity of the wave. The result was an amplitude of $1.5 \times 10^{-9}$ cm. Other fork gave results not very different.

In a later series of experiments Lord Rayleigh (Phil. Mag., 1907, 14, p. 596) found that the lowest energy stream required to excite sensation did not vary greatly between frequencies of 512 and 256.
but that the stream required increased rapidly as the frequency was reduced below 256.

The second method may be illustrated by the experiments of M. Wien (Wied. Ann., 1889, xxxvi. 834). He used a spherical Helmholtz resonator resonating to the tone to be measured. The orifice, which is usually placed to the ear, was enlarged and closed by a corrugated plate like that of an aneroid barometer, and the motion of this plate was indicated by means of a mirror which had one edge fixed, while the other was attached to a style fixed to the centre of the plate. When the plate vibrated the mirror was vibrated about the fixed edge, and the image of a reflected slit was broadened out into a band, the broadening giving the amplitude of vibration of the plate.

From subsidiary experiments (for which the original memoir must be consulted) the pressure variations within the resonator could be calculated from the movements of the plate. The open orifice of the resonator was then exposed to the waves from a source of its own frequency. Helmholtz's theory of the resonator (Rayleigh, Sound, ii. § 311) gives the pressure variations in the incident waves in terms of those in the resonator, and in these pressure variation and the amplitude of the vibrations in the waves to be measured were determined.

For minimum audible sounds Wien found a somewhat smaller value of the amplitude than Rayleigh. Lord Rayleigh says, "the streams of energy required to influence the eye and the ear are of the same order of magnitude." Wien also used the apparatus to find the decrease of intensity with increase of distance, and found that it was somewhat more rapid than the inverse square law would give.

In a later series of experiments (Science Abt. vi. 301) Wien used a telephone plate, of which the amplitude could be determined from the value of the exciting current, and he found that the smallest amplitude audible was 6.1 X 10⁻⁶ cm.

W. Zernov (Ann. d. Physik, 1906, 21, p. 131) compared the indications of Wien's resonator manometer with those of V. Althberg's sound pressure apparatus and found very satisfactory agreement.

Stationary Waves.—As a preliminary to the investigation of the modes of vibration of certain sources of sound we shall consider the formation of stationary waves. These are not really waves in the ordinary sense, but the disturbance arising from the passage through the medium in opposite directions by two equal trains. The medium is divided up into sections between fixed points, and these sections vibrate. We can form stationary waves with ease by fixing one end of a rope—say 20 ft. long—and holding the other end in the hand. When the hand is moved to and fro transversely waves are set up along the rope and directed at the fixed end. The direct and reflected systems are practically equal, and by suitably timing the vibrations of the hand for each case the rope may be made to vibrate as a whole, as two halves, as three-thirds and so on. When it vibrates in several sections, each section moves in the opposite way to its neighbours.

Let us suppose that two trains of sine waves of length λ and amplitude a are travelling in opposite directions with velocity U. We may represent the displacement due to one of the trains by

\[ y_1 = a \sin \frac{2\pi x}{\lambda} \left(x-Ut\right) \]  

(24)

where \( x \) is measured as in equation (16) from an ascending node as A in fig. 21. If we measure \( t \) from an instant at which the two trains exactly coincide, then as \( U \) for the other train has the opposite sign, its displacement is represented by

\[ y_2 = a \sin \frac{2\pi x}{\lambda} \left(x+Ut\right) \]  

(25)

The sum of the disturbance is obtained by adding (24) and (25)

\[ y = y_1 + y_2 = a \cos \frac{2\pi x}{\lambda} U t \sin \frac{2\pi x}{\lambda} \]  

(26)

At any given instant \( t \) this is a sine curve of amplitude \( 2a \cos \left(2\pi \lambda/\lambda\right)U \), and of wave-length \( \lambda \) and with nodes at \( x = a, \lambda k, \lambda, \ldots \), that is, there is no displacement at these nodes whatever the value of \( t \), and between them the displacement is always a sine curve, but of amplitude varying between \( a+2a \) and \( a-2a \). The ordinate of the curve changes sign as we pass through a node, so that successive sections are moving always in opposite directions and have opposite displacements. Each section then vibrates, and its amplitude grows through the tone to be measured. The orifice or \( T = \lambda/U \), and the frequency is \( V/\lambda \). We may represent such a train as "stationary waves" by fig. 25, where the curves give the

![Fig. 25](image)

two extreme amplitudes. The points A, B, C, D are termed "nodes," and the points half-way between them "loops."

The general character of these results may be obtained by a graphic construction. Let fig. 26 (1) represent a wave-length of each train when they are coincident. It is sufficient to take a single wave-length. The dotted curve represents the superposition, which simply doubles each ordinate. Divide the wave-length into, say, eight equal parts as marked. Then move one train marked (1) \( \lambda/2 \) to the right, and the other train (II) \( \lambda/2 \) to the left, introducing new parts of each train at one end, and sending out old parts at the other. Then we get fig. 26 (2), the dotted curve representing the resultant with amplitude \( 1/2 \) that of (1). Another movement of \( \lambda/2 \) in each direction gives (3) with resultant a straight line, and so on for (4) and (5). In (5) the displacement is entirely equal and opposite to that in (1). Further displacement will give the figures (4), (3), (2), (1) again, but with (1) and (II) interchanged. When we get back to (1) each train has been displaced through \( \lambda/2 \) and the period is \( \lambda/2 \). Further, the original nodes are always at rest, and the intervening sections vibrate to and fro.

The vibrations of certain sources of sound may be represented, at least as a first approximation, as consisting of stationary waves, and from a consideration of the rate of propagation of waves along these sources we can deduce their frequency when we know their length.

Sources of Sound.

Elementary Theory of Pipes.—The longitudinal vibration of air in cylindrical pipes is made use of in various wind instruments. We shall deduce the modes of vibration of the air column in a cylindrical pipe from the consideration that the air in motion within the pipe forms some part of a system of stationary waves, one train being formed by the exciter of the disturbance, and the other being formed by the reflection of the train at the end of the pipe.

In order to justify the use of stationary waves we must show that two such trains can move in opposite directions over the same ground without modifying each other so long as the displacement in either is small. For this it is necessary that the total force due to the sum of the displacements should be equal to the sum of the forces due to the two displacements considered separately. The medium then acts for the second train just as if it were undisturbed by the first. It is sufficient then to show that the excess of pressure at any point is the sum of the excesses due to either train separately.

If \( \omega \) is the total pressure excess and if \( \gamma \) is the total displacement at \( x \), then \( \omega = E x + \text{constant} + \text{volume} = -Edy/dx \). If \( \gamma_t \) and \( \gamma_f \) are the two separate displacements and if \( \gamma = \gamma_t + \gamma_f \), then \( \omega = E \left(dy_t/dx + dy_f/dx\right) = \omega_t + \omega_f \). This proves the proposition. It is a case of the principle of superposition of small disturbances.

Let us suppose that a system of stationary waves is formed in the air in a pipe of indefinite length, and let fig. 27 represent a part of the system. At the nodes A, B, C, D there is no displacement, but there are maximum volume and pressure changes. Consider, for instance, the point B. When the displacement is represented by AHBKC the particles on each side of B are displaced towards it.
giving a compression, and since the slope is steepest there, or 
\(-dy/dx\) a maximum, the compression is also a maximum there. 
When the displacement is represented by AH BK C the particles 
on each side of B are displaced from it, giving an extension, and since 
the slope is again the steepest, the extension is a maximum.

**Fig. 27.**

At the loops, for instance at H, the displacement is a maximum. 
The tangent to the displacement curve is always parallel to the axis, 
that is, for a small distance the successive particles are always 
equally displaced, and therefore always occupy the same volume. 
This means that at the loops while the motion is greatest there are 
no pressure changes.

We have now to select such portion of this system as will suit 
the conditions imposed by any actual pipe. There are three distinct 
types, which we will consider in succession.

1. **Pipe Closed at One End, Open at the Other.**—At the closed 
end there is no motion, for the pressure always constrains the air 
to remain in contact with the end. The closed end is therefore a node.
At the open end, as a first approximation to be corrected later, 
there are no pressure changes, for any tendency to excess can be relieved 
by immediate expansion into the outer air, and any tendency to deflect 
can be filled up by an inrush from the outer air. The open end is 
therefore a loop. It is to be noted that the center of the vibrations 
is in general at the open end, and that the two trains forming the 
stationary system consist of the direct waves from the exciters 
travelling into the tube, and the waves reflected back from the 
closed end.

In fig. 27 we may have the length AH occupying the tube. 
In this case \(AH = \lambda_1 = l\), the length of the tube, and the frequency 
\(n_1 = \frac{H}{\lambda_1} = \frac{U}{l}\). But we may also have a shorter wave-length 
\(\lambda_2\) such that the length AK occupies the tube. In this case \(AK = \lambda_2 = l\), and the frequency \(n_2 = \frac{H}{\lambda_2} = \frac{U}{2l}\).
With a still shorter wave-length \(\lambda_3\) we may have the length AL occupying the tube and 
\(AL = \lambda_3 = l\), and the frequency \(n_3 = \frac{H}{\lambda_3} = \frac{U}{3l}\), and so on, as 
we take succeeding loops for the open end.

In fig. 28 are represented the stationary wave systems of the first 
four modes, and any of the succeeding ones are easily drawn.
affected by the nodal pressure changes, while the other two vibrate only slightly. If, however, the pipe is blown strongly, the fundamental dies away, and the first overtone is predominant. Then the middle note is a loop, and the middle line becomes a column. The sounder is placed on the end of the tube, and the overtone line is closely fitted with the overtone line. This case is not exactly realized in practice, but it is closely approximated to in Kundt’s dust-tube. A glass tube, the “dust-tube,” 2 ft. or more in length, and perhaps 1 in. in diameter, has a little lymphodendron powder introduced, and the powder is allowed to run all along the tube, which is then fixed horizontally. A closely-fitting adjustable piston is provided at one end. A glass or metal rod, the “sounder,” is clamped at its middle point, and fixed along the prolongation of the axis of the dust-tube as in fig. 31, a loosely-fitting cork or card piston being fixed on one end of the sounder, which is inserted within the dust-tube. The other end of the sounder is stroked outwards with a damp cloth so as to make it sound its fundamental. Stationary waves are formed in the air in the dust-tube if the length is roughly adjusted by the closely-fitting piston, and the lymphodendron dust collects at the nodes in little heaps, the first being at the fixed end and the last just in front of the piston on the sounder. The stationary wave system adjusts itself so that its motion agrees with that of the piston. This is not exact at a node. If \( \nu \) is the velocity of longitudinal waves along the sounder, and \( L \) the length of the sounder, the frequency of vibration is \( \nu/L \). If \( L \) is the distance between successive dust-heaps, i.e., half a wave-length, then the velocity in air is \( \nu / 2L \), where \( \nu \) is the velocity of sound in the pipe. Then, since the frequencies are the same, \( 2L = \nu / \nu \) or \( L = \nu / \nu \).

The velocities in different gases may be compared by this apparatus by filling the dust-tube with the gases in place of air. If \( L \) is the internodal distance and \( U \) the velocity in a gas, \( L \) and \( U \) being the corresponding values for air, we have \( U/L = \nu/\nu \).

Kundt’s dust-tube may also be employed for the determination of the ratio of the specific heats of a gas or vapour. If \( U \) is the velocity of sound in a gas at pressure \( P \) with density \( \rho \), and if waves of length \( \lambda \) and frequency \( N \) are propagated through it, then the distance between the dust-heaps is

\[
d = \frac{\lambda}{2} \frac{U}{2\nu N} \frac{1}{\sqrt{\rho}}
\]

where \( \gamma \) is the ratio of the two specific heats. If \( d \) is measured for two gases in succession for the same frequency \( N \), we have

\[
\frac{P_1}{P_2} = \frac{\rho_2}{\rho_1} \gamma_2 \gamma_1
\]

where the suffixes denote the gases to which the quantities relate. If \( \gamma_1 \) is known this gives \( \gamma_2 \). Kundt and Warburg applied the method to find \( \gamma \) for mercury vapour (Pogg. Ann., 1876, 157, p. 356), using a double form of the apparatus in which there are two dust-tubes worked by the same clamping rod. This rod is supported at \( \frac{1}{4} \) and \( \frac{3}{4} \) of its length where it enters the two dust-tubes, as represented diagrammatically in fig. 32. It is stroked in the middle so as to excite its second mode of vibration. The method ensures that the two frequencies shall be exactly the same. In the mercury experiment the middle dust-tube, which was exhausted of air, and contained only some mercury and some quartz dust to give the heaps. It was placed in a high temperature oven, where the mercury was evaporated. The second tube containing air was outside. When the known temperature that the overtones sounder was excited, and \( d_1 \) and \( d_2 \) could be measured. From the temperature, \( P_2/\rho_2 \) was known, and \( \gamma_2/\gamma_1 \) could then be found. Taking \( \gamma_1 = 1.66 \) and \( \gamma_2 = 1.84 \), Kundt and Sir William Ramsay (Phil. Trans. A, 1895, pt. I, p. 187) also used a single dust-tube with a sounder to find \( \gamma \) for argon, and again the value was 1.66.

**Determination of Pressure Changes and Amplitude of Vibrations in Pipes.**—If the maximum pressure change is determined, the amplitude is given by equation (20), viz.

\[
\tau = \tau_0 \rho U
\]

for in the stationary wave system the pressure change and the amplitude are both double those in either train, so that the same relation holds.

Determinations of the pressure changes, or extent of excursion of the dust-tube, on sounding organ pipes have been made by A. Kundt (Pogg. Ann., 1868, 35, 136), A. J. Topler and L. Boltzmann (Pogg. Ann., vol. 141, or Rayleigh, *Amplitude of Sound*, vol. II, £ 4320), and E. Mach (Öpvisch-abkustischen Forsuche, 1877). Mach’s method is perhaps the most direct. The pipe was fixed in a horizontal position, and along the top run a platinum wire wetted with sulphuric acid. When the wire was heated by an electric current a fine line of vapour descended from the wire, the whole being surrounded by a wave of air, a stroboscopic method being used to get the position of the wave line at a definite part of the vibrating air. Mach found an excursion of 1 cm at the end of an open pipe 133 cm long. The amplitude found by the other observers was of the same order. For the vibration of air in other cavities than long cylindrical pipes we refer to Rayleigh’s Sound, vol. II, chs. 12 and 16.

**Propagation of Waves in Pipes of Circular Section.**—Helmholtz investigated the velocity of propagation of sound in pipes, taking into account the viscosity of the air (Rayleigh, Sound, II, £ 347), and Kirchhoff investigated it, taking into account both the viscosity and the heat communicated between the air and the walls of the pipe (loc. cit. II, £ 350). Both obtained the value for the velocity

\[
U = \frac{C}{\sqrt{\pi N}}
\]

where \( U \) is the velocity in free air, \( R \) is the radius of the pipe, \( N \) the frequency, \( C \) is a constant, equal to the coefficient of viscosity in Helmholtz’s theory, but less simple in Kirchhoff’s theory. Experiments on the velocity in pipes were carried out by H. Schneebeck (Pogg. Ann., 1869, 136, p. 296) and by T. J. Seebeck (Pogg. Ann., 1870, 139, p. 904) which disagreed with this result as far as \( R \) is concerned, but the diminution of velocity was found to be more nearly proportional to \( N^{-3} \). Kundt also obtained results in general agreement with the formula (Rayleigh, Sound, II, £ 396). He used his dust-tube method.

**Elementary Theory of the Transverse Vibration of Musical Strings.**

We shall first investigate the velocity with which a disturbance travels along a string of mass \( m \) per unit length when it is stretched with a constant tension \( T \), the same at all points. We shall then show that on certain limitations two trains of disturbance may be superposed so that stationary waves may be formed, and thence we shall deduce the modes of vibration with pipes.
by proper adjustment of its length and tension vibrates in unison and divides itself into one or more loops or ventral segments easily discernible by a spectator. If the length of the thread be kept invariable, a certain tension will give but one ventral segment; the fundamental note of the thread is then of the same pitch as the note of the body to which it is attached. By reducing the tension to one quarter, the first harmonic of the thread will be seen to be increased to two, indicating that the first harmonic of the thread is now in unison with the solid, and consequently that its fundamental is an octave lower than it was with the former tension; thus confirming the law that \( n \) varies as \( \sqrt{T} \). In like manner, on further lowering the tension to one ninth, three ventral segments will be formed, and so on.

The law that, \textit{ceteris paribus}, \( n \) varies inversely as the thickness may be tested by forming a string of four lengths of the single thread used before, and consequently of double the thickness of the latter, when, for the same length and tension, the compound thread will exhibit double the number of ventral segments presented by the single thread.

The other laws admit of similar illustration.

**Longitudinal Vibrations of Wires and Rods.**

Subject to a limitation which we shall examine later, the velocity of a longitudinal disturbance along a wire or rod depends only on the material of the rod, and not upon the cross-section. Since the forces called into play by an extension or compression of the material are proportional to the cross-section, it follows that if we consider any case and then another case in which, with the same longitudinal disturbance, the cross-section is doubled, the force in the second case is doubled as well as the mass to bequelled. The acceleration therefore remains the same for the two cases, and the velocity is unaltered. We shall find the velocity of propagation, just as in previous cases, from the consideration of transfer of momentum.

Suppose that a disturbance is travelling with velocity \( U \) unchanged in form along a rod from left to right. Let us move the rod from right to left, so that the undisturbed parts move with velocity \( U \). Then the disturbance remains fixed in space. Let \( A \) be a point in the disturbance, and \( B \) a point in the undisturbed part. The material between \( A \) and \( B \), though continually changing, is always in the same condition, and therefore the momentum within \( AB \) is constant. Hence the amount carried out at \( A \) is equal to that carried in at \( B \).

New momentum is transferred in two ways, viz. by the force acting between contiguous portions of a body and by the transfer of moving matter. At \( B \) there is only the latter kind, and since the transfer of matter is \( \rho dU \), where \( \rho \) is the undisturbed density and \( dU \) is the undisturbed cross-section, since its velocity is \( U \), the passage of momentum per second is \( \rho dU U^2 \). At \( A \), if the velocity of the disturbance relative to undisturbed parts of the rod is \( U \) from left to right, the velocity relative to \( A \) is \( U - u \). If \( \rho \) is the density at \( A \), and \( \omega \) the cross-section, then the momentum carried past \( A \) is \( \rho dU (U - u) \). But if \( y \) is the displacement at \( A \), \( dy/dx \) is the extension at \( A \), and the force acting is a pull across \( A \) equal to \( Y dy/dx \), where \( Y \) is Young’s modulus of elasticity. Then we have

\[
Y dy/dx + \rho dU (U - u)^2 = \rho dU U^2 ,
\]

Now

\[
u U = -dy/dx ,
\]

for the particle at \( A \) moves over \( dy \) backwards, while the disturbance moves over \( U \). Also since \( dx \) has been stretched to \( dx + dy \),

\[
\rho dU (1 + dy/dx) = \rho dU,
\]

Substituting from (28) in (27)

\[
Y dy/dx + \rho dU (1 + dy/dx)^2 = \rho dU U^2 ,
\]

and substituting from (29) in (30)

\[
Y dy/dx + \rho dU [1 + (\rho dU)(dy/dx)^2] = \rho dU U^2 ,
\]

whence

\[
Y dy/dx = \rho dU U^2 ,
\]

or

\[
U = Y/\rho, \]

where now \( \rho \) is the normal density of the rod. The velocity with which the rod must travel in order that the disturbance may be fixed in space is therefore \( \rho Y/\rho \), or, if the rod is kept fixed, this is the velocity with which the disturbance travels.

This investigation is subject to the limitation that the diameter of the cross-section must be small compared with the wave-length. When the rod extends or contracts longitudinally it contracts or

...
extends radially and in the ratio \( a \), known as Poisson’s ratio, which in metals is not far from \( 4 \). Let us suppose that the rod is circular, of radius \( r \) and that the mass per unit length of the surface is \( \rho \). The longitudinal extension is \( d\gamma/ds \), and therefore the radial contraction is \( \eta = -dy/ds \). If then \( \gamma = a \sin \frac{2\pi n}{\lambda} (x-U) \), \( \eta = \frac{2\pi \sigma a}{\lambda} \cos \frac{2\pi n}{\lambda} (x-U) \).

If \( r \) is the order of \( \lambda \), \( \eta \) is the order of \( \gamma \); and the kinetic energy of the rod is then given by  
\[
K = \frac{1}{2} \int_{-\lambda/2}^{\lambda/2} \rho \left( \frac{d\gamma}{ds} \right)^2 dx = \frac{\pi^2 \rho}{\lambda^2} \int_{-\lambda/2}^{\lambda/2} (x-U)^2 dx.
\]

But our investigation entirely leaves this out of account, and it is therefore faulty. In fact, the forces are then no longer parallel to the axis. There are shears of the order \( d\gamma/ds \) and the simple Young’s modulus \( E \) can no longer be taken to represent the actual condition (see Rayleigh, Sound, i. § 157). But keeping \( r \alpha \) small we may as before form stationary waves, and it is evident that the series of fundamental and overtones will be just as with the air in a pipe. As we shall have the same three types—fixed at one end, free at both ends, fixed at both ends—with fundamental frequencies respectively

\[
\sqrt{\frac{\pi}{2}} \frac{\gamma}{\rho}, \sqrt{\frac{\pi}{2}} \frac{\gamma}{\rho}, \text{ and } \sqrt{\frac{\pi}{2}} \frac{\gamma}{\rho}.
\]

The overtones will be obvious.

For an iron wire \( W/r \) is about \( 10^3/\lambda \), so that for a frequency of 500 in a wire fixed at both ends a length about 5 metres is required. If the wire is stretched across a room and stroked in the middle with a damp cloth the fundamental is easily obtained, and the first harmonic can be brought out by stroking it at a quarter the length from one end. A glass or brass rod free at both ends may be held by the hand in the middle and stroked one or more times with a damp cloth. If it is clamped at one-quarter and three-quarters of the length from the ends, and is stroked in the middle, the first harmonic sound can only be obtained for the material of the rod by clamping it in the middle and obtaining the frequency of the fundamental when \( W = 4\pi^2 n^2/\rho \).

The value thus obtained is generally appreciably greater than that obtained by a statistical method in which the rod is pulled out by an applied tension.

Rods of different materials may be used as sounders in a Kundt’s dust tube, and their Young’s moduli may be compared, since

\[
\frac{\gamma}{\rho} \propto \frac{1}{E}.
\]

Torsional Vibrations of Rods and Wires.—The velocity of propagation of a torsional disturbance along a wire of circular section may be found by the transfer of momentum method, remembering that we must now take into account the effect of rotation by angular momentum. Let the disturbance be supposed to travel unchanged in form from left to right with velocity \( U \). Now suppose that the wire or rod is moved from right to left with velocity \( V \). The disturbance is then fixed in space. Let A be a point in the disturbance and B a point in the undisturbed portion. The condition of the matter between A and B remains constant, though fresh matter keeps coming in at B and going out of the fundamental, \( U \) is not in the harmonic series. If the fork be mounted on a resonance box or held in front of a cavity resounding to the fundamental and not to the first overtone, the fundamental is brought out in great purity.

Vibrations of Plates.—The most important example of this type is the tuning-fork, which may be regarded as consisting of two parallel bars clamped together at the base. The first overtone has frequency 6-25 that of the fundamental. The vibration of a plate is for the most part interesting rather than obtained by a statistical method in which the rod is pulled out by an applied tension.

The upper line of annexed figures shows how the sand arranges itself in three cases, when the plate is square. The lower line gives the same in a sort of idealised form. It is comparatively easy to produce the fundamental, by clamping and releasing the plate, and, at the same time, one or more other nodal points ought to be touched with the fingers while the bow is being applied. In this way, any of the possible configurations may be easily produced.

In the simpler sand-figures, to hold the plate firmly between two fingers of the thumb and placed at a point where at least two nodal lines meet, for instance the centre in (1) and (2), and to draw a violin bow downwards across the edge near the middle of a ventral segment. But with larger plates, which alone will furnish the more complicated figures. The best results are obtained with the same number of such segments, the position of the nodal lines being, however, different.
Circular nodal lines unaccompanied by intersecting lines cannot be produced in the manner described; but may be got either by drilling a small hole through the centre, and drawing a horse-hair along its edge, or by attaching a long thin elastic rod to the centre of the plate, at right angles to it, holding the rod by the tip of the finger, and stretching a little piece of cloth or paper, or any other thin membrane stretched over a square, circular, &c., frame, when the consequence of a sufficiently powerful vibrating blow. The membrane itself was made to vibrate in unison, and, by using sand, as in previous instances, the nodal lines were depicted to the eye, and seen to vary in form, position, and intensity of the vibration, as the pressure of the percussion was changed. The drum-tympani on the drum of the ear, has, in like manner and on the same principles, the property of repeating the vibrations of the external air which it communicates to the inner parts of the ear.

**BELLS**

**Singing Knobs.**—A "jet tube," i.e. a tube a few inches long with a fine nozzle at the end, may be made by passing a small quantity of a vessel to which oil-gas, or other, hydrogen, is supplied. The supply is regulated so that when the gas is lighted the flame is half or three-quarters of an inch high. A "sounding tube," say an inch in diameter, and somewhat more than twice the length of the jet tube, is then lowered over the flame, as in the figure. When the flame is less than half an inch thick, the tube the air is set in vibration, and the sounding tube gives out its fundamental note continuously, so long as it appears to lengthen, but if the reflection is viewed in a vertical mirror revolving about a vertical axis or in Koenig's cube of mirrors, it is seen that the flame is really intermittent, jumping up and down once with each vibration, sometimes apparently going within the jet tube at its lowest point. For a given jet tube there is a position of the second tube which takes the greatest, as obtained by trial. The jet tube, for a reason which will be given when we consider the maintenance of vibration, must be less than half the length of the sounding tube.

A series of pipes of lengths to give any desired series of notes may be arranged. If two pipes in series are mounted, a simple example of resonance may be obtained. One is adjusted so as just not to sing. The other is then made to sing and frequently the first will be set singing also.

**Sensitise Flares and Jets.**—When a flame is just not firing, any one of a certain range of notes sounded near it may make it flare while the note is sounding. This was first noticed by John Le Conte (Phil. Mag., 1858, 15, p. 232), and later by W. F. Barrett (Phil. Mag., 1867, 33, p. 204). Barrett showed that a burner for ordinary gas pressure might be made of glass tubing about $\frac{1}{2}$ in. in diameter contracted to an orifice $\frac{1}{4}$ inch in diameter, the orifice being nicked by a pair of scissors into a V-shape. The flame rises up from the burner in a long thin column, but when an appropriate note is sounded it suddenly drops down and thickens. Barrett further showed by using smoke jets that the flame is not essential. John Tyndall (Sound, ii. p. 420) made a number of beautiful experiments with jets at higher pressure than ordinary, say 10 in. of water, from a pin-hole.statistics. The flame may be 16 in. high, and on receiving a suitably high sound suddenly drops down, the critical point being at the orifice. Lord Rayleigh (Sound, ii. p. 370), using as a source a "bird-call," a whistle of high frequency, formed a series of stationary waves by reflection at a flat surface. Placing the sensation near the different parts of the sheet, the whole was excited, not at the nodes where the pressure varied, but at the loops where the motion was the greatest and where there was little pressure change. In his Sound (ii. ch. 21), it will be seen that a thin sheet of paper or damp cloth or cardboard, when the velocity of the jet is gradually increased, there is a certain range of velocity for which the jet is unstable, so that any deviation from the straight rush-out tends to increase as the jet moves up. If then the jet is just on the point of instability, and is subjected as its base to alternations of motion, the sinusoids impressed on the jet become larger and larger as it flows out, to the point of breaking down, formed over the jet. The sensitive jet is very easily made by putting a piece of fine wire gauze or string into it, above a pin-hole burner and igniting the gas above the gauze. On adjusting the gas so that it burns in a thin column, and just below it, exciting it by passing the series of notes, going down and roaring when a note is sounded. If a tube be placed over such a flame it makes an excellent singing tube. The flame of an incandescent gas mantle if turned low is frequently sensitive to the blowing of the palms, and then breaks up into drops which travel at different rates, collide, and scatter. But if a tuning-fork of appropriate frequency be set vibrating with its stilt in contact with the holder of the pipe from which the jet issues, the jet appears to go over in one complete revolution. The lamp may jump down, for instance, to each tick of a neighbouring clock.

**Sautv's Liquid Jets.**—If a jet of water issues at an angle to the horizontal from a round pinhole orifice under a few inches pressure, it will act as an air jet, and by oscillating it horizontally, and breaks up into drops which travel at different rates, collide, and scatter. But if a tuning-fork of appropriate frequency be set vibrating with its stilt in contact with the holder of the pipe from which the jet issues, the jet appears to go over in one complete revolution. The lamp may jump down, for instance, to each tick of a neighbouring clock.

Interruption illumination, however, with frequency equal to that of the fork shows at once that the jet is really broken up into drops, one for each vibration, and that these move over in a steady procession. The cylindrical form of jet is unstable if its length is more than $\pi$ times its diameter, and usually the irregular disturbances it receives at the orifice go on growing, and ultimately become irregular disturbances are impressed on the jet at intervals of time which depend on the diameter and speed of outflow (they must be somewhat more than $\pi$ times its diameter apart), and the disturbances being on the jet go on repeating, and are broken down into drops, which all move with the same velocity one after the other. An excellent account of these and other jets is given in C. V. Boys' Sound (1887, 40), 10.

**Maintenance of Vibrations.**—When a system is set vibrating and left to itself, the vibration gradually dies away as the energy leaks out either in the waves formed or through friction. In order that the vibration may be maintained, a periodic force must be applied to aid the internal restoring force which tends to bring the system back to its equilibrium position, or weaken it on the outgoing journey, or both. Thus if a pendulum always receives a slight impulse in the direction of motion just about the extreme point, this impulse may be sufficient to counteract the force if received before passage through the lowest point, and to a decrease if received after that passage, and in either case it tends to maintain the swing. If the bob of the pendulum is iron, and a coil is placed just below the centre of swing, then, if a current passes through the coil, while and only while the bob is moving towards it, the vibration is maintained. If the current is on while the bob is receding the vibration is checked. It is always on only acts as the value of gravity were increased, and does not help to maintain or check the vibration, but merely to shorten the period.

In a common form of electrically maintained fork, the fork is horizontal, and a small electromagnet is fixed between them. The circuit of the electromagnet is made and broken by the vibration of the fork in different ways—say by a special switch attached to the train, he found that the circuit which the fork was just not made when the fork is at rest. When it is set vibrating contact lasts during some part of this in the outward swing. But partly owing to the delay in making contact through the carriage driven on the contact piece, and partly owing to the delay in establishing full current through self-induction, the attracting force does not rise to once to its full value in the beginning, whereas in the return journey the mercury tends to follow up the contact piece, and the full current continues up to the instant of break. Hence the attracting force does more work per unit length of fork than is done in the outward swing. The balance is available to increase the vibration.

In the organ pipe—this in the common whistle—a thin sheet of air is forced through a narrow slit at the bottom of the embouchure, and escapes against the walls of the pipe at right angles, which are sharp. The disturbance made at the commencement of the blowing will no doubt set the air in the pipe vibrating in its lowest fundamental, and other harmonics, which will be sustained by the suspended body swinging in its natural period, but we are to consider how the vibration is maintained when once set going. When the motion due to the vibration is up along the pipe from the embouchure to the pipe mouth, it is set rocking as the sheet-like stream in with it to the inside of the sharp edge. This sheet does work on the air, aiding the motion. When the motion is reversed and the air moves out of the pipe, the air is first set rocking out of the sharp edge, and no work is done against it by the air in the pipe. Hence the stream of air does work during half the vibration and this is diminished during the other half, and so it goes on increasing the motion until the supply of energy in blowing is equal to the loss by friction and sound.

**Electrically Maintained Fork.**
The maintenance of the vibration of the air in the singing tube has been explained by Lord Rayleigh (Sound, vol. ii. § 322 A) as due to the way in which the heat is communicated to the vibrating air. When the air in a pipe open at both ends is vibrating in its simplest mode, the air is alternately moving into and out from the centre. During the quarter swing ending with greatest nodal pressure, the kinetic energy is changed to potential energy manifested in the increase of pressure. Then, at the next quarter swing, the kinetic energy in the second quarter is again kinetic in the second quarter swing, then in the third quarter it is changed to potential energy again, but now manifested in the decrease of pressure. In the last quarter swing it is changed to kinetic again and so on. Now some of the air is poured away at the end of the first quarter swing, at the instant of greatest pressure, heat is suddenly given to the air. The pressure is further increased and the potential energy is also increased. There will be more kinetic energy, the waves will travel faster and the vibration tends to grow. But if the heat is given at the instant of greatest rarefaction, the increase of pressure lessens the difference from the undisturbed pressure, and lessens the potential energy, so that during the return less kinetic energy is formed and the vibration tends to die away. And what is true for the extreme points is true for the half periods of which they are the middle points; that is, heat given during the compression half damps the vibration, and during the extension half damps it. Now let us apply this to the singing tube. Let the gas jet tube be of somewhat less than half the length of the singing tube, and let the lower end of the jet tube be in a wider tube or cavity so that it may be regarded as an "open end." When the air in the singing tube is vibrating, it forces the gas in the jet tube to vibrate in the same period and in such phase that at the nozzle the pressure in both tubes shall be the same. The lower end of the jet tube being open, it is a loop, and the node may be regarded as in an imaginary prolongation of the jet tube above the nozzle. It is evident that the pressure condition will be fulfilled only if the motions in the two tubes are in the same direction at the same time, closing into and opening out from the nodes together. When the motion is upwards gas is emitted; when the motion is downwards it is checked. The gas enters in the half period from least to greatest pressure. But there is a slight delay in ignition, partly due to expulsion of incombustible gas drawn into the jet tube in the previous half period, so that the most copious supply of gas and heat is thrown into the quarter period just preceding greatest pressure, and the vibration is maintained. If the jet tube is somewhat less than half the sounding tube there will be a node in it, and now the condition of equality of pressure requires opposite motions in the two at the nozzle, for their nodes are situated on opposite sides of that point. The heat communicated in one tube is partially in the other, but the vibration just preceding greatest rarefaction, and the vibration is not maintained.

Interference of Sound.

When two trains of sound waves travel through the same medium, each particle of the air, being simultaneously affected by the disturbances due to the different waves, moves in a different manner than it would if only acted on by each wave singly. The waves are said mutually to interfere. We shall exemplify this subject by considering the case of two waves travelling in the same direction through the air. We shall then obviously be led to the following results:

If the two waves are of equal length $\lambda$, and are in the same phase (that is, each producing at any given moment the same state of motion in the air particles), their combination is simply the sum of them. If the wave-lengths differ, the effect is equal to that of a wave of the same length $\lambda$, but by which the excursions of the particles are increased, being the sum of those due to the two component waves respectively, as in fig. 41, 1.

If the two interference waves, being still of same length $\lambda$, be in opposite phases, or so that one is in advance of the other by $\frac{1}{4}\lambda$, and consequently one produces in the air the opposite state of motion to the other, then the resultant wave is one of the same length $\lambda$, but the excursions of the particles are decreased, being the difference between those due to the component waves as in fig. 41, 2. If the amplitudes of vibration which mutually interfere are moreover equal, the effect is the total mutual destruction of the vibratory motion.

Thus we learn that two musical notes, of the same pitch, conveyed to the ear through the air, will produce the effect of a single note of the same pitch, but of increased loudness, if they are in the same phase, but may affect the ear very slightly, if at all, when in opposite phases. If the difference of phase be varied gradually from zero to $2\lambda$, the resulting sound will gradually decrease from a maximum to a minimum.

Among the many experimental confirmations which may be adduced of these propositions we will mention the following:

Take a circular air column, and produce the sound of Chladni's figures, and cut out of a sheet of pasteboard a piece of the shape ABOCD (fig. 42), consisting of two circular quadrants of the former, and a piece of the latter, being the plate. Let, now, the plate be made in the usual manner to vibrate so as to exhibit two nodal lines coinciding with two rectangular diameters. If the ear be placed right above the centre of the plate, the sound will be scarcely audible. But, if the pasteboard be interposed so as to intercept the vibrating segments AOB, DOC, the note becomes much more distinct. The reason of this is, that the node for each of the plate lines of vibration is also a node in the same direction, but oppositely to the segments AOB, DOC. Hence, when the pasteboard is in its place, there are two waves of same phase starting from the two former segments, and reaching the ear after equal distances of transmission through the air, are again in the same phase, and produce on the ear a conjunct impression. But when the pasteboard is removed, there is then at the ear opposition of phase between the first and the second pair of waves, and consequently a minimum of sound.

A tubular piece of wood shaped as in fig. 43, and having a piece of thin membranous stretched over the opening at the top C, some dry sand being strewn over the membranous, is so placed over a circular or rectangular vibrating plate that the ends A, B lie over the segments of another such as AB, CD, forming the previous figure, which are in the same state of motion. The sand at C will be set in violent movement. But if the same ends A, B be placed over oppositely vibrating segments (such as AOD, COD), the sand will be scarcely, if at all, affected.

If a tuning-fork in vibration be turned round before the ear, four positions will be found in which it will be inaudible, owing to the mutual interference of the oppositely vibrating prongs of the fork. On interposing the hand between the ear and either prong of the fork the audibility of some sounds becomes manifest because then one of the two interfering waves is cut off from the ear. This experiment may be varied by holding the fork over a glass jar into which water is poured to such a depth that the air-column now expresses the sound of the fork when suitably placed, and then turning the fork round.

Helmholtz's double siren is well calculated for the investigation of the effects of interference. For instance, the simple mechanism is found in the instrument, by means of which the fixed upper plate can be turned round and placed in any position relatively to the lower one. If, now, the apparatus be so set that the notes from the upper and lower chest are in unison, the upper fixed plate may be placed in four positions, such as to cause the air-current to be cut off in the one chest at the exact instant when it is freely passing through the other, and vice versa. The two waves, therefore, are the more in opposition the more one is turned, and the result is a faint sound. On turning round the upper chest into any intermediate position, the intensity of the sound will increase up to a maximum which occurs when the air in both chests is being admitted and cut off contemporaneously.

If two organ pipes in unison are mounted side by side on a wind-chest with their ends close together, and are blown for a very short time, they will be heard as if only one pipe was sounded, usually in less than a second the sound dies away to a small fraction of that due to either alone. Yet the air within the pipes is vibrating more vigorously than ever, but in opposite phases in the two pipes. This may be demonstrated by furnishing both pipes with mouthpiece flaps placed in the same vertical plane. When the flames are viewed in a revolving mirror and the pipes are blown, each image of one flame lies between one image of the flame produced in the other pipe by Lord Rayleigh (Scientific Papers, i. 409), is not the common wind chest, but the nearness of the open ends, so that the outrush from one pipe can supply the irrush to the other, and the converse. If, therefore, the two pipes are slightly out of tune when sounded separately together they sound a common note which may be higher than that due to either alone. Lord Rayleigh (loc. cit.) points out that this...
SOUND

is due to reduction of the end correction. When the air rushes out from one pipe, it has not to force its way into the open air, but finds a cavity being prepared for it close at hand in the other pipe, and if the air in one tube is compressed to the same extent at the ends are more easily reduced. Even the longer pipe may be effectively shorter than the corrected shorter pipe when sounding alone.

Beats.

When two notes are not quite in unison the resulting sound is found to alternate between a maximum and minimum of loudness, and this initial alternation of successive maxima and minima has been given the name of Beats. Their origin is easily explainable. Suppose the two notes to correspond to 200 and 203 vibrations per second; at some instant of time, the air particles, through which the waves are passing, will be similarly displaced by both, and consequently the joint effect will be a sound of some intensity. But, after this, the first or less rapidly vibrating note will fall behind the other, and cause a diminution in the joint displacements of the particles, till, after the lapse of one-sixth of a second, it will have fallen behind the other by half a vibration. At this moment, therefore, opposite displacements will be produced of the air particles, the resultant sound due to them will be at a minimum. This will be followed by an increase of intensity until the lapse of another sixth of a second, when the less rapidly vibrating note will have lost another half-vibration relatively to the other, or one vibration reckoning from the original period of time, and the two component vibrations will again conspire and reproduce a maximum effect. Thus, an interval of one-third of a second elapses between two successive maxima or beats, and there are produced three beats per second. By similar reasoning it may be shown that the number of beats per second is always equal to the difference between the numbers of vibrations in the same time corresponding to the two interfering notes. The more, therefore, these are out of tune the more rapidly will the beats follow each other.

The formation of beats may be illustrated by considering the disturbance at any point due to two trains of waves of equal amplitude $a$ and of nearly equal frequencies $n_1$, $n_2$. If we measure the time from an instant at which the two are in the same phase the resultant disturbance is

$$y = a \sin 2\pi n_1 t + a \sin 2\pi n_2 t - 2a \cos \left(\frac{n_1 - n_2}{2} \right)$$

which may be written in the form

$$y = 2a \cos \left(\frac{n_1 + n_2}{2} \right) \cos \left(\frac{n_1 - n_2}{2} \right)t + \text{a value which ranges between } a \text{ and } 2a \text{ with frequency } n_1 - n_2.$$

The sound swells out and dies down $n_1 - n_2$ times per second, or there are $n_1 - n_2$ beats per second. If, instead of considering one point in a succession of instants, we consider a succession of points along the line of propagation at the same instant, we evidently have waves of amplitude varying from $2a$ down to $0$, and then up to $2a$ again in distance $U(n_1 - n_2)$.

The phenomena of beats may be easily observed with two organ-pipes put slightly out of tune by placing the hand near the open end of each, with two musical strings on a resonant chest, or with two tuning-forks of the same pitch mounted on their resonance boxes, or held over a resonant cavity (such as a glass jar), one of the forks being put out of tune by loading one prong with a lump of beeswax. If the forks are fixed on a solid piece of wood which can be grasped with the hand, the beat will be actually felt by the hand. If one prong of each fork be furnished with a small plain mirror, and a beam of light from a luminous point be reflected successively by the two mirrors, so as to form an image on a distinct screen, when one fork alone is put in vibration, the image will move on the screen and be seen as a line of color varying from black to white and back again, as the fork is tuned. So, when two sounds are heard and one of them is slightly out of tune, this line may either be increased or diminished permanently in length according to the difference of phase between the two sets of vibrations. But if the forks be not quite in tune then the length of the image will be found to fluctuate between a maximum and a minimum, thus making the beats sensible to the eye. This graph is also well suited for the same purpose, and so in an especlal magnification by an opening cut in the wood or cardboard round the upper box, a note is produced by it more or less out of tune with the note formed by the lower chest, according as the handle is moved more or less rapidly, and most audible beats ensue.

have already explained how beats are used on Schechter's tonometer to give a series of forks of known frequencies. Beats also afford an excellent practical guide in the tuning of instruments, but more so for the higher notes of the register, inasmuch as the same number is generally given as a guide for the higher notes, as the number of high pitch than by two notes of low pitch. Thus, two low notes of 32 and 30 vibrations respectively, whose interval is therefore $\frac{32}{30}$ or $\frac{16}{15}$, should not be sounded together, while the same number of beats are given by notes of $32 \times 16$ (four octaves) of high pitch and $32 \times 15$ (three octaves) of low pitch. The first of the preceding) or 512, and 514 vibrations, which are only slightly out of tune.

Beats and Dissonance. As the interval between two tones, and consequently the number of beats, increases the effect on the ear becomes more and more unpleasant. The sound is jarring and harsh, and we term it a "dissonance" or "discord." In the middle notes, the interval between the fundamental and its overtones gives beats, but the beats are about 30. Thus the interval $b'$c' with frequencies 495 and 528, giving 33 beats in a second, is very dissonant. But the $b'$c" gives nearly twice as many beats and is not nearly so dissonant. The minor third $a'^t$ with 88 beats per second shows scarcely any roughness, and when the beats rise to 132 per second the result is no longer unpleasant.

These are then led to conclude that beats are the physical foundation for dissonance. The frequency of beats giving maximum dissonance rises as we rise higher in the musical scale, and as we descend. Thus $b'^t$ and $b'^c'$ have each 66 beats per second, and the minor third is nearly a dissonance. But as the interval is increased to a major third, the frequency of beats increases until the higher partials, when it is increased to a major sixth, the frequency of beats doubles. Smith (Harmonics, 2nd ed., 1759, p. 95) states that Sauveur "inferred that octaves and other simple concords, whose vibrations coincide very often, are agreeable and pleasant because their beats are not to be heard at all, and that the dissonance which Smith (Harmonics, 2nd ed., 1759, p. 95) states that Sauveur "inferred that octaves and other simple concords, whose vibrations coincide very often, are agreeable and pleasant because their beats are not to be heard at all, and that the dissonance which is caused by an interval of the seventh, where the frequency of the beats between the fundamentals is far beyond the number which is unpleasant. Smith, though recognizing the unpleasantness of beats, could not accept Sauveur's theory, and, indeed, it received no acceptance till it was rediscovered by Helmholtz, to whose investigations, recorded in his Sensations of Tone, we owe its satisfactory establishment.

This, suppose a fundamental 256 has present with it overtones harmonics 512, 768, 1024, 1280, &c., and that we sound with it the major seventh with fundamental 480, and having harmonics 960, 1440, &c. The two sets may be arranged thus

and we see that the fundamental of the second will beat 32 times per second with the first overtone of the first, giving dissonance. The first overtone of the second will beat 64 times per second with the second of the first, and at such height in the scale this frequency will be unpleasant. The very marked dissonance of the major seventh is thus explained. We can see, too, at once how the octave 256 is a much less troublesome. Let the two tones with their harmonics overlap be

The fundamental and overtones of the second either coincide with or fall slightly below the overtone in the first, and there is no approach to a dissonant frequency of beats, and the concord is perfect.

But obviously in either the octave or the fifth, if the tuning is incorrect, beats occur all along the line between the two tones and coincide with perfect tuning. Thus it is easy to detect a want of tuning in these intervals.

The above remarks on instruments rich in overtones may be explained as arising from beats between successive overtones. Thus, if a note of frequency $64$ is sounded, and if all the successive overtones are present, the difference of frequency will be $4$, and the beats will be very audible. The other audible beats in the middle of the scale, say to overtones $256$ and $320$ or to $512$ and $576$. Thus Helmholtz explains the jarring and braying which are sometimes heard in bass voices. These cases must serve to illustrate the theory.

Dissonance between Pure Tones.—When two sources emit only pure tones we might expect that we should have no dissonance when, as in octaves and fifths, the frequency is greater than the range of harshness. But the interval is still dissonant, and this is to be explained by the fact that the two tones unite to give a third tone of the frequency of the beats, easily heard when the two primary tones are loud. This tone may be within dissonance range of one of the primaries. Thus, take the major seventh with frequencies $256$ and $380$. There will be a tone frequency $480-256=224$, and this will be very dissonant with $256$.

The second overtone of $459$ was discovered by Georg Andreas Sorge in 1840, and independently a few years later by Joseph Tartini, after whom it is named. It may easily be heard when a double whistle with notes of different pitch is blown strongly, or when the notes of the same whistle are played at different speeds. It is heard, too, when two notes on the harmonium are loudly sounded. Formerly it was generally supposed that the Tartini tone was due to the beats between the two notes, but recent investigation shows that the difference was equivalent, as far as the ear is concerned, to a superposition on the two original tones of a smooth sine displacement of the same periodicity as that variation. This view has still some supporters, and among its recent advocates are Koepenick and Herrem. In the middle of the octave it is very difficult to suppose that the same sensation would be aroused by a truly periodic displacement represented by a smooth curve, and a displacement in which the period is only in the amplitude of vibration. For a full discussion of this see Helmholtz’s Theory of Sound, Chap. V.

No explanation is given by the supposition; it is merely a statement which can hardly be accepted unless all other explanations are tried.

Combination Tones.—Helmholtz has given a theory which certainly accounts for the production of a tone of the frequency of the beats and for other tones all grouped under the name of “combination tones” and in his Sensations of Tone (Ch. 11) he examines the beats due to these combination tones and their effects in producing dissonance. The example we have given above of the major seventh requires explanation.

The reader is referred to the full discussion by Helmholtz. We shall conclude by a brief account of the ways in which combination tones may be produced. There appears to be no doubt that they are produced, and the only question is whether these accounts sufficiently for the intensity of the tones actually heard.

Combination tones may be produced in three ways: (1) in the neighbourhood of the source; (2) in the receiving mechanism of the ear; (3) in the process of conversion of the wave to sound.

1. We may illustrate the first method by taking a case discussed by Helmholtz (Sensations of Tone, app. xvi.) where the two sources are reeds or pipes blown from the same wind-chest. Let us suppose that with constant excess of pressure, $p$, in the wind-chest, the amplitude produced is proportional to the pressure, so that the two tones issuing may be represented by $pa\sin 2\pi n t + pb\sin 2\pi n t$. Now as each source loses the wind periodically it affects the pressure in the chest so that we cannot regard this as constant, but may take it as better represented by $pa\sin 2\pi n (t+\epsilon)+pb\sin 2\pi n t$. Then the issuing disturbance will be

$$|p+a|\frac{\sin (2\pi n t+\epsilon)+p\sin (2\pi n t)}{|a\sin 2\pi n t+b\sin 2\pi n t|}$$

and

$$\alpha\sin \cos \epsilon -\alpha^2 \cos (\alpha n t+\epsilon)$$

or

$$\frac{\alpha}{2}f\sin \frac{b\epsilon}{2} \sin (\alpha n t+\epsilon).$$

Thus, accompanying the two original pure tones there are (1) the octave of each; (2) a tone of frequency $(m-n)t$; (3) a tone of frequency $(m+n)t$. The second is termed by Helmholtz the difference tone, and the third the summing tone. The amplitudes of these tones are proportional to the products of $a$ and $b$ multiplied by the square of the pressure amplitudes. The intensity of the pressure and produce new combination tones with the original tones, or with each other, and such tones may be termed of the second, third, and. &c., order. It is evident that we may have tones of frequency $hn_1+h\sin (hn_1t-knt)$, where $k$ and $h$ are any integers. But as inasmuch as the successive orders are proportional to $k x^2 \lambda^2$, or $\mu x^2 \lambda^2$, and $\lambda$ and $\mu$ are small, they are of rapidly decreasing importance, and it is not certain that any beyond those in equation (35) correspond to our actual experience of dissonance.

2. The second mode of production of combination tones is by the mechanism of the receiver, is discussed by Helmholtz (Sensations of Tone, App. xxi.) and Rayleigh (Sound, p. 68). For a fundamental the sound is represented by a jaggish curve. No explanation is given by the supposition; it is merely a statement which can hardly be accepted unless all other explanations are tried.

3. The third mode of production of combination tones was discovered by Lord Rayleigh in 1878, who found that if two tones of the frequencies $(N+1)p$ and $(N+1)q$ were produced in it produces just the same set of combination tones. But probably in practice there is not a sufficient interval between source and hearer for the combination tones to grow to any importance, and they might be only a small addition to those formed in the source or the ear.

Helmholtz’s Scientific Papers contains many experimental and mathematical contributions to the science. H. von Helmholz treats the theoretical aspects of sound in his Vorlesungen über die mathematischen
The operation of sounding is readily performed in shallow water by letting down a weight or "lead" attached to a cord, which is marked off into fathoms by pieces of leather, rag and twine. The bottom of the weight usually presents a hollow, which is filled with tallow, so that a portion of the material from the bottom may be brought up and give an indication of its nature as well as an assurance that it has really been touched.

For depths over 20 fathoms sounding machines are often employed, and for deep soundings they are practically indispensable. In them wire, the use of which for this purpose was introduced by Sir William Thomson (Lord Kelvin), has entirely superseded hemp gear. Its smooth surface and minute section, reducing friction to a minimum, give a rapidity of descent of about 100 fathoms per minute, and this velocity is not materially diminished even at great depths. Reeling in may be accomplished at nearly the same rate. Soundings are thus obtained with a degree of accuracy not formerly possible. The apparatus is light, compact and automatic in its action. Soundings with wire can be carried out at night with the same facility as in daytime, and in almost any circumstances of wind and weather short of a strong gale, against which the ship could not steam or face the sea. A sounding of 1000 fathoms may be obtained in twenty-five minutes from the time the weight is lowered to the time the order is given to put the ship on her course, or in half that time if sounding from astern and going ahead on getting bottom; 2000 fathoms will require forty-five minutes and 3000 fathoms seventy-five minutes. Beyond that depth, much greater caution being required, the time occupied is correspondingly increased, and reeling in must then be done very deliberately.

A sounding of 5260 fathoms was obtained near the island of Guam by the U.S. cable-surveying ship "Nero." Soundings at such depths may occupy as long as five or six hours.

Among the sounding machines in general use the Lucas carries nearly 6000 fathoms of 20-gauge wire, and is fitted with two brakes—one a screw brake for holding the reel when required, the other an automatic brake for stopping the reel when the weights strike the bottom. A guider for the purpose of winding the wire uniformly on to the reel is also attached, and is worked by a small handle. After leaving the reel the wire passes over a registering wheel, the dial of which indicates the amount of wire run out. Similar machines of smaller size are supplied for use in boats. The large machine is represented in fig. 1.

**SOUNDING** (for derivation see SOUND above), the term used for measuring the depth of water (and so, figuratively, of anything). The process of ascertaining the depth of the sea has been practised from very early times for purposes of navigation, but it is only since the introduction of submarine telegraphy that extensive efforts have been made to obtain a complete knowledge of the contour of the ocean-bed (see OCEAN).
Heaving in is accomplished by means of a hemp "swifter" or driving belt, which conveys the motion of the drum of a donkey engine to the drum carrying the wire of the sounding machine. It being impracticable to regulate the speed of the engine by hand according to the heaving, it is usual to ship the sudden and excessive strains on the wire so caused, an ingenious mechanical arrangement has been fitted by which frictional disks, geared by cog-wheels and capable of adjustment, are provided with a combined wheel actuated by the hemp swifter and the revolving drum carrying the wire. By this arrangement the latter can be controlled as desired, both in speed and direction of rotation. When the upper cylinder is turned, the frictional disks, which may be set by experiment to act at any given tension of the wire. As the tension approaches this limit, the velocity of revolution of the drum is automatically checked; and if the tension further increases, the frictional disks are overcome, thus causing the wire to run out, until the tension is relieved sufficiently to allow the frictional disks again to act in the direction of heaving in. The drum may be stopped instantly by moving the lever in the proper direction to throw the apparatus out of gear.

Galvanized-steel wire of 20-gauge and 21-gauge is supplied on drums in lengths of 5000 fathoms. The 20-gauge wire, when new, has a breaking strain of 240 lb, and the smaller wire 190 lb. The large machines will hold sufficient quantity of the larger wire for the deepest soundings; there is therefore no longer any necessity for the smaller wire. An additional use to which it is appropriated is for the在国内的 ships. The zinc wears off to a considerable extent with constant use; it is necessary to pass the wire through an oily wash whenever soundings are suspended for a time, and the surface layers on the drum should be kept clean and free from grease. A fortnight's continuous use is about the limit to the trustworthiness of any piece of wire; no amount of care will prevent it from becoming brittle and breaking when handled. The wire, in the hand, sounding machines, etc., should be condemned and passed on to the boats' machines. A magnifying glass will assist in examining its condition. Taut and even winding on the reel from the drum is most important; otherwise, when heaving up after a sounding, the sounder rotates for each layer as it comes in to sink down amongst the previous layers loosely reeled on, with the result that at the next sounding slack turns will suddenly develop on running out, to the great risk of the wire. The wire is liable to cut grooves in the interior of the swivelling frame, and a file must constantly be applied to smooth these down, or they will rip the splices. A roller of hard steel, underneath which wire passes, which is placed in rear of the swivelling frame, obviates this to a great extent.

Splices are made about 5 ft. in length, one being laid round the other in a long spiral of about one turn per inch. A seizing of five turns is laid over each end and for 2 in. up the splice, no end being allowed to project, and solder is then applied to the whole length of the splice. Three more seizures should be placed at intervals. Splices are the weakest parts of the wire, and their method of making is well known. A zinc frame is set up, and another is placed behind it. The zinc examined and their position noted, so that in heaving in they may be eased round the wheel with the guider nearly in the centre, to avoid tearing.

Under 3000 fathoms a lead of 30 to 40 lb weight can be recovered, and no detaching rod is necessary. At a little risk Sounding and Raising of Sinksers. Splices may be left so as to pass the wire, when sounding from astern up to that of 4000 fathoms. In this case, the line is adapted to a double flap valve to retain the bottom specimen. The sinkers WW, each 25 lb in weight, conical in form, and pierced with a cylindrical hole through which the Driver rod passes loosely, are slung by wires from the wheel to the side of the ship and so placed and passing over the stud G. A stud K on each side of the tube fits loosely into the slot H in the lower part of the sailing lever MM, and the spring T is taken by the sounding wire, the sinkers remain suspended; but on striking the bottom, the wire slackens, and the weight of the sinkers draws the slipping lever down till the stud K bears against the upper part of the slot H. When the sounding wire is brought to bear against the upper end of the standard EF, being thereby forced outward sufficiently to ensure that the weight acting at the point G will tilt the slipping lever right over, and thus disengage the sling. The tube being then drawn up, the sinkers are left behind. In descending, the valves at top and bottom, opening upwards, allow the water to pass through the ship and the sudden lift on the buoyant weight but on drawing up they are closed, thus retaining the plug of mud with which the tube is fitted. The fathoms of water under 2000 fathoms conical weights are sufficient. In deeper water a third cylindrical weight of not over 20 lb should be put in between. It is important to interpose a piece of hemp line, some 10 fathoms long, between the end of the wire (into which the weight is fitted) and the thimble, leading to the lead or rod. This tends to prevent the wire from kinking on the lead still about the bottom of the ship. A lead, about 2 lb in weight, wrapped round the hemp just below the junction, keeps the wire taut while the hemp slacks. Small brass screw stoppers, fitted with a hempen tail to secure to a cleat, hold the wire during the sounding if necessary to repair lines or clear slack turns. When the springs are replaced with a spring balance, by which the amount of strain is seen and the deck engine worked accordingly. A system of signals is required by day and by night, by which the officer superintending the sounding machines, the helmsman, main engine and deck engine.

**Method of Sounding.**—The machine is placed on a projecting platform on the forecastle. An endless hemp swifter, led through blocks with large sheaves, connects the sounding machine and deck engine, and when heaving in is kept at a tension of 2000 lb, a block set up with a jigger. As the wire runs out, the regulating screw of the brake must be gradually screwed up, so as to increase the power of the brake in proportion to the amount of wire out. The regulating screw is marked for each 500 fathoms.

In fairly smooth water the brake will at once act when the weight strikes the bottom and the reel stops. Under 3000 fathoms one spring only is sufficient, but for greater depth use two springs. If the ship is pitching and rolling heavily, the automatic brake must be assisted by the screw brake to ensure the reel not overrunning. The marks on the regulating screw are intended only as a guide; the real test is that the brake is sufficient to keep the wire balanced. The ship's speed must be kept steady, which may be known by the swivelling frame being just lifted off the stop. As the wire weighs 7½ lb for each 500 fathoms, the 500-fathoms mark on the screw should be at the position in which the ship has been steered. When the ship is pitching and rolling, the fathometer mark, 15 lb; and so on. This can be tested and the marks verified.

**Handling the Ship.**—Sounding from forward enables the ship to be handled with greater ease to keep the wire up and down, and avoid being drawn in. If the ship is pitching and rolling heavily, the automatic brake must be assisted by the screw brake to ensure the reel not overrunning. The marks on the regulating screw are intended only as a guide; the real test is that the brake is sufficient to keep the wire balanced. The ship's speed must be kept steady, which may be known by the swivelling frame being just lifted off the stop. As the wire weighs 7½ lb for each 500 fathoms, the 500-fathoms mark on the screw should be at the position in which the ship has been steered. When the ship is pitching and rolling, the fathometer mark, 15 lb; and so on. This can be tested and the marks verified.

The temperature of the water is usually taken at intervals of 100 fathoms down to 2000 fathoms, and at closer intervals in the first 100 fathoms. If a second wire machine is available; the observations may be made from aft whilst the sounding is being taken forward. A 30-lb weight is suspended to the ship's side, the end of the line is led down, and the registering thermometers are secured to the wire by metal clips at the back of the cases, at the required intervals. To avoid heavy loss, not more than four thermometers should be on the wire at one time; each having a thermometer is usually attached to the line a short distance above the lead. The primary object of the machine called the submarine siren is to observe the effect of the approach of a ship to shallow water: it has been instrumental in discovering many unsuspected banks in imperfectly surveyed waters. By means of a
Submarine
Sentry.

Warning. The vertical depth at which the sentry sets itself when a length of wire is paid out is not changed by any variation of speed between 3 and 13 knots, and is read off on the dial on the watch. One set of graduations on the dial indicates the amount of wire out; the other two sets refer to the red and black kites respectively, and show the depth at which the sentry is towing. By this machine single soundings down to 40 fathoms can be taken at any time while the ship is under way. The sentry being let down slowly, the gong will indicate when the bottom is touched, and the dial corresponding to the kite used will show at once the vertical depth at the place where the sentry struck.

By removing the kite and substituting a lead, with atmospheric sounder or other automatic depth gauge, flying single soundings up to 100 fathoms can be obtained by a small manipulator without stopping the ship. The winch is secured to the deck a short distance from the stern; the towing wire passes from the drum under a roller fairlead at the foot of the winch, thence through an iron block with sheave of large diameter, suspended from a short davit on the stern rail and secured to the sling of the sentry. The dial being set to zero with the sentry at the water's edge, the ship's speed is reduced to 8 or 9 knots, and the wire paid out freely until the kite is fairly in the water, when the brake should be applied steadily and without jerking, veering slowly until the required depth is attained, when the pawl is put on the ratchet wheel and the speed increased to 12 knots if desired when using the black kite or 10 knots with the red kite.

The kite in its position when being towed is indicated in fig. 3. The point of the catch C, passing through a thimble M in the short leg of the sling, is slipped into the hole at the top of trigger T, which is hinged at K and kept in its place by the spring S attached to the hook H. On the trigger striking the bottom the catch is released, the short leg of the sling slips off, and the sentry, which then rises to the surface, is left towing by the long leg. The winch is fitted with two handles for heaving in the wire; one gives great power and slow speed, and the other, acting on the drum spindle direct, winds in quickly. The wire supplied with the machine has a steady breaking strain of about 1000 lb. Using the black kite at a speed of 7 knots, the strain on the wire is about 150 lb, and at 10 knots about 300 lb. The red kite increases the strain largely.

SOUSA, LUÍS DE [MANOEL DE SOUSA COUTINHO] (1555–1632). Portuguese monk and prose-writer, was born at Santarem, a member of the noble family of Sousa Coutinho. In 1576 he broke off his studies at Coimbra University to join the order of Malta, and shortly afterwards was captured at sea by Moorish pirates and taken prisoner to Algiers, where he met Cervantes. A year later Manoel de Sousa Coutinho was ransomed, and landing on the coast of Aragon passed through Valencia, where he made the acquaintance of the poet Jaime Falção, who seems to have inspired him with a taste for study and a quiet life. The national disasters and family troubles increased this desire, which was confirmed when he returned to Portugal after the battle of Alcacer and had the sorrow of witnessing the Spanish invasion and the loss of his country's independence. Between 1584 and 1586 he married Luisa de Magdalena de Vilhena, widow of D. John of Portugal, the son of the poet D. Manoel de Portugal, to whom Camoens had dedicated his seventh ode. Settling at Almada, on the Tagus opposite Lisbon, he divided his time between domestic affairs, literary studies and his military duties as colonel of a regiment. His patriotic dislike of an alien rule grew stronger as he saw Portugal exploited by her powerful partner, and it was ultimately brought to a head in 1590. In that year, to escape the pest that devastated Lisbon, the governors of the kingdom for Phillip II. decided to move their quarters to his residence; thereupon, finding his protest against this arbitrary resolution unheeded, he set fire to his house, and to escape the consequences of his courageous act had to leave Portugal. Going to Madrid, he not only escaped any penalty, owing no doubt to his position and influence at the Spanish court, but was able to pursue his literary studies in peace and to publish the works of his friend Jaime Falção (Madrid, 1600).

Nothing is known of how he passed the next thirteen years, though there is a tradition that, at the instance of a brother resident in Panama, who held out the prospect of large commercial gains, he spent some time in America. It is said that fortune was unpropitious, and that this, together with the news of the death of his only child, Ana Luísa, caused his return home about 1604. In 1613 he and his wife agreed to a separation, and he took the Dominican habit in the convent of Bemfica, while D. Magdalena entered the convent of the Sacramento at Alcantara. According to an old writer, the motive for their act was the news, brought by a pilgrim from Palestine that D. Magdalena's first husband had survived the battle of Alcacer, in which he was supposed to have fallen, and still lived; Garrett has immortalized the legend in his play Frei Luiz de Sousa.

The story, however, deserves no credit, against whose natural resolution it is that the pair took their resolution to leave the world for the cloister from motives of piety, though in the case of Manoel the captivity of his country and the loss of his daughter may have been contributory causes. He made his profession on the 8th of September 1614, and took the name by which he is known as a writer, Frei Luiz de Sousa. In 1616, on the death of Frei Luiz Cacegas, another notable Dominican who had collected materials for a history of the order and for a life of the famous archbishop of Braga, D. Frei Bartholomew of the Martyrs, the task of writing these books was confided to Frei Luiz. The Life of the Archbishop appeared in 1619, and the first part of the Chronicle of St Dominic in 1622, while the second and third parts appeared posthumously in 1662 and 1678; in addition he wrote, by order of the government, the Annals of D. John III, which were published by Herulano in 1846. After a life of about nineteen years spent in religion, he died in 1632, leaving behind him a memory of strict observance and personal holiness.

The Chronicle of St Dominic and the Life of the Archbishop have the defect of most monastic writings—they relate for the most part only the good, and exaggerate it without scruple, and they admit all sorts of prodigies, so long as these tend to increase devotion. Briefly, these books are panegyrics, written for edification, and are not histories at all in the critical sense of the word. Their order and arrangement, however, are admirable, and the lucid, polished style, purity of diction, and simple, vivid descriptions, entitle Frei Luiz de Sousa to rank as a great prose-writer. His metaphors are well chosen, and he employs an appropriate vocabulary and locutions, and makes full use of those charming diminutives in which the Portuguese language is rich. His prose is characterized by elegance, sweetness and strength, and is remarkably free from the repetitions and faults which have characterized the age. In addition to his other gifts, Frei Luiz de Sousa was a good Latin poet. There are many editions of the Life of the Archbishop, and it appeared in French (Paris, 1663, 1679 and 1825), in Italian (Rome, 1727–1728), in Spanish (Madrid, 1645 and 1727) and in English.
SOUSSLIK—SOUTH AFRICA

(London, 1800). The Historia de S. Domingos may be read in a modern translation (6 vols. in 12mo, Lisbon, 1855). Authorities.—Obras de D. Francisco Alexandre Lobo, ii. 61–171; Innocencio da Silva, Dicionario bibliographico portuguez, v. 327, xvi, 72; Dr Sousa Viterbo, Manoel de Sousa Vieira (Lisbon, 1802). (E. Pr.)

SOUSSLIK, or Susillus, the vernacular name of a European burrowing, rodent mammal, nearly allied to the marmots, but of much smaller size and of more slender and squirrel-like build (see Rodentia). The species, Spermophilus (or Citillus) citillus, is rather smaller than an ordinary squirrel, with minute ears, and the tail reduced to a stump of less than an inch in length. The general colour of the upper parts is yellowish grey, with or without a rusty tinge, which is, however, always noticeable on the head; while the underparts are lighter. The range of this species embraces southern Germany, Austria and Hungary to the south of Russia. Farther east it is replaced by more or less closely allied species; while other species extend the range of the genus across central and northern Asia, and thence, on the other side of Bering Strait, all through North America, where these rodents are commonly known as gophers. Many of the species have medium or even long tails, while some are nearly double the size of the typical representative of the group. All, however, have large cheek-pouches, whence the name of pouched marmots, by which they are sometimes called; and they have the first front-toe rudimentary, as in marmots. They are divided into several subgenera. One of the most striking American species is the striped gopher, S. (Lecomynia) tridecominatus, which is marked on each side with seven yellow stripes, between which are rows of yellow spots on a dark ground. The common souslik lives in dry, treeless plains, especially on sandy or clayey soil, and is never found either in forests or on swampy ground. It forms burrows, often 6 or 8 ft. deep, in which food is stored up and the winter sleep takes place. Each burrow has but one entrance, which is closed up when winter approaches; a second hole, however, being previously driven from the sleeping place to the entrance of the burrow, is opened into the ground. This second hole is opened the next year, and used as the ordinary entrance, so that the number of closed up holes round a burrow gives an indication of the length of time that it has been occupied. Souslits feed on roots, seeds and berries, and occasionally on animal food, preying on eggs, small birds and mice. They bring forth in the spring from four to eight young ones, which, if taken early, may be easily tamed. Souslits are eaten by the inhabitants of the Russian steppes, who consider their flesh an especial delicacy. (R. L.)

SOUTAIGNE, the French term adopted into English from its Spanish equivalent especially used for the general daily dress worn by the secular Roman clergy in France, Italy, Spain and Portugal. The Med. Lat. sublatus, adopted in O. Fr. as solane, in Spanish and Italian, as solana, and Por. as solaina, meant an under-skirt, and is formed from subitus, beneath, sub, under. (See Cassock.)

SOUTH, ROBERT (1634–1716), English divine, was born at Hackney, Middlesex, in September 1634. He was educated at Westminster school and at Christ Church, Oxford. Before taking orders in 1658 he was in the habit of preaching as the champion of Calvinism against Socinianism and Arminianism. He was at this time strongly interested in the Restoration, and was a conspicuous figure in the political and religious scene. His influence was strong against the various Nonconformist sects. In 1676 he was appointed chaplain to Lawrence Hyde (afterwards earl of Rochester), ambassador-extraordinary to the king of Poland, and of his visit he sent an interesting account to Edward Pococke in a letter, dated Dantzic, 16th December, 1677, which was printed along with South's Posthumous Works in 1717. In 1678 he was presented to the rectory of Jarp, Oxfordshire, and in 1693 published with transparent anonymity Animadversions on Dr Sherlock's Book, entitled a Vindication of the Holy and Ever Blessed Trinity, in which the views of William Sherlock (q.v.) were attacked with much sarcastic bitterness. Sherlock, in answer, published a Defence in 1694, to which South replied in Trilethim Charged upon Dr Sherlock's New Notion of the Trinity, and the Charge Made Good. The controversy was carried by the rival parties into the pulpit, and occasioned such keen feeling that the king interposed to stop it. During the greater part of the reign of Anne South remained comparatively quiet, and it is said that he ranked himself among the partisans of Sacheverell. He declined the see of Rochester and the deanery of Westminster in 1713. He died on the 8th of July 1716, and was buried in Westminster Abbey.

South had a vigorous style and his sermons were marked by homely and humorous appeal. His wit generally inclines towards sarcasm, and it was probably the knowledge of his quarrelsome temperament that prevented his promotion to a bishop'ssee. He was noted for the extent of his charities. He published a large number of single sermons, and they appeared in a collected form in the months of November and December, with additions to the second edition of his lifetime in 1715. There have been several later issues; one in two volumes, with a memoir (Bohn, 1845). His Opera postuma latina, including his will, his Latin poems, and his orations while public orator, with a memoir of his life, was published in 1752, and a second edition, in 7 vols. was published at Oxford in 1823, another in 5 vols. in 1842. See also W. C. Lake. Classic Preachers of the English Church (1st series, 1877). The contemporary notice of South by Anthony Wood in his Athenea is strongly hostile, said to be due to a jest made by South at Wood's expense.

SOUTH AFRICA. As a geographical unit South Africa is usually held to be that part of the continent south of the middle course of the Zambezi. The present article (1) deals with that part of Africa as a whole, (2) outlines the constitution of the British possessions forming the Union of South Africa, and (3) summarizes the history of the country from the time of its discovery by Europeans.

I.—General Features

In the geographical sense stated South Africa lies between 16° and 35° S. and 12° and 36° E., narrows from 1600 m. from west to east along its northern border to some 600 m. of coast facing south. Its greatest length south-west to north-east is also about 1600 m. It has an area of about 1,333,600 sq. m. It comprises the Union of South Africa (i.e. the provinces of Cape of Good Hope, Natal, with Zululand, the Orange Free State and the Transvaal) and Bechuanaland, Basutoland and Southern Rhodesia, all British possessions; German South-West Africa, and the southern part of Portuguese East Africa. By some writers Northern Rhodesia is included in South Africa, but that district belongs more accurately to the central portion of the continent. Other writers confine the term to the British possessions south of the Zambezi, but in this case British South Africa is the proper designation. South African standard time, adopted in 1903, is that of 30° E., or two hours in advance of Greenwich.

Physiographical Features.—There is a marked uniformity in physical features throughout South Africa. The coast line, from the mouth of the Kuname on the west to the delta of the Zambezi on the east, is little indented and contains only two sheltered natural harbours of any size—Saldanha Bay on the west and Delagoa Bay on the east. At Port Natal, however, the removal of the sand bar at its entrance has made available a third magnificent harbour, while at Table Bay (Cape Town) and at other places ports have been constructed. South Africa presents, however, a solid land mass without peninsulas of any size or any large islands off its coasts. Moreover, behind the low-lying coasts, which extend in general from the estuary of the mouth of the rivers, rise ramparts of hills shutting off the interior. This conformation of the country has been a powerful influence in determining its history and development. Here and there the mountains.
which run in lines parallel to the coast, approach close to the sea, as at Table Bay. In the south-east, in the Drakensberg, they attain heights of 10,000 to 11,000 ft., elsewhere the highest points are between 8000 and 9000 ft. They form terrace-like steps leading to a vast tableland (covering about 900,000 sq. m.) with a mean elevation of 4000 ft., the highest part of the plateau—the High Veld of the Transvaal—being fully 6000 ft. above the sea. In its southern part the plateau has a general tilt to the west, in the north it tilts eastward. This tilt determines the hydrographical system. In the south the drainage is to the Atlantic, chiefly through the Orange River, in the north to the Indian Ocean. The larger streams include the Zambesi, Limpopo and other streams from the north.

A large number of smaller rivers flow from the outer mountain ramps and flow direct to the sea. In consequence of their great slope and the intermittent supply of water of the rivers—except the Zambesi—are un navigable save for a few miles from their mouths. The central part of the interior plateau, covering some 120,000 sq. m., is arid and is known as the Kalahari Desert. The western region, both plateau and coastlands, specially that part north of the Orange, is largely semi or wholly desert, while in the Cape province the terrace lands below the interior plateau are likewise arid, as is signified by the name Hottentot-land, or the same karsaa (Karoo). The southern and eastern coastlands, owing to different climatic conditions (see infra) are very fertile.

The geological structure is remarkably uniform, the plateau consisting mainly of sedimentary deposits resting on crystalline rocks. The Karroo system (sandstones and marls) includes immense areas (see AFRICA, § Geology). Intrusive dikes—locally known as ironstone—by preventing erosion are often the cause of the flat-topped hills which are a common feature of the landscape. The Witwatersrand series of the Transvaal includes auriferous conglomerates which have been worked since 1886 and constitute the richest gold-mines in the world. The diamondiferous areas at Kimberley and in the Pretoria district are likewise the richest known. Coal beds are widely distributed in the eastern districts while there are large copper deposits in the west, both at the Cape and in German territory.

Climate.—The general characteristics of the climate are determined more by the physical conformation of the land than its proximity to the equator. The eastern escarpments (the Drakensberg, &c.) of the plateau intercept the rain-bearing winds from the Indian Ocean, so that over the greater part of the interior the rainfall is slight (5 to 24 in.). This, added to the elevation of the land, makes the climate in general dry, bracing and suitable for Europeans, notwithstanding that the northern part is within the tropics. Temperatures in the eastern districts range between 40° and 70° F. Only along the south-eastern coast and in some of the river valleys is the climate of a markedly tropical character; here the rainfall is considerable and the washed plains have an equable current. The Cape peninsula and the western coast receive the cold currents from the Antarctic regions. Except in southern and western Cape Colony and along the Atlantic coast, summer is the rainy season.

Flora and Fauna.—In consequence of the deficient rainfall over the greater part of the country the flora is not luxuriant and there are few large forests. Coarse grasses are the characteristic vegetation of the tablelands, the thorn or ironwood (Acacia) common. In sufficiently moist places, however, the bush, composed mainly of stunted mimosa, acacias, euphorbia, wild pomegranate, bitter aloes and herbaceous plants, forest patches are found in the kloofs and seaward sides of the mountains; willows often form the watercourses; heaths and bulbous plants are common in some areas. In the semi-tropical regions south-east of the Drakensberg, i.e. the coastlands of Natal and Portuguese East Africa, the vegetation is abundant, and mangroves, palms, baobabs and bombax tree are found. Here, and also in the upper Limpopo valley, cotton, tobacco, and rubber vines are found. Among the timber trees are species of pine, cedar, ebony, ironwood, stinkwood and sneezewood. Flowering plants include various species of terrestrial orchids, the so-called arum lily (Richardia Africana), common in low-lying moist land, and the white everlasting flower, found abundantly in some regions of Cape Colony. Of non-indigenous flora are the oak, poplar, blue gum, the Australian wattle, the vine, and almost every variety of fruit tree and European vegetables. In suitable regions tea, coffee, sugar and rice, as well as tobacco and cotton, are cultivated. In the western districts of the Cape viticulture is largely followed.

The soil is everywhere rich, but the lack of perennial water and the absence of irrigation works on a large scale retards agriculture. Most of the veld is divided into huge farms devoted to the rearing of cattle, sheep, goats and horses. On the Karroo are numerous pastoral farms. Lucerne is very largely grown as fodder for the cattle.

The native fauna was formerly very rich in big game, a fact sufficiently testified by the names given by the early European settlers to the mountains and streams. The lion, elephant, rhinoceros, hippopotamus, giraffe, buffalo, quagga and other large animals were, however, during the 18th and 19th centuries driven out of the more southern regions (though a few elephants and buffaloes, now carefully preserved, are still found at the Cape), the quagga being totally exterminated. In the Kalahari and in the eastern lowlands (from Zululand to the Zambesi delta) most of these animals are still found, and, as well as a large number of smaller antelopes and various kinds of fowl, the leopard (called a tiger in South Africa) is still fairly common in all mountainous regions. Spotted hyenas and jackals are also numerous. The kudu is now the most common of the larger antelopes, the dikkor and klipspringer are among the smaller antelopes still existing in large numbers. Baboons are common in some districts. Birds include the ostrich, great kori bustard, the eagle, vulture, hawk and eagle, francolin, golden cuckoo, loorie, scarlet and yellow kingfishers, lapwings, parrots, pelicans and flamingoes. There are thirty varieties of snakes. Locusts are conspicuous among the common plagues of the country. In Rhodesia and the east coast the teetse fly is found and termites are widely distributed.

Inhabitants.—The aborigines of South Africa are represented by the Bushmen and Hottentots, now found in any racial purity only in the Kalahari and in the southern part of German South-West Africa. All the other natives, popularly called Kaffirs, are members of the Bantu-negroid family, of whom they here form three distinct branches: (1) the Zulu-Xhosas, originally confined to the south-east seaboard between Delagoa Bay and the Great Fish River, but later (19th century) spread by conquest over Gazaland, parts of the Transvaal, and Rhodesia (Matabeleland), (2) the Bechuanas, with the kindred Barotas, on the continental plateau from the Orange to the Zambezi, and ranging westwards to the Kalahari desert and the Lake Ngami region; (3) the Ova-Herero and Ova-Mpe, confined to German South-West Africa between Walisih Bay and the Kunene River.

All these mixed Bantu peoples are immigrants at various periods from beyond the Zambesi. The Bechuana, who occupy by far the largest domain, and preserve the totemic tribal system, were probably the first arrivals from the north and the north-east coastlands. As early, probably, as the 8th century A.D. they had formed a settlement on the Olifants River at Soafa, 130 m. from the mouth of the Zambezi, but they got no further south nor do they appear to have penetrated inland, though they traded for gold and other articles with the inhabitants of the northern part of the plateau—the builders of the zimbabwes and other ruins in which is now Rhodesia (q.v.). The Asiatic inhabitants of South Africa of the present day are mainly Indian.

1 Estimations.  2 1907.
cooliess brought to Natal since 1860. The white races represented are mainly Dutch and British; colonization by European races dating from the 17th century. There are a few thousand Germans and Portuguese, chiefly in the territories belonging to their respective countries. The table on p. 404 shows the inhabitants, white and coloured, in the different territories into which South Africa is divided, and also the area of these territories.

It will be seen that the population is sparse, less than 61 persons per square mile. (Excluding the Bechuanaland Protectorate and Lichtenstein, which has a very large area, the population is slightly over 7 per square mile.) In British South Africa the coloured races are nearly five times as numerous as the whites. The majority of the British and Portuguese immigrants are of pure blood, and the coloured population includes in the Cape province 298,334 persons of mixed blood (chiefly white and Hottentot) and in Natal 100,916 Asiates. Save in the German colony the official returns do not discriminate between the nationalities of the white inhabitants. Those of British and Dutch origin are probably about equal in numbers, but a very large proportion of the British inhabitants live in the towns, the country population being in the main Dutch. Cape Town (pop. 1904, 77,688), Port Elizabeth (32,959), East London (25,220) and Kimberley (34,331) in the Cape province; Durban (67,847) in Natal, Johannesburg (155,580) and Pretoria (120,733) in the Transvaal, and Salisbury and Bulawayo are the chief towns in Southern Rhodesia. The only town of any size outside the British possession is Lourenço Marques (32,500). When the boundary dispute about the British capital between the capital of the colony was settled in 1900, the line was drawn from the Victoria Falls into the Congo basin, where it serves the Katanga mineral area. The distance from Cape Town to Katanga is over 2,100 miles. The German territory is also provided with railways; the main line from Lourenço Marques to Beira, a standard gauge is 3 ft. 6 in. and in 1910 some 12,000, miles of railway were opened. In nearly every instance the railways are state owned. While gold and diamond mining continue the greatest prosperity, railways also are frequently the cause of new mining be added. In the Cape, Natal and the Transvaal coal mining is largely developed; in the Transvaal and the Cape tobacco is grown extensively; sugar, tea and other tropical and sub-tropical products are largely cultivated in Natal and the Portuguese territory, and, since 1905, measles have become an important article of export. There are few manufactures; the main of wine and branly in the Cape province, and flour-milling. Cattle and mealies constitute the most valuable possessions of the natives.

The imports are of a general nature, textiles and food-stuffs being the most important.

The peninsula has a very small rainfall in many parts of South Africa, and its unequal distribution necessitates a system of artificial irrigation unless much of the land be allowed to remain uncultivated. But in many regions the soil is deficient in phosphates and potash, and their cultivation is badly needed in the districts where the soil is exceptionally fertile. Before 1877 little was done to make use of the water resources of the country. In that year the Cape legislature provided for the constitution of irrigations boards, and in 1891, the irrigation operations were undertaken by the government, and the advice of engineers acquainted with Egyptian and Indian irrigation works sought. A report was drawn up by Sir (then Mr) Wm. Whitfield, who estimated the cost of the Orange Free State and the Transvaal, 3,000,000 acres which could be brought under irrigation at a cost of about £30,000,000. The value of the land, in its arid condition, alone, was £40,000,000. Not only the South African governments, was, however, then in a position to undertake large works. At the Cape the census of 1904 gave 151,688 acres as the area under irrigation, and 2,877 acres as the area under rice. In the Transvaal, the irrigation district a canal (completed in 1904) 21 m. long took off from the Bredie River and fertilized a large area, with the result that the potato crop at the second richest district in the province. Over the Karroo and other arid regions some 10,000 bороdlez have been sunk to depths varying from 50 to 300 ft., their yield being 60,000,000 gallons per annum. The rainfall of the Cape Province (e.g. in the Graaff Reinet district) has increased from 20s. to £2 per morgen. More important, however, are the supplies to be derived from the control of flood water, millions of cubic feet of many years being now utilized. Into the Tugela River, which had done little to promote irrigation, but during 1905-1907 a strong intercolonial commission investigated the subject as it affected the Transvaal, Natal and the Cape Province. The result of the report was that the Winterton Irrigation Settlement (18,000 acres) was formed on the upper Tugela. In 1909 an irrigation congress representative of the Governments of British South Africa was held at Robertson, in the Cape province.

Commerce.—All the British states and territories are members of postal, telegraphic and customs unions. The customs are of a protective character, while there is a rebate on goods from Great Britain and British possessions (see below, History). There is internal free trade throughout the Union of South Africa. The railways are worked by the Union Government, with the exception of the external trade of British South Africa, which was established in July 1905. The statistics issued by the bureau showed a total volume of £20,479,000 in 1909-1910. Of this £25,644,000 was put as the value of raw gold exported, and £5,257,000 as the value of the diamonds (whipped out of the Union) worth £14,397,000 passed through Portuguese ports. For 1907 the figures were: Value of total trade £74,153,000; imports £25,920,000, exports £48,233,000. Goods valued at £4,036,000 received through Portuguese ports are reckoned as imports in the import statistics; shipments of goods from Portuguese ports are regarded as exports in the export figures. In 1909 the value of gold imported was £29,795,000; the value of exports was £57,973,000. In 1908 the figures were: Total trade £57,903,000; imports £24,455,000 (including £4,652,000 via Portuguese ports) and £5,060,000 (including £13,000 from Portuguese ports). The raw gold exported was valued at £32,047,000 but the export of diamonds fell to £4,796,000. In 1909 the value of the imports into British South Africa was returned as £29,842,000; the value of the exports was £51,151,000. Of the imports over £16,850,000 came from the United Kingdom, over £2,240,000 from Australia, £2,480,000 from Germany, and £1,980,000 from the United States. The exports over £500,000. In the four years the imports from British South Africa were about 58% from other parts of the empire 13%. Of the exports 54% went into the United Kingdom, and the rest into the Union, the quantity of South African produce, especially wool, shipped to England ultimately however finds its way to other countries. Next to Great Britain the countries doing most trade with South Africa are Australia, New Zealand, Germany, The United States, Canada, Brazil, India, Belgium, Holland and France.

Religion.—The great majority of the white inhabitants are Protestants. Most of those of Dutch descent are members of the Dutch Reformed Church (Nederduitstalige Hemelkark), the state church of the early Cape colonists, or of churches formed by discontented members of the original church such as the Afrikaners (The Boer Churches). A branch of the Dutch Reformed Church is the Separatist Reformed Church of Holland. These churches are Calvinistic in doctrine and Presbyterian in organization. Until 1843 the Cape synod was controlled by government commissioners; since then it has been given position, and gained its formal independence. Each of the separate synods has separate synods with independent authority for the congregations of Dutch Reformed Churches in the Cape, Orange Free State and Transvaal provinces. The Dopper and the Dissenter's synods. Besides these churches there are a number of Lutheran congregations among the Dutch speaking population.

The South African races of Dutch descent are divided, mainly, into Anglians, Wesleys and Presbyterians. The Baptists and Congregationalists are smaller bodies. All form independent churches in communion with the mother churches in Great Britain. The oldest established is that of the Presbyterians. The Anglican

---

1 The total amount rebated in 1908 was £450,017.

2 Including North-West Rhodesia.

3 For the six months January to June 1910 the figures were: imports £14,776,000; exports £24,443,000.
organization dates from 1847. Being declared by judicial decision in 1863 a voluntary body, the Anglicans formed "The Church of the Province of South Africa." It is divided into the dioceses of Cape Town, Graham's Town, Maritzburg (Natal), Kafraria, Bloemfontein (Orange Free State), Mafeking, and Ladysmith. The last-named diocese is part of Portuguese East Africa south of the Sabi river; the Mashonaland diocese includes the Portuguese territory between the Sabi and the Zambezi. German South-West Africa and Rhodesia in the Anglican Communion, Bishop Mau- tan is the archbishop of Cape Town. The constitution of the church was drawn up at a provincial synod in 1870. It accepts the doctrines of the Church of England, but acknowledges none save its own ecclesiastical tribunals, or such other tribunal as may be accepted by the provincial synod—in other words it rejects the authority of the English privy council. Bishop Colenso of Natal and other Anglicans held that the authority of the provinces and bishops regarding themselves as in all respects members of the Church of England. This was, especially in Natal, the cause of prolonged controversy among the members of the Anglican community. By 1910 the practical amalgamation of the two bodies was effected (see further Natal.)

The Roman Catholics are a comparatively small body; the majority of their adherents are found in the Cape and Natal. At the head of the organization in the South (but not in the colony of Natal) is the Roman Catholic bishop of Cape Town. The Roman Catholics entered the field later on. By the end of the 19th century fully 5% of the total native population professed Christianity.

The Jews form a small but influential community. There are some thousands of Jews in the Cape, and the large numbers in Natal, where there is also a large Jewish popula- tion. At Lourenço Marques the Chinese colony has its own temple and religious services.

Law.—The basis of the common law of British South Africa is the Roman-Dutch law as it existed in Holland at the end of the 17th century. This was simply the old Roman jurisprudence embodied in the legislation of Justinian, modified by custom and legislative provision during the course of the centuries which witnessed the growth of civilization in Europe; and it is to all intents and purposes the jurisprudence which was the foundation of the Code Napoléon. It was in part closely akin to the "modern Roman law" which is practised widely over the continent of Europe, and even in Scotland, at the present day. The authorities upon the common law in South Africa are: the Dutch commentators upon the civil law, the statute law of Holland, the decisions of the Dutch courts, and, failing these, the corpus juris civilis itself.

In the period which has elapsed since the establishment of British rule at the Cape the law has been considerably modified and altered, both by legislation and by judicial decisions, and it is not too much to say that at the present time there exists hardly any material difference in principle over the greater part of the field of jurisprudence between the law of England and the law of South Africa. The law of contracts, the law of torts, the mercantile law, the law relating to shipping and insurance, not to mention other subjects, are practically identical with those of England; and even the criminal law is virtually the same, though the greater elasticity of the civil jurisprudence allows fewer opportunities for the escape of malefactors, notably in cases of fraud or falsity in any form, than exist under the law of England. The constitution of the courts is based on the example of the English judiciary, and the bases, practice and procedure are practically the same in both criminal and civil cases as in England. All serious cases of crime are tried before a judge and jury, with the same formalities and safeguards as in England, while minor offences are dealt with by stipendiary magistrates possessing a limited statutory jurisdiction. In criminal cases it is necessary for the jury to find a unanimous verdict. In civil cases either party may demand a jury, a privilege which is seldom exercised; but in a civil case the verdict of the majority of jurors prevails.

The most marked difference between the English and South African systems of law is, as might be expected, to be found in the law relating to real property. In South Africa there is a rigid and universal application of the principle of registration. The title to land is registered, in all cases; and so, with a few exceptions, is every servitude or easement, mortgage or charge, upon land. With regard to the devolution of property upon death, it may be remarked that the law of intestine succession applies equally to real and personal estate, there being no law of primogeniture. The rules of distribution in intestacy differ, however, very considerably from those established in England. There is absolute freedom of testamentary disposition in the law of the Roman-Dutch common law of South Africa. The effect of marriage upon the property of the spouses is, by the Roman-Dutch law and in the absence of any ante-nuptial contract to the contrary, to bring about a complete community of property, virtually a universal partnership between husband and wife, subject to the sole and absolute control of the husband while the marriage lasts. The courts have, however, the right to interfere for the protection of the wife in case of any flagrant abuse of the power thus vested in the husband. Ante-nuptial agreements may be of any nature the parties may choose. Such agreements must in all cases be publicly registered. Upon the dissolution of a marriage in community of property, or in the event of a judicial separation a communitas bonorum, the property of the spouses is divided as upon the liquidation of a partnership. It is not necessary here to refer particularly to certain exceptions to this general rule in cases of divorce. By the common law gifts between husband and wife during marriage are void as against creditors. This rule cannot be evaded even by ante-nuptial agreement. By the statute law of Natal post-nuptial agreements between spouses are permitted under certain conditions, to which it is not possible now to refer at length. Divorce is granted to either spouse for either adultery or malicious desertion, the distinctions established by the English law of divorce being disregarded.

Language.—The languages spoken in South Africa by the inhabitants of European descent are English and Dutch, the latter chiefly in the form of a patois colloquially known as the Taal. (German and Portuguese are spoken in the possessions of those countries, but a knowledge of English or Dutch is frequent even in those territories.) The history of the Dutch language in South Africa is intimately bound up with the history of the South African Dutch people. The basis of the language as spoken to-day is that 17th-century Dutch of Holland which the first settlers brought to the country; and although the Dutch of Holland and the Dutch of South Africa differ very widely to-day, Cape Dutch differs less widely from the Dutch language of the 17th century than from the modern Dutch of Holland. The tongue of the vast majority of the Dutch-speaking inhabitants may thus be said to be a degenerate dialect of the 17th-century Dutch of Holland, with a very limited vocabulary. The limiting of the vocabulary is due to two reasons. In the first place, the early settlers were drawn principally from the peasant class, being chiefly discharged soldiers and sailors; and, further, when once settled, the necessity for making the language intelligible to the natives by whom the settlers were surrounded led

For the sections here incorporated on South African law and language we are indebted to the late J. W. Leonard, K.C. (d. 1909), twice attorney-general of Cape Colony.
to a still further simplification of speech structure and curtailment of the vocabulary. There thus grew up an ungrammatical dialect of Dutch, suited only to the most ordinary requirements of the everyday life of a rural population. It became a language with neither a syntax nor a literature. At the same time it remained in character almost entirely Dutch, no French—in spite of the incorporation into the population of the Huguenot emigrants—and only a few Malay words finding a place in the Taal. But so side by side with this language of everyday life a purer form of Dutch has continued to exist and find its uses under certain conditions. It must be borne in mind that the Boers of every grade have always been more or less sedulously instructed in religious subjects, at all events to the extent required to fit them for formal membership of their church, and in all their wanderings they have usually been attended by their pastors. The Dutch Bible and Catechism are written in pure Dutch. The language of the Dutch Bible is as majestic as that of the English version. Moreover, the services of the Church have always been conducted in grammatical though simple Dutch; and the clergy, in their intercourse with the people, have as a general rule abstained from conversing in the ordinary dialect. The Boer thus has but slight difficulty in reading and understanding pure Dutch. Under the influence of Africander nationalism strenuous efforts have been made to teach the language in the schools throughout the greater part of South Africa. In the Transvaal and Orange Free State education was imparted almost exclusively in Dutch. All public business in the government offices and law courts was conducted in the language, and the Transvaal at the time of its annexation by Great Britain was being gradually inundated by officials, railway servants and others introduced from Holland, who spoke modern Dutch. Officially throughout the Union of South Africa both languages are now on a footing of equality.

Throughout South Africa a number of words, mainly Dutch, are in general use by the English-speaking inhabitants and also, to a considerable extent, among the natives. The most common of these words, with their English meanings, are here set forth. When not otherwise stated the words are of Dutch origin:

<table>

</table>

**Spruit** (literally shoot, spruiten, to spring up), stream, small river. The name given to intermittent streams liable to sudden freshets.

**Stoep** (the name step), the small step, the veranda given to the platform or veranda of a house. The stoep is shaded by a roof and is a favourite rendez-vous for the household and for visitors. Formerly all South African houses had stoeps, but in the central parts of the larger towns the buildings are now without verandas.

**Trek** (literally, pull, tug, trekken, to draw or pull), to leave a place, to make a journey; also the distance covered in a journey.

**Veld** (field). The name given to open plains and to the grass-covered plateaus of the interior.

**Vleli** (a hollow filled with water during rainy weather.

**Uitspan** (to unharness."

**Uitlander** i.e. a foreigner.

**Uitvoer** (from Dutch uit, out."

A number of Dutch words frequently used in place-names may be instanced: rhenoster (rhinoceros) ollfiant (elephant), mooi (pretty), modder (dirt), klip (cliff), berg (mountain), burg or stadt (town), zwart (black). ideal (little), grootie (great), breedie (broad), nieuwen (new), zuur (sour), bokke (buck)."

The Constitution of South Africa

In accordance with the provisions of an act of the British Parliament (South Africa Act 1909) Cape Colony, Natal, the Transvaal and Orange River colonies were united under one government in a legislative union under the British crown. The Union of South Africa as the new state is named, was established on the 31st of May 1910. Upon its formation the colonies named became provinces of the Union. In the case of the Orange River colony its title was changed to Orange Free State province. The colonial legislatures were abolished, provincial councils, with strictly subordinate and delegated powers, were set up, and provincial administrators (local men) replaced the various governors. The history of the movement which led to unification is given in the following section. The main provisions of the constitution are as follows:

The executive government of the Union is vested in the king and may be exercised by the sovereign in person. It is, however, administered by a governor-general, who holds office during the king’s pleasure. The governor-general can dismiss ministers and dissolve parliament. He is, however, subject to the control and influence of the House of Assembly. The legislature is divided into two houses: the Legislative Assembly, comprising 100 members elected by the people for a term of years, and the Senate, consisting of 10 members. The number of members of each house may at any time be increased by an act of the Union. The House of Assembly is elected for a term of years. The Senate is elected for longer periods than three years unless they are or become members of either house of parliament. The control and administration of native affairs (which before the Union was, except at the Cape, largely in the hands of the colonial governors personally) is vested exclusively in the governor in council and to the same authority is entrusted all matters specially or differentially affecting Asatics throughout the Union.

The legislative power is vested in a parliament consisting of the Sovereign, a Senate, and a House of Assembly. The Senate consists of 40 members, 8 representatives from each province, and 8 members nominated by the governor-general in council. The House of Assembly is elected by the people for a term of years.

For a detailed examination of the constitution and a comparison of it with the federal constitutions of Canada and Australia see "South Africa Union," by A. Berriedale Keith, in the Journ. Soc. Comp. Legislation for October 1909.
The House of Assembly consists (as originally constituted) of 121 members, elected by single-membered constituencies, each constituting a separate and equally important part of the general public. Of these members the Cape Province returns 51, the Transvaal 36, and Natal and Orange Free State 17 each. As population increases the total number of members may be raised to 150. The seats allotted as heretofore are determined by the number of adult male or female adults as ascertained by a quinquennial census, the quota for a constituency being obtained by dividing the total number of such adults by five. This right to vote is vested in all members of the establishment of the Union. The commission charged with the delimitation of constituencies is permitted to vary the quota as much as 15% either way. Members of the House of Assembly must be British subjects, or of European descent, they must be qualified to be registered as voters and have lived for five years within the Union. A general election must take place every five years, and all polls must be taken on the same day. There may be a by-election every year, so arranged that twelve months shall not elapse between the last day of one session and the first sitting of the next session.

The qualifications of all ordinary voters are those which existed in the several colonies at the establishment of the Union, save that "no member of His Majesty's regular forces on full pay" can be registered as a voter. As the franchise laws in the several colonies differed the qualifications of voters in the provinces differ also. In the Transvaal and Orange Free State franchise is restricted to white adult male British subjects. In neither province is there any property qualification, but a six months' residence before registration is required. In Natal there is a property qualification. In that province coloured persons are not by name debarred from the franchise, but they are in practice excluded. In the Transvaal from the provisions of the law no colour bar exists and there are a large number of Kaffr voters (see CAPE COLONY: Constitution). Parliament may alter the qualifications for the vote, but no law which would deprive coloured persons in the Transvaal of the franchise of the franchise of the franchise may be passed by both houses of parliament sitting together and at the third reading be agreed to by not less than two-thirds of the total number of members of both houses.

Save as subject to another law, to the British parliament the Union parliament is a sovereign body. The provinces have no original authority, possessing only such powers as are delegated to them by the parliament. In certain cases the governor-general must sign all provincial bills, e.g. any bill abolishing the coloured vote in the Cape province. The king is given the power to disallow any law within a year of it having received the assent of the governor-general.

With regard to bills the two houses are not in a position of equality. Bills appropriating revenue or money, or imposing taxation, must originate in the House of Assembly and may not be amended by the Senate. If a bill passed by the Assembly has been rejected also in the Senate, provision is made for a joint sitting of both houses, when members vote and decide upon the measure concerned as one body. In the case of a money bill rejected by the Senate a joint sitting of both may be held, and if the Senate has failed to pass the bill. Every minister of state may sit and speak in either house, but can vote only in the house of which he is a member. Any member on the opposite side of a member as a minister of state. Members of parliament are paid £40 a year, £3 being deducted from this allowance for every day's absence during the session.

The Courts of Judicature for South Africa were created at the establishment of the Union. The former Supreme, High and Circuit Courts of the several colonies then became provincial and local divisions of the Supreme Court of South Africa, which consists of two divisions, namely the Supreme Court and the Appellate Division. Appeals from the decisions of the provincial and local divisions of the court and from those of the High Court of southern Rhodesia, must be made to the appellate division of the Supreme Court. Unless special leave of the privy council be obtained there can be no appeal from the decisions of the Appellate Division, save in admiralty cases. This restriction of the power of appeal to the privy council is much greater than are the restrictions upon appeals from the Commonwealth of Australia, where appeals to the privy council lie by right from the supreme courts. The difference arises from the fact that the Commonwealth is a federation of states; whereas the Union of South Africa is but one state with but one Supreme Court. One result of this unification of the courts of South Africa is that any province may be governed by the governor-general in council and styled the attorney-general of the province.

Among the general provisions of the constitution the most important is that both the English and Dutch languages are official languages of the Union and are treated on a footing of equality; all records of parliament, and all laws and other general public importance or interest issued by the government of the Union must be in both languages. (Persons in the public service at the establishment of the Union cannot, however, be dismissed with because of lack of knowledge of either English or Dutch.) Other general provisions exact free trade throughout the Union, but the customs and excise leviable under the constitution as of 1854 remain in force unless parliament otherwise provides. All commissions who had been naturalized in any of the colonies are naturalized throughout the Union. All rights and obligations under conventions and protocols are brought into binding on any of the colonies have devolved upon the Union.

The harbour of Cape Town, Port Elizabeth, East London and Durban are state owned, as are also nearly all the railways in the Union. The railway revenue is divided into two portions, one of which is a separate fund. The administration of the railways, ports and harbours is entrusted to a board of not more than three commissioners (at present four) appointed by the governor-general in council and styled the minister of state. Each commissioner holds office for five years and may be reappointed. The board is directed to administer its service on business principles, due regard being had to agricultural and industrial development, &c., within the Union. So far as may be the total earnings are not to be more than are sufficient to meet necessary outlays.

**Provincial Administration.** — While the Union parliament has full power to make laws for the whole of the Union, to provincial councils have been delegated the immediate control of affairs relating solely to the provinces. The subjects delegated to the councils include direct taxation within the provinces for local purposes, making of local laws (only the sole credit of the provinces) with the consent of the minister of agriculture (within the limits defined by parliament) and municipal institutions, divisional councils, and other local institutions. The control of elementary education was also guaranteed to the provincial councils up to 1915, and thereafter until parliament otherwise provides.

The councils consist of not fewer than 25 members and not more than the number of members returned by the province to the House of Assembly. Each council is entitled to send a member to the Union parliament, and to be consulted on the subject of the franchise, as far as possible, to be the same as the parliamentary constituencies. (In the Cape and Transvaal provinces they were the same in 1900; Natal and Orange Free State returning only 17 members to the House of Assembly, the parliamentary constituencies have been rearranged.) The qualifications (or electors) are the same as for parliament, and any person qualified to vote is qualified to be a member of the council. As in the Cape province coloured persons are qualified to vote, they are thus also qualified to be members of the provincial council. Any member of the provincial council who becomes a member of either House of parliament or that thereupon resigns from the council. Each provincial council continues for three years from the date of its first meeting and is not subject to dissolution save by the governor of time.

The executive power in each province is invested in an officer appointed by the government and styled provincial administrator. He holds office for five years. The administrator is assisted by an executive committee of four persons elected from among its own members, or otherwise, by the provincial council on the proportional representation principle. The administrator and any other member of the executive committee, not being a member of the council, has the right to take part in the proceedings of the council, but has not the right to vote. The provincial councils have not the right to make laws, but ordinances, which must receive the assent of the governor-general in council before becoming valid.

(F. R. C.)

**III.**—**History.**

The history of South Africa is, almost entirely, that of its colonization by European races, of their conflicts with, and influence over, its native inhabitants, and of the struggle for supremacy between the British and Dutch settlers. The little that is known concerning the doings of the natives before the appearance of the white man belongs to the domain of ethnology. Rather the name of the native who first reached the southern part of Africa there was but one place in it where a civilized race held sway. This was at Sofala, the most southerly post of the East African Arabs. From that port the Arabs traded for ivory, slaves and (principally) gold with Bantu peoples of the far interior—the Rhodesia of to-day. These natives, whose earliest existing buildings may go back to the time of the Norman Conquest, were in a higher state of
development than the Bushmen and Hottentots living farther south. The part played by the various native races in modifying the character of the European colonization will be best considered as they successively came into contact with the white settlers. At this point it is only necessary to state that at the same time as the Europeans were slowly extending northward from the south-western point of the continent, a conquering race of Bantu negro stock, originating from somewhere beyond the Zambesi, was spreading southward along the western side of the country.

A. From the Discovery of the Cape to the Great Trek.—What led to the discovery of America led also to the discovery, exploitation, and colonization of South Africa. In the 16th century the great European powers of Spain, Portugal, and England began to explore the new lands. Portugal first established a foothold in the Cape of Good Hope in 1488. Nine years after the discovery of the Cape by Diaz another Portuguese expedition was fitted out under Vasco da Gama. Da Gama entered Table Bay, but did not land. Thence he pushed on round the coast, landed in Mossel Bay, then sailing up the south-east coast he sighted land again on the 25th of December 1497, and named it in honour of the day, Natal. Still proceeding northwards he entered the Quillimane River and eventually reached India.

For many years subsequent to this date South Africa represented merely an inconvenient promontory to be rounded on the voyage to the Indies. Ships stopped at different ports, or rather at such few natural harbours as the inhospitable coast offered, from time to time, but no attempt was made by the Portuguese to colonize the southern end of the continent. On the west coast their southernmost settlement for a long period was Benguella, and the history of Angola (q.v.) had not until the last quarter of the 18th century any close connexion with that of South Africa. On the east coast the Portuguese were masters of Sofala by 1506, and a trading-post was first established in Delagoa Bay in 1545. Here alone Portugal obtained an important footing in South Africa. From Sofala vessels sailed southwards, discovered Benguela on the coast of Namibia in 1511, and entered the west coast of Africa on the coast the Portuguese made no attempt to form permanent settlements or trading stations along the coast. It was too barren a shore to prove attractive when the riches of East Africa and India were available.

The first Europeans to follow in the wake of the Portuguese voyagers were the English. In 1601 the English East India Company fitted out a fleet of five vessels, which sailed from Torbay. After four months at sea they dropped their anchors in Table Bay, where they remained for seven weeks before proceeding eastwards. From that time forward Table Bay was regarded as an occasional port of call for British ships, and in 1620 two English captains formally took possession of the Cape in the name of James I. This patriotic act was not, however, sufficiently appreciated by either King James I. or the English East India Company to evoke any official confirmation on their part. Meanwhile the Dutch East India Company had been formed in Holland, and the Dutch had entered keenly into the competition for the glittering prizes of Eastern commerce. In 1648 one of their ships was stranded in Table Bay, and the shipwrecked crew were left to forage for themselves on shore for several months. They were so pleased with the resources of the country that on their return to Holland they represented to the directors of the company the great advantages that would accrue to the Dutch Eastern trade from a properly provided and fortified station of call at the Cape. The result was that in 1652 a fort and vegetable gardens were laid out at Table Bay by a Dutch expedition sent for the purpose under a surgeon named Jan van Riebeeck.

In 1657 a few soldiers and sailors, discharged by the Dutch East India Company, had farms allotted them, and these men constituted the first so-called "free burghers." Dutch East India Company. By this step the station became a plantation or settlement. More settlers were landed from time to time, including a number of orphan girls from Amsterdam, and during 1688-1689 the colony was greatly strengthened by the arrival of some three hundred Hugenots (men, women and children), who were located at Stellenbosch, Drakenstein, and Franschhoek. In the meantime the Hottentots were absorbed in the Dutch population, but they have had an enduring influence on the character of the people. The little settlement gradually spread eastwards, and in 1754 the country as far as Algoa Bay was included in the colony. At this time the white colonists numbered eight to ten thousand. They possessed numerous slaves, grew wheat in sufficient quantity to make it an article of export, and were famed for the good quality of their wines. But their chief wealth was in cattle. Such prosperity as they enjoyed was in despite of the system of government prevailing. All through the latter half of the 17th century and for many years after Riebeeck's time there was no time between the colonists and the government. The administration of the Dutch East India Company was of an extremely despotic character. The most complete account of the company's tenure and government of the Cape was written in 1857 by E. B. Watermeyer, a Dutch colonist of Dutch descent residing in Cape Town. He points out that it was after failing to find a route by the north-east to China and Japan that the Dutch turned their eyes to the Cape route. The Cape of Good Hope subsequently "became not a colony of the Republic of the United Provinces, but a dependency of the Dutch Chartered General East India Company" for mercantile purposes; and to this fact principally can be traced the slow progress, in all but extension of territory, of a country which was settled by Europeans within thirty years of the time when the Pilgrim Fathers, the founders of a mighty empire, landed at Plymouth to plant democratic institutions and European civilization in the West."

On the settlement under van Riebeeck, and the position in it which the so-called "free burghers" enjoyed, this candid Dutch writer throws an interesting light. He says, "The people... were no colonists intending permanently to settle at the Cape. The proposition that any freemen or burghers not in the pay of the company should be encouraged to cultivate the ground was flatly rejected. About three hundred of the burghers who came from Europe were not colonists intending permanently to settle at the Cape. The temporary and occasional character of the burghers' residence was of such a character that they did not even enjoy the natural advantage of being born in the place where they had lived eight years. Thus, for example, the inhabitant of Stellenbosch had been back in Holland for four years. This was a complete misnomer. The first burghers were, in truth, a mere change from paid to unpaid servants of the company. They thought, in obtaining their discharge, that they had much improved their condition, but they soon discovered the reverse to be the fact. And henceforward, to the end of the last [18th] century, we find the constantly repeated and well-founded complaint, that the company rather than the burghers possessed the advantages of a free community. The burghers were not even allowed the fruit of their own toil. The natural effect of this narrow and tyrannous rule was discontent, amounting often to disaffection. After a time every endeavour was made to escape beyond the immediate control of the authorities. Thus the 'trekking' system, with its attendant evils, the bane of South Africa, was born. By their illiberal spirit, which sought but temporary commercial advantage in competition with the Eastern trade, the Dutch authorities themselves, although generally honestly disposed towards the natives, created the system which caused their oppression and extermination." When it is borne in mind that the Dutch at the Cape were for one hundred and forty-three years under the rule of the Dutch East India Company, the importance of a correct appreciation of the nature of that period to an understanding of the African history is obvious. The modern writer approaches Watermeyer either in the completeness of his facts or the severity of his indictment. Referring to the policy of the company, Watermeyer says:

1 The date usually assigned (1486), on the authority of De Barros, has been shown to be incorrect (see D'Az.)
The Dutch colonial system as exemplified at the Cape of Good Hope, or rather the system of the Dutch East India Company (for the nation should not wholly suffer under the condemnation just incurred by those who flogged or oppressed or robed the burghers as may possess them, and serve in bondage from generation to generation. And if such Hottentots should escape, the owner shall be entitled to follow them up and punish them, according to their merits in his discretion.

1 It was not until the time of Ryk Tulbagh (governor of the colony, 1751–1771) that the Chamber of Seventeen permitted foreign ships to trade in the Cape. Great merchants like van Asbeck and de Graeff were the leaders of the Dutch colonists. But, as a monopoly, it was almost without one redeeming feature, and was a dishonour to the Dutch nation's national name. In all things political it was a debasement; in all things commercial, a degradation. The Dutch East India Company cared nought for the progress of the colony—provided only that they had a refreshment station for their rich laden fleets, and that the English Fleet never pillaged or plundered there. For whatever it may .

And as to the ordinary Hottentot, already in service, brought up at the places of Christians, the children of these shall be compelled to serve until their twenty-fifth year, and may not go into the service of any other person save by their master's consent; that no Hottentot, in future deserting his service shall be entitled to refuge or protection in any part of the colony, but that the authorities throughout the country shall have it in view as a matter of course, whenever the alleged cause of desertion, send back the fugitive to his master.

After one hundred and forty-three years the rule of the Dutch East India Company came to an end at the Cape. What its principles were we already have seen. Watermeyer recapitulates its effects as follows:

The effects of this pseudo-colonization were that the Dutch, as a commercial nation, destroyed commerce. The most industrious race of Europe, they repressed industry. One of the freest states in the world, they became a despotic state in which falsely-called free citizens were enslaved. These men, in their turn, became tyrants. Under anarchy was the result. Some national feeling may have lingered, but, substantially, every man in the country, of every hue, was benefited when the influx of the tyranny of the Dutch East India Company was removed.

To this one further note must be added. The Trek Boers of the 19th century were the lineal descendants of the Trek Boers of the 18th. What they had learnt of government from the Dutch East India Company they carried into the wilderness with them. The end of the 19th century saw a revival of this same tyranny and colonial monopoly in the Transvaal. If Watermeyer's formula, "In all things political, purely despotic; in all things commercial, purely monopolist," was true of the government of the Dutch East India Company in the 18th century, it was equally true of Kruger's government in the latter part of the 19th.

The rule of the Dutch East India Company was extinguished (September 1795) by the occupation of the colony by the British, who acted on behalf of the prince of Orange, Holland having fallen under the control of the revolutionary government of France. Following the peace of Amiens the colony was handed over (February 1803) by Great Britain to a commissioner of the Batavian Republic. During the eight years the British held the Cape notable reforms in the government were effected, but the country remained essentially Dutch, and few British settlers were attracted to it. Its cost to the British exchequer during this period was £16,000,000. The Batavian Republic entertained very liberal views as to the administration of the country, but they had little opportunity for giving them effect. In less than three years (January 1806) the Cape was reconquered by the British, who were at war both with France and Holland. The occupation was at first of a provisional character, but by the third additional article to the convention with the Netherlands of the 15th of August 1814 the country was definitely ceded to Great Britain. In consideration of retaining the Cape and negro territories now ceded by the Dutch to the British, the British at the Cape, title to Cape Colony is thus based upon conquest, treaty and purchase. The wishes of the inhabitants were not consulted, and among them resentment was felt at the way in which their future was thus disposed of. The Europeans at the Cape at that time numbered about 27,000.

Before tracing the history of South Africa during the 19th century, the early relations of the white settlers with the natives may be briefly reviewed. The natives first encountered at the Cape were the Hottentots (q.v.). They were at that time occupied, the Cape peninsula, and inhabited the rounded country, and in the early days of the settlement caused the colonists a considerable amount of trouble. An extract from the diary of van Riebeeck in 1659 will illustrate the nature of the relations existing between colonists and natives at that time:

3rd June.—Wet weather as before, to the prevention of our operations. Our people who are out against the plundering Hottentots, can effect nothing, neither can they effect anything against their masters. But, thus during the whole week they have been vainly trying to get at our cattle, and we have been trying vainly to get at their persons; but we will hope that we may once fall in with them in fine weather, and that the Lord God will be with us.
SOUTH AFRICA

Next to the Hottentots the white settlers encountered the Bushmen (q.v.). When first known to the early colonists they were inveterate stock thieves, and were treated as wild animals, to be shot whenever an opportunity occurred. Such opposition as Hottentots and Bushmen were able to offer to European colonization was not difficult to overcome (see Cape Colony: History). The expansion of the colony was little retarded by native opposition until the Dutch government adopted the slave trade, and made its adherents in South Africa, and the meeting of these rival invaders was the cause of many bloody conflicts. At first the Cape government endeavoured to come to an amicable arrangement with the new power threatening its eastern border, and in 1780 it was agreed that the Great Fish River should be the permanent boundary between the colonial and Bantu territories. The Bantus or Kaffirs (q.v.), as they were universally called, then held all the coast-lands between Delagoa Bay and the Great Fish River, and for many years they were strong enough to bar the further progress eastward of the white races. But the agreement of 1780 was impossible of fulfilment. The peace was broken in 1796 by an invasion of the colonial territory by the Kaffirs, and this conflict proved to be but the first of a series of Kaffir wars which lasted for a century. In 1811 it was deemed necessary to expel the Kaffirs from the Zuurveld, and the British headquarters in that campaign became the site of Graham's Town. In 1817-1819 the Kaffirs returned and laid waste a large area. They were driven back and the country up to the Keiskama River annexed to the colony; but the disaster which nearly overwhelmed the eastern province convinced Lord Charles Somerset, then governor of the colony, of the necessity for a line of frontier forts and a more numerous settlement of colonists. Representations on the matter in England, coupled with assurances from Somerset as to the fertility of the district, induced the British government to vote £50,000 for the purpose of sending out a number of emigrants. Applications were called for, and no fewer than 90,000 were received. Of these, only 4000 were selected and shipped to South Africa. They were landed in 1820, in Algoa Bay, where they founded Port Elizabeth and the Albany settlement. Among these settlers were a number of married men with families. Of these families, half were of Scotch origin, half of English, and came from all grades of society. Among them were cadets of old families, retired officers, professional men, farmers, tradesmen, mechanics and labourers. They encountered many difficulties and some suffering in their early days, but on the whole they thrived and prospered. Their descendants, the Atherstones, Bowkers, Barbers, Woods, Whites, Turveys, and a number of other well-known frontier families, are to-day the backbone of the eastern district of the Cape, and furnish the largest portion of the progressive element in that province. Among them was a gifted Scotsman named Thomas Pringle (1789-1834). His poems, including "Afair in the desert I love to ride," depict the scenes of those early days in glowing lines. The vast spaces of the veld, the silence of the solitude, the marvellous, varied and abundant animal life, the savage, half-wild character of the natives and the wild adventure of the early colonists have been caught with a true spirit of genius. Since his day no one, unless it be Olive Schreiner in The Story of an African Farm, has so vividly painted the life and the atmosphere of that vast continent lying to the south of the Zambezi.

Various Protestant missions had sent agents among the natives during the closing years of the 18th century, and after the definitive acquisition of the Cape by Great Britain, the number of missionaries in the country greatly increased. Many became pioneers, settling in regions beyond the limits of British jurisdiction. Others remained within Cape Colony, while several were stationed among the Kaffirs along the colonial border. The missionaries from the first often found themselves at variance with the Dutch and also the British settlers, whose methods of dealing with the natives often deserved condemnation. At this period Dr John Philip (q.v.), of the London Missionary Society, was dealing with the most prominent of the missionaries in the colony, and his influence was powerful with the home government. The publication in 1828 of his book Researches in South Africa had an important effect on the future of the country. The British government hereafter adopted the principle that the Bantu tribes at the Cape conform to it. The equality of all free Hottentots and other free persons of colour with the white colonists was decreed in that year (1820). Philip's action lacked discrimination, and his faith in the natives was excessive. His charges greatly embittered the Boers, who were further aggrieved by the emancipation of the slaves. The Slave Emancipation Act, freeing all slaves throughout the British Empire, came into force in December 1834. The slaves in Cape Colony, who consisted of negroes from Mozambique, natives of Madagascar, and of Hottentots and Malays were estimated at the time at 36,000. The Cape governments—both Dutch and British—had been consistently averse from the importation of slaves in large numbers, and the great majority of the slaves were therefore Hottentots. The sum voted by the British government to slave-owners in Cape Colony, out of a total compensation paid of £20,000,000, was £1,250,000 (the official estimate of their value being £3,000,000). This money was only made payable in London, and the farmers were compelled to sell their claims for compensation to agents, who frequently paid a merely nominal price for them. In many instances farmers were unable to obtain native labour for a considerable time after the emancipation, and in several cases ruin was the result. A very bitter feeling was thus created among the Dutch colonists.

The championship of the natives by the missionaries led to attacks, in part justified, upon the policy of the missions not only by the Dutch, but by the British colonists. The zeal of the missionaries frequently outran their discretion. This was especially the case in early days. They not only endeavoured to protect and guide the natives beyond the colonial border, but among the Hottentots within the colony they instilled notions of antipathy to the white farmers, and withdrew large numbers of them from agricultural pursuits. Their general attitude may be explained as a reaction against the abuses which they saw going on around them, and to a misconception of the character of the Hottentot and Bantu races. A longer experience of all the African negroid races has led to a considerable modification in the views originally held in regard to them. The black man is not simply a morally and intellectually undeveloped European, and education, except in rare instances, does not put him on an equality with the European. But, admitting all that may be justly urged against the extreme attitude of some of the missionaries, no prejudiced man will deny that their work on the whole has been a good one. The fair fame of Great Britain has more than once been upheld in South Africa at the instigation and by the conduct of these intrepid pioneers. Robert Moffat and David Livingstone among the Bechuana, E. Cassalis among the Basutos, François Coillard among the Barotse, James Stewart in Cape Colony, to name but a few of the great missionaries, have all had an excellent influence upon the natives. They have (besides their purely spiritual work) opposed the sale of alcohol, denounced inhumanity from the farmers, encouraged the natives to labour and taught them how to labour. "Practical education, begun about 1840, now occupies a position little, if at all, inferior to that of doctrinal teaching, and the effect is an excellent one. Strong testimony to the beneficial result of their labours was borne by a thoroughly impartial commission, presided over by Sir Godfrey Lagden, which in 1903-1905 investigated the status and condition of the natives of South Africa.

To return to the period of Dr Philip's activity. Largely upon

1 It appears that the first persons to treat the Bushmen other than as animals to be destroyed were two missionaries, Messrs J. J. Kicherer and Edwards, who in the early years of the 19th century devoted themselves to ameliorating the lot of these aborigines.

2 The slaves, after passing four years in a species of apprenticeship, were finally freed on the 1st of December 1838.

3 At this time (c. 1815-1840) numbers of persons brought discredit on the missionary cause by their illiteracy, narrow-minded prejudices
his advice it was decided to create a band of native states on the northern and eastern frontiers of the colony. These treaty states, as they were called, were intended to serve a double purpose; they would be a barrier protecting the colony from the inroads of hostile tribes, and they would enable native civilized nations to grow up (under the tutelage of the missionaries) strong enough to protect themselves from the encroachments of the whites. In fact, neither of these results followed. With one exception, that of Moshesh, the chief of the Basutos, none of the chiefs with whom treaties were made were men powerful enough to found kingdoms, nor had they, in most cases, any better right than their neighbours to the territory recognized as theirs by the British government. Moreover, to treat these men as independent or semi-independent princes was a complete mistake; the nature of the treaty state system is now seen to have been inevitable. The first treaty of this kind was concluded on the 11th of December 1834 with a Griqua chief named Andries Waterboer. This chieftain lived north of the Orange river in the district now known as Griqualand West, and ruled over some 4000 people, a bastard race sprung from the intercourse between Boers and native women. In 1843 two more of these treaty states were established, one under Adam Kok (the third of that name) and the other under Moshesh. Adam Kok had under him a small number of Griquas, who dwelt in the country east of that occupied by Waterboer (see Griqualand East). And east of this country, again, was a tract of territory occupied by Basutos under Moshesh. In the same way Pondoland was established as a treaty state in 1844. The distinction between these states must be remembered to understand arising subsequent developments. Moshesh ruled over a region largely mountainous and over a people numerous and virile; Pondoland was somewhat remote and was densely inhabited by warlike Kaffirs; the two Griqua states were, however, missionary creations; they were thinly inhabited and occupied open plains easy of access—hence their ultimate collapse. The year which witnessed the emancipation of the slaves and the creation of the first treaty states also saw the breaking out of another disastrous Kaffir war. Fighting began in December 1834, and lasted nearly a year. The Kaffirs wrought great havoc, and Sir Benjamin D'Urban (p. 80), the governor, in order to secure peace, extended the boundary of the colony to the Kei river. The Kaffirs had suffered much injustice, especially from the commando-repressal system, but they had also committed many injustices, and for the disturbed state of the border the vacillating policy of the Cape government was largely to blame, Sir Benjamin's policy—which had the cordial approval both of the Dutch and the British colonists—was one of close settlement by whites in certain districts and military control of the Kaffirs in other regions, and it would have done much to ensure peace. Lord Glenelg, secretary for the colonies in Lord Melbourne's second administration, held that the Kaffirs were in the right in the quarrel, and he compelled D'Urban to abandon the conquered territory, a mistaken decision adopted largely on the advice of Dr Philip and his supporters. Thus at this time (1836) a critical state had arisen in South Africa. The colonists had lost their slaves, the eastern frontier was in a state of insecurity, native interests appeared to be preferred to those of the whites. The British immigrants of 1820 were still struggling against heavy odds; the Dutch colonists were in a state of great indignation. In these circumstances what is known as the Great Trek occurred. It lasted from 1836 to 1840. During that period no fewer than 7000 Boers (including women and children), impatient of British rule, emigrated from Cape Colony into the great plains beyond the Orange river, and across them again into Natal and into the fastnesses of the Zoutspanberg, in the northern part of the Transvaal. In view of the vast consequences ensuing from this exodus of Dutch families from the Cape a somewhat detailed consideration and in some cases lax sexual morality. These persons "assembled to themselves the important office of teachers in the missionary schools within the colony. See H. Cloete's The Great Boer Trek, lecture II.

1 See F. R. Cana, South Africa from the Great Trek to the Union (London, 1900), pp. 295–307 for the full text of Retief's manifesto.

admitted. This sentiment, which found formal recognition later on in the constitution of the South African Republic, was held in fullest force by the voortrekkers. Summing up, it may be said that the exasperation caused by just grievances unremedied was no stronger a motive with the trekkers than the desire to be free from the restraints imposed on British subjects and the wish to be able to deal with the natives according to their own fashion.

The departure of so large a number of persons caused serious misgiving both to the Cape and the home governments. The trekkers had been told by the lieutenant-governor of the eastern province (Sir Andries Stockenstrom) that he was not aware of any law which prevented any British subject from settling in another country, and in the words of Piet Retief's declaration they quoted the colony 'under the full assurance that the English government was ready to take no more to require of us, and will allow us to govern ourselves without its interference in future.'

The British government thought otherwise; they held that the trekkers could not divest themselves of their allegiance to the Crown. Moreover, though the farmers might leave British territory they were still held to be liable to the jurisdiction of British courts. An act passed in 1836 (the Cape of Good Hope Punishment Act) empowered the colonial courts to deal with offences committed by British subjects in any part of South Africa up to the 25th degree of south latitude. Intended by its authors to prevent the natives from aggression on the part of white men and to check the depredations of the tribes, the Kaffirs, Bechuana, &c., the act led in fact to the assertion of British authority in regions beyond the Cape frontier.

B. From the Foundation of the Republics to Majuba.—While the home government was seeking to prevent the expansion of the white races the first steps had been taken by a body of Englishmen to found a new colony at Natal. Since 1824 a few traders had been settled at Port Natal, and in 1834 formal petition was made that their settlement should be recognized as a British colony. The request was opposed, and not without reason, by the Boers, and the Dutch emigrant farmers under Retief entered the country by way of the Drakensberg. Retief, like his English predecessors at Port Natal (known also since 1834 as Durban), sought a formal grant of territory from the chief of the Zulu nation, the Zulus being the acknowledged overlords of the tribes living in Natal. Retief and his party were, however, treacherously murdered by Dingaan, the Zulu king (February 1838). Other trekkers followed in the wake of Retief, and attacking Dingaan avenged the massacre.

The Boers then established a republican government at Maritzburg. Though most anxious to avoid any extension of responsibility in South Africa, Great Britain recognized the potential danger arising from the creation of an independent state on the coast. The Boers at first rejected offers of accommodation. Troops were then sent to the country, and finally a settlement was made by Henry Cloete, the British commissioner, with the Boer leaders, and Natal constituted a British colony in 1843. Many Boers, dissatisfied with this arrangement, withdrew beyond the Drakensberg. Natal shortly afterwards received a considerable number of emigrants from England. The inhabitants have since been predominantly British. At first Natal was dependent on Cape Colony. In 1856 it was constituted a separate colony, but it did not possess self-government until 1863. A notable departure from the labour policy of the other states was made by Natal in 1896, when Indian coolies were introduced. At the time the matter attracted little attention, but the Asiatic inhabitants speedily increased, and forty years later they outnumbered the whites (see NATAL).

It had taken the British government nearly ten years to decide on the annexation of Natal; its policy towards the Boers settled north of the Orange was marked by the same hesitation (see ORANGE FREE STATE). By 1847, when Sir Harry Smith became high commissioner, the failure of the treaty state policy was evident. Sir Harry, deeming no other course open to him, proclaimed (February 1848) the country between the Orange and Vaal rivers British territory, under the name of the Orange River Sovereignty. Sir Harry laid, in the previous December, extended the northern frontier of Cape Colony to the Orange, and had reconquered the territory on the Kaffir border (Orange River Sovereignty), which D’Urban had been forced to abandon. The

extension of British rule north of the Orange was opposed by Andries Pretorius, who, being defeated at Boompats, withdrew north of the Vaal, where, though not interfered with by the British, the Boers split up into several rival parties. In the Sovereignty difficulties arose in defining the reserves of the native chiefs, and with the Basutos there were armed conflicts. The home government (the first Russell administration), which had reluctantly consented to confirm Sir Harry Smith’s annexation of the Orange River territory, on learning of these difficulties, had begun to regret its course, and in 1857 informed the Boers that the ultimate abandonment of the Sovereignty was a settled point.

In fulfilment of their settled policy to keep the British South African dominions within the smallest possible limits, the cabinet decided to recognize the independence of the Boers living beyond the Vaal. This recognition, the necessary preliminary to the abandonment of the Orange River Sovereignty, was made in the Sand River Convention on the 17th of January 1852. The Transvaal thus became an independent state, or rather it formed a number of mutually independent communities. The Boers did not consider themselves free.

The British government meantime pursued its policy of abandonment, and in February 1854, by the Bloemfontein Convention, formally recognized three independent states, the Orange Free State, the Transvaal, and the Natal Republic, which, now became the Orange Free State. A clause was inserted in the Bloemfontein Convention stating that Great Britain had no alliance with any native chiefs or tribes to the north of the Orange, with the exception of the Griqua chief Adam Kok. Numerous protests were made by many of the inhabitants of the Orange River Sovereignty against the abandonment of it by the British government, but the duke of Newcastle, who was then colonial secretary in Lord Aberdeen’s administration, replied that the decision was in accordance with the ORANGE FREE STATE.

The abandonment of the Orange River Sovereignty marked the close of the eventful period in South African history which began eighteen years before with the Great Trek. At the beginning of that time there was but one civilized government in South Africa— Cape Colony; at its close there were five separate states or provinces, three, the Cape, Natal and British Kaffiria, owning allegiance to Great Britain, and two forming Boer republics—the Transvaal and Orange Free State. While vast additional territories had been occupied by British or Boer the unity of administration, which had hitherto prevailed, was lost. The number of people of the white races in South Africa, had been lost. Whether or not a wiser policy on the part of Great Britain would have secured the continued allegiance of all the Boers it is impossible to say; the fact that numbers of Boers remained in Natal under British rule, and that the majority of the Boers who settled between the Orange and the Vaal desired to remain British subjects, points to that conclusion. With justice the Boers complained of the course actually adopted by the British authorities. They might at the outset either have let the trek Boers go, and given them their blessings and liberty, or they might have controlled the trek and

1 Part of the territory thus reannexed was added to Cape Colony while the region between the Keiskamma and Kei was created a separate territory under the name of British Kaffiria.

1 Despatch of Earl Grey, dated October 21st, 1851, printed in Correspondence Relative to the State of the Kaffir Tribes (C. Feb. 1853).
made effective their contention that the trekkers were still
British subjects. As has been demonstrated the action taken
was one of vacillation between these two courses, and was
complicated by a native policy which, though well intentioned
and intelligible, needlessly irritated the white colonists (British
and Dutch) and did not prevent bloodshed. In the words of
Mr Paul Botha, a Boer writer, England first blew hot and then
blew cold. But in 1854 a definite standpoint appeared to have
been reached—Great Britain would confine her energies to the
Cape and Natal, leaving the republics to work out their own
destinies undisturbed. It was at this juncture that Sir W. Grey
sent the Rev. P. J. du Plessis to the Cape Colony. A gifted
and far-seeing man, he had no sooner arrived than he
addressed himself with energy and diligence to the
great problems awaiting him. His first care was to ameliorate
the condition of Cape Colony. He resolved that in dealing
with the natives on the eastern frontier an attempt should
be made to civilize them and thus do away with the
necessity of periodical warfare. Grey's efforts to promote
good government in Kaffiria received unexpected help in
consequence of the extraordinary delusion among the Ama-Xosa
in 1855, which resulted in the death of many thousands of natives
(see Cape Colony: History). Land left derelict was occupied
by colonial farmers, and over 2000 German immigrants were
introduced by Sir George and settled along the frontier (1858-
1859). By this time the colonists of British descent predominated
in the eastern provinces—a circumstance which had important
bearings on the future of the colony.

Sir George Grey found it impossible to maintain a policy of
total abstinence from the affairs of the republics. The party in
the Free State which had objected to independence being forced
upon it was still strong and made overtures for a closer
connection to the Free State and the Transvaal. In the conflicts between the Freemen
and the Basutos Grey's intervention was sought. All the
evidence before Sir George, and the study he made of the Boer
character, convinced him that the barriers separating the various white communities were largely artificial. He sought to
remedy the mistake which had been made, and in 1858 he submitted
a scheme of federation between the various South African states. In a memorable despatch to Sir E. Bulwer Lytton,
then colonial secretary in the second Derby administration,
he wrote (November 19, 1858): "If you pleased to adopt the
scheme of dividing South Africa into many states, bound together by no ties of union, it was thought that the
mother country derived no real benefit from the possession of this
part of the African continent, except in holding the seaport of Simon's Town. It was further thought that the occupation by
Great Britain of the country beyond the Orange River had been a
bubbling and a farce, in which the Cape colonists were all interested:
for that it was to them a great gaming table and out of the reach
of the police. . . . Although these European countries lying beyond
our colonies are treated as separate nations, their inhabitants bear
the same family names as the inhabitants of this colony, and maintain
with them ties of the closest intimacy and relationship. . . .
Think there can be no doubt that in any great public, or popular,
or national question and movement the mere fact of calling these
people different nations would not make them so, nor would the
fact of a rich profit be a stream running between them. The
sympathies or prevent them from acting in union. . . . Experience
has shown that the views which led to the disembarkment of South
Africa were mistaken ones. . . . What therefore I would recommend
would be that. . . . measures should be taken which would permit
of the several states and legislatures of this country forming among
themselves a federal union.

When he penned this despatch Grey was well aware of the
distraught condition of the Free State and the agitation for a
change in its government. He held that the federation of that
state with Cape Colony was preferable to its union or federation
with the Transvaal, and it was with considerable satisfaction
that he learned that on the 7th of December of the same year
(1858) the Free State had passed a resolution in favour of a "union or alliance with the Cape Colony" and
sought to ascertain the views of the Cape legislature on the
subject. In bringing the matter before the Cape parliament in March
1859 Grey stated that in his opinion it would confer a lasting
benefit upon Great Britain and upon the inhabitants of South
Africa if it could succeed in devising a form of federal union.
Unfortunately, Grey's views did not meet with the approval of the British government. Had they been
supported it is highly probable that federation would have been effected. But the golden opportunity was lost. When
Grey attempted to persevere with his scheme he was recalled.
He left Cape Town in August 1859, but on his arrival in
England he found that there had been a change of ministry.
The new colonial secretary, the duke of Newcastle, reinstated
his predecessor in the office of British minister to the Cape
government. The first project for reunion thus came to naught, but from that
time forward it was recognized in South Africa that federation would
afford the best solution of most of the difficulties that beset the
country. The Transvaal was perhaps the greatest sufferer through Grey's failure, that country continuing for years in a
distracted condition. The Free State, under the guidance ofSir John Brand, who became president in 1864, attained
a considerable measure of prosperity. Its difficulties with the
Basutos were at last composed, and Moishees and his people
1868 definitely taken under British protection. The
policy of non-interference proclaimed in 1854 had proved impracticable, and the annexation of Basutoland was an open
confession of the fact. In 1871 the country was annexed to Cape Colony, but its pacification proved a task of great difficulty.

Up to the year 1870 the Dutch considerably outnumbered the
British inhabitants; indeed, save in Natal, in the eastern province
and in Cape Town, the British inhabitants were com-
paratively few. The industries were almost entirely pastoral,
and remained chiefly in the hands of the
Dutch. The continual feuds with the Kaffirs, and also the
continual desire to trek into new countries, all tended to keep
back farming, and the country in the years 1867 to 1870 was in a
generally very depressed condition. But in 1870 the era of commer-
cial expansion began. In that year, following smaller finds of
diamonds on the banks of the Vaal and Orange rivers, the diamond
mines of Du Toits Pan and Bultfontein were opened up.
In 1869 gold had been found in the Lydenburg and Zoutpansberg
districts in the Transvaal, and diggers had resorted there from
different parts of the world; moreover, in the far interior, in the
territories of Mashonaland, Thomas Baines had reported dis-
coveries of gold. Among the purely British, a new spirit
began to blow. The discovery of diamonds had added a considerable asset to the
wealth of Cape Colony. The revenue derived from the
export of ostrich feathers in 1890 was recorded at half a million.
It was, however, the discoveries of diamonds and gold that
crystallized determined the development of the country. A large
population grew up, first at Kimberley, afterwards at Barberton,
and finally at Johannesburg—a population modern in its ideas,
energetic, educated, cosmopolitan, appreciating all the resources
that modern civilization had to offer them, and with a strong
partiality for the life of the town or the camp rather than that
of the farm and the veld. The majority of the Boers remained
very much what they had been in the 17th century. Their
life of continual strife with natives, continual trekking to fresh
pastures, had not been conducive to education or the enlarge-
ment of intellectual outlook. In religion they were Calvinistic,
fanatic, and their old traditions of Dutch East India government,
together with their relation to the natives, developed a spirit of
caste and even tyranny.

It was at this stage of affairs that responsible government
was granted to Cape Colony (1872). From that time down to
the annexation of the Transvaal in 1877, the Carnarvon
Council, the home government of Paul Bocasa, Great
Britain "blew hot" in South Africa. A great change
began to make itself felt in Great Britain in the late sixties and
early seventies of the 19th century. The constitution of the
Dominion of Canada (1867-1873) was an evidence of that feeling.
1 Sir E. Bulwer Lytton wrote (Feb. 11, 1859): "H.M. Government
are not prepared to partake of the settled policy of their
predecessors by advising the resumption of British sovereignty in
any shape over the Orange Free State."
With the advent to power of the Disraeli ministry in 1874 the nascent Imperial spirit grew in strength. Lord Carnarvon (the 4th earl), when under-secretary for the colonies in 1858–1859, had regarded Grey's federation proposal with disfavour, but later, as secretary of state, he had introduced the bill for the federation of the Canadian provinces. He now returned to the Colonial Office filled with the idea of doing for South Africa what had been done in British North America. Recent events in South Africa had appeared for a brief period to favour a union of its various colonies and states. The intimation of the impending grant of self-government to Cape Colony was regarded by both Boer republics as bringing nearer the prospect of their union with the British colonies. But just at that time differences arose between Great Britain and the republics as to the ownership of the Kimberley diamond fields which estranged the Boers (see Kimberley and Transvaal). In the Transvaal Pretorius was succeeded by T. E. Burgers, a man totally unfit to govern a country distracted by factions, harassed by wars with natives, and with an almost deplotted exchequer. Yet in the condition of the Transvaal Lord Carnarvon found another argument in favour of federation. Union with the neighbouring states would, he thought, cure its ills and promote the general welfare of South Africa. As a preliminary step he accepted an offer from J. A. Froude to visit South Africa unofficially, and by travelling through its different states find out what were the obstacles to confederation and the means by which such obstacles might be removed. Froude landed at Cape Town on the 21st of September 1874, and having visited Natal, the Free State and Pretoria as well as Cape Colony, sailed for England on the 10th of January 1875. In the three and a half months he had spent in the country he had reached the conclusion expressed by the duke of Newcastle nearly twenty years previously, namely, that all England needed there was Table Bay—or the Cape peninsula—as a naval and military station. The South African states, he believed, might be left in internal affairs to work out their own future. These views coincided with those of Lord Carnarvon, who looked to federation as a means of relieving the Imperial government of some of the heavy responsibilities pressing upon it in South Africa, and he asked Froude to return to the Cape to take part in a conference in South Africa on the federation scheme. The offer was accepted, and Froude reached Cape Town again in June 1875. Lord Carnarvon’s despatch (May 4, 1875), indicating his views, had preceded the arrival of Froude, and had incensed J. C. Molteno, the Cape premier, by its disregard of the colony’s self-governing powers. A motion was carried in the Cape parliament affording that any movement for federation should originate in the Transvaal and not in England. Froude on his arrival was much chagrined at the attitude taken by the Cape parliament, and conducted an oratorical campaign throughout the country in favour of federation. His speeches were lacking in judgment and tact, and created an unfavourable impression. The conference was not held, and Froude returned to England in the autumn.

Lord Carnarvon was far from abandoning his plan. The Transvaal was now in a condition bordering on anarchy, and numbers of its inhabitants were supposed to be looking to Great Britain for protection. Another party in the Transvaal was seeking alliances with Germany and Portugal, and the danger of foreign interference was a further cause for action. In August 1876 the colonial secretary assembled a conference on South African affairs in London, nominating Froude as representative of Griqualand West. President Brand represented the Free State. Another member of the conference was Sir Theophilus Shepstone. (9.6) Neither Cape Colony nor the Transvaal was represented.

1 At Sir Henry Barkly’s request Lord Carnarvon’s predecessor, Lord Kimberley, had in November 1871 given him (Sir Henry) authority to summon a meeting of representatives of the states and colonies to consider the “conditions of union,” but the appointment of the diamond fields had occurred meantime and Sir Henry thought the occasion inopportune for such a conference.

2 For Froude’s views and actions, see especially the blue book C. 1399 (1876), containing his report to the government.

and the conference was abortive, President Brand having no permission from his state to consider federation. That subject was, in fact, not discussed by the delegates. In view of the troubles in the Transvaal, and in furtherance of Carnarvon’s federation scheme, Shepstone was, on the 5th of October following, given a dormant commission to annex the republic “if it was desired by the inhabitants and in his judgment necessary.” The secretary of state thought the advice of Sir Bartle Frere as his chief agent in carrying through confederation was necessary, and instructed him as governor of Cape Colony and high commissioner for South Africa, Sir Henry Barkly, sharing the views of the Cape ministry that the time was inopportune to force such a step upon South Africa. In a letter dated the 13th of October, offering Frere the post Barkly was about to vacate, Lord Carnarvon wrote:—

... The war between the Transvaal republic and the natives has had this further effect; it rapidly ripened all South Africa for the union of the South African colonies and states. I am indeed now considering the details of a bill for their confederation, which I desire to introduce next session, and I propose to press, by all means in my power, my confederation policy in South Africa.

The time required for the work of confederating and of consolidating the confederated states Lord Carnarvon estimated at not more than two years, and he was sanguine enough first of Annexation in the Transvaal. Frere, who had reached Cape Town on the 31st of March, learnt on the 16th of April that the annexation had taken place. He was inclined to regard Shepstone’s act as premature, and he realized that it stirred very deeply Dutch national feeling throughout South Africa. Though anxious to promote Carnarvon’s policy, Frere found it necessary to call for immediate attention. The Basuto and Kafr tribes were giving trouble, and the 40,000 trained Zulu warriors under Cetywayo threatened the peace both of Natal and the Transvaal. In the same month (Aug. 1877) in which the British parliament passed the act, foreshadowed by the secretary of state, “for the union under one government of such of the South African colonies and states as may agree thereto,” another war with the Kafris broke out. This conflict lasted until May 1878, and largely absorbed the energies of Sir Bartle Frere. In the meantime a specie famine had set in, and the distress due to federation, put forward by the Molteno ministry, a scheme which in its essence anticipated the form of government established in 1910—had met with no support from Frere or the home ministry. In January 1878 Lord Carnarvon resigned, and the driving force of the federation scheme thus disappeared. It was not, however, finally dropped until 1880. In July of that year proposals for a confederation conference were submitted to the Cape parliament. At that time Paul Kruger and Piet Joubert, delegates from the Transvaal Boers, were in Cape Town, and they used their influence to prevent the acceptance of the proposals, which were shelved by the ministry accepting the “colony proposals, which were shelved by the ministry accepting the...
previous question”) (June 26). Thus ended an attempt which lacked the element essential to success—spontaneity.

Confederation had, for the time being, ceased to be a living issue some time before its formal shelving by the Cape parliament. The Kaffir War of 1879 was followed by war with the Zulus. Frere, believing that the Zulu power was a standing menace to the peace of South Africa, and that delay in dealing with Cetwywayo would only increase the danger, sent an ultimatum to the chief in November 1878. The invasion of Zululand began in January 1879, and was speedily followed by the disaster at Isandhlwana and by the defence of Rorke’s Drift and of Eshowe. But at the battle of Ulundi in July the Zulu power was crushed, and a little later Cetwywayo was taken prisoner (see ZULULAND: History). The removal of the Zulu danger did not, however, restore harmonious relations with the British and the Boers in the Transvaal. The malcontent Boers became a powerful element in the country. They were largely influenced by an important section of the Dutch community in western Cape Colony, which carried on a campaign against annexation, seeing in it a blow to the ideal they had begun to entertain of a united South Africa of a Dutch republican type. Sir Garnet Wolseley, at this period (June 1879—May 1880) high commissioner of South-East Africa, gave the Transvaal a legislative council, but the members were all nominated. This could not be regarded as a realization of the promise of a liberal constitution, and it had an injurious, though limited, effect on the Boer community. After the receipt in December 1879 of the reports of Mr Gladstone’s speeches during his Midlothian campaign—in which he denounced annexation as obtained by means dishonourable to Great Britain—the Boers expected nothing less than the retrocession of the country.

There was one strong reason against retrocession, concerning which the Boers—if they gave it thought—would naturally be silent. To the British mind in general it was apparently non-existent. It had, however, been seen and its strength recognized by Sir Garnet Wolseley during his brief governorship of the Transvaal. Wolseley, in a despatch dated the 13th of November 1879 said:—

The Transvaal is rich in minerals; gold has already been found in quantities, and there can be little doubt that larger and still more valuable goldfields will sooner or later be discovered. Any such discoveries would sooner bring a large British population here. The time must eventually arrive when the Boers will be in a small minority, as the country is very sparsely peopled; and would it not therefore be a very near-sighted policy to recede now from the position taken up here, simply because for some years to come the retention of 2000 or 3000 troops may be necessary to reconsolidate our power.

As Lord Morley in his Life of Gladstone says, “this pregnant and far-sighted warning seems to have been little considered by English statesmen of either party at this critical time or afterwards, though it proved a vital element in any far-sighted decision.”

The result of the general election of 1880 was to place Mr Gladstone in power. The new administration, notwithstanding Mr Gladstone’s public utterances, declared their intention of retaining British sovereignty in the Transvaal, coupling with that decision a pious hope for the speedy accomplishment of confederation so as to allow of free institutions being given to Natal and the Transvaal. The disillusionment occasioned by this decision caused the Boer delegates then to face up to the help to wreck the federation proposals (see supra). But it was unwilling with the time to undo the work of Sir T. Shepstone, the Liberal cabinet were prepared to get rid of the chief British representative in South Africa—partly to please the extreme Radicals among their followers. Accordingly on the 2nd of August 1880 Frere received a telegraphic despatch from Lord Kimberley (the new secretary of state for the colonies) announcing his recall. Frere’s task was one of extreme delicacy; he chose to face difficulties rather than evade them, and had he been unfettered in his action might have accomplished much more than he was able to do; in its main lines his policy was sound. (See Frere, Sir Henry Bartle.)

Finding that the Gladstone administration would not give up the Transvaal voluntarily, the Boers now determined on rebellion. Hostilities began in December 1880, and eventually a series of engagements ended in the rout (Feb. 27, 1881) of a small British force which had occupied Majuba Hill the previous evening. The killed included the general in command, Sir George Colley. Meanwhile the resolution of Mr Gladstone to restore annexation to the Transvaal had been shaken by the Boer declaration of independence. After the events of this resolution this was further weakened; and when, after a British reverse at Ingogo (Feb. 8), overtures were made by Mr Kruger on behalf of the Boers, the cabinet was strongly inclined to come to terms. The news of Majuba did not turn it from its purpose. Opinions will always differ as to the course adopted by the Liberal government. “We could not,” wrote Mr Gladstone, “because we had failed on Sunday last, insist on shedding more blood.” It is at all events abundantly clear that had the Boers not resorted to arms they would not have gained the support of the cabinet. Sir Evelyn Wood, who had succeeded Colley as general in command and governor of Natal, under instructions from home, concluded a treaty of peace on the 22nd of March. The terms agreed upon were elaborated in a convention signed at Pretoria in August following. By this instrument the Transvaal was granted self-government subject to British suzerainty and the control of the foreign relations of the state. In 1884 the Gladstone administration made further concessions by the London convention of that year. This last document still, however, reserved for Great Britain certain rights, including the power of veto over treaties concluded by the Boers with any power other than the Orange Free State. But the success of the Transvaal Boers both in war and diplomacy had quickened the sense of racial unity among the Dutch throughout the country, and there arose a spirit of antagonism between the Dutch and the British which affected the whole future of South Africa.

Before, however, dealing with the relations between the British and the Boers subsequent to 1881 brief reference may be made to affairs in which other powers were concerned; affairs which were the pretext to the gaining of the support of the cabinet. In 1884-85 the Germans in South-West Africa were concerned in a dispute with the Germans in South-West Africa, and when the German colony in the Transvaal, was secured for Great Britain. It was not on the west coast only that Germany made efforts to secure a footing in South Africa. In September 1884 an attempt was made to secure St Lucia Bay, on the coast of Zululand. Here, however, Great Britain stood firm. St Lucia Bay had been ceded to the British by the Zulu king Panda in 1843, and this cession has always been regarded as valid. Eventually Germany agreed to make no annexation on the east coast of Africa south of Delagoa Bay. With the proclamation of a British protectorate over the coast of Pondoland in January 1885 the coast-line from the
mouth of the Orange to Delagoa Bay (save for the small stretch of Amatonga shore-line) became definitely British. To Delagoa Bay, or rather to the southern part of the bay, Great Britain had laid unsuccessful claim. On the northern bank of the chief estuary of the bay the Portuguese had from the 16th century onward maintained a precarious foothold; it was their most southerly station on the east coast of Africa. In 1823 treaties had been concluded by the British with tribes inhabiting the southern shores of the bay. Neither the Portuguese nor the British claims seemed of much importance until the rise of the South African republic. Anxious for a seaport, the Transvaal Boers in turn laid claim to Delagoa Bay. This brought the dispute between Great Britain and Portugal to a head, the matter being referred in 1872 to the president of the French republic for arbitration. In 1875 an award was given by Marshal MacMahon entirely in favour of the Portuguese (see Delagoa Bay). As a port outside British control Delagoa Bay was a source of strength to the Boers, especially as the railway was under their control. In the war which began in 1899 munitions of war and recruits for the Boers were freely passed through Delagoa Bay.

C. The Struggle for Supremacy between British and Dutch.—Bechuanaland, through which territory runs the route to the far interior—the countries now known as Rhodesia Annexed. —was acquired, despite the strong desire of the Gladstone administration to avoid further annexations in South Africa. At first the encroachments on Bechuanaland territory by Boers from the Transvaal were looked upon with comparative indifference. The Boers respected neither the frontier laid down by the Pretoria convention nor that (modified in their favour) drawn in the London convention. But missionary influence was strong; it was reinforced by the growing strength of the imperialistic spirit and by the fears excited by Germany’s intrusion on the south-west coast. An expedition was sent out in October 1884 under Sir Charles Warren; the Boers, who had set up the “republics” of Goshen and Stellaland, were obliged to give way, and the country was annexed (see Bechuanaland). It was in connection with this affair that Cecil Rhodes first came into prominence as a politician. As a member of the Cape parliament he undertook a mission, before the arrival of Warren, to the Goshen and Stellaland Boers, endeavouring, unsuccessfully, to obtain from them a recognition of British sovereignty. The acquisition of Bechuanaland by Great Britain was the essential preliminary to the development of the schemes which Rhodes entertained for the extension of British rule into Central Africa. In his endeavours to realize this aim he had to contend with the new spirit of national consciousness animating the Boers, which found expression in the formation of the Afrikander Bond.

In its external, as in most of its internal policy, the Transvaal was controlled from 1881 onward by Paul Kruger, who was elected president of the state in 1883. Yet Kruger was scarcely the real leader in the nationalist movement to which the successful revolt of 1880–81 gave strength. The support given by the Cape Colony Dutch to the malcontent Transvaal Boers has already been mentioned. During the 1880–81 revolt many Free Stateburgers, despite the moderating influence of President Brand, joined the Transvaal commandoes. Now a definite effort was made to build up a united South Africa on anti-British lines. In the latter part of 1881 a Dutch pastor at the Paarl, a town in western Cape Colony named Du Toit, in a paper called De Patriot, suggested the organization of an Afrikaner Bond; in the same year Carl Borckenheim, a German resident in the Free State, advocated such a bond in his paper, the Bloemfontein Express. The Bond was formed, its work being almost confined to Cape Colony. It held its first congress at Graaf Reinet in 1882. In the “programme of principles” upon which its constitution was modelled it was set forth that:

While in itself acknowledging no single form of government as the only suitable form, and whilst acknowledging the form of government existing at present [the Bond] means that the aim of our national development must be a united South Africa under its own flag.

In the following year the Farmers’ Protection Association was amalgamated with the Bond, and the joint organization fell under the control of J. H. Hofmeyr, the leader of the Dutch party in Cape Colony. Under Hofmeyr, the political contentment of all declarations inconsistent with allegiance to the British Crown were omitted from the Bond’s constitution. It remained, however, a strong nationalist organization, which in practice was inimical not so much to the British connexion as to the British section of the population and to the development of the country on enlightened lines. (For the Afrikander Bond see further Cape Colony: History, and Hofmeyr.)

Not long after the Warren expedition the valuable gold fields which Sir Garnet Wolseley had foreseen would be discovered in the Transvaal were actually found. By 1886, the year in which Johannesburg was founded, the wealth of the Witwatersrand fields was demonstrated. The revenue which these discoveries brought into the Transvaal treasury increased the importance of that state. The new industrial situation created had its effect on all parties in South Africa, and in some measure drew together the British and Dutch sections outside the Transvaal. A customs union between Cape Colony and the Free State was concluded in 1889, to which later on all the other South African states, save the Transvaal, became parties.

Kruger remained implacable, bigoted, avuncular, determined in the policy of Rhodes in 1890 to maintain for an alliance with the Free State. Brand refused to be ensnared in Kruger’s policy, and the negotiations to no agreement. (For details of this episode see Orange Free State: History.) Not many months afterwards (July 1888) the Free State lost by death the wise, moderating guidance of Sir John Brand. The new president, F. W. Reitz, one of the founders of the Bond, in 1889 committed the Free State to an offensive and defensive alliance with the Transvaal. Kruger thus achieved one of the objects of his policy. Within the Transvaal a great change was coming over the population. There flocked to the Rand many thousands of British and other Europeans, together with a considerable number of Americans. This influx was looked upon with disfavour by Kruger and his supporters, and, while the new comers were heavily taxed, steps were speedily taken to revive the franchise laws so that the immigrants should have little chance of becoming burghers of the republic. This exclusion policy was even applied to immigrants from the other South African countries. A system of oppressive trade monopolies was also introduced. The situation with which the Boers were called upon to deal was one of extreme difficulty. They could not keep back the waves of the new civilization, they feared being swamped, and they sought vainly to maintain intact their old organization while reaping the financial benefit resulting from the working of the gold mines. The wider outlook which would have sought to win the Uitlanders (as they were called) to the side of the republic was entirely lacking. The policy actually followed was not even stationary; it was retrogressive.

Meanwhile, and partly through distrust of the Kruger policy, there was growing up in Cape Colony a party of South African Imperialists or, as they have been called, Afrikander Imperialists, who came to a large extent under the influence of Cecil Rhodes. Among these were W. P. Schreiner (afterwards premier of the colony) and J. W. Leonard (sometime attorney-general) and, to some extent, Hofmeyr. From the time of his entrance into politics Rhodes endeavoured to induce the leading men in the country to realize that a development of the whole country could and should be accomplished by South Africans for South Africans. He fully admitted that the cry which had become so popular since 1889 of “Africa for the Afrikanders” expressed a reasonable aspiration, but he constantly pointed out that its fulfilment could most...
advantageously be sought, not, as the Kruger-party and extremists of the Bond believed, by working for an independent South Africa, but by working for the development of South Africa as a whole on democratic, self-reliant, self-governing lines, under the shelter of the British flag. Hofmeyr was among those whom Kruger's attitude drove into a loose alliance with Rhodes. In 1884, having the power in his hands when the Scalen ministry fell, Hofmeyr had put into office a ministry dependent upon the Bond, and had talked of a possible Dutch rebellion in Cape Colony if the Boer freebooters in Bechuanaland were ejected; in 1890 Rhodes became premier with Hofmeyr's approval and support. Rhodes remained in office as prime minister until January 1896. During this period he planned for the development and public life of South Africa to be greater than that of any other man. He used his period of power to put into execution his plans for the extension of British dominion over the country up to the Zambesi.

In 1888 Rhodes had succeeded in inducing Sir Hercules Robinson, the high commissioner, to allow J. S. Moffat, the British resident at Bulawayo, to enter into a treaty with Lobengula, the Matabele chief. Under this treaty Lobengula bound himself not to make a treaty with any other foreign power, nor to sell or in any other way dispose of the "young buffalo" without the sanction of the high commissioner. This step prevented the country from falling into the hands of Germany, Portugal or the Boers. The treaty was followed by the formation of the British South Africa Company, which obtained a royal charter in 1889, and by the occupation of Mashonaland in 1890. Difficulties with the Portuguese followed, but the Salisbury administration firmly upheld British claims, with the result that the British sphere of influence was extended not only to the Zambesi but beyond to the shores of Lake Tanganyika (see AFRICA: § 3). In 1893 a war was fought with the Matabele by Dr L. S. Jameson, the administrator of Mashonaland, and Bulawayo was occupied. The name Rhodesia was conferred upon the country in 1894 (see RHODESIA). Living in Cape Town and at the head of the government, Rhodes used every effort to demonstrate to the Cape Colonists that the work he was doing in the north must eventually be to the advantage of Cape Colonists and their descendants. On the whole, Hofmeyr and his friends were well pleased at having secured the co-operation of the big Englishers. Rhodes, or, as he was at one time called by Mr J. X. Merriman, an old parliamentary hand and treasurer-general during part of Rhodes's premiership, had some power with the "youthful burghees." In 1891 the Bond Congress was held at Kimberley, and harmony appeared to reign supreme. During his term of office Mr Rhodes addressed himself to bringing together all interests, as far as was practicable, to do so. He showed that his views of the situation were broad and statesmanlike. His handling of the native question in Cape Colony gave general satisfaction. Rhodes was also a firm believer in the federation of the South African states and colonies, and he sought to promote this end by the development of inter-state and inter-colonial railway systems, and the establishment of common customs, tariffs, and inter-colonial free trade under a customs union. The persistent opponent to both these measures was the Transvaal. In matters of domestic legislation, such as taxation and excise, Rhodes fell in to a considerable extent with Dutch prejudices.

While in the rest of South Africa there was a growing feeling of trust between the Dutch and British, accompanied by increasing trade and the development of agriculture, the condition of the Transvaal was becoming serious. At first the new-comers to the Rand had to bear much of the economic and political burdens to which they were subjected, but as they grew in numbers and found their burdens increased they began to agitate for reforms. In 1892 (the year in which the railway from Cape Town reached the Rand), the National Union was founded at Johannesburg by ex-Cape Colonists of the Imperial progressive party. For three years petitions and deputations, public meetings and newspaper articles, the efforts of the enlightened South African party at Johannes burg and Pretoria, were all addressed to the endeavour to induce President Kruger and his government to give some measure of recognition to the steadily increasing Uitlander population. Urgent representations were also made by the British government. President Kruger remained as impenetrable as adamant. Nine-tenths of the state revenue was coming from the Uitlanders, yet they had not even any municipal power. By a law of 1891 the British and naturalized and enfranchised if they reside in the country of five years, but between 1890 and 1894 the franchise laws were so altered as to render it practically impossible for any foreigner to become a burgheer. By the law of 1894 the immigrant must have been at least 14 years in the country and be 40 years old before in the most favourable circumstances he could be admitted to the franchise. The Uitlanders once more petitioned, over 34,000 persons signing a memorial to the Raad for the extension of the franchise. The appeal was refused (August 1895). Up to the period that the law was passed the President and the government had not hinted that Kruger and his following would listen to reason; nor did they realized that such an expectation was vain. Rhodes, who had large interests in the Rand mines, had consistently endeavoured to conciliate the extreme Boer section in the Transvaal and win it over (as had happened in the case of the Cape Dutch) to a policy which should benefit the whole of South Africa. He was even willing to see the Transvaal obtain a seaport (at Kosi Bay, in Amatongaland) if in return it would join the customs union. This opportunity Kruger let slip; and in May 1895, on the representation of Sir H. Loch, the Rosebery administration annexed Amatongaland, thus making the British and Portuguese frontier conterminous. This action, finally blocking the Boer road to the sea, taken by a Liberal government, was clear indication that Great Britain was determined to maintain her supremacy in South Africa.

The situation in August 1893 was thus one of extreme tension. There had been a change of ministry in Great Britain and Joseph Chamberlain had become colonial secretary. Sir Hercules Robinson, who was regarded sympathetically by the Dutch population of South Africa, had succeeded to the high commissioner's post. But the English government were hopeful that Kruger might yet even be induced to modify his policy; the Uitlanders now entertained such hope and they prepared to appeal to arms to obtain redress of their grievances. The first proposals for an armed rising came from Rhodes in June, but it was not until November that the Uitlander leaders came to a definite understanding with the Cape premier as to the course to be pursued. To lay before South Africa the true position of affairs in the Transvaal, Charles Leonard issued a manifesto as chairman of the National Union. It concluded with a list of demands (see TRANSVAAL), their gist being "the establishment of this republic as a true republic" with equitable franchise laws, an independent judicature and free trade in South African products.

This manifesto, issued on the 26th of December, called a public meeting for the night of Monday the 6th of January 1896, "not with the intention of holding the meeting, but as a blind to cover the simultaneous rising in Johannesburg and seizing of the arsenal in Pretoria on the night of Saturday the 4th of January (fitpatrick, The Transvaal from Within, ch. iii.). Had the Transvaal government given way under the latter threat, the reformers would have been satisfied. Of this, however, there was no expectation. The arrangement with Rhodes included the use of an armed force belonging to the Chartered Company, and led by Dr Jameson. Accordingly some troops were brought from Rhodesia and stationed near Mafeking, a few miles from the Transvaal frontier. For some weeks the plot appeared to progress
Rhodes had intended to withdraw from Cape politics and devote his energies for a time entirely to Rhodesia, but the pressure put upon him by a section of the British colonists was so strong that he determined to throw in his lot with them.

In the Transvaal, meantime, the situation of the Uitlanders grew worse. The monopoly and concessions regime continued unchecked, the naturalization laws were not amended, while the judicature was rendered subservient to the executive (see Transvaal: History). The gold mining industry was fostered only so far as it served to provide revenue for the state, and large sums from that revenue were used in fortifying Pretoria and in the purchase of arms and ammunition. This process culminated in 1895 when the Boers of the Transvaal, after a long period of tension, decided to use force to break the crisis by invading the Transvaal on the evening of December the 29th. The Transvaal government, meantime, had obtained some knowledge of what was being projected, and the Raid ended in a forced surrender (January 2, 1896) to a superior force of Boers. The Reform Committee, i.e. the Uitlander leaders, after holding Johannesburg for a week or two, also surrendered, and by the 9th of January the plot had ended in complete failure. Mr Chamberlain still desired Kruger to grant immediate reforms and propounded a scheme of "Home Rule" for the Transvaal and was invited by Kruger to come to Pretoria, pressing the Transvaal on the subject, and nothing was done.2

The Jameson raid had a profound effect on the history of South Africa. It greatly embittered racial feeling throughout the country; it threw the Free State Boers completely on to the side of the Transvaal; it destroyed the alliance between the Dutch in Cape Colony and the Imperialists led by Rhodes. It did more, it divided British opinion, sympathy for the Boer republics leading in some cases to a disregard for the real grievances of the Uitlanders. It also gave a much desired opportunity for the intrusion of other powers in the affairs of the Transvaal, and a danger to themselves of a united South Africa under a Dutch republican flag. This scheme found many supporters in Cape Colony. A suspicion that the Colonial Office in London was cognizant of Rhodes's plans further excited Dutch national feeling, and the Bond once more became actively anti-British. Rhodes had resigned the premiership of the Cape a few days after the Raid, and during the greater part of 1896 was in Rhodesia, where he was able to bring to an end, in September, a formidable rebellion of the Matabele which had broken out six months previously.

A section of the Dutch potential was not however disposed to sacrifice the development of industries and commerce for racial considerations; while sharing the political aspirations of Kruger and Steyn the wiser among them wished for such a measure of reform in the Transvaal as would remove all justifications for outside interference. Nevertheless the cleavage at the Cape between the Dutch and British grew. Sir Gordon Sprigg, who had become Premier of Cape Colony in succession to Rhodes, found his position untenable, and in October 1898 he was succeeded by a Bond ministry under Mr W. P. Schreiner. The term "Progressive" was now formally adopted by the British mercantile communities in the large towns and among the sturdy farmers of British descent in the eastern province. On returning to South Africa after the Raid inquiry at Westminster in 1897, 3 In his evidence before the House of Commons Select Committee which inquired into the Raid, Rhodes did not object to the continued existence of the republic "for local matters," but desired a federal South Africa under the British flag. See Blue Book (165) 1897 P. 211 also Sir Lewis Mitchell's Life of Rhodes, vol. ii. ch. xxx.

1 Jameson and the other raiders were handed over to the British government for punishment. Four of the Reform leaders were convicted on October 27th and the sentences were commuted to a fine of £25,000 each. For details of the Reform movement and Jameson Raid see Transvaal: History.

Rhodes informed the House of Commons Select Committee that the belief that the Boers intended to introduce the influence of another foreign power in the already complicated system of South Africa "greatly influenced " him in promoting the revolt. Germany at the time of the Raid was prepared to intervene, and on the 3rd of January 1896 the German Emperor, by telegram, congratulated Kruger that "without appealing to the help of friendly powers" the Boers had overcome Jameson.

At the end of 1898 the feelings of the Uitlanders were brought up to fever pitch. The police service, which was violent where it should have been reasonable, and blind where it should have been vigilant, had long been a source of great irritation. On the 18th of December a Boer policeman, in pursuit of an Englishman named Edgar, whom he wished to arrest for an alleged assault on another man, entered his house and shot him dead. The deepest indignation was aroused by this incident, and was still further increased by the trivial way in which the case was dealt with by the court. The killing of Edgar was followed by
the breaking up of a public meeting at Johannesburg, and in March the Uitlanders handed to the high commissioner a petition for intervention with 21,684 signatures attached to it (see TRANSVAAL: History). On the 4th of May 1899 Sir Alfred Milner felt it his duty to report at some length by cable to Mr Chamberlain, the concluding passages of this message, which had summed up the whole South African situation in a few words, were:

"The case for intervention is overwhelming. The only attempted answer is that things will right themselves if left alone. But, in fact, the policy of leaving things alone has been tried for years, and it has led to nothing but worse. It is not true that the Boers are going to the Lord. They were going from bad to worse before the raid. We were on the verge of war before the raid, and the Transvaal was on the verge of revolution. The effect of the raid has been to give the Boers a new lease of life, with the old consequences."

The spectacle of thousands of British subjects kept permanently in the position of helots, constantly suffering under undoubted grievances, and calling vainly to Her Majesty's government for redress, does steadily undermine the influence and reputation of Great Britain, and the respect for British government within the queen's dominions, and is like to result in a breach which the Boers only, preaches openly and constantly the doctrine of a republic embracing all South Africa, and supports it by menacing references to the intentions of the Transvaal, its alliance with the Orange Free State, and the active sympathy which, in case of war, it would receive from a section of Her Majesty's subjects. I regret to say that, this doctrine, supported as it is by a ceaseless stream of malignant reports and brilliant inventions of the British and Boer government, is beginning to have a great effect upon a large number of our Dutch colonists. Language is frequently used which seems to imply that the Dutch have some superior right even in this colony to their fellow-citizens of British birth. Thousands of men peacefully disposed and, if left alone, perfectly satisfied with their position as British subjects, are being drawn into disaffection, and there is a corresponding excitement on the side of the Boers."

I can see nothing which will put a stop to this mischievous propaganda but some striking proof of the intention of Her Majesty's government not to be ousted from its position in South Africa. And yet the time is not like to present any injustice. It is impossible to obtain for the Uitlanders in the Transvaal a fair share in the government of the country which owes everything to their exertions. It could be made perfectly clear that our action was not directed against the existence of the republic. We should only be demanding the re-establishment of rights which now exist in the Orange Free State, and which existed in the Transvaal itself at the time of, and long after, the withdrawal of British sovereignty. It would be no selfish demand, as either of the peoples in this case of British birth would benefit by it. It is asking for nothing from others which we do not give ourselves. And it would certainly be to the good of both the political interests in South Africa; and though temporarily it might aggravate, it would ultimately extinguish the race feud, which is the great bane of the country.

In view of the critical situation Milner and Kruger met in conference at Bloemfontein on the 31st of May. Milner practically confined his demands to a five years' franchise, which he hoped would enable the Uitlanders to work out their own salvation. On his side Kruger put forward inadmissible demands (see TRANSVAAL), and the conference broke up on the 5th of June without any result. A new franchise law, on a seven years' naturalization basis, was passed in July by the Transvaal volksraad, but the law was hedged about with many restrictions. Messrs Hofmeyr and Harboldt, the one the leader of the Bond and the other the Cape minister of agriculture, visited Pretoria to reason with Kruger. They found him deaf to all arguments. The fact is that the Boers had made up their minds to a trial of strength with Great Britain for supremacy in South Africa. At the time which from a military standpoint they thought most opportune (October 9) an ultimatum was handed to the British agent at Pretoria, and a war was at once precipitated, which was not to close for over two and a half years. (A.P.H.; F.R.C.)

D. From the Annexation of the Dutch Republics to the Union.—An account of the Anglo-Boer War of 1899-1902 will be found under TRANSVAAL. After the surrender of Cronje at Paardeberg (February 1900) to Lord Roberts, Presidents Kruger and Steyn offered to make peace, but on terms which should include the acknowledgment of "the incontestable independence of both republics as sovereign international states"; the Boers also sought, unavailingy, the intervention of foreign powers. The British government had decided that the continuation of either republic was inadmissible; to preserve the Boer Republics.

Last Efforts to Rescue the Boers. On the 28th of May 1900 the annexation of the Cape Free State was formally proclaimed, and on the 1st of September the Transvaal was also annexed to the British Empire. A few days later ex-President Kruger fled to Brazil, where President de la Rivera, Sir Alfred Milner, and Sir Richard Solomon. He also secured the help of a considerable number of young Oxford men who became known as "the Milner Kindergarten."
work the high commissioner had the support of Mr Chamberlain, 
who paid a visit to South Africa which extended from Christmas 
1902 to the end of February 1903. He sanctioned the calling 
of an inter-colonial conference, which led to a customs convention 
including all the British possessions in South Africa, and to 
united action regarding railway rates and native questions.¹ 
The great expenditure incurred during the war had led to 
much deception as to the growth of trade, while the large sums 
spent on repatriation and other temporary work main-
tained this deception for some time after the war had 
ceased. But before 1903 had ended it was manifest 
that this had been a spurious activity, and a period of marked 
commercial depression, lasting until 1909, ensued. This 
depression was in considerable measure due to, and was largely 
aggravated by, the comparative inactivity of the Rand mines, 
and that inactivity was due in turn to the insufficiency of native 
labour—Kaffirs being employed to do all the unskilled work on 
the mines. At the close of 1903 the mine-owners, to meet the 
deficiency, asked for permission to import Chinese. The consent 
of the high commissioner and of the home government was 
obtained, and in June 1904 the first batch of coolies reached the 
Rand. They came on three-years’ indentures, over 50,000 
Chinese being eventually brought over. This introduction of 
Chinese labour met with considerable opposition. The South 
African objections were economic and racial, based on the 
results which had followed the introduction of Indian coolies into 
Natal. In Natal these coolies had been allowed to remain after 
the completion of their indentures, and had succeeded in prac-
tically monopolizing the petty trade of the country. They had 
also rapidly multiplied, so that by 1904 they were more numerous than 
the whites in the colony. The introduction of this large 
alien element, leading from 1895 onwards to the passing of 
restrictive measures in Natal, was a mistake which South Africans 
elsewhere had no desire to repeat. But these objections were 
overcome by regulations which made repatriation compulsory, 
and which definitely restricted the coolies to unskilled labour in 
the mines. These regulations also met the objections voiced 
by Australians and New Zealanders that the country won for 
Great Britain at such cost had been thrown open to hordes of 
Asiatics. In Great Britain, however, the restrictive regulations 
were precisely those which aroused criticism, the objection taken 
being that the conditions imposed were of a servile character, if 
they did not actually make the coolies "slaves." In the attacks 
made upon the Unionist government this cry was loudly 
voiced by the Liberal party in England, and in the political 
campaign which followed, the "Chinese Slavery" issue un-
doubtedly helped to swell the majority obtained by Sir H. 
Campbell-Bannerman in January 1906. Milner's own object in 
assenting to the introduction of the Chinese was—besides 
aiding to put the gold mining industry on a more stable basis—
to obtain revenue for the great task he had on hand, ² re-
starting the colonies on a higher plane of civilization than they 
had ever previously attained ³; and in respect of the working 
of the mines and consequently in providing revenue the intro-
duction of the Chinese proved eminently successful; but in 
February 1906 the Campbell-Bannerman administration felt it 
incumbent to announce that no ordinance imposing "servile 
conditions" would be sanctioned. The point as to whether the 
original conditions were or were not servile was never legally 
tested, for eventually on the grant of self-government to the 
Transvaal the Botha cabinet decided (June 1907) not to renew 
the indentures nor to permit any new importation of coolies. 
This meant the end of the Rand and the line of empire. The 
alteration, and the Transvaal was able to bring pressure upon 
Portugal to permit the recruiting of many thousands more 
Kaffirs from Mozambique province. By February 1910 the 
last of the coolies had been repatriated. 

¹ This action was on the lines of the commercial federation 
scheme of Cecil Rhodes, who had died in March 1902. 
² This should be taken to give the Transvaal "representative govern-
ment," This decision was made public in July of that year, and 
was followed by marked political activity. The 
³ The Boers in the Transvaal, headed by Louis Botha, 
formed an association which was called Het Volk 
(the people), and in the Orange Colony a similar 
organization, the Oranje Unie, was formed. On the 31st 
of March 1905 the text of the new constitution was issued 
by letters patent. Short of granting full self-government, it 
was of a liberal character. It provided that the legislative 
council was to consist of not fewer than six or more than nine 
official members, and, provisionally, of not fewer than 
three or more than thirty-five elected members. Seats were to be 
allotted on a voters' (not population) basis, and there was to be 
an automatic redistribution of seats as voters increased or 
decreased in given localities. These provisions—subsequently 
adopted in the electoral law of the Union of South Africa—were 
made to secure equal rights for the British and Dutch sections of 
the community. The promulgation of the Lyttelton constitution 
was quickly followed by the retirement of Lord Milner. He 
left South Africa in April 1905, and was succeeded as high 
commissioner and governor of the Transvaal and Orange River 
colonies by Lord Selborne. But before the new constitution 
could be established a change of ministry in Great Britain put 
the Liberals in office, with Sir Henry Campbell-Bannerman as 
premier (Dec. 1906).

A sudden change was now made. Sir H. Campbell-Bannerman, 
with several of his colleagues in the ministry, held that the 
annexation of the republics had not been justified, 
Self-
government, 
but there was no question now, as there had been in 
1881, of a restoration of independence; that matter 
the Boers themselves had settled by their acceptance of British 
sovereignty. The Liberal leader held, however, that the Boers 
should be given self-government at once. Experience, he 
declared ⁴ had proved, unfavourable to the working of representa-
tive institutions, and it was safer and better to begin with responsi-
ble government. Moreover, the cabinet looked forward, without 
forcing it in any way, to the federation of South Africa. In the 
Transvaal the burghers of British origin were about equal in 
number with those of Dutch origin, and the fairly even balance 
of parties might be held to be a guarantee against retrogression; in 
the Orange River Colony it was notorious that the grant of self-
government meant handing over the control of the country 
not simply to the Boers, but to that section of them which since 
the war had exhibited the greatest racial bitterness. In these 
circumstances the decision of the Liberal cabinet, however 
generous, was fraught with peril. But the policy of complete 
trust in the Boers was a bold one, which was justified by 
success.

The new letters patent instituting self-government in the 
Transvaal were issued on the 12th of December 1906; the elections 
were held in February 1907, and gave the Het Volk party a clear 
majority of seven (in a house numbering 69 members) over all 
other parties. General Botha became premier, with Mr Smuts 
as colonial secretary. In the Orange River Colony the first 
elections under the self-government constitution were held in 
November 1907, and out of 38 seats in the House of Assembly 
Oranje Unie candidates secured 29. A ministry was formed 
with Mr A. Fischer as premier and Generals Hertzog and de Wet 
as prominent colleagues. These triumphs of the Dutch section 
of South Africans were followed in the general election in Cape 
Colony early in 1908 by a sweeping victory of the Bond, 
helped by the votes of the franchise of unfranchised rebels. J. J. 
Jannsen—who had been premier of the colony since the Progressive victory at the 
election of 1904—was succeeded as premier by Mr J. X. Merriman, 
who was regarded as a Bond nominee. Thus, working within 
constitutional lines, the Dutch Afrikanders had attained in three 
of the four self-governing colonies, political supremacy. 
The situation in 1908 was, however, radically different from 
that which existed before the war of 1899-1902. Then half the 
white population of the Transvaal were as "helots"; now the 
⁴ In a speech in the House of Commons, February 19, 1906.
ex-Uitlanders held 26 seats in the Transvaal parliament, and were able to exercise an effective influence over legislation. Both the war of 1899-1902 and the grant of self-government to the new colonies were necessary preliminaries to the success of any unification scheme, but the causes which now led to the question of closer union being raised were not political but economic. Since the development of the diamond and gold mining industries the coast colonies had unduly neglected their own resources and had relied chiefly on the forwarding trade. Hence there was jealousy and competition between the Cape and Natal and a tendency to use the railways (which were state owned), by means of rebates, to counteract the effects of common customs dues. Then, too, the discovery of coal in Natal was the last straw of Lorenço Marques for the Rand trade. In a time of acute trade depression this commercial rivalry was disastrous to the welfare of South Africa. In March 1906 the customs convention was provisionally renewed (on a strongly protective basis, and with preference for British goods) but there was a distinct prospect of a tariff war when the convention expired in 1908. Again it was known that the Transvaal and Orange River colonies on their attainment of self-government would each demand full control of their own resources, to the detriment of the unitary services which Lord Milner had established. There were, moreover, other differences on such questions as Asiatic immigration, the status of natives, mining, agriculture, &c. Thus the antagonism between the various states on economic lines was at the end of 1906 greater than any racial divisions. The leading South African statesmen realized that unless an effort to remedy this condition was made without delay affairs would go from bad to worse. In these circumstances Dr Jameson, as premier of Cape Colony, took the first overt step to reopening the question of federation. In a minute dated the 28th of November 1906 the Cape ministry declared its belief that the question which was causing so much friction should be called for solution "by some duly constituted South African authority responsible to all parties in the country," and it appealed to Lord Selborne, as high commissioner, to review the situation in such a manner that the people of South Africa might form a competent judgment on the question. In answer to this appeal, which was backed by the Natal ministry, Lord Selborne drew up a despatch (dated Jan. 7, 1907) in which the whole case for closer union was set forth in a masterly manner. For insight and breadth of view the despatch ranks with that which Sir George Grey drew up in 1858. In the fifty dangers that had elapsed the case for closer union had become overwhelming and the dangers of isolation much greater. Four or five administrations, the despatch pointed out, were pursuing rival interests, whereas the country had but one interest. Reviewing one by one the questions on which rivalry existed, Lord Selborne showed that the internal self-government which each colony enjoyed accentuated the difficulty of dealing with these questions as a whole. Stability—the thing which South Africa required above everything else—was unattainable so long as there were five separate governments developing different systems in all branches of public life, but no national government could flourish there. "The Transvaal people . . . are not self-governing in respect to South African affairs because they have no South African government with which to govern." Only by the creation of a central government could South Africa be wisely and successfully governed. The opportunity for testing the strength of the movement for closer union came with the meeting of an intercolonial conference in May 1908 to consider the thorny questions of tariff and railway rates. In the meantime the Jameson ministry had given place to the Bond nominee ministry with Mr Merriman as premier (see CAPE COLONY: History), but the movement initiated by Jameson had received the support of the Bond as well as that of the Botha administration. The delegates at the conference were all representative of the parties in power; that is, with the exception of the Natal delegates, they all represented Dutch ideals in politics. Nevertheless they unanimously resolved "that the best interests and the permanent prosperity of South Africa can only be secured by an early union, under the crown of Great Britain, of the several self-governing colonies," and they recommended the calling of a national convention entrusted with the task of drawing up a draft constitution. Thus for the first time for two generations both the chief white parties of the Union of South Africa recognized the value of a national convention. No appeal was made to the electorate, but the colonial parliaments rightly interpreted public opinion in endorsing the recommendations of the conference. Delegates representative of all parties were appointed, and the national convention to consider the question of union met at Durban in October 1908.

The most prominent members of the convention were Sir Henry de Villiers, chief justice of Cape Colony (president), ex-President Steyn (vice-president), Generals Botha, Smuts, de Wet and Delarey, Messrs Smuts, Botha, Burgers and de Wessel (Sir), Dr Jameson, Sir George Farrar and Sir Percy Fitzpatrick, the last two the leading representatives of the Transvaal Progressives (i.e. the ex-Uitlanders). The greatness of the opportunity was rightly stated by the governor of Natal (Sir Matthew Nathan), who declared that the convention might create a commonwealth which should add to and not draw upon the strength of the empire—a commonwealth which in culture as in power would be among the foremost nations of the world. After sitting at Durban for a month, the convention adjourned to Cape Town and concluded its elaboration of a draft constitution by February 1910. The draft document, known as the Cape Town convention, put forward three new ideas: it set forth, (a) the basis of parliamentary representation, (b) the status of the natives with respect to the franchise, (c) the position of the Dutch language, (d) the form of government.

The adjustment of tariff and railway rates gave little trouble when once it was agreed to consider the country as a unit. Points (a) and (b) both concerned the franchise, but each had its separate issue (a) raising the question of representation as it concerned the Dutch population, and (b) the question of the status of the Kafirs. A draft of the franchise would be made to force union on a Dutch Afrikaner basis, which might have resulted had the basis of representation adopted been the total European population. To this the Progressive party objected, and they gained support from Botha, Smuts and other prominent Dutch delegates for their contention that "equal rights" could only be secured by making the basis of representation the number of voters as from the United Kingdom system (as in the Anglos speaking areas). As finally settled, the number of European male adults was chosen as the basis of representation. As the Transvaal and Orange colonies already possessed manhood suffrage, and as the property qualifications in the coast colonies were low, this alteration made little difference. Point (b) raised a graver issue still. The Cape delegates found themselves in isolation in advocating the extension of the electoral system which prevailed in their colony, where there was no colour bar to the exercise of the franchise. The merits of the Cape system—to minimize the differences between the white and native races, typified in the declaration of "equal rights to all civil and political offices from the freeholders (as opposed to the franchise), as advocated by the Natal delegates as by those from the ex-Boer republics), which would keep the native races in permanent inferiority, cannot here be discussed; it may be stated, however, that the admittance of Kaffirs to the franchise in the Cape had not been attended with the evil consequences feared. At the convention a way out of the difficulty—for a time at least—was found in a compromise, namely, that in the state about to be created the Kaffirs would be entitled to vote in the Natal constituency where they had been seated before union was effected. Thus in the Cape the Kaffir would have a right to the franchise, but not in the other divisions of the country. Point (c) was decided by placing, for the first time, official and Dutch languages on a footing of perfect equality. As to (d) the
issue was between a federal and a unitary form of government. Federation was supposed to afford protection to the smaller communities—Natal and the Orange River Colony—and in Natal there was much anxiety lest its interests should be submerged. Nevertheless, with the advocates of unification gained a complete victory and a form of government was agreed to which made the union of South Africa as close as that of the United Kingdom.

Among the provisions of the constitution were: the choice of Pretoria as the seat of administration and of Cape Town as the seat of the legislature, the renaming of the Orange River Colony, Orange Free State Province; the provision of three membered constituencies and of proportional representation, and the safeguarding of the smaller communities by giving Natal and the Orange River colonies more members of parliament than they were entitled to on the voter basis.

The draft constitution was made public on the 9th of February, 1909, and was adopted by the Transvaal parliament in its entirety. The Orange River parliament also approved with only slight alterations; the Natal parliament made some amendments, but they were of a minor character. The opposition to union among an influential number of old Natalians—intensely jealous for local independence—was however so marked that it was decided that before Natal was committed to union a referendum on the subject should be taken. Apart from this doubtful attitude of Natal, the chief danger to the draft constitution of the Cape was that it did not remain true to its "one vote one value" principle, its three-membered constituencies and its scheme for proportional representation, threatened Dutch supremacy in the rural districts, and aroused the opposition of Hofmeyr, who secured the passage of amendments through the Cape parliament which destroyed the principle of equal rights. Such was the position when the convention reassembled in May at Bloemfontein to consider the amendment of the various legislatures. Through the firmness of the Transvaal delegates, supported by the Progressives, the principle of equal rights was retained; the concession made to the Cape in the abandonment of proportional representation, while one-membered constituencies were substituted for three-membered constituencies. The document embodying the alterations in the draft act was signed on the 11th of May and the convention dissolved. In June the referendum on union was taken in Natal, and resulted in a complete rout of the separatists. There voted, for the draft act 11,121, against it 3701—majority for union 7420.

South Africans had thus after seventy years of discord agreed upon union. It was a momentous step, the essential preliminary to that fusion of the white races of South Africa upon which the prosperity of the country depends; and a step rendering the ultimate establishment of imperial union a delegation of its powers to England, and, recast in the form of an imperial bill, it was submitted to the parliament at Westminster. The imperial government made but one alteration of consequence—that explicitly placing the control and administration of matters "specially or differentially affecting Asiatics" in the sole control of the union parliament. The bill passed through parliament unaltered, the only jarring note in the debates in either house concerning the exclusion of natives from the franchise (save in the Cape province). This decision was deplored by all parties in the Transvaal, but it wasiversal, while it was declared that to alter a decision deliberately contrary to South African sentiment would be a disaster.

The measure, known as the South Africa Act 1909 received the Royal Assent on the 20th of September, and subsequently the 31st of May 1910—the eighth anniversary of the signing of the articles of peace at Pretoria—was fixed as the date for the formal establishment of the Union.

The interval between the passing of the South Africa Act and the establishment of union was employed by the various colonies in putting their houses in order. This task, on the economic side, was rendered easier by the gradual return of commercial prosperity. An agreement between the Transvaal and the Portuguese further agreed to facilitate the recruitment of natives in their territory for work in the Rand mines, and in consequence Kaffirs were obtained in sufficient numbers to replace the Chinese coolies as they were repatriated. The agreement was to last ten years, and provision was made for its recognition by the government of the Union. The native protectorates, Basutoland, Swaziland and Bechuanaoland had been left by the South Africa Act under direct imperial control. As to Natal and Zululand, there was a disposition to leave to the new government the task of dealing with the natives there but both the Transvaal and Natal adopted an Asiatic exclusion policy which gave rise to much friction. In the Orange River Colony General Hertzog aroused much opposition by administering the education act in a way which forced the teaching of Dutch in a rather arbitrary fashion. This was a point of importance, inasmuch as, by the Act of Union, elementary education was left (for five years) in the hands of the provinces. The divergence of views was so great that shortly after the union had been established private schools were opened in opposition to those of the provincial administration.

In the autumn of 1909 it became known that Lord Selborne, whose services in bringing about the union were generally recognized, would not remain in the government. This was due to an alteration in the law, augurating the new form of government, and the choice of the British government fell on the home secretary, Mr Herbert Gladstone (who was in March 1910 created Viscount Gladstone of Lanark) as first governor-general of the Union.

Lord Gladstone had the responsibility of summoning the first prime minister of the Union—a task rendered more difficult as the decision had to be taken before the first election to the Union parliament was held. There had been a strong agitation for a coalition cabinet, and negotiations took place to this end between General Botha and Dr Jameson. These efforts ended in failure. They had met with the determined opposition of Mr Merriman (the Cape premier), of the Orange Free State Boers, and of the Bond, which had lost the counsel of Hofmeyr. That typical leader of the Cape Afrikaners had died in London, whither he had gone as one of the delegates to lay the draft constitution before the British parliament. Towards the end of May, Lord Gladstone called upon General Botha to form a ministry, which was constituted from the ranks of the existing cabinets and included Natal ministers as well as strong Boer partisans like Mr Fischer and General Hertzog. Mr Merriman declined to serve under General Botha. The formal proclamation of the Union took place on the 31st of May. The first general election, held on the 16th of September, was, perhaps inevitably, fought to a large extent on racial lines. The Dutch Afrikaner candidates stood as "Nationalists," while their opponents took the name of Unionists. In Natal the British section of the electorate (four-fifths of the whole) preferred to maintain an independent attitude. The elections, which resulted in a Nationalist majority of 13 over all other parties, showed that the Unionists were stronger than had been thought. They secured 37 seats, while 13 were held by Natal Independents. The polls were remarkable for the defeat of three ministers—General in failing, Sir Percy Fitzpatrick (at Pretoria), Sir George Farrar (by Sir George Farrar, Mr Moodie, and Mr Moodie in Natal. General Botha decided to retain office, and seats for him and Mr Hull were found by means of by-elections. Mr Mood was nominated to the senate, as were, among others, Mr W. P. Schreiner and ex-President Reinart (who became president of that body). On the 4th of November the first session of the Union Parliament was opened by the duke of Connaught.

1 Unless otherwise stated the place of publication is London.

SOUTHWALL NORWOOD, an urban district in the Brentford parliamentary division of Middlesex, England, suburban to London, 12 m. W. of St Paul's Cathedral, on the Great Western railway. Pop. (1891), 7569; (1901), 13,300. Brickfields, flour-mills and chemical works are established in the district, which is also largely residential. The Grand Junction Canal serves Southall. Cattle markets are held weekly under a grant of William III. The Elizabethan manor-house of Southall remains, and the parish church of Norwood, though greatly restored, has Early English and Decorated portions, acanointed tomb dated 1547 and brasses of the 17th century.

SOUTH AMBOY, a city of Middlesex county, New Jersey, U.S.A., on Raritan Bay at the mouth of the Raritan river, about 27 m. S.W. of New York City. Pop. (1900) 6549 (1700 Founders-1900); (1901) 10,477. It is served by the line of the Central of New Jersey, and the Raritan River railways. A railway drawbridge and a traffic bridge across the river connect the city with Perth Amboy. South Amboy is an important point for shipments of coal from the Pennsylvania mines. The Pennsylvania Railroad Company and the Susquehanna Coal Company have coal docks here and the latter has large storage yards. Among the city's industries are the mining of clay and sand, and the manufacture of terra cotta. South Amboy, originally a part of South Amboy township (incorporated in 1798), was laid out in 1835, was incorporated as a borough in 1888, and became a city under a general state law in 1908.

SOUTH AMERICA. The early physical history of the South American continent as recorded in the rocks has been extensively obliterated or greatly obscured by the events of its later history. The early land areas are supposed to be only approximately suggested by the present exposures of granite and gneisses. The largest of these old land areas is the east of the continent, extending with a few interruptions from the mouth of the Rio de la Plata to within a short distance of the mouth of the Amazon river. North of the present Amazon valley and occupying the present highlands of Guiana, north-east Brazil, and south-east Venezuela was another one of these old land areas—a large island or a group of islands. A chain of islands extended from the Falkland Islands along what is now the entire west side of the continent. Upon these ancient shores were laid down the sedimentary beds of the Cambrian seas. At the close of the Cambrian period the continent was elevated, many of the former islands were joined together, and the continental land area was considerably enlarged. The Silurian seas, however, still covered the basin of the Paraguay, extending from the Serra do Mar on the Brazilian coast to the axis of the Andes on the west, and covering at the same time a considerable part of the basin of the Rio São Francisco, filling the straits between the Andes and the Matto Grosso highlands and opening east through the region now occupied by the lower valley.

During the Devonian period there was a still further enlargement of the continent through elevation and the joining of islands, and the disappearance of the old Silurian sea in the basin of the Rio São Francisco on the east of the continent. In early Carboniferous times the sea still covered a narrow belt through the lower part of the Amazon valley, and part of what is now the Andes lying south of the equator. During Permian times the basin of the Paraguay and the south-east coast of Brazil was covered with lagoons and swamps in which here and there coal beds were laid down. At the close of this period molten lavas broke through the earth's crust and flowed over and buried large areas in what is now Paraguay and south Brazil. There was a general depression of the continent during the Cretaceous period and the ocean covered most of the continent as we now know it. The Serra do Espinhaço along the east coast of Brazil was above water and the coast line between the Rio de la Plata and Cape St Roque was little different from what it is at present. But through the highlands of Brazil from near Fernambuco west there was a broad sound containing many islands extending to the base of the Andes and possibly connecting with the Pacific Ocean. In the extreme north there were also many islands, bays and sounds, while a continental mass occupied the region of the Antilles. To the south the Atlantic Ocean filled most of the lower Paraguay basin and washed the eastern bases of the Andes. There was shallow-water connexion during this period between South America and southern India, through the Antarctic regions, probably by way of Australia.

In Early Tertiary times great changes took place in the geography of South America. The continent rose much higher than its present elevation, the coast-lines were extended oceanward, and the continent was considerably larger than it is at present. The Abrolhos Islands on the east coast of Brazil were then a part of the mainland and the seashore was some 200 m. further east. The Falkland Islands were also at that time a part of South America and had connexion through the Antarctic regions or through the south Pacific Ocean with New Zealand and Australia, and through the West Indies region with Cuba and North America. Toward the close of Tertiary times the continent sank again beneath the ocean and salt water flowed into the Amazon and Orinoco valleys, turning the Guiana highlands again into an island or group of islands, and again separating the continent from land connexion with other continents. The valleys of Rio Magdalena, Rio Cauca and Lake Maracaibo were bays that covered large areas of adjacent territory.

It was during the Tertiary period that the continent took on its most characteristic features. Volcanic activity culminated; the Andes rose from low ridges and islands near sea-level to be one of the greatest mountain systems of the globe. This elevation was partly due to the uplifting of the continent en masse, partly to faulting and folding of the rocks, and partly to the pouring out of lavas and the accumulations upon the surface about vents of other volcanic outcrops. This volcanic activity was not confined to the main range of the Andes, but extended into Venezuela and the islands along the north coast, to the plains of Patagonia, the highlands of the Paraná basin and as far east as the islands of Fernando de Noronha. In recent times volcanic activity has greatly diminished over the continent and has entirely ceased along its eastern and north-eastern parts. The great elevation and depression of the continent deeply affected the climate over certain large areas. For example, along the east coast, where winds blew on-shore, the rainfall was greatly increased during the elevation, while the later depression brought about a corresponding diminution of the rainfall. In Pleistocene times the south of the continent stood somewhat lower than it does at present, so that the ocean covered the plains of Patagonia. During the glacial epoch the south of the continent and as far north as latitude 37° on the west coast was covered with glaciers that flowed down from the high mountain ranges. On the east side of the mountains the glaciers did not extend so far north as they did on the west side. The glaciers through the high Andes were also larger and longer than they are at present; there were no glaciers in the eastern or Brazilian portion of the continent.

Physical Geography.—The South American continent rises abruptly from the ocean floor along nearly all of its coast, but the steepness of the continental margin is more marked on the
western than on the eastern side. From Valparaiso to the Isthmus of Panama, a distance of 3000 m., the great Andes themselves are but the upper or subaerial portions of mountains whose bases are 10,000 ft. below the surface of the Pacific Ocean. South of Valparaiso the 10,000-foot contour lies well out from the coast, but opposite the Straits of Magellan it approaches within 150 m. of the coast-line. On the east side of the continent the 1000-foot submarine contour keeps at a distance of from 50 to 150 m. off the shore nearly to Bahia, Brazil; from Bahia northward and around Cape St Roque this same contour is close inshore, and the ocean-floor sinks abruptly to a depth of 5000 ft. North-west of Cape St Roque the continental shelf of shallow waters widens until opposite the mouth of the Amazon the 1000-foot contour is 300 m. off the coast. The broad shelf follows along this part of the coast as far as the island of Trinidad, west of which it narrows, though the islands along the northern shores of Venezuela all stand upon and form parts of this shallow continental shelf.

The Cordillera is a broad ridge upon which rise many great isolated peaks. Near its northern end the range divides: one branch, the Western Cordillera, continuing northward near the coast; the Merida branch swings eastward and ends with the northern side of the island of Trinidad, while a third division, the Sierra de Perija, runs northward between the valley of the Magdalena and Lake Maracaibo. The western slope of the main Cordillera is steep, and is scored by narrow steep-sided valleys; the eastern slope is usually more gentle, and the valleys are less precipitous. Upon the Cordilleran ridge rise many of the highest peaks in the world. The following are some of the most noted, with their elevations:

The snow-line of the mountains is generally lower on the east than on the west side. Of the Andean peaks those of Cotopaxi, Tunguragua, Maipo and Sananga are the highest active volcanoes in the world. There are many glaciers in the Andes even beneath the equator itself; and though these glaciers are small and mostly confined to the highest peaks, toward its southern end along Smyth Channel and in the Straits of Magellan, they are considerable and flow far down the slopes, and at several places enter the sea.

The eastern side of the continent is in strong physical contrast with the western. North of the Strait of Magellan the coast is flat as far as the northern part of Rio Grande do Sul. From latitude 29° 30' to 19° 30' the Serra do Mar makes this the most picturesque portion of the coast of South America. The mountains rise in many places directly from the seashore to an elevation of 5000 ft. In places these form bare granite walls, while in others they are covered from base to summit with the most luxuriant tropical vegetation. On this part of the coast are some of the finest and most beautiful harbours in the world, notably those of Rio de Janeiro, Santos and Victoria, formed by a depression that submerged the coastal valleys.

The range or group of mountain ranges known under the general name of Serra do Mar falls away toward the north and west in a gently sloping plateau commonly called the Brazilian highlands. On this Brazilian plateau the highest points of which the elevations are known are as follows:

North of latitude 20° the high mountains swing inland and the coast is as low as far as latitude 17° 25'; north of this the coast is

1 Various authorities differ in their estimates of these elevations.
bordered by a wall of brightly coloured bluffs from 60 to 250 ft. high which continue with occasional interruptions to the mouth of the Amazon. About Cape St Roque the coast is covered with sand dunes. From the Abrolhos Islands northward to longitude 37° 40' W., Rio de Janeiro, and the Guanaíba and Guanabara bays, the Amazon and the Guayas lakes are several miles off shore and many miles in length and breadth, while in other places they follow the coast-line for a hundred miles or more with a few interruptions, now touching the shore, and now standing out two or three miles from it. Along the part of the coast where the coral reefs occur are also reefs of hard sandstone that are often mistaken for coral reefs. These stone reefs stand like artificial walls or breakwaters across the mouths of the smaller rivers and the choked bays. The reefs style is formed and the coral reefs are the parts of the coast where the coral reefs occur are also reefs of hard sandstone that are often mistaken for coral reefs. This highland region is mostly forest-covered, but it contains also large tracts of open grassland peppered with open grassland peppered with

Further lakes occur throughout the entire length of the Andes; the shocks are sometimes of sufficient violence to do serious damage to cities and towns and to destroy many lives. Such disturbances are particularly frequent in Peru, where they are also of considerable importance.

The eastern coast of South America has remarkably few islands, and these are mostly small, except Trinidad off the coast of Venezuela.

**Islands.**

and the islands of the Marajo group in the mouth of the Amazon. Trinidad (area 1755 sq. m.) is the largest of the group and the capital of the colony — the most extensive deposit of asphalt known. West and north of Trinidad, and lying farther off the coast, are several small islands of historical interest and commercial importance: Tobago, Margarita, Blanquilla and the Curaçao group. Off Cape St Roque (230 m.) is the small Fernando de Noronha group of volcanic islands. The main island has an area of only 12 sq. m. Though this island is separated from the mainland by a channel 13,000 ft. deep, it really stands upon the submerged corner of the South American continent.

The Rocos is a small island 80 m. west of Fernando de Noronha, the Falkland Islands in lat. 51° cover an area of 6600 sq. m.; their shores are lined by long tortuous channels that have the appearance of having been made by the depression of a hilly land surface. One of these channels separates the two main islands. Mt. Adams, the highest peak of the group, which stands upon the submerged edge of the continent, from which it is separated by a shallow sea. Its flora and fauna show that it was formerly a part of the mainland. The Tierra del Fuego group of small islands has an area of less than 6 sq. m. It consists of a large number of small islands and islets that border the west coast as far north as latitude 42°, are all the higher portions of the continental margin left above water when this part of the continent was depressed. The islands of Juan Fernandez in the same latitude as Valparaiso, and the Galapagos group immediately under the equator are the only ones on the west coast worthy of mention.

The Amazon, the Orinoco and the Paraguay are the main rivers of South America, the Amazon is the largest of the South American rivers, but it is the largest in the world. The total navigable length of the main stream from Pará to the head of navigable from the mouth of the Amazon in Peru is 3000 m.; and branches and tributaries include the hundreds of navigable parallel side channels that accompany the main stream from its mouth almost to the mouth of the Javari. Of these tributaries the largest are navigable for long distances. Except at Obidos the Amazon is nowhere connected to a single channel, but it spreads over a vast flood-plain and flows with a sluggish current through thousands of side channels that swamps and proceeds. The distance from the mouth to the upper point at Manaus is about 35 miles. For the most part the land along the stream is low, flat, marshy and at times under water. At a few places, however, notably at Ereô, Obidos, Vela Pobre, Pará, Pará-nápolis, and Almêirim river, topped hills are visible from the river. The banks of this channel and of its side channels are everywhere covered with a dense forest. The valley, however, is not all forest-covered. From near the mouth of the river, and extending up the Orinoco and the Guayas to the mouth of the Guayas, there is a large expanse of open grassy campos, interrupted only by the wooded banks of streams and rivers. From the north side of the Amazon for about 500 m. and extend into British Guiana and the region of the headwaters of Rio Branco. The upper Paraguay and the adjacent corridor in the Paraguay basin are covered with a thick growth of vegetation that forms a dense growth across a low watershed, while on the south it is separated by a narrow divide from the Paraguay basin. The Orinoco rises in the highlands between Venezuela and Brazil, flows westward and north-wards across a broad and flat, covered with a dense forest, and then southward through a dense forest into the Atlantic. Along its lower course the banks of the stream are covered with dense forests; in its upper course the mountainous highlands are visible along its right bank, while on its left are vast stretches of tangled and dense growth that extends from the bottom of the Corrida Merida field. The main stream is navigable during a part of the year for a distance of 1000 m. or more.

Under the name of Rio de la Plata may be included the Uruguay and the Paraguay, which enter the ocean through the La Plata estuary, and the Paraná which is the most important branch of the Paraguay. It is a noteworthy feature of the streams entering the Uruguay basin that many of those flowing through the arid regions on the west are more or less brackish, while those from the rainy forest-covered regions of Brazil are all fresh-water streams. The upper Paraguay is a sluggish stream winding through grass-covered plains dotted with palm trees and covered with the usual forest. The lower Paraguay is a great flat, almost perfectly flat, covered with rank vegetation and the remains of it with great swamps, and it is the mouth of this river where it bends sharply to the right and enters the Atlantic. It flows entirely through a hilly or mountainous country. It is navigable along its lower course nearly to the falls of Pauleno, 140 m. from the mouth, and also above the falls. In Colombia the Maguana is a crooked muddy stream about 2000 m. long and navigable as far as Honda.

The lakes of South America are mountain lakes in the Andes or along its base. Lake Titicaca in Bolivia is, in respect of elevation and position, the most remarkable of its size in the world. Its surface is 12,545 ft. above sea-level. It has an area of nearly 500 sq. m. and a maximum depth over 700 ft., and never freezes over. This lake discharges into a marsh that is supposed to have no outlet. Lake Jujin or Chichinachocha on the plateau east of Lima has an altitude of 13,380 ft., and covers an area of 200 sq. m. Along the eastern base of the Andes in southern Argentina is a series of lakes whose basins were probably made by the glaciers that formerly flowed down from the mountains on the west. There are many lakes, both large and small, scattered over the entire south side of the great mountain range on the eastern side of the Andes, is a large number of lakes also on the east side of the Andes, and all above the falls. In Colombia the Maguana is a crooked muddy stream about 2000 m. long and navigable as far as Honda.

**Flora.**—The warm, wet, tropical portions of South America are especially favourable to the development of plant life. This continent has therefore furnished an unusually large number of the world's useful plants. Among these are several valuable rubbers, rubber-producing plants, cotton, potato, tomato, mandioca, pineapple, cacao, cinchona, ippea, vegetable ivory, cocoa, the chocolate plant and Paquayan tea, which are used for a variety of purposes such as coffee, sugar-cane, oranges and bananas have been introduced and are extensively cultivated. The flora of the continent embraces a large number of peculiar types that originated either in the highlands of Brazil or in the Andes.

The flora of the Amazon valley may be taken as the type of that of the moist tropical valleys. The forests are so dense, rank and massive that anything but a narrow lane has been left in the most characteristic and beautiful trees, and reach their greatest development in the Amazon region. They take on a great variety of forms: some have trunks 100 ft. and more in height while others have trunks 20 ft. and under; the leaves are variously shaped, from two feet or more in diameter, while others are as slender as a lead pencil. Bamboo grow to an enormous size and form dense thickets of a kind never seen in the temperate region. The shaded portions of the trees are frequently inlaid with beautiful ferns, palms and orchids, and others which small as to be invisible to the microscopic, while others reach dimensions of trees. For the most part the plants of the open campos have a stunted appearance and few flowers. These trees are widely distributed.

A noteworthy feature of these tropical forests is that they are seldom made up of trees of a single species or of but few species. In

SOUTH AMERICA
the high table-lands of southern Brazil, however, the araucanian pine 
grows in beautiful forests as far north as Barcarena in the highlands 
near the headwaters of Rio São Francisco. In the north-west of 
the continent the western slopes of the Andes are covered with a 
dense growth of cactus, while on the eastern side the slopes are 
relatively bare. In the high mountains the flora is scanty and bears a 
general resemblance to that of the temperate regions; 60% of 
the genera are like those of the temperate zones, but the species 
are peculiar to the Andes. In the south of the continent plant life 
is necessarily less tropical.

Fauna.—The fauna of South America includes a large number of 
species but relatively a small number of individuals will be true of all 
the forms of life within the tropical portions of that continent. The 
land mammals are nearly all small; the tapir is the largest of them, and is found only in 
the north-west of the continent. There are many reptiles, 
including snakes, all of them arboreal in their habits. The only 
reptiles that are at all abundant are lizards, and in some places alligators. 
The alligators do not extend south of the La Plata region. Of snakes, 
only the boa constrictor and the water boa are large. Of these, like 
all other kinds, are not abundant. Certain ruminants having long 
woolly hair are found only in the high Andes; these are the llamas, 
alpacas and vicuñas. The llama has been domesticated for 
carrying small loads. The condor, the largest living bird of 
flight, inhabits the lofty Andes. The insects of the highest moun-
tains are related genetically, but not specifically, to those of the 
temperate institutional populations. It is understood 
that there has been no migration across the inter-
mediate region since the glacial epoch. Owing to temperature and 
oclimatic conditions the life forms of the high Andes, whether animal 
or vegetable, are related to those of the climate of the high regions 
which extend to the south than to those of the lower regions to the north.

The fresh-water fish fauna of the Amazon region is the richest 
in the world. The distribution of species shows that the Amazon basin has 
been evolving separately, but is connected through the drainage of the three 
great river systems, namely, the Orinoco, the Amazon and the Paraguay.

Inhabitants.—At the time of the discovery of the South American 
continent by Europeans, these races inhabiting it differed greatly 
among themselves in customs, languages and civilization. They 
had then generally developed the arts of spinning, weaving and the 
manufacture of pottery, and locally were skilled in certain kinds of 
metalurgy. They took a great pride in their architecture and agriculture. 
Many of these peoples have necessarily been profoundly affected by the 
invansion of European races and the importation of African races, but 
in some localities their descendants still form the bulk of the popula-
tion, and the native American language is often heard.

Immediately after the discovery of South America the western 
and northern portions of the continent and the region of the Rio de 
la Plata began to be colonized by Spaniards, while the eastern portion 
was colonized by the Portuguese. To these races were added 
Africans, for many years imported as slaves, especially into Portuguese 
territory. Of late there has also been a large immigration of 
Italians into South America, and the native races there have 
been considerably changed. These changes in the population of 
the continent have been made by the steady immigration of the 
Europeans, by the introduction of African slaves and by 
the natural growth of the white population. South America is therefore pre-eminent-
ly a Latin continent; its few British, Dutch and German colonies count 
for less in the general ensemble of its population than do the depleted 
aboriginal races themselves.

Political Geography.—The continent was first visited by Euro-
peans in 1498, when Columbus upon his third voyage touched 
at the mouth of the Orinoco. Other navigators followed and 
sailed along the northern and eastern coasts, and by 1500 the coast had been visited as far 
south as the Rio de la Plata. In 1513 Balboa discovered 
the Pacific Ocean in the Gulf of Panama, and in 1520 Magellan 
(propagly Magalhães) passed through the straits of Magellan 
and crossed the Pacific Ocean. Inland the earliest explorations 
followed the Amazon river, but beside from the discovery of 
the size, course, and character of the river and its immediate 
shores, they were of but little importance. Great impulse to exploration 
and development was given by the silver mines of Peru and later by the discovery of gold and diamonds in the highlands of Brazil.

The early settlement of South America by Europeans began 
shortly after the discovery of the continent. These settlements 
were originally colonies under the control of Spain and of 
Portugal, and they remained for some time dependencies of the 
mother countries. Eventually, however, they became indepen-
dent. For many years most of these countries were more or 
less disturbed by internal dissensions and revolutions, but in 
process of time, and as industries and commerce have become 
better established, the governments have become more stable.

The political divisions of the continent are best seen upon an 
ordinary map, and verbal descriptions of them are therefore 
omitted. Brazil is the largest and most important single country. 
The bulk of the remainder is divided into several Spanish-speaking 
republics that border the continent from Venezuela in the north to Patagonia on the south, while between Venezuela and the 
Brazilian frontier on the north-east are three comparatively 
small countries known as British Guiana, Dutch Guiana and 
Guyana. These Guianas are the only places at which colonies 
under European control are established on the mainland of South America. There are, however, a few islands that belong 
to European countries, such as Trinidad, Tobago and the Falk-
land Islands to Great Britain, and Curaçao, Bucay Ayre and Oruba 
to Holland.

Industries and Commerce.—The industry that gave the first great 
impetus to the settlement of South America by Europeans was 
mining. The silver deposits of the Andes awakened 
the cupidity of adventurers shortly after the discovery 
of the continent, and large numbers of persons were induced into that 
calling, many of whom found only that what had begun in that part 
of the world in prehistorical times has continued down to the present day.

The Potosí mines of Bolivia are supposed to have yielded in all over 
the five hundred million dollars' worth of silver. The 
guano of the coast of Peru and the nitre beds of Chile are now, and 
have long been, among the most important and valuable natural deposits of the kind in the world. In the world's production of 
Chile ranks third; in the production of Peru ranks third.

In 1653 gold was found in the highlands of Brazil, and within a 
few years Minas Gerais ("General Mines") became the principal mining district of 
the world. The mines reached their greatest productiveness between 1752 and 
1761, when the annual yield was worth about six million dollars. 
These years were followed by a decline, and the principal source of revenue was 
the export of ostrich feathers. In the latter part of the 18th century 
Manaus mines in the hard rocks have been opened, some have been 
worked out and exhausted, and some are still in operation. The 
total gold production of all South America for the year 1895 
was estimated at about $13,000,000.

In 1729 or possibly a little earlier diamonds were also discovered 
in the gold districts of Brazil, and a fresh impetus was given to 
European immigration and to the importation of African slaves to 
settle South America. Brazil was the leading gold-producing region of the world. 
The diamonds are found in three widely separate districts: 
in the region of the Rio de la Plata; in the district of Bahia in the vicinity of Lençóes, and on the headwaters of the 
Paraguay river in the state of Matto Grosso. The Bahia 
region also produces carbonados, or the black diamonds used in 
the manufacture of diamonds. The market value was the 
market value of the diamond production of Brazil from 1729 to 1885 
at $100,000,000. Of late years Brazil has led the world in the 
production of nonamethyst, which occurs on the surface of the 
domestic and agricultural industries in Brazil were long 
limited to the gold and diamond mines. These were chiefly 
suitable to tropical countries. Those that have reached the greatest 
growth are the growing of sugar cane and the manufacture 
of sugar, and the growing and preparation of cotton, 
coffee and tobacco. Sugar is made mostly near the sea-coast from 
the Rio de Janeiro northward along the eastern side of the 
continent. Cotton is grown in the interior from Bahia northward, 
where the climate is most favorable for the production of cotton, 
beef cattle. 

The most important pastoral industries are in the region of the 
Rio de la Plata, where wool growing has reached a marvellous development.

The manufacturing industries are necessarily not so well developed 
as those of other countries. In the 18th and 19th centuries many 
the home countries were interested in the building up of an export trade, 
and manufacturing in the colonies was therefore discouraged, even by
direct legislation, while trade with other than the parent countries was prohibited. For some time after the independence of the new countries, facilities for export were poor, and the lack of established commercial relations and facilities retarded their growth. The development of manufacturing industries has been more marked of late years, though internal development is still far from complete.

The exterior commercial relations of South America were at first naturally and necessarily with Spain and Portugal. In time other European countries established relations with the rising South American states, the relative importance of Spain and Portugal in South American commerce has greatly diminished, and the bulk of trade is now with other countries.

**Exports and Imports of Three South American Countries**

**Chief Exports of Three American Countries**

(In millions sterling.)

- Argentina: Animals and products 48, Agricultural products 23, Coffee 33, Rubber 19, Nitrates 17, Copper 2.
- Brazil: Coffee 33, Rubber 19.
- Chile: Copper 2.

**Settlement.**—The continent as a whole is but sparsely settled. The total population in 1905 was reckoned to be 38,492,000. About half of it, including all the most inaccessible portions, had a population probably not much exceeding what it had at the period of the discovery. It averaged five persons to the square mile, while in North America it was 13 and in Europe 104 to the square mile. The most thickly populated parts are on and near the sea-coast. On the east seaboard a more densely populated narrow belt follows the coast from near Natal just south of Cape St Roque to and south of Buenos Aires. About the cities of Pernambuco, Bahia, Rio de Janeiro, Sao Paulo, Rio Grande do Sul, Montevideo and Buenos Aires the areas of greater density widen, and, in some instances (notably near Rio de Janeiro, Sao Paulo and Buenos Aires) extend inland for several hundred miles. In the west, a considerable populated belt begins on the west coast about latitude 42° and follows northward and eastward to the island of Trinidad on the Venezuelan coast, a stretch of more than 800 miles, and almost entirely uninhabited. Several of the largest cities of South America compare favourably with the finest cities of Europe. The best streets of Rio de Janeiro, Montevideo, Buenos Aires and Valparaiso are among the most attractive of any in the world. The large cities are all well supplied with water, lighted with electricity, possess facilities for transport and are supplied with public libraries, museums of science and arts and educational institutions.

**Communications.**—The commercial relations of South America with the outside world are maintained by a large number of regular and well-equipped lines of steamers running between its ports and European ports. There is also a large freighting business done by steamers sailing at irregular periods, and by sailing vessels. Conexions with the interior of the continent were for a long time confined to navigation along the principal streams and to tedious overland travel by pack animals and by the mule. Since 1858, however, when the first 50-mile section of the Dom Pedro II railway from Rio de Janeiro to Queimados was opened, railways have extended far inland and even across the Andes. The boring of the tunnel railway between Buenes Aires and Valparaiso was completed in November 1900. Railway building has been especially active in Brazil and in the Argentine Republic. From Rio de Janeiro and Sao Paulo lines now penetrate the high plateaus and valleys, while from Buenos Aires lines reach the most productive portions of the Argentine Republic, and bring some portions of the interiors of these countries into close communication with the rest of the world. In the meanwhile river and coastwise navigation has greatly developed.

The railway mileage of the various countries was approximately as follows in 1906:

- Argentina Republic: 11,450
- Bolivia: 700
- Brazil: 10,408
- Chile: 2,800

**Miles of Railway.**

- Argentina: 11,450
- Bolivia: 700
- Brazil: 10,408
- Chile: 2,800

**Southampton, Earl of**
SOUTHAMPTON, 3RD EARL OF

Spain in 1543, and was created Baron Wriothesley of Titchfield in 1544. Having been lord keeper of the privy seal for a few months, he became lord high chancellor in 1544, in which capacity he became notorious by his proceedings against Anne Askew. He was one of the executors of her will, and in accordance with the dead king's wishes he was created earl of Southampton in February 1547. However, he had committed an offence in appointing four persons to relieve him of his duties as lord chancellor and advantage was taken of this to deprive him of his office in March, when he also ceased to be a member of the privy council. Again in the council Southampton took a leading part in bringing about the fall of Somerset, but he had not regained his former position when he died on the 30th of July 1550. His successor was his son, Henry (1545-1581), the 2nd earl, one of the Roman Catholic nobles who conspired for the release of Mary Queen of Scots. He died on the 4th of October 1581, and was succeeded by his son, Henry, the 3rd earl (see below).

For the career of the 3rd earl see Lord Campbell, Lives of the Lord Chancellors; E. Foss, Judges of England; and the various state papers and letters of the reign of Henry VIII.

The 3rd earl was succeeded by his son Thomas (1607-1667) as 4th earl. When the dispute began between the king and the parliament he took the side of the latter, but soon the violence of its leaders drove him into the arms of Charles, one of whose most loyal advisers he remained thenceforward. He was however very anxious for peace, and treated on behalf of the king with the representatives of the parliament in 1643, and again at Oxford in 1645. Having paid over £6,000 to the state, Southampton was allowed to live unmolested in England during the Commonwealth period, and on the restoration of Charles II. he was made lord high treasurer. As treasurer he was remarkable for his freedom from any taint of corruption and for his efforts in the interests of economy and financial order. He died without sons on the 16th of May 1667, when his titles became extinct.

Much of his property passed to his eldest daughter Elizabeth (d. 1693), wife of Edward Noel, 1st earl of Gainsborough (1641-1682). The name of the earl is perpetuated in London in Southampt on Row and Southampton Street, Holborn, where his London residence stood. After the death of Lady Gainsborough the London property of the earl passed to her sister Rachel, wife of William, Lord Russell, the patriot, and later to the dukes of Bedford.

In 1670 the mistress of Charles II., Barbara, countess of Castlemaine, was created duchess of Cleveland and countess of Southampton. Her son, Charles Fitzroy (1662-1730), was created duke of Grafton in 1682, and his youngest son, the 4th earl of Southampton, was created in 1780 in favour of Charles Fitzroy (1737-1797), a grandson of Charles Fitzroy, 2nd duke of Grafton, he being thus, like the holders of the dukedom of Southampton, descended from Charles II. and the duchess of Cleveland. The title is still held by his descendants.

SOUTHAMPTON, HENRY Wriothesley, 3rd EARL OF

(1573-1624), one of Shakespeare's patrons, was the second son of Henry Wriothesley, 2nd earl of Southampton, and his wife Mary Browne, daughter of the 1st Viscount Montague. He was born at Cowdray House, near Midhurst, on the 6th of October 1573, and dedicated to the title in 1581, when he came a royal ward, under the immediate care of Lord Burghley. He entered St John's College, Cambridge, in 1585, graduating M.A. in 1589; and his name was entered at Gray's Inn before he left the university. At the age of seventeen he was presented at court, where he was soon counted among the friends of the earl of Essex, and was distinguished by extraordinary marks of the queen's favour. He became a munificent patron of poets. Nashe dedicated his romance of Jack Wilton to him, and Gervase Markham his poem on Sir Richard Grenville's last fight. His name is also associated with Barnabe Barnes's Porthugh and Parthenica, and with the Worldes of Worde of John Florio, who was for some years in his personal service as teacher of Italian.

But it is as a patron of the drama and especially of Shakespeare that he is best known. "My Lord Southampton and Lord Rutland," writes Rowland White to Sir Robert Sidney in 1599, "come not to the court ... They pass away the time in London merely in going to play every day" (Sydney Papers, ed. Collins, ii. 132). Venus and Adonis (1593) is dedicated to Southampton in terms expressing respect, but no special intimacy but in the dedication of Love's Labour's Lost (1594) the tone is very different. "The love I dedicate to your lordship is without end ... What I have done is yours; what I have to do is yours; being part in all I have, devoted yours." Nicholas Rowe, on the authority of Sir William Davenant, stated in his Life of Shakespeare that Southampton on one occasion gave Shakespeare a present of £1,000 to complete a purchase.

Nathan Drake in his Shakespeare and his Times (1810; vol. ii. pp. 62 seq.) first suggested that Lord Southampton was the person to whom the sonnets of Shakespeare were addressed. He set aside Thomas Thorpe's dedication to the "onlie begetter" of the sonnets, "Mr W. H.," by adopting the very unusual significance given by George Chalmers to the word "begetter," which he takes as equivalent to "procuring." "Mr W. H." was thus to be considered only as the bookseller who obtained the MS. Other adherents of the Southampton theory suggest that the initials H. W. (Henry Wriothesley) were simply reversed for the sake of concealment by the publisher. It is possible in any case that too much stress has been laid on Thomas Thorpe's mystification. The chief arguments in favour of the Southampton theory are the agreement of the sonnets with the description of Southampton, the friendly relations known to have existed between Southampton and the poet, and the correspondence, at best slight, between the energetic character of the earl and that of the young man of the sonnets. Mr Arthur Acheson (Shakespeare and the Rival Poet, 1903) brings much evidence in favour of the theory, first propounded by William Minto, that George Chapman, whose style is parodied by Shakespeare in the 21st sonnet and in Love's Labour's Lost, was the rival poet of the 78th and following sonnets. Mr Acheson goes on to suppose that Chapman's erotic poems were written with a view to gaining Southampton's patronage, and that that nobleman had refused the dedication as the result of Shakespeare's expostulations. The obscurity surrounding the subject is hardly lightened by the dialogue between H. W. and W. S. in Willobe his Aviso, a poem printed in 1549 as the work of Henry Willobie (q.v.). If the sonnets were indeed addressed to Southampton, the earlier ones urging marriage upon him must have been written before the beginning (1593) of his intrigue with Elizabeth Vernon, cousin of the Earl of Essex, which ended in 1598 with a hasty marriage that brought down Queen Elizabeth's anger on both the connecting parties. In May 1601, however, the earl of Southampton was committed to the Tower in consequence of the "Southampton" theory of the sonnets cannot be regarded as proved, and must in any case be considered in relation to other interpretations (see Shakespeare).

Meanwhile in 1596 and 1597 Southampton had been actively employed, having accompanied Essex on his two expeditions to Cadiz and to the Azores, in the latter of which he distinguished himself by his daring tactics. In 1598 he had a brawl at court with Ambrose Willoughby, and later in the same year he attended Sir Robert Cecil on an embassy to Paris. In 1599 he went to Ireland with Essex, who made him general of his horse, but the queen insisted that the appointment should be cancelled, and Southampton returned to London. He was deeply involved in Essex's conspiracy against the queen, and in February 1601 he was sentenced to death. Sir Robert Cecil obtained the commutation of the penalty to imprisonment for life.

On the accession of James I. Southampton resumed his place at court and received numerous honours from the new king. On the eve of the abortive rebellion of Essex he had induced the players at the Globe theatre to revive Richard II., and on his release from prison in 1603 he resumed his connexion with the stage. In 1603 he entertained Queen Anne with a performance

Roger Manners, 5th earl of Rutland, a close ally and friend of Southampton.
of Love’s Labour’s Lost by Burbage and his company, to which Shakespeare belonged, at Southampton House.

Southampton took a considerable share in promoting the colonial enterprises of the time, and was an active member of the Virginia company’s council. He seems to have been a born fighter, and engaged in more than one serious quarrel at court, being imprisoned for a short time in 1603. He was in more serious disgrace in 1621 for his determined opposition to Buckingham. He was a volunteer on the Protestant side in Germany in 1614, and in 1617 he proposed to fit out an expedition against the Barbary pirates. In 1624 he and his elder son enrolled themselves as volunteers for the United Provinces of the Netherlands against Spain. Immediately on landing they were attacked with fever, to which both succumbed, the father surviving until the roth of November 1625.

There are numerous portraits of Southampton, in which he is depicted with dark arrow hair and blue eyes, compatible with Shakespeare’s description of a “man right fair.” Sir John Beaumont (1583–1627) wrote a well-known elegy in his praise, and Gervase Markham wrote of him in a tract entitled Honour in his Perfection, or a Treatise in Commendation of . . . Henry, Earl of Oxford, Henry, Earl of Southampton, Robert, Earl of Essex (1624).

For further information see “Memoirs of Henry Wriothesley, the third Earl of Southampton,” in Boswell’s Shakespeare (1821), xx. 427 sqq., where many of the elegies on Southampton are printed; also two of his Sonnets (1817), and Sidney Lee, Life of William Shakespeare (1869); Gerald Massey, The Secret Drama of Shakespeare’s Sonnets (1888); Samuel Butler, Shakespeare’s Sonnets Reconsidered (1896), where there is some distinctive criticism of the Southampton theory (ch. v–vii.); an article by William Archer, “Shakespeare’s Sonnets. The Case against Southampton,” in the Fortnightly Review (Dec. 1897); and Sidney Lee’s article on Southampton in the Dict. Nat. Biog., arguing in favour of his identity with the hero of the sonnets. P. Alvor in Das neue Shakespeare Evangelium (Munich, 1906), brings forward a theory that Southampton and Rutland were the authors of the Shakespeare tragedies and comedies respectively, and borrowed William Shakespeare’s name to secure themselves from Elizabeth’s suspicion.

SOUTHWAMPTON, a municipal, county, and parliamentary borough of Hampshire, England, a seaport, and county in itself, 79 m. S.W. by S. from London by the London & South-Western railway. Pop. (1901), 104,824. It is finely situated near the head of Southampton Water, an inlet of the English Channel which forms the estuary of the river Test; on a peninsula bounded east by the river Itchen. There are considerable remains of the old town walls, dating from Norman times, but strengthened and traversed by the redevelopment which occurs on the western side, where for a distance of nearly 100 yds. the wall is arched on its exterior face. The wall was strengthened by towers at intervals, such as the Arundel Tower at the north-western corner. The site of the castle, on the western side near the water, is built over, but the wall is well seen here. The castle was originally a Saxon fortress, and was rebuilt on the erection of the walls. It was partly demolished in 1659, and in 1805 its reconstruction was begun by the marquess of Lansdowne, but was not completed. Near the site there are some very ancient houses, one of which, known as King John’s Palace, is of the highest interest, as it is considered to be earlier than any example of the 12th century in England, and is well preserved. Of the ancient town gates the Bar or North Gate, South Gate, West Gate, and Blue Anchor Gate remain. The first three are important; and the South and West gates date from the early 14th century, while Bar Gate, as it stands, is later, and retains excellent Decorated work. Numerous early vaults remain below the houses within the walls. The two old churches, St Michael’s, the central tower and lofty spire of which rise from Norman arches, and Holy Rood, partly Decorated, are greatly modernised. St Michael’s contains a Norman font of black marble, comparable with that in Winchester Cathedral. All Saints’ Church dates from 1795, and among numerous modern churches St Mary’s, erected from designs by G. E. Street, is noteworthy, and occupies the site of a Saxon church. The chapel of St Julian, where French Anglican services are held, is of transitional Norman architecture, greatly altered by restoration. It was originally attached to the hospital of God’s House, founded in the time of Henry III. for eight poor persons, the existing buildings of which are modern. In the chapel are buried the earl of Cambridge, Lord Scrope, and Sir Thomas Grey, who were executed in 1415 outside the Bar Gate for conspiracy against Henry V. The chapel was allocated as a place of worship by Queen Elizabeth to certain Protestant Walloon refugees. The priory of St Denys, an Augustinian foundation of 1124, gives name to a suburb by the Itchen, and has left only fragmentary ruins.

In the municipal offices interesting ancient regalia and records are kept. The Guildhall, used as a court-house, is in the upper part of Bar Gate. Noteworthy modern buildings are the public library, corn exchange, custom-house, and assembly rooms. The Hartley Institution, founded under the will of Mr H. R. Hartley, contains a library, museum, art gallery, lecture hall, laboratories, and school of science and art associated with that of South Kensington, London; the foundation was created for the advancement of natural history, astronomy, antiquities, and classical and Oriental literature. The Edward VI. grammar school was founded in 1550 and reorganized in 1875, and occupies modern buildings. Alderman Taunton’s trade school was founded in 1757 and includes a technical department. The ordnance survey office is the headquarters of the ordnance survey department of Great Britain and Ireland. The Royal South Hampshire Infirmary is the principal of numerous benevolent and charitable institutions. To the north of the old town are the East and West Parks and the Hampshire county cricket ground, and to the south the small Queen’s Park. Southampton Common, with its fine avenue, north of the town, was formerly part of the manor of Shirley. There is a statue in the parks of Dr Isaac Watts, the theologian (1674–1748), a native of the town, in whose memory the Watts Memorial Hall was erected in 1875. The headquarters of the Royal Southampton and the Royal Southern Yacht Clubs are in the town.

The history of the modern importance of Southampton as a port begins with the creation of a pier and harbour commission in 1803, and the erection of the Royal Victoria Pier (opened by Princess, afterwards Queen, Victoria) in 1831. But its present prosperity really dates from the opening of railway communication with London in 1840. The harbour is one of the finest natural harbours in the kingdom, and has the advantage of a double tide, the tide of the English channel giving it high water first by way of the Solent and two hours later by way of Spithead. In 1892 the docks, which lie at the southern end of the peninsula, became the property of the London & South-Western Railway Company. They measure about 300 acres; comprising extensive quays in both the Test and the Itchen.
SOUTHAMPTON—SOUTH AUSTRALIA

rivers, with 28 ft. and upwards of water at low water of ordinary spring tides, and over 15,000 linear feet of accommodation; the Empress dock, 18½ acres, with a depth of 26 ft. at low water spring tide; the outer dock, 16 acres, with 18 ft. at low water spring tide; and the inner dock, 10 acres. In 1907 the construction of a new dock was undertaken, to cover 16 acres, with a depth of 40 ft. below low water. There are also two coal barges docks capable of floating 10,000 tons of coal at one time. There are five dry docks, having from 29 ft. to 12 ft. depth of water over blocks at neaps. The Prince of Wales, or No. 5 dry dock, opened in 1897, was the first of a series of dry docks, and the first of its size in the world; it is 750 ft. long by 87½ ft. wide at sill, and 112 ft. at cope level. In 1905 a sixth graving dock was opened, having a length of 875 ft., and a width of 90 ft. at sill and 125 ft. at cope level. The principal passenger steamers sailing from the port are those of the Royal Mail Steam Packet Company for the West Indies and the Pacific (via Panama) and for Brazil and the River Plate, &c., and the Union-Castle line for the Cape of Good Hope, Natal, East Africa, &c., both of which companies have their headquarters here. New York is served by the American line, the North German Lloyd line, &c. Regular steamers serve the Channel Islands, Cherbourg and Havre, the principal English ports, Dublin, Belfast and Glasgow; and local steamers serve Cowes (Isle of Wight) and other neighbouring ports. The South-Western Company owns the local railway stations (Town and Dock and Southampton West, besides suburban stations), but through connexions are made with the north by way of the Great Western and Great Central and the Midland and South-Western Junction railways. Among the principal imports are cocoa, coffee, grain (including Indian corn), fruit, provisions (including butter, eggs and potatoes from France and the Channel Islands), wines and spirits, sugar, wool, and other foreign and colonial produce. Exports are all kinds of manufactured goods, such as cotton, linen, woollen, worsted and leather goods, machinery and hardware.

Southampton gives name to a suffragan bishopric in the diocese of Winchester. The parliamentary borough returns two members. The county borough was created in 1888. The town is governed by a mayor, sheriff, senior and junior bailiffs, 13 aldermen, and 39 councillors. The area, which includes the suburbs of Shirley, Freemantle and others, is 4,501 acres.

History.—There was a Roman settlement of some importance on the south bank of the river Itchen, near the site of the E. bank of the Itchen. It was walled, and inscribed stones, coins, pottery, &c., have been found. It is probable that after the Danish invasions of the 11th century the modern Southampton (Hantune, Shukhampton) gradually superseded the Saxon Hantune as the latter did the Roman settlement, the site being chosen for its stronger position and greater facilities for trade. It was a royal borough before 1086, and a charter of Henry II. (1154-5) declares that the men of Southampton shall hold their guild liberties and customs and as in the time of Henry I. Richard I. In 1189 freed the burgesses from the annual, wool, and other customs. In 1215 John repeated the grant and gave them the farm of the customs of their own port and those of Portsmouth at a yearly rent of £300. Henry III. in 1256 granted all the liberties and customs enjoyed by Winchester. Grants and confirmations were made from the reign of Henry III. to Henry VI., that of 1401 (2 Henry IV.) granting further to the mayor and bailiffs cognisance of all pleas to be held in the Gildhall (gwythala). The charter of incorporation was given by Henry VI. in 1445, under which the town was governed by a mayor, 2 bailiffs and burgesses, while by charter of 1447 the neighbouring district was amalgamated with the town through a district county under the title of "the town and county of the town of Southampton." Further privileges were granted by successive kings, and a charter was finally given by Charles I. in 1640. Southampton has returned two members to parliament since 1295. The inhabitants appear to have had a prescriptive right to hold a cattle-market, which was confirmed by Henry IV. in 1400, and later by Elizabeth. Markets on Wednesday for cattle and Friday for corn are now held. Trinity fair, dating from the year 1443, is now a pleasure fair. In medieval times Southampton owed its importance to the fact that it was the chief port of Winchester. It had a large import and export trade, and in the 13th century was the second wine port in England. Wool was very largely exported, and the fact that it was brought to this port to be shipped probably led to the first establishment of the woollen trade in the W. of England. The rise of London as a port, the prohibition of the export of wool, the loss of the Winchester market after the suppression of the monastic institutions, and the withdrawal of the court led to the gradual decline of trade from the 16th century onwards until railways and docks, and in the 19th century new dockyards gave Southampton the position it holds to-day.

SOUTHAMPTON, a township of Suffolk county, New York, occupying the western part (W. of Easthampton) of the south-eastern peninsula of Long Island, S. of the Peconic Bay and N. of the Atlantic Ocean. Pop. (1900), 10,371; (1910), 11,240. Separated from the ocean by a narrow beach, it is in the south-west corner of the " Township." The town is the nearly landlocked East Bay and Shinnecock Bay, and farther east are Mecox Bay (landlocked) and other ponds near the ocean. At Canoe Place, an old portage, Shinnecock Bay and Peconic Bay are less than 3 m. apart. On the northern shore of the township are the small settlements called Flanders, Southport, Sebonac, North Haven and North Sea. Near the south shore and served by the Long Island railway are Speonk, Westhampton, Quogue, Good Ground, Shinnecock Hills, Southampton (pop. in 1910, 2,500), Water Mill and Bridgehampton, from which there is a branch line of the Long Island railway to Sag Harbor. Good sailing and sea-bathing are obtained at several places; and the golf links of the Shinnecock Golf Club, at Shinnecock Hills, is one of the best in the country. The first "summer cottages" were built near the village of Southampton in the latter part of the decade 1870-1880, and the summer colony was long called the "New York Annex" or the "Annex." The village of Southampton has been called the Newport of Long Island; in it is the Rogers Memorial Library (1893). The whale fishery was formerly important; it began here about 1660. The Shinnecock Indians long took part in it and many of the beach houses in the south part of the "Township" were held on the 31st of December 1876. The Indians now on the reservation are mostly mixed bloods with a large proportion of negro blood. Southampton was settled in 1650, probably before Southold, by a "company of undertakers" formed in March 1639 at Lynn, Massachusetts, who received from James Farrow, agent of the proprietor, William Alexander, Lord Stirling, a patent dated the 17th of April 1640 for 8 m. square of land and whose deed from the Indians is dated the 13th of December 1649. Their first attempt to settle was broken up by the Dutch. The name may have been taken in honour of Henry Wirral, earl of Southwell. The settlement was a commercial scheme, and in spite of the rigid Puritanism of Abraham Pierson, their first pastor and a sympathizer with New Haven, the people voted to attach themselves to Connecticut (1643). The Mosaic law was adopted for the government of the township. In 1678 Governor Edmund Andros, in a note to the home government, said: "Our principal places of trade are New York and Southampton, except Albany for the Indians." The village of Southampton was incorporated in 1834.

SOUTH AUSTRALIA, a British colonial state, forming part of the Commonwealth of Australia. (For map, see Australia.) It lies between 129° and 141° E. long., has Queensland, New South Wales and Victoria on the E., Western Australia on the W., and the Southern Ocean on the S. Originally its northern line was 26° S. lat.; but by the addition of the Northern Territory the area was extended from 386,970 sq. m. to 903,690, and the northern border carried to the Indian Ocean;
but by acts of 1910 this territory was made over to the federal government. It is, however, described below.

The southern coast-line shows two large gulfs, Spencer and St Vincent—the first 180 m. long, the other too. Spencer Gulf is open to the ocean, while St Vincent Gulf is partly sheltered by Kangaroo Island, with Investigator Straits as its western and Backstairs Passage as its eastern entrance. Yorke Peninsula separates the two gulfs. Eyre’s Peninsula is to the west of Spencer Gulf, and at its southern extremity are Port Lincoln, Sealaford Bay and Coffin’s Bay, of which the first is the most important. Along the Great Australian Bight are several small bays, and the junction of South and Western Australia is on the Bight. Going eastward from the Gulf of St Vincent is Encounter Bay, through which there is an entrance to the West Australian coast. The Gulf of Carpentaria, to the north of the Murray river. The Coorong is the name given to the narrow sheet of water, nearly 200 m. long, formed by the Murray and separated from the ocean by a very narrow strip of land. Laccopede and Rivoli Bays are the only other important indentations of this coast. In Northern Territory are several important indentations, Melville, Adam, Arnhem and Raffles Bays, Van Diemen’s Gulf, Port Essington and Port Darwin (lat. 12° S.).

The Gulf of Carpentaria divides the territory from Cape Yorke Peninsula of Queensland, the more important inlets on the shore of the gulf in Northern Territory being Caledon Bay and Limmen Bay. South of Cape Yorke Peninsula is Kangaroo Island, situated at the mouth of the Gulf of St Vincent; it is also the longest Australian island, measuring 210 m. by 83 m. at its widest part. Off the north coast of Northern Territory are Melville and Bathurst Islands, the Wessel group, and Groote Eylandt in the Gulf of Carpentaria.

Mountain ranges are not an important feature of the country, which, on the whole, is level, not being slightly undulating. In the south of the state the principal ranges run north and south; the Mount Lofty range, beginning at Cape Jervis, runs parallel with St Vincent’s Gulf and at one end of it is Mount Lofty Range, having an elevation of 2330 ft. The Flinders range rises on the eastern shores of Spencer Gulf and extends north for several hundred miles, terminating near the so-called Lake Blanche; there is in this range several isolated peaks which attain 3000 ft., the most prominent being Mt Remarkable, 3100 ft., Mt Brown, about the same height, and Mt Arden and Serle, about 3000 ft. The Gawler range, running across Eyre’s Peninsula, south of the lakes, attains an elevation of about 2000 ft. at several points. Beyond Lake Torrens the ranges tend in the direction of north-west and afterwards run parallel with the coast, a continuation of the ranges. The southern part of the Northern Territory is traversed by several minor ranges, but the country has not been thoroughly explored and the heights and direction of the ranges have not been in all cases determined; no elevation above 2000 ft. has, however, been discovered.

South Australia is by no means a well-watered country, but there are some fine streams in the north of Northern Territory. In South Australia proper the Murray enters the sea at Lake Alexandrina, after having received the drainage of three states. The Torrens, Wakefield, Hindmarsh, Tuman and Gawler are unimportant streams; on the banks of the first named is situated the town of Inglewood. From Queensland flows the Barcoo, or Cooper’s Creek, into Lake Eyre, which also receives the Macumba, with its tributary the Alberga, and several other rivers. These are rivers only when they are filled with the torrential rains of the interior, and for the most part are deposits of destitute of water. Northern Territory is marked by an absence of water except at the extreme north, where there are several fine rivers, some of which are navigable for over 100 m.; the most noteworthy are: the Roper, flowing into Limmen Bight in the Gulf of Carpentaria, the Liverpool, the South Alligator, the Adelaidas, the Daly and the Victoria. There are numerous lakes shown on the maps of South Australia, but none are permanent; they are depressions filled by the rivers in times of flood, but otherwise waterless or containing shallow pools of salt water. (T. A. C.)

Geology.—South Australia may be divided geologically into four parts, the geology of each of which is so distinct that they may be conveniently considered apart. These divisions are (1) the Great Valley of South Australia and the adjacent highlands that border it, (2) the Lake Eyre Basin, (3) the Western Plateau, (4) the basin of the Lower Murray, with (5) the Northern Territory.

The western division consists of a plateau of Archean gneisses, granites and schists, which extend southward from the Eyre Peninsula on the south to the northern coasts on Port Darwin. In the south-western corner of the state the Archean plateau is bounded on the north by the boundary between the outcrops of the Nullarbor plains, which extend from the shore of the Great Australian Bight to the foot of the great Victorian desert. Thence northward, the Archean rocks form the whole foundation of the country, and extend all the way to the east of the Gulf of Carpentaria, and in the exposures near Palmerston, on Port Darwin. This plateau bears occasional deposits of laterite. The chief of these are the Ordovician rocks of the Macquarie Ranges, which extend from west to south-east, and represent part of the older Palaeozoic mountain chain, which appears to have once extended across the north-east of the Ordovician rocks of the Maccollan2 Chain are the Cambrian deposits of Tempe Downs and the head of the Herbert river. Some Jurassic fresh-water deposits occur in basins on the plateau, having been thrown down, in the hope of forming a flowing well at Lake Phillipson.

In contrast to the striking uniformity of the Western Plateau is the geological complexity of the part of South Australia known as the Great Valley of South Australia, which is termed as "the so-called Spencer Gulf. The country is underlain by Archean and granitic rocks; they are exposed in the Gawler Range to the west, in the Archean outcrops near the New South Wales frontier to the north, and along the coast near Port Augusta to the east. The outcrops continue along the western edge of the Murray basin. The highlands of South Australia consist mainly of contorted Lower Palaeozoic rocks, including the best representative in Australia of the Cambrian system, known as the "the Cambrian succession. These Cambrian deposits, in addition to their stratification of Cambrian fauna, contain a long belt of glacial deposits, the discovery of which is due to W. Howchin. These highlands form the whole of the mountains of the country to the east of Lake Torrens; they extend southward to the highlands behind Adelaide, and form the axis of Kangaroo Island, while a branch from them forms the backbone of Yorke Peninsula. The highlands end to the north along a line of break of slope and abrupt change in the direction of the land. The Willouran and Hergott ranges, to the south of Lake Eyre. The country to the west of Lake Torrens is a plateau, capped by the Lake Torrens Quartzites, which are apparently of Upper Palaeozoic age. This plateau has been separated from the South Australian highlands by the formation of the rift valley, in which lie Lake Torrens and Spencer Gulf. St Vincent Gulf occupies a foundered area between the Mount Lofty range and the Yorke Peninsula and Kangaroo Island. The south-eastern corner of South Australia is occupied by the basin of the Lower Murray, which in middle Cainozoic times was occupied by a sea, in which was laid down a thick deposit of marine sands and clays. The most characteristic and rich fossil fauna from the cliffs beside the Murray. In the southern part of this district there is a western continuation of the basaltic sheets so conspicuous in Victoria. Some of them have been ejected out of existence, others still well marked. The best extinct crater known is Mt Gambier.

The Lake Eyre basin occupies a vast depression to the north of the South Australian highlands; it is bounded to the west by a line of mountainous country and the Great Salt Desert, which connect the north-western end of the South Australian highlands with the mountains on the Archean plateau at the head of the Macumba and the Finke rivers. The Lake Eyre basin was occupied later in Cainozoic times by a sea, which extended southwards from the Gulf of Carpentaria; and it appears to have been bounded to the south by the northern edge of the South Australian highlands. The valley of Lake Eyre is a drainage gap of Cainozoic times, the downs formation. After the retreat of this sea the clays were covered by the Desert Sandstone, which has been cut up by denudation into isolated plateaux and tent-shaped hills. On the margin of the Desert Sandstone is the Sandstone Beds; they extend southwards to the Great Sandhills and are interbedded with the Desert Sandstone, and the fossil is fixed as Upper Cretaceous. The origin of the Desert Sandstone has given rise to considerable discussion; but it is no doubt in the main a formation of Cainozoic age, as of the Downs formation, although it has been considered of local volcanic action, but they have probably been changed by the aborigines. Extensive estuarine deposits of Pliocene or early Pleistocene age, with a rich fauna of marsupials and birds, occur on the plains to the east of Lake Eyre.

The Northern Territory includes the mountains of the Maccollan Chain, and all the country thence to the northern coast. It consists of a mountain plateau covered in places by Cambrian and Ordovician deposits. To the north of the Victoria river and the Roper...
River, the country rises into a high, dissected table-land of Archean rocks; but round the coast there is a coastal plain including Permocarboniferous, Cretaceous and Cainozoic deposits. The Cretaceous deposits include ammonites of the variius type and a species of Arthrodires. The chief mineral product of South Australia is copper, the mines of which occur in Cambrian limestones along the western edge of the state; the most important are the Peake and Burra. Gold occurs in numerous small mines in the South Australian highlands; and also in the Western Plateau, as in the Tarcoola goldfield; and in the Northern Territory, in the Arunta goldfield, at Coober Pedy, and the Goyder Lakes. Gold is also scattered in the Arnhem Peninsula of the Northern Territory; but hitherto the gold-mines of South Australia have been less important than those of any other of the Australian states. The only coal deposits are at Mount Dore, in the Flinders Ranges, and at Leigh’s Creek, east of Lake Torrens, where they have been mined.

Some of the geological information regarding South Australia is scattered in a series of reports, mainly by H. Y. L. Brown, published in the parliamentary papers of South Australia. There are also numerous reports by R. Tate, W. Howchin, &c. in the Trans. R. Soc. S. Austral. The geology of the Macdonnell range is described in the reports of the Horn Expedition, and the fauna of Lake Callal- bana in Memoirs issued by Stirling and Zeitz, published by the Royal Society of South Australia. The literature is catalogued in Gill’s Library of South Australia. In Northern Australia the lakes of the Lake Eyre basin and its adjacent islands in J. W. Gregory, The Dead Heart of Australia (1906). The Miocene marine fauna has been catalogued last by Dennett and Kistler, Records of Marine Invertebrates, 1905, 3, 4 (J. W. G.).

Fauna.—South Australia is not separated from the neighbouring continent by any natural boundaries; hence the fauna includes many animals which are also to be found in the land lying to the east. The southern half of the continent is tropical; and it possesses a tropical fauna, which is, however, practically identical with that of Northern Queensland. In spite of its immense extent north and south, and a corresponding diversity in climate, the colony is poorer in animal life than its neighbours. It possesses thirty-five genera of mammals. These include both genera of the order Monotremata—the Echidna, or spiny anteater, and the Ornithorynchus, represented by a single species—on land also in Eastern Australia and Tasmania. The other order of Mammalia associated with Australia, the Marsupialia, is well represented in South Australia. It contains seven genera of Macropodidae or kangaroos, including the wallaby and kangaroo rat; four genera of Phalangistidae, or opossums, and five species of Dasyuridae, or “native cats.” Two genera of this family are peculiar to the region—the Caenolestes and the Antechinomys; the latter is found in the interior. It is a mouse-like animal with large ears, and is remarkable for the elongation of its fore-arm and hind-foot and for the complete absence of the hallux. The Phascolodons, or wombat, one of the species of which is represented in South Australia, and the curious Myrmecobius, or ant-eater of Western Australia. This remarkable animal is about the size of a squirrel; it possesses fifty-two teeth (a greater number than any known quadruped), and, unlike any other of its order, has no hind feet. The young springing from nipples concealed amongst the hair of her abdomen. The Choroerus, with peculiar slender limbs and a pouch opening backwards, is found in the interior. The remaining Monotremata are the duck-billed, ornithorhynchus, and a few species of Muridae, the mouse family, and Chiroptera, or bats. There are about seven hundred species of birds, including sixty species of parrots. Of the 9 families peculiar to the Australian region, 5 are well represented, including the Meliphagidae (honey-suckers), Cuculidae (cockatoos), Platyrrhina (broad-tailed and grass parakeets), Megapodidae (mound-makers) and Casuarinidae (casewarriors). The last-named family is represented by the Dromais, or emu, which is hunted in some parts of the colony. Reptiles are fairly represented: there are fifteen species of poisonous snakes. The lizards are very peculiar; South and Western Australia contain twelve peculiar genera. No true crocodilia exist in the continent, but frogs and toads are plentiful.

Flora.—The plant species resemble those of the eastern colonies and Western Australia, but are more varied in the south. The country supports a large number of eucalypts. Eucalyptus areas are also a large desert of forests or of timber trees. The Eucalyptus family, so valuable for timber and gum as well as for sanitary reasons, are fairly represented. Acacias are abundant, the last-named genus containing an article of commerce, Flitch gum, which has much of the valuable sugar-gum, Eucalyptus Corymbosa, which is being now preserved in forest reserves. Its timber is very hard and strong, not warping, resisting damp and all diseases. The Gymnosperms include a few species of Grevillea. Tamarix indica occurs in Arnhem land, with native rice, rattans and wild nutmeg. The cedar of the Indian variety. Pines are numerous in the south, palms in the north; among the most beautiful is the Kemia acuminata. Banksias are very common in sandy districts. Flowering shrubs are common in the south. There are 130 known grasses in Northern Territory.

Climate.—The climate of South Australia proper is, on the whole, extremely healthy, and in many respects resembles that of southern Europe. In the south-eastern corner of the state the spring and winter seasons are most pleasant, and although the thermometer occasionally registers high in summer, the heat is dry and much more endurable than a much lesser heat in a moist climate. In the interior districts, however, the heat is sometimes very trying to Europeans. In Northern Territory the climate is of a tropical character, except on the table-lands where it is comparatively cool. Observation has determined the area of the state adapted by reason of seasonal rain to the cultivation of cotton and rice, and in this area crops are almost certain; agriculture outside this area is, however, purely speculative. The average rainfall at Adelaide taken for a period of 52 years was 21-204 in. As the rain falls at seasonable times, the quantity is always certain. The highest and the minimum shade temperature recorded at Adelaide Observatory in 1905 was 109-7°; the highest for any Australian city; the minimum was 34°8 and the mean temperature 61-1.

Population.—The population of South Australia in 1860 was 124,112, and the province was third in importance among the states forming the Australasian group. In 1870 the population stood at 183,797, and in 1880 at 267,573; in 1890 it was 319,414; in 1901, 362,504; and at the end of 1905, 376,208. These figures are inclusive of the population of Northern Territory, the province of South Australia, properly so-called, containing 374,308 inhabitants, and Northern Territory, 3810, the respective density of the two divisions being one person per square mile and one per 128 sq. m. The estimated population of Adelaide in 1905 was 175,000. The number of males in 1905 was 197,487, and the females 186,721. The births in the same year were 8868 and the deaths 504, representing 23-44 and 10-05 per 1000 population respectively. The birth-rate has declined greatly.

Dividing the years from 1861 to 1905 into five-yearly groups the following were the average births rates:

<table>
<thead>
<tr>
<th>Period</th>
<th>Births per 1000 of Population.</th>
</tr>
</thead>
<tbody>
<tr>
<td>1861-1865</td>
<td>44-14</td>
</tr>
<tr>
<td>1866-1870</td>
<td>40-60</td>

<td>26-90</td>
</tr>
<tr>
<td>1901-1905</td>
<td>24-96</td>
</tr>
</tbody>
</table>

Illegitimate births are less frequent in South Australia than elsewhere in Australia; in 1905 the proportion of illegitimate to total births was 4·37%. The death-rate has always been remarkably low, not having exceeded 13 per 1000 in any year since 1866. The averages for each quinquennial period from 1861 were as follows:

<table>
<thead>
<tr>
<th>Period</th>
<th>Deaths per 1000 of Population.</th>

</tbody>
</table>

The excess of births over deaths in 1905 was 5071 or 13·48 per 1000 of population. The number of marriages celebrated during 1905 was 126,744, and the number of divorces and judicial separations during the ten years ending with 1905 was 72.
The people are mainly of British race; out of 362,604 persons whose birthplace was ascertained at the census of 1901, 348,352 were of British or Australian parentage, the number born in the Commonwealth being 289,440, and in South Australia itself 271,671; 9306 were born on the continent of Europe, of whom 9264 were Germans, and 93 Scandinavians and 3253 were Chinese. The total foreign-born element of the population numbered only 3.73%.

The census showed the number of breadwinners in the state to be 153,266—120,328 males and 32,968 females. Agriculture, the main industry, provided employment for 33,039 persons, of whom 33,039 were males and 1147 females. Pastoral pursuits employed 4193, dairying 2868 and mining 6301. The industrial class may be divided into: (a) persons engaged in manufacturing industries, 18,165 males, 6761 females; (b) persons engaged in the construction of buildings, railways, roads, &c., numbering 8652; and (c) persons engaged in other industrial pursuits, 7677—these are chiefly persons whose census description is 'laborer'. The commerical class, including trades of all kinds as well as persons engaged in finance, numbered 20,165, namely 17,080 males and 3085 females. The professional class comprised 5572 males and 3485 females, or a total of 8857; while the domestic class comprised persons engaged in providing board and lodging, hotel and restaurant keepers, as well as servants—numbered 17,981, namely 3452 males and 14,529 females. The former was the largest class amongst the 132,296 breadwinners; the remainder of the population, consisting of 290,398 persons (64,094 males and 145,214 females) were dependent on the breadwinners.

Administration.—South Australia, as one of the states of the Commonwealth, returns six senators and seven representatives to the Federal parliament. The local parliament consists of a Legislative Council and a House of Assembly. The former has eighteen members, elected by the districts into which the state is divided, for that purpose, the franchise being limited to persons with freehold or leasehold estate, and to occupiers of dwellings of £25 annual value; while the Assembly contains 42 members, elected by 13 districts; the electoral qualifications for the Assembly are the attainment of the age of 21 years, and having been upon the electoral roll not less than six months. Women have the right to vote.

Local Government.—Adelaide was the first Australian city to acquire the right of self-government; on the 31st of October 1840 the first municipal elections in Australia were held in that city. There are 33 municipal councils and 142 district councils in the settled parts of the state, the area under local government being about 43,000 sq. m. Local rates are assessed upon the assessed annual value of the properties liable to be rated; and the amount of such assessed value is divided into a fixed rate of 6d. 2d. 6d. on the capital value £5 millions. The revenue of the various local bodies in 1905 was £542,725, of which £107,255 was obtained from rates, £435,470 was derived from endowment and other sources; £104,489 was spent on public works. The total debt of the local bodies in that year was £102,261.

Education.—The South Australian system of popular education in their present stage dates from 1873, the date of the Education Act; the existing system is capable of being employed on local war vessels, or as a light artillery land force.

Minerals.—South Australia, though without coal, was the first Australian colony to have a metallic mine, and the first to possess a gold-mine. In 1841 the wheel of a dray, going over a hill near Adelaide, disclosed to view silver-lead ore. In the midst of the bad times prosperity was ensured by the discovery of tin, silver, copper and lead; in 1879, tin and silver, while in 1891, lead and copper. The wonderful Burra Burra copper was first wrought. The land, 10,000 acres, cost £10,000; and for several years the dividends to shareholders were 800% per annum. The first colonial general export was 30 tons of lead ore, value £128, in 1843. The copper declined as prices fell. It was £22,983 in 1885, when rates were £5 10 a ton, but £76,486 ten years before with £90. In 1886 most of the mines were closed. Between 1850 and 1900 north of Adelaide a very rich copper district exists. Lead is very abundant. Manganese, nickel, bismuth, antimony and silver have been mined. Tin is seen in granitic places. Iron occurs in the Australian district and in the northern Northern Territory. The amount of the debt at certain periods beginning with 1861 was:

<table>

Defence.—As part of the Commonwealth the defence of South Australia is undertaken by the Federal government. On the 31st of December 1905 the defence force of the state totalled 5066 men, comprising 1262 partially paid troops, a paid staff of 37 and 378 Revenue Marine, 128 Revenue Lifeboatmen, 442,030; £5,555,692; land; income and other taxes, £4,132,090; railway lines, £1,247,891, public lands, £192,337; other revenue, £92,784. The government expense in 1905 was £778,000, or £4. 48. 3d. per inhabitant; from that time it rose rapidly until in 1881 it stood at £2,172,000, or £7. 16s. 1d. per head; in 1901 it was £2,734,000, or £8. 11s. 1d. per head. The expenditure for the year ended the 30th of June 1905 was as follows: railway working expenses, £4,676,636; public instruction, £1,181,583; interest and charges of public debt, £1,049,463; other services, £915,261. The debt charges amount to £3, 11s. 8d. per head, and absorb 36.25% of the total revenue of the state. Against this must be placed the net return from services upon which the loan moneys were expended: this amounts to about £746,459, so that the real burden of the state debt is reduced by this amount. In 1905 the public debt of the state stood at £28,727,905, which is equal to 27s. 1d. per head; and the purposes for which the debt was incurred were: railway construction and equipment, £13,739,557; public works, £1,376,381; education and scholarships, £1,010,735; and other works and services not producing direct revenue, £89,990,952. These figures include the debt of the Northern Territory. The amount of the debt at certain periods beginning with 1861 was:
Wallaroo are still worked, but the production has greatly fallen off. In 1900 the value of copper raised in the province was £366,015, and the gross production to the end of that year amounted to £22,321,960. The output in 1893 was 1,357,730 long tons, and in 1897 the production of the state was valued at £2,850,555, in 1881 at £2,011,809, in 1891 at £3,955,479, and in 1905 at £1,359,551.

Land System.—The aggregate area of South Australia, exclusive of the Nilgiris and Northern Territory, is computed to be 5,300,000 sq. m. of which 2,424,244,800 acres. About 136,828 sq. m., or a little more than one-third, represent the limits within which the country is at present occupied. The 46 counties proclaimed to date embrace an area of 804,437,050 sq. m., which 34,156,760 acres are purchased, 353,326 acres are partly purchased and 1,217,735 acres have been granted for public purposes, making the total alienated, wholly or conditionally, 4,442,766 acres; 176,517 acres are set apart, but not granted, for forest purposes, and 42,870,817 acres are still in possession of the Crown but occupied under various kinds of tenure, chiefly for pastoral purposes. In addition to the land alienated, there are 17,104,062 acres held by Crown by 19,511 lessees for farming or grazing purposes. Outside the counties are 299,617 sq. m. or 191,754,880 acres, of which 11105 acres are purchased, 23 granted for public purposes, 76,376,700 held in pasture, 4978 lessors of sheep or cattle farms, leaving 151,184,130 acres open for pastoral settlement, if suitable.

Agriculture.—South Australia is essentially an agricultural state. In 1863 it was stated that 'at least a fifth of the cultivated land was held for sale into lots with the view of settling the people on arrival, and concentrating them, instead of having them scattered as in the neighbouring colonies, in which pastoral pursuits completely dwarfed the farming interests.' The area under wheat fell for years after the opening of theredits to Sydney, Melbourne, Brisbane, Perth and Auckland. As neighbours became wheat-producers, Adelaide merchants had to seek markets in Natal, Mauritius, the Cape, or even Europe. At all times the state has lent every assistance to agriculture. As the colony suffers more from drought than anything else, public reservoirs are constructed and artesian wells are sunk. Forest culture has been especially encouraged, and the establishment of nurseries for the trees, fruits and vegetables of other lands so good in hand. Hundreds of thousands of trees are planted annually.

The industry is wheat-growing; out of 3,442,766 acres under cultivation in 1905, 1,757,036 acres were under wheat for grain and 317,924 under wheat for hay. In some parts of South Australia fine yields are obtained; but taking it as a whole, the yield of the province is light. During the ten years 1891-1901 the average production was 1,91,754,880 acres of which 2,424,244,800 acres varied from a minimum of 17 bushels in 1897 to a maximum of 61 bushels in 1895. South Australian wheat is of excellent quality and strength, and well known in European markets, to which it is sent in wheat since 1858. There has been little expansion of wheat cultivation since 1880; nor, indeed, has there been any material expansion in the total area under crop. Up to the year 1890 there was no area devoted to the cultivation of any crop except wheat; but repeated failure of crops, due to want of seasonal rain, has disheartened farmers, and much land that was formerly cultivated now lies fallow; 1,087,057 acres were fallow in 1905. The following table gives the area of wheat harvested for grain at specified intervals from 1861:

</table>

The great expansion following 1881 was due to the opening up of trade with the western districts of New South Wales. The exports of domestic produce, the value of which is given in the last column, when compared with the other figures in the table, show how greatly the province depends upon its re-export trade. The chief items of export are 'tallow and fats' and 'vegetables'. The value of these is very variable, depending so largely upon the rainfall, which in South Australia is extremely uncertain. In 1884 the value of wheat and flour export was £41,106, and in 1885 £49,066, falling to £263,426 in 1886, but rising again to £2,175,835 in 1887 and falling again to £219,457 in 1889. The value of these named there have been great fluctuations; in 1898 the export fell to £251,986; in 1899 it was £75,951; in 1900 it was £1,649,441; and in 1903 it was £87,235.

Railways.—The first railway was opened in 1856, and connected Adelaide with its port, and the following year saw a line constructed to Gawler, 25 m. from Adelaide. The inability of the government to borrow money at reasonable rates greatly retarded the construction of railways in the province, and in 1875 there were less than 200 m. of line; in the next ten years 800 m. were opened for traffic, and in 1895 there were 1746 m. in the state proper and 146 m. in Northern Territory. The first adhesion to a mail steamers was in 1863. The construction of a line from the capital to the state capital was at £14,766,465 and the net earnings at £38,590; this represents 157% on the capital. The other line, from the state capital to the seaport at its outstanding loans was in the same year 3&7%: there was therefore a loss of 0-15% upon the working of the lines; but the state claims that the indirect benefits of railway construction are of greater importance. The capital expenditure for the year 1905 was £1,318,821, and the working expenses £726,403; the net profit per average mile open being £297, and per train mile 54-68 pence. In 1905 the number of passengers carried was 2,338,061, and 2,303,641 freight cartons. South Australia has two gauges, namely 508 m. of 5 ft. 3 in., and 1384 m. of 3 ft. 6 in. gauge. The line joining Adelaide with the Victorian border, as well as the line to the eastern limit of the state, is single.

Posts and Telegraphs.—In 1905 there were 711 post-offices in the state of which 299 were also telegraph stations. The business transacted was: letters and postcards transmitted, 26,230,337; telegrams delivered, 1,677,770; newspapers and periodicals, 2,630,854. The total revenue from these services for the year 1905 was £274,842, and the expenditure £259,556; in these sums are included the
telephone revenue and expenditure, the former amounting to £5,851,
The latter of £3,550. A revenue received by the Commonwealth
government. The use of telephones in Adelaide is rapidly extending;
in 1905 there were eleven exchanges and 2,254 telephones in actual use.
There were 6,092 m. of telegraphic lines in operation that year,
the state-owned line by which communication with Europe and the
East is maintained.

Banking.—The assets of all the banks of issue trading in South
Australia amounted to £7,623,060; the liabilities to £7,633,060; these latter comprised deposits
at call and at interest, £6,866,281; notes and bills in circulation,
£351,533; and other liabilities £52,929. Among the assets were coin
and bullion £8,609,660. The South Australian people are very thifty,
and thirty-one in every hundred have accounts with the savings banks.
On the 30th of June 1905 the depositors numbered 126,821,
the amount of their credit being £4,380,355, a sum equal to
£39,831 for each head of the population. Taking the deposits
and savings banks together, the total was £11,186,639, which is equal to
£29, 12s. 4d. per inhabitant.

History.—Though the coast of Northern Territory was well
known to Portuguese and Spanish navigators as early as perhaps
1530, being called Great Java, it was not surveyed till 1644, when
Teaman laid down the line of shore pretty accurately. The
western part of the southern coast had been seen and named
Nuyt’s Land in 1627. But Flinders, by his discovery of the two
great gulfs, Kangaroo Island and Encounter Bay, in 1802,
was the first to reveal South Australia proper. Captain Sturt
descended the Murray in 1829, and looked over the hills near
Adelaide. The first to direct attention to a settlement there
was Major Baron, who communicated with the colonial office in
February 1831. His suggestion was to establish, at no charge
to the British government, a private company, that should settle a party on Yorke Peninsula. He believed a large river
entered Spencer Gulf. In August Colonel Torrens and others
proposed to purchase land between 13° and 14°—500,000 acres
at 3s. an acre. Some were in favour of Spencer Gulf, others of
Kangaroo Island, and a few for the mainland towards the Murray.
Memorials in 1832 sought a charter for the South Australian
Company. The conferring of extensive powers of self-government
and sales was to pay the passages of free labour, chiefly young
married people, and no convicts were ever to be sent thither.
Lord Goderich did not favour the scheme, and thought a colony
with free institutions might prejudice the interests of New South
Wales, while free trade would interfere with the English naviga-
tion laws. After much negotiation, the English authorities
regarded the scheme more favourably, but would not consent
to give the company the powers they sought. The company
receded in their demands, and offered security for the proper
observance of law and order, while depositing cash for the
purchase of land. Captain Sturt in 1833 informed the colonial
secretary that Spencer Gulf and Kangaroo Island were objection-
able, but that the eastern side of St Vincent Gulf was the best locality.
In 1835 the ministry got an act passed for the erection of a colony under commissioners appointed by the
Crow, who would be responsible for their acts to the British
government. It was arranged that a local government should
be established when the settlement had 50,000 people. Mr George Fife Angus advanced a large sum as security to the
state. Though the first settlers were sent to Kangaroo Island,
all were afterwards gathered on the Adelaide plains. The
colonists had to endure severe privations and that in the winter
of December, 1836. Great delay took place in the survey of land.
The South Australian Company purchased large tracts from
the commissioners at 12s. per acre and sold at 20s. A general
speculative spirit arrested progress. Governor Gawler went into
extravagant outlay on public buildings, &c., and drew and against
fear upon the English treasury. Such difficulties arose that
the British rulers had to suspend the charter in 1841 and make
South Australia a Crown colony. A revival of prosperity took place when the farms were tilled and poverty had taught pru-
dence. Copper and lead mines were subsequently discovered.
Kapunda in 1843, and the Burra Burra copper-mine in 1845,
greatly aided in the restoration of commercial credit. The gold
fever in Victoria drew off numbers in 1852; but the good prices
then realized for breadstuffs gave a great impetus to farming.
In 1836 the colony was given its own constitution and self-
government. On the attainment of autonomy Governor McFarlane, in all the districts, Electrical expenses partially
nominated legislature, made use of the following words:

"I confidently expect that the extended political power en-
trusted to the people of this country, and the universal sufragce
conceded by the new constitution, will prove in reality a safe
and conservative measure; and whilst conferring the utmost
possible power of self-government, will render stronger and yet enduring than ever the cherished ties of affection and
loyalty which link this province to the throne of our respected
and beloved sovereign." This prediction appears to have been
amply verified: South Australia enjoys the reputation of being
one of the most progressive and at the same time one of the most
stable of existing communities. From its origin as the venture
of private enterprise the state has passed through orderly
stages of evolution up to the zenith of democratic government.
Such alterations as have been made in the constitution have been
in the direction of a still further enlargement of the franchise.
Payment of members proved to be the corollary of manhood
suffrage. In 1887 a temporary act was passed for the payment of
£300 a year to each member of both houses, and in 1890
the law was made permanent. Thus was rendered possible
the direct representation of all classes. Soon afterwards the
democratic party in the legislature asked for a more extended
vote than had ever been proposed. Such an extension formed a considerable proportion of the membership of both houses,
and includes in its ranks men of the highest intelligence, ind-
ustry and eloquence. In 1894 the principle of "one man one
vote" was extended to that of "one adult one vote" by the
inclusion of women as voters on terms of absolute equality
with men. There is no bar to the election of women to parlia-
ment whenever the electors think fit to be so represented.
The delegates to the Federal convention and to the Common-
wealth parliament were in South Australia elected by the
combined vote of men and women. Elections were formerly
held in successive batches, but since 1899 they have taken place
annually in January. The electoral districts and the electorate
are rigidly limited, both as to objects and amount, and a declaration
of money thus expended has to be filed by every candidate.
Experience has demonstrated that, owing to the intrusion of
the personal element, general elections have often failed to afford
cumulative evidence of the state of the popular will. Attention
was therefore directed towards the referendum as a means of
obtaining an unquestionable verdict on important public issues,
although no general statute was formulated on the subject.
In 1896, at the general elections, the following questions were
submitted to the electors: "Do you favour (1) the continuance
of the present system of education in the state schools? (2) the
introduction of scriptural instruction in the state schools during
school hours? (3) the payment of a capitation grant to denomi-
national schools for secular results?" An overwhelming
majority pronounced in favour of (1) and against (2) and (3).
Again, in 1899, a direct vote was similarly taken on the question
of household franchise for the legislative council. Undoubtedly
the practical application of the referendum in South Australia
facilitated the adoption of this principle in the ratification and
in the method of amendment of the Commonwealth constitu-
tion. The right of the Second Chamber to suggest amendments
to bills which it has not power to amend was borrowed by the
Commonwealth from the constitution of South Australia as

as to practical and scientific husbandry is disseminated among the farmers by means of an agricultural bureau, with numerous branches throughout the state. A journal is published conjointly by the departments of agriculture and industry, containing reports of the proceedings of the bureaus and articles by government officers, together with industrial topics and matters of interest to agriculturists, and also particulars furnished by the various bureaus as to prospects of employment in various districts.

SOUTH BEND, a city and the county-seat of St Joseph county, Indiana, U.S.A., at the head of navigation and on the southern bend (hence the name) of the St Joseph river of Michigan, and (by rail) 86 m. E. by S. of Chicago. Pop. (1900), 35,990; of whom 8601 were foreign-born (including 3953 Poles and 2402 Germans); (1910, census), 53,684. Land area (1906), 6-2 sq. m. It is served by the Grand Trunk, the Lake Shore & Michigan Southern, the Michigan Central, the New Jersey Indiana & Illinois, the Chicago, Indiana & Southern, and the Vandalia railways, and by four inter-urban electric lines. Among the principal buildings are the city-hall, the county-court-house, the public library, and the Oliver Hotel. In Notre Dame, a suburb, are St Mary's College and Academy (Roman Catholic, chartered 1825) for girls, and the university of Notre Dame du Lac (Roman Catholic, first opened in 1842, and chartered in 1844). In 1910 the university had 87 instructors, 1005 students, and a library of 60,000 volumes. It is the headquarters of the order of the Holy Cross, whose sisters have charge of St Mary's College and Academy. South Bend ranked fourth among the manufacturing cities of the state in 1900. Of its industrial establishments include carriage and wagon works (those of the Studebaker brothers. Major industries (Company being the largest in the world), plough and agricultural machine works—the Oliver Chilled Plow Works, founded by James Oliver (1823-1900), being particularly well-known—the wood-working department of the Singer Sewing Machine Company, iron and steel foundries, flour-mills, and paper and pulp mills. The water-supply is obtained from 122 artesian wells, with a daily capacity of about 24,000,000 gallons. South Bend was the site of an Indian village and of a French trading post. It was settled about 1830, laid out about 1831 (when it became the county-seat of St Joseph county), incorporated as a village in 1835, and chartered as a city in 1865.

SOUTH BETHLEHEM, a borough of Northampton county, Pennsylvania, U.S.A., on the Lehigh river, about 57 m. N.W. of Philadelphia, and opposite Bethlehem, with which it is connected by bridges. Pop. (1900), 13,241, of whom 3322 were foreign-born and 115 were negroes; (1910 census), 19,073. It is served by the Lehigh Valley, the Philadelphia & Reading, the Central of New Jersey and the Lehigh & New England railways. The borough is the seat of Lehigh University. This institution was founded in 1865 by Asa Packer, who then gave $5,000,000 and 60 acres (later added 115 acres) of land in the borough, and by his will to the university library $500,000, and to the university an endowment of $1,500,000 and a large interest (about one-third) in his estate. The university was chartered in 1866; it embraces a school of technology, with courses in civil, mechanical, metallurgical mining, electrical and chemical engineering, electrometallurgy and chemistry, and a school of general literature (1878), with classical and Latin-scientific courses. In 1898-1900 it had 68 instructors, 1790 students, and a library of 127,000 volumes. The principal building of the university is Packer Hall (1869), largely taken up by the departments of civil engineering, the chemical and metallurgical laboratory, the physical and electrical engineering laboratory, the steam engineering laboratory, Williams Hall for mechanical engineering, &c., Saucon Hall for the English department, Christmas Hall, with drawing-rooms and the offices of the Y.M.C.A., the Sayre astronomical observatory, the Packer Memorial Church, the university library (1867) dormitories (1907) given by Andrew Carnegie, Drown Memorial Hall, a students' club, the college commons, and a gymnasium. The city is the seat of a Protestant Episcopal bishop. The Bethlehem Steel Company manufactures here iron and steel, including Bessemer steels, armour plate, steel rails, government ordnance, drop forgings, iron and steel castings, stationary engines, gas engines, hydraulic pumps, projectiles, steel shaft and pig iron; zinc is smelted and refined; and there are large hosiery and knitting mills, and silk mills and cigar factories. The total value of the borough's factory products increased from $9,996,054 in 1900 to $15,775,411 in 1905, an increase of 73%.

In 1846 a water-cure was established where St Luke's hospital now stands, in the adjoining borough of Fountain Hill (pop. in 1900, 1241), and for a few years this attracted a considerable number of visitors during the summer season. In 1853 works were established for the manufacture of white oxide of zinc from a calamine found here, in the next year metallic zinc was produced, and in 1865 the first sheet made in America was rolled here. The borough was incorporated in 1865.

SOUTHBOROUGH, a township of Worcester county, Massachussets, U.S.A., on the Quinnaquith river (which here falls 165 ft.), about 20 m. S.S.W. of Worcester. Pop. (1900), 10,025, of whom 3468 were foreign-born; (1910 census), 12,592. Area, about 20 sq. m. The township is served by the New York, New Haven & Hartford railway, and by inter-urban (electric) lines to Worcester and Springfield. The Southbridge public library (1876) contained 22,000 volumes in 1910. Optical goods, cotton, woolen and print goods, cutlery and shuttles are the principal manufactures; in 1905 the value of the total factory product was $4,301,853. The factory of the American Optical Company here is probably the largest of its kind in the world.

In 1827 a poll parish, named the Second Religious Society of Charlton, and popularly called Honest Town, was formed from the west part of Dudley, the south-west part of Charlton and the south-east part of Sturbridge; and in 1816 this parish became the township of Southbridge.

See the Leaflets published (1901 sq.) by the Quinnaquath Historical Society of Southbridge.

SOUTH CAROLINA, a South Atlantic state of the United States of America, and one of the original thirteen, lying between latitudes 32° 2' and 36° 17' N. and between longitudes 78° 30' and 85° 20' W. It is bounded N. by North Carolina, E. by North Carolina and the Atlantic Ocean, S.E. by the Atlantic Ocean, S.W. and W. by the Savannah, Tugaloo and Chattooga rivers, which separate it from Georgia. Its total area is 39,089 sq. m., and of this 9,494 sq. m. are water surface.

Surface Features.—South Carolina is mainly in the Coastal Plain and Piedmont Plateau regions, but in the north-west it extends slightly into the Appalachian Mountain region. Locally the Coastal Plain region is known as the low country, and the Piedmont region is known as the Carolinas' up-country. The coast, about 200 m. in length, is generally low. For 60 m. south-west of the North Carolina border it is unbroken and lined with a smooth, hard beach of light-coloured sand, but below this it becomes increasingly broken by coves and is lined with flat and low sea-islands that increase in size and number toward the Georgia border. For about 10 m. back from the coast the Coastal Plain region is occupied very largely by salt marshes. Then, although still continuing flat, the surface rises at the rate of about 25 ft. per mile for 40 m. or more; beyond this it rises more rapidly, reaches a maximum elevation in Lexington county of about 100 ft. above the sea, and then becomes increasingly broken into rolling plateaus and deep valleys to the Fall Line, which marks the boundary between the Coastal Plain and the Piedmont Plateau. The Fall Line, at which the south-east flowing rivers fall from higher levels, is a geological formation of crystalline rocks, and somewhat lower levels in the softer rocks of the Coastal Plain, passes in a general south-west direction from the North Carolina boundary through South Carolina and the adjoining counties of Georgia, to the Savannah river opposite Augusta, Georgia. The Piedmont Plateau region, rising gradually from an elevation of about 500 ft. along the Fall Line to 1000 ft. or more in the north-west, is a plateau broken by undulating ridges and deeply cut valleys, and a section of South Carolina which is traversed by the Appalachian Mountain region a few mountains of the Blue Ridge rise abruptly from the foot-hills to 3413 ft. in Mt Pinnacle, 3218 ft. in Caesars Head, and 1315 ft. in Table Rock. The highest point in the state is Sassafras Mountain (3548 ft.) in the Blue Ridge and on the North Carolina state line. The mean elevation of the entire state is about 350 ft. The principal rivers rise in the Appalachian Mountains
and flow south-east into the Atlantic Ocean. In the middle section the Santée river is formed by the confluence of the Wateree, which is known in North Carolina as the Catawba, and the Congaree, which flows south-westward. The river, being formed by the commencement of this system embraces about one-half the area of the state. In the north-east the Great Pee Dee and its tributaries—the Little Pee Dee, White and Black Rivers—meet the Congaree, while the main stream is a continuation below the Fall Line of the Yadkin river, which rises in the mountains of North Carolina. On the Georgia border the Chattahoochee river, rising in the Blue Ridge, becomes a tributary of the Tallapoosa. Almost to the margin of the granitic soil is a heavy mixture of sand and clay, but on the hillsides of the river basin it is a heavy clay of reddish colour, and sand having been washed down to form the soils of the Coastal Plain region. The soils of all sections of the Coastal Plain region are a reddish or yellowish clay. In the upper section of the Coastal Plain region the soil is for the most part a loose sand, but lower down it becomes a loam turned brown by the action of air and by more fertile topsoil. 

**Agriculture.**—The number of farms in South Carolina was 1,93,864 in 1880, 115,008 in 1890 and 154,166 in 1900—the number for the two last named years not including farms of less than 3 acres and in the Piedmont region. As the yield of cotton in the state was 12,859 bales in 1880, it was in 1890, 13,154,652 bales, of which 4,132 acres were improved; in 1900, 13,185,652 bales were improved; and in 1900, 13,985,614 bales, of which 5,757,741 bales were improved, according to the census, to the value of $22,311,562. Farmers, machinery and livestock, was $84,079,720 in 1880; $119,849,272 (average value per farm, $104) in 1890; and $135,391,196 (average value per farm $182) in 1900; while the average value per acre of farming increased from $0,09 in 1890, to $109 in 1900. Of farms of 1000 acres and more there were 1635 in 1880 and 1010 in 1900; of between 500 acres and 1000 acres were 3695 in 1880 and 2314 in 1900; of 200 acres and less than 10 acres there were 13,612 in 1880 and 29,044 in 1900; of 20 acres and less than 50 acres there were 3688 in 1880 and 2861 in 1900. Farms worked by owners numbered 45,645 in 1880 and 60,471 in 1900; by cash tenants, 24,347 in 1880 and 20,406 in 1900. The total amount of land rented was 13,821 acres in 1880 and 37,838 in 1900. Of the 155,355 farms in the state in 1900, 85,351 were worked by negroes of whom 22% were owners of farms; 47% cash tenants and 37% share tenants. 

The soil is the longest and most productive of rice, but this industry has declined, and South Carolina is now supplied with rice from both Louisiana and Texas. Cotton is the state's most valuable product. The average yield of the staple crop, in 1880, was 18,899,415 bales, in 1890, 18,311,562 and in 1900, 13,985,614 bales. The net average number of acres of cotton was 6,326,967 in 1890, and 2,833,953 in 1900. Of the 19,386,846,000 acres of cotton land in the state, 13,985,614 bales. The net average number of acres of cotton was 6,326,967 in 1890, and 2,833,953 in 1900. Of the 19,386,846,000 acres of cotton land in the state, 13,985,614 bales. In 1880, it was the fourth state in the cotton crop. The average value of cotton per bale in 1880 was $6.09; in 1890, $7.28; in 1900, $7.48. The average value of cotton per bale was $7.48 in 1900. In 1890, cotton was worth $7.48 per bale. The average value of cotton per bale was $7.48 in 1900. In 1890, cotton was worth $7.48 per bale. 

**Fauna.**—The principal animals and birds in South Carolina are deer, squirrels, opossums, musk-rats, raccoons, minks, geese, ducks, turkeys, "partridge" (quail or bobwhite), woodcock and snipe. Foxes, bears, wolves, lynx (wild cats) and otters are very rare, and raccoons (panthers) and their short, white fur, have disappeared. Common among birds of prey are owls, hawks, and kites, and there are many turkey buzzards. Song birds are numerous and abound in the Carolina pines, carolina doves, mocking birds, blue birds, robins, wrens, chickadees, warblers, sparrows, bobolinks (red birds or rice birds), meadow larks and orioles. In the bays and lower courses of the rivers are porpoises, eels, and small fish, such as perch, pike, eel, flat-fish, drum, bluefish, sunfish, sheepshead, weakfish or skeetauge, grigger, and several other kinds of fish. Oysters, crabs, shrimps and terrapins are also abundant here, and in the inland streams are species of catfish and many species of trout. 

**Flora.**—From the number of palmettoes along the coast the Carolina palmetto has become popularly known as the Palmetto state. Some of the plants which grow from the ocean up to the magnolias, the live oaks draped with long gray moss, and the redis-covered marshes. In the swamps there are cypress and some gum and bay trees. In most of the uplands of the Coastal Plain region the hard-leaf pines, not uncommon, are found. In the uplands of the Piedmont are found short-leaf pine, laurel, hickory, cypress, oak, bald cypress, chestnut, sycamore and tulip trees also abound. On the mountains the cypress trees, laurel, white pine and hemlock. Among indigenous shrubs are the sessile laurel, mountain laurel, elder and viburnum. And vines that bear edible fruits or nuts the state has the blackberry, grape, pawpaw, persimmon, plum, crabapple, hickory, cherry, walnut, chestnut, horehound, phlox, flowering, maples and cherry. Also the emerald grass, the blue grass, bear grass, and also beady cherry. Both medicinal and flowering plants are exceptionally abundant. Among the former are the ginseng, snakeroot, bloodroot, bore-hound, thoroughwort, redroot (Geanthe, blue fleabane), black root, red root and the latter are jasmines, azaleas, lilies, roses, violets, honeysuckle and goldenrod. Venus's-flytrap is found along the coast. 

The prevailing annual temperature is comparatively mild and equitable. At Charleston, for example, the mean annual winter temperature is 51° F. the mean summer temperature 81° F., the mean annual temperature 66° F., and the range of extremes from 104° F. to 7° F. Toward the north-west the mean winter temperature decreases to 47° F. at Columbia and to 49° F. at Greenville; the mean summer temperature decreases only to 80° F. as far as Columbia, but from there to Greenville declines to 73° F.; and the mean annual temperature decreases to 62° F. at Columbia and to 58° F. at Greenville. The range of extremes increases to 108° F. (106° to 8°) at Columbia, and then decreases to 102° F. (97° to 5°) at Charleston, and to 95° F. (74° to 10°) in the state line. It is an interesting fact that in 11° F. at Santuck, Union county, in February 1900, to 106° F. at Columbia in August 1900. For the whole state the mean annual temperature is 63° F., the mean summer temperature 79° F., and the mean winter temperature 46° F. January is the coldest month and July the warmest. The mean annual rainfall for the state is about 49 in., and its distribution is very even. Extremes for the various ranges only from 35 to 53 in. of rainfall. In 1890, the rainfall was 44 in., in 1891, 41 in., in 1892, 47 in., in 1893, 45 in., in 1894, 46 in., in 1895, 44 in., in 1896, 41 in., in 1897, 44 in., in 1898, 43 in., in 1899, 42 in., in 1900, 42 in. Seventeen inches, or more than one-third, falls during the summer, and for the other seasons the range is only from 10 in. for autumn to 10 in. for winter. This is a phenomenon that is very uncommon in the south-east of the state, and whenever there is rainfall the same effect is performed on the same day as it falls; but in the centre and north-west occasionally covers the ground to a depth of several inches. The prevailing winds change in the west along the coastal plain and from the north-east in the uplands. Rains and fogs sometimes occur in the west section, and the east section occasionally suffers from West Indian hurricanes. 

**Soil.**—In general the soils of the Piedmont Plateau region such as have been formed by the disintegration of the under-lying rocks. These consist mostly of granite and grueith, but in the north-central section there is trap-rock, and in the south-east the alluvial plain. The soils of the Coastal Plain region are a reddish or yellowish clay. In the upper section of the Coastal Plain region the soil is for the most part a loose sand, but lower down it becomes a loam turned brown by the action of air and by more fertile topsoil. 

**The special census of 1905 was confined to manufacturers under the federal system, and the statistics above for 1900 have been reduced to the same standard to make them comparable with the statistics for 1905.**
1905, 59,441. Except in number, the rural establishments showed greater increases than the urban. The number of farms was 135,006 in 1905; in 1897, 129,449; and the number of urban establishments in 1905, 195; in 1905, 220; but the capitalization of the rural establishments increased from $50,457,928 in 1900 to $107,099,898 in 1905; while the urban establishments were increased from $12,662,165 to $15,480,093; the value of the products of the rural establishments increased from $4,930,816 to $6,887,748; while that of the urban establishments increased from $2,647,518 to $5,981,369. In 1905 the value of the products in rural establishments increased from $6,616,506 to 50,744, while those in urban establishments increased from 7909 to 8097. More than half of the manufacturing establishments were in the manufacturing cities, of which the chief are Charleston, Greenville, Sumter, Anderson and Rock Hill. The manufacture of cotton goods was much the most important industry in 1905 and 1905, and showed a remarkable growth. The capital invested in this industry was $39,258,946 in 1900 and $63,337,429 in 1905; the value of the products was $29,723,919 in 1900 and $49,437,644 in 1905; the average number of wage-earners was 30,201 in 1900 and 37,271 in 1905; and the amount of wages, $5,666,830 in 1900 and $7,701,689 in 1905. The number of establishments was 80 in 1905; the number of producing spindles in 1900 was 1,431,349, and in 1905, 2,864,092; and the number of looms in 1900, 42,653, and in 1905, 72,702. The use of domestic cotton increased from 485,824 bales to 776,379 in 1905 and for foreign cotton increased from $14,909,520 to $30,451,189. In the same period the amount of foreign cotton used increased from 210 bales in 1900 to 776,379 in 1905, and the consumption of it from $2,218,020 in 1900 to $31,020,189. The principal market for the mills of the state was plain cloths for printing or converting, of a quality finer than No. 20 warp, of which there were produced 322,980,981 sq. yds., valued at $1,712,626, in 1897, as compared with 97,341,586 sq. yds., valued at $3,171,198 in 1900. Other products and their values in 1900 and 1905 were as follows: brown or bleached sheetings and shirtings, 315,104,393 sq. yds. ($1,133,075) in 1900 and 249,777,474 sq. yds. ($1,203,384) in 1905; yarns for, 31,045,189; the value of 555,467 cars of cotton in 1900 was 2,636,090,000; in 1905, 2,936,000,000. The number of railroad passengers increased from 37,271,583 to 59-9% of the total, or 782,321, were negroes or of Negro descent, and 401-6% were whites; but there was a slight fall-off in the percentage of negroes, this having been 59-9% in 1890. Of the total population, 99.6% were native-born. Therefore, in 1890, 554,436 native whites, 5,528 persons of foreign birth, 121 Indians and 67 Chinese. Of the inhabitants born in the United States, 52,521 were natives of North Carolina, and 13,544 were natives of Georgia, and of the foreign-born 2075 were Germans, and 1131 were natives of Ireland. Of the total population, 17,628 were of foreign parentage—i.e. either one or both parents were foreign-born—and 2503 were of German and 1697 of Irish parentage on both the father's and the mother's side. In 1905 there were in the state 65,933 members of different religious denominations, of whom the Baptist bodies were the strongest with 341,456 communicants; the Methodist bodies had 249,169 communicants; the Presbyterians, 53,533; the Roman Catholics, 12,652; and the Episcopalians, 19,317. The chief cities are Charleston, Columbia (the capital), Spartanburg, Greenville, Sumter, Anderson and Rock Hill.

Admission.—South Carolina was governed from 1670 to 1719 under the Carolina provincial charter of 1665, from 1719 to 1776 under commissions and instructions from the Crown, and after 1776 under the constitutions of 1776, 1778, 1790, 1826, 1865, 1868 and 1895. An amendment to the constitution may be proposed by either house of the legislature; if it is approved by two-thirds of the members elected to each it must then be submitted to the people to be voted on at the next general election for members of the state house of representatives; and if it receives a favourable vote of a majority and subsequently a majority vote in each house of the next general assembly it becomes part of the constitution. A constitutional convention to revise the constitution may be called by a two-thirds vote in each house, subsequently ratified by a majority vote of the electors of the state.

Effective protection against a possible restoration of negro rule seems to have been aimed at in the suffrage provisions of the new constitution. Two plans of registration were provided, one temporary, the other permanent. Up to the 1st of January 1898 all persons of whatever race could register; provided they could read any section of the constitution or understand and explain it when read to them by the registration officer, and all persons so registered were qualified voters for life. The obvious intention was to disfranchise illiterate negroes, but not illiterate whites. Under the permanent plan, however, this distinction will gradually disappear. Those who should apply for registration after the 1st of January 1898 must be able to read and write the constitution submitted to them by the registration officer, or must show that they have paid all taxes for the previous year on property worth $300 or more. Other requirements for voters

1 In this class are included the manufactures of only four cities, Charleston, Columbia, Greenville and Spartanburg, which in 1900 had populations of 50,000 or more.
are: residence in the state for two years (except that ministers in charge of organized churches and teachers of public schools need have a residence in the state of six months only), in the county for one year, and in the polling precinct for four months, and the payment six months before election-time of a poll-tax. Idiots, insane persons, paupers, convicts and persons convicted of certain crimes (enumerated in the constitution) and not pardoned by the governor are disqualified from registering or voting.

Under the constitution of 1895 the governor holds office for two years and is eligible for re-election. The governor and the lieutenant-governor must be thirty years old and must have been citizens of the United States and citizens and residents of the state for five years. The governor has a veto power, extending to the separate items in appropriation bills, which may be overcome by a two-thirds majority in each house of the General Assembly; he may also be allowed to the governor for vetoing bills or joint resolutions passed by the General Assembly, or only two days if the General Assembly adjourn before three days have elapsed. The lieutenant-governor is the presiding officer of the senate, and succeeds the governor if the governor is removed from office by impeachment, death, resignation or otherwise. Other administrative officers of the state, each elected for two years, are a secretary of state, a comptroller-general, an attorney-general, a treasurer, an adjutant and inspector-general, and a superintendent of education. The legislature, officially styled the General Assembly, and is composed of a Senate and a House of Representatives. The House of Representatives is composed of 124 members elected every two years and apportioned among the counties according to population; the Senate of one member from each county, elected for a term of four years, the term of one-half of the senators ending every two years. Annual sessions of the General Assembly are held, beginning on the second Tuesday in January. In 1904 the legislature submitted an amendment providing for biennial sessions and it was ratified by a popular vote in 1904. The new constitution provides in the event of a vacancy in the Senate, the governor by joint ballot with the lieutenant-governor, shall fill said vacancy. The question came up again in the session of 1905. Attention was then called to the fact that the new amendment would make other changes in the constitution necessary, and the matter was referred to a legal commission.

The judicial power is vested in a Supreme Court and two circuit courts, a court of common pleas having civil jurisdiction, and a court of general sessions having criminal jurisdiction. The supreme court consists of a chief justice and three associates, elected by a joint vote of the General Assembly for a term of four years. Each of the circuit judges is elected in the circuit for the term of four years. The magistrates or justices of the peace are appointed by the governor—a wise provision, because under the constitution of 1868 negroes were frequently elected who could neither read nor write.

Local Government.—The unit of local government in South Carolina is the county, which, the state constitution provides, "shall be a body politic and corporate." The constitution also provides for the establishment of a new county, "whenever one-third of the qualified electors within the area of each section of an old county proposed to be cut off from a new county shall petition the General Assembly for the establishment of such new county. The governor shall order an election within a reasonable time thereafter, and if two-thirds of the voters vote "yes," the General Assembly at the next session shall establish the new county provided that no section of a county shall be cut off without the consent of two-thirds of those voting in such section; that no new county shall contain less than one hundred and twenty-four, the whole number of inhabitants of the state, nor shall it have less assessed taxable property than one and one-half million dollars, nor shall it contain an area of less than four hundred square miles; and that no old county shall be reduced to less area than one hundred and twenty-four square miles, to less assessed taxable property than two million dollars, nor to a smaller population than fifteen thousand inhabitants." The General Assembly may also provide for the consolidation of two or more counties if a majority of the voters concerned approve, but such election shall not be held oftener than once in four years in the same counties. Counties are divided into townships and under the constitution each "shall constitute a body politic and corporate," but in 1910 there were no separate township governments. The county (except the existing districts of towns) is the purpose of convenience in adjusting taxes. Municipal government machinery is prescribed by a general state law which provides for the acquisition by municipalities of waterworks and lighting-plant companies, for levying and collection of taxes, registration and licences, and regulates bonded debts. Cities and towns are permitted to exempt, by ordinance, certain classes of manufactories from taxation, and provided such ordinances are ratified by a majority of the electors.

Miscellaneous Laws.—The elaborate precautions taken to prevent lynching are a peculiarity of the constitution of 1895. Any officer—state, county or municipal, through neglect or connivance, permitting a person to be seized and lynched, thereby becomes ineligible to hold any office of trust or profit in the state unless pardoned by the governor. The county in which the crime occurred, without recommendation for a pardon, shall pay all damages of not less than $2000 to the legal representative of the person lynched; the county is authorized, however, to recover this amount from the persons engaged in the lynching. A fourth feature is that South Carolina has applied the principle of direct primary nominations to all elective officials from governor down. United States senators are in practice elected by the people, for the legislature merely registers the result of the primary. Since an absolute majority of the votes is required, it is often necessary to hold a second primary in which only the two leading candidates are considered (see act of the 22d of December 1888, and corresponding acts of 1895 and 1897). The act of 1888 prescribed that in each county, where disfranchisement of registered voters is not allowed to be a basis of disfranchisement of county officers, the governor, or in his absence, the mayor or sheriff of the county in which the office is not allowed in any circumstances; this is a constitutional provision. Divorces were not permitted before 1868 and the provisions of the constitution of that year and of an act of 1885 (holding diversions of marriage from two years) were repealed in 1878. A married woman may hold, acquire and dispose of property as if she were single, and the descent of the estate of a husband dying intestate is the same as that of a widow dying intestate, the survivor being entitled to one-third of the estate if there are one or more children, and to one-half of the estate if there are no children or other lineal descendants. Terminal courts (courtesy is a terminal court) were abolished in 1880, except as to the credible debt of a major, or to the husband and wife jointly are exempt from attachment, levy or sale except for taxes, purchase money or debts contracted in making improvements or repairs. The exemption of the homestead continues for the benefit of the widow or for the children alone, while minors or not, provided it is occupied by some of them, and it may be partitioned among the children regardless of debts. The number of hours' labor for operatives and employes in cotton and woolen mills is limited to sixty a week and must not exceed eleven in any one day, except for making up lost time to the extent of sixty hours in any one year. A prohibition bill introduced in the legislature in 1895, was defeated. The state adopted a Tillman Reform plantation, replaced by a substitute measure, which established a dispensary system, based upon the Gothenburg plan. This system went into effect in July 1893 and was in force for four years, when the bill was defeated. The act is in accordance with a chemical analysis, and sold them to consumers in packages of not less than one half-pint; the dispensaries were open from June to September. The state would, by its own laws, not to 15 per cent; and no liquor was drunk on the premises; there was a state dispensary commissioner and a state board of control; and the profits were divided between the state, the counties and the municipalities, the share of the state being devoted to educational purposes. The state dispensary was opposed by the old conservative faction, by the saloon keepers, and by the radical prohibitionists. The Supreme Court of the state by a vote of two to one, founded in Aid of the state laws in the enforcement of the act, but in October a change in the personnel of the court brought about a reversal. The Supreme Court of the United States held that the act of 1897 that the provisions of the statute forbidding the importation of liquor by anyone except certain state officials were in violation of the interstate commerce clause of the constitution (Scott v. Donald, 165 U.S. 58). Under the Brice act, in 1904, the legislature of each county of each county of each county the choice between dispensary and prohibition, with the proviso that if they adopt the latter they must pay the extra taxes necessary to enforce it, several counties adopted prohibition; all pari-mutuel licenses were declared contraband, each county was required to vote to prohibit the sale of liquor or to establish a dispensary, the sale of intoxicating liquors by retailers and dealers may be made only through county dispensaries, which may not sell at night or on Sunday, or to inebriates or minors. The constitution of 1895 forbade a restoration of prohibition; under the law of 1896 the sale of alcohol made it a misdemeanor to solicit orders for liquor in the state.
Education.—As early as 1710 public school education was provided for indentured children. The present free-school system was established in 1868. The educational system is under the supervision of the state department of education, whose officers are under the control of a board composed of the governor and not exceeding seven other persons appointed by the governor. The constitution of 1895 ordered a three-levy school. The present high-school system dates from 1818. In 1909 there were 990 public schools, six of which required a full four-years course. The per capita expenditure according to enrollment was $4-98 for each white pupil and $1-37 for each negro. In 1909 it was $10-34 for each white pupil and $1-70 for each negro. The schools are supported by taxation; they formerly received the profits from the dispensary. The maximum local tax levy is eight mills. Under Fleming's school law (1817), which with developments in agriculture, chemistry, mechanics and electricity, textiles and military, and academic and preparatory courses: Winthrop Normal and Industrial College for Girls (1865) at Rock Hill; and the Coloured Normal Institute (1867) at Columbia, South Carolina. The University of South Carolina College of Medicine at Orangeburg. Among the other higher institutions of learning are the college of Charleston (1749, non-sectarian), Newberry College (1856, Presbyterian); College of the Holy Cross (1858, Baptist) at Columbia, South Carolina College of the Holy Cross (1858, Baptist); The College of Charleston (1872, non-sectarian) at Charleston, South Carolina; and the College of Charleston (1876, Methodist Episcopal South) at Spartanburg; for women, Converse College (1890, non-sectarian) at Spartanburg, the College for Women (1896, Presbyterian) at Columbia, Columbia College (1889, non-sectarian) near Columbia, Greenville Female College (1884, Baptist) at Greenville; and, from 1854 until 1890, the College of the Charleston County, and until 1904 the Williamson Female College,Methodist Episcopal South at Greenwood, and the Due West Female College (1859, Associate Reformed Presbyterian) at Due West; and for negroes, Claflin University (1869, Methodist Episcopal South); South Carolina A&M College (formerly Allen University) (1881, African Methodist Episcopal) at Columbia, and several normal and industrial schools. There are theological seminaries at Columbia (1829, Presbyterian), at Due West (1837, Associate Reformed Presbyterian), and at Mount Pleasant (1898, Lutheran).

Charities, etc.—The state has no board of public charities, and under the present constitution the county commissioners are over-seers of all charitable institutions. In Charleston and other towns are provided for by the municipal authorities. The county commissioners of each county have charge of the poor-house of the county, and appoint and remove the examiners, and an examiners and report annually to the judge of the Court of General Sessions, who submits this report to the grand jury. Each poor-house must have sufficient tillable land to give employment to all paupers who are capable of labor. There is an asylum for the aged, sick, and blind (1849, since 1875 a state institution) at Cedar Springs, and a state hospital for the insane, founded in 1821 at Columbia by Samuel Farrow (1760-1824) and opened in 1828. The state penitentiary is also at Columbia.

Finance.—The revenues of the state are derived mainly from the general property tax, fees, licences, dispensary profits and phosphate royalties. At the beginning of the Civil War the public debt was $8,514,862-91 and the credit of the state was bound. The obligations contracted in support of the war, amounting to about $3,000,000, were of course nullified by the Fourteenth Amendment. There were so many irregularities and so much corruption connected with the collection of these issues that it was impossible to discover their exact amount. Estimates of the total debt in 1872 vary from $28,000,000 to $33,000,000. The first step towards repudiation was taken by the "carte-blanche" legislature of 1873, when it provided for the issue of consolidated bonds to replace the outstanding obligations at the rate of fifty cents on the dollar. Nearly six million dollars worth were declared null and void on the first presentation at the market by the owners. The Democrats to power in 1877 a further investigation was made and the government finally assumed responsibility for $6,406,606. The greater part of this was funded under an act of October 1892, and $6,356,885 was paid out and authorized to be paid further in 1899 by a tax on phosphate beds. In 1909 the funded debt amounted to $6,356,885. The legislature is forbidden to create any further debt without a special act of the state, unless the proposition be submitted to the voters of the state and by a two-thirds majority. After the abolition of the state dispensary system in 1907 a State Dispensary Commission was created for winding up the business of the dispensary and distributing about $900,000 (of which $100,000 was still due) of dispensary funds. Two companies brought suit for money owed for liquor sold to the state dispensary; the commission resisted the suit on the ground that as a court and as a representative of the state it could not be sued; the circuit court and the circuit court of appeals overruled this plea and put the funds into the hands of a receiver; in April Court of Appeals held that the suit was not maintainable in the Federal Supreme Court, upholding the commission and restoring to it the fund. Banks are subject to the supervision of an examiner and in addition are required to make weekly reports to the comptroller-general.

History.—The history of South Carolina may be divided into four main periods: the period of discovery and exploration (1520-1653); the period of proprietary rule (1663-1719); the period of royal rule (1710-1776); and the period of statehood (from 1776). The first Europeans to visit the coast were a party of Spaniards from Cuba in 1520. In 1562 some French Protestants under Jean Ribault made an unsuccessful attempt to establish a colony near the mouth of the Broad river (see Port Royal). In 1629, Charles I. granted to his attorney-general, Sir Robert Heath, all the territory lying between the 31st and the 36th parallels and extending from sea to sea, but no settlement was made, and in 1663 the same territory was offered to the Dutch who refused to enter into the scheme. The colony of Carolina was chartered by Charles II. in 1672. The charter extended the authority of the crown to the extent of the 30th parallel (1621-1683) prepared for the colony a elaborate feudal system of government which would have been obsolete even in Europe (see North Carolina). Subsequent issues in 1670, 1682 (Jan. 12), 1682 (Aug. 17), and 1698 modified the original plan to some extent. The constitutions possess more than a mere antiquarian interest. They helped to arouse that feeling of discontent among the colonists which culminated in the overthrow of proprietary rule, and they encouraged the large plantation system which constituted the foundation of the slave-holding aristocracy.

The first permanent English settlement was made in April 1670 at Albemarle Point, on the west bank of the Ashley river, but as the situation proved unfavourable the government and most of the people moved over in 1680 to the neck between the Ashley and the Cooper rivers, the site of the present city of Charleston. The area of settlement was gradually extended along the coast in both directions, but did not penetrate far into the interior. The province was soon divided into three coast counties: Berkeley, extending from the Stono river to the Santee and including Charleston; Craven to the north of the Santee and Colleton to the south of the Stono. In addition to those settlers who came direct from England there were many Englishmen from Barbadoes and French Protestants, both of which classes exercised considerable influence upon the history of the colony. It was largely due to the Barbadian connexion that South Carolina was for many years more closely associated with the island than with the continental colonies. Her political history during the colonial era is the story of a struggle between popular and prerogative interests, first between the people and the lords proprietors, later between the people and the Crown. In 1739 the proprietors and the Crown finally and finally raised the question of the propriety of the Carolina cake for the use of the colony. The right to hold a suffrage, to seek redress of grievances, and to vote and to be voted for the house of commons and the governor and lieutenant-governor was secured by the constitution of 1705, and this franchise was maintained in 1729. The first African slaves were brought to the colony in 1620. The abolition of slavery was delayed by the legislature until 1790, when it was finally abolished by a two-thirds majority. The 3rd of January, 1865, the General Assembly passed an act declaring the abolition of slavery from the state, to take effect immediately. This act was finally declared unconstitutional by the United States Supreme Court, and the state was forced to assume the cost of maintaining the freedmen. The state was subsequently divided into two parts, and in 1861 the common house, elected by the people, secured the privilege of initiating legislation. The truce was followed by a controversy
between Churchmen and Dissenters. A test act requiring members of the assembly to conform to the Church of England and to take the sacrament of the Eucharist according to the rites and usages of that Church (1704) was defeated only through the intervention of the Whig House of Lords in England. By an act of the 30th of November 1706, which remained in force until the War of American Independence, the Church of England was made the established religion. After a few years of peace and prosperity there came another attack upon the proprietors which culminated in the revolution of 1719 and the downfall of proprietary rule. Acting on the advice of Chief Justice Nicholas Trott (1663-1740) the proprietors adopted a reactionary policy, vetoed several popular laws, and refused to afford protection from the attacks of the Indians. The people rebelled, overthrew the existing government and elected their leader James Moore (1667-1729) as governor. The result of the revolution was accepted in England, and the colony at once came under royal control, although the rights of the proprietors were not extinguished by purchase until 1720. Theoretically South Carolina and North Carolina constituted a single province, but, as the settlements were far apart, there were always separate local governments. Until 1691 each had its own governors, from 1691 to 1712 there was usually a governor at Charleston and a deputy for the northern settlements, and after 1712 there were again separate governors. The first attempt to define the boundary was made in 1732, but the work was not completed until 1785.

The change from proprietary to royal government scarcely affected all the constitutional development of the province. The popular branch of the assembly continued to encroach upon the powers of the governor and council. By 1760 the council had almost ceased to exercise any real control over legislation. They rarely initiated or amended a bill of any kind, never a revenue measure. Public officials chosen nominally by the General Assembly were really the nominees of the lower house. In the conduct of his executive functions the governor found himself constantly hampered by committees of the Assembly. In other words, whatever they conceived of as the factors not the South Carolinians throughout the colonial era were tending towards independence. The demands of the British government after 1760 were not especially unreasonable or tyrannical, but they were made upon a people who were too long accustomed to having their own way. As the spirit of rebellion developed the sentiment in favour of colonial union gained in strength. Thomas Lynch (c. 1720-1776), Christopher Gadsden (1724-1803), and John Rutledge (1739-1800) attended the Stamp Act Congress of 1765, an intercolonial committee of correspondence was appointed in 1773, and delegates were sent to the Continental Congress in 1774 and 1775. A council of safety appointed by a Provincial Congress practically took charge of the government in June 1775. The Assembly was formally dissolved on the 15th of September. Governor William Campbell (d. 1778) fled from the town, and royal government came to an end. In the conflict with the mother country the people had the advantage of long experience in fighting. There had been wars with the Spanish in 1686, 1702-04, 1740, with the Spanish and French in 1706, with pirates in 1718, with the Yemasse Indians in 1715 and the Cherokees in 1760-61, and a slave uprising in 1739. The state suffered severely during the War of Independence, the numbers and influence of the Loyalists serving to embitter the conflict. In the summer of 1776 the British, under Sir Henry Clinton and Sir Peter Parker attempted to capture Charleston and summon the South Carolinians to their standard, but on the 28th of June the fleet was repulsed in an assault on Fort Moultrie. Clinton returned, however, early in 1780, and, as he surrounded the city on all sides with an overwhelming force, General Benjamin Lincoln, who was defending it with about 7000 men, surrendered (May 12) to avoid certain destruction. The British thenceupon continued southward, destroyed all until and until near the close of the war a new American army, first under Horatio Gates and later under Nathanael Greene, was engaged in driving them out. The principal engagements fought within the state were Camden (Aug. 16, 1780), King's Mountain (Oct. 7, 1780), Hobkirk's Hill (April 25, 1781), and Eutaw Springs (Sept. 8, 1781).

The most significant feature in the early history of the state was the struggle between the Low Country, which centred including Charleston, and the Up Country, which was settled largely by Scotch-Irish, who came down the mountain valleys from North Carolina, Virginia and Pennsylvania. The great planters of the low country had wealth, the small farmers of the up country had numbers. Under the first state constitution, adopted in March 1776, the low country element maintained the ascendency which they had possessed during the colonial period. In 1786 they were forced to consent to the removal of the seat of government to Columbia (final removal, 1790) and in 1808 to a reapportionment of the representation, based partly on wealth and partly on numbers. There was to be one representative for every sixty-sixths and part of the whole number of white inhabitants of the state and one for every sixty-second part of the taxes raised by the legislature. More harmonious relations were in time established, partly because of improvements in the methods of transport, but mainly as a result of outside pressure in the form of criticism of slavery and the adoption by the national government of an economic policy which favoured the manufacturers at the expense of the agricultural interests. In 1832 there was a majority from each section in favour of Nullification (q.v.), and the legislature called the famous Nullification Convention (April 7-10, 1832), at which the ordinance of November 1832 was formally passed. The ordinance declared that certain acts of Congress imposing import duties “are unauthorized by the Constitution of the United States and violate the true meaning and intent thereof, and are null and void and no law, nor binding upon this state, its officers or citizens.” President Jackson was ready to use force against the state; and the tariff, over which the whole disagreement had arisen, was changed in such a way as to effect a compromise with the state. From about 1828 to 1861 South Carolina superseded Virginia as the leader of the South. She stood for states' rights and federal power. John C. Calhoun was her political philosopher and George McDuffie her political economist. Her secession, on the 29th of December 1860, was followed by the formation of the Southern Confederacy, the bombardment of Fort Sumter (April 12, 1861) and the Civil War (1861-65). Although few battles were fought within her limits, because of the distance from the frontier, South Carolina made many sacrifices in the interest of her section. With a white population of 291,300 at the beginning of the conflict, the state put into the field during the four years 62,858 effective men, with an enrolment, including whites and blacks, of 84,800 men, and 3000 whites and negroes, Northern adventurers and disreputable native whites. There followed an orgy of crime and corruption. The Assembly Hall was furnished with clocks costing $600 dollars each, sofas at $200, and other articles in proportion. A restaurant and bar were kept in the State House at which the members of the legislature and their friends could procure refreshments free of cost. The debt of the state was increased from $5,000,000 in 1868 to more than $18,000,000 in 1872. Crime among the negroes became so frequent that the whites were compelled to have their property insured (see Klu Klux Klan). In the spring of 1868 the state adopted a new constitution in conformity with the Reconstruction Acts of Congress, and elected state officers and congressmen, and on the 25th of June the state was readmitted
to the Union. The inauguration of General Wade Hampton (1818–1902) as governor, and the final withdrawal of United States troops in 1877, marked the downfall of negro rule.

The political history of the state since 1877 presents some interesting features. Practically the entire white population is Democratic, partly for historical reasons and partly because of a feeling that union is necessary to maintain white supremacy. The old warfare between the Up Country and the Low Country has been renewed in a modified form in the conflict between Reformers and Conservatives. The triumph of the Reformers culminated in the founding of Clemson Agricultural College (1889), the establishment of the state dispersive system for the sale of intoxicating liquors (1893), the election of Benjamin R. Tillman (b. 1847) to the United States Senate (1894) over M. C. Butler (1836–1900), and the work of the constitutional convention of 1895.

BIBLIOGRAPHY—For general description see Michael Tumey, Report on the Geology of South Carolina (Columbia, 1848), the Handbook of South Carolina; Resources, Institutions, and Industries of South Carolina, published by the State Department of Agriculture, Commerce and Immigration (Columbia, 1907; 2nd ed., 1908), the Annual Reports of the same department and its other publications; and W. G. Simms, Geography of South Carolina (Charleston, 1807). For Administration see D. D. Wallace, The Civil Government of South Carolina (Dallas, 1906); E. L. Whitney, Government of the Colony of South Carolina, in Johns Hopkins University Studies, 1st ser., 1896; E. B. Rutledge, Local Government of South Carolina (Charleston, 1899); B. C. Peach, Free Schools in South Carolina, in Johns Hopkins University Studies, vol. 1, no. 12 (Baltimore, 1883); Colyer Meriwether, History of Higher Education in South Carolina (Washington, 1889), in Circulars of Information of the United States Bureau of Education, No. 3. There is no general history of South Carolina. The standard work for the colonial period is Edward McCrady's The History of South Carolina under the Proprietary Government, 1670–1710 and his History of South Carolina under the Royal Government, 1719–1776 (ibid. 1899), which are accurate and interesting, but neglect the manuscript sources at Columbia. Other histories are Alexander Hewitt, Historical Account of the Rise and Progress of the Colonies of South Carolina and Georgia (London, 1779), freely used by later writers; David Ramsay, History of South Carolina (2 vols., Charleston, 1809), little more than a reprint, without acknowledged, of Hewitt; and William J. Rivers, Sketch of the History of South Carolina to the Close of the Proprietary Government, 1719 (Charleston, 1860), which was utilized by McCrady in his first volume and was the first history of the colony. In historical periodical work in the United States, the most distinctive and political in character are three doctors' monographs: Edson L. Whitney, Government of the Colony of South Carolina (Baltimore, 1853), based too exclusively on the statutes; D. D. Wallace, Constitutional History of South Carolina from 1670 to 1773 (Charleston, S. C., 1899; new ed., 1908), a very brief summary; and W. Roy Smith, South Carolina as a Royal Province, 1719–1776 (New York, 1903), based on the manuscript sources at Columbia. The standard work for the War of Independence is Edward McCrady, The History...
of South Carolina in the Revolution, 1776-1783 (2 vols., New York, 1901). Other books on the subject are: History of the Revolution of South Carolina from a British Colony to an Independent State (2 vols., Trenton, 1873); William Moultrie, Memoirs of the American Revolution, so far as it relates to the States of North and South Carolina (2 vols., Charleston, 1821); and R. W. Gibbes, Documentary History of the American Revolution (3 vols., Columbus, 1854). A very lurid account of the period is given by John Drayton, Memoirs of the American Revolution relating to the State of South Carolina (2 vols., Charleston, 1821); and R. W. Gibbes, Documentary History of the American Revolution (3 vols., Columbus, 1854). The last is a direct translation from the extreme nationalistic and anti-slavery point of view. For the Civil War and Reconstruction, see James Ford Rhodes, History of the United States from the Compromise of 1850 (5 vols., New York, 1893-1901); James S. Pike, The Prostrate State; or South Carolina under Negro Government (New York, 1874); Carl Schurz, Report on the States of South Carolina, Georgia, &c. (Washington, 1865, being 39th Congress, 1st session, Sen. Ex. Doc. 2); Hillary A. Herbert and others, Why the Solid South? (Baltimore, 1890); and John P. Hollis, The Early Period of Reconstruction in South Carolina (Baltimore, 1905), containing an excellent discussion of the period from 1865 to 1868. For the religious history see Frederick Dalcho, An Historical Account of the Protestant Episcopal Church in South Carolina from the first Settlement of the Province to the War of the Revolution (Charleston, 1820); G. D. Bernheim, History of the Church of England in the State of South Carolina (Friendship, 1811); and the North Carolina Colonial Records (10 vols., Raleigh, 1886-1890), useful for the early period; B. R. Carroll, Historical Collections of the South Carolina Historical Society Collections (5 vols., Charleston, 1857, 1858, 1859, 1887 and 1897—vol. v. contains the Shaftesbury Papers).

SOUTHCOTT, JOANNA (1750-1814), English religious fanatic, was born at Gitt sham in Devonshire. Her father was a farmer and she herself was for a considerable time a domestic servant. She was originally a Methodist, but about 1792, becoming persuaded that she possessed supernatural gifts, she wrote and dictated prophecies in rhyme, and then announced herself as the woman spoken of in Rev. xii. Coming to London at the request of William Sharp (1749-1824), the engraver, she began to "seal" the 144,000 elect at a charge varying from twelve shillings to a guinea. When over sixty she affirmed that she would be delivered of Shiloh on the 19th of October 1814, but Shiloh failed to appear, and it was given out that she was in a trance. She died of brain disease on the 20th of the same month. Her followers are said to have numbered over 100,000, and only became extinct at the end of the 19th century.

SOUTHCOTT—SOUTH DAKOTA

portion a part of the Prairie Plains region, and its western portion a part of the Glacial Plains. The surface of this plain, however, varies from level to gently undulating in the east and south, where it has been washed by waters and which rises to a height of 7216 ft. The state as a whole has a mean elevation of 2000 ft., with 270 sq. m. below 1000 ft.; 42,300 sq. m. between 1000 and 2000 ft.; 23,000 sq. m. between 2000 and 3000 ft.; and 19,800 sq. m. between 3000 and 5000 ft.; and 1360 sq. m. between 5000 and 8000 ft.

In the extreme north-east there is a range of low hills known as the Coteau des Prairies, which encloses the state in a S.S.E. direction through Marshall, Roberts, Grant, and Barnes counties and maintains an almost constant altitude of from 1950 to 2050 ft. It forms the divide between the headwaters of the Minnesota and the Red River of the North, the latter flowing south and west of the Coteau des Prairies lie vast stretches of plains, including the valleys of the Big Sioux and James rivers. This region presents no striking topographic features except the numerous small lakes which occupy the hollows created by the continental ice-sheet. The greater part of the James River Valley lies in the bed of the extinct Lake Dakota, which was once a very extensive body of water, and a plain, from 150 to 300 ft. above the valleys; the latter and the flat tops of the mesas are sometimes covered with a scanty soil and a sparse growth of grass. These Bad Lands were once a fairly level plain, but Intricate stream erosion produced a series of ridges and gorges on a scale of small proportions. The Bad Lands of the White River are also noted for their wealth of animal fossils, which have been found in such quantities as to show that the strata to which they belong were deposited by the Missouri during the Pliocene period. The surface of the Missouri River varies from 150 to 600 ft. above the plains, and between this river and the hills proper lies the Red Valley, a tract about 3 m. wide and bordered on the inner side by the main mass of limestone and crystalline rocks which have in general a height of 4000 or 5000 ft. above the sea—some ridges and peaks rise higher still. Upon this limestone plateau there is a central area of high ridges, among them the rough crags of Harney, Custer and Dodge peaks. Between the ridges of the central area and the plains and badlands, narrow and winding valleys have cut deep gorges and canyons, and among the ridges the granitic rocks have assumed many strange forms. Though rising from a semi-arid plateau, these mountains have sufficient rainfall to make an abundant vegetation, and have derived their name from the fact that their slopes are dark with heavy forests. Cathedral Park in the southern portion, Spearfish Canon in the central area, and many other similar sites are well worthy of notice: while the Crystal Cave, near Piedmont, and the Wind Cave, near Hot Springs, are almost unrivalled.

With the exception of the extreme north-east, the state lies within the Great Plains system, and its streams enter the state near the centre of the northern boundary, pursing a winding south-easterly course, and from its intersection with the 43rd parallel of N. lat. to its junction with the Missouri River from 200 to 400 m. The Big Sioux river rises in the Coteau des Prairies in the north-east and flows almost directly south for nearly 200 m., in the lower part of its course forming

SOUTH DAKOTA, one of the North Central states of the American Union, lying between 42° 28' and 45° 57' N. Lat. and 96° 26' and 104° 3' W. long. It is bounded N. by North Dakota; E. by Minnesota and Iowa; S. by Nebraska; and W. by Wyoming and Montana. Lake Traverse and the Big Stone Lake separate the state in part from Minnesota; the Big Sioux River forms most of the boundary between South Dakota and Minnesota, and the Missouri River separates the state from Nebraska. South Dakota has an extreme length, east and west, of 380 m., an extreme width, north and south, of 224 m., and a total area of 77,615 sq. m., of which 747 sq. m. are water-surface.

Topography.—With the exception of the Black Hills district in the south-west, the state is a wide rolling plain, with its eastern
the boundary between South Dakota and Iowa. To the west of the river, the parallel sierras of the James and Big Sioux river, which rises in North Dakota and follows a general course southward until it joins the Missouri river near Yankton. From the west the Missouri receives the Grand, Moreau or Owl, Cedar, and Cheyenne rivers. Of these the Blue is the most important, being formed by two branches, the Belle Fourche and the South Fork, which, after almost completely encircling the Black Hills, unite at a point nearly 35° north of the 100° west meridian. South Dakota is drained in its lower courses through seepage and evaporation. The Minnesota river has its source in the north-east, and the Big Stone Lake which occupies about 25 sq. m. in its basin, and is a connecting link between its headwaters and the rest of the stream. North of this lake lies Lake Traverse, 27 m. long and 3 m. wide, whose waters flow north into the Bois de Sioux river, whence they flow into the Mississippi. The waters of the upper Missouri of South Dakota east of the Missouri river is dotted with numerous lakes, ranging from small ponds to bodies of water from 10 to 15 m. in diameter. The plains, except in the south-east corner, are made up by sheets of water-bearing sandstone, which carry a volume of water under such pressure that in the valleys of the James river and the Missouri river and its western tributaries a strong surface flow may be obtained from artesian wells. In the region south of the thousand wells had been sunk east of the Missouri, and the flow was estimated at 7,000,000 gallons per day. 

Fauna and Flora.—Large game within the state is practically extinct. However, the size of the game that remains is such that the prairies have vanished, but a few mountain sheep still graze on the grass-covered mesas in inaccessible portions of the Bad Lands. There, too, the grey (or timber) wolf and the coyote are found. The smaller wild animals do not differ from those found in other parts of the Middle West.

The total woodland area has been estimated at 2500 sq. m., about 32% of the area, and is restricted to the hills in the Hills district. All the higher lands of this area are covered by forests; but the Red Valley, lying between the ridges and the main upland, is treeless. Most of the forest consists of poplar, pine, birch, spruce, aspen, white birch, and the older, red cedar, white elm and cottonwood are among the other varieties found. With the exception of narrow strips of woodland along the courses of the larger streams, the rest of the state consists of grassland, which are usually covered with bunch-grasses. In the more arid regions the sage-brush and cactus make their appearance. Two national forests contained (190) 2222 sq. m. in 1905.

Climate.—The climate of South Dakota is of a continental type. Owing to the northern latitude, comparatively high altitudes, and the great distance from the ocean, there are great annual variations of temperature and a very small amount of rainfall. The state is coldest in the northeastern and warmest in the region south of the Cheyenne and west of the Missouri river. The isothermal lines trend from south-east to north-west. The winters are long and marked by exceedingly low temperatures, but as they are driest and, in the central and eastern parts of the state, they would be in a more humid region. The mean winter temperature ranges from 13°F. at Aberdeen in the northern part of the state during the month of January. On the average, it is lowest in January, being 3°F. below zero. The mean temperature for January is 68° with an extreme record of 104°; the mean for the winter is 15° with an extreme record of -41°. At Ashcroft, in the extreme north-west, the annual mean temperature is 44°; the mean for the summer is 68°; and for the winter 4°, while the highest and lowest temperatures ever recorded are respectively 114° and 44°. The average annual amount of rainfall for the state is about 20 in., ranging from 13-9 in. at Ashcroft to 29 in. at Aberdeen. It is usually greatest in the valleys of the James and Big Sioux rivers and least in the extreme north-central and northwestern parts of the state. The average amount of rainfall for the spring is 6.5 in. While wheat is the state's largest product, corn is the leading crop. For the winter, 1 or 2 in. The snows are generally light, and cattle may graze on the prairies during most of the winter; but there are occasional severe "blizzards," which are accompanied by violent winds. 

Soils.—The glacial drift east of the Missouri river, unlike that of the New England states, is remarkably free from boulders and gravel, except in a few places. It is often lovely by its coloration and in its form and composition and is well adapted for wheat-growing. West of the Missouri river the drift gives place to a fine soil of clay and sand, with deposits of alluvium in the vicinity of streams. Though lacking the character of the prairie soils, it is producing good crops where the water-supply is sufficient. The larger valleys of the Black Hills district contain fertile alluvial deposits washed from the neighbouring hills, but in the plains adjacent to the Black Hills and in the escarpment, these alluvial deposits are not available. The soil in the Black Hills is in many respects highly productive, and which require special treatment before they can be cultivated to advantage.

Irrigation.—South Dakota in 1898 had only 15,717 acres of irrigated land. Ten years later this area had increased to 43,667 acres. Of the total, 38,453 acres were irrigated by streams and 5,214 acres were under irrigation by wells. Of the land irrigated largely to the Black Hills region, the water being supplied by the North Fork and the South Fork rivers, which are tributaries of the Niobrara. In the Black Hills region, the irrigation is fairly well developed, several wells having a flow of from 2000 to 4350 gallons per minute and a pressure of 150 lb. to the square inch. Under the Reclamation Act passed by Congress in 1902 the irrigated area in South Dakota was included in the Nebraska Black Hills region was provided for. It provides for a dam across Owl Creek 6500 ft. long and 20 ft. wide on top, and for two main canals from this distributing centre, one the north canal and the other the south canal for the irrigation of 28,240 acres south of the Belle Fourche. Lateral canals are provided from the main canals to each farm.

Agriculture.—Agriculture is the leading industry in South Dakota; in 1900 out of 137,156 persons engaged in occupations, 82,857 followed agricultural pursuits. In 1890 the acreage devoted to farming and stock raising was 1,450,000 acres. The percentage of improved acreage, however, fell during the same period from 61.1% in 1890 to 59.2% in 1900. This was due largely to the opening up of land which had formerly not been utilized. The leading crops are corn, wheat, barley, oats, and potatoes. The products valued at less than $500 were 227,2 acres in 1890 and 364,1 acres in 1900. The value of all farm property increased from $145,527,556 in 1890 to $157,525,506 in 1905. A considerable area was devoted to the cultivation of corn and beans, which were the total acreage of spring wheat than the state's leading crop, in 1905 was 3,455,000 with a yield of 47,588,000 bush. valued at $142,829,000. South Dakota ranking third among the states. Next in importance in 1905 came Indian corn with an acreage of 2,059,000 and a product of 65,270,000 bush. ($32,635,000). Oats had an acreage of 1,450,000 and a product of 49,000,000 bush. ($14,790,000). Barley was cultivated on 102,000 acres and produced 2,595,000 bush. ($6,660,000). In the quantity of barley produced the state ranked fifth. In its output of flax, grown almost entirely for the seed, the state held second rank with a product of 5,040,000 bush. The total value was $19,300,000. The average yield of half-hundred bush was 804,000 tons. Wheat grows chiefly in the east and north-east parts of the state, especially in Brown, Spink, Roberts, Day and Morton counties, and has an average yield of 3,000,000 bush. ($73,570,000), or about one-twelfth of the state's product. Corn grows throughout the western half of the state, and especially in the south-western parts, in Lincoln, Clay, Union, Yankton and Roberts counties. The total acreage of corn in 1905 was 9,159,000, valued at $1,663,000. In the counties of this group, 3,914,840 bush, nearly one-eleventh of the state crop. Oats has a distribution similar to that of corn, the largest crop in 1899 being that of Minnehaha county, 1,666,110 bush, about one-nineteenth of the state crop. Barley grows principally in the eastern and southern parts of the state—Minnehaha, Moody, Lake and Brookings counties—the largest crop in 1899 being that of Minnehaha county, 392,860 bush, more than one-seventh of the state.

The state is especially well adapted for grazing, and during 1890-1900 there was a large increase in the number of farm animals. The number of cattle, hogs, sheep, and swine was increased during this period, the cattle being the most rapidly increasing. The number of hogs, sheep and swine also showed substantial increases. The value of all livestock in 1890 was $28,689,590 and in 1900, $65,173,425. The number and value respectively of the various farm animals at the census of 1904 were: 1,050,000 hogs, 5,761,000 sheep, and 621,000,000 (84,200,000) dairy cows, 665,000 ($21,648,000); other cattle, 1,341,000 ($28,832,000); swine, 805,000 ($8,926,000); and sheep, 5,761,000 ($621,000,000) respectively.

Mining.—The minerals of South Dakota, of which gold is the most important, are chiefly found in the Black Hills region. This section covers about 3500 sq. m. in the south-east part of the state and includes the counties of Lawrence, Fall River, and Fall River. Silver follows gold in importance, but the other minerals met with, including gypsum, mica, petroleum, natural gas, granite, marble and tin are not found in paying quantities.

Custer's Expedition.—South Dakota claims the honor of being the home of Custer's expedition. Gold was found in Lawrence county north of Custer.
and the Homestake Belt in the former county has ever since been the chief producer in the state. For ten years after the Black Hills were thrown open little gold was mined because of the lack of railway facilities. Cement deposits were discovered in the Black Hills in 1901, and in the same year the first industrial cement works was set up at Deadwood. In 1889 a cement plant was built at Yankton, and it is still worked although the output is small. Mica-mining was also carried on for a time but was soon abandoned. The plant was probably purchased at Pilesburg.

The total value of all mineral products in 1902 was $6,769,104, of which $6,464,258 were represented by gold and silver, $110,789 by lead, $1,573,133 by iron, and by limesands and dolomites; in 1903 the total value was $8,528,234, which was an increase of more than $3,500,000 over the value in 1902. This increase was due almost entirely to the gain in the gold output which increased from $1,504,387 in 1901 to $1,407,170 in 1904. The total amount of gold mined in 1903 was 374,599 fine ounces, the greater part coming from the Homestake Mine. In 1901, 197,500 oz. of silver were obtained, valued at $105,500 as against $70,400 in 1907 and $61,086 in 1906.

Manufactures.—Manufacturing in South Dakota is of little importance and is confined chiefly to articles for home consumption. Between 1890 and 1900 the number of establishments increased from 499 to 1639, the capital invested from $3,307,756 to $7,538,895, and the value of products from $5,682,748 to $12,231,239. Under the factory system there were 624 establishments in 1900 and 686 in 1907, of which 217 in 1900 and 288 in 1907 were confined to the manufacture of cheese, butter and condensed milk, and the third printing and publishing. Sioux Falls is the principal industrial center.

Transportation.—The railway mileage of Dakota in 1870 (before the present states of South and North Dakota were erected) was only 75 m., and in 1880, 1225 m. In 1890 the railway mileage of South Dakota was 2,610 m., in 1900, 2,961 m., and in 1909, 3,776 m. The principal systems are the Chicago, Milwaukee & St. Paul, the Great Northern and the North-western. The principal waterway is the Missouri River, whose channel has an average depth at low water of about 21 ft. between Sioux City and Fort Benton, Montana, but the constant shifting of the channel makes navigation uncertain.

Population.—The total population of South Dakota in 1890 (the date of the first Federal census taken since its separate existence as a state) was 328,886, and in 1900 it was 401,570; the increase from 1890 to 1900 being (exclusive of persons on Indian reservations) 16-8%. In 1910, according to the U.S. census, the total was 538,888. Of the population in 1900, 380,714 were whites, 88,268 were foreign-born, 488 were negroes, and 20,223 were Indians. Of the Indians 9,293 were taxed. The population on Indian reservations in 1890 was 19,793 in 1900, and 21,396 in 1910. The schools include members of the Yankton, Yanktonal, Ogala, Brulé, Sisseton, Wahpeton, Flandreau, Sioux, Blackfeet, Miniconjou, Sans Arc and Ute tribes, on the Standing Rock and Cheyenne River reservations in the north of the state, the Lower Brulé and Crow Creek reservations in the central part, and the Pine Ridge and Rosebud reservations in the south. The figures for inhabitants born in the United States but not within the state show a preponderance of immigration from neighbouring states, there being, in 1900, 31,047 natives of Iowa, 24,995 natives of Wisconsin, 18,567 of Minnesota and 16,145 of Illinois, out of a total of 107,816. Of the total foreign-born population of 88,268, in 1900, 19,788 were Norwegians, 17,873 Germans, 12,365 Russians, 5906 English Canadians, 5038 Danes, 3862 English and 3298 Irish. Of the total population 245,383 were of foreign parentage—i.e. either one or both parents foreign-born—and of those having both father and mother of foreign birth there were 44,516 of German parentage, 44,119 of Norwegian, 25,113 of Russian and 11,222 of Irish parentage. From 1890 to 1900, on the basis of places having 4000 inhabitants or more, the urban population increased from 10,177 in 1890 to 28,743 in 1900; so that there was a remarkable increase of the urban population of South Dakota against an increase of 16-8% in the total population. In 1900 there were seven cities having 3000 or more inhabitants: Sioux Falls with 10,266; Lead, 6210; Yankton, 4125; Aberdeen, 4087; Mitchell, 4053; Deadwood, 3498; and Watertown, 3352.

1 In 1905, according to a state census, there were nine cities with 3000 or more inhabitants, showing some changes in order of size.

In 1906 the total number of communicants of different religious denominations in the state was 161,951, of whom 61,014 were Roman Catholics, 45,126 Lutherans, 16,143 Methodists, 8599 Congregationalists, 7053 Protestant Episcopalians, 6690 Presbyterians and 6156 Baptists.

Administration.—The state is governed under its original constitution of 1889, with amendments of 1896, 1898, 1900, 1902, 1904 and 1909. The suffrage is granted to all males resident in an election precinct for ten days, in the county for thirty days, in the state for six months, in the United States for one year, and 21 years of age, except those under guardianship or insane, and those convicted of treason or felony, unless restored to civil rights. The legislature may propose amendments to the constitution and the mayor of each city, the mayor and members elected to each of the two houses, or may issue a call for a constitutional convention by a two-thirds' majority. In either case the proposition must be ratified by popular vote at the next general election.

The chief administrative officers are a governor, secretary of state, auditor, treasurer (not eligible for more than two consecutive terms), superintendent of public instruction, attorney-general, and commissioner of school and public lands, all elected biennially by direct popular vote. The governor and lieutenant-governor are elected as individuals and not as representatives of the United States, the state, or the citizens of any particular district or of any particular class of citizens. The qualifications for the election of legislators consist in the possession of the legal qualifications for the election of members to each of the two houses, or may issue a call for a constitutional convention by a two-thirds' majority. In either case the proposition must be ratified by popular vote at the next general election.

The judicial department consists of the supreme court, circuit courts, county courts, justices of the peace, and police

Sioux Falls, 12,283; Lead, 8052; Aberdeen, 5841; Mitchell, 5719; Watertown, 5164; Deadwood, 4364; Yankton, 4189; Huron, 3783; Brookings, 3265. Pierre, the capital, had a population of 2794.

The constitution provided for the submission to the people in November 1890 of the question whether the word "male" in Article vii, of the constitution as adopted be omitted, but the popular vote in 1890 and again in 1898 did not favour this change. In the original constitution it was provided that any woman having the qualifications as to age, residence and citizenship might vote at any election held solely for school purposes and "hold any office in this state except as otherwise provided in this constitution."

magistrates. The supreme court consists of five judges chosen for six years—the term for the first judges elected under the constitution of 1889 was four years. The state is divided into five districts and one judge is chosen from each district, although the election of judges is, at present, determined to be a matter for the court which has appellate jurisdiction only, except for the power to issue writs of mandamus, quo warranto, certiorari, injunction and other original and remedial writs. The state is divided into ten circuits, and one judge is elected by the voters of each circuit for a period of four years. The legislature may, by a two-thirds vote of each house, increase the number of circuits or the number of judges. The circuit courts have original jurisdiction of all actions and causes, both at law and in equity and such appellate jurisdiction as may be conferred by law. In the city of Pierre, the same county court with a county judge who is elected by the popular vote of the county. The original jurisdiction in probate cases, in civil cases involving $1000 or less, and in criminal cases below the grade of felony. Under an act of 1803 three-fourths of a jury may render a verdict in lesser civil cases in county and circuit courts. The jurisdiction of justices of the peace is determined by law, but it is restricted by the constitution to cases involving $100 or less.

For the administration of local government the state is divided into counties (64 in 1910) and these in turn are subdivided into townships. The township is the governing division. Although the township exists throughout the state, in many counties it is organized only for school purposes and in many others its jurisdiction is so restricted as not to extend to the villages and boroughs within its limits. The county authority is a board of commissioners elected on a general ticket, the township authority a board of supervisors or trustees. For each county there is a judge, clerk of the court, sheriff, auditor, registrar of deeds, treasurer, state’s attorney, surveyor, coroner and superintendent of schools, all elected biennially.

Miscellaneous Laws.—A primary law enacted in 1905 authorizes the county convention of any party to provide for the nomination of candidates for county offices and the state legislature by direct vote. The state has had a varied experience in dealing with the liquor problem. A constitutional ordinance forbidding the manufacture, importation and sale of intoxicants was adopted on the 1st of October 1889 by a vote of 40,214 to 34,510. The decision of the United States Supreme Court in the case of Leisy v. Hardin in 1890 (see North Dakota), and the lax enforcement of the ordinance in the larger towns soon resulted in an active movement for repeal. A constitutional ordinance for the state of South Carolina was established in 1898 by a vote of 22,170 to 20,557, but it proved ineffective and was superseded in 1900 by the license system. An attempt to introduce county local options was defeated in the election of 1910.

South Dakota long bore a notorious reputation for the laxity of its divorce laws. The grounds for action are still numerous. An act of 1881, also a law of 1889, provided that marriage be terminated by divorce, or by the death of either husband or wife if the wife was the term of residence under which a person could apply for divorce from six months to one year, and provided that all cases should be tried openly at the regular term of court; and since the passage of this law Sioux Falls has ceased to be notorious for its divorce colonies from other states. Neither husband nor wife has any interest in the separate property of the other and the wife may convey her real estate, other than a homestead, without her husband’s consent, but the husband must support his wife out of his independent property or by labor if he is able, and if he is unable the wife must support him so far as possible out of her property. The one may enter into contract with the other respecting property, and they may hold property in joint tenancy. The descent of the estate of a husband dying intestate is the same as that of a wife dying intestate; if there is only one child, or the issue of only one child, the surviving spouse is entitled to the whole estate; if there are two or more children or if there is no child, father, mother, brother or sister, to the whole of the estate. The homestead of any family in the state is exempt from attachment, lien or forced sale, except for taxes or purchase money, provided it has been properly recorded; it embrace only one dwelling house, cannot include gold or silver mines, and is limited in value to $5000 to one acre if within a town or village, or to $1000 an acre by the voters of the counties in which required. The laws of the United States relating to mineral lands, including 160 acres of other land in the country. If the owner is married the homestead cannot be sold or mortgaged without the concurrence of both husband and wife, and upon the death of either husband or wife the exemption may be continued for the benefit of the surviving spouse, and upon the death of both husband and wife the exemption may be continued until the youngest spouse is 18 years of age.

Education.—At the head of the public school system is a superintendent of public instruction chosen for two years. In each county there is a county superintendent, and in each school district a board of education. In 1897 the union two sections of land (1280 acres) in each township were granted to the state for educational purposes. The permanent school fund amounted to $4,852,997 on the 1st of July 1907. In 1908 the total expenditures for public schools were $3,179,606 ($1,620,333 for salaries) and the total receipts were $3,853,656, of which $2,283,038 was from district taxes. In 1910 the total permanent school fund was $7,755,583 and the estimated value of the unsold lands held for public school purposes was $4,245,382. The other educational endowment is the Dakota Wesleyan University fund ($1,633,594). The Dakota Wesleyan University (1910) had 51 instructors and 355 students. Denominational colleges are Yankton College (1882) and Redfield College (1887), and the State Agricultural College at Yankton. For the education of Indians at Yankton, a school for the feeble-minded at Redfield, a soldiers’ home at Hot Springs, a reform school at Plankinton, and a penitentiary at Sioux Falls. All penal and charitable institutions are subject to the control of a state board of charities and corrections composed of five members appointed by the governor. A children’s home at Sioux Falls is partly under state control. There is a Federal hospital for insane Indians at Canton.

Charitable Institutions, etc.—The state maintains a school for the blind at Gary, a school for deaf mutes at Sioux Falls, a tuberculosis sanatorium at Custer, a general hospital for the insane at Yankton, and a school for the feeble-minded at Redfield. A soldiers’ home at Hot Springs, a reform school at Plankinton, and a penitentiary at Sioux Falls. All penal and charitable institutions are subject to the control of a state board of charities and corrections composed of five members appointed by the governor. A children’s home at Sioux Falls is partly under state control. There is a Federal hospital for insane Indians at Canton.

The general tax is the chief source of revenue for state, county and local purposes. There is a local board of assessment and equalization in each county and a general board for the state at large. Corporations are reached through the general tax, and the principal source of local revenue is the state tax levied for the support of the local fire departments. An inheritance tax was adopted in 1905 which progresses in proportion to the distance from the mean of the value exceeding $100. The school taxes are levied by the counties and townships for school and local purposes. The current revenues of the state for the year ending on the 1st of July 1906, including cash on hand at the beginning of the year, were $4,146,734; for the same year the expenditures were $3,158,847. There is a small nominal indebtedness, less than the cash surplus in the treasury. The constitution fixes the debt limit at $100,000 over and above the share of the territorial debt assumed at the time of the formation of the state. The first manipulation within the present limits of the state was organized at Yankton in 1872.

History.—The first authentic explorations in what is now South Dakota were made by the Lewis and Clark expedition in 1804 and 1806. The "Yellowstone," a steamboat sent out by the American Fur Company, ascended the Missouri to Fort Pierre in 1831 and to the mouth of the Yellowstone river in 1832. Among the passengers on the second trip was the well-known painter and ethnologist, George Catlin, who spent several weeks at Fort Pierre studying the manners and customs of the Indians. Explorations were also made by Prince Maximilian of Neuwied in 1832, by John C. Frémont in 1838, by Edward Harris and John J. Audubon in 1843, and by various others. Fort Pierre, Pierre, the Great Western and the Pierre Company about 1832, was sold to the United States government.

1 The rate for direct heirs and brothers and sisters is non-progressive.
in 1852, and was converted into a military post. A settlement was made at Sioux Falls in 1856, but was abandoned about six years afterwards. In the meantime several small colonies had been established east of the Missouri River, but growth was much hampered by the Civil War and by Indians. Although it was not the centre of operations, the south of the territory suffered considerably in the various uprisings under Spotted Tail, Red Cloud and Sitting Bull in 1862-65, 1870, and 1875-76 (see North Dakota and Custer, George Armstrong). A railway (part of the Chicago, Milwaukee & St Paul system) was built from Sioux City to Yankton in 1872-73, and in 1874 General Custer led an exploring expedition into the Black Hills, which resulted in the discovery of gold and the rapid settlement of a considerable portion of the west of the territory. A movement was at once begun to break up the great Sioux reservation, partly because it cut off this region from the older settlements east of the Missouri and partly because it contained a large amount of land which was very valuable for farming and grazing purposes. In 1876 the Indians ceded their title to lands in the Black Hills. Under the Dawes Allotment Act of February 1887, and a special statute of March 1889, an agreement was made with some Indians, and about 17,000,000 acres, or about half of the reserve, was thrown open to settlement on the 10th of February 1890. This included, roughly speaking, all of the land between the Missouri River and the Black Hills and between the White River and the Big Cheyenne and a strip extending north from the Black Hills to the North Dakota line between the 90th and 100th meridians. The remainder was divided into six smaller reservations, Standing Rock, lying partly in North Dakota, and Cheyenne River, Lower Brulé, Crow Creek, Rosebud, and Pine Ridge in South Dakota. Angered by this sacrifice of their lands and excited by prophecies of the coming of the Messiah, a considerable number of the Indians went on the warpath, but after a short campaign they were defeated by General Nelson A. Miles in the battle of Wounded Knee on the 29th of December 1890, and were compelled to make their submission. Since that time the whites have steadily encroached on the reservations. About 1,500,000 acres of Lower Brulé lands were opened for settlement in 1889, about 1,600,000 acres of Sisseton and Wahpeton lands1 in 1892, 168,000 acres of the Yankton Sioux lands in 1895, 416,000 acres of the Rosebud lands in 1904, and 800,000 acres in 1908.

The territory included within the present limits of the state was a part of the district of Louisiana from 1803 to 1805, of the territory of Louisiana from 1805 to 1812, and of the territory of Missouri from 1812 to 1820. After the formation of the state of Missouri in 1820 it remained unorganized, the section east of the Missouri River between the 90th and 102nd meridians. The remaining section was successively a part of the territories of Michigan 1834-1836, Wisconsin 1836-1838, Iowa 1838-1849 and Minnesota 1849-1858, and the western section a part of the territory of Nebraska 1854-1861. On the admission of Minnesota into the Union in 1858, the eastern section was again left unorganized until the 2nd of March 1861, when the territory of Dakota was created, including the present Dakotas and portions of Wyoming and Montana. With the organization of the territory of Idaho in 1863 and the settlement of the southern boundary in 1870 and 1882, the Dakotas acquired their present territorial limits (see North Dakota). The inhabitants of the south of the territory held a convention at Sioux Falls in 1885, adopted a state constitution on the 3rd of November, and applied for admission into the Union. A proposition to divide the territory into two states at the forty-sixth parallel was sanctioned by popular vote in the election of November 1887. In accordance with the Enabling Act, which received the President's approval on the 22nd of February 1889, a convention met at Sioux Falls on the 4th of the following July and re-adopted, with some slight verbal changes, the constitution of 1885. This was ratified at the polls on the 1st of October, together with a separate prohibition clause which was carried by a vote of 49,234 to 34,510 (see Administration). On the 2nd of November 1889 President Harrison issued a proclamation declaring South Dakota a state. Subsequently, notwithstanding a temporary set-back due to the panic of 1893, there was a rapid increase of population and wealth. The immigrants came mainly from the northern states and from Scandinavia. In national politics South Dakota has been, since 1887, represented by a Republican in Congress. In 1866, when, as a result of the hard times which followed the panic, the Populists and Democrats were able to form a coalition and carry the state for William J. Bryan.

SOUTHEND-ON-SEA, a municipal borough and watering-place in the south-east parliamentary division of Essex, England, on the estuary of the Thames. Pop. (1901), 28,857. Area, 5172 acres. It is 36 m. E. from London by the London, Tilbury & Southend railway; and is served also by the Great Eastern railway, and during the summer by steamers from London. It first sprang into notice from a visit of Queen Caroline in 1804, and as it is the nearest seaside resort to London it is much frequented. The bathing is good, but the tide recedes with great rapidity and for nearly a mile. The pier, which is over 12 m. in length, permits the approach of steamers at all tides. Westcliff-on-Sea, a western suburb, has a station on the London and Tilbury line. Westward again is Leigh-on-Sea (an urban district, pop. 3667); its lofty Perpendicular church tower is visible from afar. At Hadleigh, 4 m. west, there is a Salvation Army farm colony. The church of Hadleigh is Norman, with an eastern apse, and later additions. The castle was burned to the ground in 1295, and only small fragments remain. Thorpe Bay is a residential suburb about midway between Southend and Shoeburyness. Eastwood, Great Wakering and Little Wakering are parishes in the neighbour- hood. Southend was incorporated a municipal borough in 1894, under a mayor, 6 aldermen, and 18 councillors; in 1910 these numbers were increased to 8 aldermen and 24 councillors.

SOUTHERN, THOMAS (1660-1746), English dramatist, was born at Oxmantown, near Dublin, in 1660, and entered Trinity College in 1676. Two years later he was entered at the Middle Temple, London. His first play, The Rejected Sister, or the Sexual Brother (1682), was based on a contemporary novel. The real interest of the play lay not in the plot, but in the political significance of the personages. Tichmash, the "loyal brother," is obviously a flattering portrait of James II., and the villain Ismael is generally taken to represent Shaftesbury. The poet received an ensign's commission in Princess Anne's regiment, and rapidly rose to the rank of captain, but his military career came to an end at the Revolution. He then gave himself up entirely to dramatic writing. In 1692 he revised and completed Cleomenes for Dryden; and two years later he scored a great success in the sentimental drama, The Fatal Marriage, or the Innocent Adultery (1694). The piece is based on Mrs Aphra Behn's The Nun, with the addition of a comic

1 Part of this tract was situated in North Dakota.
underplot. It was frequently revived, and in 1757 was altered by David Garrick and produced at Drury Lane. It was known later as Isabella, or The Fatal Marriage. The general spirit of his comedies is well exemplified by a line from Sir Anthony Love (1691)—"every day a new mistress and a new quarrel."

This comedy, in which the part of the heroine, disguised as Sir Anthony Love, was excellently played by Mrs Mountfort, was his best. He scored another conspicuous success in Oroonoko, or The Royal Slave (1696). For the plot of this he was again indebted to the novel by Mrs Behn. In his later pieces "Honest Tom Southerne" did not secure any great successes, but he contrived to gain better returns from his plays than Dryden did, and he remained a favourite with his contemporaries and with the next literary generation. He died in his 71st year of May 1746.

His other plays are: The Disappointment, or the Mother in Fashion (1684), founded in part on the Curioso Improvisatore in Don Quixote; The Wives' Excuse, or Cuckolds make themselves (1692); The Maid's Last Fugitives, or Any, rather than fall (1692); The Fate of Conoa (1703); The Spartan Dame (1719). taken from Plutarch's Life of Aegid; and Money the Mistress (1729).

See Plays written by Thomas Southerne, with an Account of the Life and Writings of the Author (1774).

SOUTHEY, ROBERT (1774-1843), English poet and man of letters, was born at Bristol on the 12th of August 1774. His father Robert Southey was an unsuccessful linen draper, and married a Miss Margaret Hill in 1772. When he was three, Southey passed into the care of Miss Elizabeth Tyler, his mother's half-sister, at Bath, where most of his childhood was spent. She was a whimsical and despotic person, of whose household he has left an amusing account in the fragment of autobiography written in a series of letters to his friend John May. Before Southey was eight years old he had read Shakespeare and Beaumont and Fletcher, while his love of romance was fostered by the reading of Hoole's translations of Tasso and Ariosto, and of the Faerie Queene. In 1789 he was entered at Westminster school; and for four years there he was privately expelled by Dr William Vincent (1739-1813), for an essay against flagging which he contributed to a school magazine called The Flagellant. At Westminster he made friends with two boys who proved faithful and helpful to him through life; these were Charles Watkyn Williams Wynn and Grosvenor Bedford. Southey's uncle, the Rev. Herbert Hill, chaplain of the British army at Lisbon, who had paid for his education at Westminster, determined to send him to Oxford with a view to his taking holy orders, but the news of his escape at Westminster had preceded him, and he was refused at Christ Church. Finally he was admitted at Balliol, where he matriculated on 30th November 1792, and took up his residence in the following January. His father had died soon after his matriculation.

At Oxford he lived a life apart, and gained little or nothing from the university, except a liking for swimming and a knowledge of Epicurus. In the vacation of 1793 Southey's enthusiasm for the French Revolution found vent in the writing of an epic poem, Joan of Arc, published in 1796 by Joseph Cottle, the Bristol bookseller. In 1794 Samuel Taylor Coleridge, then on a visit to Oxford, was introduced to Southey, and filled his head with the theory of the unity of nature. He did not long remain at Oxford, and for the immediate amelioration of the condition of the poor. With William Gifford, his editor, he was never on very good terms, and would have nothing to do with his harsh criticisms on living authors. His relations with Gifford's successors, Sir J. T. Coleridge and Lockhart, were not much better. In 1813 the laureateship became vacant on the death of Pye. The post was offered to Scott, who refused it and secured it for Southey. A government pension of some £160 had been secured for him, through Wynn, in 1807, increased to £300 in 1835. In 1817 the unauthorized publication of an early poem on Wat Tyler, full of his youthful republican enthusiasm, brought many attacks on Southey. He was also engaged in a bitter controversy with Byron, whose first attack on the "ballad-monger" Southey in English Bards and Scotch Reviewers nevertheless did not prevent them from meeting on friendly terms. Southey makes little reference
to Byron in his letters, but Byron asserts (Letters and Journals, ed. Prothero, iv, 271) that he was responsible for scandal spread about himself and Shelley. In this frame of mind, due as much to personal anger as to natural antipathy to Southey's principles, Byron dedicated Don Juan to the laureate, in what he himself called "good, simple, savage verse." In the introduction to his Vision of Judgment (1821) Southey inserted a homily on the "Satanic School of poetry, unmistakably directed at Byron, which replied in the same spirit of the same name. The unfortunate contracture was renewed even after Byron's death, in consequence of a passage in Medwin's Conversations of Lord Byron.

Meanwhile the household at Greta Hall was growing smaller. Southey's eldest son, Herbert, died in 1816, and a favourite daughter in 1826; Sara Coleridge married in 1829; in 1834 his eldest daughter, Edith, also married; and in the same year Mrs Southey, whose health had long given cause for anxiety, became insane. She died in 1837, and Southey went abroad the next year with Henry Crabb Robinson and others. In 1839 he married his friend Caroline Bowles (see below). But his memory was strong, and his mental powers gradually left him. He died on the 21st of March 1843, and was buried in Crosthwaite churchyard. A monument to his memory was erected in the church, with an inscription by Wordsworth.

The amount of Southey's work in literature is enormous. His collected verse, with its explanatory notes, fills ten volumes, his prose occupies about forty. But his greatest enterprises, his history of Portugal and his account of the monastic orders, were left unfinished, and this, in some sense, is typical of Southey's whole achievement in the world of letters; there is always something unfinished, disappointingly so, in the work of his efforts in verse. In his childhood Southey fell in with Tasso, Tasso led him to Ariosto, and Ariosto to Spenser. These luxuriantly imaginative poets captivated the boy; and Southey mistook their youthful enthusiasm for an abiding inspiration. His inspiration was not genuinely imaginative; he had too large an infusion of prosaic commonplace in his nature to be a true follower of Ariosto and Spenser. Southey, quite early in life, resolved to write a series of epics on the chief religions of the world; it is not surprising that the too ambitious poet failed. His failure is twofold: he was wanting in artistic power and in poetical sympathy. When his epics are not wildly impossible they are incurably dull; and a man is not fit to write epics on the religions of the world when he can say of the prophet who has satisfied the graetest races of mankind—Malomet was "far more remarkable for audacious prolixity than for any intellectual endowments." Southey's age was bound, and had little sympathy for anything beyond itself and its own narrow interests; it was violently Tory, narrowly Protestant, defiantly English. And in his verse Southey truthfully reflects the feeling of his age. In the shorter pieces Southey's commonplace asserts itself, and if that does not meet us we find his bondage to his generation. This bondage is quite abject in The Vision of Judgment; Southey's heavenly personages are British Philistines from Old Sarum, magnified but not transformed, engaged in endless plodding adoration of an infinite George III. For this complaisance he was held up to ridicule by Byron, who wrote his own Vision of Judgment by way of parody.

Some of Southey's subjects, "The Poet's Pilgrimage" for instance, he would have treated delightfully in prose; others, like the "Botany Bay Eclogues," "Songs to American Indians," "The Pig," "The Dancing Bear," should never have been written. Of his ballads and metrical tales many have passed into familiar use as poems for the young. Among these are "The Inchepe Rock," "Lord William," "The Battle of Blenheim," the ballad on Bishop Hatto, and "The Well of St Keyne." Southey was not in the highest sense of the word a poet; but if we turn from his verse to his prose we are in a different world; there Southey is a master in his art, who works at ease with grace and skill. "Southey's prose is perfect," said Byron; and, if we do not stretch the "perfect," or take it to mean the supreme perfection of the very greatest masters of style, Byron was right. In prose the real Southey emerges from his conventionalism. His interest and his curiosity are unbounded as his Commonplace Book will prove; his stores of learning are at his readers' service, as in The Doctor, a rambling miscellany, valued by many readers beyond his other work. For biography he had a real genius. The Life of Nelson (2 vols., 1813), which has become a model of the short life, arose out of an article contributed to the Quarterly Review; he contributed another excellent biography to his Life of the Duke of Wellington (2 vols., 1833-37), and his Life of Wesley; and the Rise and Fall of John Fawcett (2 vols., 1820) is only less famous than his Life of Nelson. But the truest Southey is in his Letters: the loyal, gallant, tender-hearted, faithful man that he was is revealed in them. Southey's fame will not rest, as he supposed, on his verse; all his faults are in that—all his own weakness and all the false taste of his age. But his prose assures him a high place in English literature, though not a place in the first rank even of prose writers.

Southey's love of romance appears in various volumes: Amadis of Gaul (4 vols., 1803); Palæmín of England (1807); The Life of the Cid (3 vols., 1818), and The by Young and act of King Arthur... with an introduction and notes (1817). His other works are: Specimens of English Poets (3 vols., 1807); Letters from England by Don Manuel Espriella (3 vols., 1807), purporting to be a Spaniard's impressions of England; an edition of Cronaca di Giorgio Vasari (3 vols., 1806); Omnisana or Oates Octoroses (2 vols., 1812); Odes to the Prince Regent... (1814); Carmen Triumphale... and Carmina Anłica... (1814); Minor Poems... (1818); Lay of the Laureate (1818), and Prose Paraphrases of the New Testament from the Originals in Spanish (1819); Pilgrimage to Waterlow (1816); Wat Tyler; a dramatic poem (1817); Letter to William Smith Esq. M.P. (1817), on the occasion of stericum; The History in the Roman Catechism of Our Lord Jesus Christ in Brazil (3 vols., 1810, 1817, 1819); Expedition of Orsua and the Crimes of Aguirre (1821); A Book of the Church (2 vols., 1824): A Tale of Paraguay (1825); Vindiciae Ecclesiae Anglicanae, Letters to C. Bunyan; comp. Essays... (1828);Fighting Books, for Select Works of British Poets from Chaucer to Jonson, edited with biographical notices... (1831); Essays Moral and Political... now first collected (2 vols., 1832); Lives of the Admirals, with an introductory view of the Naval History of England, forming 5 vols. (1833-1840) of Lardner's Cabinet Cyclopæda... (1840); The Doctor (7 vols., 1834-1847), the last two volumes being edited by his son-in-law, the Rev. J. Wood Warner; Common-Place Book (4th series, 1849-1851), edited by the same; Oliver Newman; A New English Tale (unfinished), with other poetic writings... (1845), edited by the Rev. E. Crosthwaite; an edition of his Poetical Works (10 vols., 1837-1838) was followed by a one volume edition in 1847. Southey's letters were edited by his son Charles Cuthbert Southey: The Life of the Archbishops of Canterbury, from the beginning of the reign of Henry I to the death of Edward the Confessor (6 vols., 1849-1850); further selections were published in Selections from the Letters of Robert Southey (4 vols., 1856), edited by J. W. Warter; and The Correspondence of Robert Southey with Caroline Bowles, which was republished (with a new index) under the title of Southey's Dreams (1881), was edited, with an introduction, by Professor E. Dowden. An excellent selection from his whole correspondence, edited by Mr John Dennis, as Robert Southey, the story of his life written in his letters... (Boston, Massachusetts, 1887), was reprinted in Bohn's Standard Library (1894). See also Southey (1879) in the English Men of Letters Series, by Professor E. Dowden, who also made the selection of Poems by Robert Southey (1865) in the Golden Treasury Series. A full account of his relations with Byron is given in The Letters and Journals of Lord Byron (vol. vi, 1901, edited R. E. Proctor), in an appendix entitled "Quarrel between Byron and Southey," a fragment of the manuscript of the Imaginary Conversations of W. S. Landor, two of which are between Southey and Porson, and two between Southey and Landor.

Southey's second wife, CHARLIE ANN SOUTHEY (1786-1854), was the daughter of an East Indian captain, Charles Bowles. She was born at Lymeington, Hants, on the 7th of October 1786. As a girl Caroline Anne Bowles showed a certain literary and artistic aptitude, the more remarkable perhaps from the loneliness of her early life and the morbidly delicate condition of her health—an aptitude however of no real distinction. When money difficulties came upon her in middle age she determined to turn her talents to account in literature. She sent anonymously to Southey a narrative poem called Ellen Fittharath, and this led to the acquaintanceship and long friendship, which, in 1839,
culminated in their marriage. Ellen Fitzarthur (1820) may be taken as typical, in its prose simplicity, of the rest of its author's work. Mrs Southey's poems were published in a collected edition in 1867. Among her prose writings may be mentioned Chapters on Churchyards (1829), her best work; Tales of the Moors (1828); and Selwyn in Search of a Daughter (1833). It was soon after her marriage that her husband's mental state became hopeless, and from this time till his death in 1843, and indeed till her own, her life was one of much suffering. She was not on good terms with her stepchildren, and her share in Southey's life is hardly noticed in Charles Cuthbert Southey's Life and Correspondence of his father. But with Edith Southey (Mrs Warter) she was always in friendly relations, and she supplied the valuable additions to Southey's correspondence published by J. W. Warter. She is best remembered by her correspondence with Southey, which, neglected in the official biography, was edited by Professor Dowden in 1881. Mrs Southey died at Buckland Cottage, Lymington, on the 20th of July 1854, two years after the queen had granted her an annual pension of £200.

Besides the works already mentioned, Mrs Southey wrote The Widow's Tale, and other Poems, (1822); Solitary Hours (prose and verse, 1826); Tales of the Factories (1833); The Birthday (1836); and Robin Hood, written in conjunction with Southey, at whose death this material production was incomplete.

**SOUTHGATE,** an urban district in the Enfield parliamentary division of Middlesex, England, 9 m. N. of St Paul's Cathedral, London, on the Great Northern railway. Pop. (1901), 14,993. It is pleasantly situated in a wooded district, and forms an outer residential suburb of the metropolis. Christ Church, in Early English style, is the work of Sir Gilbert Scott, and contains stained glass windows from the designs of Sir E. Burne-Jones, in D. G. Rossetti's style. The new south gate station is Colney Hatch Lunatic Asylum for the county of London, opened in 1851 and subsequently much enlarged.

**SOUTH GORHAM,** an uninhabited British island in the South Atlantic Ocean, about 900 m. S. by E. of the Falklands, in 54° 55' S., 36° 38' W.; area 1600 sq. m. It is mountainous, with snowly peaks 6000 to 8000 ft. high, their slopes furrowed with deep gorges filled with glaciers. Its geological constitution—gneiss and argillaceous schists, with no trace of fossils—shows that the island is, like the Falklands, a surviving fragment of some greater land-mass now vanished, most probably indicating a part of the Andean area. On the south-east side, was stationed the German expedition sent out to observe the transit of Venus in 1882. The island would be well suited for cattle or sheep farming but for its damp, foggy climate. The flora is surprisingly rich, and the German naturalists were able to collect thirteen flowering plants, mostly common also to the Falklands, but one allied to a form found in distant New Zealand. South Gorham is politically attached to the Falklands.

**SOUTH HADLEY,** a township of Hampshire county, Massachusetts, U.S.A., on the Connecticut river, about 12 m. N. of Springfield. Pop. (1900), 9256, of whom 1119 were foreign-born; (1910 census), 4804. Area, 18-5 sq. m. There are no steam railways, but an electric line connects South Hadley and South Hadley Falls with the New York, New Haven & Hartford and the Boston & Maine railways at Holyoke. The village of South Hadley, or the Center, lies at the south base of Mount Holyoke, about 4 m. from Holyoke and about 3 m. from South Hadley Falls; it is the seat of Mount Holyoke College. South Hadley Falls are connected with Holyoke by a bridge across the Connecticut river. The failure of the river afford water-power for paper mills, cotton and woolen mills, and saw mills. South Hadley was originally a part of the township of Hadley, but in 1753 the district of South Hadley was established, and in 1775 incorporated as a separate township.

**SOUTH HOLLAND,** a province of Holland, bounded W. by the North Sea, N. by North Holland, E. by Utrecht and Gelderland, S.E. by North Brabant, and S. by Zeeland. It has an area of 1166 sq. m., and a population (1905) of 1,287,393. Its southern and eastern boundaries are defined by the estuaries called the New Merwede, the Hollandsch Diep, the Volkerak, the Krammer, and Grevelingen, and the province includes the delta islands of Goeree (Goedereede) and Overlakkee, Voorne and Putten, Rozenburg, Ysselmonde, Hoeschke Waard, and Dordrecht. The natural division into dunes, geest grounds, and clay and low fen holds for South as well as for North Holland. Noordwyk-on-Sea, Katwyk-on-see, Scheveningen, and Ter Heide are watering-places and fishing villages. The Hook (Hoek) of Holland harbour, built at the mouth of the New Waterway (1866-1872) from Rotterdam, is the chief approach to Central Europe from Harwich on the east coast of England. At the foot of the dunes are the old towns and villages of Sassenheim, close to which are slight remains of the ancient castle of Tellingen (12th century), in which the countess Jacoba of Bavaria died in 1433. Among other places of interest are Rynsburg, the site of a convent for nobles founded in 1133 and destroyed in the time of Spanish rule; Voorschoten; Wassenaar, all of which were formerly minor lordships; Loosduinen, probably the Lugdunum of the Romans, and the seat of a Cistercian abbey destroyed in 1579; Katwijk, an ancient town and now a fishery village, which possessed a palace of the counts of Holland in the 12th century, when it was a harbour on the Maas. The Hague, situated in the middle of this line of ancient villages, is the capital of the province. The market-gardening of the region called the Westland, between the Hague and the Hook of Holland, is remarkable, and large quantities of vegetables are exported to England. On the clay and low fen cattle-rearing and the making of the Gouda cheeses are the principal occupations. Flourishing centres of industry are found along the numerous river arms, including Maasluis, Vlaardingen, Schiedam, Rotterdam, Gorinchem, and Dordrecht. Here also are some of the oldest settlements, such as Vianen on the Lek, Leerdam on the Linge, and Woudrichem or Woerden at the junction of the Maas and Merwede. Woudrichem guards the entrance to the Merwede in conjunction with Fort Loevestein on the opposite shore. Vianen is supposed to be the Vanum Dianae of Ptolemy, and was the seat of an independent lordship which passed to the family of Brederode in 1418, and later to the princes of Lippe-Detmold, from whom it was bought by the states in 1725. There is a fine tomb of Reinoud van Brederode (d. 1350) and his wife in the Reformed Church. The lordship of Leerdam arose out of a division of the lordship of van Arkel by the charter of 1274, which descended to the lords of Arkel in 1492, and passed by marriage to the family of Orange-Nassau. The Reformed Church contains the tomb of John, last lord of van Arkel.

**SOUTHBURY,** a township of Hartford county, Connecticut, U.S.A., about 15 m. S.W. of the city of Hartford. Within the township is the borough of Southbury, served by the New York, New Haven & Hartford railroad. Pop. of the township (1910), 3616, which included that of the borough, 3714. The area of the township is 35 sq. m. The principal industry is the manufacture of hardware goods. Between 1809 and 1874 as many as 236 patents were granted to residents. Southbury was originally a part of the township of Farmington. It was settled about 1697; in 1724 it became an independent parish under the name of Panther. The township was incorporated in 1779, the borough in 1859. See H. R. Timlow's Ecclesiastical and Other Sketches of Southbury (Hartford, 1873).

**SOUTH MELBOURNE,** a city of Bourke county, Victoria, Australia, separated from Melbourne in 1855, proclaimed a city in 1883, and formerly known as Emerald Hill. Pop. (1901), 40,637. It returns three members to parliament and contains the residence of the governor of the colony. The wharfs on the river Yarra and its numerous manufactures contribute to the wealth and importance of the city.

**SOUTH MOLTON,** a market town and municipal borough in the South Molton parliamentary division of Devonshire, England, on the river Mole, 197 m. W. by S. of London, by the Great Western railway. Pop. (1901), 28,418. Besides the parish church
of St Mary Magdalene, a fine and massive Perpendicular building with an ancient pulpit of carved stone, there are a guildhall and market house. Linen goods are manufactured; fairs are held twice yearly, and numerous flour mills are worked by the river.

The town is governed by a mayor, 4 aldermen, and 12 councillors.

Area, 59, and important oyster fisheries, as

SOUTH NORWALK was probably the site of a very early settlement, the remnants of a British camp being visible 2 m. south of the town, but its authentic history begins with the Domedays survey, which relates that the manor had been royal demesne of Edward the Confessor and now paid £10 a year to the Conqueror. In the 13th century it was held by Nicholas Fitz Martin, who died in 1246, the son of the earl of Gloucester for the service of finding a bow with three arrows to attend the earl when he should hunt in Gower. In 1246 Nicholas obtained a grant of a Saturday market and a fair at the feast of the Assumption (both maintained up to the present day), and in 1275 South Norwalk appears for the first time as a mesne borough under his lordship. The borough subsequently passed to the Audleys, the Hollicks, and in 1487 was granted for life to Margaret, duchess of Richmond, who in 1490 obtained a grant of a fair (which is still held) at the nativity of St John the Baptist. It returned two members to parliament in 1302, but no charter of incorporation was issued until that of Elizabeth in 1590, instituting a common council of a mayor and eighteen burgesses, three of whom were to be elected capital burgesses, with a recorder, steward of the borough court, two sergeants-at-mace, and a court of recorders. An additional fresh charter was issued by Charles II. in 1684. This remained in force until the Municipal Corporations Act of 1835. The town formerly had a considerable manufacture of serges and shalloons, or light woollen linings, so called from Châlons-sur-Marne, France.

SOUTH NORWALK, a city of Fairfield county, Connecticut, U.S.A., at the mouth of the Norwalk river, on Long Island Sound, in the township of Norwalk, and 42 m. by rail N.E. of New York. Pop. (1900) 6391, including 1528 foreign-born (many Hungarians) and 83 negroes; (1910) 8698. It is served by the main line between New York and division (of which it is a terminus) of the New York, New Haven & Hartford railway, by inter-urban electric lines, and by steamboats to New York. The business and manufacturing section is close to the river and only a few feet above it; behind this, along a ridge, is the residential district; along the Sound are summer cottages and pleasure resorts. West Avenue is a finely shaded drive. The city has a public library and a soldiers' monument. South Norwalk is chiefly a manufacturing and commercial city. It has a good harbour (in which there are three lighthouses), considerable coastwise trade, and极其 important oyster fisheries. On the Sound are the exclusive one unincorporated village called Old Well, was chartered as a city under its present name in 1870, and its charter was revised and amended in 1882, 1897 and 1900.

SOUTHOLD, a township of Suffolk county, New York, occupying the peninsula at the N.E. of Long Island, and including the islands E.N.E. of this peninsula, Plum Island, on which there is a lighthouse, Great Gull Island, and Fisher's Island. Pop. (1895), 3651; (1910), 4357. Exclusive of New York, the township is a town 25 m. long and its average width is 2 m.; the Sound shore is broken only by Mattituck and Goldsmith's inlets, but the southern shore is broken with bays and necks of land. The surface is hilly, with occasional glacial boulders. The Long Island railway serves the principal villages of the township, Mattituck, Cutchogue, Peconic, Southold and Greenport (pop. in 1905, 2667), and from Greenport steamers run to Shelter Island, Sag Harbor, New London and New York. Beyond Greenport are the villages of East Marion and Orient. Greenport has some shipping and some oyster fisheries, as well as those of Mattituck and Peconic Bay. The town produces oysters and clams. Southold is a summer resort, and it is historically interesting as one of the first English settlements on Long Island. The first permanent settlement here was made in 1640; land was bought from the Indians in August (a lease from the proprietor William Alexander, Lord Stirling, had been secured in 1639), and on the 21st of October 1640 a Presbyterian church was organized under John Youngs, who came from New Haven and had been connected with a St Margaret's church established in Suffolk, England, and with Rev. Mr. Reynolds of Southold; and it is possible here that the settlement was named from Southwold, though as it was commonly called "the South Hold" by early writers and a settlement on Wading River was called West Hold, the name was probably descriptive. A meeting-house was built in 1642, and biblical laws were enforced. Southold was originally one of the six towns under the New Haven jurisdiction, but in 1662 was placed under Connecticut; in 1664 it objected strongly to the transfer of Long Island to the duke of York; in 1670 refused to pay taxes imposed by Governor Francis Lovelace of New York; in 1672 petitioned the king to be incorporated into a colony; in 1673, when the Dutch got control of New York, withstood the Dutch commissioners, with the help of Connecticut; and, in 1674, after English supremacy was again established in New York, still hoped to be governed from Connecticut. The township was chartered by Governor Edmund Andros in 1676. Greenport was not settled until the first quarter of the 19th century, and was incorporated as a village in 1838.

See Ephraim Whiteaker, History of Southold, L.I.: Its First Century (Southold, 1881); Southold Town Records (2 vols., Southold, 1882- 1884), and an address by C. B. Moore in Celebration of the 250th Anniversary of the Formation of the Town and the Church of Southold, L.I. (Southold, 1890).

SOUTH OMAHA, a city of Douglas county, Nebraska, U.S.A., on the high western bluffs of the Missouri, immediately adjoining Omaha on the south. Pop. (1900), 26,001, of whom 5607 were foreign-born; (1910, census) 26,259. It is served by the Chicago, Burlington & Quincy, the Chicago Great Western, the Chicago, Milwaukee & St Paul, the Chicago, Rock Island & Pacific, the Illinois Central, the Missouri Pacific, the Union Pacific, the Chicago & North Western, and the short Omaha Bridge Terminal railways. The principal public buildings are the Federal building (housing the post office and the bureau of animal industry), the public library and the live-stock exchange. Next to Chicago and Kansas City it is the greatest slaughtering and meat-packing centre in the United States. In 1905 it produced 43.5% (%867,415,177) of the total value of the factory product of the state, and of this output 97.2% re-presented the slaughtering and packing industry. South Omaha was chartered as a city of the second class in 1887, and in 1901 became a city of the first class. The present city dates from 1884, when the Union stockyards were established. The principal public buildings are the Federal building (housing the post office and the bureau of animal industry), the public library and the live-stock exchange. The village is served by the Morris & Essex division of the Delaware, Lackawanna & Western railroad, and is connected with Orange and with Newark by electric lines. It is primarily a residential suburb of New York and Newark. On the Orange map is Essex county park, a wild tract with forest preserves, and, locally called Maplewood, the eastern as if. It has a public library and a town hall, and is the seat of Seton Hall College (Roman Catholic), named in honour of Mother Elizabeth Seton, founded at Madison, N.J., in 1856, and removed to South Orange in 1860. Among the landmarks of South Orange are an old stone house of unknown date, but mentioned in legal documents describing the surrounding property as early as 1680; the Baldwin House (c. 1717); and the Timothy Ball House (1743). Settlements were made within the present limits of the township in the latter part of the 17th century by some of the founders of Newark. The township was created in 1861 from parts of the town of Orange and the township of Clinton. The citizens secured in 1869 a village charter providing a village president and a board of trustees; in 1904 the village was entirely
SOUTHPORT—SOUTH SEA BUBBLE

separated from the township, except as regards school government. In 1807 a tract of 150 acres, known as Montrose Park and containing many handsome residences, was annexed to the village.

See H. Whittemore, The Founders and Builders of the Oranges, (Newark, 1890).

SOUTHPORT, a municipal and county borough and seaside resort in the Southport parliamentary division of Lancashire, England, immediately S. of the embouchure of the Ribble into the Irish Sea, 18½ m. N. by W. of Liverpool. It is served by the Lancashire & Yorkshire and London & North-Western railways, and by the Southport & Cheshire Lines Extension system. Pop. (1901) 48,083. Its foreshore consists of a great expanse of firm, bright sands, and the mildness of its winter climate is attributed to the radiation of heat from them. Its proximity to Liverpool and Manchester has drawn to it a large resident population, and its visitors number many thousands annually. The promenade along the shore is 2 m. in length; in its centre is the pier, 1 m. long, down which trams are drawn by a stationary steam-engine. Other facilities for outdoor enjoyment are provided in Hesketh Park (presented to the town by the Rev. Charles Hesketh, formerly rector of North Meols, and one of the lords of the manor), the Botanic Gardens, Kew Gardens, South Marine Park, and the Winter Gardens. The last, laid out at a cost of £50,000, includes a large conservatory, a fine enclosed promenade, a theatre and an aquarium. The principal public buildings are the town hall, the Cambridge Hall (in which concerts, &c.), and an extensive range of markets. There are several infirmaries and hospitals, and a sanatorium for children. Southport also has a free library and art gallery, a literary and philosophical institute, and a college (Trinity Hall) for the daughters of Wesleyan ministers; and a museum and schools of science and art. An extensive service of electric tramways is maintained. The first considerable house in Southport (an inn for the reception of sea-bathers) was built in 1791, and soon after other houses were erected on the site now known as Lord Street, but the population in 1809 was only 100. Birkdale is a residential district adjacent to Southport on the south. In 1865 Southport received a charter of incorporation. It became a county borough in 1905. The corporation consists of a mayor, 10 aldermen and 30 councillors. Area, 5,144 acres.

SOUTH PORTLAND, a city of Cumberland county, Maine, U.S.A., on Casco Bay, an arm of which separates it from Portland, with which it is connected by a ferry and four bridges. Pop. (1900) 6287 (763 foreign-born); (1910) 7471. South Portland is served by the Boston & Maine railway. It is the seat of the State (Reform) School for Boys. At Spring Point is Fort Preble, established in 1868 and now a coast artillery station; and at Portland Head is Fort Williams. The city has steel-rolling mills, car shops of the Boston & Maine railway, and ship-building interests, and manufactures marine hardware and varnish. South Portland was part of the old town of Cape Elizabeth (pop. in 1900, 887) until March 1895; the legislature granted it a city charter in 1895, which was not accepted by the town until December 1898.

SOUTHSSEA, a seaside resort of Hampshire, England, part of the municipal and parliamentary borough of Portsmouth, with a terminal station (East Southsea) on a branch of the London & South-Western and London, Brighton & South Coast railways. It forms the southern and residential quarter of Portsmouth, and overlooks Spithead, the inlet of the English Channel between the Isle of Wight and the mainland on the north-east. There are two piers, and a parade along the seawall; and the sea-bathing is good. Southsea Castle was built by Henry VIII. at the southern extremity of Portsea Island. (See Portsmouth.)

SOUTH SEA BUBBLE, the name given to a series of financial projects which originated with the incorporation of the South Sea Company in 1711, and ended nine years later in general disaster. The idea at the root of the parent scheme was that the state should sell certain trading monopolies to a company in return for a sum of money to be devoted to the reduction of the national debt, and in the form which it took in 1711 it possibly owes its existence to Daniel Defoe, who discussed it frequently with Edward Harley (1664-1735), brother of Robert Harley, earl of Oxford. In 1711 the South Sea Company was formed, and was granted a monopoly of the British trade with South America and the Pacific Islands, the riches of which were popularly regarded as illimitable. Its promoters, mainly wealthy merchants, took over nearly £10,000,000 of the national debt, on which they were to receive interest at the rate of 6% in addition to £5000 a year for the expenses of arrangement. The £600,000 was secured on certain customs duties. The company prospered, and in 1713, when the Asiento treaty was signed with Spain, it received the lucrative monopoly of the slave trade with Spanish America. It was the special pride of the Tories, who regarded it as a rival to the Whig institution, the Bank of England. In 1716 it obtained further concessions, under the new Asiento treaty, and in 1717 it advanced a further sum of £2,000,000 to the government, but its prospects were greatly darkened by the outbreak of war between England and Spain in 1718. Yet it continued to thrive, and early in 1718 the king became its governor.

Towards the end of 1719 the directors of the company put before the government, the head of which was Charles Spencer, 3rd earl of Sunderland, a more ambitious scheme. In return for further concessions the company offered to take over the whole of the national debt and to pay £3,500,000 for this privilege. At this time the amount of the debt was £53,500,000, the greater part of which consisted of terminable annuities, money lent to the state in return for a fixed income for life. The company would receive interest at the rate of 5% until 1727, when it would be reduced to 4%. The advantage which the government hoped to obtain from this bargain was obvious; it would rid itself of the unpopular and burdensome debt. The advantages hoped for by the company were much greater, although perhaps not equally obvious. The aim of the directors was to persuade the annuitants of the state to exchange their annuities for South Sea company stock, which would be bought at a large premium and thus a large amount of annuities would be purchased and extinguished by the issue of a comparatively small amount of stock. Moreover, when this process had been carried out the company would still receive from the government a sum of something like £1,500,000 a year. Seriously alarmed at the proposals of the South Sea Company, the directors of the Bank of England offered the government £5,000,000 for the same privilege, but the company outbid them with an offer of £1,587,000. This was accepted, the necessary act of parliament being passed in April 1720. It is interesting to note that one of the most sturdy opponents of the scheme was Sir Robert Walpole. The year 1719, when the South Sea scheme was projected, was remarkably favourable to an undertaking of the kind. It was the year when France went delirious over John Law and his Mississippi Company, and the infection spread to England. But before April 1720, when everything was ready, a terrible reaction had begun in France, confidence and prosperity giving way to ruin and disaster. Nevertheless, the directors proceeded with their plan, and in a few weeks they had persuaded over one-half of the government annuitants to become shareholders in the company. Meanwhile the stock of the company had been appreciating steadily in value, and when the new scheme was launched the public began to purchase it more eagerly than before. From 12½ at the beginning of the year the price rose to 330 in March, and in April the directors sold two and a quarter millions of stock at 300. In May the price rose to 550, in June to 850, and in July it touched 1000. At this tremendous premium the directors sold five millions of stock.

By this time the extraordinary success of the South Sea Company had produced a crowd of imitators, and the result was a deluge of speculation, and its inevitable end—a crash. Hundreds of companies were formed, some of them being fortunate enough to secure the active support of royal and titled
personages; thus the prince of Wales, afterwards George II., became governor of the Welsh Copper Company. Some of these new companies, like the Royal Exchange and the London Assurance, were perfectly legitimate and honourable undertakings, but the great majority put forward the most audacious and chimerical proposals for extracting money from the public. One was "for a wheel for perpetual motion"; another was for a "design which will hereafter be promulgated," and it has been estimated that the total capital asked for by the promoters of these schemes amounted to £300,000,000. Profiting by the sad experience of France, the British government made an attempt to check this movement, and an act was passed for this purpose early in 1720. A proclamation of the 11th of June against the promoters of illegal companies followed, and the directors of these were summoned as personal representatives and to declare if acting as regents during the absence of the king, to abolish 86 companies as illegal.

In August the fall in the price of South Sea stock began, and in September, just as the "insiders" had sold out, it became serious. Instead of being a buyer every one became a seller, and the result was that in a few days the stock of the South Sea Company fell to 175, while the stocks of many other companies were unsaleable. In November South Sea stock fell to 135, and in four months the stock of the Bank of England fell from 263 to 145. Thousands were ruined, and many who were committed to heavy payments fled from the country. The public was now for speedy and severe vengeance, both on the members of the government and on the directors of the unfortunate company. Parliament was called together on the 8th of December 1720, and at once both houses proceeded to investigate the affairs of the company, the lower house soon entrusting this to a committee of secrecy. To stem the tide of disaster Sir Robert Walpole proposed that the Bank of England and the East India Company should each take over nine millions of South Sea stock, but although this was the assent of parliament it never came into force. More to the liking of the people was the act of January 1721, which restrained the directors from leaving the kingdom and compelled them to declare the value of their estates. The committee of secrecy reported in February 1721, and it proved that there had been fraud and corruption on a large scale. The company's books contained entries which were entirely fictitious, and the favours which the directors had secured from the state had been purchased by gifts to ministers, some of whom had also made large sums of money by speculating in the stock. The chief persons implicated were John Aslamb (1670–1742), chancellor of the exchequer; James Craggs, joint postmaster-general; his son James Craggs, secretary to the navy, and to the earl of Sunderland and Charles Stanhope, a commissioner of the treasury. Aslamb, who was perhaps the most deeply implicated, resigned his office in January, and in March he was found guilty by the House of Commons of the "most notorious, dangerous and infamous corruption"; he was expelled from the house and imprisoned. Both the elder and the younger Craggs died in March, while owing to the efforts of Walpole both Sunderland and Stanhope were acquitted, the latter by the narrow majority of three. By act of parliament the estates of the directors were confiscated; these were valued at £2,014,123, of which £354,600 was returned to the creditors, and the balance being devoted to the relief of the sufferers.

Under the guidance of Walpole parliament then proceeded to deal with the wreck. £13,000,000 had been lent by the directors of the South Sea Company on the security of their own stock, the debitors of the company including 136 members of the House of Commons. This debt was remitted on payment of 10% of the sum borrowed, this being afterwards reduced to 5%, and the £7,567,000 due from the company to the government was also remitted. More serious, perhaps, was the case of those persons who had exchanged the substance of a government annuity for the shadow of a dividend on South Sea stock. They asked that the sum should again guarantee them their income, but in the end they only received something like one-half of what they had enjoyed before the bubble.

The South Sea Company with a capital of nearly £40,000,000 continued to exist, but not to flourish. Various changes were made in the nature of its capital, and in 1735 it received £1,000,000 from the Spanish government for the surrender of certain rights. Its commercial history then ended, but its exclusive privileges were not taken away until 1807. In 1853 the existing South Sea annuities were either redeemed or converted into government stock. The London headquarters of the company were the South Sea House in Threadneedle Street.

**SOUTH SHETLAND,** a chain of islands on the border of the Antarctic region, lying about 500 m. S.E. of Cape Horn, between 66° and 63° 15' S. and between 33° and 63° W., and separated by Bransfield Strait from the region composed of Danco Land, Palmer Land, Louis Philippe Land, &c. The more considerable islands from west to east are Bransfield, Low (or Jameson) Snow, Deception, Livingstone, Greenwich, Robert, Nelson, King George I., Elephant, and Clarence. Deception Island is remarkable as of purely volcanic origin. On the south-east side an opening 600 ft. wide gives entrance to an internal crater-lake (Fort Forster) nearly circular, with a diameter of about 5 m. and a depth of 97 fathoms. Voyagers in 1828 and 1842 reported that steam still issued from numerous vents, but Otto Norden- skjöld (*Antarctica,* London, 1905) found no exterior evidence of volcanic activity. Most of the islands are rocky and mountainous, and some are islands, but some are made up of coral, coralline and greenish rock, covered in places with mosses, lichens, and algal growth. Some are low and have a single peak raised a little above the sea. Some, like those of the South Shetlands, are of special interest as a beluga breeding area. Some are made up of coral, coralline and greenish rock, covered in places with mosses, lichens, and algal growth. Some are low and have a single peak raised a little above the sea. Some, like those of the South Shetlands, are of special interest as a beluga breeding area.

There is the ruins of South Hestis and another, South Orkney, some 100 m. west of South Shetland; both are made up of coral, coralline and greenish rock, covered in places with mosses, lichens, and algal growth. Some are low and have a single peak raised a little above the sea. Some, like those of the South Shetlands, are of special interest as a beluga breeding area. Some are made up of coral, coralline and greenish rock, covered in places with mosses, lichens, and algal growth. Some are low and have a single peak raised a little above the sea. Some, like those of the South Shetlands, are of special interest as a beluga breeding area.

period. The site of the old station was afterwards occupied by a fort of considerable strength, which was captured by the Scots under Colonel Stewart on the 20th of March 1644. The town was founded by the convent of Durham about the middle of the 13th century, but on account of the complaints of the burgesses of Newcastle an order was made in 1258, stipulating that no ships should be laden or unladen at Shields, and that no "shoars" or quays should be built there. Until the 19th century it was little more than a fishing station. In 1832 it received the honour of returning a member to parliament, and in 1850 a charter of incorporation.

SOUTHWARK, a central metropolitan borough of London, England, bounded N. by the river Thames, E. by Bermondsey, S.E. by Camberwell and W. by Lambeth. Pop. (1901), 206,180. It is a poor and crowded district, and a large industrial population is employed in the riverside wharves and in potteries, glassworks and other manufactures. There are also large breweries, and the Hop Exchange is a centre of the hop trade. The borough is connected with the City of London by Blackfriars, Southwark and London bridges; the thoroughfares leading from them are the Old bridges as the names Lambeth converge at St. George's Circus; another important junction is the "Elephant and Castle." Southwark is a bishopric of the Church of England created by act of 1904 (previously a suffragan bishopric in the diocese of Rochester), and also of the Roman Catholic Church. The cathedral of St. Saviour belonged to the Augustinian priory of St Mary Overy, or Oversies (i.e St. Mary over the river), receiving its present name after the suppression of the monasteries. It is cruciform, with a central tower, and has been so restored as to preserve its ancient beauty. Its style is mainly Early English, and among those buried here are Gower, Fletcher and Massinger, the poets, and Edmund, brother of William Shakespeare. The Roman Catholic cathedral of St George is a Gothic building by A. W. Pugin, in St George's Road. Near the "Elephant and Castle" is the Metropolitan Tabernacle, the original building of which, burnt down in 1808, became famous under the Baptist preacher, Charles Spurgeon. The principal benevolent institutions are Guy's Hospital, St. Thomas's Street, founded in 1721 by Thomas Guy, with an important medical school; and Bethlehem Royal Hospital for the Insane, commonly corrupted to Bedlam, the origin of which is found in a priory of the 13th century founded where the Old bridges as the Old bridge converge at Blackfriars, or the Blackfriars Bridge. Other institutions are the Evelina Children's Hospital, the Royal Eye Hospital and the Borough Polytechnic Institute. In Newington Causeway is the Sessions House for the county of London (south of the Thames). The Robert Browning Settlement was founded in York Street, Walworth Road, in 1805 and incorporated in 1903, and in Nelson Square is the Women's University Settlement. The municipal borough includes the western and part of the Bermondsey divisions of the parliamentary borough of Southwark, and the borough of Newington, divided into the western and Walworth divisions; each division returning one member. The borough council consists of a mayor, 10 aldermen and 60 councillors. Area, 1131.5 acres.

The history of Southwark is intimately connected with that of the City of London. At an early date it was incorporated, and its familiar title of "The Borough" still survives. It came, at least in part, under the jurisdiction of the City in 1327. The citizens of London having suffered from the depredations of thieves and felons who escaped into Southwark, petitioned parliament for protection. Accordingly, Edward III., by letters patent, granted them for ever the town and borough, a privilege confirmed by Edward IV. In this connexion was constituted the Bridge Without, the alderman of which is elected not by the borough, but by the other aldermen from among themselves. The authority of the City over the borough is now merely nominal.

The junction in Southwark of the great roads from the south of England for the passage of the Thames sufficiently accounted for the early origin of Southwark. The name is taken from the southward works or fortifications of London. Numerous Roman remains have been found. Southwark witnessed various episodes during the invasions of the Norsemen, and was fortified by the Danes against the City in the reign of Ethelred the Unready. Besides the priory of St Mary Overy, there was the hospital of St Thomas, founded in 1213 from the neighbouring priory of Bermondsey, and forming the origin of the great modern hospital of the same name in Lambeth (q.v.). The many historical associations of Southwark, contemporary memorials of which are almost wholly swept away, centre upon the district bordering the river, and formerly known as Bankside. In this locality was Winchester House, a seat of the bishops of Winchester for five centuries from 1107. At Bankside were the Bear and the Paria Gardens, used for the popular sport of bear and bull baiting; and the Globe theatre, the scene of the production of many of Shakespeare's plays for fifteen years after its erection in 1599. Southwark was further noted for its inns and its prisons. Among the first, the name of the "Tabard" is well known from its mention by Chaucer in detailing the company of pilgrims for Canterbury. Charles Dickens had an early acquaintance with Southwark, as his father was confined in the Marshalsea, one of several prisons here. The prison no longer extant, and the church of St George the Martyr, where many prisoners, including Bishop Bonner (d. 1561), were buried, figure in the novel Little Dorrit. The existing church dates from 1736.

SOUTHWELL, Robert (c. 1561-1595), English Jesuit and poet, son of Richard Southwell of Horsham St Faith's, Norfolk, was born in 1560/61. The Southwells were affiliated with many noble English families, and Robert's grandmother, Elizabeth Shelley, figures in the genealogy of Shelley the poet. He was sent very young to the Roman Catholic college at Douai, and thence to Paris, where he was placed under a Jesuit father, Thomas Darbyshire. In 1580 he joined the Society of Jesus, after a two years' novitiate, passed mostly at Tournay. In spite of his youth he was made prefect of studies in the English college of the Jesuits at Rome, and was ordained priest in 1584. It was in that year that an act was passed, forbidding any English-born subject of the Queen who had entered into priest's orders in the Roman Catholic Church since her accession to remain in England longer than forty days on pain of death. But Southwell at his own request was sent to England in 1586 as a Jesuit missionary with Henry Garnett. He went from one Catholic family to another, administering the rites of his Church, and his main became Jacob Breyfogle, the first earl of Arundel, and was in prison convicted of treason. It was to him that Southwell addressed his Epistle of Comfort. This and other of his religious tracts, A Short Rule of Good Life, Triumphs over Death, Mary Magdalen's Tears and a Humble Supplication to Queen Elizabeth, were widely circulated in manuscript. That they found favour outside Catholic circles is proved by Thomas Nash's imitation of Mary Magdalen's Tears in Christ's Tears over Jerusalem. After six years of successful labour Southwell was arrested. He was in the habit of visiting the house of Richard Bellamy, who lived near Harrow and was under suspicion on account of his connexion with Jerome Bellamy, who had been executed for sharing in Anthony Babington's plot. One of the daughters, Anne Bellamy, was arrested and imprisoned in the gatehouse of Holborn. She revealed Southwell's movements to Richard Topcliffe, who immediately arrested him. He was imprisoned at first in Topcliffe's house, where he was repeatedly put to the torture in the vain hope of extracting evidence about other priests. Transferred to the gatehouse at Westminster, he was so abominably treated that his father petitioned Elizabeth that he might either be put to death, or confined for life, or removed in any case from "that filthy hole." Southwell was then lodged in the Tower, but he was not brought to trial until February 1595. There is little doubt that much of his poetry, none of which was published during his lifetime, was written in prison. On the 20th of February 1595 he was tried before the court of King's Bench on the charge of treason, and was hanged at Tyburn on the following day. On the scaffold he denied any evil intentions towards the Queen or her government.

St Peter's Complaint with other Poems was published in April.
1905 without the author's name, and was reprinted thirteen times during the next forty years. A supplementary volume entitled *Masonic* appeared later in 1905, and *A Fourte feauld Meditation of the foure last things* in 1666. This, which is not included in Dr A. B. Grosart's reprint (1872) in the Fuller Worthies Library, was published by Mr Charles Edmonds in his *Isham Reprints* (1865). *A Hundred Meditations of the Love of God*, in prose, was first printed from a MS. at Stonyhurst College. Southwell's essay is enthusiastic in manner. But his frequent use of antithesis and paradox, the varied and fanciful imagery by which he realizes religious emotion, though they are indeed in accordance with the poetical conventions of his time, are also the unconstrained expression of an ardent and concentrated imagination. Ben Jonson told Drummy of Hawthornden that he would willingly have destroyed many of his own poems to be able to claim as his own Southwell's "Burning Babe," an extreme but beautiful example of his fantastic treatment of sacred subjects. His poetry is not, however, all characterized by this elaboration. Immediately preceding this very piece in his collected works is a carol written in terms of the utmost simplicity.

See Dr Grosart's edition already mentioned. Southwell's poems were also edited by W. B. Turnbull in 1856. A memoir of him was drawn up soon after his death. Much of the material was incorporated in Bishop Challoner's *Maiestas Missionariae Præstolato* (1741), and the MS. is now in the Public Record Office in Brussels. See also Sidney Lee's account in the *Dict. Nat. Bio*. Alexis Possoz. *Victoria* (R. E. Smith) (1866) gives a life of Henry Foley's *Recherches de l'Église Provincial de la France*, *Histoire des manuscrits de la France*, and certain works of the Labourers in the 17th and 18th centuries, 1877 (1. 501-587). Foley's narrative includes copies of the most important documents connected with his trial, and gives full information of the original sources.

**SOUTHWELL**, a cathedral city in the Newark parliamentary division of Nottinghamshire, England, 16 m. N.E. of Nottingham by a branch of the Midland railway. Pop. (1901), 3161. The minster church of St Mary became a cathedral on the foundation of the episcopal see in 884. The see covers the greater part of Nottinghamshire and Derbyshire, with small portions of Leicestershires, Lincs and Staffordshire. The foundation of the earliest church here is attributed to the missionary Paulinus in the first half of the 7th century. Another followed, after the devastations of the Northmen, in 960, on the foundation of King Edgar. The building of the present church began in the reign of Henry I. Henry VIII., after the dissolution of the monasteries, contemplated the erection of the church into a cathedral. The cathedral is a magnificent cruciform building, 306 ft. in length, with massive Norman nave (61 ft. wide), transects, central and two western towers; and Early English choir with transepts. There is an octagonal chapter house, rented by that at York, exhibiting the Decorated style in its highest development. It is connected with the church by a cloister. The archbishops of York had a palace here dating from the 15th century. The "great chamber" was restored in 1882, and since 1904 the building has been converted into a residence for the bishops of Southwell.

The erection of the church at Southwell (Suwell, Sutwell, Suthowell), probably the cause of the origin of the town, is attributed to the archbishop of York in the 7th century. In 998 land at Southwell was granted to the archbishop by Edwy. A detailed description of the great man is given in Domesday. Southwell remained under the lordship of the see of York until it was taken over by the ecclesiastical commissioners. It was called a borough in the 15th century and down to the 17th, but no charter of incorporation is known. The town never returned representatives to parliament. In the reign of Edward I. the archbishop claimed by prescriptive right a five-days' fair at Pentecost, a three-days' fair at the translation of St Thomas and a Saturday market. Fairs are now held in April and December. The market was still held on Saturdays in 1894, but was then very small.
