Copyright, in the United States of America, 1911, by The Encyclopædia Britannica Company.
INITIALS USED IN VOLUME XXVI. TO IDENTIFY INDIVIDUAL CONTRIBUTORS,\(^1\) WITH THE HEADINGS OF THE ARTICLES IN THIS VOLUME SO SIGNED.

**A. A. R.**  
A. Adams Reilly.  
Joint-author of *Life and Letters of J. D. Forbes.*

**A. Bo.**  
Auguste Boudinjon, D.D., D.C.L.  
Professor of Canon Law at the Catholic University of Paris. Honorary Canon of Paris. Editor of the *Canonistis contemporain.*

**A. B. G.**  
Alfred Bradley Gough, M.A., Ph.D.  
Sometime Casberd Scholar of St John's College, Oxford. English Lector in the University of Kiel, 1896-1905.

**A. Ca.**  
Arthur Cayley, LL.D., F.R.S.  
See the biographical article: *Cayley, Arthur.*

**A. Ch.**  
Alfred Chapman, M.Inst.C.E.  
Designer and Constructor of Sugar-Machinery.

**A. C. C.**  
Albert Curtis Clark, M.A.  
Fellow and Tutor of Queen's College, Oxford, and University Reader in Latin. Editor of Cicero's *Speeches* (Clarendon Press).

**A. C. G.**  
Albert Charles Lewis Gotthilf Guenther, M.A., M.D., Ph.D., F.R.S.  

**A. C. McG.**  
Professor of Church History, Union Theological Seminary, New York. Author of *History of Christianity in the Apostolic Age*; &c. Editor of the *Historia Ecclesiae* of Eusebius.

**A. D. G.**  
Alfred Denis Godley, M.A.  
Fellow and Tutor of Magdalen College, Oxford, and Public Orator in the University. Author of *Socrates and Athenian Society*; &c. Editor of editions of Tacitus.

**A. F. P.**  
Albert Frederick Pollard, M.A., F.R.Hist.S.  

**A. G.**  
Major Arthur George Frederick Griffiths (d. 1908).  
H.M. Inspector of Prisons, 1878-1896. Author of *The Chronicles of Newgate; Secrets of the Prison House*; &c.

**A. Ha.**  
Adolf Harnack, D.Ph.  
See the biographical article: *Harnack, Adolf.*

**A. He.**  
Arthur Hervey.  
Formerly Musical Critic to the *Morning Post* and to *Vanity Fair*. Author of *Masters of French Music; French Music in the Nineteenth Century.*

**A. H.-S.**  
Sir A. Houtum-Schindler, C.I.E.  
General in the Persian Army. Author of *Eastern Persian Irak.*

**A. H. S.**  
Rev. Archibald Henry Sayce, D.D., LL.D.  
See the biographical article: *Sayce, Archibald H.*

**A. J. G.**  
Rev. Alexander James Grieve, M.A., B.D.  
Professor of New Testament and Church History, Yorkshire United Independent College, Bradford. Sometime Registrar of Madras University, and Member of Mysore Educational Service.

**A. L.**  
Andrew Lang, LL.D.  
See the biographical article: *Lang, Andrew.*

\(^1\) A complete list, showing all individual contributors, appears in the final volume.
A. MÜLLER, Ph.D. (1848-1892).  
Formerly Professor of Semitic Languages in the University of Halle.  
Author of "Islam im Morgen- und Abendland."  
Editor of Orientalische Bibliographie.

A. M. F.*  
Vice-Admiral R.N.  
Admiralty Representative on Port of London Authority.  
Acting Conservator of River Mersey.  
Hydrographer of the Royal Navy, 1904-1909.  
Author of "Hydrographical Surveying; &c.

A. N.  
ALFRED NEWTON, F.R.S.  
See the biographical article: NEWTON, ALFRED.

A. P. H.  
ALFRED PETER HILLIER, M.D., M.P.  
Author of "South African Studies: The Commonweal;" &c.  
Served in Kaffir War, 1878-1879.  
Partner with Dr L. S. Jameson in medical practice in South Africa till 1896.

REV. ARCHIBALD R. S. KENNEDY, M.A., D.D.  
Professor of Hebrew and Semitic Languages in the University of Edinburgh.  
Professor of Hebrew in the University of Aberdeen, 1887-1894.  
Editor of "Exodus" in the Temple Bible.

A. S.  
ARTHUR SHADWELL, M.A., M.D., LL.D.  
Member of the Council of Epidemiological Society.  
Author of The London Water Supply; Industrial Efficiency; Drink, Temperance and Legislation.

A. Sp.  
ARCHIBALD SHARP, Consulting Engineer and Chartered Patent Agent.

A. S. C.  
ALAN SUMMERLY COLE, C.B.  
Formerly Assistant Secretary, Board of Education, South Kensington.  
Author of "Ornament in European Slik; Catalogue of Tapestry, Embroidery, Lace and Egyptian Textiles in the Victoria and Albert Museum;" &c.

A. S. P-P.  
ANDREW SETH PRINGLE-PATTSOn, M.A., LL.D., D.C.L.  
Professor of Logic and Metaphysics in the University of Edinburgh.  
Gifford Lecturer in the University of Aberdeen, 1911.  
Fellow of the British Academy.  
Author of Man's Place in the Cosmos; The Philosophical Radicals; &c.

A. Wa.  
ARTHUR WAUGH, M.A.  
Formerly literary adviser to Kegan Paul & Co.  
Author of Alfred Lord Tennyson; Legends of the Wheel; Robert Browning in "Westminster Biographies."  
Editor of Johnson's Lives of the Poets.

A. W. H.*  
ARTHUR WILLIAM HOLLAND.  
Formerly Scholar of St John's College, Oxford.  
Bacon Scholar of Gray's Inn, 1900.

A. W. R.  
ALEXANDER WOOD RENTON, M.A., LL.B.  
Puisne Judge of the Supreme Court of Ceylon.  
Editor of Encyclopaedia of the Laws of England.

C. B.*  
CHARLES BÉMONT, D.LITT.  
See the biographical article: BÉMONT, C.

C. C.  
CHARLES CREIGHTON, M.A., M.D.  
King's College, Cambridge.  
Author of A History of Epidemics in Britain; Jenner and Vaccination; Plague in India; &c.

C. E.  
SIR CHARLES NORTON EDGECOMBE ELIOT, K.C.M.G., LL.D., D.C.L.  
Vice-Chancellor of Sheffield University.  
Formerly Fellow of Trinity College, Oxford.  
H.M.'s Commissioner and Commander-in-Chief for the British East Africa Protectorate; Agent and Consul-General at Zanzibar; Consul-General for German East Africa, 1900-1904.

C. F. A.

SUBMARINE MINES. A submarine mine is a weapon of war used in the attack and defence of harbours and anchorages. It may be defined as “A charge of explosives, moored at or beneath the surface of the water, intended by its explosion to put out of action without delay a hostile vessel of the class it is intended to act against.” It differs from the torpedo (q.v.) in being incapable of movement (except in the special form of drifting mines, which are not moored, but move with the tide or current). But this subdivision into two distinct classes was not made till 1876. Prior to that date the term “torpedo” was used for all explosive charges fired in the water.

Submarine mines may be divided into two main classes, controllable and uncontrollable, or, as they are often classified, “electrical” or “mechanical.” In the first class the method of firing is by electricity, the source of the electric power whether by battery or dynamo being contained in a firing station on shore and connected to the mines by insulated cables. By simply switching off the electricity in the firing station, such mines are rendered inert and entirely harmless. In the second class, the means of firing are contained in the mine itself, the source of power being a small electric battery, or being obtained from a pistol, spring or suspended weight. In all mines of this class the impulse which actuates the firing gear is given by a ship or other floating object bumping against the mine. When mechanical mines have once been set for firing they are thus dangerous to friend and foe alike. Safety arrangements are employed to prevent the firing apparatus working while the mine is being laid, and clockwork is sometimes added to render the mine inactive after a certain definite time or in case the mine breaks away from its mooring. Their principal advantages, as compared with the electrically controlled mines, are cheapness and rapidity of laying. “Controllable” mines are absolutely under the control of the operator on shore, their condition is always accurately known, and if any break adrift not only is the fact at once known but the mines themselves are harmless. Another advantage is that when fired by “observation” as described below, they are placed at depths which will be well below the bottom of any vessels passing through the mine field. They can thus be used in channels which have to be kept open for traffic during hostilities.

Electrical mines take rather longer to prepare and lay out than the other class, as the electrical cables have to be laid and jointed, and they require rather more skill and training in the operators employed to lay and fire the mines. Such mines represent the highest development of this form of warfare, and the details given below refer mainly to this class of mine.

Electrical mines are arranged on two systems according to the method of ascertaining the proper moment to apply the firing current to the mine cables. These methods are by “observation” or by “circuit closer.”

The “observation” system depends on two careful observations made by an operator on shore, one of the exact position in which the mines are laid, the other of the track of hostile ships passing over the mine field. The position of the mines when laid is marked on a special chart, on which the track of ships crossing the mine field can also be plotted. When the track is seen to be crossing the position of a mine, a switch is closed on shore and the mine is fired. To allow for errors in observation such mines are fitted with large charges of explosive and are usually arranged in lines of two, three or four mines placed across the channel, all the mines in a line being fired together. Observation mines are placed either resting on the bottom or moored at depths which are well below the bottom of any friendly vessels and (except that anchoring in the mine field must be forbidden for fear of injury to cables) such mines offer no obstruction to friendly traffic.

In the “circuit closer” or “C.C.” system, each mine contains a small piece of apparatus which is set in action by the blow of a vessel or other object against the mine. When set in action, this apparatus completes an electrical circuit in the mine, through which the mine can be fired, if the main switch on shore is closed. If it is not wished to fire, the C.C. is restored to its ordinary condition either automatically by a spring in the mine, or by an electrical device operated from the shore.

Such mines are necessarily placed near the surface, and are to this extent an interference with friendly traffic. A vessel passing by mistake through a mine field of this class would run no risk of an explosion while the mines are inactive, but might do some damage to the mines.

This class of mine is used in side channels which it is intended to close entirely, or to reduce the width of navigable channels where too wide to be defended by observation mines. Their principal advantage is that if the firing switch is closed they are effective in fog or mist, when observation mines could not be worked, and when the guns of the defence would be equally out of action. As they are fired only when close against the side of a ship, the charge can be comparatively small and the mines themselves are handy and easy to lay.

Compared with observation mines they use much less cable, as the action of the C.C. is such that only the mine which is struck can be fired. Several mines of this class can therefore share one cable from the shore, though in practice details of mooring and arrangement limit the number connected to one cable to four. A set of mines on one cable is referred to as a “group.”

The arrangements for firing the mines are contained in a firing station on shore, in which is the battery or other source of
electrical power for firing, and the necessary apparatus for testing the system of mines, which is usually done daily. To let the operator in the firing station know when the C.C. of a mine has been struck and the mine is ready to fire, a small electrical apparatus is provided in the firing station for each group of mines. This arrangement strikes a bell when the C.C. is worked and also closes a break in the firing circuit. The operator can then close the main switch and fire the mine, or if acting on the order to "fire all mines that signal" he has already closed his main switch, the signalling apparatus, in the act of striking the bell, completes the firing circuit. A similar piece of apparatus is connected to each observing instrument, the completion of the circuit of any line at the observing station then gives a signal in the firing station and the firing circuit is completed.

The firing station can be on a vessel moored near the mine field, but is more usually on shore, where it can be made absolutely secure against any form of attack. But the observing stations must be on shore to give stability to the observing instruments, they cannot be entirely protected as they must have a small opening facing the mine field, but can be made very inconspicuous.

Any explosive can be used in submarine mines, provided adequate means are taken to explode the charge, but the explosive which is easiest to handle and is in most general use is wet gun-cotton with a small dry primer and detonator to start ignition. The detonators for electrical mines are on the "low tension" system, that is, firing is effected by the heating of a small length of wire called a "bridge," round which is placed a priming which ignites and detonates a small charge of fulminate of mercury.

The charge is contained in a steel mine-case, which has an "apparatus" inside to contain the electrical arrangements and the C.C. when used. Cases for observation mines are usually cylindrical in shape for mines to rest on the bottom and spherical for buoyant mines. The weight of charge is about 500 lb and the size of a buoyant case for this charge would be four feet in diameter. Cases for contact mines are spherical, about 39 in. in diameter, and can hold 100 lb of gun-cotton. They are always buoyant. Buoyancy is provided for by an air-space inside the case. Buoyant cases are moored to a heavy weight or "sinker," the connexion being by a steel wire rope, or in electrical mines, the cable itself. The cable is carefully insulated and protected with a layer of steel wires. An earth return is used for the electrical circuit.

The employment of mines in any defence must depend entirely on the general character of the defence adopted, which will itself depend on the size and importance of the harbour to be defended and other details (see COAST DEFENCE). The rôle of mines in a defence is to act as an obstacle to detain ships under fire and compel them to engage the artillery of the defence. Thus mines find their greatest usefulness in the defence of harbours with long channels of approach. Mine fields can be destroyed by "creeping" for and cutting the electric cables, by "sweeping" for the mines themselves with long loops of chain or rope or by destroying the mines with "countermines." To guard against any of these, the mine field should be protected by gun fire and lit at night by electric lights. As vessels sunk by mines may obstruct the channel, mines should not be used in very narrow channels.

Although the scientific development of submarine mining is the work of the last fifty years, attempts to use drifting charges against ships and bridges are recorded as early as the 16th century. Mines were used by the Americans in 1777, and in 1780 Robert Fulton produced an explosive machine which he called a "torpedo," and which was experimented with, not very successfully, up to 1815. In 1834 the Russians used mechanical mines in the Baltic, but without any marked success. The first application of electricity to the explosion of submerged charges was made by Sir Charles Pasley in the destruction of wrecks in the Thames and of the wreck of the "Royal George" at Spithead in 1839 and subsequent years. The first military use of electrically-fired mines was made in the American Civil War of 1861-65 when several vessels were sunk or damaged by mines or torpedoes. From this date onwards the American nations experimented with mines, and they were actually used in the Franco-German War of 1870, the Russo-Turkish War of 1878 and the Spanish-American War of 1898. But the most interesting example of mine warfare was in the attack and defence of Port Arthur during the Russo-Japanese War (95-96). Both sides used the mechanical mines only, and bombs.

SUBSIDY (through Fr. from Lat. subsidium, reserve troops, aid, assistance, from subdivere, literally "to sit or remain behind"), aid, subvention, assistance granted especially in money. The word has a particular use in economic history and practice. In English history it is the general term for a tax granted to the king by parliament, and so distinguished from those duties, such as the customs duties, which were raised by the royal prerogative; of these subsidies there were many varieties; such was the subsidy in excess of the customs on wool, leather, wine or cloth exported or imported by aliens, later extended to other articles and to native exporters and importers (see Tonnage and Poundage); there was also the subsidy which in the 14th century took the shape of a glass or term subsidy. Apart from this application the term, in modern times, is particularly applied to the pecuniary assistance by means of bounties, &c., given by the state to industrial undertakings (see Bounty). Subsidies granted by the state to literary, dramatic or other artistic institutions, societies, &c., are generally styled "subventions" (Lat. subvenire, to come to the aid of).

SUCCESSION (Lat. successio, from succedere, to follow after) the act of succeeding or following, as of events, objects, places in a series, &c., but particularly, in law, the transmission or passing of rights from one to another.

In every system of law provision has to be made for a readjustment of things or goods on the death of the human beings who owned and enjoyed them. Succession to rights may be considered from two points of view: in some ways they depend on the personality of those who are concerned with them: if you hire a servant, you acquire a claim against a certain person and your claim will disappear on his death. But personal relations are commonly implicated in the arrangement of property: if a person borrows money, the creditor expects to be paid even should the debtor die, and the actual payment will depend to a great extent on the rules as to inheritance. Succession, in the sense of the partition or redistribution of the property of a former owner is, in modern systems of law, the subject of many rules. Such rules may be based on the will of a deceased person. They will be found in such articles as Administration; Assets; Executors and Administrators; Inheritance; Intestacy; Legacy; Will; &c. There are cases, however, in which a will cannot be expressed; this eventuality is discussed in the present article, and there can be no doubt that it is the most characteristic one from the point of view of social conditions. It represents the normal course of succession, and is to what ought to be the normal course of succession in the readjustment of property after the death of a citizen. We shall dwell chiefly on the customs of succession among the nations of Aryan stock. Other customs are noticed in the articles on Village Communities; Mahomedan Law; &c.

We have to start from a distinction between personal goods and the property forming the economic basis of existence for the family which is strongly expressed in early law. War booty, proceeds of hunting, clothes and ornaments, implements fashioned by personal skill, are taken to belong to a man in a more personal way than the land on which he dwells or the cattle of a herd.
The character of this kind of property has a decisive influence on the modes of succession to it. This part of the inheritance is widely considered in early law as still in the power of the dead even after demise. We find that many savage tribes simply destroy the personal belongings of the dead: this is done by several Australian and Negro tribes (Post, Grundriss der ethnologischen Jurisprudenz, pp. 174–5). Sometimes this rule is modified in the sense that the goods remaining after deceased persons have to be taken away by strangers, which leads to curious customs of looting the house of the deceased. Such customs were prevalent, for example, among the North American Indians of the Delaware and Iroquois tribes. Evidently the nearer relations dare not take over such things on account of a tabu rule, while strangers may appropriate them, as it were, by right of conquest.

The continuance of the relation of the deceased to his own things gives rise in most cases to provisions made for the dead out of his personal succession. The habit of putting arms, victuals, clothes and ornaments in the grave seems almost universal, and there can be no doubt that the idea underlying such usages consists in the wish to provide the deceased with all matters necessary to his existence after death. A very characteristic illustration of this conception may be given from the customs of the ancient Russians, as described about 921 by the Arabian traveller Ibn Fadlan. The whole of the personal property was divided into three parts: one-third went to the family, the second third was used for making clothes and other ornaments for the dead, while the third was spent in carousing on the day when the corpse was cremated. The ceremony itself consisted in the following: the corpse was put into a boat and was dressed up in the most gorgeous attire. Intoxicating drinks, fruit, bread and meat were put by his side; a dog was cut into two parts, which were thrown into the boat. Then, all the weapons of the dead man were brought in, as well as the flesh of two horses, a cock and a chicken. The concubine of the deceased was also sacrificed, and ultimately all these objects were burned in a huge pile, and a mound thrown up over the ashes. This description is the more interesting because it starts from a logical point of view, that is, even in the case of the dead, some of them being affected, as it were, to his personal usage. This rule continues to be observed in Germanic law in later times and became the starting point of the doctrine of succession to personal property in English law. According to Glanville (vii. 5, 4), the chattels of the deceased have to be divided into three equal parts, of which one goes to his heir, one to his wife and one is reserved to the deceased himself. The same reservation of the third to the deceased himself is observed in Magna Charta (c. 26) and in Bracton's statement of Common Law (fol. 60), but in Christian surroundings the reservation of the dead man's part was taken to apply to the property which had to be spent for his soul and of which, accordingly, the Church had to take care. This lies at the root of the common law doctrine observed until the passing of the Court of Probate Act 1857. On the strength of this doctrine the bishop was the natural administrator of this part of the personality of the deceased.

The succession to real property, if we may use the English legal expression, is not governed by such considerations or the needs of the dead. Roughly speaking, three different views may be taken as to the proper readjustment in such cases. Taking the principal types in a logical sequence, which differs from the historical one, we may say that the aggregate of things and claims relinquished by a deceased person may: (1) pass to relatives or other persons who stood near him in a way determined by law. Should several persons of the kind stand equally near in the eye of the law the consequence would be a division of the inheritance. The personal aspect of succession rules in such systems of inheritance. (2) The deceased may be considered as a subordinate member of a higher organism—a kindred, a village, a state, &c. In such a case there can be no succession proper as there has been no individual property to begin with. The cases of succession will be a relapse of certain goods used by the member of a community to that community and a consequent rearrangement of rights of usage. The law of succession will again be constructed on a personal basis, but this basis will be supplied not by the single individual whose death has had to be recorded but by some community or union to which this individual belonged. (3) The aggregate of goods and claims constituting what is commonly called an inheritance may be considered as a unit having an existence and an object of its own. The consequence of the death of an individual owner will, as in case 2, be treated as an accidental fact. The unity of the inheritance and the social part played by it will constitute the ruling considerations in the arrangement of succession. The personal factor will be subordinated to the real one.

In practice pure forms corresponding to these main conceptions occur seldom, and the actual systems of succession mostly appear as combinations of these various views. We shall try to give briefly an account of the following arrangements: (1) the joint family in so far as it bears on succession; (2) voluntary associations among co-heirs; (3) division of inheritance; (4) united succession in the shape of primogeniture and of junior right.

The large mass of Hindu juridical texts representing customs and doctrines ranging over nearly 5000 years contains many indications as to the existence of a joint family which was considered as the corporate owner of property and therefore did not admit in principle of the opening of succession through the death of any of its members. The father or head of such a joint family was in truth only the manager of its property during lifetime, and though on his demise this power and right of management had to be regulated anew, the property itself could not be said to pass by succession: it remained as formerly in the joint family itself. In stating this abstract doctrine we have to add that our evidence shows us in practice only characteristic consequences and fragments of it, but that we have not the means of observing it directly in a consistent and complete shape during the comparatively recent epochs which are reflected in the evidence. It is even a question whether such a doctrine was ever absolutely enforced in regard to the whole body of personal property. Under the influence of personal apparel and objects acquired by personal will and strength fell to a great extent under the conception of separate property. Gains of science, art and craft are mentioned in early instances as subject to special ownership and corresponding rules of personal succession are framed in regard to them (Jolly, Tagore lectures on Partition, Inheritance and Adoption, 94). But on the other hand there are certain categories of movable goods which even in later law are considered as belonging to the family community and incapable of partition, e.g. water, prepared food, roads, vehicles, female slaves, property destined for pious uses and sacrifices, books. When law became rationalized these things had to be sold in order that the proceeds of the sale should be divided, but originally they seem to have been regarded as owned by the joint family though used by its single members. And as to immovables—land and houses—they were demonstrably excluded in ancient customary law from partition among co-heirs.

In Greek law the most drastic expression of the joint family system is to be found in the arrangements of Spartan households, where brothers clustered round the eldest or "keeper of the hearth" (ερημαδώος), and not only the management of property but their marriages were dependent on the unity of the shares and on the necessity of keeping down the offspring of the younger brothers. With the Romans there are hardly any traces of a primitive family community excluding succession, but the Celtic tribal system was to a great extent based on this fundamental conception (Seebohm, Tribal System in Wales).

*The term illustrates the intimate connexion between inheritance and household religion in ancient Aryan custom.*
During three generations the offspring of father, grandfather and great-grandfather held together in regard to land. The consequence was that, although separate plots and houses were commonly reserved for the uses of the smaller families included within the larger unit, the death of the principal brought about an equalization of shares first per stirpes and ultimately per capita until the final break-up of the community when it reached the stage of the great-grandsons of the original founder. But the most elaborate system of family ownership is to be observed in the history of the latest comers among the Aryan races—the Slavs. In the backward mountain regions which they occupied in the Balkan Peninsula and in the wilderness of the forests and moors of Eastern Europe they developed many characteristic tribal institutions and, among these, the joint family, the Zadruga, inokoshtina. The huge family communities of the southern Slavs have been described at length by recent observers, and there can be no doubt that their roots go back to a distant past (see Village Communities). There is no room in them for succession proper: what has to be provided for is the continuity of business management by elders and the repartition of rights of usage and maintenance, a repartition largely dependent on varying customs and on the policy of the above-mentioned elders. In Russia the so-called large family appears as a much less extensive application of the same idea. It extends rarely over more than three generations, but even as a cluster of members gathering around a grandfather or a great-uncle it presents an arrangement which hampers greatly private enterprise and staves off succession until the moment when the great household breaks up between the descendants of a great-grandfather.

In Germanic law we catch a glimpse of a state of things in which side relations were not admitted to succession at all. The Frankish Edict of Chilperic (a.d. 571) tells us that if somebody died without leaving sons or daughters, his brother was to succeed him and not his neighbours (non vicini). This has to be construed as a modification of the older rule according to which the neighbours succeeded and not the brother. Under "neighbours" we cannot understand merely people connected with a person by proximity of settlement, but rather his kinsmen in their usual capacity of neighbours. The fact that kinsmen forming a settlement have precedence of such near relations as the brothers is characteristic enough, especially, as even the succession of sons and daughters is mentioned in a way which shows that there was still some doubt whether neighbouring kinsmen should not take inheritance instead of the latter. These are systems of a very archaic arrangement based on a close tribal community between the members of a kindred. Such a community is not apparent in later legal custom, but there are many signs of a close union between members of the same family. The law of Scania, a province of his own, shows us a group settled around a grandfather. His sons even when married held part of the property under him and it is with some difficulty that they and their wives succeed in separating some of the goods acquired by personal work or brought in by marriage from the rest of the household property (Scanian Law, Danish Text i. 5). The same arrangement appears in Lombard law as regards brothers who remain settled in a common house (Edict of Rothari c. 167). Of course, in all such cases, there could be no real inheritance and succession, but merely the stepping in of the next generation into the rights and duties of the representative of an older generation on the latter's demise. In legal terminology it is a case of accretion and not of succession.

The next stage in the development of succession is presented by an arrangement which was common in Germany, viz. by the management of property under the rule of so-called Ganerbshaft. Ganerben is the same as the Latin coheredes, comparitices, consories. A capitulare of 816 mentions such communities of heirs holding in common (cf. Boretius Capitularia, i. 282). Within the community the shareholders could dispose of any part of the property by his single will. Legally and economically all transactions had to proceed from common consent and common resolve. This did not preclude the possibility of any one among the shareholders claiming his own portion, in which case part of the property had to be meted out to him according to fair computation (swascara). There was no legal constraint over the shareholders to remain in common: division could be brought about either by common consent or by claims of individuals, and yet the constant occurrence of these settlements of co-heirs shows that as a matter of fact the necessity of keeping together and not to break up the unit of property by division. The customary union of co-heirs appears in this way as a corrective of the strict legal principle of equal rights between heirs of the same degree. In English practice the joint management of co-heirs is not so fully described, but there can be no doubt that under the older Saxon rule admitting heirs of the same degree to equal rights in succession the interests of economic efficiency were commonly preserved by the carrying on of common husbandry without any realization of the concurrent claims which would have broken up the course of succession. This accounts for the fact that notwithstanding the prevalence among the early English of the rule admitting all the sons or heirs in the same position to equal shares in the inheritance, the organic units of hides, yardlands, &c. are kept up in the course of centuries. In the management of so-called gevallkind succession in Kent partition was legally possible and came sometimes to be effected, but there was the customary reaction against it in the shape of keeping up the "yokes" and "sulungs." A trace of the same kind of union between co-heirs appears in the so-called parage communities so often mentioned in Domesday Books.

In all these cases of co-heirs and joint management is kept up by purely economic means and considerations. The legal possibility of partition is admitted by the side of it. It is interesting to watch two divergent lines of further development springing from this common source; on the one side we see the full realization of individual right resulting in frequent divisions; on the other side we watch the rise of legal restraints on subdivision resulting in the establishment, in respect of certain categories of property, of rules excluding the plurality of heirs for the sake of preserving the unity of the household. The first system, of course, most easily carried out in countries where individualistic types of husbandry prevail. In Europe it is especially prevalent in the south with its intense cultivation of the arable and its habits of wine and olive growing. We shall not wonder, therefore, that the unrestricted subdivision among heirs is represented most completely by Roman law. Not to speak of the fact that already in the XIT. Tables the principal mode of inheritance was considered to be inheritance by will while intestate succession came in as a subsidiary expedient, we have to notice that there is no check on the disposition of property among heirs of the same degree. The only survival of a régime of family community may be found in the distinction between heredes sui (heirs of their own) and heredes extranei (outside heirs of the deceased). The first entered by their own right and took possession of property which had belonged to them potentially even during their ancestor's life. The latter drew their claims from their relationship to the deceased and this did not give them a direct hold on the property in question. Apart from that the civil law of ancient Rome favoured complete division and the same principle is represented in all European legislation derived from Roman law or strongly influenced by it. Sometimes, as in the French Code Civil, even the wish of the owner cannot alter the customary subdivision as no person can make a will depriving any of his children of their legal share. In full contrast with this mode of succession prevailing in romanized countries we find the nations proceeding from Germanic stock and strongly influenced by feudalism developing two different kinds of restraints on subdivision. In Scandinavian law this point of view is expressed by the Norwegian customs as to Odal. The principal estates of the country, which, according to the law of the Gulating have descended through five generations in the same family, cannot be dispersed and
alienated at pleasure. They are considered as rightly belonging to the kindred with which a historical connexion has been established. In order to keep these estates within the kindred they are to descend chiefly to men; women are admitted to property in them only in exceptional cases. Originally it is only the daughter of a man who has left no sons and the sister of one who has left no children and no brothers that are admitted to take Odal as if they were men. Nieces and first-cousins are admitted in the sense that they have to pass the property to their nearest male heir. They may, in certain eventualities, be bought out by the nearest male relative. A second peculiarity of Odal consists in the right of relations descending from one of the common ancestors to prevent strangers from acquiring Odal estate. Any holder of such an estate who wants to sell it in its entirety or in portion has first to apply to his relatives and they may acquire the estate at the price proposed by a stranger less one-fifth. Even if no relative has taken advantage of this privilege an Odal estate sold to a stranger may be bought back into the family by compulsory redemption if the relatives subsequently find the means and have the wish to resort to such redemption. Odal right does not curtail the claims of the younger sons or of any heirs in a similar position. As a matter of fact, however, customary succession in Norwegian peasant families sets great price on holding the property of the household well together. It is keenly felt that agaard (farm) ought not to be parcelled up into smaller holdings, and in the common case of several heirs succeeding to the farm, they generally make up among themselves who is to remain in charge of the ancestral household: the rest are compensated in money or helped to start on some other estate or perhaps in a cottage by the side of the principal house. In medieval England, France and Germany the same considerations of economic efficiency are felt as regards the keeping up of united holdings, and it may be said that the lower we get in the scale of property the stronger these considerations become. If it is possible, though not perhaps profitable, to divide the property of a large farm, it becomes almost impossible to break-up the smaller units—so-called yardlands and ooxgans. Through being parcelled up into small plots, land loses in value, and, as to cattle, it is impossible to divide one ox or one horse in specie without selling them. No wonder that we find practices and customs of united succession arising in direct contradiction with the ancient rule that all heirs of the same degree should be admitted to equal shares. Glanville mentions expressly that the socagers of his time held partly by undivided succession and partly by divided inheritance. The relations of feudalism and serfdom contributed strongly towards creating such individual tenancies. It was certainly in the interest of the lord that his men, whether holding a military fief or an agricultural farm, should not weaken the value of their tenancies by dispersing the one or the other among heirs. But apart from these interests of over-lords there was the evident self-interest of the tenants themselves and therefore the point of view of unification of holdings is by no means confined to servile tenements or to military fiefs. The question whether the successor should be the eldest son or the youngest son is a secondary one. The latter practice was very prevalent all through Europe and produced in England what is termed the Borough English rule. The quaint name has been derived from the contrast in point of succession between the two parts of the borough of Nottingham. The French burgesses transmitted their tenements by primogeniture, while in the cases of the English tenure who has left no children or brothers usual explanation of this passage of the holdings to the youngest is found in the fact that the youngest son remains longest in his father's house, while the elder brothers have opportunities of going out into the world at a time when the father is still alive and able to take care of his land. This is well in keeping with the view that customs of united succession arise in connexion with compensation provided for co-heirs waiving their claims in regard to settlement in the original household. The succession of the youngest appears also very characteristic in so far as it illustrates the break up into small tenancies, as the youngest in the family is certainly not a fit representative of hierarchy and authority and could not have been meant to rule anything but his own restricted household.

One more feature of the ancient law of succession has to be noticed in conclusion, viz. the exclusion of women from inheritance in law. There can be no doubt that in regards movable goods women held property and transmitted it to their males with right from the earliest time. According to German conception personal ornaments and articles of household furniture are specially effected to their use and follow a distinct line of succession from woman to woman (Gerade). Norse law puts women and men on the same footing as to all forms of property equated to movable goods (Loisée); but as to land there is a prevalent idea that men should be privileged. Women are admitted to a certain extent, but always placed behind men of equal degree. Frankish law originally excluded women from inheritance in land, and this exclusion seems as ancient as the patriarchal system itself, whatever we may think about the position of affairs in prehistoric times when rules of matriarchy were prevalent. A common-sense explanation of one side of this doctrine is tendered by the law of the Thuringians (Lex Anglorum et Wernironum, c. 6). It is stated there that inheritance in land goes with the duty of taking revenge for the homicide of relatives and with the power of bearing arms. One of the most potent adversaries of this system of exclusion proved to be the Church. It favoured all through the view that land should be transmitted in the same way as money or chattels. A Frankish formula (Marcellus) shows us a father who takes the prudent step to endow his daughter with a piece of land according to natural affection in spite of the strict law of his tribe. Such instruments were strongly backed by the Church, and the view that women should be admitted to hold land on certain occasions had made its way in England as early as Anglo-Saxon times.

any other person in possession or expectancy." The property which is liable to pay the duty is in reality or leasehold estate in the United Kingdom and part of the value subject to the duty, will be the value of the estate, as claimed by virtue of English, Scottish or Irish law. Personality in England bestowed abroaD by a person domiciled abroad is not subject to succession duty. Successions of a husband or a wife, successions where the principal value is under £500, and individual successions under £20, are exempt from duty. Leasehold property and personally directed to be converted into real estate are liable to succession, not to legacy duty. Special provision is made for the collection of duty in the cases of joint tenants and where the successor is also the predecessor. The duty is payable on the chargeable amount, the actual charge paid before the duty is paid to the liability of the successor is transferred to the alienor. It is, therefore, usual in requisitions on title before conveyance, to demand for the payment of the purchaser the production of receipts for succession duty, as such receipts are an effectual protection notwithstanding any suppression or misstatement in the account on the footing of which the duty was assessed or any insufficiency of such assessment. The duty is by this act directed to be assessed as follows: on personal property, if the successor takes a limited estate, the duty is payable on the annuity or year's income estimated according to the period during which he is entitled to receive the annuity or yearly income, and the duty is payable in four yearly installments free from interest. If the successor takes absolutely he pays in a lump sum duty on the principal value. On real property the duty is payable in eight half-yearly installments without interest on the capital value of an annuity equal to the annual value of the property. Various minor changes were made. By the Customs and Inland Revenue Act 1881, personal estates under £500 were exempted. By the Customs and Inland Revenue Act 1888 a duty of 1% is charged on successions already paying a 5% and an additional 1% on successions paying more than 5%. By the Customs and Inland Revenue Act 1889 an additional duty of 1% called estate duty was payable on successions over £10,000.

The Finance Acts 1894 and 1900 effected large changes in the duties payable on death (for which see Estate Duty; Legacy). As regards the succession duties they enacted that payment of the estate duties thereby created should include payment of the additional duties mentioned above unless the value of the estate or property (in the case of deceased person child of deceased) are exempted from payment of any succession duties. The succession duty payable under the Succession Duty Act 1853 was in all cases to be calculated according to the principal value of the property, i.e. its selling value, and though still payable by instalments at 3% is chargeable. The additional succession duties are still payable in cases where the estate duty is not charged, but such cases are of small importance and in practice are not as a rule charged.

United States.—The United States imposed a succession duty by the War Revenue Act of 1895 on all legacies or distributive shares of personal property exceeding $10,000. It is a tax on the privilege of succession. Devises or distributions of land are not affected by it. The rate of duty runs from 75 cents on the $100 to $5 on the $100, if the legacy or share in question does not exceed $25,000. On those over that value the rate is 1 ½ times those up to $100,000, twofold on those from $100,000 to $500,000, 2½ times on those from $500,000 to a million, and threefold for those exceeding a million. This statute has been supported as constitutional by the Supreme Court. Many of the states also impose succession duties, or transfer taxes; generally, however, on collateral and remote successions; sometimes progressive, according to the amount of the legacy or share. The real estate succession duties are as important as those personal to real estate successions as well as those to personal property. If a citizen of state A owns registered bonds of a corporation chartered by state B, which he has put for safe keeping in a deposit vault in state C, his estate may thus have to pay four succession taxes, one to state A, to which he belongs and which, by legal fiction, is the seat of all his personal property; one to state B, for permitting the transfer of the bonds to the legatees on the books of the corporation; one to state C, for allowing them to be removed from the deposit vault for that purpose; and one to the United States.

**Succinic Acid**

Succinic acid, C₂H₄(CO₂H)₂. Two acids corresponding to this empirical formula are known—namely ethylene succinic acid, H₂O·C₂H₄·CH₂·C₂O₂H and ethyldiene succinic acid CH₂=C(CH₂·CO₂H)

Ethylene succinic acid occurs in amber, in various resins and lignites, in fossilized wood, in many members of the natural orders of Papaveraceae and Compositae, in unripe grapes, urine and blood. It is also found in the thymus gland of calves and in the spleen of cattle. It may be prepared by the oxidation of fats and of fatty acids by nitric acid, and is also a product of the fermentation of malic and tartaric acids. It is usually obtained by the distillation of the mother-liquors from the fermentation of calcium malate or ammonium tartrate. Syntheticly, it may be obtained by reducing malic or tartaric acids with hydrides of acrid (R. Schmitt, Ann., 1860, 114, p. 106; V. Dessaingues, ibid., 1860, 115, p. 120; by reducing fumaric and maleic acids with sodium amalgam; by heating bretmamic acid with silver to 130° C.; in small quantity by the oxidation of acetic acid with potassium persulphate (C. Moritz and R. Wolfenstein, Ber., 1890, 32, p. 2534). By the hydrolysis of succinonitriile (from ethylene dibromide) C₂H₂(C=O)Br₂—C₂H₄(CN)₂—C₂H₂(CO₂H)₂; by the hydrolysis of β-cyanacetone (from acetic ester with monochloracetic ester and hydrolysis of the resulting ethane tricarboxylic ester (RO₂C₂CH₂CH₂CO₂R; this method is applicable to the preparation of substituted succinic acids. It is also produced by the electrolysis of a concentrated solution of potassium ethyl malonate.

It crystallizes in prisms or plates which melt at 185° C. and boil at 235° C. with partial conversion into the anhydride. It is readily soluble in water. Aqueous solutions of the acid are decomposed in sunlight by uranium salts, with evolution of carbon dioxide and the formation of propionic acid. Potassium succinic acid, in concentrated sulphuric acid, forms a white crystalline precipitate, and in water. The sodium salt on distillation with phosphorus trichloride gives thiophene. The esters of the acid condense readily with aromatic aldehydes and ketones to form γ-substituted itaconic acids and γ-alkyl pyrotaurinic acids (H. Stobbe, Ann., 1899, 308, p. 71). γ-Oxycacid are formed when aldehydes are heated with sodium succinate and sodium acetate. Numerous salts of the acid are known, the basic ferric salt being occasionally used in quantitative analysis for the separation of iron from aluminium.

Succinyl chloride, obtained by the action of phosphorus pentachloride on succinic acid, is a colourless liquid which boils at 190° C. In many respects it behaves as though it were dichlorobutyrolactone, C₆H₄(CCl₂)₂CO₂H on reduction it yields butyro-lactone, and when condensed with benzene in the presence of aluminium chloride it yields hexamethylpyridine. Succinic anhydride, CH₂=C(CH₂·CO₂H)₂ is obtained by heating the acid or its sodium salt with acetic anhydride; by the action of acetyl chloride on the barium salt; by distilling a mixture of succinic acid and succinyl chloride, or by heating succinyl chloride with anhydrous oxalic acid. It crystallizes in plates which melt at 120° C., and distils without decomposition. It is slowly dissolved by water with the formation of the acid. It can be distilled readily by heating with baryta water it yields succinamic acid, HO·C₂H₂·CH₂·CONH₂, and with alcoholic ammonia at 100° C. it gives succinamide.

The imino hydrogen atom is easily replaced by metals. Distillation with zinc dust gives pyrrol (gln.). By the action of bromine in alkaline solution it is converted into β-bromopropionic acid. Succinimide, CH₂(CONH₂)₂, best obtained by the action of ammonia to the sodium succinate and ethyl carbonate at 243° C., and is soluble in hot water. Succinimide, CH₂(CN)₂, is obtained by the action of potassium cyanide on ethylene dibromide or by the electrolysis of a solution of potassium cyanide and succinic acid. It is insoluble in water, and by the reduction with sodium in alcoholic solution it yields tetraethylenediamine (putrescine) and pyrrolidine.

Methyl succinic acid (pyrotaurinic acid), HO·C₂H₂·CH₂·C₂H₂·CO₂H, is formed by the dry distillation of succinic acid; by heating pyruvic acid with concentrated hydrochloric acid to 180° C.; by the reduction of citraconic and mesaconic acids with sodium amalgam; and by
the hydrolysis of α-cyano-butyric acid. It crystallizes in small prisms which melt at 112° C. and are soluble in water. It forms an anhydride when heated. The sodium salt on heating with the action of malonic acid and the alkali metal gives succinic acid.

Ethyldene succinic acid or succinic acid, CH₂COOH₂, is produced by the hydrolysis of α-cyano-butyric acid and by the action of methyl iodide on sodio-malonic ester. It crystalizes in prisms of melting point at 120° C. (T. Salzer, Journ. Prakt. Chem., 1856, l. 57, p. 497), and dissolve in water. It does not yield an anhydride, but when heated loses carbon dioxide and leaves a residue of propionic acid. It may be distinguished from the isomeric ethylene succinic acid by the fact that its sodium salt does not give a precipitate with ferric chloride.

SUCHER, ROSA (1840- ), German opera singer, née Hasselbeck, was the wife of Josef Sucher (1844-1906), a well-known conductor and composer. They were married in 1876, when she had already had various engagements as a singer and he was conductor at the Leipzig city theatre. Frau Sucher soon became famous for her performances in Wagner's operas, her seasons in London in 1882 and 1892 proving her great capacity both as singer and actress; in 1886 and 1888 she sang at Bayreuth, and in later years she was principally associated with the opera stage in Berlin, retiring in 1903. Her magnificent rendering of the part of Isolde in Wagner's opera is especially remembered.

SUCHET, LOUIS GABRIEL, Duc D'ALBUFERA DE VALENCIA (1797-1826), marshall of France, one of the most brilliant of Napoleon's generals, was the son of a silk manufacturer at Lyons, where he was born on the 2nd of March 1799. He originally intended to follow his father's business; but having in 1792 served as volunteer in the cavalry of the national guard at Lyons, he manifested military abilities which secured his rapid promotion. As chef de bataillon he was present at the siege of Toulon in 1793, where he took General O'Hara prisoner. During the Italian campaign of 1796 he was severely wounded at Genoa and on the 11th of October. In October 1797 he was appointed to the command of a demi-brigade, and his services, under Joubert in the Tirol in that year, and in Switzerland under Brune in 1797-98, were recognized by his promotion to the rank of general of brigade. He took no part in the Egyptian campaign, but in August was made chief of the staff to Brune, and restored the efficiency and discipline of the army in Italy. In July 1799 he was made general of division and chief of staff to Joubert in Italy, and was in 1800 named by Masséna his second in command. His dexterous resistance to the superior forces of the Austrians with the left wing of Marshal Ney's army, when the right and centre were shut up in Genoa, not only prevented the invasion of France from this direction but contributed to the success of Napoleon's crossing the Alps, which culminated in the battle of Marengo on the 14th of June. He took a prominent part in the Italian campaign till the armistice of Treviso. In the campaigns of 1805 and 1806 he greatly increased his reputation at Austerlitz, Saalfeld, Jena, Pultusk and Ostrolenka. He obtained the title of count on the 10th of March 1808, married Mlle de Saint Joseph, a niece of Joseph Bonaparte's wife, and soon afterwards was ordered to Spain. Here, after taking part in the siege of Saragossa, he was made commander of the army assembled at 16. He governor of the province, which, by wise and (unlike that of most of the French generals) disinterested administration no less than by his brilliant valour, he in two years brought into complete submission. He annihilated the army of Blake at Maria on the 14th of June 1809, and on the 22nd of April 1810 defeated O'Donnell at Lerida. After being made marshal of France (July 8, 1811) he in 1812 achieved the conquest of Valencia, for which he was rewarded with the title of Duc d'Albufera da Valencia (1812). When the tide set against the French Suchet defended his conquests step by step till compelled to retire into France, after which he took part in Soult's defensive campaign. By Louis XVIII. he was on the 4th of June made a peer of France, but, having during the Hundred Days commanded one of Napoleon's armies on the Alpine frontier, he was deprived of his peerage on the 24th of July 1815. He died near Marseilles on the 3rd of January 1826. Suchet wrote Mémoires dealing with the Peninsular War, which were left by the marshal in an unfinished condition, and the two volumes and atlas appeared in 1829-334 under the editorship of his former chief staff officer, Baron St Cyr-Nogués.

See C. H. Barrault-Rouillon, Le Maréchal Suchet (Paris, 1854); Choumara, Considérations militaires sur les mémoires du Maréchal Suchet (Paris, 1840), and the Peninsular War, inspired, it is supposed, by Soult; and Lieutenant-General Lamarque's obituary notice in the Spectateur militaire (1826). See also bibliography in article Peninsular War.

SU-CHOW. There are in China three cities of this name which deserve mention.

1. Su-chow-Fu, in the province of Kiang-su, formerly one of the largest cities in the world, and in 1907 credited still with a population of 500,000, on the Grand Canal, 55 m. W.N.W. of Shanghai, with which it is connected by railway. The site is practically a cluster of islands to the east of Lake Tai-hu. The walls are about 10 m. in circumference and there are four large suburbs. Its silk manufactures are represented by a greater variety of goods than are produced anywhere else in the empire; and the publication of cheap editions of the Chinese classics is carried to great perfection. There is a Chinese proverb to the effect that to be perfectly happy a man ought to be born in Su-chow, live in Canton and die in Eee-chow. The nine-storied pagoda of the northern temple is one of the finest in the country. In 1866 Su-chow was captured by the T’ai-pings, and when in 1863 it was recovered by General Gordon the city was almost a heap of ruins. It has since largely recovered its prosperity, and besides 7000 silk looms has cotton mills and an important trade in rice. Of the original splendour of the place some idea may be gathered from the beautiful plan on a slab of marble preserved since 1247 in the temple of Confucius and reproduced in Yule’s Marco Polo, vol. i. Su-chow was founded in 434 by Ho-lu-Wang, whose grave is covered by the artificial hill of the Tiger, in the vicinity of the town. The literary and poetic designation of Su-chow is Ku-su, from the great tower of Ku-su-tai, built by Ho-lu-Wang. Su-chow was opened to foreign trade by the Japanese treaty of 1895. A Chinese and European school was opened in 1908.

2. Su-chow, formerly Tsiu-tsan-tsian, a free city in the province of Kan-suh, in 30° 48’ N., just within the extreme north-west angle of the Great Wall, near the gate of jade. It is the great centre of the rubarb trade. Completely destroyed in the great Mahommedan or Dungan insurrection (1865-72), it was recovered by the Chinese in 1873 and has been rebuilt.

3. Su-chow, a commercial town situated in the province of Sze-ch’u-en at the junction of the Min River with the Yang-tse-Kiang, in 28° 46’ 50’ N. Population (1907) about 50,000.

SUCKLING, SIR JOHN (1609-1664), English poet, was born at Whitton, in the parish of Twickenham, Middlesex, and baptized there on the 10th of February 1609. His father, Sir John Suckling (1560-1627), had been knighted by James I. and was successively master of requests, comptroller of the household and secretary of state. He sat in the first and second parliaments of Charles I’s reign, and was made a privy councilor. During his career he amassed a considerable fortune, of which the chief was his marriage at the age of eighteen. He was elected to Trinity College, Cambridge, in 1633, and was entered at Gray’s Inn in 1637. He was intimate with Thomas Carew, Richard Lovelace, Thomas Nabbes and especially with John Hales and Sir William Davenant, who furnished John Aubrey with information about his friend. In 1628 he left London to travel in France and Italy, returning, however, before the autumn of 1630, when he was knighted. In 1631 he volunteered for the force raised by the marquess of Hamilton to serve under Gustavus Adolphus in Germany. He was back at Whitehall in May 1632; but during his short service he had been present at the battle of Breitenfeld and in many sieges. He was hand- rich and generous; his happy gift in verse was only one of many accomplishments, but it commended him especially to Charles I. and his queen. He says of himself ("A Sessions of the Poets") that he "prized black eyes or a lucky hit at bowls above all the trophies of wit." He was the best card-player and the best bowler at court. Aubrey says that he
invented the game of cribbage, and relates that his sisters came weeping to the bowling green at Piccadilly to dissuade him from play, fearing that he would lose their positions. In 1634 great scandal was caused in his old circle by a beating he received at the hands of Sir John Digby, a rival suitor for the hand of the daughter of Sir John Willoughby; and it has been suggested that this incident, which is narrated at length in a letter (Nov. 10, 1634) from George Garrard to Strafford, had something to do with his beginning to seek more serious society. In 1635 he retired to his country estates in obedience to the proclamation of the 20th of June 1632 enforced by the Star Chamber against absentee land-holders and other noblemen. His collection of "Sessions of the Poets" was circulated in MS., and about the same time he wrote a tract on Socionism entitled An Account of Religion by Reason (pr. 1646).

As a dramatist Suckling is noteworthy as having applied to regular drama the accessories already used in the production of masques. His Aeglaura (pr. 1638) was produced at his own expense with elaborate scenery. Even the lace on the actors' coats was of real gold and silver. The play, in spite of its felicity of diction, lack of dramatic unity, and the criticism of Hogarth (Short Discourse of the English Stage), that it seemed "full of flowers, but rather stuck in than growing there," is not altogether unjustified. The Goblins (1638, pr. 1646) has some reminiscences of The Tempest; Brennoral, or the Discontented Colonel (1639, pr. 1646) is a satire on the Scots, who are the Lithuanian rebels of the play; a fourth play, The Sad One, was left unfinished owing to the outbreak of the Civil War. Suckling raised a troop of a hundred horse, at a cost of £12,000, and accompanied Charles on the Scottish expedition of 1639. He shared in the earl of Holland's retreat before Duns, and was ridiculed in an amusing ballad (pr. 1650), in Musarum deliciae, "on Sir John Suckling's most war-like preparations for the Scottish war."

He was elected as member for Bramber for the opening session (1640) of the Long Parliament; and in that winter he drew up a letter addressed to Henry Jermyn, afterwards earl of St Albans, advising the king to discountest the opposition leaders by making more concessions than they asked for. In May of the following year he was implicated in an attempt to rescue Strafford from the Tower and to bring in French troops to the king's aid. The plot was exposed by the evidence of Colonel George Godley, and Suckling fled beyond the seas. The circumstances of his short exile are obscure. He was certainly in Paris in the summer of 1641. One pamphlet related a story of his elopement with a lady to Spain, where he fell into the hands of the Inquisition. The manner of his death is uncertain, but Aubrey's statement that he put an end to his life by poison in May or June 1642 in fear of poverty is generally accepted.

Suckling's reputation as a poet depends on his minor pieces. They have wit and fancy, and at times exquisitely felicity of expression. "Easy, natural Suckling," Millamant's comment in Congreve's Way of the World (Act iv., sc. i.) is a just tribute to their spontaneous quality. Among the best known of them are the "Ballade upon a Wedding," on the occasion of the marriage of Roger Boyle, afterwards earl of Orrery, and Lady Margaret Howard, "I prithee, send me back my heart," "Out upon it, I have loved three whole days together," and "Why so pale and wan, fond lover?" from Aeglaura. "A Sessions of the Poets," describing a meeting of the contemporary versifiers under the presidency of Apollo to decide who should wear the laurel wreath, is the prototype of many later satires.

A collection of Suckling's poems was first published in 1646 as Fragments aurea, the so-called Selections (1638) published by the

4 Approved by Aubrey to Sir John Mennis (1659-1671). See also a song printed in the tract, Vox borealis (Harl. Misc. iii. 235).
The Sudan has an ethnological rather than a physical unity, and politically it is divided into a large number of states, all now under the control of European powers. These countries being separately described, brief notice only is required of the Sudan as a whole.

Within the limits assigned it has a length of about 4000 m. extending southwards at some points 1500 m., with a total area of over 2,000,000 sq. m., and a population, approximately, of 40,000,000. Between the arid and sandy northern wastes and the well-watered and arable Sudanese lands there is a transitional zone of level grassy steppes (partly covered with mimosas and acacias) with a mean breadth of about 60 m. The zone lies between 17° and 13° N., but towards the centre reaches as far south as 15° N. Excluding this transitional zone, the Sudan may be described as a moderately elevated region, with extensive open or rolling plains, level plateaus, and abutting at its eastern and western ends on mountainous country. Crystalline rocks, granites, gneisses and schists, of the Central African type, occupy the greater part of the country. Towards the south-east, slates, quartzites and iron-bearing schists occur, but their age is not known. The Congo sandstones do not appear to extend as far north. The Nubian sandstone borders the Libyan desert on the south and south-west, but it is doubtful if this sandstone is of Cretaceous or earlier date.

The Sudan contains the basin of the Senegal and parts of three other hydrographic systems, namely: the Niger, draining southwards to the Atlantic; the central depression of Lake Chad; and the Nile, flowing northwards to the Mediterranean. Lying within the tropics and with an average elevation of not more than 1500 to 2000 ft. above the sea, the climate of the Sudan is hot and in the river valleys very unhealthy. Few parts are suitable for the cultivation of European crops although the grazing is good, but from North Africa by the Saharan desert, the inhabitants, who belong in the main to the negro family proper, are thought to have received their earliest civilization from the East. Arab influence and the Moslem religion began to be felt in the western Sudan as early as the 9th century and had taken deep root by the end of the 11th. The existence of native Christian states in Nubia hindered for some centuries the spread of Islam in the eastern Sudan, and throughout the country some tribes have remained pagan. It was not until the last quarter of the 19th century that the European nations became the ruling force.

The terms western, central and eastern Sudan are indicative of geographical position merely. The various states are politically divisible into four groups: (1) those west of the Niger; (2) those between the Niger and Lake Chad; (3) those between Lake Chad and the basin of the Nile; (4) those in the upper Nile valley.

The first group includes the native states of Bondu, Futa Jallon, Masina, Mossi and all the tribes within the great bend of the Niger. In the last quarter of the 19th century they fell under the control of France, the region being styled officially the French Sudan. In 1900 this title was abandoned. The greater part of what was the French Sudan is now known as the Upper Senegal and Niger Colony (see SENEGAL, FRENCH WEST AFRICA, &c.).

The second group of Sudanese states is almost entirely within the British protectorate of Northern Nigeria. It includes the sultanate of Sokoto and its dependent emirates of Kano, Bida, Zaria, &c., and the ancient sultanate of Bornu, which, with Adamawa, is partly within the German colony of Cameroon (see NIGERIA and CAMEROON). The third or central group of Sudanese states is formed of the sultanates of Bagirmi (q.v.) with Kanem and Wadai (q.v.). Wadai was the last state of the Sudan to come under European influence, its conquest being effected in 1909. This third group is included in French Congo (q.v.).

The fourth group consists of the states conquered during the 19th century by the Egyptians and now under the joint control of Great Britain and Egypt. These countries are known collectively as the Anglo-Egyptian Sudan (see below).

For the regions west of Lake Chad the standard historical work is the Travels of Dr. Heinrich Barth (5 vols., London, 1857–1858). Consult also P. C. Meyer, Derforschungsgeschichte und Staatenbildungen der Westsudan (Gotha, 1897), an admirable summary with bibliography and maps; Karl Kummer, The Sudan (London, 1907); Lady
SUDAN

Lugard, A Tropical Dependency (London, 1905); and the bibliographies given under the various countries named. For sources and references under the unit of State or Department, the important work is that of Gustav Nachtigal, Sahara und Sudan (3 vols., Berlin 1879–1880). See also Boyd Alexander, From the Niger to the Nile (2 vols., London, 1907); Karl Kumm, Paulitschke’s Die Sudanländer (Freiburg, 1885).

The Anglo-Egyptian Sudan

The region which before the revolt of the Arabized tribes under the Mahdi Mahomed Ahmed in 1881–83 was known as the Egyptian Sudan has, since its reconquest by Bondaries and Area. the Anglo-Egyptian expedition of 1856–58, been under the joint sovereignty of Great Britain and Egypt. The limits of this condominium differ slightly from those of the Egyptian Sudan of the pre-Mahdi period. It is bounded N. by Egypt, the 2nd parallel of N. latitude being the dividing line), E. by the Red Sea, Eritrea and Abyssinia, S. by the Uganda Protectorate and Belgian Congo, W. by French Congo. North of Darfur is the Libyan Desert, in which the western and northern frontiers meet. Here the boundary is undefined.1

As thus constituted the Anglo-Egyptian Sudan forms a compact territory which, being joined southwards by the Uganda Protectorate, brings the whole of the Nile valley from the equatorial lakes to the Mediterranean under the control of Great Britain. The Anglo-Egyptian Sudan extends north to south beyond the limits of the Nile. The Sudan is a distinctly marked intermediate zone of steppes. In the southern district, between 5° and 10° N., huge swamps extend on either side of the Nile and along the Bahr-el-Ghazal.

From north to south the Sudan is traversed by the Nile (q.n.), and all the great tributaries of that river are either partly or entirely within its borders. The most elevated district is a range of mountains running parallel to the Red Sea. These mountains, which to the south of the Abyssinian highlands, present their steepest face eastward, attaining heights within the Sudan of 4000 to over 7000 ft. Jebel Erba, 7430 ft., and Jebel Soturba, 6880 ft. (both between 21° and 22° N.), are the highest peaks in the Sudan. Westward the mountains slope gradually to the Nile valley, which occupies the greater part of the country and has a general level of from 600 to 1600 ft. In places, as between Suakin and Berbera, the land is level. The Nile, the mountainous approach close to the river. Beyond the Nile westward extend vast plains, which in Kordofan and Dar Nuba (between 10° and 11° N.) are broken by hills reaching 3000 ft. Farther west, in Darfur, the country is more elevated, the Jebel Mufarab (between 5° and 10° N. 5000 to 6000 ft. high. In the south-west, beyond the valley of the Bahr-el-Ghazal, the country gradually rises to a ridge of hills, perhaps 2000 ft. high, which running south-east and north-west form the water-parting between the Nile and the Congo.

Apart from the Nile system, fully described elsewhere, the Sudan has two other rivers, the Gash and the Baraka. These are intermediate and not unlike the eastward-flowing White Nile, and flow in a general northerly direction. The Gash enters the Sudan near Kassala and north of that town turns west towards the Nile, while the Baraka, which rises in the same part of the country, flows north-west and then south-west towards the Red Sea. The Gash nevertheless fertilizes a considerable tract of country. The Khor Baraka lies east of the Gash. It flows towards the Red Sea in the neighbourhood of Trinkitat (some 50° m. south of Suakin), but about 30 m. from the coast forms an inland delta. Except in seasons of great rain its waters do not reach the sea.

The Coast Region.—The coast extends along the Red Sea north to south from 22° N. to 18° N., a distance following the indentations of the Red Sea. These indentations are numerous but not deep, the general trend of the coast being S.S.E. The most prominent headland is Ras Rawaya (21° N.) which forms the northern shore of Dokhana Bay. There are a few good harbours, Port Sudan and Suakin being the chief ports. South of Suakin is the shallow bay of Trinkitat. A large number of islands, or shoals off the coast, and low scrub stretches for ten to twenty miles, and is traversed by khors (generally dry) with ill-defined shifting channels. Beyond this plain rise the mountainous region, the seaward slopes often bear a considerable amount of vegetation.

The Desert Zone.—The greater part of the region between the coast and the Nile is the Nubian Desert. It is a rugged, rocky, barren desert, scored with khors, wadis, along which is scanty vegetation. The desert character of the country increases as the river is neared, but along either bank of the Nile is a narrow strip of cultivable land. Westwards of the Nile the climate is hot and dry, the scrublands of the oasis country, even in the point of the Arabian influence. The country enclosed by the Nile, the Athara and the Blue Nile, the so-called Island of Meroë, consists of very fertile soil, and along the eastern frontier, by the upper courses of the White Nile, there are extensive grasslands. This is mainly open, steppe-like country with extensive tracts of cultivable land and a central mountain massif, the Jebel Marra (see SENNAR KORDOFAN, DARFUR).

Climate.—The country lies generally within the tropics, and as the greater part of it is far removed from the ocean and less than 1500 ft. above the sea it is extremely hot. The heat is greatest in the central regions, least in the desert zone, where the difference between summer and winter is marked. Even in winter, however, the temperatures are high. Of this region the Arabs say "the soil is like fire and the wind like a flame." Nevertheless, the dryness of the air renders the climate healthy. The steppe countries, Kordofan, Darfur, are also healthful after the autumn rains. Between Khartum, centrally situated, the minimum temperature is about 40° F., the maximum 113°, the mean annual temperature being 80°, January is the coldest and June the hottest month. Violent sand-storms occur in places. The rainy season, from August to January, is usually divided into two parts, the "great rainy season" is from mid-June to September, there are some 10 in. of rain during the year. The number of days on which rain falls rarely exceeds, however, fifteen. The rainfall increases to about 20 in. per annum in the eastern and southern regions. In the swamp district and throughout the Bahr-el-Ghazal heavy rains (40 in. or more a year) are experienced. The period of the heaviest rain begins from April to September. In the maritime district there are occasional rains from August to December and January. In the soud region thunderstorms are frequent. Here the temperature averages about 85° F., the air is always dry; in the river is especially low.

Flora.—In the deserts north of Khartum vegetation is almost confined to stunted mimosa, and in the less arid districts, scanty herbage. Between the desert and the cultivated Nile lands is an open growth of samar, hashab (Acacia terek) and other acacia trees. Between Khartum and 12° N. forest belts line the banks of the rivers and khors, in which the most noteworthy tree is the sant or sant (Acacia arbores). Farther from the rivers are open woods of Balantides nepetoides, hashab, 8c, and dense thickets of losh (Linceta rubra) and kitte (Acacia mellifera). These open woods cover a considerable part of Kordofan, the hashab and tahl trees being the chief producers of gum arabic. South of 12° N. the forest landscape is lost, and the chief feature of the grasslands is the characteristic to that described. On the Blue Nile the forest trees alter, the most abundant being the babanuss (Sudan ebony) and the Erythrina crista galli. While gigantic baobabs, called tebelidi in the Sudan, and tarfi (Sterculia divaricata) are numerous. In southern Kordofan and in the higher parts of the Bahr-el-Ghazal the slag and ebony are also common, as well as African mahogany (Khayal) and the Acacia senegal. The Bahr-el-Ghazal province also are many rubber-producing lianas, among them the Lantolophia ovarteris. There are also forest regions in the Bahr-el-Jbel, in the Mongola mudra, and along the Abyssinian-Egyptian border. The regions of the Blue Nile are vaste prairies covered with tall coarse grass. Cotton is indigenous in the valley of the Blue Nile, and in some localities the jatropha is very plentiful. The castor-oil plant grows in almost every province, (see also Vegetable of the swamp region, NILE.)

Fauna.—Wild animals and birds are numerous. Elephants are abundant in the Bahr-el-Ghazal and Bahr-el-Jbel forests, and are found in fewer numbers in the upper valley of the Blue Nile.
The hippopotamus and crocodile abound in the swamp regions, which also shelter many kinds of water-fowl. The lion, leopard, giraffe and various kinds of antelope are found in the plain and in the open woods. In the forests are numerous bright-plumed birds and many species of monkeys. The ground, mosses and the trees being too prickly for climbing. Snakes are also plentiful, many poisonous kinds being found. In the steppe regions of Kordofan, Darfur, &c., and in the Nubian Desert ostriches are fairly plentiful. Insect life is very abundant, especially south of 12° N. The Nile valley north of Khartum the inhabitants are of very mixed origin. This applies particularly to the so-called Nubians who inhabit the Dongola muduria (see Nubia). Elsewhere the inhabitants north of 12° N. are of mixed Arab descent. In the Nubian Desert the chief tribes are the Ababda and Bisharit, the last named grazing their camels in the mountainous districts towards the Red Sea. In the region south of Berber and Susakin is the Hadendoa. The Jaalil, Hassania and Shukria inhabit the country between the Atbara and Blue Nile; the Hassania and Hadendoa are to be found in the Gash, and the Shukria in the Gash. The Kabbalish occupy the desert country north of Kordofan, which is the home of the Baggara tribes. In Darfur the inhabitants are of mixed Arab and negro blood.

Of negro Nilotic tribes there are three or four main divisions. The Shilluks occupy the country along the west side of the Nile northward from about Lake Abou. The country east of the Nile is divided between the Bari, Nuer and Dinka tribes. The Dinkas are also widely spread over the Bah尔-el-Ghazal province. South of Kordofan and west of the Shilluk territory are the Nubas, apparently the original stock of the Nubians. In the south of Kordofan the Bah尔-el-Ghazal are the Dongola. Some other tribes, and along the Nile-Congo water-parting are the A-Zande or Niam-Niam, a comparatively light-coloured race. All the tribes mentioned are separately noticed.

Social Conditions.—In contrast with the Egyptians, a most industrious race, the Sudanese tribes, both Arab and negro, are as a general rule indolent. Where wants are few and simple, where houses need not be built nor clothes worn to keep out the cold, there is little stimulus to exertion. Many Arabs "clothed in rags, with only a mat for a house, prefer to lead the life of the free-born sons of the desert, no matter how large their herds or how numerous their followings." (Egypt, No. 1 [1904], p. 147.) Following the establishment of British control slave-raiding and the slave trade were stopped, but domestic slavery continues. A genuine desire for education is manifest among the Arabic-speaking peoples and slow but distinct moral improvement is visible among them. Among the riverain "Arabs" some were found to supply labour for public works, and with the money thus obtained cattle were bought and farms started. The Dongolese are the keener traders in the country. The Arab tribes are all Mahomedans, credulous and singularly liable to fits of religious excitement. Most of the negro regions are pagan, but some of them who live in the northern regions have embraced Islam.

**Divisions and Chief Towns.**—Darfur is under native rule. The rest of the Sudan is divided into mudurias (provinces) and these are subdivided into mandurias. The mudurias are Harfa, Reda, Dongola and Berber in the north (these include practically all the region of the Blue Nile), Kordofan, Heshim, Gezira (or Suakin), of which Kassala and Sennar in the east; Kordofan in the west; and Bah�-el-Ghazal, Upper Nile (formerly Fashoda) and Mongalla in the south. The mudurias vary considerably in size.

In the west, Kordofan, Khartoum, the capital, has a population of about 70,000, is built in the broad fork formed by the junction of the White and Blue Niles. Opposite Khartoum, on the west bank of the White Nile, is its rival, Omdurman (q.v.). (Louis), capital of the Sudan during the Mahdist War. On the Nile north of Khartoum are several ports of Berber, Abu Hamed, Merawi (Morowe), Dongola and Wadi Halfa. On the Red Sea are Port Sudan and Suakin. Kassala and El-Fasher are the chief ports of the Cash (these towns are separately noticed.) On the Blue Nile are Kamlin, Sennar, Wad Medani (q.v.), pop. about 20,000, a thriving business centre and capital of the Blue Nile muduria, and Rosseires, which marks the point of navigation by steamers of the river. At South is a town in the Kassala muduria close to the Abyssinian frontier, and Gedaref lies between the Blue Nile and Atbara a little north of 1° N. El Obeid, the chief town of Kordofan, is 250 m. south and west by south of Khartum. Duiem, capital of the White Nile muduria, is the river port for Khartoum. El Fasher, the capital of Darfur, is 500 m. W.S.W. of Khartoum. All the towns named, with the exception of El Fasher, are port cities. In the south of the Sudan there are no towns properly so called. The native villages are composed of straw or palm huts; the places inhabited by Europeans or Egyptians are merely posts, where the agents of the European or British business companies (Fashoda, now renamed Kodok, is the headquarters of the Upper Nile muduria.

**Communications.**—North of Khartoum the chief means of communication is by railway; south of that city by steamer. There are two railways, a railway on the Wadi Halfa line to the Red Sea, and another affording access to the Red Sea. The first line runs from the Nile at Wadi Halfa across the desert in a direct line to Abu Hamed, and from there goes by the old British road and follow the left bank of the Nile to Khartum. At Khartoum the Blue Nile is bridged and the railway is continued south through the Gezira to Sennar. Thence it turns west, crosses the White Nile near Abba Island, and runs to El Obeid for a distance of 121 m., then to El Obeid Junction for 27 m., then to Khartum is 575 m.; from Khartoum to Obeid is 350 m. The railway from the Nile to the Red Sea starts from the Halfa-Khartoum line at Atbara Junction, a mile north of the Atbara confluence. It runs south on the west of the line of the railway, and to Atbara for 278 m. from Atbara Junction, the line divides, one branch going north to Port Sudan, the other south to Suakin. The total distance from Port Sudan to Khartum is 138 m. The line to Suakin being 4 m. longer. Besides these main lines a railway, 138 m. long, runs from Abu Hamed on the right bank of the Nile to Kairema (opposite Merawi) in the Dongola muduria below the Fourth Cataract. (The line is independent of the Nile.) At the junction of this line at Kairema the Nile to Kerma, 201 m. from Halfa, was abandoned in 1903.) The railways are owned and worked by the state.

In connexion with the Khartoum-Halfa railway steamers ply on the route between Port Sudan and Halfa, and the railway from Alexandria ends. The distance by rail and steamer between Khartoum and Alexandria is about 1490 m. Steamers run on the Nile between Kerenia and Kairema, and above Khartoum the government launches ply from Khartoum to the Protectorate. The Rabbani steamer to Port Sudan runs from February 1st to the end of September, and the Kordofan steamer to Suakin runs from March 1st to the end of September. During flood season there is also a steamer service on the Blue Nile. Powerful dredgers and cutting machines are used to keep open communications in the upper Nile and Bah尔-el-Ghazal.

The ancient caravan routes Korosko-Abu Hamed and Berber-Suakin are still used by the nomads, and the main routes between Khartoum and the towns and the Nile. On some of these roads a motor car service is maintained.

From Port Sudan and Suakin there is a regular steamer service to Alexandria via the Suez Canal. There are also services to Alexandria, the Red Sea ports of Arabia, Aden and India.

There is an extensive telegraphic system. Khartoum is connected by direct line with El Obeid, and lines of this first order also exist to the following places: Northern Desert (2500 m.); Khartoum other lines go to Kassala and the Red Sea ports. In some places the telegraph wires are placed 16 ft. in. above the native wire to protect them from the effects of bad weather. Three telegraphic connexion between Alexandria and Mombasa (2500 m.). From Khartoum other lines go to Kassala and the Red Sea ports. In some places the telegraph wires are placed 16 ft. in. above the ground wire and protected by iron pipes.

**Agriculture and other Industries.**—North of Khartoum agricultural land is confined to a narrow strip on either side of the Nile and to the few areas in the Libyan Desert. In the Gezira and in the Bah尔-el-Ghazal provinces, and in the Gedaref and Kordofan regions, there are wide areas of arable land, as also in the neighbourhood of Kassala along the banks of the Cash. In Kordofan and Darfur cultivation is confined to the Khors or valleys. The chief grain crop is durra, the cultivation of sugarcane is also very extensive in several districts. On lands near the rivers the durra is sown after the flood has gone down and also at the beginning of the rainy season. Considerable quantities of wheat and barley are also
SUDAN

Each of the mudirates into which the country is divided is presided over by a mudir (governor) responsible to the central government at Khartoum. The governor-general, the chief of the various departments of state and the mudirs are all Europeans, the majority being British military officers. The minor officials are nearly all Egyptians or Sudanese. Revenue is derived as above, about 60% from the customs and revenue-earning departments (i.e., steamers, railways, posts and telegraphs), and 40% to the rest from taxes on land, date-trees and animals, from royalties on gum, ivory and ostrich feathers, from licences to sell spirits, carry arms, &c., and from fees paid for the shooting of game. Expenditure is largely on public works, education, justice and the army. Financial affairs are managed from Khartoum, but control over expenditure is exercised by the Egyptian financial department. The revenue, which in 1898 was £35,000, for the first time exceeded a million in 1909, when the amount realized was £60,000. The expenditure in 1899 was £1,153,000. Financially the government had been, up to 1910, largely dependent upon Egypt. In the years 1901-1909 £43,000,000 was advanced from Cairo for public works in the Sudan; in the same period a further sum of about £27,000,000 had been found by Egypt to meet annual deficits in the Sudan budgets (see Egypt, No. 1 [1910], pp. 5-6).

Justice.—The Sudan judicial codes, based in part on those of India and in part on the principles of English law and of Egyptian commercial law, provide for the recognition of "customary law," so far as applicable and "not repugnant to good conscience." In civil cases, all elements are tried by a court, consisting of the mudir (or a judge) and two magistrates, which has general competence. The magistrates are members of the administrative staff, who try minor cases without the help of the mudir (or judge). The governor-general possesses revising powers in all cases. Civil cases of importance are heard by a judge (or where no judge is available by the mudir or his representative); minor civil cases are tried by magistrates. From the decision of the judges an appeal lies to the legal secretary of the government, in his capacity of judicial commissioner. Jurisdiction in all legal matters, as regards personal status of Mahomedans is administered by a grand kadi and a staff of subordinate cadis. The police force of each mudiria is independently organized under the control of the mudirs.

Education.—Education is in charge of the department of public instruction. Elementary education, the medium of instruction being Arabic, is given in kuttab or village schools. There are primary schools in the chief towns where English, Arabic, mathematics, and in some cases land-measuring is taught. There are also government industrial workshops, and technical schools for girls. The Gordon College at Khartoum trains teachers and judges to complete their technical courses and has annexed to it a secondary school. The college also contains the Wellcome laboratories for scientific research. Among the pagan negro tribes Protestant and Roman Catholic missions are established. These missions carry on educational work, special attention being given to industrial training.

Defence.—The defence of the country is entrusted to the Egyptian army, of which several regiments are stationed in the Sudan. The governor-general is sirdar (commander-in-chief) of the army. A small force of British troops is also stationed in the town—chiefly at Khartoum. They are under the command of the governor-general in virtue of an arrangement made in 1905, having previously been part of the Egyptian command.

For topography, &c., see The Anglo-Egyptian Sudan, a compendium prepared by officers of the Sudan government and edited by Count Gleichen (2 vols., London, 1905); for administration, finance and trade, see Official Reports [by the British agent at Cairo] on Egypt and the Sudan, since 1884 (2 vols., London, 1884); no. 2, 1885); by Colonel D. H. Stewart. Consult also J. Petherick, Travels in Central Africa (2 vols., London, 1862); W. Junker, Travels in Africa, 1873-1879 (3 vols., London, 1880); S. G. Schweinfurth, Der Sudan und seine Verbindungen mit dem Arabischen und Ostafrika, der Sudan und das Scengebiet (Gotth., 1890); F. D. Schoenfeld, Ethnografie und der ägyptische Sudan (Berlin, 1901); C. E. Muriel, Report on the Forests of the Sudan (Cairo, 1901); H. W. Hetherly, Bird Hunting on the White Nile (London, 1902). For ethnology.

grown. Other foodstuffs raised are lentils, beans, onions and melons. The date-palm is cultivated along the Nile valley below Khartoum, and in the west banks of the Dongola and Beni-Suef districts in the neighbouring oases. Dates are also a staple product in Darfur and Kordofan. Ground-nuts and sesame are grown in large quantities for the oil they yield, and cotton of quality equal to that found in India is produced. The Sudan was indeed the original home of Egyptian cotton.

For watering the land by the river banks (water-wheels) are used, oxen being employed to turn them. There are few irrigation systems; and in most of the native plantations, about 1,500,000 acres were under cultivation. In 1910 a system of basic irrigation was begun in Dongola mudiria.

Trade. The chief export products. The gum is obtained from the Kordofan and in the forests modern of the Nile Valley of the red sand, the best gum coming from Kordofan. It is of two kinds, kaasab (white) and laab (red), the white being the more valuable. An oil is obtained from the Batariels, where there are Para and Ceara rubber plantations—and in the l'obat district. The wood of the sun tree is largely used for boat-building and for fuel, and the mahogany tree yields excellent timber. Fibre is made from several trees and plants. Elephants are hunted for the sake of their ivory. The wealth of the Arab tribes consists largely in their herds of camels, horses and cattle. They also keep ostrich farms, the feathers being of good quality. The Dongola breed of horses is noted for its strength and hardiness. The camels are bred in the desert north of Berber, between the Nile and Red Sea, in southern Dongola, in the Hadendua country and in northern Kordofan. The bigher camel is considered first rate and is richer than the camel of Egypt. The camel, horse and ostrich are not found south of Kordofan and Sennar. The negro tribes live mostly in the southern and central parts of the country, and the camel and the cattle are generally small and the sheep yield little wool. The Arabs use the camel as draught-animals as well as for their milk and flesh; the negro tribes as a rule do not eat their oxen. Poultry are plentiful, but of poor quality. Donkeys are much used in the central regions; they make excellent transport animals.

Mineral Wealth.—In ancient times Nubia, i.e., the region between the Red Sea and the Nile south of Egypt and north of the Sudal, Berber line, was worked for gold. Reins of an extensive gold-mine exist near Jebel Erba at a short distance from the sea. In 1905 gold mining recommenced in Nubia, in the district of Um Nabardy. The mineral is rich desert. The railway line from Haifa and Abu Hamid. A light railway, 30 m. long, opened in June 1905, connects Um Nabardy with the government railway system. The producing stage was reached in 1908, and between September 1908 and August 1909 the mines yielded 4,000 oz. of gold. Small quantities of gold-dust are obtained from Kordofan, and gold is found in the Beni-Shangul country south-west of Sennar, but this region is within the Abyssinian frontier (agreement of the 15th of May 1902). There is lignite in the Dongola mudiria and iron ore is found in Darfur, southern Kordofan and in the Bahl-el-Ghazal. In the last-named mudiria iron is worked by the natives. In the district of the Hafet-el-Ghazal, the country is rich in copper, the mines having been worked intermittently from remote times.

The chief products of the Sudan for export are gum, ivory, ostrich feathers, dates and rubber. Cotton, cottonseed, and grain (durra, wheat, barley) sesame, livestock, hides and skins, beeswax, mother-of-pearl, senna and gold are also exported. Before there was little trade with Britain, the customs have been liberalized in order to trade with Egypt via the Nile, and the great cost of carriage hindered its development. Since the completion of the railway named goods can be put on the world's markets at a much cheaper rate. Besides the Egyptian and Red Sea routes there is considerable trade between the eastern mudirates and Abyssinia and Eritrean, and some trade south and west with Uganda and the Congo countries. The Red Sea ports trade largely with Arabia and engage in pearl fishery. The principal imports are cotton goods, food-stuffs (flour, rice, sugar, provisions), timber, tobacco, spirits (in large quantities), iron and machinery, candles, cement and perfumery. The value of trade with the Mahomedan countries in 1898–99 was £670,000, and in 1908 only, had increased in 1905 to over £1,500,000. In 1908 the exports of Sudan produce were valued at £651,000; the total imports at £6,929,000.

Government. The administration is based on the provisions of the Convention signed on the 19th of January 1859 between the British and Egyptian governments. The executive and governmental powers are represented by a governor-general appointed by Egypt on the recommendation of Great Britain. In 1910 a council consisting of four ex officio members and from two to four non-official nominated members was created to advise the governor-general in the exercise of his executive and legislative functions. Subject to the power of veto retained by the governor-general all questions are decided by a majority of the council.

1 A £ (pound Egyptian) is equal to £1, os. 6d. British currency.
For dating the earliest example of such a fusion to the exact period of the Egyptian Old Empire. It is certain in any case that the process was commonly repeated at different dates and in different parts of the country from Aswan to Axum, and to the stimulation which resulted from it must be ascribed the principal political and intellectual movements of the Sudanese nations. Thus the Ethiopians who usurped the crown of the Pharaohs from 740–660 B.C. were of a mixed stock akin to the modern Barabra; the northern Nubians who successfully defied the Roman emperors were under the lordship of the Blemmyes (Blemmyes), an East African tribe, and the empire of the Candace dynasty, no less than the Christian kingdoms which succeeded it, included many heterogeneous racial elements. The ethnological history of the Sudan will therefore be concerned with the evolution of what may be called East African or East Central African civilizations.

Up to the present, however, this aspect has been obscured, for until 1907 scholars had little opportunity of studying ancient Ethiopia except as a colonial extension of Egypt. From the purely Egyptological standpoint there is much of value to be learned from the Sudan. The Egyptian penetration of the country began, according to the evidence of inscriptions, as early as the Old Empire. Under the XIIth Dynasty colonies were established in the Memphite territory, and the fortresses of the empire, including that at Nimrod near the site of the modern city, were founded.

During the XVIIIth Dynasty the political subjugation was completed and the newly won territories were studded with cities and temples as far south as the Fourth Cataract. Some two hundred years later the priests of Amen (Ammon), flying from Thebes, founded a quasi-Egyptian capital at Napata. But after this date Egypt played no part in the evolution of Ethiopia. Politically moribund, it succumbed to the attacks of its virile southern neighbours, who, having emerged from foreign tutelage, developed according to the natural laws of their own genius and environment. The history of Ethiopia therefore as an independent civilization may be said to date from the 6th century B.C., though archaeological research may be able to carry its infant origins to a remoter past.

Of the thousand years or more of effective Egyptian occupation many monuments exist, but on a broad general view it must be pronounced that they owe their fame more to the accident of survival than to any special intrinsic value. For excepting Philae, which belongs as much to Egypt as to Ethiopia, Abu Simbel is the only temple which can be ranked among first rate products of Egyptian genius. The other temples, attractive as they are, possess rather a local than a universal interest. Similarly while the exploration of the Egyptian colonies south of the First Cataract has added many details to our knowledge of political history, of local cults and provincial organization, yet with one exception it has not affected the known outlines of the history of civilization. This exception is the discovery made by Dr G. A. Reisner that the archaic culture first detected at Nagada and Abydos and then at many points as far north as Giza extended southwards into Nubia at least as far as Gerf Husain. This was wholly unexpected, and if, as seems probable, the evidence stands the test of criticism, it is a new historical fact of great importance. The government expedition found traces between Aswan and Korosko of the principal periods and that this early date down to the Christian era. The specimens obtained are kept in a separate room of the Cairo Museum, where they form a collection of great value.

The work of the Pennsylvanian expedition, however, while adding only a few details to the archaeology of the Egyptian periods, has opened a new chapter in the history of the African races. No records indeed were discovered of the founders of the first great Ethiopian kingdom from FIankhi to Tigrhak, nor has any fresh light been thrown upon the relations which that remarkable king Ergameues maintained with the Egyptian Ptolemyes. But the exploration of sites in the southern half of Lower Nubia has revealed the existence of a wholly unsuspected civilization which grew up during the first six centuries after Christ. The history of the succeeding periods, moreover, has been partially recovered and the study...
of architecture enriched by the excavation of numerous churches dating from the time of Justinian, when Nubia was first Christianized, down to the late medieval period when Christianity was extirpated by Mahomedanism.

The civilization of the first six centuries A.D. may be called "the Indo-Nubian period" in which not only the site and period where it is situated but the name of the people living on the borders of the Roman Empire who inhabited much of the Hellenistic tradition in minor arts but combined it with a remarkable power of independent origination. The sites on which it has been observed range from Dakhla to Halfa, that is to say within the precise limits which late Latin and Greek writers assign to the Blemmyes, and there is good reason to identify the people that evolved it with this hitherto almost unknown barbarian nation. Apart from this, however, the greatest value of the new discoveries will consist in the fact that they may lay the foundations for a new documentary record of past ages. For the graves yielded not only new types of statues, bronzes, ivory carvings and painted pottery—all of the highest artistic value—but also a large number of stone stelae inscribed with funerary formulae in the Meroitic script.

In the course of sixty years the small collection of Meroitic inscriptions made by Lepsius had not been enlarged and no progress had been made towards decipherment. But the treasures of Shabul and Karanog alone yielded 170 inscriptions on stone, besides some inscribed ostraka. This mass of material brought the task of decipherment within the range of possibility, and even without any bilingual record to assist him, Mr. F. L. Griffith rapidly succeeded in the first stages of translation. As further explorations bring more inscriptions to light the records of Ethiopia will gradually be placed on a firm documentary basis and the names and achievements of its greatest monarchs will take their place on the roll of history.

Ancient Monuments south of Halfa.—Ruins of pyramids, temples, churches and other monuments are found along both banks of the Nile almost as far south as the Fourth Cataract, and again in the "Island of Merowe." In the following list the ruins are named as met with on the journey south from Wadi Halfa (Opposite town that on the east bank are the remains of Shabul, where was found the stela, now at Florence, com- memorating the conquest of the region by Senwosret (Usetertes) I. of Egypt (c. 2750 B.C.). Forty-three miles farther south are the ruins of the twin fortresses of Kumba and Semna. Here the Nile narrows and passes the Semna cataract, and graven on the rocks are ancient records of "high Nile." At Amara, some 50 m. above Semna, are the ruins of a temple with Meroitic hieroglyphics. At Sai Island, 130 m. above Halfa, are remains of a Christian church. Thirteen miles south of Sai at Sobel are the ruins of a temple commemorating Amenophis (Amenhotep) III. (c. 1414 B.C.) to whose Taha was dedicated a temple at Sedeninga, a few miles to the north. At Sesebi, 40 m. higher up the Nile, is a temple of the hecateic king Akhenaton re-worked by Seti I. (c. 1372 B.C.). Opposite Hanek at the Third Cataract on Tombol Island are extensive ancient granite quarries, in one of which lies an unfinished colossus. On the east side of the river near Kerma are the remains of an Egyptian city. Argo Island, a short distance higher up, abounds in ruins, and those at Old Dongola, 320 m. from Halfa, afford evidence of the town having been of considerable size during the time of the Christian kingdom of Dongola. From Old Dongola to Merowe (a distance of 100 m. by the river) are numerous ruins of monasteries, churches and fortresses of the Christian era in Nubia—notably at Jebel Deka and Magal. In the immediate neighbourhood of Jebel Barkal (the "holy mountain" of the ancient Egyptians), a flat-topped hill which rises abruptly from the desert on the right bank of the Nile a mile or two above the existing village of Merawi (Merowe), are many pyramids and six temples, the pyramids having a height of from 35 to 60 ft. Pyramids are also found at Zuma and Kurrk on the right bank, and at Tangasi on the left bank of the river, these places being about 20 m. below "Merawi." That village is identified by some archaeologists with the ancient Napata, which is known to have been situated near the "holy mountain." On the left bank of the Nile opposite Merawi are the pyramids of Nut, and a few miles distant in the Wadi Ghazal are the ruins of a great Christian monastery, where were found gravestones with inscriptions in Greek and Coptic. Ruins of various ages extend from Merawi to the Fourth Cataract.

Leaving the Nile at this point and striking direct across the Bayuda Desert, the river is regained at a point above the Athbara confluence. Thirty miles north of the town of Shendi are the remains of two Meroitic shrines (Meroë and Merawi) in three distinct groups. Nearly one of these pyramids was taken "the treasure of Queen Candace" now in the Berlin Museum. Many of the pyramids have a small shrine on the eastern side inscribed with debased Egyptian or Meroite hieroglyphics. These pyramids are on the right bank of the Nile, that is in the "Island of Merowe." Portions (including a harbour) of the site of the city of Merowe, at Begerawia, not far from the pyramids named, were excavated in 1909-1910 (see Merowe). In this region, and distant from the river, are the remains of several cities, notably Naga, where are ruins of a church, one of the Classic style. On the east bank of the Blue Nile, about 13 m. above Khartum at Soha, Merawi, the site of some monasteries, is named "the village of a Christian basilica. Farther south still, at Cetena on the White Nile (in 1904), and at Wad el-Hadid, some miles north of Sennar, on the Blue Nile (in 1908), Christian remains have been observed.

Between the Nile at Wadi Halfa and the Red Sea are the remains of towns inhabited by the ancient miners who worked the district. The most striking of these towns is Deraheib (Castle Beautiful), so named from the picturesque situation of the castle, a large square building with pointed arches. The walls of some buildings have been considerably extant in the Nile valley between Egypt and Abyssinia—did not embrace Christianity until the 6th century, considerably later than their Abyssinian neighbours. The Arab invasion of North Africa in the 7th century, which turned Egypt into a Mahomedan country, had not the same effect in Nubia, the Moslems, though they frequently raided the country, being unable to hold it. On the ruins of the ancient Ethiopian states arose the Christian kingdoms of Dongola and Alas, with capitals at Dongola and Soba, respectively. These kingdoms continued to exist until the middle of the 14th century or later (see Dongola; Mudiaria). Meanwhile Arabs of the Beui Omayyia tribe, under pressure from the Beni Abbas, had begun to cross the Red Sea

SUDAN

A. From the Earliest Time to the Egyptian Conquest.—The southern regions of the Anglo-Egyptian Sudan are without recorded history until the era of the Egyptian conquest in the 18th century. In the northern regions, known as Ethiopia or Nubia, Egyptian influence made itself felt as early as the 3rd millennium B.C., and in process of time powerful states grew up with capitals at Napata and Meroë (see Meroë, vol. iii, § 4 Archaeology and ETHIOPIA and EGYPT). The Nubians, that is the dwellers in the Nile valley between Egypt and Abyssinia—did not embrace Christianity until the 6th century, considerably later than their Abyssinian neighbours. The Arab invasion of North Africa in the 7th century, which turned Egypt into a Mahomedan country, had not the same effect in Nubia, the Moslems, though they frequently raided the country, being unable to hold it. On the ruins of the ancient Ethiopian states arose the Christian kingdoms of Dongola and Alas, with capitals at Dongola and Soba, respectively. Meanwhile Arabs of the Beui Omayyia tribe, under pressure from the Beni Abbas, had begun to cross the Red Sea

HISTORY

as early as the 8th century and to settle in the district around Sennar on the Blue Nile, a region which probably marked the southern limits of the kingdom of Aloa. The Omayya, who during the following centuries were reinforced by further immigrants from Arabia, intermarried with the negroid races, and gradually Arab influence became predominant and Islam the nominal faith of all the inhabitants of Sennar. In this way a barrier was erected between the Christians of Nubia and those of Abyssinia. By the 15th century the Arabized negro race of the Blue Nile had grown into a powerful nation known as the Funj (q.v.), and during that century they extended their conquests north to the borders of Egypt. The kingdom of Dongola had already been reduced to a condition of anarchy by Moslem invasions from the north. Christianity was still professed by some of the Nubians as late as the 16th century, but the whole Sudan north of the lands of the pagan negroes (roughly 12° N.) was then under Moslem sway. At that time the sultans of Darfur (q.v.) in the west and the sultans or kings of Sennar (the Funj rulers) in the east were the most powerful of the Mahomedan potentates.

The first of the Funj monarchs acknowledged king of the whole of the allied tribes, of which the Hameg were next in importance to the Funj, was Amara Dunkas, who reigned c. 1484–1526.1 During the reign of Adlan, c. 1500–1603, the fame of Sennar attracted learned men to his court from such distant places as Cairo and Bagdad. Adlan's great-grandson Badi Abu Daku attacked the Shilluk negroes and RAIDed Kordofan. This monarch built the great mosque at Sennar, almost the only building in the town to survive the ravages of the dervishes in the 19th century. In the early part of the 18th century there was war between the Sennar and the Abyssinians, in which the last named were defeated with great slaughter. It is said that the cause of quarrel was the seizure by the king of Sennar of presents sent by the king of France to the Negus. The victory over the "infidel" Abyssinians became celebrated throughout the Mahomedan world, and Sennar was visited by many learned and celebrated men from Egypt, Arabia and India. Towards the end of the 18th century the Hameg wrested power from the Funj and the kingdom fell into decay, many of the tributary princes refusing to acknowledge the king of Sennar. These disorders continued up to the time of the conquest of the country by the Egyptians.

B. From the Egyptian Conquest to the Rise of the Mahdi.—The conquest of Nubia was undertaken in 1820 by order of Mehmet Ali, the pasha of Egypt, and was accomplished in the two years following. In its consequences this proved one of the most important events in the history of Africa. Mehmet Ali never stated the reasons which led him to order the occupation of the country, but his leading motive was, probably, the desire to obtain possession of the mines of gold and precious stones which he believed the Sudan contained. He also saw that the revenue of Egypt was falling through the diversion, since about 1800, of the caravan routes from the Nile to the Red Sea ports, and may have wished to recapture the trade, as well as to secure a country whence thousands of slaves could be brought annually. Mehmet Ali also wished to crush the remnant of the Mamelukes who in 1812 had established themselves at Dongola, and at the same time to find employment for the numerous Albanians and Turks in his army, of whose fidelity he was doubtful. Mehmet Ali gave the command of the army sent to Nubia to his son Ismail, who at the head of some 4000 men left Wadi Halfa on October 15th. Following the Nile route he occupied Dongola without opposition, the Mamelukes fleeing before him. (Some of them went to Darfur and Wadai, others made their way to the Red Sea. This was the final dispersal of the Mamelukes.) With the nomad Shagia, who dominated the district,
Kassaia founded. In 1837 the pasha himself visited the Sudan, going as far as Fazokl, where he inspected the goldfields.

In 1849 Abd-el-Latif Pasha became governor-general and attempted to remedy some of the evils which disfigured the administration. He remained in office, however, little more than a year, too short a period to effect reforms. The Sudan was costing Egypt more money than its revenue yielded, though it must not be forgotten that large sums found their way illicily into the hands of the pashas. The successors of Mehemet Ali, in an endeavour to make the country more profitable, extended their conquests to the south, and in 1853 and subsequent years trading posts were established on the Upper Nile, the pioneer European merchant being John Petherick, who rendered great service in opening up the country for trade. The French established a station at Atbara for ivory only, but those who followed him soon found that slave-raiding was more profitable than elephant hunting. The viceroy Said, who made a rapid tour through the Sudan in 1857, found it in a deplorable condition. The viceroy ordered many reforms to be executed and proclaimed the abolition of slavery. The reforms were mainly inoperative and slavery continued. The project which Said also conceived of linking the Sudan to Egypt by railway remained unfulfilled. The Sudan at this time (c. 1863) is described by Sir Samuel Baker as follows: ‘The country is a barren one, with little or no water; it consists of sandstone hills, which are covered with scrub and thorny bushes; the inhabitants are scattered and wandershackled as they are, for want of water, for their cattle.’

In 1857 Bahr-el-Ghazal was annexed, and the viceroy continued his efforts to suppress slave raids. A large force was sent under Colonel Lupton, engaged in 1859 against some of the slave-raiders, and in the following year was again sent under Baker. At this period Zobeir’s dominions were approximately those of the present province of Darfur, and he was a great slave-raider. In 1862 Zobeir’s brother, Obeid, succeeded him as chief. In 1864 a large expedition went up the Nile, under an officer named De Graff, who was a very remarkable man. He captured Obeid and returned to the capital with a large number of slaves. The next year another expedition was sent up the Nile by Said’s orders, and a great number of slaves was captured. In 1866 another expedition was sent up the Nile, under Major Gordon, who, having succeeded Lupton in the command, was ordered to continue the war against the slave-raiders. He captured Obeid and a great number of slaves was taken, and a large number of Europeans was rescued. The expedition returned to the capital in 1867, having captured a large number of slaves and having destroyed many of the slave-raiders’ strongholds.

execution (assuming that the Egyptian authorities were sincere in proposing reforms).

C. The Rise and Power of Mahdism.—The Mahdist movement, which was utterly to overthrow Egyptian rule, derived its strength from two different causes: the oppression under which the people suffered, and the measures taken to prevent the Baggara (cattle-owning Arabs) from slave trading. Venality and the extortion of the tax-gatherer flourished anew after the departure of Gordon, while the fearlessness of his successors inspired in the Baggara a contempt for the authority which prohibited them pursuing their most lucrative traffic. When Mahommed Ahmed (q.v.), a Dongolese, proclaimed himself the long-looked-for Mahdi (guide) of Islam, he found most of his original followers among the grossly superstitious villagers of Kordofan, where the government and local equality and a community of goods, while denouncing the Turks as unworthy Moslems on whom God would execute judgment. The Baggara perceived in this Mahdi one who could be used to shake off Egyptian rule, and their adhesion to him first gave importance to his "mission." Mahommed Ahmed became at once the leader and the agent of the Baggara. He married the daughters of their sheikhs and found in Abdullah, a member of the Taasha section of the tribe, his chief supporter. The first armed conflict between the Egyptian troops and the Mahdi's followers occurred in August 1881. In June 1882 the Mahdi's forces occupied Kordofan and captured Omdurman. The capture of El Obeid on the 17th of January 1883 and the annihilation in the November following of an army of over 10,000 men commanded by Hicks Pasha (Colonel William Hicks [q.v.] formerly of the Bombay army) made the Mahdi undisputed master of Kordofan and Sennar. The next month, December 1883, saw the surrender of Slatin in Darfur, whilst in February 1884 Osman Digna, his amir in the Red Sea regions, inflicted a crushing defeat on some 4,000 Egyptians at El Teb near Suakin. In April following Lupton Bey, governor of Bahr-el-Ghazal, whose troops and officials had embraced the Mahdist cause, surrendered and was sent captive to Omdurman, where he died on the 8th of May 1884.

On learning of the disaster to Hicks Pasha's army, the British government (Great Britain having been since 1852 in military occupation of Egypt) insisted that the Egyptian government should evacuate such parts of the Sudan as they still held, and General Gordon was despatched, with Lieut.-Colonel Donald H. Stewart, to Khartoum to arrange the withdrawal of the Egyptian civil and military population. Gordon's instructions, based largely on his own suggestions, were not wholly consistent; they contemplated vaguely the establishment of some form of autonomous government on the surrender of Egyptian authority, and among the documents with which he was furnished was a firman creating him governor-general of the Sudan. Gordon reached Khartoum on the 18th of February 1884 and at first his mission, which had aroused great enthusiasm in England, promised success. To smooth the way for the retreat of the Egyptian garrisons and civilians he issued proclamations announcing that the suppression of the slave trade was abandoned, that the Mahdi was sultan of Kordofan, and that the Sudan was independent of Egypt. He enabled some thousands of refugees to make their escape to Assuan and collected at Khartoum troops from some of the outlying stations. By this time the situation had altered for the worse and Mahdism was gaining strength among tribes in the Nile valley at first hostile to its propaganda. As the only means of preserving authority at Khartoum (and thus securing the peaceful withdrawal of the garrison) Gordon repeatedly telegraphed to Cairo asking that Zobeir Pasha might be sent to him, his intention being to hand over to Zobeir the government of the country. Zobeir (q.v.), a Sudanese Arab, was probably the one man who could have withstood successfully the Mahdi. Owing to Zobeir's notoriety as a slave-raider Gordon's request was refused. All hope of a peaceful retreat of the Egyptians was thus rendered impossible. The Mahdist movement now swept northward and on the 20th of May Berber was captured by the Mahdists and Khartoum invested. For this time the energies of Gordon were devoted to the defence of that town. After months of delay due to the vacillation of the British government a relief expedition was sent up the Nile under the command of Lord Wolseley. It started too late to achieve its object, and on the 25th of January 1885 Khartoum was captured by the Mahdi and Gordon killed. Colonel Stewart, Frank Power (British consul at Khartoum) and M. Herbin (French consul), who (accompanied by nineteen Greeks) had been sent down the Nile by Gordon in the previous September to give news to the relief force, had been decoyed ashore and murdered (Sept. 18, 1884). The fall of Khartoum was followed by the end of the British expedition, Dongola being evacuated in June 1885. In the same month Kassala capitulated, but just as the Mahdi had practically completed the destruction of the Egyptian power he died, in this same month of June 1885. He was at once succeeded by the khaliifa Abdullah, whose rule continued until the 2nd of September 1898, when his army was completely overthrown by an Anglo-Egyptian force under Sir H. (afterwards Lord) Kitchener. The military operations are described elsewhere (see Egypt: Military Operations), and here it is only necessary to consider the internal situation and the character of the khaliifa's government. The Mahdi had been regarded by his adherents as the only true commander of the faithful, endowed with divine power to conquer the whole world. He had at first styled his followers dervishes (i.e. religious mendicants) and given them the jibba as their characteristic garment or uniform. Later on he commanded the faithful to call themselves ansar (helpers), a reference to the part they were to play in his career of conquest, and at the time of his death he was planning an invasion of Egypt. He had liberated the Sudanese from the extortions of the Egyptians, but the people soon found that the Mahdi's rule was even more oppressive than that of their former masters. And after the Mahdi's death the situation of the peasantry in particular grew rapidly worse, neither life nor property being safe. Abdullah set himself steadfastly to crush all opposition to his own power. Mahommed Ahmed had, in accordance with the traditions which required the Mahdi to have four khaliifas (lieutenants), nominated, besides Abdullah, Ali wed Helu, a sheikh of the Degheim and Kenana Arabs, and Mahommed esh Sherif, his son-in-law, as khaliifas. The (other khaliifaship was vacant having been declined by the sheikh es Sennusi [q.v.]). Wad Helu and Sherif were stripped of their power and gradually all chiefs and amirs not of the Baggara tribe were got rid of except Osman Digna, whose sphere of operations was on the Red Sea coast. Abdullah's rule was a pure military despotism which brought the country to a state of almost complete agricultural and commercial ruin. He was also almost constantly in conflict either with the Shilluks, Nuers and other negro tribes of the south; with the peoples of Darfur, where at one time an anti-Mahdi gained a great following; with the Abyssinians; with the Kabbabish and other Arab tribes who

*Writing from Darfur in April 1879 Gordon said: "The government of the Egyptians in these far-off countries is nothing but one of brigandage of the worst description. It is so bad that all hope of ameliorating it is hopeless."

1 The Sudanese spoke of all foreigners as "Turks." This arose from the fact that most of the higher Egyptian officials were of Turkish nationality and that the army was officered mainly by Turks, Albanians, Circassians, &c., and included in the ranks many Bashish-Bazucks (irregulars drawn from the Sudan).

2 He had been sent to Khartoum in 1882 on a mission of inquiry, and he drew up a valuable report, Egypt, No. 11 (1885).

3 It is unnecessary here to enter upon a discussion of the precise nature of the table of government on the surrender of Egyptian power, or the measures in which he carried them out. The material for forming a judgment will be found in Gordon's Journals (1885), Morley's Life of Gladstone (1903), Fitzmaurice's Life of Granville (1905), and Cromer's Modern Egypt (1906). (See also Gordon, Charles George.)
had never embraced Mahdism, or with the Italians, Egyptians and British. Notwithstanding all this opposition the khilfa found in his own tribesmen and in his black troops devoted adherents and successfully maintained his position. The attempt to conquer Egypt ended in the total defeat of the dervish army at Toski (Aug. 3, 1898). The attack upon the Egyptian forces were but partly successful. Emin Pasha, to whose relief M. Stanley had gone, evacuated Wadelai in April 1890. The greater part of the region and also most of the Bahr-el-Ghazal relapsed into a state of complete savagery.

In the country under his dominion the khilifa’s government was carried on after the manner of other Mahomedean states, but pilgrimages to the Mahdi’s tomb at Omdurman were substituted for pilgrimages to Mecca. The arsenal and dockyard and the printing-press at Khartum were kept busy (the workmen being Egyptians who had escaped massacre). Otherwise Khartum was deserted, the khilfa making Omdurman his capital and compelling disaffected tribes to dwell in it so as to be under better control. While Omdurman grew to a huge size the population of the country generally dwindled enormously from constant warfare and the ravages of disease, small-pox being endemic. The Europeans in the country were kept prisoners at Omdurman. Besides ex-officials like Slatin and Lupton, they included several Roman Catholic priests and sisters, and numbers of Greek merchants established at Khartum. Although several were killed, the Khartum garrison was loaded with chains and repeatedly flogged, it is a noteworthy fact that none was put to death. From time to time a prisoner made his escape, and from the accounts of these ex-prisoners knowledge of the character of Dervish rule is derived in large measure. The fanaticism with which the Mahdi had inspired his followers remained almost unbroken to the end. The khilfa after the fatal day of Omdurman fled to Kordofan where he was killed in battle in November 1899. In January 1900 Osman Digna, a wandering fugitive faktah of Khartum’s days, was captured in Tanganyika. His amir of importance surrendered to the sultan of Darfur. Mahdism as a vital force in the old Egyptian Sudan ceased, however, with the Anglo-Egyptian victory at Omdurman.1

D. The Anglo-Egyptian Condominium.—Of the causes which led to the reconquest of the Sudan—the natural desire of the Egyptian government to recover lost territory, the equally natural desire in Great Britain to “avenge” the death of Gordon were among them—the most weighty was the necessity of securing for Egypt the control of the Upper Nile, Egypt being wholly dependent on the waters of the river for its prosperity. That control would have been lost had a European power other than Great Britain obtained possession of any part of the Nile valley; and at the time the Sudan was reconquered (1896-98) France was endeavouring to establish her authority on the river between Khartum and Gondokoro, as the Marchand expedition from the Congo to Fashoda demonstrated. The Nile constitutes, in the words of Lord Cromer, the true justification of the policy of re-occupation, and makes the Sudan a priceless possession for Egypt.2

The Sudan having been reconquered by the joint military and financial efforts of Great Britain and Egypt, the British government claimed “by right of conquest” to share in the settlement of the administration and legislation of the country. To meet these claims an agreement (which has been aptly called the constitutional charter of the Sudan) between Great Britain and Egypt, was signed on the 10th of January 1899, establishing the joint sovereignty of the two states throughout

---

1 In the autumn of 1903 Mahomed-el-Amin, a native of Tunis, proclaimed himself the Mahdi and got together a following in Kordofan. He was captured by the governor of Kordofan and publicly executed at El Obeid in April. 1899, Abd-el-Kader, a Hauzin Arab and ex-dervish, rebelled in the Blue Nile province, claiming to be the prophet Issa (Jesus). On the 29th of that month he murdered Mr C. C. Scott-Moncrieff, deputy inspector of the province, and the Egyptian garrison was promptly crushed. Abd-el-Kader was captured and was hanged on the 17th of May.

2 Egypt, No. 1 (1905), p. 119.
commercial development of the country, a railway from the Nile near Berber to the Red Sea was built (1904-1906). This line shortened the distance from Khartoum to the nearest seaport by nearly 1000 m., and by reducing the cost of carriage of merchandise enabled Sudan produce to find a profitable outlet in the markets of the world. At the same time river communications were improved and the numbers of wells on caravan roads increased. The government, which was anxious to prevent works to regulate the Nile floods, and those of the river Gash.

To the promotion of education and sanitation, and in the administration of justice, the government devoted much energy with satisfactory results. Indeed the regenerative work of Great Britain in the Sudan has been fully as successful and even more remarkable than that of Great Britain in Egypt. A large part of this work has been accomplished by officers of the British army. Some of the most valuable suggestions about such matters as land settlement, agricultural loans, &c., emanated from officers who a short time before were performing purely military duties. Nevertheless civil servants gradually replaced military officers in the work of administration, army officers being liable to be suddenly removed for war or other service, often at times when the presence of officials possessed of local experience was most important. In efficiency and devotion to duty the Egyptian officials under the new régime also earned high praise.

The relations of the Sudan government with its Italian, Abyssinian and French neighbours was marked by cordiality, but with the Congo Free State difficulties arose over claims made by that state to the Bahr-el-Ghazal (Sudan, Sec. 3). Congo State troops were in 1904 stationed in Sudanese territory. The difficulty was adjusted in 1906 when the Congo State abandoned all claims to the Ghazal province (whence its troops were withdrawn during 1907), and it was agreed to transfer the Lado enclave (q.v.) to the Sudan six months after the death of the king of the Belgians. Under the terms of this agreement the Lado enclave was incorporated in the Sudan in 1910. As to the general state of the country Sir Eldon Gorst after a tour of inspection declared in his report for 1909, "I do not suppose that there is any part of the world in which the mass of the population have fewer unsatisfied wants."

**AUTHORITIES.—Summaries of ancient and medieval history will be found in E. A. Wallis Budge, The Egyptian Sudan (2 vols., 1907) and The Anglo-Egyptian Sudan (1905), edited by Count Gleichen. The story of the Egyptian conquest and events up to 1899 will be found in A. Delaporte, Histoire de l'Egypte Moderne (1899). Mahdistie History is treated under the name of Mehemet Ali (Paris, 1898). For the middle period of Egyptian rule see Sir Samuel Baker's Ismaïlia (1874); Col. Gordon in Central Africa, edited by G. Birkbeck Hill (4th ed., 1885), being extracts from Gordon's private papers. See Soudan by G. E. A. Slatin (1900), and Soudan by Gessi Pasha (1892); and Der Sudan unter ägyptischer Herrschaft, by R. Buchta (Leipzig, 1889). The rise of Mahdistie and events down to 1900 are set forth in (Sir) F. R. Wingate's Mahdistie and the Egyptian Sudan (1903). This book contains translations of letters and proclamations of the Mahdi and Khalifa. For this period the Journals of Major General Gordon at Khartoum (1885); F. Power's Letters from Khartoum during the Siege (1885), and the following four books written by prisoners of the derelicts are specially valuable: Slatin Pasha, Fire and Sword in the Sudan (1896); Father J. Ohrwalder (from the MSS. of, by F. R. Wingate), Ten Years' Captivity in the Hotel's Camp (1882-1892) (1902); Father Paolo Rosendoli, I miei dodici anni di prigionia in mezzo ai servizi del Sudan (Mondovi, 1903); C. Neufeldt, A Prisoner of the Khaleefa (1890). See also G. Dujarric, L'Etat mahdiste du Soudan (Paris, 1901). For the British official history see the Sudan Campaign (1890); for the campaigns of 1896-98, H. S. L. Allford and W. D. Sword, The Egyptian Soudan, its Loss and Recovery (1896); G. W. Steevens, With Kitchener to Khartoum (Edinburgh, 1899). The story of the Fashoda incident is told in British official despatches; consult also for this period G. Hanotaux, Fashoda (Paris, 1912); Paulin, La Fashoda, de la France 1898-1899 (Paris, 1899), and R. K. de Caix, Fashoda, la France et le protectorat de l'Egypte (Paris, 1899). Lord Cromer's Modern Egypt (1908) covers Sudanese history for the years 1881-1907. Consult also the authorities cited under Egypt, Modern History, and El-F.'s, History of the Egyptian Sudan (London, 1895). Unless otherwise stated the place of publication is London."

**SUDATORIUM**—SUDURY. In order to obtain the great heat required, the whole wall was lined with vertical terra-cotta flue pipes of rectangular section, placed side by side, through which the hot air and the smoke from the suspensura passed to an exit in the roof.

**SUDURY, SIMON OF** (d. 1381), archbishop of Canterbury, was born at Sudbury in Suffolk, studied at the university of Paris, and became one of the chaplains of Pope Innocent VI., who sent him, in 1356, on a mission to Edward III. of England. In October 1361 the pope appointed him bishop of London, and he was soon serving the king as an ambassador and in other ways. In 1373 he succeeded William Witlesey as archbishop of Canterbury, and during the rest of his life was a partisan of John of Gaunt. In July 1377 he crowned Richard II., and in 1378 John Wycliffe appeared before him at Lambeth, but he only took proceedings against the reformer under great pressure. In January 1380 Sudbury became chancellor of England, and the revolting peasants regarded him as one of the principal authors of their woes. Having released John Ball from his prison at Maidstone, the Kentish insurgents attacked and damaged the archbishop's property at Canterbury and Lambeth; then, rushing into the Tower of London, they seized the archbishop himself. Sudbury was dragged to Tower Hill and, on the 14th of June 1381, was beheaded. His body was afterwards buried in Canterbury Cathedral. Sudbury rebuilt part of the church of St Gregory at Sudbury, and with his brother, John of Chertsey, he founded a college in this town; he also did some building at Canterbury. His father was Nigel Theobald, and he is sometimes called Simon Theobald or Tybald.

**SUDURY, a post town and outport of Nipissing district, Ontario, Canada, on the Canadian Pacific railway, 443 m. W. of Montreal. Pop. (1901), 7199. It lies on the river Stour (which is navigable up to the town), 59 m. N.E. from London by the Great Eastern railway. All Saints' parish church, consisting of chancel, nave, aisles and tower, is chiefly Perpendicular—the chancel being Decorated. It possesses a few ancient monuments, and in 1882 was purchased for £2,000 by St Peter's, a new church. St Peter's is Perpendicular, with a finely carved nave roof. St Gregory's, once collegiate, is Perpendicular. It has a rich spire-shaped font-cover of wood, gilt and painted. The grammar school was founded by William Wood in 1491. There are some old half-timbered houses, including one very fine example. The principal modern buildings are the town-hall, Victoria hall and St Leonard's hospital. Coco-nut matting is an important manufacture; silk manufactures were transferred from London during the 19th century, and horsehair weaving was established at the same time. There are also flour-mills, malt-kilns, lime-works, and brick and tile yards. The town is governed by a mayor, 4 aldermen and 12 councillors. The borough lies wholly in the administrative county of West Suffolk. Area, 1925 acres.

The ancient Saxon borough of Sudbury (Sudbury, Suderby, Suthberia) was the centre of the southern portion of the East Anglian kingdom. Before the Conquest it was a borough owed by the mother of Earl Morcar, from whom it was taken by William I., who held it in 1086. It was alienated from the Crown to an ancestor of Gilbert de Clare, 9th earl of Gloucester. In 1271 the earl gave the burgesses their first charter confirming to them all their ancient liberties and customs. The earl of March granted a charter to the mayor and bailiffs of Sudbury in 1290, and again in 1445 the men and tenants of Sudbury obtained a royal confirmation of their privileges. They were incorporated in 1553 under the name of the mayor, aldermen and burgesses of Sudbury, and charters were granted to the town by Elizabeth, Charles II. and James II. Its constitution was reformed by the act of 1835. It was represented in parliament by two burgesses from 1558 till its disfranchisement in
SUDD—SUEBI

1844. The lord of the borough had a market and fair in the 13th century, and three fairs in March, July and December were held in 1792. Markets still exist on Thursdays and Saturdays. Weavers were introduced by Edward III., and the town became the chief centre of the Suffolk cloth industry after the Restoration.

SUDD, or Sando (an Arabic word meaning “to dam”), the name given to the vegetable obstruction which has at various dates closed the lower Nile to navigation. It is composed of masses of papyrus and um suf (Vossia corbea) and the earth adhering to the roots of those reeds. Mingled with the papyrus and um suf (Arabic for “mother-of-wool”) are small swimming plants and the light brittle amble. The papyrus are sometimes found along the Nile banks and the connected lagoons between 7° N. and 13° N. Loosened by storms these reeds drift until they lodge on some obstruction and form a dam across the channel, converted by fresh arrivals into blocks that are sometimes 25 m. in length, and extend 15 to 20 ft. below the surface. These masses of decayed vegetation and earth, resembling peat in consistency, are so much compressed by the force of the current that men can walk over them everywhere. In parts elephants could cross them without danger. The present day breach at Sudd near Bahr el-Ghazal was opened or the burst of the Sudd. (For sudd cutting see Nile.)

In the Bahr-el-Ghazal the sudd, being chiefly composed of small swimming plants, is of less formidable nature than that of the main stream.

Consult, O. Deuerling, Die Pflanzeneren der afrikanischen Flüsse (Munich, 1909), a valuable monograph; and the bibliography under Nile, especially Captain H. G. Lyona, The Physiography of the Nile and its Basin (Cairo, 1906).

SUDERMANN, Hermann (1857— ), German dramatist and novelist, was born on the 30th of September 1857 at Matziken in East Prussia, close to the Russian frontier, of a Mennonite family long settled near Elbing. His father owned a small brewery, and his mother, the former Amalie Gier, received his early education at the Realschule in Elbing, but, his parents having been reduced in circumstances, he was apprenticed to a chemist at the age of fourteen. He was, however, enabled to enter the Realgymnasium in Tilsit, and to study philosophy and history at Königsberg University. In order to complete his studies Sudermann went to Berlin, where he was tutor in several families. He next became a journalist, was from 1881-1882 editor of the Deutschen Reichsbalt, and then devoted himself to novel-writing. The novels and romances Im Zwielicht (1886), Frau Sorge and Der Katensteg (1888), and Der Katensteg (1894) failed to bring the young author as much recognition as his first drama Die Ehre (1899), which inaugurated a new period in the history of the German stage. Of his other dramas the most successful were Sodoms Ende (1891), Heimat (1893), Die Schmetterlingsschlacht (1894), Das Glück im Winkel (1895), Morituris (1896), Johannes (1898), Die drei Reiferedern (1900), Johannesfeuer (1900), Es lebe das Leben! (1902), Der Sturmgesselse Sobrates (1903) and Stein unter Steinen (1905). Sudermann is also the author of a powerful social novel, Es war (1904), which, like Frau Sorge and Der Katensteg, has been translated into English.

See W. Kawerau, Hermann Sudermann (1897); H. Landsberg, Hermann Sudermann (1902); H. Jung, Hermann Sudermann (1902); H. Schoen, Hermann Sudermann, poète dramatique et romancier (1903); and L. A. X. Körner, Hermann Sudermann (1907).

SUB, EUGÈNE [Joseph Marie] (1804–1857), French novelist, was born in Paris on the 20th of January 1804. He was the son of a distinguished surgeon in Napoleon’s army, and is said to have had the empress Josephine for godmother. Sue himself acted as surgeon both in the Spanish campaign undertaken by France in 1823 and at the battle of Navarino (1828). In 1829 his father’s death put him in possession of a considerable fortune, and he settled in Paris. His naval experiences supplied much of the materials of his first novels, Kernock le pirate (1830), Atar-Gull (1831), La Salamandre (2 vols., 1832), La Concarachia (4 vols., 1833-1834), and others, which were composed at the height of the romantic movement of 1830. In the quasi-historical style he wrote Jean Cavalier, ou Les Fanatiques des Cevennes (4 vols., 1836) and Latelraumont (2 vols., 1837). He was strongly affected by the Socialistic ideas of the day, and these prompted his most famous works: Les Mystères de Paris (10 vols., 1842-1843) and Le Juif errant (10 vols., 1844-1845), which were among the most popular specimens of the roman-feuilleton. He followed these up with some singular and not very edifying books: Les Sept péchés capitaux (16 vols., 1847-1849), which contained stories to illustrate each sin, Les Mystères du peuple (1849-1856), which was suppressed by the censor in 1857, and several others, all on a very large scale, though the names of all too long live in an exaggerated form. Several of his books, among them the Juif errant and the length of his study of the coup d’état of the 2nd of December 1851. This exile stimulated his literary production, but the works of his last days are on the whole much inferior to those of his middle period. Sue died at Annecy (Savoy) on the 3rd of August 1857.

SUEBI, or Suevi, a collective term applied to a number of peoples in central Germany, the chief of whom appear to have been the Marcomanni, Quadi, Hermunduri, Semnones and Langobardi. From the earliest times these tribes inhabited the basin of the Elbe. To the north and west of these barbaric territories seem to have lain about the lower reaches of the river, while the Semnones lay south. The Marcomanni occupied the basin of the Saale, but under their king, Maroboduus, they moved into Bohemia during the early part of Augustus’s reign, while the Quadri, who are first mentioned in the time of Tiberius, lay farther east towards the sources of the Elbe. The former home of the Marcomanni was occupied by the Hermunduri a few years before the Christian era. Some kind of political union seems to have existed among all these tribes. The Semnones and Langobardi were at one time subject to the dominion of the Marcomannic king Maroboduus, and at a much later period we hear of Langobardic troops taking part against the Romans in the Marcomannic War. The Semnones claimed to be the chief of the Suebic peoples, and Tacitus describes a great religious festival held in their tribal sanctuary, at which legations were present from all the other tribes.

Tacitus uses the name Suebi in a far wider sense than that defined above. With him it includes not only the tribes of the basin of the Elbe, but also all the tribes north and east of that river, including even the Swedes (Suiones). This usage, which is not found in other ancient writers, is probably due to a confusion of the Suebi with the agglomeration of peoples under their supremacy, which as we know from Strabo extended to some at least of the eastern tribes.

In early Latin writers the term Suebi is occasionally applied to any of the above tribes. From the 2nd to the 4th century, however, it is seldom used except with reference to events in the neighbourhood of the Pannonian frontier, and here probably means the Quadi. From the middle of the 4th century onward it appears most frequently in the regions south of the Main, and the names Alamanni and Suebi are used synonymously. The Alamanni (q.v.) are the descendants of the ancient Suebi. It is likely that they had been joined by one or more other Suebic peoples, from the Danubian region, or more probably from the middle Elbe, the land of the ancient Semnones. It is probably from the Alamannic region that those Suebi who came who joined the Vandals in their invasion of Gaul, and eventually founded a kingdom in north-west Spain. After the 1st century the term Suebi seems never to have been applied to the Langobardi and seldom to the Bavarii (Bavarians), the descendants of the ancient Marcomanni. But besides the Alamannic Suebi we hear
also of a people called Suebi, who shortly after the middle of the 6th century settled north of the Unstrut. There is evidence also for a people called Suebi in the district above the mouth of the Scheldt. It is likely that both these settlements were colonies from the Suebi of whom we hear in the Anglo-Saxon poem *Widsith* as neighbours of the Angles, and whose name may possibly be preserved in Schwabstedt on the Treene. The question has recently been raised whether these Suebi should be identified with the people whom the Romans called *H eruli*. After the 7th century the name Suebi is practically only applied to the Alamannic Suebi (Schwaben), with whom it remains a territorial designation in Württemberg and Bavaria until the present day.

See *Caesar, De bello gallico*, i. 37, 51 seqq., iv. 1 seqq., vi. 9 seqq.; *Strabo*, p. 290 seqq.; *Tacitus, Germany*, 38 seqq.; K. Zeuss, *Die Deutschen und die Nachbarstämme*, pp. 85 seqq., 315 seqq.; C. Bremer in Paul’s *Grundriss* (2nd ed.), iii. 915-950; H. M. Chadwick, *Origin of the English* (1925). *Suessula* has been identified with a road which ran from Neapolis through Accrae, and on to the Via Appia, which it reached just west of the Caudine pass. On the hills above Cancello to the east of *Suessula* was situated the fortified camp of M. Claudius Marcellus, which covered Nola and served as a post of observation against Hannibal in Capua.

**SUECA**, a town of eastern Spain, in the province of Valencia, near the left bank of the river Júcar, and on the Silla-Cullera railway. Pop. (1900), 14,435. *Sueca* is separated from the Mediterranean Sea (7 m. east) by the Sierra de Cullera. It is a modern town, although many of the houses have the flat roofs, view-turrets (*miradores*) and horseshoe arches characteristic of Moorish architecture. There are a few handsome public buildings, such as the hospital, town-hall and theatre. Sueca has a thriving trade in grain and fruit from the Júcar valley, which is irrigated by waterways created by the Moors.

**SUESS, EMIL** (1834-1914), Austrian geologist, was born in Vienna on the 28th of August 1834, his father, a native of Saxony, having settled there as a German merchant. Three years later the family removed to Prague, and in 1845 to Vienna. Eduard Suess was educated for commercial life, but early displayed a bent for geology. At the age of nineteen he published a short sketch of the geology of Carlsbad and its mineral waters; and in 1852 he was appointed an assistant in the Imperial museum of Vienna. There he studied the fossil Brachiopoda, and manifested such ability that in 1857 he was appointed professor of geology at the university. In 1862 he relinquished his museum duties, and gave his whole time to special research and teaching, retaining his professorship until 1901. Questions of ancient physical geography, such as the former connexion between northern Africa and Europe, occupied his attention; and in 1862 he published an essay on the soils and water-supply of Vienna. He was elected a member of the town council, and in 1869 to a seat in the Diet of Lower Austria, which he retained until 1895. Meanwhile he continued his geological and palaeontological work dealing with the Tertiary strata of the Vienna Basin, also turning his attention to the problems connected with the evolution of the earth’s surface-features, on which he wrote a monumental treatise. This, the great task of his life, embodied the results of personal research and of a comprehensive study of the work of the leading geologists of all countries; it is entitled *Anleitung der Erde*, of which the first volume was published in 1885, the second in 1888, and pt. i. of the third volume in 1901. The work has been translated into French, and (in part) into English. Sueß was elected a corresponding member of the Institute of France in 1889, and a foreign member of the Royal Society in 1894. In 1896 the Geological Society of London awarded to him the Wollaston medal.

**SUESSELA** is a small town of Campania, Italy, in the plain 13 m. W. of the modern Cancello, 9 m. S.E. of the ancient Capua. Its earlier history is obscure. In 339 B.C. it obtained municipal rights from Rome. In the Samnite and Hannibalic wars it was strategically important as commanding the entrance to the Caudine pass. Sula seems to have founded a colony here. It is frequently named as an episcopal see up till the 10th century A.D., and was for a time the chief town of a small Lombard principality. It was several times plundered by the Saracens, and at last abandoned by the inhabitants in consequence of the malaria. The ruins of the town lie within the Bosco d’Acerra, a picturesque forest. They were more conspicuous in the 18th century than they now are, but traces of the theatre may still be seen, and débris of other buildings. Oscar tombs were excavated there between 1878 and 1886, and important finds of vases, bronzes, &c., have been made. The dead were generally buried within slabs of tufa arranged to form a kind of sarcophagus (see F. von Eitner, *Urnenfelder*, ii. p. 235 seqq.). *Suesseula* lay on the line of the Via Popilia, which seems to have been a road which ran from Neapolis through Accrae, and on to the Via Appia, which it reached just west of the Caudine pass.

**SUEZ** (T. A.S. *suevii*; Lat. *suevium*), an ancient tract along the north-west coast of Asia Minor. In the district of Sassin, near the site of the ancient city of Teais. The Sasanians had a large district called *Suecia* there.

**SUETONIUS TRANQUILLUS, GAIUS**, Roman historian, lived during the end of the 1st and the first half of the 2nd century A.D. He was the contemporary of Tacitus and the younger Pliny, and his literary work seems to have been chiefly done in the reigns of Trajan and Hadrian (A.D. 98-118). His father was military tribune in the XXXIst legion, and he himself began life as a teacher of rhetoric and an advocate. To us he is known as the biographer of the twelve Caesars (including Julius) down to Domitian. The lives are valuable as original works, and are without the guidance of Tacitus. As Suétionus was the emperor Caligula’s private secretary (magister epistolatorum), he must have had access to many important documents in the imperial archives, such as the decrees and transactions of the senate. In addition to written and official documents, he picked up in society a mass of information and anecdotes, which, though of doubtful authenticity, need not be regarded as mere inventions of his own. They give a very good idea of the kind of court gossip prevalent in Rome at the time. He was a friend and correspondent of the younger Pliny, who when appointed governor of Bithynia took Suetonius with him. Pliny also recommended him to the favourable notice of the emperor Trajan, "as most upright, honourable, and learned, man, whose persons often remember in their wills because of his merits," and he begs that he may be made legally capable of inheriting these bequests, for which under a special enactment Suetonius was, as a childless married man, disqualified. Hadrian’s biographer, Aelius *Spartianus*, tells us that Suetonius was deprived of his private secretaryship because he had not been sufficiently observant of court etiquette towards the emperor’s wife during Hadrian’s absence in Britain.

The *Lives of the Caesars* always has been a popular work. It is rather a chronicle than a history. It gives no picture of the society of the time, no hints as to the general character and tendencies of the period. It is the emperor who is always before us, and yet the portrait is drawn without any real historical judgment or insight. It is the personal anecdotes, several of which are very amusing, that give the lives their chief interest; but the author panders rather too much to a taste for scandal and gossip. None the less he throws considerable light on an important period, and next to Tacitus and Dio Cassius is the chief (sometimes the only) authority. The language is clear and simple. The work was continued by *John of H处mesius* (330-391), who wrote a history of the emperors from Nerva to Elagabalus (now lost). Suetonius was a voluminous writer. Of his *De viris illustribus*, the lives of Terence and Horace, fragments of those of Livy and the elder Pliny and the greater part of the chapter on grammarians and rhetoricians, are extant. Other works by him (now lost) were: *Praxis* (= *lexipalbriki* = patchwork), in ten books, a kind of encyclopaedia; the *Roman Year*, *Roman Inscriptions*, *General Geography*, *Obituaries* of the Greeks, *Roman Public Spectacles*, *On the Kings*, *On Cicero’s Republic*.

*Editio princeps*, 1470; editions by great scholars: Erasmus, Isaac Casaubon, J. G. Graevius, P. Burmann; the best complete modern edition is still that of G. C. Baumgarten-Crusius (1853); recent editions by H. T. Peck (New York, 1889); Leo Frémond (1906); M. Ihm (1907). Editions of separate lives: *Augustus*, by E. S. Shackburgh (with useful introduction, 1896); *Claudius*, by H. Smilde (1896), with notes and parallel passages from other authorities. The best editions of the text are by C. L. Roth (1886), and A. Reifferscheid (not including the *Lives*, 1890). On the *De viris illustribus*, see
SUEZ—SUEZ CANAL

G. Körte in Dissert. philol. heliog. (1900), vol. iv.; and, above all, A. Macé, Essai sur Sûleône (1800), with an exhaustive bibliography. There are English translations by Philemon Holland (reprinted in the 17th century), and by Thomson and Forester (in Bohn’s Classical Library).

SUEZ, a port of Egypt on the Red Sea and southern terminus of the Suez Canal (q.v.), situated at the head of the Gulf of Suez in 25° 58’ 57” N., 33° 31’ 18” E. It is 86 m. E. by S. of Cairo in a direct line but 148 m. by rail, and is built on the north-west point of the gulf. Pop. (1897), 25,347.

From the quays on the heights to the south, there is a superb view to the south with the Jebel Ataka on the right, Mt Sinai on the left and the waters of the gulf between. Suez is supplied with water by the fresh-water canal, which starts from the Nile at Cairo and is terminated at Suez by a lock which, north of the town, joins it to the gulf. Before the opening of this canal in 1863 water had to be brought from “the Wells of Moses,” a small oasis 3 m. distant on the east side of the gulf. About 2 m. south of the town are the harbours and quays constructed on the western side of the Suez Canal at the point where the canal enters the gulf. The harbours are connected with the town by an embankment and railway built across a shallow, dry at low water save for a narrow channel. On one of the quays is a statue to Thomas Waghorn, the organizer of the “overland route” to India. The ground on which the port is built has all been reclaimed from the sea. The accommodation provided includes a dry dock 470 ft. long, 100 ft. broad and nearly 36 ft. deep. There are separate basins for warships and merchant ships, and in the roadstead at the mouth of the canal is ample room for shipping. Suez is a quarantine station for pilgrims from Mecca; otherwise its importance is due almost entirely to the ships using the canal.

In the 7th century a town called Kolzum stood, on a site adjacent to that of Suez, at the southern end of the canal which then joined the Red Sea to the Nile. Kolzum retained some of the trade of Egypt with Arabia and countries farther east long after the canal was closed, but by the 13th century it was in ruins and Suez itself, which had supplanted it, was also, according to an Arab historian, in decay. On the Ottoman conquest of Egypt in the 16th century Suez became a naval as well as a trading station, and here fleets were equipped which for a time disputed the mastery of the Indian Ocean with the Portuguese. According to Niebuhr, in the 18th century a fleet of nearly twenty vessels sailed yearly from Suez to Jidda, the port of Mecca and the place of correspondence with India. When the French occupied Suez in 1798 it was a place of little importance, and the conflicts which followed its occupation in 1800 by an English fleet laid the greater part in ruins. The overland mail route from England to India by way of Suez was opened in 1837. The regular Peninsular & Oriental steamer service began a few years later, and in 1857 a railway was opened from Cairo through the desert. This line is now abandoned in favour of the railway which follows the canal from Suez to Ismailia, and then ascends the Wadi Tumilat to Zagazig, whence branches diverge to Cairo and Alexandria.

SUEZ CANAL—Before the construction of the Suez Canal there was no direct water communication between the Mediterranean and the Red Sea, but at various eras such communication existed by way of the Nile. Trade between Egypt and countries to the east was originally overland to ports south of the Gulf of Suez; the proximity of the roadstead at the head of that gulf to Memphis and the Delta nevertheless marked it as the natural outlet for the Red Sea commerce of Lower Egypt. The fertile Wadi Tumilat extending east of the Nile valley almost to the head of the gulf (which in ancient times reached north to the Bitter Lakes) afforded an easy road between the Nile and the Red Sea, while the digging of a navigable canal connecting the river and the gulf gave the northern route advantages not possessed by the desert routes farther south, e.g. that between Cairo and Alexandria. Aristotle, Strabo and Pliny attribute to the legendary Sesostris (Kolzum, Arist.) the first of the pharaohs to build a canal joining the Nile and the Red Sea. From an inscription on the temple at Karnak it would appear that such a canal existed in the time of Seti I. (1380 B.C.) This canal diverged from the Nile near BABISTAS and was carried along the Wadi Tumilat to Heroopolis, near Pithom, a port at the head of the Heroopolite Gulf (the Bitter Lakes of to-day). The channel of this canal is still traceable in parts of the Wadi Tumilat, and its direction was frequently followed by the engineers of the fresh-water canal. Seti’s canal appears to have fallen into decay or to have been too small for later requirements, for Pharaoh Necho (660 B.C.) began to build another canal; possibly his chief object was to deepen the channel between the Heroopolite Gulf and the Red Sea, then probably sitting up. Necho’s canal was not completed—according to Herodotus 120,000 men perished in the undertaking. Darius (520 B.C.) continued the work of Necho, rendering navigable the channel of the Heroopolite Gulf, which had become blocked. Up to this time there appears to have been no connexion between the waters of the Red Sea and those of the BABISTAS—HEROPOLOIS canal; vessels coming from the Mediterranean ascended the Pelusiac arm of the Nile to BABISTAS and then sailed north to HEROPOLOIS, where their merchandise had to be transferred to the Red Sea ships. Ptolemy Philadelphus (285 B.C.) connected the canal with the waters of the sea, and at the spot where the junction was effected he built the town of Arsinoe. The dwindling of the Pelusiac branch of the Nile rendered this means of communication impossible by the time of Cleopatra (31 B.C.). Trajan (A.D. 98) is said to have repaired the canal, and, as the Pelusiac branch was no longer available for navigation, to have built a new canal between BABISTAS and BABYLON (Old Cairo), this new canal being known traditionally as AMMIS (600 B.C.) and of course A NNIS AUGUSTUS. According to H. R. Hall, however, “It is very doubtful if all works of this kind, large or small, were undertaken in the times of the Romans; and it is more probable that the new canal was the work of ‘Amr” (the Arab conqueror of Egypt in the 7th century). The canal was certainly in use in the early years of the Moslem rule in Egypt; it is said to have been closed c. A.D. 770 by order of Abu Ja’far Mansur, the second Abbasid caliph and founder of Baghdad, who wished to prevent supplies from reaching his enemies in Arabia by this means. Amr’s canal (of which the Khalig which passed through Cairo and was closed in 1897 is said to have formed part) had its terminus on the Red Sea south of the Heroopolite Gulf near the present town of Suez. In this neighbourhood was the ancient city of Clyisma, to which in Amr’s time succeeded Kolzum, perhaps an Arabic corruption of Clyisma. The exact situation of Clyisma is unknown, but Kolzum occupied the site of Suez, the hills north of which are still called Kolzum. After the closing of the canal in the 8th century it does not appear for certain that it was ever restored, although it is asserted that in the year 1000 Sultan Hakim rendered it navigable. If so it must speedily have become choked up again. Parts of the canal continued to be filled during the Nile inundations until Mehemet Ali (A.D. 1817) ordered it to be closed; the closing, however, was not completely effected, for in 1891 the old canal from BABISTAS still flowed as far as KASSASSIN. This part of the canal, after over 2500 years of service, was utilized by the French engineers in building the fresh-water canal from Cairo to Suez in 1861–1865. This canal follows the lines of that of Amr (or Trajan).

Maritime Canal Projects.—Apart from water communication between the Mediterranean and the Red Sea by way of the Nile, the project of direct communication by a canal piercing the Isthmus of Suez was entertained as early as the 7th century A.D. by Harun-al-Rashid, who is said to have abandoned the scheme, being persuaded that it would be dangerous to lay open the coast of Arabia to the Byzantine navy. After the discovery of the Cape route to India at the close of the 15th century, the Venetians, who had for centuries held the greater part of the trade of the East with Europe via Egypt and the Red Sea, began negotiations with the Egyptians for a canal across the isthmus, but the conquest of Egypt by the Turks put an end to these designs. In 1671 Leibnitz in his proposals to Louis XIV. of France regarding an expedition to Egypt recommended the making of a maritime canal, and the Sheikh al-Balad Ali Bey (c. 1770) wished to carry out the project. Bonaparte when in Egypt in 1798 ordered the
Isthmus to be surveyed as a preliminary to the digging of a canal across it, and the engineer he employed, J. M. Lepère, came to the conclusion that there was a difference in level of 29 ft. between the Red Sea and the Mediterranean. This view was combated at the time by Laplace and Fourier on general grounds, and was finally disproved in 1846-1847 as the result of surveys made at the instance of the Société d'Études pour le Canal de Suez. This society was organized in 1846 by Prosper Enfantin, the Saint Simonist, who thirteen years before had visited Egypt in connection with a scheme for making a canal across the isthmus of Suez, which, like the canal across the isthmus of Panama, was part of the Saint Simonist programme for the regeneration of the world. The expert commission appointed by this society reported by a majority in favour of Paul Tบอล's plan, according to which the canal would have run from Suez to Alexandria by way of Cairo.

For some years after this report no progress was made; indeed, the society was in a state of suspended animation when in 1854 Ferdinand de Lesseps came to the front as the chief exponent of the idea. He had been associated with the Saint Simonists and for many years had been keenly interested in the question. His opportunity came in 1854 when, on the death of Abbas Pasha, his friend Said Pasha became viceroy of Egypt. From Said on the 30th of November 1854 he obtained a concession authorizing him to constitute the Compagnie Universelle du Canal Maritime de Suez, which should construct a ship canal through the isthmus, and soon afterwards in concert with two French engineers, Linant du Delay and Mougel Bey, he decided that the canal should run in a direct line from Suez to the Gulf of Pelusium, passing through the depressions that are now Lake Timsa and the Bitter Lakes, and skirting the eastern edge of Lake Menzala. In the following year an international commission appointed by the viceroy approved this plan with slight modifications, the chief being that the channel was taken through Lake Menzala instead of along its edge, and the northern termination of the canal moved some 17½ m. westward where deep water was found closer to the shore. This plan, according to which there were to be no locks, was the one ultimately carried out, and it was embodied in a second and amplified concession, dated the 5th of January 1856, which laid on the company the obligation of constructing, in addition to the maritime canal, a fresh-water canal from the Nile near Cairo to Lake Timsa, with branches running parallel to the maritime canal, one to Suez and the other to Pelusium. The concession was to last for 99 years from the date of the opening of the canal between the Red Sea and the Mediterranean, after which, in default of other arrangements, the canal passes into the hands of the Egyptian government. The confirmation of the sultan of Turkey being required, de Lesseps went to Constantinople to secure it, but found himself baffled by British diplomacy; and later in London he was informed by Lord Palmerston that in the opinion of the British government the canal was a physical impossibility, that if it were made it would injure British maritime supremacy, and that the proposal was merely a device for French interference in the East.

Although the sultan's confirmation of the concession was not actually granted till 1866, de Lesseps in 1858 opened the subscription lists for his company, the capital of which was 200 million francs in 400,000 shares of 500 francs each. In less than a month 314,404 shares were applied for; of these over 200,000 were subscribed in France and over 96,000 were taken by the Ottoman Empire. From other countries the subscriptions were trifling, and England, Austria and Russia, as well as the United States of America, held entirely aloof. The residue of 85,506 shares was taken over by the viceroy. On the 25th of April 1859 the work of construction was formally begun, the first spadeful of sand being turned near the site of Port Said, but progress was not very rapid. By the beginning of 1862 the fresh-water canal had reached Lake Timis, and towards the end of the same year a narrow channel had been formed between that lake and the Mediterranean. In 1863 the fresh-water canal was continued to Suez.

So far the work had been performed by native labour; the concession of 1856 contained a provision that at least four-fifths of the labourers should be Egyptians, and later in the same year Said Pasha undertook to supply labourers as required by the engineers of the canal company, which was to house and feed them and pay them at stipulated rates. Although the wages and the terms of service were better than the men obtained normally, the system of forced labour was strongly disapproved of in England, and the khedive Ismail who succeeded Said on the latter's death in 1863 also considered it as being contrary to the interests of his country. Hence in July the Egyptian foreign minister, Nubar Pasha, was sent to Constantinople with the proposal that the number of labourers furnished to the company should be reduced, and that it should be made to hand back to the Egyptian government the lands that had been granted it by Said in 1856. These propositions were approved by the sultan, and the company was informed that if they were not accepted the works would be stopped by force. Naturally the company objected, and in the end the various matters in dispute were referred to the arbitration of the emperor Napoleon III. By his award, made in July 1864, the company was allowed 38 million francs as an indemnity for the abolition of the corvee, 16 million francs in respect of its retrocessions of that portion of the fresh-water canal that lay between Wadi, Lake Timis and Suez (the remainder had already been handed back by agreement), and 90 million francs in respect of the lands which had been granted it by Said. The company was allowed to retain a certain amount of land along the canals, which was necessary for purposes of construction, erection of workshops, &c., and it was put under the obligation of finishing the fresh-water canal between Wadi and

1 These formed part of the 176,622 shares which were bought for the sum of 5,976,582 from the khedive by England in 1875 at the instance of Lord Beaconsfield (q.v.).
Suez Canal

Suez to such dimensions that the depth of water in it would be 25 metres at high Nile and at least 1 metre at low Nile. The supply of Port Said with water it was allowed to manage by any means it chose; in the first instance it laid a double line of iron piping from Timsa, and it was recognized that the original plan of supplying the town by a branch of the fresh-water canal was carried out. The indemnity, amounting to a total of 84 million francs, was to be paid in instalments spread over 15 years.

The abolition of forced labour was probably the salvation of the enterprise, for it meant the introduction of mechanical appliances and of modern engineering methods. The work was divided into four contracts. The first was for the supply of 250,000 cubic metres of concrete blocks for the jetties of Port Said; the second, for the first 60 kilometres of the channel from Port Said, involved the removal of 22 million cubic metres of sand or mud; the third was for the next length of 13 kilometres, which included the cutting through the high ground at El Ghar; and the fourth and largest was for the portion between Lake Timsa and the Red Sea. The contractors for this last section were Paul Borel and Alexandre Levalley, who ultimately became responsible also for the second or 60 kilometres contract. For the most part the material was soft and therefore readily removed. At some points, however, as at Shaluf and Serapeum, rock was encountered. Much of the channel was formed by means of dry docks. Through Lake Menzala, for instance, native workmen made a shallow channel by scooping out the soil with their hands and throwing it out on each side to form the banks; dredgers were then floated in and completed the excavation to the required depth, the soil being delivered on the other side of the banks through long spouts. At Serapeum, a preliminary shallow channel having been dug out, water was admitted from the fresh-water canal, the level of which is higher than that of the ship canal, and the work was completed by dredgers from a level of about 20 ft. above the sea. At this point the soil, composed largely of loose sand, risen 60 ft. above the sea, the contractor, Alphonse Couvreux, employed an excavator of his own design, which was practically a bucket-dredger working in the dry. A long arm projecting downwards at an angle from an engine on the bank carried a number of buckets, mounted on a continuous chain, which scooped up the stuff at the bottom and discharged it into wagons at the top.

In 1865 De Lesseps, to show the progress that had been made, entertained over 100 delegates from chambers of commerce in different parts of the world, and conducted them over the works. In the following year the company, being in need of money, realized 10 million francs by selling to the Egyptian government, the estate of El Wadi, which it had purchased from Said, and it also succeeded in arranging that the money due to it under the award of 1864 should be paid off by 1869 instead of 1875. Its financial resources still being insufficient, it obtained in 1867 permission to invite a loan of 100 million francs; but though the issue was offered at a heavy discount it was only fully taken up after the attractions of a lottery scheme had been added to it. Two years later the company got 30 million francs from the Egyptian government in consideration of abandoning certain special rights and privileges that still belonged to it and of handing over various hospitals, workshops, buildings, &c., which it had established on the isthmus. The government liquidated this debt, not by a money payment, but by agreeing to forego for 25 years the interest on the 176,602 shares it held in the company, which was thus enabled to raise a loan to the amount of the debt. Altogether, up to the end of the year (1869) in which the company was sufficiently advanced to be opened for traffic, the accounts of the company showed a total expenditure of 432,867,882 francs, though the International Technical Commission in 1859 had estimated the cost at only 200 million francs for a canal of larger dimensions.

The formal opening of the canal was celebrated in November 1869. On the 16th there was an inaugural ceremony at Port Said, and next day 68 vessels of various nationalities, headed by the "Aigle" with the empress Eugénie on board, began the passage, reaching Ismailin (Lake Timsa) the same day. On the 19th they continued their journey to the Bitter Lakes, and on the 20th they arrived at Suez. Immediately afterwards regular traffic began. In 1870 the canal was used by nearly 500 vessels, but the receipts for the first two years of working were considerably less than the expenses. The company attempted to issue a loan of 20 million francs in 1871, but the response was small, and it was only saved from bankruptcy by a rapid increase in its revenues.

The total length of the navigation from Port Said to Suez is 100 m. The canal was originally constructed to have a depth of 8 metres with a bottom width of 22 metres, but it soon became evident that its dimensions must be enlarged. Certain improvements in the channel were started in 1876, but a more extensive plan was adopted in 1885 as a result of the inquiries of an international commission which recommended that the depth should be increased first to 8.1 metres and finally to 9 metres, and that the width should be made on the straight parts a minimum of 65 metres between Port Said and the Bitter Lakes, and of 75 metres between the Bitter Lakes and Suez, increasing on curves to 80 metres. To pay for these works a loan of 100 million francs was issued. These wide-laws greatly improved the facilities for ships travelling in opposite directions to pass each other. In the early days of the canal, except in the Bitter Lakes, vessels could pass only one at a time, and on the remaining part of the canal a collective length of less than 4 miles, but owing to the widenings that have been carried out, passing is now possible at any point over the greater part of the canal, one vessel stopping while the other proceeds on her way. From March 1887 navigation by night was permitted to ships which were provided with electric search-lights, and now the great majority avail themselves of this facility. By these measures the average time of transit, which was about 36 hours in 1886, has been reduced by half. The maximum speed permitted in the canal itself is 10 kilometres an hour.

The company of the canal was authorized to charge by its concession of 1856 was 10 francs a ton. In the first instance they were levied on the tonnage as shown by the papers on board each vessel, but from March 1872 they were charged on the gross register tonnage, computed according to the method of the British Merchant Shipping Act 1854. The result was that the shipowners had to pay more, and, objections being raised, the whole question of the method of charge was submitted to an international conference which met at Constantinople in 1875. It fixed the dues at 10 francs per net register ton (English reckoning) with a surtax of 4 francs per ton, which, however, was to be reduced to 1 franc in the case of ships having on board papers showing their net tonnage calculated in the required manner. It also decided that the surtax should be gradually diminished as the traffic increased, until in the year after the net tonnage passing through the canal reached 2,600,000 tons it should be abolished. De Lesseps protested against this arrangement, but on the sultan threatening to enforce it, if necessary by armed intervention, he gave in and brought the new tariff into operation in April 1874. By an arrangement with the canal company, signed in 1876, the British government, which in 1875 by the purchase of the khedive's shares, had become the largest single investor, agreed to negotiate to secure that the successive reductions of the tariff should take effect on fixed dates, the sixth and last installment of 50 centimes being removed in January 1884, after which the maximum rate was to be 10 francs per official net ton. But before this happened British shipowners had started a vigorous agitation against the rates, which they alleged to be excessive, and had even threatened to construct a second canal. In consequence a meeting was arranged between them and representatives of the canal company in London in November 1883, and it was agreed that in January 1885 the dues should be reduced to 9 francs a ton, that subsequently they should be lowered on a sliding scale as the dividend increased, and that after the dividend reached 25% all the surplus profits should be applied in reducing the rates until they were lowered to 5 francs a ton. Under this arrangement they were fixed at 7½ francs.
SUFFOLK, EARLS AND DUDES OF SUFFOLK, 1ST DUKE OF

per ton at the beginning of 1906. For ships in ballast reduced rates are in force. For passengers the duties remain at 10 francs a head, the figure at which they were originally fixed.

By the concessions of 1854 and 1856 the dues were to be the same for all nations, preferential treatment of any kind being forbidden, and the canal and its ports were to be open "comme passages neutres" to every merchant ship without distinction of nationality. The question of its formal neutralization by international agreement was raised in an acute form during the Egyptian crisis of 1882-83, and in August of the latter year a few weeks before the battle of Tel-el-Kebir, navigation upon it was suspended for four days at the instance of Sir Garnet Wolseley, who was in command of the British fleet which was then sitting at Constantinople. Various proposals were put forward to ensure the use of the canal to all nations, and ultimately at Constantinople on the 20th of October 1888 Great Britain, Germany, Austria, Spain, France, Italy, the Netherlands, Russia and Turkey signed the Suez Canal Convention, the purpose of which was to ensure that the canal should "always be free and open, in time of war as in time of peace, to every vessel of commerce or of war, without distinction of flag." Great Britain, however, in signing, formulated a reservation that the provisions of the convention should not in any way be so far as they were compatible with the actual situation, namely the "present transitory and excep-
tional condition of Egypt," and so far as they would not fetter the liberty of action of the British government during its occupancy of that country. But by the Anglo-French agreement of the 8th of April 1904 Great Britain declared her adherence to the stipulations of the convention, and agreed to their being put in force, except as regards a provision by which the agents in Egypt of the signatory Powers of the convention were to meet once a year to take note of the due execution of the treaty. It was by virtue of this new agreement that the Russian warships proceeding to the East in 1904-1905 were enabled to use the Canal although passages were promised to Spanish warships in 1808 during the war between Spain and the United States.

L'Isthme et le Canal de Suez, historique, état actuel, by J. Charles-Roux (2 vols., Paris 1901), contains reprints of various official documents relating to the canal, with plates, maps and a bibilography extending to 1499 entries.

SUFFOLK, EARLS AND DUKES OF. These English titles were borne in turn by the families of Ufford, Pole, Brandon, Grey and Howard. A certain holder of land in Suffolk, named John de Peyton, had a younger son Robert, who acquired the lordship of Ufford in that county and was known as Robert de Ufford. He held an important place in the government of Ireland under Edward I. and died in 1298; his son Robert (1279-1316) was created Baron Ufford by a writ of summons to parliament in 1309, and increased his possessions by marriage with Cicely, daughter and heiress of Robert de Valois. This Robert had several sons, one of whom was Sir Ralph de Ufford (d. 1346), justicier of Ireland, who married Maud, widow of William de Burgh, earl of Ulster, and daughter of Henry Plantagenet, earl of Lancaster. Robert's eldest surviving son, another Robert (d. 1358-1369), was an associate of the young king Henry III., and one of the nobles who arrested Roger Mortimer in 1330. In 1337 he was created earl of Suffolk. The earl was employed by Edward III. on high military and diplomatic duties and was present at the battles of Crecy and Poitiers. His son William, the 2nd earl (c. 1339-1382), held important appointments under Edward III. and Richard II. He played a leading part in the suppression of the Peasants' Revolt in 1381, but in the same year he supported the popular party in parliament in the attack on the misgovernment of Richard II. Although twice married he left no sons, and his earldom became extinct, his extensive estates reverting to the Crown.

In 1385 the earldom of Suffolk and the lands of the Uffords were granted by Richard II. to his friend Michael Pole (c. 1350-1389), a son of Sir William atte Pole, a baron of the exchequer and a merchant (see Pole Family). After an active public life as the trusted advisor of Richard II. Pole was dismissed from his office of chancellor, was impeached and sentenced to death, but escaped to France, where he died. His titles and estates were forfeited, but in 1399 the earldom of Suffolk and most of the estates were restored to his son Michael (c. 1361-1415). Michael, the 3rd earl (1394-1415), was killed at the battle of Agincourt, and the earldom passed to his brother William (1396-1459), who was created earl of Pembroke in 1443, marquess of Suffolk in 1444, and duke of Suffolk in 1448 (see Suffolk, William de la Pole, Duke of). The duke's son, John, 2nd duke of Suffolk (1447-1491), married Elizabeth, daughter of York, duke of Clarence, and King Edward IV., by whom he had six sons. The eldest, John (c. 1466-1510), was created earl of Lincoln, and was named heir to the throne by Richard III. He was killed fighting against Henry VII. at the battle of Stoke, and was attainted. His brother Edmund (c. 1472-1513) should have succeeded his father in the dukedom in 1491, but he surrendered this to Henry VII. in return for some of the estates forfeited by the earl of Lincoln, and was known simply as earl of Suffolk. Having incurred the displeasure of the king, he left his own country in 1501 and sought help for an invasion of England. Consequently he was sentenced to death 1504, having entered into a marriage contract with a lord of the French court. He was kept in prison until 1513, when he was beheaded by Henry VIII. His brother Richard now called himself duke of Suffolk, and put forward a claim to the English crown. Known as the "white rose," he lived abroad until 1525, when he was killed at the battle of Pavia.

In 1514 the title of duke of Suffolk was granted by Henry VIII. to his friend, Charles Brandon (see Suffolk, Charles Brandon, Duke of) and it was borne successively by his two sons, Henry and Charles, becoming extinct when Charles died in July 1551. In the same year it was revived in favour of Robert Pole, 3rd earl of Lincoln, and the earldom of Dorset, who had married Frances, a daughter of the first Brandon duke. Grey, who bore the title of marquis of Dorset in 1530, was a prominent member of the reforming party during the reign of Edward VI. He took part in the attempt to make his daughter, Jane, queen of England in 1553, but as he quickly made his peace with Mary he was not seriously punished. In 1554, however, he took part in the rising headed by Sir Thomas Wyatt; he was captured, tried for treason and beheaded in February 1554, when the dukedom again became extinct. In 1603 Thomas Howard, Lord Howard de Walden, son of Thomas Howard, 4th duke of Norfolk, was created earl of Suffolk, and the earldom has been held by his descendants to the present day (see Suffolk, Thomas Howard, 1st earl of).
of France. He was accredited to negotiate various matters with Louis, and on his death was sent to congratulate the new king Francis I. An affection between Suffolk and the dowager queen Mary had subsisted before her marriage, and Francis roundly charged him with an intention to marry her. Francis, perhaps in the hope of Queen Claude's death, had himself been on of her suitors for the widow of her first husband, and Mary asserted that she had given him her confidence to avoid his importunities. Francis and Henry both professed a friendly attitude towards the marriage of the lovers, but Suffolk had many political enemies, and Mary feared that she might again be sacrificed to political considerations. The truth was that Henry was anxious to obtain from Francis the gold plate and jewels which had been given or promised to the queen by Louis in addition to the reimbursement of the expenses of her marriage with the King; and he practically made his acquiescence in Suffolk's suit dependent on his obtaining them. The pair cut short the difficulties by a private marriage, which Suffolk announced to Wolsey, who had been their fast friend, on the 5th of March. Suffolk was only saved from Henry's anger by Wolsey, and the pair eventually agreed to pay to Henry £24,000 in yearly instalments of £1,000, and the whole of Mary's dowry from Louis of £20,000, together with her plate and jewels. They were openly married at Greenwich on the 13th of May. The duke had been twice married already, to Margaret Mortimer and to Anne Browne, one of whom, Anne, was sent to the court of Margaret of Savoy. After his marriage with Mary, Suffolk lived for some years in retirement, but he was present at the Field of the Cloth of Gold in 1520, and in 1523 he was sent to Calais to command the English troops there. He invaded France in company with Count de Buren, who was at the head of the Flemish troops, and laid waste the north of France, but disbanded his troops at the approach of winter. Suffolk was entirely in favour of Henry's divorce; but Catherine of Aragon, and in spite of his obligations to Wolsey he did not scruple to attack him when his fall was imminent. The cardinal, who was acquainted with Suffolk's private history, reminded him of his ingratitude: "If I, simple cardinal, had not been, you should have had no tongue to make any such report in despite of us." At Wolsey's disgrace Suffolk's influence in court daily increased. He was sent with the duke of Norfolk to demand the great seal from Wolsey; the same noblemen conveyed the news of Anne Boleyn's marriage to Queen Catherine, and Suffolk acted as high steward at the new queen's coronation. He was one of the commissioners appointed by Henry to dismiss Catherine's household, a task which he found distasteful. He supported Henry's ecclesiastical policy, receiving a large share of the plunder after the suppression of the monasteries. In 1544 he was for the second time in command of an English army for the invasion of France. He died at Guildford on the 24th of August in the following year.

After the death of Mary Tudor on the 24th of June 1533 he had married in 1534 his ward Catherine (1520-1580), Baroness Willoughby de Eresby in her own right, then a girl of fifteen. His daughters by his marriage with Anne Browne were Anne, who married firstly Edward Grey, Lord Powys, and, after the dissolution of this union, Randal Harworth; and Mary (b. 1510), who married Thomas Stanley, Lord Montague. By Mary Tudor he had a son, Edward, earl of Lincoln (1516-1534); Frances, who married Henry Grey, marquess of Dorset, and became the mother of Lady Jane Grey; and Eleanor, who married Henry Clifford, second earl of Cumberland. By Katherine Willoughby he had two sons who showed great promise, Henry (1535-1553) and Charles (c. 1537-1557), dukes of Suffolk. They died of the sweating sickness within an hour of one another. Their tutor, Sir Thomas Wilson, compiled a memoir of them, Vita et obitus duorum fratrum Suffolkensium (1553).

There is abundant material for the history of Suffolk's career in the Letters and Papers of Henry VIII. (ed. Brewer in the Rolls Series). See also Dugdale, Baronage of England (1657), and G. E. C., Complete Peerage. An account of his matrimonial adventures is in the historical appendix to a novel by E. S. Holt entitled The Harvest of Yesterday.

**SUFFOLK, THOMAS HOWARD, 1ST EARL OF (1561-1626),** second son of Thomas Howard, 4th duke of Norfolk, was born on the 24th of August 1561. He behaved very gallantly during the attack on the Spanish armada and afterwards took part in other naval expeditions, becoming an admiral in 1590. Created Duke of Norfolk by James I in 1607, he married in July 1603, he was lord chamberlain of the royal household from 1603 to 1614 and lord high treasurer from 1614 to 1618, when he was deprived of his office on a charge of misappropriating money. He was tried in the Star-chamber and was sentenced to pay a heavy fine. Suffolk's second wife was Catherine (d. 1633), widow of the Hon. Richard Rich, a woman whose avarice was partly responsible for her husband's downfall. She shared his trial and was certainly guilty of taking bribes from Spain. One of his three daughters was the notorious Frances Howard, who, after marrying her first husband, Robert Devereux, earl of Essex, married Robert Carr, earl of Somerset, and instigated the poisoning of Sir Thomas Overbury. The earl died on the 28th of May 1626. He built a magnificent residence at Audley End, Essex, which is said to have cost £200,000. One of Suffolk's seven sons was Sir Robert Howard (1585-1653), who inherited Clun Castle, Shropshire, on the death of his brother, Sir Charles Howard, in 1622. He was twice imprisoned on account of his illicit relations with Frances, Viscountess Purbeck (d. 1645), a daughter of Sir Edward Coke, and after sitting in the House of Commons was expelled from the House of Commons for executing the king, and was dismissed from the Privy Council. He died on the 22nd of April 1653. Another of Suffolk's sons was Thomas, earl of Suffolk (d. 1675), who was a member of the royalist party during the Commonwealth, and later he associated himself with the opposition to the arbitrary rule of Charles II., but turning informer he was pardoned for the conviction of Lord William Russell and of Algernon Sydney in 1683. On the death of William's son, Charles, the 4th lord, in 1715 the barony of Howard of Escrick became extinct.

Suffolk's eldest son, THEOPHILUS, 2nd earl of Suffolk (1584-1649), was captain of the band of gentlemen pensioners under James I. and Charles I., and succeeded to the earldom in May 1626, obtaining about the same time some of the numerous offices which had been held by his father, including the lord-lieutenancy of the counties of Suffolk, Cambridge and Dorset. He died on the 3rd of June 1640, when his eldest son James (1619-1689) became 3rd earl. This nobleman, who acted as earl marshal of England at the coronation of Charles II., died in January 1689 when his barony of Howard de Walden fell into abeyance between his two daughters. He later married Thomas Wilson, compiled a memoir of them, Vita et obitus duorum fratrum Suffolkensium (1553).

1 Having thus fallen into abeyance in 1689 the barony of Howard de Walden was revived in 1764 in favour of John Griffin Griffin, 7th viscount Eglinton, who was one of the bishops of Derry, Frederick Augustus Hervey, 4th earl of Bristol, a descendant of the 3rd earl of Suffolk, became the sole heir to the barony. On Bristol's death in 1779, one of his grandsons passed the barony to Augustus Ellis (1799-1868), a grandson of the bishop's eldest son, John Augustus, Lord, Edward (1757-1796), who had predeceased his father. It was thus separated from the marquessate of Bristol, which passed to the bishop's only surviving son, and it has since been held by the family of Ellis.
became 4th earl of Suffolk. George's nephew, Henry, the 6th earl (c. 1670-1718), who was president of the board of trade from 1715 to 1718, left an only son, Charles William (1653-1722), who was succeeded in turn by his two uncles, the younger of them, Charles (1675-1733) becoming 9th earl on the death of his brother Edward in June 1731. This earl was the husband of Henrietta countess of Suffolk (c. 1661-1767), the mistress of George II., who was a daughter of Sir Henry Hobart, bart., of Blickling, Norfolk. When still the Hon. Charles Howard, he and his wife made the acquaintance of the future king in Hanover; after the accession of George I. to the English throne in 1714 both husband and wife gained posts in the household of the prince of Wales, who, when he became king as George II., publicly acknowledged Mrs Howard as his mistress. She was formally separated from her husband before 1731 when she became countess of Suffolk. The earl died on the 28th of September 1733, but the countess, having retired from court and married the Hon. George Berkeley (d. 1746), lived until the 26th of July 1767. Among Lady Suffolk's friends were the poets Pope and Gay and Charles Mordaunt (earl of Peterborough).

A collection of Letters to and from Henrietta Countess of Suffolk, and other Skapery of Samuel Pepys, the Hon. George Berkeley, was edited by J. W. Croker (1824).

The 9th earl's only son Henry, the 10th earl (1706-1745), died without sons in April 1745, when his estate at Audley End passed to the descendants of the 3rd earl, being inherited in 1762 by John Griffin Griffin (1719-1797), afterwards Lord Howard de Walden and Lord Braybrooke. As owners of this estate the ears of Suffolk of the Howard line had hitherto been hereditary visitors of Magdalene College, Cambridge, but this office now passed away from them. The eldest son of Suffolk was inherited by Henry Bowes Howard, 4th earl of Berkshire (1666-1757), who was the great-grandson of Thomas Howard (c. 1396-1450), the 3rd earl of Suffolk, Thomas having been created earl of Berkshire in 1566. Since 1745 the two earldoms have been united, Henry Molyneux Paget Howard (b. 1877) succeeding his father, Henry Charles (1833-1898), as 19th earl of Suffolk and 12th earl of Berkshire in 1898.

SUFFOLK, WILLIAM DE LA POLE, DUKE OF (1396-1450), second son of Michael de la Pole, second earl of Suffolk, was born on the 16th of October 1396. His father died at the siege of Harfleur, and his elder brother was killed at Agincourt on the 15th of October 1415. Suffolk served in all the later French campaigns of the reign of Henry V., and in spite of his youth held high command on the marches of Normandy in 1421-22. In 1423 he joined the earl of Salisbury in Champagne, and shared his victory at Crécy. He fought under John, duke of Bedford, at Verneuil on the 17th of August 1424, and throughout the next four years was Salisbury's chief lieutenant in the direction of the war. When Salisbury was killed before Orleans on the 3rd of November 1428, Suffolk succeeded to the command. After the siege was raised, Suffolk was defeated and taken prisoner by Jeanne d'Arc at Jargeau on the 12th of June 1429. He was soon ransomed, and during the next two years was again in command on the Norman frontier. He returned to England in November 1431, after over fourteen years' continuous service in the field.

Suffolk had already been employed on diplomatic missions by John of Bedford, and from this time forward he had an important share in the work of administration. He attached himself naturally to Cardinal Beaufort, and even thus early seems to have been striving for a general peace. But public opinion in England was not yet ripe, and the unsuccessful conference at Arras, with the consequent defection of Burgundy, strengthened the war party. Nevertheless the cardinal's authority remained supreme in the council, and Suffolk, as his chief supporter, gained increasing influence. The question of Henry VI.'s marriage brought him to the front. Humphrey of Gloucester favoured an Armagnac alliance. Suffolk brought about the match with Margaret of Anjou. Report already represented Suffolk as too friendly with French leaders like Charles of Orleans, and it was with reluctance that he undertook the responsibility of an embassy to France. However, when he returned to England in June 1444, after negotiating the marriage and a two years' truce, he received a triumphant reception. He was made a marquess, and in the autumn sent again to France to bring Margaret home. The French contrived to find occasion for extorting a promise to surrender all the English possessions in Anjou and Maine, a concession that was to prove fatal to Suffolk and his policy. Still for the time his success was complete, and his position as the personal friend of the young king and queen remained secure. Humphrey of Gloucester died in his bed at Exeter on 17th February 1447, within a few days, and six months later Cardinal Beaufort died also. Suffolk was left without an obvious rival, but his difficulties were great. Rumour, though without sufficient reason, made him responsible for Humphrey's death, while the peace and its consequent concessions rendered him unpopular. So also did the supersession of Richard of York by Edmund Beaufort, duke of Somerset, in the French command. Suffolk's promotion to a dukedom in July 1448, marked the height of his power. The difficulties of his position may have led him to give some countenance to a treacherous attack on France's enemies during the summer of 1446 (March 1446). The renewal of the war and the loss of all Normandy and the direct consequences.

When parliament met in November 1449, the opposition showed its strength by forcing the treasurer, Adam Molyneux, to resign. Molyneux was murdered by the sailors at Portsmouth on the 9th of January 1450. Suffolk, realizing that an attack on himself was inevitable, boldly challenged his enemies in parliament, appealing to the long and honourable record of his public services. On the 7th of February and again on the 9th of March the Commons presented articles of accusation dealing chiefly with alleged maladministration and the ill success of the French policy; there was a charge of aiming at the throne by the betrothal of his son to the little Margaret Beaufort, but no suggestion of guilt concerning the death of Gloucester. The articles were in great part baseless, if not absurd. Suffolk, in his defence on the 13th of March, denied them as false, untrue and too horrible to speak more of. Ultimately, as a sort of compromise, the king sentenced him to banishment for five years. Suffolk left England on the 1st of May. He was intercepted in the Channel by the ship "Nicholas of the Tower," and next morning was beheaded in a little boat alongside. The "Nicholas" was a royal ship, and Suffolk's murder was probably illegal on the king's political opponents.

Popular opinion at the time judged Suffolk as a traitor. This view was accepted by Yorkist chroniclers and Tudor historians, who had no reason to speak well of a Pole. Later legend made him the paramour of Margaret of Anjou. Though utterly baseless, the story gained currency in the Mirrour for Magistrates, and was adopted in Shakespeare's 2 Henry VI. (act iii. sc. ii.). Suffolk's best defence is contained in the touching letter of farewell to his son, written on the eve of his departure (Paston Letters, i. 143), and in his noble speeches before parliament (Rolls of Parliament, v. 176, 175). Of the former Lingard said well that it is "difficult to believe that the writer could have been either a false subject or a bad man." The policy of peace which Suffolk pursued was just and wise; he foresaw from the first the personal risk to which its advocacy exposed him. This alone should acquit him of any base motive; his conduct was "throughout open and straightforward" (Stubbs). Whatever his defection as a statesman, he was a gallant soldier, a man of culture and a loyal servant.

Suffolk's wife, Alice, was widow of Thomas, earl of Salisbury, and granddaughter of Geoffrey Chaucer. By her he had an only son John, second duke of Suffolk.

BIBLIOGRAPHY.—Suffolk is necessarily prominent in all contemporary authorities. The most important are J. Stevenson's Wars of the English in France, 1415-1485 (in French), J. F. Bernard's Beaufort and his Correspondents (in French); and the works of M. de Pressense, useful for his military career. T. Basin and Matthieu d'Escouchy for his fall (all these are published by the Société de l'Histoire de

France. For modern accounts see especially W. Stubbs, Constitutional History (lavoisier), The Political History of England, vol. iv., 1857; E. Pastoreau, Histoire de Charles VII. See also H. A. Napier's Historical Notices of Swincombe and Eveline (1835).

C. L. K.

SUFFOLK, an eastern county of England, bounded N. by Norfolk, E. by the North Sea, S. by Essex and W. by Cambridgeshire. The area is 1486-8 sq. m. The surface is as a whole but slightly undulating. In the extreme north, the Alde district is included. Mildenhall, a small area of fen, is the extreme northwards along the western boundary, and thence by Bury St Edmunds to Thetford. The coast-line has a length of about 62 m., and is comparatively regular, the bays being generally shallow and the headlands rounded and only slightly prominent. The estuaries of the Deben, Orwell and Stour, however, are between 10 and 12 m. in length. The shore is generally low and marshy, with occasional clay and sand cliffs. It includes, in the declivity of the eastern flank of English land. Like the Norfolk coast, this shore has suffered greatly from inroads of the sea, the demolition of the ancient port of Dunwich (2246) forming the most noteworthy example. The principal seaside resorts are Lowestoft, Southwold, Aldeburgh and Felixstowe. The rivers flowing northward are the Lark, in the north-west corner, which passes in a north-westerly direction to the Great Ouse in Norfolk; the Little Ouse or Brandon, also a tributary of the Great Ouse, flowing by Thetford and Brandon and forming part of the northern boundary of the county; and the Waveney, which flows past Yoxford and forms the northern boundary of Suffolk from Palgrave till it falls into the mouth of the Yare at Yarmouth. The Waveney is navigable from Bungay, and by means of Oulton Broad also communicates with the sea at Lowestoft. The rivers flowing in a south-easterly direction to the North Sea are the Blyth; the Alde or Ore, which has a course for nearly 10 m. parallel to the seashore; the Deben, from Debenham, flowing past Woodbridge, up to which it is navigable; the Orwell or Gipping, which becomes navigable at Stowmarket, whence it flows past Needham Market and Ipswich; and the Stour, which forms nearly the whole southern boundary of the county, receiving the Breth, which flows past Lavenham and Hadleigh; it is navigable from Sudbury. At the union of its estuary with that of the Orwell is the important port of Harwich (in Essex). The county has no valuable minerals. Flints are worked, as they have been from pre-historic times; a considerable quantity of clay is raised and lime and whiting are obtained in various districts.

Geology.—The principal geological formations are the Chalk and the Tertiary deposits. The former occupies the uplands, where covered by superficial drift, in the central and north-west portions of the county, and it extends beneath the Tertiaries in the south-east and east. In the extreme north-west round Mildenhall the Chalk borders a tract of fen land in a range of low hills from Haverhill by Newmarket and Bury St Edmunds to Thetford. The Chalk is quarried near Ipswich, Bury St Edmunds, Mildenhall and elsewhere; at Brandon the chalk flints for gunlocks and building have been exploited for nearly thirty years. The Tertiary formations include Thanet sand, seen near Sudbury; and Reading Beds and London Clay which extend from Sudbury through Hadleigh, Ipswich, Woodbridge and thence north-east as far as Wisbech. The boundary of these and the Crag is the "Suffolk Bone Bed," with abundant mammalian and phosphatic nodules. Glacial gravel, sand and chalky boulders are scattered over much of the county, generally forming stiffer soils in the west and lighter sandy soils in the east. Pebble gravels occur W. of Woodbridge and Glemstone, implements, at Hoxne; while old river-gravels of still later date border the present river valleys. The chalk and gault have been penetrated by a boring at Stutton, revealing a hard pan of sandstone rock, 25 ft. thick.

Agriculture.—Suffolk is one of the most fertile counties in England. In the 18th century it was famed for its dairy products. The high prices of grain during the Wars of the French Revolution led to the introduction of corn crops. The boundary, of the county, and its pastures, and it is now one of the principal grain-growing counties in England. There is considerable variety of soils, and consequently in modes of farming in different parts of the county. The sandy soils, prevailing in the south-west, are interspersed with tracts, more or less marshy, on which cattle are grazed. The best land adjoins the northern boundary of Suffolk, with patches of lighter and easier soil. In the south-west and the centre is much finer grain-land having mostly a clay subsoil, but not so tenacious as the clay in Essex. In climate Suffolks has an annual rainfall at Bury St Edmunds is rather less than 24 in. Towards the north-west the soil is generally poor, consisting partly of sand on chalk, and partly of peat and open moor. Some 324,000 acres of the total area of the county is covered with cultivation. barley, oats and wheat are the most important of the grain crops. The breed of horses known as Suffolks is the most valued for agricultural purposes in England. They are best adapted to extensive farming and are especially valuable, the improvement of which great pains have been bestowed. The old Suffolk cows, famous for their great milking qualities, were of various colours, yellow predominating. The improvement in London and Ipswich, &c. Many cattle, mostly imported from Ireland, are grazed in the winter. The sheep are nearly all of the black-faced improved Suffolk breed, a cross between the old Norfolk horned sheep and Southdowns. The breed of pigs most common is black and small.

Manufactures and Trade.—The county is essentially agricultural, and the most important manufactures relate to this branch of industry. They include the raising and rearing of agricultural implements, especially at Ipswich, Bury St Edmunds and Stowmarket, and that of artificial manures at Ipswich and Stowmarket, for which coprolites are dug. Malting is extensively carried on throughout the county, and many of the manufactures at Stowmarket and Woodbridge are gun flints are still made at Brandon. At other towns small miscellaneous manufactures are carried on, including silk, cotton, linen, woollen, and horsehair and coir-netting making. The principal ports are Lowestoft, Southwold, Aldeburgh, Woodbridge and Ipswich. Lowestoft is the chief fishing town. Herrings and mackerel are the fish most abundant on the coast.

Communications.—The main line of the Great Eastern railway, from London to Lowestoft, passes through Suffolk, continuing north into Norfolk. The east Suffolk branch from Ipswich serves Woodbridge, Saxmundham, Halesworth, and Beccles, with the western branch from Felixstowe reaching to Lowestoft; while the Southwold Light railway connects with that town from Halesworth. The other principal branches are those from Stowmarket to Bury St Edmunds and westward into Cambridge, via Sudbury. The Essex lines are from Manningtree to Colchester and Thetford, and from Long Melford to Haverhill, which is the northern terminus of the Colne Valley railway.

Population and Administration.—The area of the ancient county is 952,710 acres, with a population in 1891 of 371,215, and in 1901 of 384,293. Suffolk comprises 21 hundreds, and for administrative purposes divided into the counties of East Suffolk (557,854 acres) and West Suffolk (390,914 acres). The following are municipal boroughs and urban districts:

(1) EAST SUFFOLK. Municipal boroughs—Aldeburgh (pop. 2,405), Blyth (5,698), Ely (3,290), Halesworth (3,815), Lowestoft (6,810), Woodbridge (1,027), and Yarmouth (3,290). Urban districts—Bungay (3,141), Felixstowe and Walton (8,195), Diss (3,295), Leiston-Sizewell (3,295), Oulton Broad (4,044), Saxmundham (1,428), Stowmarket (4,162), Woodbridge (4,640), and Yarmouth (3,295). The county and the towns of any importance are: Brandon, Clare, Debenham, Framlingham, Halesworth, Mildenhall, Needham Market and Orford. For parliamentary purposes the county constitutes five divisions, each returning one member, viz. Ipswich, Lowestoft, Bury St Edmunds, Sudbury, and Woodbridge. The last-named returns one member and Ipswich two; part of the corporal county is in the Great Eastern railway district. There is one court of quarter sessions for the two administrative counties, which is usually held at Ipswich for east Suffolk, and then by
adjournment at Bury St Edmunds for west Suffolk. East Suffolk is divided into 11 and west Suffolk into 8 petty sessional divisions. The boroughs of Bury St Edmunds, Ipswich, Sudbury, Eye, Lowestoft and Southwold have separate commissions of the peace, and the three first-named have also separate courts of quarter sessions. The total number of civil parishes is 519. The ancient county contains 465 ecclesiastical parishes and districts, wholly or in part; it is situated partly in the diocese of Ely and partly in that of Norwich.

History.—The county of Suffolk (Sudbole, Sudholce) was formed from the south part of the kingdom of East Anglia which had been settled by the Angles in the latter half of the 5th century. The most important Anglo-Saxon settlements appear to have been made at Sudbury and Ipswich. Before the end of the Norman dynasty strongholds had arisen at Eye, Clare, Walon and Framlingham. Probably the establishment of Suffolk as a separate shire was scarcely completed before the Conquest, and although it was reckoned as distinct from Norfolk in the Domesday Survey of 1086, the fiscal administration of Norfolk and Suffolk remained under one sheriff until 1575. The boundary of the county has undergone very little change, though its area has been considerably affected by coast erosion. Parts of Gorleston and Thetford, which formerly belonged to the ancient county of Norfolk, are now within the administrative county of Suffolk, and other slight alterations of the administrative boundary have been made. Under the Local Government Act of 1888 Suffolk was divided into the two administrative counties of east and west Suffolk.

At first the whole shire lay within the diocese of Dunwich which was founded c. 631. In 673 a new bishopric was established at Elmham to comprise the whole of Norfolk which had formerly been included in the see of Dunwich. The latter came to an end with the incursion of the Danes, and on the revival of Christianity in this district Suffolk was included in the diocese of Elmham, subsequently removed from South Elmham to Thetford and thence to Norwich. In 1835-1836 the archdeaconry of Sudbury was transferred by the ecclesiastical commissioners to the diocese of Ely. This archdeaconry had been separated from the original archdeaconry of Suffolk in 1127. In 1256 the latter included thirteen deaneries which have since been subdivided, so that at present it contains eighteen deaneries; Sudbury archdeaconry which comprised eight deaneries in 1256 now in 17. There were also three districts under peculiar jurisdiction in Canterbury and one under that of Rochester.

The shire-court was held at Ipswich. In 1831 the whole county contained twenty-one hundreds and three municipal boroughs. Most of these hundreds were identical with those of the Domesday Survey, but in 1086 Babergh was rated as two hundreds, Gosford, Ipswich and Parham as half hundreds and Samford as a hundred and a half. Hoxne hundred was formerly known as Bishop's hundred and the hills which were included later in Thredling hundred were within Claydon hundred in 1086. Two large ecclesiastical liberties extended over more than half of the county; that of St Edmund contained the hundreds of Risbridge, Thedwarray, Thingoe, Gosford, Lackford and Blackbourn in which the king's writ did not run, and St Aethelreda of Ely claimed a similar privilege in the hundreds of Carlesford, Colneis, Plumesgate, Loeis, Wilford and Thredling. Among others who had large lands in the county with co-extensive jurisdiction were the lords of the honor of Clare, earls of Gloucester and Hereford and the lords of the honor of Eye; held successively by the Bigods, the Uffords and the De la Poles, earls of Suffolk. The Wingfields, Bacons and Haves have been closely connected with the county.

Suffolk suffered severely from Danish incursions, and after the Treaty of Wedmore became a part of the Danelag. In 1173 the earl of Leicester landed at Walton with an army of Flemings and was joined by Hugh Bigod against Henry II. In 1237 and the succeeding years a great part of the county was in arms for Thomas of Lancaster. Queen Isabella and Mortimer having landed at Walton found all the district in their favour. In 1330 the county was raised to suppress the supporters of the earl of Kent; and again in 1381 there was a serious rising of the peasantry chiefly in the neighbourhood of Bury St Edmunds. Although the county was for the most part Yorkist it took little part in the Wars of the Roses. In 1525 the artisans of the south strongly resisted Henry VIII.'s forced loan. It was from Suffolk that Mary drew the army which supported her claim to the throne. In the Civil Wars the county was for the most part parliamentarian, and joined the Association of the Eastern Counties for Peace against the Parliamentarians.

The county was constantly represented in parliament by two knights from 1290, until the Reform Bill of 1832 gave four members to Suffolk, at the same time disfranchising the boroughs of Dunwich, Orford and Aldeburgh. Suffolk was early among the most populous of English counties, doubtless owing to its proximity to the continent. Fishing fleets have left its ports to bring back cod and ling from Iceland and herring and mackerel from the North Sea. From the 14th to the 17th century it was among the chief manufacturing counties of England owing to its cloth-weaving industry, which was at the height of its prosperity during the 17th century. In the 18th and 19th centuries its agricultural resources were utilized to provide the rapidly-growing metropolis with food. In the following century various textile industries, such as the manufacture of sail-cloth, cocoa-nut fibre, horse-hair and clothing were established; silk-weavers migrated to Suffolk from Spitalfields, and early in the 19th century an important china factory flourished at Lowestoft.

Antiquities.—Of monastic remains the most important are those of the great Benedictine abbey of Bury St Edmunds, noticed under that town; the college of Clare, originally a cell to the abbey of Beverley, and afterwards to St Peter's Westminster, was converted into a college of secular canons in the reign of Henry VI., still retaining much of its ancient architecture, and now used as a boys' school; the collegiate church of the Augustinian priory of Bury; and the remains of the Grey Friars' friary in Norwich. A peculiarity of the church architecture is the use of flint for purposes of ornamentation, often of a very elaborate kind, especially on the towers and parapets of the towers. Another characteristic is the round towers, which are confined to East Anglia, but are considerably more numerous in Norfolk than in Suffolk, the principal being those of Little Saxham and Hernehithe, both good examples of Norman. It is questionable whether there are any remains of pre-Norman architecture in the county. The Decorated is well represented, but by far the greater proportion of the churches are Perpendicular, fine examples of which are so numerous that it is hard to select examples. But the churches are chiefly in the east and the exquisite ornate building at Lavenham in the west may be noted as typical, while the church of Long Melford, another fine example, should be mentioned. A very fine example of late Perpendicular, and remarkable features are the open roofs and woodwork (as at St Mary's, Bury St Edmunds, Earl Stonham and Stonham Aspall, Ufford and Blithbury), and the fine fonts.

The remains of cricket are comparatively unimportant, the principal being the entrenchments and part of the walls of Bungay, the ancient stronghold of the Bigods; the picturesque ruins of Mettening, built by John de Norwich in the reign of Edward III.; Wingfield, surrounded by a deep moat, with the torrent walls and the drawbridge still existing; the splendid ruin of Framlingham, with high and massive walls, originally founded in the 6th century, but restored in the 13th; the outlines of the extensive fortress of Clare Castle, anciently the baronial residence of the earls of Clare; and the fine Norman keep of Orford Castle, on an eminence overlooking the sea. Among the many fine residences within the county there are several that are of interest: the remains of the abbeys of Clare, Ely, of the Convent of Wilford, the ruins of the priories of Wilford, Holy Cross, the site of the palace of the earls of Huntingdon, and the ruins of the palace of the earls of Gloucester. The abbeys are those of Clare, Ely, and of the manor of Huntingdon, the latter being a Roman fortress.

Editor's note: This text is a portion of the 19th-century history of Suffolk, including details on its history, administration, and cultural elements, such as the role of monasticism and cricket. It provides a comprehensive overview of the county's development from early settlement through to the 19th century, highlighting significant events, economic activities, and architectural features.
SUFFRAGE—SUFFREN SAINT TROPEZ

SUFFRAGE (Lat. suffragium), the right or the exercise of the right of voting in political affairs; in a more general sense, an expression of opinion, assent or approval; in ecclesiastical use, the short intercessory prayers in litanies spoken or sung by the people as distinguished from those of the priests or ministers. (Suffrage, Registration and Voting; and Suffrage Movement; Women: § Political Rights.) The etymology of the Latin word suffragium has been much discussed. It is usually referred to sub- and the root of strangere, to break, and its original meaning must thus have been a piece of broken tile or a potsherd on which the names or initials of the candidates were inscribed and used as a voting tablet or tabella. There is, however, no direct evidence that this was ever the practice in the case of voting upon legislation in the assembly (see W. Corssen, Uber Ausprache, &c., des Lateinischen Sproche, i. 397, and Mommsen, Römische Geschichte, iii. 472 b. i.).

SUFFREN SAINT TROPEZ, PIERRE ANDRÉ DE (1720–1788), French admiral, was the third son of the marquis de Saint Tropez, head of a family of nobles of Provence which claimed to have emigrated from Lucca in the 14th century. He was born in the Château de Saint Canat in the present department of Aix on the 17th of July 1729. The French navy and the Order of Malta offered the usual careers for the younger sons of noble families of the south of France who did not elect to follow the Church. The common lot between the Order and the old French royal navy was close. Pierre André de Suffren was destined by his parents to belong to both. He entered the close and aristocratic corps of French naval officers as a "garde de la marine"—cadet or midshipman, in October 1743, in the "Solide," one of the line of battleships which took part in the confused engagement off Toulon in 1744. He was then in the "Pauline" in the squadron of M. Macémar de a cruise in the West Indies. In 1746 he went through the duc d'Anville's disastrous expedition to retake Cape Breton, which was ruined by shipwreck and placed his reputation. Next year (1747) he was taken prisoner by Hawke in the action with the French convoy in the Bay of Biscay. His biographer Cunat assures us that he found British arrogance offensive. When peace was made in 1748 he went to Malta to perform the cruises with the galleys of the Order technically called "caravans," a reminiscence of the days when the knights protected the pilgrims going from Saint John d'Arc to Jerusalem. In Suffren's time this service rarely went beyond a peaceful tour among the Greek islands. During the Seven Years' War he had an undoubted good fortune to be present as lieutenant in the "Ornée" in the action against the "Neptun" (q.v.), which, if not properly speaking a victory, was at least a defeat for the French and was followed by the surrender of the English garrison of Minorca. But in 1757 he was again taken prisoner, when his ship the "Océan" was captured by Boscawen off Lagos. On the return of peace in 1763 he intended again to do the service in the caravans which was required to qualify him to hold the high and lucrative posts of the Order. He was, however, named to the command of the "Camélion," a 26-pee—a vessel of mixed square and lateen rig peculiar to the Mediterranean—in which he cruised against the pirates of the Barbary coast. Between 1767 and 1771 he performed his caravans, and was promoted from knight to commander of the Order. From that time till the beginning of the War of American Independence he commanded vessels in the squadron of evolution which the French government had established for the purpose of giving practice to its officers. His nerve and skill in handling his ship were highly commended by his chiefs. In 1778 and 1779 he formed part of the squadron of D'Estaing (q.v.) throughout its operations on the coast of North America and in the West Indies. He led the line in the action with Admiral John Byron, off Grenada, and his ship, the "Fantasque" (64), lost 62 men. His letters to his admirals show that he strongly disapproved of D'Estaing's half-hearted methods. In 1780 he was captain of the "Zélie" (74), in the combined French and Spanish fleets which captured a great English convoy in the Atlantic. His candour towards his chief had done him no harm in the opinion of D'Estaing. It is said to have been largely by the advice of this admiral that Suffren was chosen to command a squadron of five ships of the line sent out to help the Dutch who had joined France and Spain to defend the Cape against English attack, and then to go on to the East Indies. He sailed from Brest on the 22nd of March on the cruise which has given him a unique place among French admirals, and puts him in the front rank of sea commanders. He was by nature even more vehement than able. The disasters which had befallen the navy of his country during the last two wars, and which, as he knew, were due to bad administration and timid leadership, had filled him with a burning desire to retrieve its honour. He was by experience as well as by temperament impelled with the formal manner being of his colleagues, which consisted of preserving their own ships rather than at taking the English, and though he did not dream of restoring the French power in India, he did hope to gain some such success as would enable his country to make an honourable peace. On the 16th of April 1782 he found the English expedition on its way to the Cape under the command of Commodore, commonly called Governor, George Johnstone (1730–1787), at anchor in Porto Praya, Cape de Verdes Islands. Remembering how little respect Boscawen had shown for the neutrality of Portugal at Lagos, he attacked at once. Though he was definitely supported as there was not much injury as he suffered and proposed to the English that in him they had to deal with an admiral of quite a different type from the Frenchmen they had been accustomed to as yet. He pushed on to the Cape, which he saved from capture by Johnstone, and then made his way to the Isle de France (Mauritius), then held by the French. M. D'Orves, his superior officer, died as the united squadrons, now eleven sail of the line, were on their way to the Bay of Bengal. The campaign, which Suffren now conducted against the English admiral Sir Edward Hughes (1720?–1794), is famous for the number and severity of the encounters between his ships and those of his officers. On the 31st of March 1782, he took the French ship "Aussprache" (q.v.) in the battle of February 1782, south of Madras; on the 12th of April near Trincomalee; on the 6th of July off Cuddalore, after which Suffren seized upon the anchorage of Trincomalee compelling the small British garrison to surrender; and again near that port on the 3rd of September. No ship was lost by Sir Edward Hughes in any of these actions, but none were taken by him. Suffren attacked with unprecedented vigour on every occasion, and if he had not been ill-supported by some of his captains he would undoubtedly have gained a distinct victory; as it was, he maintained his squadron without much loss. In the action of April 1782, he fought his last battle against Hughes (April 20, 1783), with fourteen ships to eighteen he forced the English admiral to retire to Madras, leaving the army then besieging Cuddalore in a very dangerous position. The arrival of the news that peace had been made in Europe put a stop to hostilities, and Suffren returned to France. While refitting at the Cape on his way home, several of the vessels also returning put in, and the captains waited on him. Suffren said in one of his letters that their praise gave him more pleasure than any other compliment paid him. In France he was received with enthusiasm, and an additional office of vice-admiral of France was created for him. He had been promoted bailli in the Order of Malta during his absence. His death occurred very suddenly on the 8th of December 1788, when he was about to take command of a fleet collected in Brest. The official version of the cause of death was apoplexy, and as
he was a very corpulent man it appeared plausible. But many years afterwards his body servant told M. Jal, the historiographer of the French navy, that he had been killed in a duel by the prince de Mirepoix. The cause of the encounter, according to the servant, was that Sufien had refused in very strong language to use his influence to secure the restoration to the navy of two of the prince’s relations who had been dismissed for misconduct.

Sufien was crippled to a large extent by the want of loyal and capable co-operation on the part of his captains, and the vehemence of his own temperament sometimes led him to disregard prudence, yet he had an indefatigable energy, a wealth of resource, and a thorough understanding of the fickle and usually disregarded by French naval officers—success at sea is won by defeating an enemy and not by merely outmanoeuvring him; and this made him a most formidable enemy. The portraits of Sufien usually reproduced are worthless, but there is a good engraving by Mme de Cerneal after an original by Gérard.

The standard authority for the life of Sufien is the Histoire du Bailli de Sufien by Ch. Camut (1852). The Journal de Bord du Bailli de Sufien dans l’Inde, edited by M. More, was published in 1888. There is an appreciative study in Captain Mahan’s Sea Power in History, (D. H.) Sufien (�فیں), a term used by Moslems to denote any variety of mysticism, is formed from the Arabic word Sāfī, which was applied, in the 2nd century of Islam, to men or women who adopted an ascetic or quietist way of life. There can be no doubt that Sāfī is derived from sūf (wool) in reference to the woolen garments often, though not invariably, worn by such persons: the phrase labisā’t-sāfī (“he clad himself in wool”) is commonly used in this sense, and the Persian word pashmina-pašī, which means literally “clothed in a woolen garment,” is synonymous with Sāfī. Other etymologies, such as Sāfīd (purity)—a derivation widely accepted in the East—and sosōs, are discredited.

In order to trace the origin and history of mysticism in Islam we must go back to Mahomet. On one side of his nature the Prophet was an ascetic and in some degree a mystic. Notwithstanding his condemnation of Christian monkry (rakbāniya), i.e. of celibacy and the solitary life, the example of the Ḥanifs, with some of whom he was acquainted, and the Christian hermits made a deep impression on his mind and led him to preach the efficacy of ascetic exercises, such as prayer, vigils and fasting. Again, while Allah is described in the Koran as the One God working his arbitrary will in unapproachable supremacy, other passages lay stress on his all-pervading presence and intimate relation to his creatures, e.g. “Wherever ye turn, there is the face of Allah” (ii. 109). “We (God) are nearer to him (Man) than his neck-vein” (I. 15). The germs of mysticism latent in Islam from the first were rapidly developed by the political, social and intellectual conditions which prevailed in the two centuries following the Prophet’s death. Devastating civil wars, a ruthless military despotism caring only for the things of this world, Messianic hopes and presages, the luxury of the upper classes, the hard mechanical piety of the orthodox creed, the spread of rationalism and freethought, all this produced a condition of the deepest moral, spiritual and emotional degradation. Thousands, wolves, and disowned with worldly vanities, devoted themselves to God. The terrors of hell, so vividly depicted in the Koran, awakened in them an intense consciousness of sin, which drove them to seek salvation in ascetic practices.

Sūfism was originally a practical religion, not a speculative system; it arose, as Junayd of Bagdad says, “from hunger and taking leave of the world and breaking familiar ties and renouncing what men deem good, not from disputation.” The early Sūfis were closely attached to the Mahomedan church. It is said that Abū Hāshim of Kūfa (d. before A.D. 800) founded a monastery for Sūfis at Ramleh in Palestine, but such fraternities seem to have been exceptional. Many ascetics of this period used to wander from place to place, either alone or in small parties, sometimes living by alms and sometimes by their own labour. They took up and emphasized certain Koranic terms. Thus dhikr (praise of God) consisting of recitation of the Koran, repetition of the Divine names, &c., was regarded as superior to the five canonical prayers incumbent on every Moslem, and tawakkul (trust in God) was defined as renunciation of all personal initiative and volition, leaving one’s self entirely in God’s hands, so that some fanatics deemed it a breach of “trust” to seek any means of livelihood, engage in trade, or even take medicine. Quietism soon passed into mysticism. The attainment of salvation ceased to be the first object, and every aspiration was centred in the inward life of dying to self and living in God. “O God!” said Ibrahim ibn Adham, “Thou knowest that the eight Paradises are little compared with the honour which Thou hast done unto me, and bade me love, Thy love, and Thy giving me intimacy with the praise of Thy name, and beside the peace of mind which Thou hast given me when I meditate on Thy majesty.” Towards the end of the 2nd century we find the doctrine of mystical love set forth in the sayings of a female ascetic, Rāhība’t Basra, the first of a long line of saintly women who have played an important rôle in the history of Sūfism. Henceforward the use of symbolical expressions, borrowed from the vocabulary of love and wine, becomes increasingly frequent as a means of indicating holy mysteries which must not be divulged. This was not an unnecessary precaution, for in the course of the 3rd century, Sūfism assumed a new character. Side by side with the quietistic and devotional mysticism of the early period there now sprang up a speculative and pantheistic movement which was essentially anti-Islamic and rapidly came into conflict with the orthodox ulema. It is significant that the oldest representative of this tendency—Ma’rūf of Bagdad—was the son of Christian parents and a Persian by race. He defined Sūfism as a theosophy; his aim was to “apprehend the Divine realities.” A little later Abū Sulâmān al-Dārānī in Syria and Dhu’l-Nün in Egypt developed the doctrine of gnosis (ma’rūf) through illumination and ecstasy. The nestling of this to Pantheism was done by the great Persian Sūfī, Abū Yazīd (Bāyezd) of Bīstām (d. A.D. 874), who introduced the doctrine of annihilation (fana), i.e. the passing away of individual consciousness in the will of God.

It is, no doubt, conceivable that the evolution of Sūfism up to this point might not have been very different even although it had remained wholly unaffected by influences outside of Islam. But, as a matter of fact, such influences made themselves powerfully felt. Of these, Christianity, Buddhism and Neoplatonism are the chief. Christian influence had its source, not in the Church, but in the hermits and unorthodox sects, especially perhaps in the Syrian Euchites, who magnified the duty of constant prayer, abandoned their all and wandered as poor brethren. Sūfism owed much to the ideal of unworldliness which they presented. Conversations between Moslem devotees and Christian ascetics are often related in the ancient Sūf biographies, and many Biblical texts appear in the form of sayings attributed to eminent Sūfis of early times, while sayings ascribed to Jesus as well as Christian and Jewish legends occur in abundance. More than one Sūfi doctrine—that of tawakkul may be mentioned in particular—was decisively Christian in origin. The monastic strain which insinuated itself into Sūfism in spite of Mahomet’s prohibition was derived, partially at any rate, from Christianity. Here, however, Buddhist influence may also have been at work. Buddhism flourished in Balkh, Transoxiana and Turkestan before the Mahomedan conquest, and in later times Buddhist monks carried their religious practices and philosophy among the Moslems who had settled in these countries. It looks as though the legend of İbrahim ibn Adham, a prince of Balkh who one day suddenly cast off his royal robes and became a wandering Sūfī, were based on the story of Buddha. The use of rosaries, the doctrine of fana, which is probably a form of Nirvanism, and the system of “stationa” (maqāmat) on the road thereto, would seem to be Buddhist in their origin. The third great foreign influence on Sūfism is the Neoplatonic philosophy. Between A.D. 800 and 860 the tide of Greek learning, then at its height,
streamed into Islam from the Christian monasteries of Syria, from the Persian Academy of Janedshap in Khustain, and from the Sbians of Haran in Mesopotamia. The so-called "good" (or bad) type of Neo-Platonic theories, and the mystical writings of the pseudo-Diosynius were widely known throughout western Asia. It is not mere coincidence that the doctrine of Gnosis was first worked out in detail by the Egyptian Sufi, Dhu l-Nun (d. A.D. 859), who is described as an alchemist and theurgist. Sufism on its theosophical side was largely a product of Alex andean speculation.

By the end of the 3rd century the main lines of the Sufi mystic apprehensions were already fixed. It was now fast becoming an organized system, a school for saints, with a framework of discipline. The true devotee who longed to learn from his spiritual director, to whose guidance he submitted absolutely. These directors regarded themselves as being in the most intimate communion with God, who bestowed on them miraculous gifts (karāmāt). At their head stood a mysterious personage called the Qub (Axis): on the hierarchy of saints over which he presided the whole order of the universe was believed to depend. During the next two hundred years (A.D. 900–1100), various manuals of theory and practice were compiled: the Kitāb al Lami (the "Kulshā" by al-Qulub, the Risala of Qutb al-Mahjūb, the Kubbat al-Sakhā, the Brīda of Sakhārī, the Persian Kashf al-Mahjūb by 'Ali ibn 'Uthmān al-Hujwī in, and the famous Iḥyā by Ghazzālī. Inasmuch as all these works are founded on the same materials, viz., the Koran, the Traditions of the Prophet and the sayings of well-known Sufi teachers, they necessarily have much in common, although the subject is treated by each writer from his own standpoint. They all expatiate on the discipline of the soul and describe the process of purgation which it must undergo before entering on the contemplative life. The traveller journeying towards God passes through a series of ascending "stations" (ka'ba). He who traverses these (1) repentance, (2) abstinence, (3) renunciation, (4) poverty, (5) patience, (6) trust in God, (7) acquiescence in the will of God. After the "stations" comes a parallel scale of "states" of spiritual feeling (ajwāl), such as fear, hope, love, &c., leading up to contemplation (musākhahad) and intuition (yaqīn). It only remained to provide Sufism with a metaphysical basis, and to reconcile it with orthodox Islam. The double task was finally accomplished by Ghazzālī (q.v.). He made Islamic theology mystical, and since his time the revelation (kaḥf) of God has taken its place beside tradition (naql) as the reason (qap) as a source and fundamental principle of the faith. Protests have been and are still raised by theologians, but Musulon sentiment will usually tolerate whatever is written in sufficiently abstruse philosophical language or spoken in manifest ecstasy.

The Sūfis do not form a sect with definite dogmas. Like the monastic orders of Christendom, they comprise many shades of opinion, many schools of thought, many divergent tendencies—from asceticism and quietism to the wildest extravagances of pantheism. European students of Sūfism are apt to identify it with the pantheistic type which prevails in Persia. This, although more interesting and attractive than any other, throws the transcendental and visionary aspects of Sūfism into undue relief. Nevertheless some aspects are must be given here of the Persian theosophy which has fascinated the noblest minds of that subtle race and has inspired the most beautiful religious poetry in the world. Some of its characteristic features occur in the sayings attributed to Ḥāyezīd (d. A.D. 874), whom Buddhistics refuse unquestioningly. He said, for example, "I am the winewar and the wine and the cup-bearer, and again, "I went from God to God, until they cried from me in me, 'O Thou!'." The peculiar imagery which distinguishes the poetry of the Persian Sūfis was more fully developed by a native of Khorasan, Abā Sa'id ibn Abī l-Khair (d. A.D. 1049) in his mystical quatrains. The relationship between mirrors and the reflection thereof is by glowing and fantastic allegories of earthly love, beauty and intoxication. Henceforward, the great poets of Persia, with few exceptions, adopted as symbolic language either seriously or as a conventional manner. The Christian mystics professed: "The real basis of their poetry," says A. von Krenmer, "is a softly incubated ethical system, which recognizes in purity of heart, charity and peace the background and brings to the necessary conditions of eternal happiness. Attached to this is a pantheistic theory of the emanation of all things from God and their ultimate reunion with him. Although on the surface Islam is not directly assailed, it sustains many indirect attacks, and frequently the thought flashes out, that all religions and revelations are only the rays of a single eternal sun; that all prophets have only delivered and preserved the same truth, and that each has in due course died of beauty and eternal truth which flow from the divine soul of the world." The whole doctrine of Persian Sūfism is expounded in the celebrated Mathnawī of Jalāl ad-Dīn Rūmī, a more or less unscientific融化 and unscientific manner that its leading principles are not easily grasped. They may be stated briefly as follows:

God is the sole reality (al-Haqq) and is above all names and definitions. He is not an object of sense, but a principle, and therefore ABsolute Beauty. It is the nature of beauty to desire manifestation; the phenomenal universe is the result of this desire, according to the famous Tradition in which God says, "I was a being, and thou knowest not, and I was no being, and thou knewest me in order that I might be known." Hence the Sūfīs, influenced by Neoplatonic theories of emanation, postulate a number of intermediate worlds or descending plates of existence from the eternal universe, which accordingly has no more reality than a shadow cast by the sun. Its central point is Man, the microcosm, who reflects in himself all the Divine attributes. Man is the one, for the Sūfis by profession, who is born within him a spark of pure Being. The human soul belongs to the spiritual world and is ever seeking to be united to its source. Such unification, being a naturally attainable until death, can be enjoyed at times in the state called ecstasy (kadd), when the veil of sensual perception is rent asunder and the soul is merged in God. In the state of ecstasy the achievement of which self-annihilation is wrought by means of that divine love, to which human love is merely a stepping-stone. The true lover feels himself one with God, the only real being and agent in the universe; he is also the soul of every other being and thing, a doctrine since it is the Sūfī theosophy as it appears in Persian and Turkish poetry. Its perilous consequences are plain. It tends to abolish the distinction between God and man and to identify the concept of Not-being and has no real existence—and it leads to the delusion of the hierophant who can say, like Ḫusāin b. Manṣūr al-Hallāj, "I am the Truth." Sūfī fraternities, living in a convent under the direction of a sheikh, became widely spread before A.D. 1100 and gave rise to Dervish orders, most of which indulge in the practice of exciting ecstasy by music, dancing, drugs and various kinds of hypnotic suggestion (see Dervish).

Gentleman, the sugar, p. 327.

Gentleman, the sugar, p. 327.

Gentleman, the sugar, p. 327.
beet, carrot and other roots were identical with cane sugar.

The sugars obtained from honey were investigated by Lowitz and Proust, and the latter decided on three species: (1) cane sugar, (2) grape sugar, and (3) fruit sugar; the first has the formula C\textsubscript{6}H\textsubscript{12}O\textsubscript{6}, the others C\textsubscript{6}H\textsubscript{12}O\textsubscript{6}. This list has been considerably developed by the discovery of natural as well as of synthetic sugars.

It is convenient to divide the sugars into two main groups: monosaccharides (formerly simple sugars), and disaccharides (formerly saccharoses). The first term includes simple sugars containing two to nine atoms of carbon, which are known severally as bioses, trioses, tetroses, pentoses, hexoses, &c.; whilst those of the second group have the formula C\textsubscript{n}H\textsubscript{2n}O\textsubscript{n}, and are characterized by yielding two monosaccharose molecules on hydrolysis. In addition tri- and tetroses are known of the formula C\textsubscript{4}H\textsubscript{6}O\textsubscript{5}; these on hydrolysis yield two monosaccharose and one of a disaccharose type of three or one of a monosaccharose. It is found also that some monosaccharose behave as aldehydes whilst others contain a keto group; those having the first character are called aldoses, and the others ketoses. All sugars are colourless solids or syrups, which clear on strong heating; they are soluble in water, forming sweet solutions but difficultly soluble in alcohol. Their solutions are optically active, i.e. they rotate the plane of polarized light; the amount of the rotation is dependent upon the type of sugar and, in some cases, on the age of the solution (cf. GLUCOSE).

The rotation serves for the estimation of sugar solutions (saccharimetry). The sugar is neutral to litmus and do not combine with alkali or bases; strong bases, such as lime and baryta, yield saccharates, whilst, under certain conditions, acids and acid anhydrides may yield esters. Sugars are also liable to fermentation.\(^1\) Our knowledge of the chemical structure of the monosaccharose may be traced back as far as 1880, when Ziecke suspected some to be ketose sugars, for it was known that glucose and fructose, for example, yielded penta-acetates, and on reduction gave hexahydric alcohols, which, when reduced by hydric acid, gave normal and secondary hydroxylic alcohol. The facts suggested that the six carbon atoms formed a chain, and that a hydroxy group was attached to five of them, for it is rare that two hydroxy groups to be attached to the same carbon atom. The remaining oxygen atom is aldehydic or ketonic, for the sugars combine with hydrocyanic acid, hydroxylamine and phenylhydrazine. The correctness of this view was settled by converting from the monosaccharose to two members of the ketose fructose and and fructose, hydrolysed them to the corresponding oxo-acids, from which the hydroxy groups were split out by reduction; it was found that glucose yielded normal heptic acid and fructose normal hexahydric acid; hence glucose is an aldehyde alcohol CH\textsubscript{2}O\textsubscript{H}., CH\textsubscript{2}O\textsubscript{H}., and fructose is a keto alcohol CH\textsubscript{2}O\textsubscript{H}., CO.CH\textsubscript{2}O\textsubscript{H}.\(^2\) Kiliani also showed that arabinose, C\textsubscript{5}H\textsubscript{10}O\textsubscript{5}, a sugar found in cherry gum, was a aldopentose, and thus the common formula C\textsubscript{n}H\textsubscript{2n}O\textsubscript{n}.

Before proceeding to the actual synthesis of the sugars, it is advisable to discuss their decompositions and transformations.

1. by hydrolysia a sugar may be decomposed into monomer-carboxylic acids, which yield lactones; these compounds when reduced by sodium amalgam in sulphuric acid solution yield a sugar containing one more carbon atom. This permits the formation of sugar from a lower sugar (E. Fischer).

\[ \text{CHOH} \rightarrow \text{CHOH} \rightarrow \text{CHO} \rightarrow \text{CHO} \rightarrow \text{CHO} \]

Pentose \rightarrow Cyanhydrin \rightarrow Lactone \rightarrow Hexose.

2. Oximes.—The oximes permit the reverse change, i.e. the passage from a higher to a lower sugar. Wohl forms the oxime and converts it into an acetylated nitrile by means of acetic anhydride and acetic anhydride, acetic anhydride and acetic acid, and acetic anhydride and hydrochloric acid and the resulting acetate is hydrolysed by acting with ammonia to form an amide, which is finally decomposed with sulphuric acid.

\[ \text{CHOH} \rightarrow \text{CHOH} \rightarrow \text{CHOH} \rightarrow \text{CHOH} \rightarrow \text{CHOH} \rightarrow \text{CHOH} \]

CHO \rightarrow CN + CO + CHO.

Pentose \rightarrow Oxime \rightarrow Nitrile \rightarrow Pentose.

Ruff effects the same change by oxidizing the sugar to the oxo-acid, and further oxidizing this with Fenton's reagent, i.e. hydrogen peroxide and a trace of a ferrous salt:

\[ \text{C}_4\text{H}_6\text{O}(\text{CH}_2\text{OH}.)-\text{CHO} \rightarrow \text{C}_6\text{H}_5\text{O}_4(\text{CH}_2\text{OH}.)-\text{CO}_2\text{H} \rightarrow \text{C}_4\text{H}_6\text{O}(\text{CH}_2\text{OH}.) \]

3. Phenylhydrazine Derivatives.—Fischer found that if a molecule of phenylhydrazine acted upon one molecule of an aldose or ketose a hydrazone resulted which in most cases was very soluble in water; if three of these hydrazines reacted (one of which is reduced to ammonia and aniline) insoluble crystalline substances resulted, termed osazones, which readily characterized the sugar from which it was obtained.

\[ R \rightarrow R \rightarrow R \rightarrow R \rightarrow R \rightarrow R \]

CHO \rightarrow CH-OH \rightarrow CH-NHPh. \rightarrow CH-NHPh.

Aldose \rightarrow Hydrazone \rightarrow Osazone.

R \rightarrow R \rightarrow R \rightarrow R \rightarrow R \rightarrow R

CHO \rightarrow CH-NHPh. \rightarrow CH-NHPh. \rightarrow CH-NHPh.

A ketone \rightarrow Hydrazone \rightarrow Osazone.

On warming the osazone with hydrochloric acid the phenylhydrazone residues are removed and an osone results, which on reduction with zinc and acetic acid gives a ketose.

\[ R \rightarrow R \rightarrow R \rightarrow R \rightarrow R \rightarrow R \]

C\textsubscript{6}H\textsubscript{5}-NHPh. \rightarrow CO \rightarrow CO \rightarrow CH\textsubscript{2}OH.

Osazone \rightarrow Osone \rightarrow Ketose.

A ketose may also be obtained by reducing the osazone with zinc and acetic acid to an osmine, which with nitric acid gives the ketose.

\[ R \rightarrow R \rightarrow R \rightarrow R \rightarrow R \rightarrow R \]

C\textsubscript{6}H\textsubscript{5}-NHPh. \rightarrow CO \rightarrow CO \rightarrow CH\textsubscript{2}OH.

Osazone \rightarrow Osamine \rightarrow Ketose.

These reactions permit the transformation of an aldose into a ketone; the reverse change can only be brought about by reducing the ketone to an alcohol, and oxidizing this compound to an aldehyde. It is seen that aldoses and ketoses which differ stereochimically in the two final carbon atoms must yield the same osazone; and since d-mannose, d-glucose, and d-fructose do form the same osazone (d-glucosazine) differences either structural or stereochemical must be placed in the two final carbon atoms.\(^4\)

It may here be noticed that in the sugars there are asymmetric carbon atoms, and consequently optical isomers are to be expected. Thus glucose, containing four such atoms, can exist in 16 forms; and the realization of many of these isomers by E. Fischer may be regarded as one of the most brilliant achievements in modern chemistry. The general principles of stereochemistry being discussed in Stereiosomerism (q.v.), we proceed to the synthesis of glucose and fructose and then to the derivation of their configurations.

In 1861 Butlerow obtained a sugar-like substance, methylenitan, by fermenting the triose, acetone, and solid polyacrylonitrile; and since 188, by decomposing acrolein dibromide with baryta, and subsequently prepared by oxidizing cyanuric with bromine in alcoholic solution, and treating the product with dilute alkali at \(\alpha^2\) . Glycerin appears to yield, on mild oxidation, an aldehyde, CH\textsubscript{2}O\textsubscript{H}-(CH\textsubscript{2}OH.)-CHO, and a ketone, CH\textsubscript{2}O\textsubscript{H}-CO-CH\textsubscript{2}O\textsubscript{H}, and these condense as shown in the equation:

\[ \text{CH}_2\text{O}-(\text{CH}_2\text{OH})-(\text{CH}_2\text{OH})-(\text{CH}_2\text{OH})-(\text{CH}_2\text{OH})-\text{CH}_2\text{O}-(\text{CH}_2\text{OH})-\text{CHO} \]

The osazone prepared from α-acrose resembled most closely the glucosazine yielded by glucose, mannose, and fructose, but it was optically inactive; also the ketose which it gave after treatment with hydrochloric acid and reduction of the osone was like ordinary fructose. It was not, however, a ketose, for it was a mixture of dextro and laevo fructose, a supposition which was proved correct by an indirect method. The starting material (α-acrose) can reach mannite (a natural 1,5- O-mannitol), and both are readily converted into d-glucose, the α-acrose being formed from d-glucose, by the alcohol obtained by reducing α-acrose, with regard to optical activity. Mannite on oxidation yields an aldose, mannose, C\textsubscript{6}H\textsubscript{12}O\textsubscript{6}, which

---

\(^1\) See Fermentation; and for the relation of this property to structure see Stereoisomerism.\(^2\) Aldoses and ketoses require modification in accordance with the views of Lowry and E. F. Armstrong, which postulate a γ oxide structure (see GLUCOSE). This, however, does not disturb the tenor of the following arguments.

---

**XXVI. 2.**
on further oxidation gives a manonic acid, C\(_6\)H\(_{12}\)(OH)\(_2\)-COH; this acid readily yields a lactone. Also Killiani found that the lactone decomposed by fractional crystallization of the strychnine or brucine salts. A separation of a-acrose was made by acting with beer yeast, which destroyed the ordinary fructose and left l-fructose which was isolated as its osazone. Also (\(d+\)l) manonic acid can be split into the \(d\) and \(l\) acids by fractional crystallization of the strychnine or brucine salts. The acid yields, on appropriate treatment, \(d\)-mannose and \(d\)-maninit. Similarly the l acid yields the laevio derivatives.

The next step was to prepare glucose. This was effected indirectly, by the formation of the tetrose and oxalos of \(d\)-mannose and \(d\)-glucose showed that the stereochemical differences were situated at the carbon atom adjacent to the aldehyde group. Fischer and Piloty therefore indicated that the beetle of converting dextro- into laevo-tartaric acid; he found that both \(d\)-mannonic and \(d\)-gluconic acids (the latter is yielded by glucose on oxidation) were mutually convertible by heating with quinoline under pressure at 140°. It was then found that on reducing the lactone of the acid obtained from \(d\)-mannonic acid, ordinary glucose resulted.

Fischer's a-acrose therefore led to the synthesis of the dextro and laevo forms of mannose, glucose and fructose; and these substances have been connected synthetically with many other sugars by means of his cyahydrin process, leading to higher sugars, and Wohl and Ruff's processes, leading to lower sugars.

Certain of the relations are here summarized (the starting substance is in italics):—

If the asymmetric system adjoining the COH group, which is that introduced in synthesizing the hexose from the pentose, be eliminated, the formula at disposal may be:

\[ \text{CH}_3(\mathrm{OH}) \quad \text{or} \quad \text{CHOH} \]

When such compounds are converted into corresponding dibasic acids, COH\(_2\text{H}(\text{CH} \text{OH})_2\text{COH},\) the number of asymmetric carbon atoms in the molecule is decreased, and the compound is then no longer associated with four, but with only three different radicles. Hence it follows that the “optical” formulae of the acids derived from two pentoses having the configuration given above will be:

\[ \text{COH}_2 - \text{OH} \quad \text{COH} \]

\[ \text{COH}_2 + \text{COH}_2 \]

and that consequently only one of the acids will be optically active.

As a matter of fact, only arabinose gives an active product on oxidation; it is therefore supposed that arabinose is the compound, and consequently:

\[ \text{CH}_3(\text{OH}) - + + \text{COH} \quad \text{=} \quad \text{L-glucose} \]

\[ \text{CHOH} + + \text{COH} \quad \text{=} \quad \text{L-galucose} \]

When xylose is combined with hydroxyacetic acid and the pyranose is hydrolysed, together with L-xylo-ic acid, a second isomeric acid, L-idic acid, is produced, which on reduction yields the hexalose L-idose. When L-idonic acid is heated with pyridine, it is converted into L-ribose, but the latter is a compound of the same hexose nature as the former, and may be reduced to L-idose in a similar manner be converted into d-idonic acid, from which it is possible to prepare d-idose. It follows from the manner in which d-idose is produced that its configuration is CH\(_3\)(OH)+ + + COH.

The remaining aldohexoses discovered by Fischer are derived from d-galactose by milk-sugar. When oxidized this aldohexose is first converted into the monobasic galactonic acid, and then into d-glucuronic acid; the latter is optically inactive, so that its configuration must be one of those given in the sixth and seventh columns of the table. On reduction it yields an inactive mixture of galactonic acids, some molecules being attacked at one end, as it were, and others at the other end of the carbon chain. On reducing the lactone prepared from the inactive acid an inactive galactose is obtained from which L-galactose may be separated by fermentation. Lastly, when d-galactonic acid is heated with pyridine, it is converted into D-talose, and thence into L-talose, which is the same acid as the L-talose obtained from the fructose radical, while the first molecule is not formed from the aldose but from the ketose. D-Galactose can be obtained from the ketone L-galactose, which is obtained by oxidation of the aldose sugar. The configuration of the penta- and tris-aldoses have been determined by similar arguments; and those of the ketoses can be deduced from the aldoses.

**Disaccharoses.**

The disaccharoses have the formula C\(_6\)H\(_{12}\)O\(_6\) and are characterized by yielding under suitable conditions two molecules of a hexose: C\(_6\)H\(_{12}\)O\(_6\) + C\(_6\)H\(_{12}\)O\(_6\) = 2C\(_6\)H\(_{12}\)O\(_6\). The molecular compounds of the disaccharoses are not necessarily identical: thus cane sugar yields D-glucose and D-fructose (invert sugar); milk sugar and melibiose give D-glucose and D-galactose, whilst maltose yields only glucose. Chemically they appear to be ether arylidrides of the hexoses; but they are effectuated by the aldehyde or alcohol groups, and in consequence they are related to the ethers of glucose and other hexoses, i.e., to the glycosides. The sugar has no reducing power and does not form an hydrazone or osazone in the various other forms, and hence FeHegel’s solution and form hydrazones and osazones. D-Galactose, behaving as aldoses, i.e., as containing the group -CH(\text{OH})\-CHO. The rotation of the disaccharoses to the D- and L-glucosides was established by E. F. Armstrong (Journ. Chem. Soc., 1893, 58, 1395), who showed that cane sugar and maltose were d-glucoses, and raffinose an L-glucose of melibiose. These and other considerations have led to the proposal of an aldehyde group formula for glucose first proposed by Tollens; this view, which has been mainly developed by Armstrong and Fischer, has attained general acceptance (see GLUCOSE, GLUCOSIDE). Fischer has proposed formula for the important disaccharide sugars and has devised a method for determining how the molecule was built up, by forming the osone of the sugar and hydrolyzing, whereupon the hexose obtained indicates the aldose part of the molecule. Lactose is thus found to be glucosido-galactose and melibiose a galactosido-glucose.

Several disaccharoses have been synthetized by acting with hydroxyacetic acids on their sodium salts or sodium salts of acetic acid. Among the compounds of this type obtained from starch, the acetylated starch, is the most important sugar; it is manufactured in large quantities and its preparation is described under acetylated starch. Its preparation is described under acetylated starch.
Cuba, British Guiana and Hawaii, and in India and Java in the Old World. The numerous cultivated varieties are distinguished mainly by the colour of the internodes, whether yellow, red or purple, or striped, and by the height of the culm. Apart from the sugar-cane and the beet, which are dealt with in detail below, a brief reference need only be made here to maple sugar, palm sugar and sorghum sugar.

Maple Sugar.—This is derived from the sap of the rock or sugar maple (Acer saccharum), a large tree growing in Canada and the United States.

The sap is collected in spring, just before the foliage develops, and is procured by making a notch or boring a hole in the stem of the tree. A tree may yield 30 gallons of juice a day and continue flowing for six weeks; but on an average only about 4 lb. of sugar are obtained from each tree, 4 to 6 gallons of sap giving 1 lb. of sugar. The sap is purified and concentrated in a simple manner, the whole work being carried on by farmers, who themselves use much of the product for domestic and culinary purposes.

Jaggery.—That which comes into the European market as jaggery or khahur is obtained from the sap of several palms, the wild date (Phoenix sylvestris), the palmyn (Borassus flabellifer), the coconut (Cocos nucifera), the gomuti (Arenga saccharifera) and other of the palm family which are cultivated in a portion of the Ganges valley to the north of Calcutta. The trees are ready to yield sap when five years old; at eight years the best is obtained, and in such a tree the annual supply will till the reach thirty years. The collection of the sap (toddy) begins about the end of October and continues, during the cool season, till the middle of February. The sap is drawn off from the upper growing portion of the tree, and in the interval of each week an average tree will run in a season 350 lb. of toddy, from which about 35 lb. of raw sugar—jaggery—is made by simple and rude processes. Jaggery production is extensive in India, Ceylon, Java, and the greater part of the count made is consumed locally; it only occasionally reaches the European market.

Sorghum Sugar.—The stem of the Guinea corn or sorghum (Sorghum saccharum) has long been known in China as a source of sugar. The sorghum is harder than the sugar-cane; it comes to maturity in a season, and it retains its maximum sugar content a considerable time, giving opportunity for leisurely harvesting. The sugar is obtained by the same method as cane sugar.

Cane Sugar Manufacture.—The value of sugar-canes at a given plantation or central factory would at first sight appear Commercial Values of sugar to vary directly as the amount of saccharine content of the juice expressed from them varies. Sugar canes, and if canes with juice indicating 6° Beaune are made a basis of value or worth, say at 10s. per ton, then cane sugar with juice indicating 6° Beaune would be worth per ton

But it is obvious that it would not pay a planter to sell canes at 4s. 2d. a ton instead of at 10s. a ton, any more than it would pay a factory to make only 62-2 tons of sugar in 24 hours, or 6220 tons in the crop of 100 days, instead of 10,000 tons. Hence arises the imperative necessity of good cultivation by the planter, and of circumcision in the purchase and acceptance of canes on the part of the manufacturer.

The details of manufacture of sugar from cane and of sugar from beetroot differ, but there are five operations in the production of the sugar of commerce from either material which are common to both processes. These are:

1. The extraction of the juice.
2. The purification or clarification of the juice.
3. The evaporation of the juice to syrup point.
4. The concentration and crystallization of the syrup.
5. The drying or production of the crystals for the market by separating the molasses from them.

Extraction of Juice.—The juice is extracted from canes by squeezing them between rollers. In India at the present day there are thousands of small mills worked by hand, through which the peasant cultivators pass their canes two or three times, in order to make a sufficient quantity of raw sugar. In Barbadoes there are still many estates making good Mascarbo sugar; but as the juice is extracted from the cane by windmills, and then concentrated in open kettles heated by direct fire, the financial results are disastrous, since nearly half the yield obtainable from the canes is lost. In the best organized modern cane sugar estates as much as 12½% of the weight of the canes treated is obtained in crystal sugar of high polarizing power, although in Louisiana, where cultivation and manufacture are alike more carefully and admirably carried out, the yield in sugar is only about 7½% of the parent material. The canes are also sometimes treated, but seldom, as much as 5%. This is due to conditions of climate, which are much more favorable for the formation of saccharine in the canes than in Cuba. The protection afforded to the planters by their government, however, enables them to pursue the industry with considerable profit, notwithstanding the poor return for their labour in saleable produce.

As an instance of the influence of climatic conditions combined with high cultivation the cane lands of the Sandwich Islands may be taken. Here the tropical heat is tempered by constant trade winds, there is perfect immunity from hurricanes, the soil is peculiarly suited for cane-growing, and by the use of specially-prepared formulae and an ample supply of water at command for irrigation the land yields from 90 to 100 tons of cane per acre, from which 12 to 14% of sugar is produced. To secure this marvellous return, with an annual rainfall of 26 in., as much as 52,000,000 gallons of water is pumped per 24 hours from artesian wells on one estate alone. With an inexhaustible supply of irrigation water obtainable, there is no reason why the lands in Upper Egypt, if scientifically cultivated and managed, should not yield as abundantly as those in the Sandwich Islands.
SUGAR

In the Paris Exhibition of 1900 a cane-crushing mill was shown with three rollers 32 in. in diameter by 60 in. long. It is driven by a powerful engine through triple gearing of 42 to 1, and speeded to have a surface velocity of rollers of 15 ft. 9 in. per minute. This mill is intended to crush thoroughly and efficiently from 250 to 300 tons of canes in 24 hours. In Louisiana two mills, set one behind the other, each with three rollers 32 in. in diameter by 78 in. long, and driven by one engine through gearing of 15 to 1, can have a surface velocity of rollers of 25 ft. 6 in. per minute (or 60% more than that of the French mill described above), and they are efficiently crushing 900 to 1200 tons of canes in 24 hours. In Mauritius, Demerara, Cuba, Java and Peru double crushing and maceration (first used on a commercial scale in Demerara by the late Hon. William Russell) have been generally adopted; and in many places, especially in the Hawaiian Islands, triple crushing is adopted. By passing the canes through three consecutive sets of rollers, in order to extract everything possible of extraction by pressure) is employed. In the south of Spain, in some favoured spots where sugar-canews can be grown, they are submitted even to four successive crushings.

It has been found in practice advantageous to prepare the canes for crushing in the mills, as above described, by passing them through a preparatory series of rollers which are grooved or indented in such manner as to draw in and flatten down the canes, no matter in which way they are thrown or heaped upon the cane-carrier, and thus prepare them for feeding the first mill of the series; thus the work of crushing is carried on uninterruptedly and without constant stoppages from the mills choking, as is often the case when the feed is heavy and the canes are not prepared.

Although it cannot be said that any one system of extraction is the best for all places, yet the following considerations are of general application:—

a. Whatever pressure be brought to bear upon it, the vegetable or woody fibre of the cane, containing the juice, is held and retinted of the moment a quantity of moisture equal to its own weight, and in practice 10% more than its own weight; or in other words, 100 lb. of the best crushed meglass will consist of 47-62 lb. of fibre and 52-38 lb. of moisture—that is, water with sugar in solution, or juice.

b. Canes vary very much in respect of the quality and also as to the quantity of the juice they contain. The quantity of the juice is the test to which recourse must be had in judging the efficiency of the extraction, while the quality is the main factor to be taken into account with regard to the results of subsequent manufacture.

For the application of the foregoing considerations to practice, the subjoined table has been prepared. It shows the greatest quantity of juice that may be expressed from canes, according to the different proportions of fibre they contain, but without employing maceration or imbibition, to which processes reference is made hereafter. The percentages are representative of the original weight of the uncrushed canes.

The British Guiana Planters' Association appointed a sub-committee to report to the West India Commission on the manufacture of sugar, who stated the following:—

With cane containing 12% fibre the following percentages of juice can be expected from it in the form of juice:

<table>
<thead>
<tr>
<th>Single crushing</th>
<th>Double crushing</th>
<th>Double crushing with 12% dilution</th>
<th>Triple crushing with 10% dilution</th>
<th>Diffusion with 25% dilution</th>
</tr>
</thead>
<tbody>
<tr>
<td>76%</td>
<td>85%</td>
<td>88%</td>
<td>88%</td>
<td>94%</td>
</tr>
</tbody>
</table>

These results are equivalent to 66-88% extraction for single crushing, 74-80% for double crushing, 77-74% for double crushing with 12% dilution, 79-70% for triple crushing, and 82-72% for diffusion with 25% dilution.

To prevent the serious loss of juice left in the meglass by even the best double and triple crushing, maceration or imbibition was introduced. The meglass coming from the first mill was saturated with steam and water, in weight equal to between 20% and 25% of its weight, and placed, in the case of fresh sugar-canes, to drive away any added water, but a limit was imposed by the fact that water might be used in excess. Hence in the latest designs for large factories it has been proposed that as much normal juice as can be crushed at one time shall be added to the meglass; and the meglass shall then be so mixed with twice as much water as there is juice remaining in it; after which, on being subjected to a third crushing, it will yield a degraded juice, which would also be treated by heating. It is found that in replacing the juice of these two qualities by syrup, full to pass to the vacuum pans for cooking to crystals, the total amount of evaporation from the degraded juice is about half that required from the normal juice produced by double crushing.

Great improvements have been made in the means of feeding the mills with canes by doing away with hand labour and substituting mechanical feeders. The simplest steam-driven mechanism will take the cane waggons on to the cane-carriers. By the adoption of this system in one large plantation in California, 7000 tons of canes were crushed in 24 hours; the labour of sixty-four hands was dispensed with, and was thus made available for employment in the fields. In Louisiana the use of the mechanical feeder for crushing purposes is very general.

With a view of safeguarding themselves from breakdowns caused by the inequality of feeding, or by the action of malicious persons introducing foreign substances, such as crowbars, bolts, &c., among the canes, machines were adopted—so-called hydraulic attachments, applied either to the meglass roll or the top roll bearings. These attachments, first invented by Jeremiah Howard, and described in the United States Patent Journal as a system of machinery whereby the hydraulic pressure is used against the top cap arrangement is, that if the volume or feed is large enough to lift the top roll from the cane roll, it will simultaneously lift it from the meglass roll, so that the meglass will not be as well pressed as it ought to be; and an objection to the side cap arrangement on the meglass roll as well as to the top cap arrangement is, that in case more cane is fed in at one end of the rolls than at the other, they cannot be pushed out at all. (The object of the hydraulic attachment is, and though it may thus avoid a breakdown of the rolls, it is apt, in so doing, to break the ends off the teeth of the crown wheels by putting them out of line with one another. The toggle-joint attachment, which is simply a cylindrical wooden wheel, with the same end as the hydraulic attachments, is open to the same objections.)

The preparation of cane juice by diffusion (a process more fully described under the head of beetroot sugar manufacture) is adopted in a few plantations in Java and Cuba, in Louisiana and the Hawaiian Islands, and in one or two factories in Egypt; but hitherto, except under exceptional conditions (as at Aska, in the Madras Presidency, where the local price for sugar is three or four times the London price), it would not seem to offer any substantial advantage over double or triple crushing. With the latter system practically as much sugar as is obtained from the canes by diffusion, and the resulting meglass furnishes, in a well-appointed factory, sufficient fuel for the crop. With diffusion, however, in addition to the strict scientific control of the temperature and time of maceration, there is a further danger that the wood—has to be provided for the working off of the crop, since the spent chips or slices from the diffusers are useless for this purpose; also that the cane is truly reduced to as small a mass as possible, and to a certain extent been utilized as fuel by mixing them with a portion of the molasses, otherwise which would have been sold or converted into rum. The best results from extraction by diffusion have been obtained when the cane is boiled. It is not difficult to give the cane good water; but in the Hawaiian Islands, and in Cuba and Demerara, diffusion has been abandoned on several well mounted estates and replaced by double and triple crushing; and it is not likely to be re-introduced again, because of the extra cost of working is made up by the slight increase of sugar produced. In Louisiana diffusion is successfully worked on two or three large estates; but the general body of planters are shy of using it, although there is no lack of water, the Mississippi being near at hand.

Purification.—The second operation is the coagulation of the amalgam, and the separation of it with other impurities from the
SUGAR

38

juice which holds them in suspension or solution. The moment
the juice is expelled from the cells of the cane chemical inver-
scum, and the sooner it is stopped the better. This is effec-
ted by the addition of lime to neutralize the free acid. As cold juice
has a tendency to separate into scums and scums, it is best to use
the juice with lime when cold. This is easily done in liming or measur-
ing tanks of known capacity, into which the juice is run from the mill.
The requisite amount of milk of lime set up at 10° Beunné is then
added. In Java and Mauritius, for example, 12° Beunné milk of lime
is sometimes used, and this is equivalent to 3° Beunné milk of lime.
It is a well-known fact that a weaker solution is preferable, since the proper proportion is more
easily adjusted. In Demerara and other places the juice is then
heat under pressure up to 220° F. to 250° F. on
the field, where the juice is then heated by the steam
due to the superheated juice flashes off, and is either utilized for
and the steam supplied to the multiple effect evaporators,
or it is allowed to escape into the atmosphere. The
boiling juice is run down into subasing tanks, where it cools, and
at the same time the albumen, which has been suddenly coagulated
by the heat, is allowed to settle in the tanks. The two
of the tank, carrying with it the vegetable and other matters which
were in suspension in the juice. After reposting some time, the
clear juice is carefully decanted by means of a pipe fixed by a swivel
joint to an outlet in the bottom of the tank, the upper end of the
pipe being always kept at the surface of the liquor by a float attached
to it. Thus clear liquor alone is run off, and the mud and cloudy
liquor which is left in the tank is left undisturbed, and discharged
separately as required.

In Australia a continuous juice separator is generally used, and
preferred to ordinary subasing or filtering tanks. It is a cylin-
derical vessel provided in its bottom with a central outlet of
about the same depth. Such a vessel is conveniently made of a diameter which will give
the required circulation speed at the required distance expressed
from the cane-mill in one hour. The hot liquor is con-
ducted downwards in a continuous steady stream by a central pipe
to eight horizontal branches, from which it issues into the separator at
the level of the junction of the cylindrical and conical portions
of the vessel. Since the specific gravity of hot liquor is less than
that of cold liquor, and since the specific gravity of the scum and
particles of solid matter in suspension separates itself from it and fall to the bottom
and is discharged from the separator. Thus the liquor in the separator is
distributed over a large area relatively to its volume, and while
this is necessarily effected with but little disturbance to the contents
of the vessel, a very slow velocity is ensured for the current of
heating and subasing. In a continuous separator of which the cylindrical
portion measures 13 ft. in diameter and 6 ft. deep (a suitable
size for treating a juice supply of 4000 to 4500 gallons per hour),
the upward current in the separator has a velocity of about 1 in. per hour
and it is found that all the impurities have thus ample time to
separate themselves. The clear juice when it arrives at the top
of the separator flows slowly over the level edges of a cross canal
and reaches the under side of two rotary scrapers, formed of L-irons,
which are turned and driven by a horizontal shaft provided with
a suitable handle. The scums then settle down to the bottom of the cone, whence they are run off to the scum tank. In large separators, the heat
is generated by steam generated in an open boiler, and this
steam being supplied to the separator, and the temperature
is maintained constant. In this apparatus the scums are more perfectly automatic, an arrangement for condensing and
to and mixing with the juice the proper proportion of milk of lime
has been adapted to it; and although it may be objected that once
the albumen has been coagulated, there is a great variation in the quality of the juice coming from the mill owing
to the variations that may occur in the cans fed into the mills,
it is obviously as easy to vary the proportion with the automatic
milk of lime, than to attempt the same by removing or adding
the scum. The separator is already installed in Martinique.

In Cuba, Martinique, Peru and elsewhere the old-fashioned
double-bottomed defecator is used, into which the juice is run
direct, and then limed and heated. This defecator is
made with a hemispherical copper bottom, placed in
an outer cast-iron casing; which forms a steam jacket,
and the juice runs into the bottom through a central pipe
of the bottom. If double-bottomed defecators are used in sufficient
number to allow an hour and a half to two hours for making
each defecation, one hundred and one hundred and
forty minutes are required to be filled up by the cane-mill with juice in ten to twelve minutes.

If double-bottomed defecators are used in sufficient
time to make a perfect defecation as is obtainable by us
system; but their employment involves the expenditure of much
higher proportion of heat. In Martinique, for example, the heat from the juice, already heated
enough through the small surface of the hemispherical bottom
also the use of filter presses for treating the scums. A great
deal of skill and superstition is also required, and first cost is
comparatively large. When a sufficient number of defecators
for a two hours' defecation, it is the practice in some factories to

powdered megass have been found very efficient for removing the large quantity of impurities contained in the juice expressed from the very vigorous but rank canes grown in that wonderfully fertile country, but unless constant care is taken, it will soon occasion the water in the vacuum pans to take on a smoky and inefficient appearance. To prevent this, there is great risk of inversion in taking place, with consequent loss of sugar.

After the juice has been defatted or purified by any of the means described in the former pages, it is then ready for evaporation, and the operation hereinafter described, where it is concentrated to 26° or 28° Baumé, and is then conducted in a continuous stream either into the service tanks of the vacuum pan, if dark sugars are required, or, if a bellow is used, into rectangular or rectangular vessels, holding from 500 to 1500 gallons each, according to the capacity of the factory, and fitted with steam coils at the bottom and skinning troughs at the top, for the purpose of degreasing the juice, is then made up to the water in the bellow and skinned for about five minutes, when it is run off to the service tanks of the vacuum pans. The heat at which the syrup boils in the clarifiers, 220°F., has the property of separating a great deal of the gum still remaining in it, and thus cleansing the solution of sugar and water for crystallization in the vacuum pans; and if after skinning the syrup is run into separators or subsiders of any description, and allowed to settle down and cool before being drawn into the vacuum pan for crystallization, this cleansing process will be more thorough and the quality of the final product will be improved. Whether the improvement will be profitable or not to the planter or manufacturer depends upon the class of the vacuum pan, and the conditions of foreign tariffs, which are not infrequently hostile.

Evaporation of the Juice to Syrup.—The third operation is the concentration of the approximately pure, but thin and watery, juice to the proportions and density of the sugar cane juice. The commonest method is to pass the water in vacuo through some system of heating and evaporation. Since on an average 70% by measurement of the normal defatted cane juice has to be evaporated in the vacuum pan, this is the most important and most essential part of the total operation necessary in large estates than the open-fire batteries still common in Barbados and some of the West Indian islands, and in small haciendas in Central America and Brazil, but seldom seen elsewhere. By the battery process, the juice is boiled until it was afterwards finished in the vacuum pan, very good sugar was produced, but at a cost that would be ruinous in to-day’s markets.

In the best days of the so-called Jamaican trains in the thirteenth-quarters of a ton of coal in addition to the megass was burned per ton of sugar made, and with this for many years planters were content, because they pointed to the fact that in the central factories, then working in Martinique and Guadeloupe, with charcoal filters and triple-effect evaporator, 750 kilos of coal in addition to the megass were consumed to make 1000 kilos of sugar. All this has now been changed. It is unquestionably better and easier to evaporate in the vacuum pan, and the best and most efficient is the work of Norberto Rilleux in New Orleans in 1840, under whom improvements are in progress every year. It was Rilleux who invented the multiple-effect evaporator, now syrup, and ready to enter the vacuum pan for further concentration and crystallization. In a patent (No. 3507, 1812) granted to E. C. Howard, the principle is that the most uncrystallizable in preference to that which is most crystallizable sugar, and the patentee speaks of “a discovery I have made that no solution, unless highly concentrated, of sugar has the quality of solution of the syrup, or of evaporating water, by which the sugar would not be dissolved, or to be exposed to its boiling temperature during the period required to evaporate such solution to the crystallizing point, and stated it was necessary to make a magma of sugar and water at atmospheric temperature, and heated the same to 190° or 200°F., in a water or steam bath, and then added more sugar or a thinner magma, and the whole being then in a state of imperfect fluidity, boiled as close readily behind the stirrer, was filled into moulds and purged” (drawn). “I do further declare,” he added, “that in the application of heat to the refining of sugar in my said invention or process I have stated and mentioned the temper- ature to be selected, and in the use of the said system of evaporators, at the time it would be dissolved, and by the addition of more and more sugar and water, applied in order to preserve and secure the colour and crystalliz- ability of the sugars, and most easily to be used with precision and uniformity by means of the water bath and steam bath, yet when the same have been condensed, separated, and crystallized, to make use of higher temperatures, although less beneficial.”

Howard at any rate saw clearly what was one of the indispensable requisites for the success of his construction the temperature in order to avoid the formation of soggy colloids—

the treatment of saccharine solutions at temperatures very considerably lower than 212°F., which is the temperature of water boiling at normal atmospheric pressure. Nor was he long in providing means for securing these lower temperatures. His patent (No. 3754 of 1813) describes the closed vacuum pan and the air pump with condenser for steam by injection, the use of a thermometer immersed in the solution in the pan, and a method of ascertaining the temperature of the solution with a proof stick, and by observations of the temperature at which, while fluid and not containing grain, it could be kept boiling under different pressures shown by a vacuum gauge. A table is attached of boiling points from 115°F. to 75°F., corresponding to decreasing power of the vacuum gauge. Since Howard published his invention the vacuum pan has been greatly improved and altered in shape and construction; multiple-effect evaporators have been added, and the advantage of the ideas that the best steam in vacuo having been acknowledged, the system has been adopted in many other industries, and streams of condensers have turned their attention to the principle. In endeavouring to make the best use of the air pump and the balance of power, they have imagined many ingenious mechanical contrivances, such as currents produced mechanically to promote evaporation and crystallization, feeding the pan from many points in order to prevent the feed from soiling the floor and getting cooked, and so on. All their endeavours have obtained at best but a doubtful success, for they have overlooked the fact that the most expensive apparatus is the steam from the vacuum pan at least an equal weight (or in practice about 15% more) of steam must be condensed, and the first cost of mechanical agitators, together with the expenditure they involve for motive power and
maintenance, must be put against the slight saving in the heating surface effected by their employment. On the other hand, the advocates of admitting the feed into a vacuum pan in many minute streams appeal rather to the ignorant and incomprehending, sugar-beet grower. The result is that, roughly, a batch of 10 tons of raw sugar is to be purged at 20 ft. per hour, or 150 tons of raw sugar in a pan in a few hours, feeding it through a single pipe and valve 10 in. in diameter. Nevertheless, in the light of experience, the second position has been gained in the contest of these two theories, and purity and high quotient of impurity are being treated, injecting the feed at a number of different points in the pan does reduce the time required to boil the pan, though of no practical advantage as regards the extent of the manipulation of the size, which impedes circulation and therefore quick boiling. Watt, when he invented the steam engine, laid down the principles on which it is worked, and the separate invention of Watt and fair from the vision of the man who carried them out. The vacuum pan is erected at a height which commands the crystalizers, each of which will, as in days gone by in Cuba, hold the contents of the pan, and these in their turn are set high enough to allow the charge to fall into the feeding-trough of the center. This obviating the necessity of any labour to remove the raw sugar from the time it leaves the vacuum pan to the time it falls into the centrifugals. For this reason alone, and without taking into consideration any increase in the yield of sugar brought about by "crystallization in movement," the system is worthy of adoption in all sugar factories making crystal sugar.

Crystalizers.

There exist two kinds of sugar, the cylindrical or semi-cylindrical vessels, fitted with a strong horizontal shaft running from end to end, which is kept slowly revolving. The shaft carries arms and blades fixed in such a manner that they strike the surface of the mass of syrup, and as a result the syrup is continually thrown back from the arms while at the same time a gentle but sustained evaporation is produced by the continuous exposure of successive portions of the mass to the action of the atmosphere. In this way the crystals already formed are continually maintained in a condition of growth, and not on the idiosyncrasy of the experts who manage them; and there is no doubt that in large commercial processes of manufacture the simpler apparatus used for obtaining a desired result, and the mechanical nicety with which it is carried on for the manufacturer. The sugar made from the first syrups does not require a crystallizer in movement to prepare it for purging in the centrifugals, but it is convenient to run the syrup into the crystallizer and so empty the pan at once and leave it ready to commence another strike, while the second syrups will be better for twenty-four hours' stirring and the third sugars for forty-eight hours' stirring before they are ready for the centrifugals. Electricity has been applied, with indifferent success, but they have been very efficiently driven, each independently of the other, and more yet, by means of a modification of a Pelton wheel, supplied with water from the river, it has been found that comparatively small stream strikes the wheel with a pressure equivalent to a great head, say 300 ft., and as the quantity of water is sufficiently large to keep the wheels and so on, the greatest ease and nicety, each machine can without danger be quickly brought up to its full speed when purging high-class sugars, or allowed to run slowly when purging low-class sugars, until the heavy, gummy molasses have been expelled; and it can then be brought up to its full speed for finally drying the sugar in the basket, a boon which all practical sugar-makers will appreciate. The vacuum forced by the force-pump against the Pelton wheels returns by a waste-pipe to the tank, from which the force-pump takes it again.

Recent Progress.—The manufacture of cane sugar has largely increased in volume since the year 1901-1902. This, apart from the effects of the tariff, allude to the abolition of the sugar duties. This result of the increased employment of improved processes, carried on in improved apparatus, under skilled supervision, and with due regard to the significance of the chemical aspects of the work. Numerous central factories have been established in the countries with plant of large capacity, and many of them work day and night for six days in the week. There were 173 of these factories working in the central factories and the "Chaparra," in the province of Oriente, turned out upwards of 60,000 tons of sugar in the crop of about 1908-1909, nearly all had efficient plant for treating the excellent canes grown in that favoured island. (See Jaarboek voor suiker-

Central Factories.
The use of multiple-effect evaporation made it possible to raise the steam for all the work required to be done in a well-equipped factory, making crystals, under skilful management, and necessary in any speed now known, have been used on a large scale for decades in Essex, ground without, the aid of other fuel. The bagasse so used is now commonly taken straight from the cane mill to be crushed, designed for burning it, in its moist state and without previous drying, obtaining the necessary heat from it to suitable boilers, such as those of the multitube type or of the water-tube type. The value of fresh bagasse, or as it is called in the sugar industry, bagasse with water from which it comes, with their treatment in the mill, and with the skill used in firing; but it may be stated broadly that 1 lb of fresh bagasse will produce from 1½ lb to 2½ lb of steam, according to conditions.

The use of preparing rolls with corrugations, to crush and equalize the feed of canes to the mill, or to the first of a series of mills, has been long known. The Krajewski crusher has two V-shaped steel rolls, with V-shaped corrugations extending longitudinally across them. These rolls run at a speed about 30% greater than the speed of the first mill, to which they deliver the canes well crushed and flattened, forming a close mat of pieces of cane 5 to 6 in. long, so that the subsequent grinding can be carried out without the stoppages occasioned by the mill chocking with a heavy and irregular feed. The crusher is preferably driven by an independent engine set at the same speed by the same engine.

The Krajewski crusher was invented some years ago by a Polish engineer resident in Cuba, who took out a patent for and sold it. The patent has expired. The crushing time in the output for a given time of crushing of the Krajewski crusher has been estimated at 20 to 25% and varies with the quality of the canes; while the yield of juice or extraction is increased by 1% to 1½%.

The process of continuous defecation which was introduced into Cuba from Santo Domingo about 1900 had by 1910 borne the test of some ten years' use with notable success. The method which is known for this purpose in France is well known and has been already described, but it may be mentioned that the regulation of the admission of steam is now simplified and secured by a patent thermostat—a self-acting apparatus in which the unequal expansion of steam and water is utilized, by heat, the steam being expanded, after by the introduction of compressed air, a diaphragm which controls the steam stop-valve—and by this means a constant temperature of 210° F. is maintained in the juice within the defecator during the whole time it is at work.

Earthly matter and other matter precipitated and fallen on the copper double bottom may be dislodged by a slowly revolving scraper—say every twelve hours—and ejected through the bottom discharge cock; and thus the heating surface of the copper bottom will be kept in full efficiency. With ordinary care on the part of the men in charge, Hatton defecators will work continuously, without a skilled attention to them; and all the advantages procurable from the use of Hatton defecators as follows:

- Cold liming; heating gently to the temperature required to coagulate the albumen and not beyond it, whereby disturbance would ensue; the continuous separation of the scums; the gradual drying of the scums so as to make them ready for the fields, without carrying away juice or requiring treatment in filter presses; and the continuous supply of hot defecated juice to the evaporators, without the use of subsiding tanks or eliminators; and, finally, the saving in expenditure on plant, such as filter presses, etc., and wages.

**Beetroot Sugar Manufacture.—** The sugar beet is a cultivated variety of *Beta maritima* (nat. ord. Chenopodiaceae), different varieties of which, under the name of mangold or mangel-wurzel, are known as feeding roots for cattle. About 1760 the Berlin apothecary Marggraff obtained in his laboratory, by means of alcohol, 6-2% from sugar from a white variety of beet and 4.5% from a red variety. At the present day, the cultivation of beet sugar has been subjected to a study of many years, the improvements of cultivation, the careful selection of the variety, the grading and manuring, especially with nitrate of soda, the average beet worked up contains 7% of fibre and 93% of juice, and yields in Germany 12-70% and in France 11-6% of its weight in sugar. In Great Britain in 1910 the cultivation of beet for sugar was being seriously undertaken in Essex, as the result of careful consideration during several years. The pioneer experiments on Lord Denbigh's estates at Newham Paddox, in Warwickshire, in 1900, had produced excellent results, both in respect of the weight of the beets per acre and of the saccharine value and purity of the juice. The average weight per acre was over 253 tons, and the mean percentage of pure sugar in the juice exceeded 15%. The roots were grown under exactly the same cultivation and conditions as a crop of mangel-wurzel—that is to say, they had the ordinary cultivation and manuring of the usual root crops. The weight per acre, the saccharine contents of the juice, and the quotient of purity compared favourably with the best results obtained in Germany or France, proportioned to those achieved in other countries, who between 1868 and 1872 supplied Mr Duncan's beetroot sugar factory at Lavenham; for the weight of their roots rarely reached 15 tons per acre, and the percentage of sugar in the juice appears to have varied between 10 and 12. On the best-equipped and most skilfully managed cane sugar estates, where the climate is favourable for maturing the cane, a similar return is obtained. Therefore, roughly speaking, one ton of beetroot may be considered to-day as of the same value as one ton of cane; the value of the refuse chips in one case, as food for cattle, being about one quarter of the value of the refuse bagasse, as fuel, in the other.

But beetroot had been brought to the very threshold of perfection, and while the factories for its manipulation were worked with hydraulic presses for squeezing the juice out of the pulp produced in the raperies, the cane sugar planter in the West Indies could easily hold his own, notwithstanding the artificial competition created and maintained by sugar bounties. But the degree of perfection attained in the cultivation of the roots and their subsequent manipulation entirely altered this situation and brought about the crisis in the sugar trade referred to in connexion with the bounties (see History below) and dealt with in the Brussels convention of 1902.

In beetroot sugar manufacture the operations are washing, slicing, diffusing, saturating, sulphuring, evaporation, concentration, and packaging.

**Slicing.—** The roots are brought from the fields by carts, canals and railways. They are weighed and then dumped into a washing machine, consisting of a large horizontal cage, submerged in water, in which revolves a horizontal shaft carrying arms. The arms are set in a spiral form, so that in revolving they not only stir the roots, causing them to rub against each other, but also force them forward from the receiving end of the cage to the other end. Here they are discharged (washed and freed from any adhering soil) into an elevator, which carries them up to the top of the building and delivers them into a hopper feeding the slicer. Slicers used to consist of a number of blades, generally 6, which were fitted with knives and made 140 to 150 revolutions per minute, under the hopper which received the roots. This hopper was divided into two parts by vertical division plates, and the roots were adjusted so that they fell simultaneously into the roots and sliced and pulped them. Such machines were good enough when the juice was expelled from the small and, so to speak, polysaccharides and pulp by means of hydraulic presses. But hydraulic presses have now been used in a large number of factories; the juice is universally obtained by diffusion, and the small slices have gone out of use, because the large amount of pulp they produced in proportion to slices is not suitable for the diffusion process, in which evenly cut slices are required, which present a much greater surface with far less resistance to the diffusion water. Instead of the small slicers, machines made on the same principle, but of large dimensions, 3 ft. in diameter and 5 ft. inside, with the necessary division plates for the knives, 50 to 100 revolution under the hopper, run at 140 to 150 revolutions the disks revolve only 60 to 70 times per minute. Such a slicer is capable of efficiently slicing 300,000 kilos of roots per hour, running for 8 hours, against being changed four times in that period, or often if required, for it is simply a series of cylinders from the moment the slices show by their rough appearance that the knives are losing their cutting edges.

**Diffusion.—** The second closed, vertical, cylindrical vessels, holding generally 60 hectolitres, or 1320 gallons, and are arranged in batteries of 12 to 14. Sometimes the cells are erected in a circle, so that the spout below the slicing machine revolving at 140 revolutions, comes into contact with the inside of the centre of any of the cells. In other factories the cells are arranged in rows and are charged from the slicer by suitable telescopic pipes, and other convenient means. A circular disposition of the cells facilitates charging by the use of a single one for them, but it renders the disposal of the hot spent slices somewhat
SUGAR

difficult and inconvenient. The ejection of the cells in straight lines may cause some little complications in charging, but it allows the hot spent slices to be discharged upon a travelling band which takes them to an elevator, an arrangement simpler than any which is practicable when the cells are disposed in a circular form, especially if the sugar mill is in a continuous action and each temperature cell has altered its battery in such manner that instead of having to open a large door below the cells in order to discharge them promptly, he opens a communications door and, as the liquid and gas are expelled, the possibility of the cell, blows the whole contents of spent slices up a pipe to the drying apparatus, thus saving not only a great deal of time but also a great deal of labour of a kind which is both arduous and dangerous, especially during cold weather. The cakes, sold as food for cattle, fetch as much as $4 per ton in Rumania, where four or five beetroot factories are now at work. A cell when filled with fresh slices becomes the head of the battery, and while skilled scientific and industrial help is required to adapt the process, the best and most economical way of heating the slices, previous to admitting the hot liquor from the next cell, is by direct steam; but as the slightest attention or carelessness in the admission of direct steam might have the effect of converting sugar and thereby causing the loss of some portion of saccharine in the slices, water heaters are generally used, through which water is passed and heated up previous to admitting the dried slices. When the cell is filled up and the slices are warmed through, the liquor from the adjoining cell, which hitherto has been running out of it to the saturators, is turned into the new cell, and beginning to displace the fresh slices, runs through the saturation in the normal way. When the new cell comes into operation and becomes the head of the battery, the first or tail cell is thrown out, and number two becomes the new tail cell; or vice versa, being emptied and one filled or charged with slices and heated up, the latter becoming the head of the battery as soon as it is ready.

Saturation.—The juice, previously treated with lime in the diffusion battery, flows thence into a saturator. This is a closed vessel, into which carbonic acid gas (produced as described hereafter, is formed, and combining with the lime in the juice forms carbonate of lime. The juice, thus filled with the clear acid, is run into a filter press, where the clear juice being run off for further treatment, while the carbonate of lime is obtained in cakes which are taken to the fields as manure. The principal improvement made of recent years is in the portion of the process has been the construction of pipes through which the carbonic acid gas is injected into the juice in such a manner that they can be easily withdrawn and a clean set substituted. The filter presses remain substantially unchanged, although many ingenious but slight alterations have been made in their details. The juice, which has now become comparatively clear, is again treated with lime, which is again run through a saturator and filter presses, and comes out still clearer than before. It is then treated with sulphuric acid gas, for the purpose of decolorization, again limed to neutralize the acid, and then passed through a third saturator. The process of saturation is continued until the juice is entirely unalloyed. The number of saturations with corresponding lime and carbonates with corresponding labour and plant only one is required. The coefficient of purity is increased and the viscosity of the juice diminished. The total saving effected is stated to be equivalent to 1.9 franes per ton of beetroot worked. This system is also being tried on a small scale with sugar-cane juice in the West Indies. If by this process a more perfect defecation is obtained, the juice, obtained by treatment, will have no doubt be highly beneficial to the greatest advantage for the processes of refining in lime can be effected, because but very little is used in a cane factory in comparison with the amount used in a beet factory.

Evaporation and Crystallisation.—The clear juice thus obtained is evaporated, and it is again run into a filter press and finally into a vacuum pan, and the sugar is purified in centrifuges. From the centrifuge the sugar is either turned out without washing as raw sugar, or can be further refined. It is well washed with a spray of water and air until white, and then it is hung in the market as refined sugar, although it has never passed through animal charcoal (bone-black). The processes of evaporation and crystallization are carried on as they are in a cane sugar factory, but with this advantage, that the beet solutions are free from impurities and glucose than those obtained from sugar-canes, and are therefore easier to cool.

Carrying.—There are various systems of carrying, so-called refined, sugar or centrifugal sugar, all designed with a view of obtaining the sugar in lumps or tabs, as to appear as if it had been turned out from moulds and not from centrifugals, and great ingenuity and large sums of money have been spent in perfecting these different systems, with more or less happy results. But the great achievement of recent manufacture is the production, without the use of animal charcoal, of a cheaper, but good and wholesome sugar, in rectangular blocks, which are carried as whole units and purposes, except for making preserves of fruits in the old-fashioned way. The domestic manufacturers of the present day use this sugar; they boil the jam in sucrose and secure a product that is more wholesome and blossoms the juice in the branches rather than being exposed for a short time to a greater heat. The commercial advantage of this method is the saving of gas and the time of heating, in lessening the time by one-half a day; in drier weather, the gas is not increased, but the process by which a leaf of cold is run into the highly limed juice in the saturators is made by the calculation of limestone in a klin provided with three cleaning doors, so arranged as to be allowed to pass from 30 to 40 per cent. of fresh water每次, in order to prevent the sugar from becoming too hot in the klin, the temperature is allowed to rise to about 185 degrees C. in three hours. The gas generated in the klin is taken off at the top by a pipe to a gas-washer. In this it passes through four sheets of water, by which it is not only freed from any dust and dirt that might have been introduced, but also cooled to a temperature which permits an air-pump to withdraw the gas from the klin, through the gas-washer, and force it into the saturators, without overheating. In some factories for refining sugar made from beet or cane this system of crystallization is used, and enables the refiner to work with syrups distinctly alkaline and to economize a notable amount of animal charcoal.

Refining.—Briefly, sugar-refining consists of melting raw or unrefined sugar with water into a syrup of 27° or 28° Beaumé, or 1230 specific gravity, passing it through filtering cloth to remove the unalloyed impurities, and boiling it in a mechanical suspension, and then through animal charcoal to remove any remaining matter and lime, thus producing a perfectly clear white syrup, which, cooked in the vacuum pan and crystallized, becomes the refined sugar of commerce.

Melting Pans.—The melting pans are generally circular vessels fitted with a perforated false bottom, on which the sugar to be melted is dumped. The pans are provided with steam worms to keep the mass hot, and hoods are fitted which enable a man to keep it in movement and thoroughly mixed with the water and sweet water which are added to the sugar to obtain a solution of the specific gravity desired. Any sand or heavy matter in suspension is allowed to fall to the bottom of the pan in a "sandbox" before the melted sugar is run off to the cloth filters. In a process employed with great success in some refineries the raw sugars are washed before being melted, and thus a purer article is obtained for subsequent treatment. In this process the raw sugar is mixed with a small amount of syrup so as to form a suitable magma, and is then run into a continuous centrifugal, which separates the debris and the syrup. When it has collected, it is run out, comparatively clean, into the melting pans described above.

Filters.—Tallay bag filters are generally used for clearing the magma, and for its mechanical impurities. They were introduced years ago by the company of the "Batey" in the West Indies. The filter presses are very different in construction to-day from what they were when first employed. They consist of tanks or cisterns fitted with "hoseback" or with the flat bag fitted. Frequently bagged is suspended in a suitable manner, and in some cases the jackets of the all by means of an arched band of cloth. The sugar or liquor to be filtered flows from the melting pans. The bags, though 60 in. or more in circumference, are folded up in such a way that a worker with about 84.5 inches around his neck can pass them over them. Thus a maximum of filtering surface with a minimum of liquor in each bag is obtained, and a far greater number of bags are got into a given area that would otherwise be possible, while the danger of bursting the bags by leaving them unsupported is avoided. As the liquor goes on filtering through the bags they gradually get filled up with slime and sludge, and the bags are very soon changed and the sugar or liquor of the new batch turned on to the other side of the bags and sheaths, and hot water supplied to them to wash out all the sweets they contain. Large doors at the side of the cisterns are then opened, and as soon as the bags are filled with the syrup and are thoroughly cleaned, the cistern is turned over and the contents run off in the open air above the mud tank. By this arrangement the work of a refinery can be carried on with about one-half the cisterns otherwise required, because, although it does not reduce the number of bags with about 84.5 inches, in a given amount of work, it enables the refiner to use one cistern twice a day with
Each arranged the Beaumé mystery to size cwt., uniform filled. long similar the removed. place fitted room, "in the have arranged to come to the cistern and are arranged to form the apparatus fitted with the Charleston cisterns or filters. These are large cylindrical vessels from 20 to 50 ft. high, and of such diameter as to hold a given quantity of animal charcoal (also called "bone-black" and "char") in pig, and which is diverted from the mother-liquor. The usual size of cistern forming a convenient unit is one that will hold 20 tons of char. Each cistern is fitted with a perforated false bottom, on which a blanket or specially woven cloth is placed, to receive the char which is poured in from the trace and packed as evenly as possible until the cistern is filled. The char is then "settled" by water being slowly run on to it, in order to prevent the mixing for channels and not permeating the whole mass evenly. The cistern being thus packed and settled is closed, and the syrup from the bag filters, heated up to nearly boiling point, is admitted at the top until the cistern is quite full. A considerable process of drainage, the cisterns being allowed to escape as it is displaced by the water or syrup. In some refineries this pipe, which is carried to a higher level than the top of the cistern, is fitted with a whistle which sounds as long as the passage is full of syrup. When this passes the char is allowed to be full, and the entrance of further water or syrup is stopped. The syrup in the cistern is allowed to remain for about twelve hours, by which time quantities absorbed all the colouring matter in it, as well as the time. A cistern of practical capacity of 10 tons of char will hold, in addition, about 10 tons of syrup, and after settling, this can be pressed out by allowing second quality syrup to wash in over the first. The syrup is then washed from the top, or it may be pressed out by boiling water. By carefully watching the flow of the discharge cock of the cistern the change from the first liquor to the next is easily detected. The washed liquor runs into both openings at the bottom of the cistern to escape as it is displaced by the water or syrup. A weak solution, called "sweet water," is sometimes used for melting the raw sugar, or it is evaporated in a multiple-effect apparatus to 27° Beaumé density, passed through the char filter, and cooked in the vacuum pan like the other liquors. After the sweets have come away, cold water is passed through the char until the new liquor or lime is found in it; then a large manhole at the bottom of the cistern is opened, the charcoal is removed. In most modern refineries the cisterns are so arranged that the spent char falls on to a travelling band and is conducted to an elevator which carries it up to the drying floor of the refinery.

Retorts for Reburning Char.—The kilns are made with either fixed or revolving retorts. The former perhaps produce a little better char, but cannot be worked automatically, require less labour and attention for an equal amount of working, and consequently have proved very satisfactory. From the drying floor on which the spent char is heated up it falls by gravitation into the retort. These are set in a kiln or oven, and are kept at as even a temperature as possible, corresponding to a dull cherry-red. Below each retort, and attached to it, is a cooler formed of thin sheet-iron, which receives the hot char as it passes from the retort, and at the bottom of the cooler is an arrangement of valves which permit a certain amount of char to drop out and no more. With the fixed retorts these valves are worked from time to time to continuous labour and attention, and make room in the retort for more space. In the newer type the retort is kept open, and the charge is kept going, and the whole of the work in connexion with the char is performed mechanically, with the exception of packing the filter cisterns with fresh char. The retort is divided into several bands, and the whole is divided into a number of bands. In former days, when refining sugar or "sugar balking" was supposed to be a mystery only understood by a few of the initiated, there was a place in the refinery called the "secret room." This was a square, or made up of small rooms, which was, however, it applies not to any room, but to a small copper cistern, constructed with five or six more divisions or small canals, into which all the charcoal cisterns discharge their liquors by passing them into the second or third opening. Each cistern is fitted with a cock and swivel, in such a manner that the liquor from the cistern can be turned into the proper division according to its quality.

Vacuum Pans and Receivers.—The filtered liquors, being collected in the various service tanks according to their qualities, are drawn from the vacuum pans and boiled to crystals. These are then discharged into large receivers, which are filled by means of pumps and stirrers, and from the receivers the cooled mass passes to the centrifugal machines. As in the beetroot factories, these machines are driven by steam, and the sugar is poured into it, and turn out sugar in lumps or tablets presenting an appearance similar to what of loaf sugar made in moulds, as this kind of sugar meets with the greatest demand. Granulated sugar, so called, is made by introducing the molasses into the vacuum pans, and is passed through a large and slightly inclined revolving cylinder with a smaller one inside heated by steam. The sugar fed into the upper end of the cylinder gradually works its way down to the lower, showering itself upon the warm roll, and thus being converted into granules. When passing out at the upper end, carries off the vapour produced by the drying of the sugar, and at the same time assists the evaporation. The dry sugar thus passes into a rotating screen fitted with two meshes, so that three grades of sugar are obtained, the coarsest being that which falls out at the lower end of the revolving screen.

Recent Improvements.—Systematic feeding for the vacuum pan and systematic washing of the massecuite have been recently introduced not only into refineries, but also into sugar houses or factories on plantations of both cane and beetroot, and great advantages have resulted from their employment. The first modification of the process of feeding the cisterns; the second, lowering the level of the massecuite; the third, introducing the vacuum pan with the richest syrup, and then as the crystals form and this syrup becomes thereby less rich the pan is fed with syrup of lower density, and so on till it is equal to that of the mother-liquor to which it is added, and so on till the syrup is reduced to the lowest possible. The systematic washing of the massecuite is the reverse of this process. When the massecuite, worked on different systems, but equally successful, is first washed with syrup of low density, to assist the separation of mother-liquor of similar quality, this washing being supplemented by the injection of pure syrup of high density, or "claire," which is thus termed secondary spirit. The following is an adopted system assert that, as compared with other methods, not only do they obtain an increased yield of sugar of better quality, but also they do so at a less cost for running their machines and with a reduced expenditure on fuel and other provisions, an important fact, as the French term for syrup of 27° to 30° Beaumé specially prepared from the purest sugar.

In the modern refineries in the details of sugar refining which have come into use in late years, it should be mentioned that loaf sugar made in conical moulds, and sugars made otherwise, to resemble loaf sugar, have practically disappeared from the trade, having been replaced by cube sugar, which is found to be more economical as subject to less waste by grocers and housekeepers, and also less troublesome to buy and sell. Its manufacture was introduced into England many years ago by Messrs Henry Tate & Son, and is now generally adopted all over the world. The process and apparatus patented in March 1890 by M Gustave Adant, a foreman sugar refiner of Brussels.

The modern kiln is a combination of the process and apparatus, as communicated by the courtesy of Messrs. Henry Tate & Son.

Groups of cells or moulds are built within and against a cylindrical iron casing, by means of vertical plates inserted in grooves and set in the bottom of the casing. The moulds are inserted, or are made to turn out a slab of sugar about 14 in. long—this being about the height of the cell—and about 8 in. wide and about 3 in. to 4 in. thick. By means of a travelling crane the casing is placed within an iron drum, to which it is secured, and then is brought under an overhead vacuum pan, from which the cells are filled with masseeuite. After cooling, the casing is lifted out of the drum by a crane, assisted by compressed air, and is then conveyed by a travelling crane to a vertical centrifugal, inside of which it is made fast. Suitable provision is made for the egress of syrup from the masseeuite in the cells when undergoing purging in the centrifugal, and the efflux is divided by a fan-like division of injection of refined syrup and completed by that of "claire." When this is done, the casing is hoisted out of the centrifugal and the vertical plates and the slabs of sugar are extracted. The slabs are conveyed through a horizontal conveyor machine, by which cutting machine, provided with knives so arranged that the cutting takes place both downwards and upwards, and here the slabs are cut into cubes. The cubes fall from the cutting machine on to a conveyor machine, which sets them in rows, one to a row, in size from the rest. These latter pass to automatic weighing machines, which drop them, in quantities of 1 cwt., into wooden boxes of uniform measurement, made to contain that weight; and the boxes are then conveyed to the storehouse, ready for sale.

History and Statistics.—Strabo xv. i. 20, has an inaccurate notice from Nearchus of the Indian honey-bearing reed, and various classical writers of the first century of our era notice the sweet sap of the Indian reed or even the granulated salt-like product which was imported from India, or from Arabia
and Opone (these being entrepôts of Indian trade), under the name of saccharum or ἁῦκαρος (from Skr. sarkara, gravel, sugar), and used in medicine. The art of boiling sugar was known in Gangetic India, from which it was carried to China in the first half of the 7th century; but sugar refining cannot have then been known, for the Chinese learned the use of ashes for this purpose only in the Mongol period, from Egyptian visitors. The cultivation of the cane in the west spread from Khūtīzān in Persia. At Gūndē-Shāpur in this region sugar was prepared with art 1 about the time of the Arab conquest, and manufacture on a large scale was carried on at Shuster, Sūs and Askar-Mokram throughout the middle ages. It has been plausibly conjectured that the art of sugar refining, which the farther East learned from the Arabs, 2 was developed by the famous physicians of this region, in whose pharmacopoeia sugar had an important place. Under the Arabs the growth and manufacture of the cane spread far and wide, from India to Sūs in Morocco (Edrīsī, ed. Dozy, p. 62), and were also introduced into Sicily and Andalusia.

In the age of principal food staples sugar became the great disseminators of the cultivation of sugar; the cane was planted in Madeira in 1420; it was carried to San Domingo in 1494; and it spread over the occupied portions of the West Indies and South America early in the 16th century. Within the first twenty years of the 16th century the sugar trade of San Domingo expanded with great rapidity, and it was from the dues levied on the imports brought thence to Spain that Charles V. obtained funds for his palace-building at Madrid and Toledo. In the middle ages Venice was the great European centre of the sugar trade, and towards the end of the 17th century a Venetian citizen received a reward of 100,000 crowns for the invention of the art of making loaf sugar. One of the earliest references to sugar in Great Britain is that of 100,000 lb of sugar being shipped to London in 1319 by Tomasso Loredano, merchant of Venice, to be exchanged for wool. In the same year there appears in the accounts of the chamberlain of Scotland a payment at the rate of 18. 9½d. per lb for sugar. Throughout Europe it continued to be a costly luxury and article of medicine only, till the increasing use of tea and coffee in the 18th century brought it into the list of principal foods. The increase in the consumption is exemplified by the fact that, while in 1700 the amount used in Great Britain was 10,000 tons, in 1800 it had risen to 150,000 tons, and in 1885 the total quantity used was almost 1,100,000 tons.

In 1747 Andreas Sigismund Marggraf, director of the physical classes in the Academy of Sciences, Berlin, discovered the existence of common sugar in beetroot and in numerous other fleshy roots which grow in temperate regions. But no practical use was made of the discovery during his lifetime. The first to establish a beet-sugar factory was his pupil and successor, Franz Carl Achard, at Cunern (near Breslau) in Silesia in 1801. The processes used were at first very imperfect, but the extraordinary increase in the price of sugar on the Continent caused by the Napoleonic policy gave an impetus to the industry, and beetroot factories were established at many centres both in Germany and in France. In Germany the enterprise came to an end almost entirely with the downfall of Napoleon I.; but in France, where at first more scientific and economical methods of working were introduced, the manufacturers were able to keep the industry alive. It was not, however, till after 1830 that it secured a firm footing; but from 1840 onwards it advanced with giant strides.

It was the bounty system, by which the protectionist countries of Europe stimulated the beet sugar industry by bounties on exports, the production of sugar in bounty-paying countries was encouraged and pushed far beyond the limits it could have reached without state aid. At the same time the consumption of sugar was greatly restricted owing to the heavy excise duties imposed mainly to provide for the payment of the bounties. The very large quantity of output made available for export under these exceptional conditions brought about the flooding of the British and other markets with sugars at depressed prices, not unfrequently below the prime cost of production, to the harassment of important industries carried on by British refiners and sugar-growing colonies. In these circumstances, the British government sent out invitations on the 2nd of July 1887 for an international conference to meet in London. The conference met, and on the 30th of August 1888 a convention was signed by all the powers represented except France—namely, by Austria, Belgium, Germany, Great Britain, Italy, the Netherlands, Russia and Spain. France withdrew because the United States was not a party to it. The first article declared that "The high contracting parties engage to take such measures as shall constitute an absolute and complete guarantee that no open or disguised bounty shall be granted on the manufacture or exportation of sugar." The seventh article provided that bountied sugars (sucres primés) must be excluded from import into the territories of the signatory powers, by absolute prohibition of entry or by levying thereon a special duty in excess of the amount of the bounties, from which duty sugars coming from the contracting countries, and not bounty-fed, must be free. The convention was to be ratified on the rat of August 1890, and was to be put in force on the 1st of September 1892.

The convention of 1888 was never ratified, and it is doubtful whether its ratification was urged, for a bill introduced by the British government in 1889 to give it effect was not pressed, and it was manifest that there was hesitation—which presently became refusal—to uphold the policy of the penalties on the importation of bountied sugar imposed by the seventh article, without which the convention would be so much waste paper.

Eight years later, on the 1st of August 1896, the bounties offered by the governments of Germany and Austria-Hungary were approximately doubled, and France had a bill in preparation to increase hers correspondingly; although it was computed that they were even then equivalent to a grant of £3. 5s. per ton. So wrote Mr Chamberlain, the colonial secretary, on the 9th of November following, to the treasury. The minute plainly stated that it had become a question whether the continued enjoyment of advantages resulting from the importation of cheap bounty-fed sugar to some British industries did not involve the ruin of the British sugar-producing colonies; and that he was not prepared, as secretary of state for the colonies, to accept the responsibility of allowing matters to take their course and to acquiesce in the policy of non-intervention hitherto pursued in regard to the colonies without having satisfied himself as to what such a policy might entail as to the colonies and the exchequer. Mr Chamberlain concluded by asking whether the treasury would consent to sending a royal commission to the West Indies to inquire into the effect of the foreign sugar bounties on their principal industry.

The treasury accepted the proposal, and a royal commission proceeded to the West Indies in December 1896, and reported a few months later in 1897. Only one commissioner, however, denounced the bounties as the real cause of the utter breakdown of trade and of the grievous distress which all three had witnessed.
SUGAR

The full text in French, with an English translation, of the Sugar Convention, signed at Brussels on the 5th of March 1902 by plenipotentiaries of the governments of Germany, Austria-Hungary, Belgium, Spain, France, Great Britain, Italy, the Netherlands, and Sweden, will be found in a return presented to parliament in April 1902 (Miscellaneous, No. 5, 1902, Cd. 1013).

Table I.—Amounts (reduced to English money per cwt. avoiding due to the total net sugar bounties granted by European powers according to the computation issued by the secretary of the United States treasury on the 12th of December 1898.

Sir H. Bergene reported on the 27th of July 1907 to Sir Edward Grey that—

"The permanent session had met in special session on the 25th of July, to consider the suggestion of His Britannic Majesty's government to the effect that, if Great Britain could be relieved from the obligation to enforce the penal provisions of the convention, they would be prepared to give notice on the 1st of September next of their intention to withdraw from the 1st of September 1908 a notice which they would otherwise feel bound to give at the appointed time," and he added that "At this meeting, a very general desire was expressed that, in these circumstances, arrangements should, if possible, be made which would permit Great Britain to remain a party to the Sugar Convention."

On the 1st of August 1907 the Belgian minister in London transmitted to Sir Edward Grey a draft, additional act prepared by the commission for carrying out the proposal of His Britannic Majesty's government, and on the 28th of August following an additional act was signed at Brussels by the plenipotentiaries of the contracting parties, by which they undertook to maintain the convention of the 5th of March 1902 in force for a fresh period of five years.

On the 2nd of December 1907 Sir H. Bergene wrote to the foreign office from Brussels, reporting that a special session of the permanent commission, established under the sugar bounties convention, had opened on the 18th of November, and the principal matter for its consideration had been the application of Russia to become a party to the convention on special terms. A protocol admitting Russia to the sugar convention was signed at Brussels on the 16th of December 1907.

Sir A. H. Hardinge on behalf of Great Britain made the following declaration:

"The assent of His Majesty's government to the present protocol is limited to the provisions enabling Russia to adhere to the convention, and does not imply assent to the stipulation tending to restrict the importation of Russian sugar."

When, in April 1908, Mr. Asquith became premier, and Mr. Lloyd George chancellor of the exchequer, the sugar convention...

The matter temporarily dropped, but certain Liberal members of parliament continued to press for the withdrawal of Great Britain from the convention, it being stated that a promise had been privately given by Sir Henry Campbell-Bannerman that the government would withdraw as soon as practicable. On the 15th of July 1908, Mr Asquith said that Sir Edward Grey had announced in the House of Commons on the 6th of June 1907 that the British government intended to negotiate with the powers for the renewal of the convention, on condition that they would relinquish the penal clause, and that none of the obligations in the convention as renewed were penal or required statutory authority.

Tables II., III. (p. 773) and IV. (p. 774) give statistics of cane and beet sugar production. The quantities for India have been computed from information furnished by the India office, and publications made under authority of the secretary of state and the commercial intelligence department of the Indian government.

The whole of the sugar produced in India is consumed in the country and sugar is imported, the bulk of it being cane sugar coming from Mauritius and Java, and about 85% of the import is of high quality resembling refined sugar.
It would appear that the purchasing power of the inhabitants of India has increased of late years, and there is a growing demand for refined sugar, fostered by the circumstance that modern processes of manufacture can make a quality of sugar, broadly speaking, equal to sugar refined by animal charcoal, without using charcoal, and so the religious objections to the refined sugars of old days have been overcome. (A. C.; V. W. C.)

SUGAR-BIRD, the English name commonly given in the West India Islands to the various members of the genus Cethioidea (belonging to the Passerine family Corvicideae!) for their habit of frequenting the curving-houses where sugar is kept, apparently attracted thither by the swarms of flies. They often come into dwelling-houses, hopping from one piece of furniture to another and carefully exploring the surrounding objects with intent to find a spider or insect. In their figure and motions they remind a northern naturalist of a nuthatch, while their coloration—black, yellow, olive, grey and white—recalls to him a titmouse. They generally keep in pairs and build a domed but untidy nest, laying therein three eggs, white, blotched with rusty-red. Many species are recognized, some of them with a very limited range; three are continental, with a joint range extending from southern Mexico to Peru, Bolivia and south-eastern Brazil, while others are peculiar to certain of the Antilles, and several of them to one island only. Thus C. caboti is limited, so far as is known, to Cozumel (off Yucatan), C. tricolor to Old Providence and the Bahamas, C. flaneola (the type of the genus) to Jamaica and so on, while islands that are in sight of one another are often inhabited by different "species". The genus furnishes an excellent example of the effects of isolation in breaking up an original form, while there is comparatively little differentiation among the individuals which inhabit a large and continuous area. The non-appearance of this genus in Cuba is very remarkable. (A. N.)

SUGER (c. 1062-1151), French ecclesiastic, statesman and historian, was born of poor parents either in Flanders, at St Denis, or at TOURS. In 1111 he entered the abbey of St Denis. Until about 1104 he was educated at the priory of St Denis de l'Estre, and there first met his pupil King Louis VI. From 1104 to 1106 Suger attended another school, perhaps that attached to the abbey of St Benoît-sur-Loire. In 1106 he became secretary to the abbot of St Denis. In the following year he was made provost of Bernevail in Normandy, and in 1109 of Tourn. In 1118 he was sent by Louis VI. to the court of Pope Gelasius II. at Magnaguelle, and lived from 1121 to 1122 at the court of his successor, Calixtus II. In 1127 he was appointed treasurer and in 1128 abbot of St Denis. Until 1127 he occupied himself mainly with the temporal affairs of the kingdom, while during the following decade he devoted himself to the reorganization and reform of St Denis. In 1137 he accompanied the future king, Louis VII., into Aquitaine on the occasion of that prince's marriage to Eleanor of Aquitaine, and during the second crusade was one of the regents of the kingdom (1147-1149). He was bitterly opposed to the king's divorce, having himself advised the marriage. Although he disapproved of the second crusade, he himself, at the time of his death, on the 31st of January 1151, was preaching a new crusade.

Suger was the friend and counsellor both of Louis VI. and Louis VII. He urged the king to destroy the feudal bandits, was responsible for the royal tactics in dealing with the communal movements, and endeavoured to regularize the administration of justice. He left his abbey, which possessed considerable property, enriched and embellished by the construction of a new church built in the nascent Gothic style.

Suger was the foremost historian of his time. He was the author of a panegyric on Louis VI. (Vita Ludovici regis), and part-author of the perhaps more impartial history of Louis VII. (Historia gloriosi regis Ludovici). In his Liber de rebus in administratione sua gestis, and its supplement Libellus de consecratione ecclesiae S. Dionysii, he treats of the improvements he had made to St Denis, describes the treasure of the church, and gives an account of the rebuilding. Suger's works served to imbue the monks of St Denis with a taste for history, and called forth a long series of quasi-official annals. See O. Clerissel Les A. Suger von Saint-Denis (Berlin, 1898); A. Luchaire, Louis le Gros (Paris, 1890); F. A. Gervaise, Histoire de Suger (Paris, 1721).

SUGGESTION. By the older British writers on psychology the words "suggest" and "suggestion" were used in senses very close to those which they have in common speech; one idea was said to suggest another when it recalled that other to mind or (in the modern phrase) reproduced it. Modern studies in mental pathology and hypnotism (q.v.) have led to the use of these words by psychologists in a special and technical sense. The hypnotists of the New School rediscovered the doctrine that the most essential feature of the hypnotic state is the unquestioning obedience and docility with which the hypnotized subject accepts, believes, and acts in accordance with every command or proposition of the hypnotizer. Commands or propositions made to the subject (they may be merely implied by a gesture, a glance, or a chance remark to a third person) and accepted with this peculiarly uncritical and intense belief were called "suggestions"; and the subject that accepted them in this fashion was said to be "hypnotizable." It has also been made abundantly clear, chieflу by the labours of French physicians, that a high degree of "suggestibility" is a leading feature of hysteria, and that this fact is the key to the understanding of very many of its protean manifestations.

It is also becoming widely recognized that the suggestibility of hypnosis and of hysteria is conditioned by a peculiar state of the brain, namely a cerebral or mental dissociation, which in hypnosis is temporarily induced by the operations of the hypnotist, and in hysteria arises from some deficiency of energy in the whole psycho-physical system. In respect to these points there is now a wide consensus of opinion on the leading authorities; but as to the range and scope of suggestion in our mental life great differences of opinion still obtain. We may distinguish three principal views. Firstly, it is maintained by a number of physicians (notably by Professor Pierre Janet, whose profound studies of hysterical patients are justly celebrated) that all hypnotizable persons are hysterical and that suggestibility is a condition peculiar to hysterical subjects. In view of the assertions in recent years of several physicians of high repute to the effect that they find more than 90% of all subjects hypnotizable, it would seem that this view cannot be maintained, and that this restriction of suggestion to hysterical subjects only, and the stigmatization of suggestibility as in every case a morbid symptom, are errors arising from too exclusive occupation with its manifestations in this field. A second group consists of writers who admit that suggestion may operate in normal minds, but who, while recognizing that it is not an essentially pathological process, maintain that it is a process of very peculiar and exceptional nature that has little or no affinity with normal mental operations. They hold that suggestion, whether it occurs in morbid or in healthy subjects, always implies the coming into operation of some obviously conceived faculty or region of the mind, which is not in all men, but which usually lies hidden or submerged beneath the flow of our more commonplace mental activities. This submerged faculty or system of faculties, which is held by these authors to be operative in all processes of suggestion, is variously designated by them the secondary or submerged stratum of consciousness, the subconscious or subliminal self (see SUBLIMINAL SELF). The writers of this group insist upon the more startling of the effects producible by suggestion, the more profound changes of bodily and mental processes, such as paralysis,1

1 Known in French as Guignis, a name used for them also by some English writers. The Guignis of Hernandez (Rer. medic. N. hist. thesaurus, p. 56), a name said by him to be of native origin, can hardly be determined, though thought by Montelland (Hist. nat. oiseaux, v. 359) to be what is now known as Corvëa caercula, but that of later writers is C. cyanea. The name is probably from the Greek, and very likely analogous to the "quit" applied in Jamaica to several small birds.
contracture, hyperaesthesia, increased power of recollection, hallucinations (q.v.), &c.; and they regard dissociation as the process by which the submerged and supernormal faculty (or faculties) that they postulate is liberated from the dominance of the normal waking self.

A third view has been rapidly gaining ground and is now predominant. It connects itself with, and bases itself upon, the view of Professor Bernheim and his colleagues of the Nancy school of hypnotism. According to this view all men are normally suggestible under favourable conditions, and the hypnotic subject and the hysterical patient differ from the normal human being chiefly in that their normal suggestibility is more or less (sometimes very greatly) increased, owing to the prevalence of the state of cerebral dissociation.

According to this third view, suggestion may be defined as the communication of any proposition from one person (or persons) to another in such a way as to secure its acceptance with conviction, in the absence of adequate logical grounds for its acceptance. The idea or belief so introduced to the mind of the recipient is held to operate powerfully upon his bodily and mental processes in proportion to the degree of its dominance over all other ideas or mental processes; and the extraordinary character of the effects, both bodily and mental, of suggestion in hypnotic and hysterical subjects is held to be due to the fact that, in these conditions of mental dissociation, the dominance of the suggested idea is complete and absolute; whereas in the absence of such dissociation the operation of the suggested idea is always subject to the weakening or inhibition through the influence of many opposed or incompatible tendencies and ideas, even if these do not rise into explicit consciousness.

This third view seems justified by the facts that no sharp line can be drawn between the suggestibility of normal men and that of hypnotized or hysterical subjects, and that under favourable conditions many of the most striking results of suggestion (e.g. hallucinations, contractures, inactivity to move, insensibility of various sense-organs, and so forth) may be produced in subjects who present at the time no other symptom of the hypnotic or hysterical condition.

If, then, we recognize as we must, that the alogical production of conviction is the essence of suggestion, and that this frequently occurs in normal minds as well as in those suffering from various degrees of dissociation, it becomes necessary to define the conditions that favour the operation of suggestion in normal minds.

These conditions are resident, on the one hand, in the recipient of the suggestion, and, on the other hand, in the source from which the suggestion comes. Of the conditions of the former class three seem to be of principal importance.

(a) Defect of knowledge: the defect may be quantitative or qualitative, i.e. it may consist in the lack of knowledge of or firmly established beliefs about the subject of the proposition, or it may consist in the lack of systematic organization of such knowledge as the mind possesses. The well-trained mind is relatively insuggestible, firstly because it possesses large stores of knowledge and belief; secondly, because this mass of knowledge and belief is systematically organized in such a way that all its parts hang together and mutually support one another. On the other hand, the young child, the uncultured adult, and especially the savage, are apt to be suggestible in regard to very many topics, first, because they have relatively little knowledge; secondly, because what little they have is of a low degree of organization; i.e. it does not form a logically coherent system whose parts reciprocally support one another. Suggestion in such cases may be said to be conditioned by primitive credulity or the suggestibility of ignorance. (b) But the same person will not be found to be equally suggestible at all times under similar external conditions. There are changes of mental state which, without overstepping the limits of the normal, condition varying degrees of increased suggestibility. A man is least suggestible when his mind works most efficiently, when he is most vigorous and most wide awake; every departure from this state, due to fatigue, bodily ill-health, emotional perturbation, drugs or any other cause, favours suggestibility. (c) Persons of equal degrees of knowledge or ignorance will be found, even at their times of greatest mental efficiency, to be unequally suggestible owing to differences of native disposition; one person is by nature more open than another to personal influence, more easily swayed by others, more ready to accept their dicta and adopt their opinions for his own. Differences of this kind are probably the expression of differences in the inherent capacity of one of the fundamental instinctive dispositions of the human mind, an instinct which is called into play by the presence of persons of superior powers and the excitement of which throws the subject into an attitude of submission or subjection towards the impressive personality.

Considered from the side of the agent, suggestion is favoured by whatever tends to render him impressive to the subject or patient—great bodily strength or stature, fine clothes, a confident manner, superior abilities of any kind, age and experience, any reputation for special capacities, high social position or the occupation of any position of acknowledged authority; in short, all that is summed up by the term “personality,” all that contributes to make a personality “magnetic” or to give it prestige renders it capable of evoking on the part of others the submissive suggestible attitude. A group of persons in agreement is capable of evoking the suggestible attitude far more effectively than any single member of the group, and the larger the group the more strongly does it exert this influence. Hence the suggestive force of the popularly accepted maxims and well-established social conventions; such propositions are collective suggestions which carry with them all the immense collective prestige of organized society, both of the present and the past; they embody the wisdom of the ages. Thus, the main through the suggestive power of moral maxims, endowed with all the prestige of great moral teachers and of the collective voice of society, that the child is led to accept with but little questioning the code of morals of his age and country; and the propagation of all religious and other dogma rests on the same basis. The normal suggestibility of the child is thus a principal condition of its docility, and it is in the main by the operation of normal suggestion that society moulds the characters, sentiments, and beliefs of its members, and renders the mass of its elements harmonious and homogeneous to the degree that is a necessary condition of its collective mental life. Normal suggestion produces its most striking effects in the form of mass-suggestion, i.e. when it operates in large assemblies or crowds, especially if the members have but little positive knowledge and culture. For, when a belief is propagated by collective suggestion through the large mass of men, each falls under the suggestive sway of the whole mass; and under these conditions the operation of suggestion is further aided by the universal tendency of mankind to imitation and sympathy, the tendency to imitate the actions of, and to experience the emotions expressed by, those about one.

Conditions very favourable to mass-suggestion prevailed during the middle ages of European history; for these "dark ages" were characterized by the existence of dense populations, among whom there was free intercourse but very little positive knowledge of nature, and who were dominated by a church wielding immense prestige. Hence the frequent and powerful operations of suggestion on a large scale. From time to time fantastic beliefs, giving rise to most extravagant behaviour, swept over large areas of Europe like virulent epidemics—epidemics of dancing, of flagellation, of hallucination, of belief in the miraculous powers of relics or of individuals, and so forth. In these epidemics all the conditions favourable to normal suggestion were generally present in the highest degree, with the result that in great numbers of persons there were produced the more extreme effects of suggestion, such as are usually associated with the hysterical or hypnotic state. At the present time similar manifestations occur in a modified form, as e.g. the popular pilgrimages to Lourdes, Holywell and other places that from time to time acquire reputations for miraculous curative powers.

Auto-suggestion.—Although auto-suggestion does not strictly fall under the definition of suggestion given above, its usage to
denote a mental process which produces effects very similar to those producible by suggestion is now so well established that it must be accepted. In auto-suggestion a proposition is formulated in the mind of the subject rather than communicated from another mind, and is accepted with conviction in the absence of adequate logical grounds. Generally the belief is initiated by some external event or some bodily change, or through some interpretation of the behaviour of other persons; e.g. a man falls on the road and a wagon very nearly passes over his legs, perhaps grazing them merely; when he is picked up, his legs are found to be paralysed. The event has induced the conviction that his legs are seriously injured, and this conviction operates so effectively as to realize itself. Or a savage, suffering some slight indisposition, interprets the behaviour of some person in a way which leads him to the conviction that this person is compassing his death by means of magical practices; accordingly he lies down in deep despondency and, in the course of some days or weeks, dies, unless his friends succeed in buying off, or in some way counteracting, the malignant influence. Or, as a familiar and trivial instance of auto-suggestion, we may cite the case of a man who, having taken a bread pill in the belief that it contains a strong purgative or emetic, realizes the results that he expects.

**SUHL,** a town of Germany, in the province of Prussian Saxony, picturesquely situated on the Lauter, on the southern slope of the Thuringian Forest, 63 m. N.E. of Meiningen and 29 m. S.W. of Erfurt by rail. Pop. (1905), 13,814. The armourers of Suhl are mentioned as early as the 9th century, but they enjoyed their highest vogue from 1530 to 1634. The knights of south Germany especially prized the swords and armour of this town, and many of the weapons used in campaigns against the Turks and in the Seven Years' War are said to have been manufactured at Suhl. It has suffered considerably in modern times from the competition of other towns in this industry, especially since the introduction of the breech-loading rifle. It still contains, however, large factories for firearms military and sporting, and side arms, besides ironworks, machine-works, potteries and tanneries. The once considerable manufacture of fustian has declined. A brine spring (Soolquelle) at the foot of the neighboring Dominican is said to have been given to the town by St. Stephen, which obtained civic rights in 1527, belonged to the principality of Hennepen, and formed part of the possessions of the kingdom of Saxony assigned to Prussia by the Congress of Vienna in 1815.

**SUICIDE** (from Lat. *suici*, of oneself, and *cidium*, from caedere, to kill), the act of intentionally destroying one's own life. The phenomenon of suicide has at all times attracted a large amount of attention from moralists and social investigators. Its existence is looked upon, in Western civilization, as a sign of the presence of maladies in the body politic which, whether remediable or not, deserve careful examination. It is, of course, impossible to compare Western civilization in this respect with, say, Japan, where suicide in certain circumstances is part of a distinct moral creed. In Christian ethics and Christian law it is wrong, indeed illegal, as a *felo de se*, self-murder. It is within comparatively recent years that the study of suicide by means of the vital statistics of various European countries has demonstrated that while the act may be regarded as a purely voluntary one, yet that suicide as a whole conforms there to certain general laws, and is influenced by conditions other than mere individual circumstances or surroundings. Thus it can be shown that both causes and results of suicide differ from what they are for each country may fluctuate from year to year, yet it maintains practically the same relative proportions to the rates of other countries. The following table shows the suicide-rate for various European countries (Bertillon):—

**Table I.**

In addition to furnishing materials for an approximately accurate estimate of the number of suicides which will occur in any country in a year, statistics have demonstrated that the proportion of male to female suicides is practically the same from year to year, viz. 3 or 4 males to 1 female; that it is possible to predict the month of greatest prevalence, the modes of death adopted by men on the one hand and women on the other, and even the relative frequency of suicide amongst persons following different professions and employments; and that in most of the countries of Europe the suicide-rate is increasing. In England and Wales the annual death-rate per million from suicide has steadily advanced, as is shown by the following figures for quinquennial periods—

</table>

The reason of the high suicide-rate in some countries as compared with others, and the causes of its progressive increase, are not easily determined. Various explanations have been offered, such as the influence of climate, the comparative prevalence of insanity, and the proportionate consumption of alcoholic drinks, but none satisfactorily accounts for the facts. It may, however, be remarked that suicide is much more common amongst
Protestant than amongst Roman Catholic communities, while Jews have a smaller suicide-rate than Roman Catholics. A point of considerable interest is the increase of suicide in relation to the advance of elementary education. Ogle states that suicide is more common among the educated than the illiterate classes. It is also more prevalent in urban than in rural districts. A curious feature in large towns is the sudden outbreak of self-destruction which sometimes occurs, and which has led to its being described as epidemic. In such cases force of example and imitation undoubtedly play a considerable part, as it is well recognized that both these forces exert an influence not only in causing suicide, but also in suggesting the method, time and place for the act. No age above five years is exempted from furnishing its quota of suicidal deaths, although self-destruction between five and ten years is very rare. Above this age the proportion of suicides increases at each period, the maximum being reached between fifty-five and sixty-five. Among females there is a greater relative prevalence at earlier age periods than among males. The modes of suicide are found to vary very slightly in different countries. Hanging is most common amongst males; then drowning, injuries from fire-arms, stab and cuts, poison and precipitation from heights. Amongst females, drowning comes first, while poison and hanging are more frequent than other methods entailing effusion of blood and disfigurement of the person. The methods used in England and Wales by suicides during 1858–1897, and in Scotland during the years 1851–1897, are given in the following table:

The season of the year influences suicide practically uniformly in all European countries, the number increasing from the commencement of the year to a maximum in May or June, and then declining again to a minimum in winter. Morselli attempts to account for this greater prevalence during what may well be called the most beautiful months of the year by attributing it to the influence of increased temperature upon the organism, while Durkheim suggests that the determining factor is more probably to be found in the length of the day and the effect of a longer period of daily activity. The suicide-rate is higher in certain male occupations and professions than in others (Ogle). Thus it is high amongst soldiers, doctors, inkeepers and chemists, and low for clergy, barmen, railway drivers and stokers. The suicide-rate is twice as great for unoccupied males as for occupied males.

**Literature.**—Ogle, “Suicides in England and Wales, in relation to Age, Sex, Season, and Occupation,” Journal of the Statistical Society (1886), vol. xlix, Strahan, Suicide and Insanity (London, 1893); Mayr, “Selbstmordstatistik,” in Handwörterbuch der Staatswissenschaften (Jena, 1895); Durkheim, Le Suicide (Paris, 1897). (H. L. L.)

**Suidas**, Greek lexicographer. Nothing is known of him, except that he must have lived before Eustathius (12th–13th century), who frequently quotes him. Under the heading of Adam “the author of the lexicon (which a prefatory note states to be ‘by Suidas’)” gives a brief chronology of the world, ending with the death of the emperor John Zimisces (975), and under “Constantinople” his successors Basil and Constantine are mentioned. It would thus appear that Suidas lived in the latter part of the 10th century. The passages in which Michael Psellus (end of the 11th century) is referred to are considered later interpolations. The lexicon of Suidas is arranged alphabetically with some slight deviations, letters and combinations of letters having the same sound being placed together; thus, ηι and ιε follow δ, and ε followed π. It partakes of the nature of a dictionary and encyclopaedia. It includes numerous quotations from ancient writers; the scholiasts on Aristophanes, Homer, Sophocles and Thucydides are also much used. The biographical notices, the author tells us, are condensed from the Onomatoiogon or Pinax of Hesychius of Miletus; other sources were the excerpts of Constantine Porphyrogenitus, the chronicle of Georgius Monachus, the biographies of Diogenes Laërtius and the works of Atheneus and Philistus. The work deals with scriptural as well as pagan subjects, from which it is inferred that the writer was a Christian. A prefatory note gives a list of dictionaries from which the lexical portion was compiled, together with the names of their authors. Although the work is uncritical and probably much interpolated, and the value of the articles is very unequal, it contains much information on ancient history and life.

Edito princes, by Demetrius Chalcondyles (1499); later editions by L. Küster (1705), T. Gaisford (1834), G. Bernhardt (1834–1853) and I. Bekker (1854); see A. Daub, De S. Biographiocrorum origine scriptorum et adhuc existentibus (1832); and J. E. Sandys, Hist. of Classical Scholarship (1906), p. 497.

**Suido** (Chinese, Sui-din-chen), a town of China, capital of the province of Kulja. It is the residence of the governor-general, and was founded in 1762 during the Musulman rising, and rebuilt in 1883. It is a military town, with provision stores, an arsenal and an arms workshop. Its walls are armed with steel guns.

**Suina**, a group of non-ruminating artiodactyla ungulate mammals typified by the swine (Suidae), but also including the hippopotomus (Hippopotamidae), and certain extinct forms. (See ARTIODACTyla; HIPPOPOTAMUS; PECCARY; SWINE.) Suina occur in the form of a group of dance tunes, mostly in binary form, of a type which may be described as "decorative" (see SONATA FORMS); constituting that classical form of early 18th-century instrumental music which most nearly foreshadows the later sonata. As understood by Bach, it consists essentially of four principal movements with the insertion of one or more lighter movements between the third and the last. The first movement is the allemande, of solid and intricate texture, in slow common time and rich flowing rhythm, beginning with one or three short notes before the first full bar. The second movement is the courante, of which there are two kinds. The French courante is again an intricate movement, also beginning with one or three notes before the main beat, and in a triple time (3/4) which, invariably at the cadences and sometimes elsewhere, drops into a crossing triple rhythm of twice the pace (3/8). The effect is restless and confused, and was supposed to form a contrast to the allemande; but it seldom did so effectively. Bach's study of Copernus led him to use the French courante frequently, but he was happier with the Italian type of corrente, which did not owe its name, like the French type, to the use of spasmodic runs, but was a brilliant continuously running piece in quick triple time (3/4 or 3/8), forming a clear and lively contrast both to the allemande and to the third movement, which is generally a sarabande.

**Suicide**, the act of self-destruction. It is a phenomenon peculiar to civilized society, and is only to be observed among the more advanced. It is more common amongst the educated than amongst Roman Catholic communities, while Jews have a smaller suicide-rate than Roman Catholics. A point of considerable interest is the increase of suicide in relation to the advance of elementary education. Ogle states that suicide is more common among the educated than the illiterate classes. It is also more prevalent in urban than in rural districts. A curious feature in large towns is the sudden outbreak of self-destruction which sometimes occurs, and which has led to its being described as epidemic. In such cases force of example and imitation undoubtedly play a considerable part, as it is well recognized that both these forces exert an influence not only in causing suicide, but also in suggesting the method, time and place for the act. No age above five years is exempted from furnishing its quota of suicidal deaths, although self-destruction between five and ten years is very rare. Above this age the proportion of suicides increases at each period, the maximum being reached between fifty-five and sixty-five. Among females there is a greater relative prevalence at earlier age periods than among males. The modes of suicide are found to vary very slightly in different countries. Hanging is most common amongst males; then drowning, injuries from fire-arms, stab and cuts, poison and precipitation from heights. Amongst females, drowning comes first, while poison and hanging are more frequent than other methods entailing effusion of blood and disfigurement of the person. The methods used in England and Wales by suicides during 1858–1897, and in Scotland during the years 1851–1897, are given in the following table:

The season of the year influences suicide practically uniformly in all European countries, the number increasing from the commencement of the year to a maximum in May or June, and then declining again to a minimum in winter. Morselli attempts to account for this greater prevalence during what may well be called the most beautiful months of the year by attributing it to the influence of increased temperature upon the organism, while Durkheim suggests that the determining factor is more probably to be found in the length of the day and the effect of a longer period of daily activity. The suicide-rate is higher in certain male occupations and professions than in others (Ogle). Thus it is high amongst soldiers, doctors, inkeepers and chemists, and low for clergy, barmen, railway drivers and stokers. The suicide-rate is twice as great for unoccupied males as for occupied males.

**Authorities.**—Morselli, II Suicidio (Milan, 1879); Legoyt, Le Suicide ancien et modern (Paris, 1881); Wescott, Suicide: its History.
The sarabande is a slow movement in triple time beginning on the full bar, and with at least a tendency to the rhythm of which Handel's aria "Lascia ch'io piana" is a familiar example. Bach's sarabandes are among the most simply eloquent and characteristic of his smaller compositions. Then come the galanteries, from one to three in number. These are the only suite-movements which either have an alternative section and a da capo (with the exception of Couperin's courantes and the courante in Bach's first English suite). The commonest galanteries are: (1) the minuet, often with a second minuet which is called "trio" only when it is in real three-part writing. It is a little faster than the stately minuet in Mozart's Don Giovanni, but it is never so quick as the lively minuets of Haydn's quartets and symphonies which led to the Beethoven scherzo; and it invariably begins, unlike many later minuets, on the full bar; (2) the gavotte, a lively dance in a not too rapid alla breve time, (the textbooks say ¾ time, but there is no case in Bach which could possibly be played so slowly, whatever the time signature may be). The gavotte always begins on the half-bar. A second alternating gavotte is frequently found on a pedal or drone-bass, and is then called musette; (3) the bourrée, which is not unlike the gavotte, but quicker, and beginning on the last quarter of the bar; (4) the passepied, a lively dance in quick triple time, beginning on the third beat. These dances are not always cast in binary form, and there are famous examples of gavottes and passepieds en rondeau. Other less common galanteries are (5) the loures, a slow dance in ¾ time and dotted rhythm (dactylic in accent and amphimacer in quantity); (6) the polonaise, a leisurely triple-time piece, either a shade quicker or (as in the exquisite unattacked examples of Friedemann Bach) much slower than the modern dance-rhythm of that name, with cadences on the second instead of the third beat of the bar; (7) the air, a short movement, quietly flowing, in a more florid style than its name would suggest. It sometimes precedes the sarabande. The suite concludes with a gigue, in the finest examples of which the decorative binary form is combined with a light fugue style of the utmost liveliness and brilliance. The gigue is generally in some triple rhythm, e.g. 8 6 9 12; but examples in a graver style may be found in slow square time with dotted rhythms, as in Bach's first French suite and the sixth Partita of the Klavier-übung. In gigues in the typical fuggato style Bach is fond of making the second part either invert the theme of the first, or else begin with a new subject to be combined with the first in double counterpoint. The device of inversion is also prominent in many of his allemandes and French courantes.

All suites on a large scale, with the exception of Bach's second and third French suites, begin with a prelude in some larger form. Bach's French Suites are small suites without prelude. His English Suites all have a great first movement which, except in the first suite, is in full da capo concerto form. His clavier Partitas show a greater variety of style in the dance movements and are preceded by preludes, in each case of a different type and title. Some large suites have finales after the gigue; the great chaconne for violin solo being the finale of a partita (see Variations).

Handel's suites are characteristically nondescriptive in form, but, in the probably earlier sets published after what is called his first set, there is a most interesting tendency to make several of the movements free variations of the first. Earlier composers had already shown the converse tendency to make variations take the forms of suite movements. In general Handel's suites are effective groups of movements of various lengths, with a tendency to use recognizable suite movements of a Franco-Italian type. In modern times the term "suite" is used for almost any group of movements of which the last is in the same key as the first, and of which a fair proportion show traces of dance-rhythm, or at least use dance titles. It is often said that the suite-forms have shown more vitality under modern conditions than the classical sonata forms. But this only means that when composers do not feel inclined to write symphonies or sonatas they give their groups of movements the name of suite. Certainly there is no such thing as a definite modern suite-form distinguishable from the selection composers make, for use in concert rooms, of incidental music written for plays, such as Grieg's Peer Gynt suites.

(D. F. T.)

SUKKUR, or Sakhaw, a town and district of British India, in Sind, Bombay. The town is situated on the right bank of the Indus, 24 m. N.W. of Skikarpur. Pop. (1901), 31,316. Sukkur has always commanded the trade of Sind, and the river is now crossed by a cantilever bridge carrying the North-Western railway to Kotri. The town was ceded to the Khairpur mirs between 1809 and 1824. In 1833 Shah Shuja defeated the Talpurs here with great loss. In 1842 it came under British rule.

The District of Sukkur was created in 1901 out of part of Shikarpur district, the remainder of which was formed into the district of Larkana. Area, 5403 sq. m. It is chiefly alluvial plain, but there are slight hills at Sukkur and Rohri. In the higher-lying parts are salt lands (Kalr), or even desert in the area known as the Registan. The climate is hot, dry and enervating. The annual rainfall at Sukkur town averages only 44 in. The population in 1901 was 523,345, showing an increase of 10% in the decade. A considerable part of the district is irrigated, the principal crops being wheat, millets, rice, pulses, and oil seeds. Earthen, leathern and metal ware, cotton cloth and tussore silk are manufactured, also pipe-bowls, snuff-boxes and scissors. Lines of the North-Western railway serve the district, and there is a branch from Sukkur towards Quetta.

SULA ISLANDS (Sulla, Xulla; Dutch Soela), a chain of islands forming a prolongation of the eastern peninsula of Celebes and the Banggai Islands, Dutch East Indies. The three main islands are long and narrow (Talibu, 85 m. long, Mangoli or Mangala, 63 m. and Besi, 100 m.). The two first lie in line, separated by the narrow Chapalulu Strait; Besi extends at right angles to the south coast of Mangoli. The natives of Talibu are allied to those of the Banggai Islands and the eastern peninsula of Celebes; but immigrant Malays are the principal inhabitants. Economically, Besi is the most important island. A Dutch commissioner resides at Sanana, at its northern extremity. It is fertile, and produces wax and honey, and coal has been found.

SULCI, an ancient town (mod. S. Antioco), situated on the east coast of an island on the south-west of Sardinia. The date of its foundation is not known, but it is certainly of Carthaginian origin. The assumption that it was originally an Egyptian colony is not justified. It is surrounded by walls, of large rectangular blocks of stone, can be traced for a circuit of upwards of a mile; it extended to the low ground on the shore near the modern cemetery, where a dedicatory inscription set up by the people of Sulci in honour of Hadrian in A.D. 128 was found (F. Vivianet in Notizie degli Scavi, 1897, 407). Various discoveries have been made within the circuit, both of Phoenician and of Roman antiquities, including several statues and inscriptions and many smaller objects, gems, &c., but at present few traces of ancient buildings are left, owing to their continued destruction in medieval and modern times. A cistern of fine masonry, perhaps dating from the Punic period, 1

1 A statue of Drusus, the brother of Tiberius (?) was found in 1889.
in the low ground below the modern town, may be mentioned. Close to it, among the houses of the modern town, a solid base about 25 ft. square, belonging possibly to a lighthouse or a tomb, records the existence of a temple of Isis and Serapis during the imperial period. A bilingual inscription of the 1st century a.C. (?) in Latin and in neo-Punic records the erection of a statue to Himilcat, who had carried out a decree of the local senatus for the erection of a temple to a goddess (described in the Punic version as domina do—possibly Tanit herself) by his son Himilcat (T. Mommsen in Corp. inscr. lat. x. 7513, 7514).

The Phoenician tombs consist of a chamber cut in the rock, measuring about 14 ft. square and 8 ft. high, and approached by a staircase: some of these have been converted into dwellings in modern times. Many of the curious sculptured reliefs found in these tombs are now in the museum of Herculaneum, and proves their Phoenician origin; and the seven-branched candlestick occurs several times. The fort which occupies the highest point—no doubt the acropolis of the Punic period—is quite modern. The long, low isthmus which, with the help of bridges, connects the island with the mainland, is very likely in part or entirely of artificial origin; but neither it nor the bridges show any definite traces of Roman date. On either side of it ships could find shelter then as nowadays. On many of the tombs of Sulci is attributed by Pauserius to the Carthaginians, and the Punic antiquities found there go to indicate the correctness of his account. It is mentioned in the account of the First Punic War as the place at which the Carthaginian admiral Hannibal took refuge after his defeat by C. Sulpicius, but was crucified. In 46 B.C. the city was severely punished by Caesar for the assistance given to Pompey's admiral Nasidius. Under the empire it was one of the most flourishing cities of Sardinia. It was attacked by the Vandals and Saracens, but ceased to exist before the 13th century. Previously to this it had been one of the four episcopal sees into which Sardinia was divided. A castle in the low ground, attributed to the Inca Tulissus, to the south of the modern town, was destroyed in modern times.

See A. Taraveli in Notizie degli scavi (1906), 135; (1908), 145, 192.

(T. As.)

**SULEIMAN I.** The "Magnificent" (1494-1566), sultan of Turkey, succeeded his father Selim I. in 1520. His birth coincided with the opening year of the 10th century of Mussulman chronology (A.H. 900), the most glorious period in the history of Islam. Eventful as the age was both in Europe, where the Renaissance was in full growth, and in India, where the splendour of the emperor Akbar's reign exceeded alike that of his predecessors and his successors, Suleiman's conquests overshadowed all these. It is noteworthy that though in Turkey he is distinguished only as the law-giver (komuni), in European history he is known by such titles as the Magnificent. He was the most fortunate of the sultans. He had no rival worthy of the name. From his father he inherited a well-organized country, a discipline army and a full treasury. He united in his person the best qualities of his predecessors, and possessed the gift of taking full advantage of the talents of the able generals, admirals and viziers who illustrated his reign. If his campaigns were not always so wisely and prudently planned as those of some of his predecessors, they were in the main eminently fortunate, and resulted in adding to his dominions Belgrade, Budapest, Tesmarov, Rhodes, Tabriz, Bagdad, Nakshivan and Rivan, Aden and Algiers, and in his days Turkey attained the culminating point of her glory.

The alliance concluded by him with France reveals him at once as rising superior to the narrow prejudices of his race and faith, which rejected with scorn any union with the unbeliever, and as gifted with sufficient political insight to appreciate the advantage of combining with Francis I. against Charles V. His Persian campaign was doubtless an error, but was due in part to a desire to find occupation, distant if possible, for his Saracens, who were progressively increasing in numbers at the capital. He was perhaps swaying in firmness of character, and the undue influence exercised over him by unscrupulous ministers, or by the seductions of fairer but no less ambitious votaries of statecraft, led him to make concessions which tarnished the glory of his reign, and were followed by baneful results for the welfare of his empire. It is from Suleiman's time that historians date the rise of that occult influence of the harem which has so often thwarted the best efforts of Turkey's most enlightened statesmen.

Suleiman's claims to renown as a legislator rest mainly on the organization of the empire, or clerical class, in its hierarchical order from the Sheik-ul-Islam downwards. He reformed and improved the administration of the country both civil and military, inaugurated a new and improved system for the feudal tenures of limitory fiefs, and his amelioration of the lot of his Christian subjects is not his least title to fame. He was also not unknown to fame as a poet, under the pseudonym of "Muhibbīr" (see Hammer-Purgstall, Gesch. d. Osman. Reichs, ii. 331; and furtherTurkey: History).

Suleiman died on the 5th of September 1566, at the age of 72, conducting the siege of Szegvár. Sultan of Turkey, was a son of Sultan Ibrahim, and succeeded his brother Mahomed IV. in 1587. Forty-six years of enforced retirement had qualified him for the cloister rather than for the throne, and his first feeling when notified of his accession was one of terror for his brother's vengeance. Nor were the circumstances following his elevation to the throne of a nature to reassure him, as one of the most violent of the revolts of the janissaries ended in the murder of the grand vizier and the brutal mutilation of his family, with general massacre and pillage throughout Constantinople. The war with Austria was a succession of disasters. At this time, fortunately for the Ottoman Empire, a third great kuprili (Mustafa) arose and re-established order in the sorely-tried state (see KUPRILU). In the reforms which followed, whereby the situation of the Christian subjects of the Porte was greatly improved, Suleiman is at least to be given the credit of having allowed Mustafa Kuprili a free hand. With an improved administration Turkey's fortunes in the war began to revive, and the reconquest of Belgrade late in 1690 was the last important event of the reign, which ended in 1691 by Suleiman's death. (See also Turkey: History.)

**SULEIMANII, or SULEMANNII, the chief town of a sanjak of the same name in Asiatic Turkey. In the valley of Mosul, situated on a treeless plain in the Kurdistan Mountains, in the region known as Shehrizor, some 40 or 50 m. from the Persian frontier, at an elevation of 2805 ft. It is a military station, and was founded towards the close of the 11th century. The population is about 12,000, of whom 11,000 are Kurds, and the majority of the remaining 1000 Jews.**

**SULIMAN HILLS,** a mountain system on the Dera Ismail Khan border of the north-west frontier of India. From the Gomal river southward commences the true Suliman system, presenting an impenetrable barrier between the plains of the Indus and Afghanistan. The Suliman Mountains finally merge into the hills of Baluchistan, which are inhabited by the Marri and Bugti tribes. The chief mass of the range is known as...
SULINA—SULLA

Takht-i-Suliman or Solomon's throne. It may be seen on the western horizon from Dena Ismail Khan, a grey, flat-looking rampart rising from the lower line of mountains north and south of it, slightly saddle-backed in the middle, but culminating in a very well-defined peak at its northern extremity. The legend of the mountain is that Solomon visited Hindostan to marry Balkis, and that as they were returning through the air, on a throne supported by genii, the bride imploring the brickdove to let her look back for a few moments on her beloved land. Solomon directed the genii to scoop out a hollow for the throne on the summit of the mountain. The hollow is a cavity some 30 ft. square cut out of the solid rock, at the southern extremity of the mountain and is a place of pilgrimage for both Hindus and Mahomedans. The actual shrine is about two m. south of the highest peak. The whole mountain was traversed and surveyed by the Takht-i-Suliman Survey Expedition of 1883 (see SHERKHAN) and was found to consist of two parallel ridges running roughly north and south, the southern end of the eastern ridge culminating in a point 11,070 ft. high, which is the Takht proper on which the shrine is situated, and the western ridge culminating at its northern end in a point 11,300 ft. high known as Kaisarghar. Between these two ridges is a connecting tableland about 9000 ft. high. This plateau and the interior slopes of the ridges are covered with chilghosa (edible pine) forests. The mass of the mountain is composed of nummulite limestone. No water is to be found on the summit.

SULINA, a town in Rumania, at the mouth of the Sulina branch of the Danube. Pop. (1900), 561 r. Sulina is the only free port on the Danube, and is much used for the transhipment into sea-going vessels of grain which is brought down the river in large lighters from Rumania, Russia, Bulgaria, Servia and Austria-Hungary. No agricultural produce is grown in its neighbour- hood, owing to the reed-covered swamps with which it is surrounded. Sulina is the headquarters of the technical department of the European Commission of the Danube (q.v.). Large steamers navigate up to Galatz and Braila. In 1901, 1411 steamers and sailing craft aggregating 1,350,000 tons register cleared from Sulina for European ports carrying, besides other merchandise, nearly 13,000,000 quarters of grain. Owing to the improvements effected by the European Commission, there is a depth of 24 ft. of water on the bar, and of 18 to 22 ft. in the fairway. A lighthouse overlooks the estuary. The town contains the only English church in Rumania.

SULITELMA, a mountain on the frontier between Norway and Sweden, forming a salient (615 ft.) of the Kjol or 'keel' of the Scandinavian peninsula. The mass, composed of three peaks, is situated in 63° 10' N., and covered with a snow-field from which many glaciers descend. In these rise feeders of the Swedish rivers Lilla Lule and Pite, flowing south-east. Westward, the foothills descend upon the Skjerstad Fjord, above which are two lakes, Nedre and Ovre Vand. From Sjöstaas steamers on the Langvand and a light railway give communication between the sea and Furulund, the headquarters of the Swedish Sulitelsa Mining Company. A mountain track descends from Sulitelsa to Kvikjok (or Kvikjok), a considerable village magnificently situated on the Tarrsjock, a head-stream of the Lule Litt. This is a departure from the line of the Furulund road.

SULLA, Lucius Cornelius (138-82 B.C.), surnamed Felix, Roman general, politician and dictator, belonged to a minor and impoverished branch of the famous patrician Cornelius gens. He received a careful education, and was a devoted student of literature and art. His political advancement was slow, and he did not obtain the quaestorship until 107, when he served in the Jugurthine war under Marius in Africa. In this he greatly distinguished himself, and claimed the credit of having terminated the war by capturing Jugurtha himself. In these African campaigns Sulla showed that he knew how to win the confidence of his soldiers, and throughout his career the secret of his success seems to have been the enthusiastic devotion of his troops, whom he continued to hold well in hand, while allowing them to indulge in plundering and all kinds of excess. From 104 to 101 he served again under Marius in the war with the Cimbri and Teutones and fought in the last great battle in the Raudian plains near Verona. It was at this time that Marius's jealousy of hislegate laid the foundations of their future rivalry and mutual hatred. When the war was over, Sulla, on his return to Rome, lived quietly for some years and took no part in politics. In 93 he was elected praetor after a lavish squandering of money, and he delighted the populace with an exhibition of a hundred lions from Africa. Not till an (82) he be went as praetor at Cilicia with special authority from the senate to make Mithra- dates VI. of Pontus restore Cappadocia to Ariobarzanes, one of Rome's dependants in Asia. Sulla with a small army soon won a victory over the general of Mithradates, and Rome's client-king was restored. An embassy from the Parthians now came to solicit alliance with Rome, and Sulla was the first Roman who held diplomatic intercourse with that remote people. In the year 91, which brought with it the imminent prospect of sweeping political change, with the enfranchisement of the Italian peoples, Sulla returned to Rome, and it was generally felt that he was the man to lead the conservative and aristocratic party.

Meanwhile Mithradates and the East were forgotten in the crisis of the Social or Italic War, which broke out in 91 and threatened Rome's very existence. The services of both Marius and Sulla were given; but Sulla was the more successful, or, at any rate, the more fortunate. Of the Italian peoples Rome's old foes the Sammites were the most formidable; these Sulla van- quished, and took their chief town, Bovianum. In recognition of this and other brilliant services, he was elected consul in 88, and the next year the republic was saved by the capture of Nola in Campania. The question of the conduct of the campaign to put Mithradates again came to the front. The senate had already chosen Sulla; but the tribune Publius Sulpicius Rufus moved that Marius should have the command. Rioting took place at Rome at the prompting of the popular leaders, Sulla narrowly escaping to his legions in Campania, whence he marched on Rome, being the first Roman who entered the city at the head of a Roman army. Sulpicius was put to death, and Marius fled; and he and his party were crushed for the time.

Sulla, leaving things quiet at Rome, quitted Italy in 87, and for the next four years he was waging victory after victory against the armies of Mithradates and accumulating boundless plunder. Athens, the headquarters of the Mithradatic cause, was taken and sacked in 86; and in the same year, at Chaeronea, the scene of Philip II. of Macedon's victory more than two and a half centuries before, and in the year following, at the neighbouring Orchomenus, he scattered immense hosts of the enemy with trifling loss to himself. Crossing the Hellespont in 84 into Asia, he was joined by the troops of C. Flavius Fimbria, who soon deserted their general, a man sent out by the Marian party, now again the ascendant in the Roman state. And the year was concluded with Mithradates on condition that he should be put back to the position he held before the war; but, as he raised objections, he had in the end to content himself with being simply a vassal of Rome.

Sulla returned to Italy in 83, landing at Brundisium, having previously informed the senate of the result of his campaigns in Greece and Asia, and announced his presence on Italian ground. He further complained of the ill-treatment to which his friends and partisans had been subjected during his absence. Marius had fled in 86, and the revolutionary party, specially represented by L. Cornelius Cinna, Cn. Papirius Carbo and the younger Marius, had massacred Sulla's supporters wholesale, confiscated his property, and declared him a public enemy. They felt they must resist him to the death, and with the troops scattered throughout Italy, and the newly enfranchised Italians, to whom it was understood that Sulla was bitterly hostile, they counted confidently on success. But on Sulla's advance at the head of his 40,000 veterans many of them lost heart and deserted their leaders, while the Italians themselves, whom he confirmed in their new privileges, were won over to his side. Only the Sam- nites, who were as yet not involved in the Roman war, remained his enemies, and it seemed as if the old war between Rome and Samnium had to be fought once again. Several Roman nobles,
among them Gnaeus Pompeius (Pompey the Great), Q. Caecilius Metellus Pius, Marcus Licinius Crassus, Marcus Licinius Lucullus, joined Sulla, and in the following year (82) he won a decisive victory over the younger Marius near Praeneste (mod. Palestrina) and then marched upon Rome, where again, just before his defeat of Marius, there had been a great massacre of his adherents, in which the learned jurist Q. Mucius Scaevola perished. Rome was at the same time in extreme peril from the advance of a Samnite army, and was barely saved by Sulla, who, after a hard-fought battle, routed the enemy under Pontius Tellenus at the Cella of Rome. With the death of the younger Marius, who killed himself after the surrender of Praeneate, the civil war was at an end, and Sulla was master of Rome and of the Roman world. Then came the memorable "proscription," when for the first time in Roman history a list of men declared to be outlaws and public enemies was exhibited in the forum, and a reign of terror began throughout Rome and Italy. The title of "dictator" was revived and Sulla was in fact emperor of Rome. After celebrating a splendid triumph for the Mithradatic War, and assuming the surname of "Felix" ('Epaphroditus," "Venus's favourite") he styled himself in a dittatory style, he carried in 80 and 79 his great political reforms (see Rome: History, II. "The Republic"). The main object of these was to invest the senate, which he recruited with a number of his own party, with full control over the state, over every magistrate and every province; and the mainstay of his political system was to be the military colonies which he had established with grants of land throughout every part of Italy, to the ruin of the old Italian freeholders and farmers, who from this time dwindled away, leaving whole districts waste and desolate.

In 79 Sulla resigned his dictatorship and retired to Puteoli (mod. Pozzuoli), where he died in the following year, probably from the bursting of a blood-vessel. The story that he fell a victim to a disease similar to that which cut off one of the Herods (Acts xii, 23) is probably an invention of his enemies. The "half lion, half fox," as his enemies called him, the "Don Juan of politics" (Mommsen), the man who carried out a policy of "blood and iron" with a grim humour, amused himself in his last days with actors and actresses, with dabbling in poetry, and completing the Memoirs (commentarii, οὐρανοφυσα) of his eventful life (see H. Peter, Historiae romanae veteres, 1870). Pericles had risen to a height above his countrymen, and his end is said to have been hastened by a fit of passion, brought on by a remark of the quaker Granius, who openly asserted that he would escape payment of a sum of money due to the Romans, since Sulla was on his death-bed. Sulla sent for him and had him strangled in his presence; in his excitement he broke a blood-vessel and died on the following day. He was accorded a magnificent public funeral, his body being removed to Rome and buried in the Campus Martius. His monument bore an inscription written by himself, to the effect that he had always fully repaid the kindnesses of his friends and the wrongs done him by his enemies. His military genius was displayed in the Social War and the campaigns against Mithradas; while his constitutional reforms, although doomed to failure from the lack of successors to carry them out, were a triumph of organization. But he massacred his enemies in cold blood, and exacted vengeance with pitiless and calculated cruelty; he sacrificed everything to his own ambition and the triumph of his party.

The ancient authorities for Sulla and his time are his Life by Plutarch (who made use of the Memoirs); Appian, Bell. civ.; for the references in Cicero see Orelli’s edition mentioned above. Modern studies by C. S. Zachariä, L. Cornelius S. als Ordner des römischen Freistaates (1834); T. Lau, Lucius Cornelius Sulla (1855); E. Linfen, De bello civili Sullano (1896); P. Cantalupi, La Guerra civile Sullan (1899); W. Mann, Seven Roman Statesmen (1902); F. D. Getlach, Marius und Sulla (1856); J. M. Sunden, "De tribunica potestate a Lucio Sulla inminiata" in Skrifter utgivna av k. humanistiska Väsendskapsamnet i Upsala, v. 1897, in which it is argued that the right of proposing rogations and the right of proposing rogations was not the right of proposing rogations. See also Mommsen’s History of Rome, vol. iii., bk. iv., ch. 8, 9; Drumm, Geschichte Roms.

1 A short epigram on Aphrodite in the Greek Anthology (Anth. Pal., A. append., i, 153) is ascribed to him.

His nephew (as some say, though the degree of relationship cannot be clearly established), PUBlius CORNELIUS SULLA was consul in 66 B.C. with P. Autronius Paetus. Both were convicted of bribery, and Paetus subsequently joined Catiline in his first conspiracy. There is little doubt that Sulla also was implicated; Sallust does not mention it, but other authorities definitely assert his guilt. After the second conspiracy he was accused of having taken part in both conspiracies. Sulla was defended by Cicero and Hortensius, and entered Mr. Helmore’s school that he might be saved, and with the conviction, Sulla remained very quiet, and, whatever his sympathies may have been, took no active part in the conspiracy. When the civil war broke out, Sulla took the side of Caesar, and commanded the right wing at the battle of Pharsalus. He died in 45.

SULLIVAN, Sir Arthur Seymour (1842-1900), English musical composer, was born in London on the 13th of May 1842, being the younger of the two sons of Thomas Sullivan, a cultivated Irish musician who was bandmaster at the Royal Military College, Sandhurst, from 1845 to 1856, and taught at the Military School of Music at Kneller Hall from 1847 till his death in 1866. His mother, née Mary Coghlan (1811-1858), had Italian blood in her veins. Arthur Sullivan was brought up to music from boyhood, and he had learnt to play every wind instrument in his father's band by the age of eight. He was sent to school at Bayswater till he was twelve, and then, through Sir George Smart, he was, at his own persistent request, made a Chapel Royal chorister, and entered Mr. Helm’s school for Chapel Royal boys in Cheyne Walk. He had a fine treble voice, and sang with exceptional taste. In 1856 the Mendelssohn Scholarship at the Royal Academy of Music was thrown open for the first time for competition, and was won by Sullivan, his nearest rival being Joseph Barnby. At the Academy he studied under Sterndale Bennett, Arthur O'Leary and John Goss, and did so well that he was given an extension of his scholarship for two years in succession. In 1858, his voice having broken, he was enabled by means of his scholarship to go to study at the conservatorium of Leipzig. There he had for teachers Moscheles and Flidi for piano-forte, Hauptmann for counter-point, Rietz and Reinecke for composition, and F. David for orchestral playing and conducting. Among his fellow-students were Grieg, Carl Rosa, Walter Bache, J. F. Barnett and Edward Dannreuther. Instead of the Mendelssohn cultus which represented orthodoxy in London, German musical interest at this period centred in Schumann, Schubert and the growing reputation of Wagner, whilst Liszt and Von Bülow were the celebrities of the day. Sullivan thus became acquainted for the first time with masterpieces which were then practically ignored in England. He entered enthusiastically into the spirit of the place, and after two years' hard study returned to London in April 1861. Before doing so, however, he had composed his incidental music for The Tempest, which he had begun as a sort of diploma work. Sullivan set himself to find converts in London to the enthusiasm he had imbibed at Leipzig. He became acquainted with George Grove, then secretary of the Crystal Palace, and August Manns, the conductor there; and at his instigation Schumann's First Symphony was introduced at one of the winter concerts. Early in 1862 Sullivan showed Grove and Manns his Tempest music, and on the 4th of April it was performed at the Crystal Palace. The production was an unmixed triumph, and Sullivan's exceptional gifts as a composer were generally recognized from that moment. He had hitherto been occupying himself with teaching, and he continued for some years to act as organist at St Michael's, Chester Square, but henceforth he devoted most of his time to composition. By 1864 he had produced his "Kennworth" cantata (remembered chiefly for the lovely duet, "How sweet the Moonlight"), the "Sapphire Necklace" overture, and the five beautiful songs from Shakespeare, which include
"Orpheus with his Lute," "Oh Mistress Mine" and "The Willow Song." His attractive personality, combined with his undoubted genius and brilliant promise, brought him many friends. Costa, who was conductor at Covent Garden, gave him the post of organist, and in 1864 he produced there his L'Île Enchantée ballet. Some of his spare time was spent in Ireland, where in 1863 he began the composition of his ("Irish") Symphony in E, which was produced at the Crystal Palace in 1866. The most important event, however, at this period, as bearing upon his later successes, was his co-operation with F. C. Burnand in the musical extravaganza Cox and Box, which first showed his capacity for musical drollery. This was acted privately in 1866, and was completed for public performance in 1867, in which year Sullivan again co-operated with Burnand in Contrabandista. Meanwhile he was in request as a conductor, and was made professor of composition at the Academy. His father's sudden death in 1866 inspired him to write the fine "In Memoriam" overture, which was produced at the Norwich Festival. In 1867, besides producing his "Marmion" overture, he and Grove did a great service to their art by bringing to light in Vienna a number of lost Schubert MSS., including the Rossmanné music. About this time Sullivan induced Tennyson to write his song-cycle "The Window," to be illustrated by Millais, with music by himself. But Millais abandoned the task, and Tennyson was not happy about his share; and the series, published in 1871, never became popular, in spite of Sullivan's dainty setting. In 1869 he brought out his oratorio The Prodigal Son at Worcester, and in 1870 his overture "Di Ballo" at Birmingham. In 1871 Sullivan had become acquainted with W. S. Gilbert (q.v.), and in 1872 they collaborated in a piece for the Gaiety Theatre, called Thespis; or, The Gods Grow Old, which was a great success in spite of the limited vocal resources of the performers. In 1875 R. D'Oyly Carte, then acting as manager for Selina Dolaro at the Royalalty, approached Gilbert with a view to his collaborating with Sullivan in a piece for that theatre. Gilbert had already suggested to Sullivan an operaetta with its scene in a law court, and within three weeks of his completing the libretto of Trial by Jury the music was written. The piece succeeded beyond all expectation; and on the strength of its promise of further successes D'Oyly Carte formed his Comedy Opera Company and took the Opéra Comique Theatre. There in 1877 The Sorcerer was produced, George Grossmith and Rutland Barrington being in the cast. In 1878 H.M.S. Pinafore was brought out at the Opéra Comique. At first it did not attract large audiences, but eventually it became a popular success, and ran for 700 nights. In America it was enthusiastically received, and the two authors, with D'Oyly Carte, went over to the States in 1879, with a company of their own, in order to produce it in New York. To secure the American rights for their next opera, they brought out The Pirates of Penzance at New York in 1879. In 1880, in London, it ran for nearly 400 nights. In 1881 Patience was produced at the Opéra Comique, and was transferred later in the year to the Savoy Theatre. There all the later operas came out: Iolanthe (1882), Princess Ida (1884), The Mikado—perhaps the most charming of all—(1885), Ruddigore (1887), The Yeomen of the Guard (1888), The Gondoliers (1889). This succession of pieces by Gilbert and Sullivan had made their united names stand for a new type of light opera. Its vogue owed something to such admirable performers as George Grosssmith—famous for his "patter songs"—Rutland Barrington, Miss Jessie Bond, Miss Brandram, and later W. H. Davison and Walter Passmore; but these artists only took advantage of the opportunities provided by the two authors. In place of the old adaptations of French opéra bouffe they had substituted a genuinely English product, humorous and delightful, without a tinge of vulgarity or the commonplace. But disagreements now arose between them which caused a dissolution of partnership. Sullivan's next Savoy opera, Haddon Hall (1892), had a libretto by Sydney Grundy; and the resumption of Gilbert's copyright in Thespis, and again in 1896 in The Grand Duke, was not as successful as before. Sullivan's music, however, still showed its characteristic qualities in the Chieftain (1894)—largely an adaptation of Contrabandista; The Beauty Stone (1898), with a libretto by A. W. Pinero and J. Comyns Carr; and particularly in The Rose of Persia (1900), with Captain Basil Hood.

In the public mind Sir Arthur Sullivan (who was knighted in 1883) had during these years become principally associated with the enormous success of the Savoy operas; but these by no means exhausted his musical energies. In 1872 his Te Deum for the recovery of the prince of Wales was produced at the Crystal Palace. In 1873 he produced at the Birmingham Musical Festival his oratorio The Light of the World, in 1877 he wrote his incidental music to Henry VIII., in 1880 his sacred cantata The Martyr of Antioch, and in 1886 his masterpiece, The Golden Legend, was brought out at the Leeds Festival. The Golden Legend satisfied the most exacting critics that for originality of conception and grandeur of execution English music possessed in Sullivan a composer of the highest calibre. In 1891, for the opening of D'Oyly Carte's new English opera-house in Shaftesbury Avenue he wrote his "grand opera" Thaïs (1891). Try Julian Sturgis. The attempt to put an English opera on the stage for a long run was doomed to failure, but Ivanhoe was full of fine things. In 1892 he composed incidental music to Tennyson's Foresters. In 1897 he wrote a ballet for the Alhambra, called Victoria and Merrie England. Among his numerous songs, a conspicuous merit of which is their admirable vocal quality, the best known are "If Doughty Deeds" (1866), "The Sailor's Grave" (1872), "Thou'r Passage Hence" (1873), "I would I were a King" (1878), "King Henry's Song" (1878) and "The Last Chord" (1877). This last, hackneyed as it is, has become one of the most beautiful English songs of the 19th century. It was written in 1877, during the fatal illness of Sullivan's brother Frederic, who, originally an architect, had become an actor, and by means of his fine voice and powers as a comedian (best shown as the Judge in Trial by Jury) had won considerable success. Among Sullivan's many hymn tunes, the stirring "Onward, Christian Soldiers!" (1872) is a permanent addition to Church music. In 1876 he accepted the principalship of the National Training School of Music, which he held for six years; this was the germ of the subsequent Royal College. He received the honorary degree of Mus. Doc. from Cambridge (1876) and Oxford (1876). In 1878 he was a member of the royal commission for the Paris Exhibition. He was conductor of the Leeds Festivals from 1879 to 1898, besides being conductor of the Philharmonic Society in 1885. Apart from his broad sympathy and his practical knowledge of instruments, his work as a conductor must always be associated with his efforts to raise the standard of orchestral playing in England and his unwearying exertions on behalf of British music and British musicians. Sullivan liked to be associated in the public mind with patriotic objects, and his setting of Rudyard Kipling's "Absent-minded Beggar" song, at the opening of the Boer War in 1899, was, with the exception of The Rose of Persia, the last of his compositions brought out in his lifetime. He died suddenly on November 22nd, 1900, and his burial in St. Paul's Cathedral was the occasion of a remarkable demonstration of public sorrow. He left unpublished a Te Deum written for performance at the end of the Boer War, and an unfinished Savoy opera for a libretto by Captain Hood, which, completed by Edward German, was produced in 1901 as The Emerald Isle.

Sullivan was the one really popular English composer of any artistic standing in his time; and his celebrity as a public man has somewhat interfered with a definite judgment as to his place in the history of English music. In his own time, English musical taste developed in a very remarkable degree; and musical criticism in serious quarters was a little disinclined to do justice to what was "popular." One of the most agreeable companions, broad-minded, and free from all affectation, he was intensely admired and loved in all circles of society; and though his health was not robust, for he suffered during many years at intervals from a painful ailment, he was a man of the world who enjoyed the life which his success opened out to him without being spoilt.
SULLY, J. -- SULLY, JAMES

by it. He was always a devoted and an industrious musician, and from the day he left Leipzig his influence was powerfully exerted in favour of a wider and fuller recognition of musical culture. He was accused in some quarters of being unsympathetic towards Wagner and the post-Wagnerians, yet he had been one of the first to introduce Wagner’s music to English audiences. He was keenly appreciative of new talent, but his tastes were too eclectic to satisfy the enthusiasts for any particular school; he certainly had no liking for what he considered uninspired academic writing. Serious critics deplored, with more justification, that he should have devoted so much of his great natural gift not merely to libretti, but to the production of a number of songs which, though always musically, were really of the nature of “pot-boiling.” Sullivan was an extremely rapid worker, and his fertility in melody made it easy for him to produce what would please a large public. Moreover, it must be admitted that his great social success, so early achieved, was not calculated to nourish a rigidly artistic ideal. But when all is said, his genius remains undisputed; and it was a genius essentially English. His church music alone would entitle him to a high place among composers; and as the “Goldscheider Legend, Innaund and Invidia,” and the “Irish” symphony and the charming “incidental music” to The Tempest and to Henry VIII, form a splendid legacy of creative effort, characterized by the highest scholarly qualities in addition to those beauty which appeal to every ear. Whether his memory will be chiefly associated with these works, or rather with the world-wide popularity of some of his songs and comic operas, time alone can tell. The Savoy operas did not aim at intellectual or emotional grandeur, but at providing innocent and wholesome pleasure; and in giving musical form to Gilbert’s witty librettos Sullivan showed once for all what light opera may be when treated by the hand of a master. His scores are as his words, and fanciful qvd music as Gilbert’s verses are qvd dramatic literature. Bubbling melody, consummate orchestration, lovely songs and concerted pieces (notably the famous vocal quintets) flowed from his pen in unexhausted and inimitable profusion. If he had written nothing else, his unique success in this field would have been a solid title to fame. As it was, it is Sir Arthur Sullivan’s special distinction not only to have been prolific in music which went straight to the hearts of the people, but to have enriched the English répertoire with acknowledged masterpieces, which are no less remarkable for their technical accomplishment.

See also Sir Arthur Sullivan: Life, Letters, and Reminiscences, by Arthur Lawrence, 1899 (1st ed. 1896; 2nd ed. 1900). Besides largely autobiographical, this volume contains a complete list of Sullivan’s works, compiled by Mr Wilfrid Bendall, who for many years acted as Sir Arthur’s private secretary. (H. Ch.)

SULLIVAN, JOHN (1740-1793), American soldier and political leader, was born in Somersworth, New Hampshire, on the 18th of February 1740. He studied law in Portsmouth, N.H., and practised at Berwick, Maine, and at Durham, N.H. He was a member of the New Hampshire Provincial Assembly in 1774, and in 1774-1775 was a delegate to the Continental Congress. In 1777 he had been commissioned General of New Hampshire militia, and on the 13th of December 1774 he and John Langdon led an expedition which captured Fort William and Mary at New Castle. Sullivan was appointed a brigadier-general in the Continental army in June 1775 and a major-general in August 1776. He commanded a brigade in the siege of Boston. In June 1776 he took command of the American army in Canada and after an unsuccessful skirmish with the British at Three Rivers (June 8) retreated to Crown Point. Rejoining Washington’s army, he served under General Israel Putnam in the battle of Long Island (August 27) and was taken prisoner. Released on parole, he bore a verbal message from Lord Howe to the Continental Congress, which led to the fruitless conference on Staten Island. In December he was exchanged, succeeded General Charles Lee in command of the right wing of Washington’s army, in the battle of Trenton led an attack on the Hessians, and led a night attack against British and Loyalists on Staten Island, on the 22nd of August 1777. In the battle of Brandywine (Sept. 11, 1777) he again commanded the American right; he took part in the battle of Germantown (Oct. 4, 1777); in March 1778 he was placed in command in Rhode Island, and in the following summer plans were made for his co-operation with the French fleet under Count d’Estaing in an attack on Newport, which came to nothing. Sullivan after a brief engagement (Aug. 29) at Quaker Hill, at the N. end of the island of Rhode Island, was obliged to retreat. In 1779, Sullivan, with about 4,000 men, defeated the Iroquois and their Loyalist allies at Newburg (now Elmira), New York, on the 26th of August, burned their villages, and destroyed their orchards and crops. Although severely criticised for his conduct of the expedition, he received, in October 1779, the thanks of Congress. In November he resigned from the army. Sullivan was again a delegate to the Continental Congress in 1780-1781 and, having accepted a loan from the French minister, Chevalier de la Luzerne, he was charged with being influenced by the French in voting not to make the right to the north-east fisheries a condition of peace. From 1782 to 1785 he was attorney-general of New Hampshire. He was president of the state in 1786-1787 and in 1789, and in 1786 suppressed an insurrection at Exeter immediately preceding the Shays Rebellion in Massachusetts. He presided over the New Hampshire convention which ratified the Federal constitution in June 1788. From 1789 until his death at Durham, on the 23rd of January 1795, he was United States District Judge for New Hampshire.

SULLIVAN, THOMAS BARRY (1832-1891), Irish actor, was born at Birmingham, and made his first stage appearance at Cork about 1840. His earliest successes were in romantic drama, for which his graceful figure and youthful enthusiasm fitted him. His first London appearance was in 1852 in Hamlet, and he was also successful as Angiolo in Miss Vandenhoff’s Woman’s Heart, Evelyn in Money and Hardman in Lord Lytton’s Not So Bad as we Seem. Claude Melnotte—helen Faucit as Pauline—was also a notable performance. A tour of America in 1857 preceded a second tour, and in 1859 he took the management of the Globe in London. He completed a trip round the world in the year 1866. From 1869 to 1870 he managed the Holborn theatre, where Beverley in The Ganger was one of his most powerful impersonations. Afterwards he travelled over the United States, Canada, Australia and England. Among his later London performances were several Shakespearian parts, his best, perhaps, being Richard III. He was the Benedict of the cast of Much A do About Nothing with which the Shakespeare Memorial was opened at Stratford-on-Avon. He died on the 3rd of May 1891.

SULLY, JAMES (1843— ), English psychologist, was born on the 30th of March 1842 at Bridgewater, and was educated at the Independent College, Taunton, the Regent’s Park College, Göttingen and Berlin. He was originally destined for the Nonconformist ministry, but in 1871 adopted a literary and philosophic career. He was Grote professor of the philosophy of mind logic at University College, London, from 1892 to 1903, when he was succeeded by Carveth Read. An adherent of the associationist school of psychology, his views had great affinity with those of Alexander Bain. His monographs, as that on pessimism, are ably and readily readable, and his textbooks, of which The Human Mind (1893) is the most important, are models of sound exposition.

WORKS.—Sensation and Intuition (1824). Pessimism (1897), Illusions (1881; 4th ed., 1895), Outlines of Psychology (1884; many editions), Teacher’s Handbook of Psychology (1886), Studies of Childhood (1895), Children’s Ways (1897), and An Essay on Laughter (1902).
SULLY, DUC DE—SULLY, T.

SULLY, MAXIMILIEN DE BÉTHUNE, DUC DE (1560–1641). French statesman, was born at the château of Rosny near Montes, on the 13th of December 1560, of a noble family of Flemish descent. His father, François de Béthune, baron de Rosny, (1532–1575), was the son of Jean de Béthune, to whom in 1529 his wife Anne de Melun brought as part of her dowry a scigneure at Rosny-sur-Seine, which later (1601) was made a marquisate. Brought up in the Reformed faith, Maximilien was presented to Henry of Navarre in 1571 and was thenceforward attached to the future king of France. The young baron de Rosny was taken to Paris by his patron and was studying at the Collège de Bourgogne at the time of the massacre of St Bartholomew's Day, from which he escaped by discreetly carrying a book of hours under his arm. He then studied mathematics and history at the court of Henry of Navarre, and on the outbreak of civil war in 1573 he enlisted in the Protestant army. In 1576 he accompanied the duke of Anjou on an expedition into the Netherlands in order to regain the former Rosny estates, but being unsuccessful he attacked himself for a time to the prince of Orange. Later rejoining Henry of Navarre in Guise, he displayed bravery in the field and particular ability as an engineer. In 1583 he was Henry's special agent in Paris. In 1584 he married Anne de Courtenay, a wealthy heiress, who died, however, in 1589. On the renewal of civil war Rosny again joined Henry of Navarre, and at the battle of Ivry (1590) was seriously wounded. He counselled Henry IV.'s conversion to Roman Catholicism, but steadfastly refused himself to become a Roman Catholic. As soon as Henry's power was established, the faithful and trusted Rosny received his reward in the shape of numerous estates and dignities. On the death of D'O, the superintendent of finances, in 1594, the king had appointed a finance commission of nine members, to which he added Rosny in 1596. The latter at once made a tour of inspection through the generalties, and introduced some order into the country's affairs. He was probably made sole superintendent of finances in 1598, although this title does not appear in official documents until the close of 1601. He authorized the free exportation of grain and wine, reduced legal interest from 8% to 6½%, established a special court for the trial of cases of peculation, forbade provincial governors to raise money on their own authority, and otherwise removed many abuses of tax-collecting, abolished several offices, and by his honest, rigorous conduct of the country's finances was able to save between 1600 and 1610 an average of a million livres a year. His achievements were by no means solely financial. In 1596 he was appointed grand commissioner of highways and public works, superintendent of fortifications and grand master of artillery; in 1602 governor of Montes and of Jargeau, captain-general of the queen's gens d'armes and governor of the Bastille; in 1604 governor of Poitiers; and in 1606 duke and peer of Sully, ranking next to princes of the blood. He declined the office of constable because he would not become a Roman Catholic. Sully encouraged agriculture, urged the free circulation of produce, promoted stock-raising, forbade the destruction of forests, drained swamps, built roads and bridges, planned a vast system of canals and actually began the canal of Briare. He strengthened the French military establishment; under his direction Évrard began the construction of a great line of defences on the frontiers. Sully opposed the king's colonial policy as inconsistent with the French genius, and likewise showed little favour to industrial pursuits, although on the urgent solicitation of the king he established a few silk factories. He fought in company with Henry IV. in Savoy (1600–1601) and negotiated the treaty of peace in 1602; in 1603 he represented Henry at the court of James I. of England; and throughout the reign he helped the king to put down insurrections of the nobles, whether Roman Catholic or Protestant. It was Sully, too, who arranged the marriage between the king and Marie de Medicis in 1600.

The political rôle of Sully practically ended with the assassi- nation of Henry IV. on the 14th of May 1610. Although a member of the council of regency, his colleagues were not disposed to brook his domineering leadership, and after a stormy debate he resigned as superintendent of finances on the 26th of January 1611, and retired to private life. The queen-mother gave him 300,000 livres for his services and confirmed him in possession of his estates. He attended the estates-general in 1614, and on the whole was in sympathy with the policy and government of Richelieu. He disavowed the plots at La Rochelle, in 1621, but in the following year was arrested at Moulins, though soon released. The ban of marshal of France was conferred on him on the 18th of September 1634. The last years of his life were spent chiefly at the château of Rosny and Sully. He died at Villebon, on the 22nd of December 1641. By his first wife Sully had one son, Maximilien, marquis de Rosny (1587–1634), who led a life of dissipation and debauchery. By his second wife, Rachel de Cochefilet, widow of the lord of Châteaupers, whom he married in 1592 and who turned Protestant to please him, he had nine children, of whom six died young, and one daughter married in 1605 Henri de Rohan.

Sully was not popular. He was hated by most Roman Catholics because he was a Protestant, by most Protstants because he was faithful to the king, and by all because he was a favourite, and selfish, obstinate and rude. He amassed a large personal fortune, and his jealousy of all other ministers and favourites was extravagant. Nevertheless he was an excellent man of business, inexorable in punishing malversation and dishonesty on the part of others, and opposed to the ruinous court expenditure which was the bane of almost all European monarchies in his day. He was gifted with executive ability, with confidence and resolution, with fondness for work, and above all with an almost unexampled love of his country. He was implicitly trusted by Henry IV. and proved himself the most able assistant of the king in dispelling the chaos into which the religious and civil wars had plunged France. To Sully, next to Henry IV., belongs the credit for the happy transformation in France between 1598 and 1610 by which agriculture and commerce were benefited and foreign peace and internal order were maintained.

Sully left a curious collection of memoirs written in the second person and bearing the quaint title, Mémoires des sages et royales economies d'état, domestiques, politiques, et militaires de Hen-ry le Grand, l'exemple des roys, le prince des vertus, et des loix, et le père en effet de ses peuples francicois; et des ser- vitudes utiles, Economies des plus confidents, familiers, et utiles soldats et officiers des grands Mars des François: dédiées à la France, à tous bons soldats, et tous peuples français. The memoirs are very valuable as a record of the state of the French finances at the time of the fact that they contain many fictions, such as a mission undertaken by Sully to Queen Elizabeth in 1601, and the famous "Grand Design," a plan for a Christian republic, which some historians have taken seriously. Two volumes have been published, the third and fourth splendidly printed, nominally at Amsterdam, but really under Sully's own eye, at his château in 1638; two other volumes appeared posthumously in Paris in 1662. The abbé de l'Ecluse rewrote the memoirs in ordinary narrative form and edited them in 1743. The best edition of the original is that in J. F. Michaud and J. J. F. Poujoulat. Nouvelle collection des mémoires relatifs à l'histoire de France (1814). vols. xvi.-xvii. An English translation by Charlotte Lennox appeared in 1756 and was later revised and republished (4 vols., London, 1865).

SULLY, THOMAS (1753–1872), American artist, was born at Haverhill, New Hampshire, on the 8th of June 1753. His parents, who were both pious Quakers, took him to America when he was nine years old, settling at Charleston, South Carolina, and he was first instructed in art by a French miniature painter. Afterwards he was a
pupil of Gilbert Stuart in Boston, and in 1809 he went to London and entered the studio of Benjamin West. He returned in 1810, and made Philadelphia his home, but in 1837 again visited London, where he painted a full length portrait of Queen Victoria for the St George's Society of Philadelphia. Sully was one of the best of the early American painters. He died in Philadelphia on the 5th of November 1872. Among his portraits are those of Commodore Decatur (City Hall, New York); the actor George Frederick Cooke, as Richard III. (Pennsylvania Academy of the Fine Arts, Philadelphia); Lafayette (Independence Hall, Philadelphia; U.S. Military Academy, West Point, New York); Charles and Frances Anne Kemble, and Reverdy Johnson. His son Alfred Sully (1821–1879) an officer in the United States army, was a brigade-commander in the Army of the Potomac in 1862-63, and after 1863 commanded the department of Dakota and conducted several campaigns against hostile Indians in the north-west. In 1865 he was breveted brigadier-general in the regular army and major-general of volunteers.

SULLY-PRUDHOMME, RENÉ FRANÇOIS ARMAND PRUD- HOMME: French poet, was born in Paris on the 16th of March 1839. He was educated at the Lycée Bonaparte, where after a time he took his degree as Bachelier ès Sciences. An attack of ophthalmia then interrupted his studies and necessitated an entire change in the course of his career. The scientific habit of mind, however, which he had derived from these years of technical study never left him; and it is in the combination of this scientific bent, with a soul aspiring towards what lies above and beyond science, and a conscience perpetually in agitation, that the striking originality of Sully-Prudhomme's character is to be found. He found employment for a time in the Schneider factory at Creuzot, but he soon abandoned an occupation to which he was eminently unsuited. He subsequently decided to read law, and entered a notary's office at Paris. It was during this period that he composed those early poems which were not long in acquiring celebrity among an ever-widening circle of friends. In 1865 he published his first volume of poems, which had for sub-title Stances et poèmes. This volume was favourably reviewed by Sainte-Beuve, to whose notice it had been brought by Gaston Paris. It was at this moment that the small circle of which Leconte de Lisle was the centre were preparing the Pararnes, in which Sully-Prudhomme contributed several pieces. In 1866 Lemercier published a new edition of the Stances et poèmes and a collection of sonnets entitled Les Épreuves (1866). From this time forward Sully-Prudhomme devoted his life entirely to poetry. It was in the volume of Les Épreuves that the note of melancholy which was to dominate through the whole work of his life was first clearly discernible. In 1869 he published a translation of the first book of Lucretius with a preface, and Les Solitudes. In 1870 a series of domestic bereavements and a serious paralytic illness resulting from the strain and fatigue of the winter of 1870, during which he served in the Garde Mobile, shattered his health. In 1872 he published Les Écœurs d'angiés, Croquis italiens, Impressions de la guerre (1866-72) and Les Destins, La Résolte des héros in 1874, in 1875 Les Vaines tendresses, in 1878 L'Injustice, in 1886 Le Prisme, and in 1888 Le Bonheur. All these poems were collected and republished under the title of Poésies, occupying four volumes of his Œuvres (6 vols., 1883–1904). After the publication of Le Bonheur he practically ceased to produce verse, and devoted himself almost entirely to philosophy. He published two volumes of prose criticism L'expression dans les beaux arts (1884) and Réflexions sur l'art des vers (1882). Various monographs by him appeared from time to time in the philosophical reviews, and are among the remarkable series of essays (Revue des deux mondes, Oct. 15th, Nov. 15th, 1890) on Pascal, and a valuable study on the "Psychologie du libre arbitre" in the Revue de métaphysique et de morale (1906). He was elected to the Academy on the 8th of December 1881. On the 10th of December 1901 he was awarded the Nobel prize for literature, and devoted most of the money to the foundation of a prize for poetry to be awarded by the Société de gens de lettres. He was one of the earliest champions of Captain Dreyfus. In 1902 he wrote, in collaboration with Charles Richet, Le Problème des causes finales. During his later years he lived at Châtenay in great isolation, a victim of perpetual ill-health, and mainly occupied with his Vraie religion selon Pascal (1905). He had been partially paralysed for some time when he died suddenly on the 6th of September 1907. He left a volume of unpublished verse and a prose work, Le Lion social, which was a revision of an introduction which he had contributed to Michelet's La Bible de l'humanité.

What strikes the reader of Sully-Prudhomme's poetry first and foremost is the fact that he is a thinker; and moreover a poet who thinks, and not a thinker who turns to rhyme for recreation. The most strikingly original portion of his work is to be found in his philosophic and scientific poetry. If he has not the scientific genius of Pascal, he has at least the scientific habit of mind and a delight in mathematical certainties. In attempting to interpret the universe as science reveals it to us he has created a new form of poetry which is not lacking in a certain grandeur, of his most beautiful poems, "L'Idéal" (Stances et poèmes). His science is not due to scientific calculations, of stars so remote from our planet that their light has been on its way to us since thousands of centuries and will one day be visible to the eyes of a future generation. The second chief characteristic of Sully-Prudhomme's poetry is the extreme sensibility of soul, the profoundly melancholy note which we find in his love lyrics and his meditations. Sully-Prudhomme is above all things introspective; he penetrates into the hidden corners of his heart; he lays bare the subtle torments of his conscience, the shifting currents of his hopes and fears, belief and disbelief in face of the riddle of the universe to an extent so poignant as to be sometimes almost painful. And to render the fugitive phases and tremulous adventures of his spirit he finds incomparably delicate shades of expression, an exquisite and sensitive diction. We are struck in reading his poems by the nobility of his ideas, by a religious elevation like that of Pascal; for there is in his work something both of Lucretius and of Pascal. Yet he is far from being either an Epicurean or a Jansenist; he is rather a Stoic to whom the deceptions of life have brought pity instead of bitterness.

As an artist Sully-Prudhomme is remarkable for the entire absence of oratorical effect; for the extreme simplicity and fastidiously precise of his diction. Other poets have been endowed with a more glowing imagination; his poetry is neither exuberant in colour nor rich in sonorous harmonies of rhyme. The grace of his verse is a grace of outline and not of colour, his melody one of subtle rhythm; his verse is as if carved in ivory, his music like that of a perfect unison of stringed instruments. His imagination is inseparable from his ideas, and this is the reason of the extraordinary perspicuity of his poetic style. He extends poetry to two extreme limits; on the one hand to the borderland of the unreal and the dreamlike, as in a poem such as "Le Rêveur," (Vaines tendresses) in which he seems to express the inexpressible in precise language; on the other hand, in his scientific poems he encroaches on the province of prose. His poetry is plastic in the creation of forms which fittingly express his fugitive emotions and his elevated ideas. Both by the charm of his pure and perfect phrase, by his consummate art, and the dignity which informs all his work, Sully-Prudhomme deserves rank among the foremost of modern poets. (E. G.)

See C. Hémon, La Philosophie de Sully-Prudhomme (1907), Sully-Prudhomme by E. Zyromski (Paris 1907).

SULMONA, or Sulmona, a city and episcopal see of Abruzzi, Italy, in the province of Aquila, 40 m. by rail S.E. by E. of that town, and 107 m. E. by N. of Rome (75 m. direct). Pop. (1901), 13,372 (town), 18,247 (commune). Sulmona is situated at a height of 1322 ft. above the sea on the Giaio, a tributary of the Pescara, which supplies water-power to its paper-mills, fulling-mills and copper-works. Its cathedral of San Panfilo has a 14th-century portal. The interior has been modernized, but in the crypt are some medieval sculptures.
Sulmona has also in S. Maria della Tomba a good example of pure Gothic. S. Francesco d’Assisi occupies the site of an older and larger church, the Romanesque portal of which still stands at the end of the Corso Ovidio, and forms the entrance to the meat market. Opposite is a picturesque aqueduct of 1266 with pointed arches. S. Agostino has a good Gothic portal. The Ospedale Cívico, next to the church of the Annunziata, begun in the first half of the 15th century, shows an interesting mixture of Gothic and Renaissance styles. The window of the Palazzo Tabassi is similar, and both are due to Lombard masters. In the court of the grammar school is a fine 15th-century statue of Ovid, the most celebrated native of the town, whose memory is preserved among the peasants in songs and folk-lore. The Porta Napoli is an interesting gate of the early 14th century. Innocent VII. was a native of the town. In the vicinity of the town is Monte Mormore where Pietro di Morone lived (c. 1254) as a hermit and founded a monastery for his hermits, who after his elevation to the papacy as Celestine V. took the name of Celestines; the monastery (S. Spirito) remained till 1879, when it was transformed into a prison. There are some ruins of the imperial period, attributed, groundless, to the house of Ovid near it. The church contains a Gothic tomb of 1412 by a German master, in which Renaissance influence is, according to Burckhardt, traceable for the first time in Italy in the realistic characterization of the portrait figures.

Sulmo, a city of the Paeligni, is first mentioned during the Second Punic War (211 B.C.). It was the second town of the Paeligni in importance, Cornimontium was the Roman colony probably in the reign of Augustus, and as a municipium it continued to flourish throughout the empire. It was situated 7 m. south-east of Cornimontium on the road to Asseria, and was famous for its iron smelting. Hardly any remains of the ancient city exist above ground, owing to frequent earthquakes. A number of discoveries of tombs (both archaic and of the Roman period), &c., have however been made (cf. A. de Nino, in Notizie degli Scavi, passim). Charles V. erected it into a principality, which he bestowed on Charles Lannoy, who had captured Francis I. at the battle of Pavia. It ultimately passed to the Corono and Borghese families. The bishopric is known as that of Valva and Sulmona.

**Sulphonal**, or acetone diethyl sulphide (CH₃COCH₂CH₂SO₂NCH₂CH₂), a valuable hypnotic prepared by condensing acetone with ethyl mercaptan in the presence of hydrochloric acid, the mercaptol (CH₃COCH₂SH) formed being subsequently oxidized by potassium permanganate (E. Baumann, Ber., 1886, 19, p. 2868). It is also formed by the action of alcoholic potash and methyl iodide on ethylidene diethyl sulphide, CH₂=CH-CH₂SO₂NCH₂CH₂. (When heated to the oxygenation of dithiocarbamic acid with potassium permanganate.) It crystallizes in prisms melting at 125° C., which are practically insoluble in cold water, but dissolve in 15 parts of hot and also in alcohol and ether.

It is the *suiphonalium* of the B.P., and the *sulphonethanum* of the U.S.P. It produces lengthened sleep in functional nervous insomnia, and is also useful in insanity, being given with mucilage of acacia or in hot liquids, owing to its insolubility, or in large capsules. Its hypnotic power is not equal to that of chloral, but as it is not a depressant to the heart or respiration it can be used when morphine or chloral are contra-indicated. It is, however, a hypnotic of long action, often failing to produce sleep when taken at bedtime, but producing drowsiness and sleep the following day. The drowsiness the next day following a medicinal dose can be avoided by a saline laxative the morning after its administration. It is unwise to use it continuously for more than a few days at a time, as it tends to produce the sulphonal habit, which is attended by marked toxic effects, disturbances of digestion, giddiness, staggering gait and even paralysis of the lower extremities. These effects are accompanied by skin eruptions, and the urine becomes of a dark red colour (hematoonuria). Sulphonal is cumulative in its effects. Many fatal cases of sulphonal poisoning are on record, both from chronic poisoning and from a single large dose. Trional (CH₃)(CH₂)(CH₂)C(SO₂CH₃)₃, and tetronal, (CH₂)₃C(SO₂CH₃)₃, are also hypnotics. They are faster in action than sulphonal, and trional does not disorder the digestion.

**Sulphonic Acids**, in organic chemistry, a group of compounds of the type R-SO₂H, where R is an alkyl or an aryl group.

**Sulphonic Acid Salts.**—The members of this class may be prepared by the direct sulphonation of some paraflins (I. Worstall, Amer. Chem. Journ., 1898, 20, p. 664); by the oxidation of mercaptans with concentrated nitric acid (H. Kopp, Ann., 1840, 35, p. 346); in the form of their salts from the alkali halides and alkaline sulphites, and as esters from the alkali halides and silver sulphite. They are colourless oils or crystalline solids which are extremely hygroscopic, very soluble in water and have a strongly acid reaction. They are unaffected by heating with aqueous alkalins or acids and are stable towards concentrated nitric acid. Phosphorus pentachloride converts them into the corresponding acid chlorides, R-SO₂Cl, which are decomposed slowly by water. These chlorides, on reduction by zinc and sulphuric acid, pass readily into the mercaptans, whilst if zinc dust and alcohol be used they are converted into the sulphinic acids, R-SO₂.H.

**Methyl sulphonic acid, CH₃SO₂H,** was obtained by H. Kolbe (Ann., 1845, 54, p. 174) by reducing trichloromethyl sulphonic chloride uncertain in its action on bisulphide. Phosphorus was added to the presence of water: CS₂+3Cl₂+2H₂O = CC1₃SO₂Cl+4HCl+SCl₂, which yields a phosphorus amalgam. It is a colourless syrup which decomposes when heated above 130° C. The corresponding acid chloride is an extremely stable solid which melts at 135° C. It is formed by the action of carbon bisulphide on potassium bichromate in the presence of nitric and hydrochloric acids (Lecw, Zeit. f. Chem., 1869, p. 82).

When heated under pressure it decomposes with the final production of carbonyl and chlorine chlorides: Cl₂SO₂Cl = Cl₂SO₂Cl+CCl₃,

Ethyl sulphonic acid, CH₃CH₂SO₂H, is a crystalline deliquescent solid formed by oxidizing ethyl mercaptan or by reducing sulphonic acid chloride, CH₃CH₂SO₂H. (Kohler, Amer. Chem. Journ., 1898, 29, p. 687.)

Thiosulphonous salts of the type R-SO₂-SH are formed by the action of the thiochlorides on a concentrated solution of potassium sulphite: R-SO₂Cl + K₂S = R-SO₂K+K₂SO₂, or by the action of the salt of a sulphonic acid on an alkaline sulphite in the presence of iodine (Otto, Ber., 1891, 24, p. 144).

**Aromatic Sulphonic Acids.**—The acids of this group are very similar to the corresponding aliphatic sulphonic acids and are usually obtained by the direct heating of an aromatic hydrocarbon with concentrated sulphuric acid, fuming sulphuric acid or thionylchloride. After the action is completed they may frequently be "salted out" by adding common salt to the acid solution until no more dissolves. They are the salt of the acid separates (L. Gattermann, Ber., 1891, 24, p. 2121.) They are also formed by oxidizing thiophenols or by decomposing diazium salts with sulphurous acid. The free acids are usually hygroscopic, crystalline solids which are readily soluble in water. When heated under pressure with concentrated hydrochloric acid to about 150° C. they yield hydrocarbons and sulphuric acid. The salts usually crystallize well, and some of the alkali metals are employed in the preparation of phenols, into which they pass when fused with the caustic alkalis. When distilled with potash they yield the aromatic nitriles. The sulphonic acids with phosphorus pentachloride are converted into sulphonochlorides which are stable to cold water, but with ammonia they yield sulphonamidines, R-SO₂NH₂, and with alcohols esters of the sulphonic acids.

**Benzene sulphonate acid, C₆H₅SO₂H,** melts at 114° C. and is very deliquescent. Benzene sulphonochloride, C₆H₅SO₂Cl, is a fuming liquid which boils at 120° C. (10 mm.). The aminobenzene sulphonic acids, particularly the meta, and para compounds, are of importance owing to their employment in the colour industry. The direct sulphonation of aniline yields the para acid, C₆H₅SO₂(NH₂)H, which crystallizes in small plates and is sparingly soluble in cold water. When CO₂, Caustic potash, or alcohol is added, it yields aniline, whilst oxidation with chromic acid yields benzoquinone. In constitution it is probably to be regarded as a cyclic ammonium salt, C₆H₅(NH₂)SO₂H. When diazotized in acid solution and coupled with dimethyl aniline it yields helianthine.
the sodium salt of which is used as an indicator (g.v.). Metanitric acid C\(\text{H}_3\text{N}(\text{NH}_\text{2})\text{(SO}_2\text{H}) \) (I.3), which crystallizes in prisms, is formed by: the reduction of nitrobenzeno sulfonic acid and is used in the preparation of various azo dyes.

Sulphuric acid, R-SO₃H, are formed by reducing sulphochlorides with zinc dust; by the action of sulphur dioxide on the zinc alkyls (Hobson, Ann., 1857, 102, p. 72; 1858, 106, p. 287); by the action of sulphochlorides on mercaptans in alkaline solution; and by the action of the Grignard reagent on sulphur dioxide or thionyl chloride (Rosenheim, Ber., 1904, 37, p. 2125; Oddo, R. Acad. Lit., 1905 (5), 14 (1), p. 169). The free acids are unstable. They are readily oxidized to sulfonic acids and reduced to thioglycerols. Their alkali salts can be treated with the alkali halides yield sulphones, R-SO₂H. Ethyl sulphinic acid, C\(\text{H}_3\text{H}_2\text{SO}_2\text{H} \) is a colourless syrup. Benzene sulphinic acid, C\(\text{H}_6\text{H}_4\text{SO}_2\text{H} \) crystallizes in large prisms and acts as a reducing agent. It decomposes when heated with water under pressure: 3\(\text{C}_\text{H}_3\text{H}_2\text{SO}_2\text{H} \rightarrow \text{C}_\text{H}_3\text{H}_2\text{SO}_2\text{H} + \text{C}_\text{H}_6\text{H}_4\text{SO}_2\text{H} + \text{C}_\text{H}_2\text{H}_2\text{H} + \text{H}_2\text{O} \). The potassium salt when fused with caustic potash yields benzene and potassium sulphite.

SULPHUR [symbol S, atomic weight 32-07 (O = 16)], a non-metallic chemical element, known from very remote times and regarded by alchemists as the prime of its philosophical nature, as the principle of combustion; it is also known as brimstone (g.v.). The element occurs widely and abundantly in nature both in the free state and in combination. Free or native sulphur, known also as "virgin sulphur," occurs in connexion with volcanoes and in certain stratified rocks in several modes, viz. as crystals, and as stalactitic, encrusting, reniform, massive, earthy and occasionally pulverulent forms as "sulphur meal." It seems rather doubtful whether the unstable monoclinal modification of sulphur (\(\beta\)-sulphur) is ever found in a native state.

The crystals belong to the orthorhombic system, and have usually a pyramidal habit (fig. 1); they may be elliptical or tabular; they are rare. The cleavage is imperfect, but there is a well-marked conchoidal fracture. The hardness ranges from about 1 to 2, and the sp.gr. from 1.9 to 2.1. Crystals of sulphur are transparent or translucent and highly refractive with strong birefringence; they have a resinous or slightly adamantine lustre, and present the characteristic sulphur-yellow or orange-red peculiar to the element. Impurities render the mineral grey, greenish or reddish, bituminous matter being often present in the massive varieties. Sulphur containing selenium, for instance, is called fulvous sulphur. The isles of Vulcano and Lipari, in the Lipari islands, may be occasionally of a peculiar orange-red; and a similar colour is seen in sulphur which contains arsenic sulphide, such as that from La Souflatara near Naples. The presence of tellurium in native sulphur is rare, but is known in certain specimens from Quercettino.

Volcanic sulphur usually occurs as a sublimate around or on the walls of the vents, and has probably been formed in many cases by the interaction of sulphur dioxide and hydrogen sulphide. Sublimed sulphur also results from the spontaneous combustion of coal seams containing pyrites. Deposits of sulphur are frequently formed by the decomposition of hydroggen sulphide, on exposure to the atmosphere: hence natural sulphureous waters, especially hot springs, readily deposit sulphur. The reduction of sulphates to sulphides by means of organic matter, probably through the agency of sulphur-bacteria, may also indirectly furnish sulphur, and hence it is frequently found in deposits of gypsum. Free sulphur may also result from the decomposition of pyrites, as in pyritic shales and lignites, or from the alteration of galena: thus crystals of sulphur occur, with angles, in cavities in galena at Monteponi near Leghorn in Tuscany; while R. G. Herrick states that sulphur sometimes yields sulphur on weathering. It should be noted that the oxidation of sulphur itself by atmospheric influence may give rise to sulphurised in the presence of lime, to the formation of gypsum: thus Sulphur deposits of Sicily suffer alteration of this kind, and have their outcrop marked by a pale earthy rock called briscate.

Some of the most important deposits of sulphur in the world are situated in Sicily, especially in the provinces of Catania and Siracusa, as at Racalmuto and Cattolica; and to a less extent in the provinces of Catania, Palermo (Lercara) and Trapani (Gibellina). The sulphur occurs in Miocene marls and limestone, associated with gypsum, celestine, aragonite and calcite. It was formerly believed that the sulphur had a volcanic origin, but it is now generally held that it has either been reduced from gypsum by organic agencies, or more probably deposited from sulphur-bearing waters. Liquid occasionally enclosed in the sulphur and gypsum has been found by O. Silvestri and by C. A. H. Sjögren to contain salts like those of sulphur-springs. An important zone of sulphur-bearing Miocene rocks occurs on the east side of the Apennines, constituting a great part of the province of Forli and part of Pesaro, Cesena and Ferrara. It is a continuation of the deposits of Caltanisetta, but the latter yielding crystals coated with aspalth. Sulphur is occasionally found crystallized in Carrara marble; and the mineral occurs also in Calabria. Fine crystals occur at Conil near Cadiz; whilst in the province of Teruel in Aragon, sulphur in a compact form replaces fresh-water shells and plant-remains, suggesting its origin from sulphur-springs. nodular forms of sulphur occur in Miocene marls near Radoboj in Croatia, and near Swamowie, south of Cracow. Russia possesses large deposits of sulphur in Doghestan in Transcaucasia, and in the Transcaspian steppes. Important deposits of sulphur are worked at several localities in Japan, especially at the Kosaka mine in the province of Rikuchi, and at Yatsukoda-yama, in the province of Mutsu. Sulphur is worked in Chile and Peru. A complete list of localities for sulphur would include all the volcanic regions of the world. In the United States, sulphur occurs in the following states, in many of which the mineral has been worked: Louisiana (g.v.), Utah, Colorado, California, Nevada, Idaho, Texas and Wyoming. The Rabbit Hole sulphur-mines are in Nevada, and a great deposit in Utah occurs at Cove Creek, Beaver county. In the British Islands native sulphur is only worked in the Isle of Eigg, and is used for the manufacture of blacklead, and the production of lampblack. Carboniferous Limestone of Oughterard in Co. Galway, Ireland.

In combination the element chiefly occurs as metallic sulphides and sulphates. The former are of great commercial importance, being, in most cases, valuable ores, e.g. copper pyrites (copper), galena (lead), blende (zinc), cinnabar (mercury), &c. Of the sulphates we notice gypsum and anhydrite (calcium), barytes (barium) and kieserite (magnesium). Gasous compounds, e.g. sulphur dioxide and sulphurated hydrogen, are present in volcanic exhalations (see Volcano) and in many mineral waters. The element also occurs in the animal and vegetable kingdoms; it is present in hair and wool, and in alburnious bodies; and is also a constituent of certain vegetable oils, such as the oils of garlic and mustard. There is, in addition, a series of bacteria which decompose sulphur compounds and utilise the element thus liberated in their protoplasm (see Bacteriology).
by the combustion of the least sufficient quantity of sulphur, the rest is liquefied. The molten sulphur accumulates on the sole, whence it is by time to time run out into a square stone receptacle, from which it is again run into the interior, thus bringing itself into the shape of truncated cones weighing 110 to 130 lb each. These cakes are sent out into commerce. A calcareous with a capacity of 26,256 cub. ft. burns about two months and produces 90,000 lb of molten sulphur. The yield is in 40-50%. The immense volumes of sulphuric acid evolved give rise to much annoyance; all the minor pits suspend work during the summer to avoid destruction. In one pit of the type, the liquid, and all the material, must be at least 220 yds. from any inhabited place and 110 yds. from any field under cultivation.

More efficient is the Gilly kiln which uses coke as a fuel. The kiln consists of a series of interconnected cells which are both charged with the ore. The first cell is heated and the products of combustion are led into the second cell where they give up part of their heat to the charge. The sulphur, however, is left behind. The outer crust of the metal found in the second cell is at a sufficiently high temperature to ignite spontaneously when air is admitted. Other methods have been employed, but with varying commercial success. For example, in the Griti and Orlando processes the ore is charged into retorts and the fusion effected by superheated steam, the sulphur being run off as usual; or as was suggested by R. E. Bollman in 1867 the ore may be extracted by carbonization, the gas obtained from kilns, contains about 3% of earthy impurities, and consequently needs refining. The following apparatus (invented originally by Michel de Marseilleilles and improved since by Gill) consists essentially of a system of two forms of "refined" sulphur which command demands. It consists of a large stone chamber which communicates directly with two slightly slanting tubular retorts of iron. The retorts are charged with the metal and the volatile part is distilled off to the two crucibles by boiling off an average of 25 lbs of "refined" sulphur (50% C.). The condensed gas passes through a condenser and is caught in a vessel kept at the requisite temperature by means of the lost heat of the retort fires. The chamber has a safety valve at the top of its vault, which is closed by water in such manner that the gas will not be drawn through the chamber to the exterior.

The first puff of sulphur vapour which enters the chamber takes fire and converts the air of the chamber into a mixture of nitrogen and sulphur dioxide. The next following instamants of vapour, getting diffused throughout a large mass of relatively cold gas, condense in a kind of "snow," known in commerce and valued as "flowers of sulphur" (flores sulphuris). By conducting the distillation slowly, so that the temperature within the chamber remains not very great, it is possible to obtain the whole of the product in the form of "flowers." If compact ("roll") sulphur is wanted the distillation is made to go on at the quickest temperature. The temperature of the interior of the chamber soon rises to more than the freezing-point of sulphur (113°C), and the distillate accumulates at the bottom as a liquid, which is tapped off from time to time to be cast into the customary form of rods.

The Louisiana deposits are worked by a process devised by Herman Frasch in 1891. It consists in sinking a bore-hole, after the manner of a petroleum well, and letting in pipes centrally arranged, the outer pipe being 10 in. in diameter, the next 6 in., the next 3 in. and the innermost 1 in. In the superheated steam is forced down the outer pipe superheated steam at 330°F. to melt the sulphur. Compressed air is now driven down the 1-in. pipe and bubbles into the melted sulphur and set it in violent action with great heat, so that it rises to the surface through the outer pipes; it is then run off to settling tanks. The sulphur so obtained is 98% pure.

In some places sulphur is extracted from iron pyrites by one of two methods. The pyrites is subjected to dry distillation from out of iron or fire-clay tubular retorts at a bright red heat. One third of the sulphur is volatilized: 3FeS₂ = Fe₂S₃ + 2S and is obtained as a distillate. The second method is analogous to the calcareous method of liquefication; the ore is placed in a lime-kiln like furnace over a mass of kindled fuel to start a partial combustion of the mineral, and the process is so regulated that, by the heat generated in the interior, the mass is converted into a semi-solution which collects in the molten state on an inverted roof-shaped sole below the furnace and is then conducted into a cistern. Such pyrites sulphur is usually contaminated with arsenic, and consequently is known as Sicilian black sulphur. In Sicily, and elsewhere, it is almost free from this impurity.

Large quantities are also recovered from alkali waste (see ALKALI MANUFACTURE); another source is the spent oxide of gas manufacture (see GAS).

The substance known as "milk of sulphur" (lac sulphuris) is a very finely divided sulphur produced by the following, or some analogous, process. One part of sulphur is mixed with two parts of water, the paste produced diluted with 24 parts of water; 2-3 parts of sulphur are added; and the whole is boiled for about an hour or longer, when the sulphur dissolves. The mixed solution of the divalent and thiosulphate of sulphur is produced is clarified, diluted largely, and then mixed with enough of pure dilute hydrochloric acid to produce a feebly alkaline mixture which is then coagulated. The addition of more acid would produce an additional supply of sulphur (by the action of the H₂S₃O₄ on the dissolved H₂S); but this thiosulphate sulphur is yellow and compact, while the polysulphide part has the desired qualities, forming an extremely fine, almost white, powder. The precipitate is washed, collected, and dried at a very moderate heat.

Properties.—Sulphur exists in several allotropic modifications, but before considering these systematically we will deal with the properties of ordinary (or rhombic) sulphur. Commercial sulphur forms yellow crystals which melt at 113°C and boil at 444-53°C. The compound is under ordinary pressure (H. L. Callendar, Chem. News, 1891, 63, p. 1) just above the boiling point the vapour is orange-yellow, but on continued heating it darkens, being bluish-pink at 500°C. At temperatures below 650°C these yellow sulfur forms the compound with chlorine, forming a dissociation of the molecules. At 524°C Dumas deduced the structure S₂ from vapour-density determinations, whilst for the range 860 to 1040°C, Sainte-Claire Deville and Troost deduced the formula S₆. Blitz (Ber., 1888, 21, p. 1031, 1901, 34, p. 2490) showed that the vapour density decreased with the temperature, and also depended on the pressure. G. Preuner and W. Schupp (Zeit. phys. Chem., 1900, 69, p. 157), in a study of the dissociation isotherms over 300-850°C, detected molecules of S₂, S₃ and S₄, whilst S₅ appears to exist below pressures of 30 mm. Because of its freezing-point determinations of the molecular weight in solution indicate the formula S₆. The density of solid sulphur is 2.062 to 2.070, and the specific heat 0.172; it is a bad conductor of electricity and becomes negatively electrified on friction. It ignites in air at 363°C and in oxygen at 275-280°C (H. Moissan, Compt. rend., 1903, 137, p. 547), burning with a characteristic blue flame and forming much sulphur dioxide, recognized by its pungent odour. At the same time a little trioxide is formed, and, according to Hempel (Ber., 1890, 23, p. 1459), half the sulphur is converted into this oxide if the combustion be carried out in oxygen at a pressure of 40 to 90 atmospheres. Sulphur also combines directly with most of the elements to form sulphides. The atomic weight was determined by Berzelius, Ehrmann and Marchand, Dumas and Stan Thomsen (Zeit. phys. Chem., 1894, 13, p. 736) obtained the value 32-0660.

Allotropic Modifications.—Sulphur assumes crystalline, amorphous and (possibly) colloidal forms. Historically the most important are the rhombic (S₆) and monoclinic (S₈) forms, discussed by E. Mitscherlich in 1822 (see Ann. chim. phys., 1823, 24, p. 264). The transformations of these two forms are slow. In the presence of water, sulphur may be obtained artificially by slowly crystallizing a solution of sulphur in carbon bisulphide, or, better, by exposing pyridine saturated with sulphurhexed hydrogen to atmospheric oxidation (Ahrens, Ber., 1890, 23, p. 2708). It is insoluble in water, but readily soluble in carbon bisulphide, sulphur chloride and oil of turpentine. The common monoclinic variety is obtained by allowing a crust to form over molten sulphur by partially cooling it, and then breaking the crust and pouring off the still liquid portion, whereupon the interior of the vessel will be found coated with long needles of this variety. Like S₈ it is soluble in carbon bisulphide. Three other monoclinic forms have been described. By acting upon a solution of sodium hyposulphite with potassium bisulphate, Gernze (Compt. rend., 1884, 98, p. 144) obtained a form which he termed nacre (or pearly) sulphur; the same modification was obtained by Sabatier (ibid., 1885, 100, p. 1346) on shaking hydrogen persulphide with alcohol or ether. It is readily transformed into rhombic sulphur. Another form, mixed with the variety just described, is obtained by adding 3 to 4 volumes of alcohol to a solution of ammonium sulphide saturated with sulphur and exposing it to the air for a time. Engel's monoclinic form (Compt. rend., 1891, 112, p. 866) is obtained by mixing a solution of sodium hyposulphite with double its volume of hydrochloric acid, filtering and extracting with chloroform; the extract yielding the variety on evaporation. A triclinic form is claimed to be obtained by Friedel (Bull. soc. chim., 1879, 32, p. 14) on subliming ordinary sulphur.

1 It is a common practice of keepers of dogs to place a piece of roll sulphur in the animal's water but this serves no useful purpose owing to this property.
Amorphous sulphur or $S_n$ exists in two forms, one soluble in carbon bisulphide, the other insoluble. Milk of sulphur (see above), obtained by decomposing a polysulphide with an acid, contains both forms. The insoluble variety may also be obtained by decomposing sulphur chloride with water and other reactions. Crystallisation takes place between 200° and 250° C.

The colloidal sulphur, $S_n$, described by Debus as a product of the interaction of sulphuretted hydrogen and sulphur dioxide in aqueous solution, is regarded by Spring (Rec. trav. chim., 1906, 25, p. 253) as a hydrate of the formula $S_nH_2O$. The "blue sulphur," described by Orloff, has been investigated by Paternò and Mazzucchelli (Abs. Journ. Chem. Soc., 1907, ii. 451).

**SULPHUR**

Molten Sulphur—Several interesting phenomena are witnessed when sulphur is heated above its melting point. The solid melts to a pale yellow liquid which on cooling and heating gradually darkens and becomes more viscous, the maximum viscosity occurring at 180° C, the product being dark red in colour. This change is associated with a change in the spectrum (N. Lockyer). On continuing the heating, the viscosity diminishes while the colour remains the same. If the viscous variety be rapidly cooled, or the more highly heated mass be poured into water, an elastic substance is obtained, termed plastic sulphur. This substance, however, on standing becomes brittle. The character of molten sulphur has been mainly elucidated by the researches of A. Smith and his collaborators. Smith (Abs. Journ. Chem. Soc., 1907, ii. 20, 454, 757) forms sulphur as a mixture of two fluids, the primary of which in dynamic equilibrium, $S_n$ being light in colour and mobile, and $S_n$ dark and viscous. At low temperatures $S_n$ predominates, but as the temperature is raised $S_n$ increases; the transformation, however, is retarded by some gases, e.g. sulphur dioxide and hydrochloric acid, and accelerated by others, e.g. ammonia. The solid derived from $S_n$ is crystalline and soluble in carbon bisulphide, but that from $S_n$ is amorphous and insoluble. As to the formation of precipitated sulphur, Smith considers that the element first separates in the liquid $S_n$ condition, which is transformed into $S_n$ and finally $S_n$; the insoluble (or carbon bisulphide) forms arise when little of the $S_n$ has been transformed; whilst the soluble consist mainly of $S_n$. Similar views are adopted by H. Erdmann (Ann., 19-8, 362, p. 133), but he regards $S_n$ as the polymer $S_n$, analogous to ozone $O_3$; Smith, however, regards $S_n$ as $S_n$.

**Compounds**

Sulphuretted hydrogen, $H_2S$, a compound first examined by C. Scheele, may be obtained by heating sulphur in a current of hydrogen, or by the action of an oxidising agent on a solution of sulphur or its compounds, and being at complete at the latter temperature, dissociation taking place above this temperature (M. Bodenstein, Zeit. phys. Chem., 1899, 29, p. 315); by heating some metallic sulphides in a current of form sulphide; and also by decomposing many metallic salts with (ferrous sulphide and dilute sulphuric acid being most generally employed); by the action of sulphur on heated paraffin wax or vaseline, or by heating a solution of magnesium sulphide. It is also produced during the putrefaction of organic substances containing sulphur and is found among the products obtained in the destructive distillation of coal. To obtain pure sulphuretted hydrogen the method generally adopted consists in decomposing precipitated antimony sulphide with concentrated hydrochloric acid. As an alternative, H. Moissan (Comp. rend., 1903, 137, p. 363) condenses the gas by means of liquid air and fractionates the product.

$H_2S$ is a colourless, odourless, and offensive gas. It acts as a strong poison. It burns with a pale blue flame, forming sulphur dioxide and water. It is moderately soluble in water, the solution possessing a faintly acid reaction. This solution is not very stable, since on exposure to air it slowly oxidizes and becomes turbid owing to the gradual precipitation of sulphur. The gas is much more soluble in alcohol. It forms a hydrate of composition $H_2S.H_2O$. (De Foreman, Comp. rend., 1888, 106, p. 1357.) The gas may be liquefied by a pressure of about 17 atmospheres, the liquid so obtained boiling at –61°.8 C.; and by further cooling it yields a solid, the melting point of which is given by various observers as –82° to –86° C. (see Ladenburg, Ber., 1900, 33, p. 337). It is decomposed by the halogenes, with liberation of sulphur. Concentrated sulphuric acid also decomposes it: $H_2SO_4 + H_2S = 2H_2O + SO_2 + S$. It combines with many metals to form metallic sulphides, and also decomposes many metallic salts with consequent production of sulphides, a property which it extremely useful in chemical analysis. It is frequently used as a reducing agent; in reducing arsenates to arsenites, permanganates to manganous salts, etc., whilst in alkaline solution it converts many organic nitro compounds into the corresponding amino-derivatives. Oxidising agents rapidly unite with sulphuretted hydrogen, the primary products of the reaction being water and sulphur.

By the action of dilute hydrochloric acid on metallic polysulphides, and other products, which are obtained by a more thorough or incomplete oxidation of $S_n$ is usually considered to be $H_2S$. Thiogallate, on the other hand, is a form of $S_n$ or $S_n$. It was also examined by W. Ramsay (Journ. Chem. Soc., 1874, 12, p. 857). Hofmann, who obtained it by saturating an alcoholic solution of thioacetamide with a solution of hydrochloric acid, with an alcoholic solution of styrchmy, considered the resulting product to be $H_2S$; while P. Sabatier by fractionating the crude product in vacuo obtained an oil which boiled between 60° and 80° C. and possessed a musky odour.

Several halogen compounds of sulphur are known, the most stable of which is sulphur fluoride, $SF_6$, which was first prepared by H. Moissan and Lebeau (Comp. rend., 1900, 130, p. 866) by fractionally distilling the vitreous mass formed by the reaction of hydrogen fluoride on sulphur. It is Tasteless, colourless, and odourless gas, which is exceedingly stable and inert. It may be condensed and yields a red mass at –55° C. Sulphur hexafluoride decomposes it with formation of hydrofluoric acid and liberation of sulphur. Sulphur chloride, $SCl_2$, is obtained as a by-product in the manufacture of carbon tetrachloride from carbon bisulphide and chlorine, and on exposure to air it readily decomposes to sulphur, chlorine gas, or by the action of sulphur on sulphuryl chloride in the presence of aluminium chloride (O. Ruff). It is an amber-coloured, fuming liquid possessing a very unpleasant irritating smell. It is liquefied at –90° C. the liquid of which has a yellowish-brown tinge, is soluble in benzene and ether, and in benzine. It is decomposed by water: $2SCl_2 + 3H_2O = 4HCl + 2S + H_2SO_4$, the thiosulphuric acid produced, on gradual decomposing into water, sulphur and sulphur dioxide. Sulphur chloride is a gas with great readiness and is consequently used largely for vulcanising rubber; it also dissolves chlorine. The chloride $SCl_3$ according to the reactions $S + 3Cl_2 = SCl_3$ and $3SCl_2 + Cl_2 = 2SCl_4$ did not appear to exist, but E. Beckmann (Zeti. phys. Chem., 1899, 42, p. 1839) obtained it by distilling the product of the interaction of chlorine and $SCl_2$ at low pressures. The tetrachloride, $SCl_4$, is formed by the action of chlorine on carbon bisulphide (App. Ann., 1873, 70, p. 191), it is a yellowish-brown liquid which dissolves rapidly with rise of temperature. On cooling it solidifies to a crystalline mass which fuses at –72° C. (Ruff, ibid.).

Water dissolves it violently with formation of hydrochloric and sulphuric acids. Sulphur bromide, $SBr_2$, is a dark red liquid which boils with decomposition at about 200° C. The products obtained by the action of iodine on sulphur are probably mixtures, although E. McIlvorp (Chem. News, 1902, 86, p. 5) obtained a substance of composition $SIF_4$ (which in all probability is a chemical individual) as a reddish-coloured powder by the action of sulphuretted hydrogen on solutions of iodine.

Four oxides of sulphur are known, namely sulphur dioxide, $SO_2$, sulphur trioxide, $SO_3$, sulphur sesquisioxide, $SO_3$, and persulphuric anhydride, $SO_3$. The dioxide has been known since the earliest times, and is obtained by burning sulphur, especially in the exhalations of volcanoes and in solution in some volcanic springs. It was first collected in the pure condition by J. Priestley in 1775 (Phil. Trans., 1775, pp. 354, 361), and was adopted by A. L. Lavoisier in 1789 (Zeti. phys. Chem., 1789, 2, p. 1). It is formed when sulphur is burned in air or in oxygen, or when many metallic sulphides are roasted. It may also be obtained by heating carbon, sulphur and many metals with concentrated sulphuric acid: $C + 2H_2SO_4 = 2SO_2 + CO_2 + 2H_2O; S + 2H_2SO_4 = 2SO_2 + 2H_2O; Cu + 2H_2SO_4 = SO_2 + CuSO_4 + 2H_2O$; and by decomposing a sulphite, a thiosulphate or a thionite acid with a dilute mineral acid. It is a colourless gas which possesses a characteristic suffocating odour. It does not burn, neither does it support combustion. It is readily soluble in alcohol and in water, the solution in water characterising with increasing strength a strongly acid reaction. It is easily liquefied, the liquid boiling at –18 C., and it becomes crystalline at –72 C. (Ruff, ibid.).

It is shown by the action of chlorine or carbon tetrachloride upon a solution of potassium sulphite, $K_2SO_3$ and $KCl$, that the latter is a compound of $SO_2$ and $SO_3$, and that $S_2=Cl$. In the presence of water it frequently acts as a bleaching agent, the bleaching process in this case being one of reduction. It is frequently used as an antichlor, since in presence of water it has a strong alkaline action: $2SO_2 + 2H_2O = 2H_2SO_3$.

In many cases it acts as a reducing agent (when used in the presence of acids); thus, permanganates are reduced to manganous salts, iodates are reduced with liberation of iodine, etc., $2KMnO_4 + 3SO_2 = K_2SO_4 + 2MnSO_4 + 2H_2O; 2KIO_3 + 5SO_2 + 4H_2O = 2KI + 2H_2SO_4 + 3H_2O$.
It is prepared on the industrial scale for the manufacture of sulphuric acid, for the preparation of sodium sulphate by the Bredig point, and for use as a fuming agent and as a preservative. When compressed it is also used largely as a refrigerating agent, and in virtue of its property of neither burning nor supporting combustion it is also used as a fire extinguisher. The free acid is not readily decomposed by water, but it is readily decomposed by water with liberation of sulphur, sulphuric acid, and thiocarbonyl sulphide. It forms a hydrate with water and is used as a fuming agent. The gas is also inserted into the form of a salt, and is used as a smoke-producing agent.

There are various methods of preparing sulphuric acid, but the most important is the Voltaic process, in which the free acid is inserted into the gas in a tube at 180°C. It is then inserted into sulphuric acid, with liberation of sulphur. Numerous salts, termed sulphates, are known. Since the free acid would be diatomic, two such acids would be formed, the neutral and acid acid. They are not truly alicyclic compounds, however, but the free acid is considered to be the isomer of the oxides, hydroxides or carbones of the metals, or by processes of precipitation. Sulphuric acid may have either of the constitutions OH₂SO₃OH or OH₂SO₃O⁻, or be an equilibrium mixture of these two substances. Although the correct formula for the acid is not known, sulphates are known of both types. Sodium sulphate is almost certainly the second and the unsymmetrical type. Two ethyl sulphates are known, the first or symmetrical type being derived from ethyl sulphuric chloride and alcohol, and the second and unsymmetrical type being derived from sodium ethyl sulphate and alcohol.

Sulphur dioxide, SO₂, has been obtained as a fuming gas by decomposing the sulphur dichloride, SO₂Cl₂, with a catalytic mixture of concentrated sulphuric acid and potassium dichromate. The resulting gas is a mixture of SO₂ and SO₃, with SO₂ being the principal component. SO₂Cl₂ can be obtained by the reaction of chlorine and sulphur dioxide at high temperatures and pressures. It is also obtained by the action of chlorine on a mixture of sulphur trioxide and water. SO₂Cl₂ is a powerful oxidizing agent and is used in the preparation of a wide range of compounds, including sulphones and sulfoxides. It is a colorless gas with a pungent odor. It is also used as a bleaching and disinfecting agent.

Sulphur dioxide is a gas with a pungent odor and a reddish-brown color. It is a powerful oxidizing agent and is used in the preparation of a wide range of compounds, including sulphones and sulfoxides. It is a colorless gas with a pungent odor. It is also used as a bleaching and disinfecting agent. Sulphur dioxide is a gas with a pungent odor and a reddish-brown color. in the form of its barium salt by suspending freshly precipitated hydrated manganese dioxide in water and passing sulphur dioxide into the mixture until all is dissolved; the barium salt is then precipitated by the careful addition of barium hydroxide. Much manganese dioxide is used during the process.

Barium tetrathionates, prepared by Long (Journ. Chem. Soc., 1901, 80, p. 1) and by Davis and Ewart (Journ. Chem. Soc., 1901, 80, p. 227), have also been prepared. The tetrathionates are only sparingly soluble in water. The crystals, which are easily obtained, are about 0.01 millimetre in diameter, and are of a yellowish-green colour.

Sulphuric acid, H₂SO₄, is a colourless, odourless, liquid, or an oily liquid, having the specific gravity of 1-834 at 15°. It boils at 338°, and at about 400° the vapour dissociates into sulphur trioxide and water; at a red heat further decomposition ensues, the sulphur trioxide dissociating into the dioxide and water. It freezes to a colourless crystalline mass, melting at 10-5°. The acid is extremely hygroscopic, absorbing moisture from the atmosphere with great rapidity; hence it finds considerable application as a desiccating agent. The behaviour of aqueous solutions of sulphuric acid is very interesting. The pure acid (100% H₂SO₄) cannot be prepared by boiling down a weaker acid under any pressure (at least between 3 and 300 centimetre of mercury) an acid of the composition H₂SO₄.3H₂O or 1250SO₃H₂O being invariably obtained. Neither is there any advantage gained by mixing this hydrate with sulphur trioxide; for when such a mixture is concentrated by evaporation, sulphur trioxide is vaporized until the same hydrate is left. The pure acid, however, may be obtained by strongly cooling this hydrate.
SULPHURIC ACID

when it separates in the form of white crystals, which melt at 105°, and on gentle heating evolve sulphur trioxide and again form the same hydrate. When strong sulphuric acid is mixed with water there is a great development of heat; the heat evolved when four times its weight of water is added to one of concentrated sulphuric acid raises the temperature from 0° to 100° C. (Hence the laboratory precaution of always adding the acid to the water and not the water to the acid.) In addition to the heat evolution there is also a diminution in volume, the maximum occurrence when the components are present in the ratio \( \text{H}_2\text{SO}_4:2\text{H}_2\text{O} \), thus pointing to the existence of a hydrate \( \text{H}_2\text{SO}_4\cdot2\text{H}_2\text{O} \). A second hydrate, \( \text{H}_2\text{SO}_4\cdot\text{H}_2\text{O} \), may be obtained as rhomblic crystals, which melt at 7° and boil at 208°, by diluting the strong acid until it has a specific gravity of 1.78, and cooling the mixture; this compound is sometimes known as glacial sulphuric acid. Lead and dihydrates form freezing mixtures with snow. Other hydrates have also been described.

Reactions. — Sulphuric acid has the widest commercial application of all chemical reagents. Here only reactions of commercial utility will be considered, and reference should be made to the article SULPHUR for reactions which are more of a purely scientific interest. In its reactions Sulphuric acid exhibits the properties of a strong oxidizing and dehydrating agent, and its power of expelling other acids from their salts.

In the first group we have to notice the use of iron or zinc and dilute sulphuric acid for the manufacture of hydrogen gas. Hydrogen is used directly for the purposes of combustion, or in the nascent condition, for reduction purposes, as generally is the case in organic chemistry (see ANILINE). It is worthy of notice that while many valuable processes depend upon dilute sulphuric acid for their success, the use of the concentrated acid has been of considerable number of commercial processes. Hydrochloric, hydrobromic, hydriodic, hydrofluoric, nitric, phosphoric and many other acids are manufactured by the action of sulphuric acid on their salts: the alkali and chlorine industries, and also the manufacture of bromine and iodine, employ immense quantities of this acid.

In organic chemistry sulphuric acid is extensively employed. Its immense affinity for the elements of water makes it a valuable dehydrating and condensation agent. It extracts the elements of water from formic acid, giving carbon monoxide; from oxalic acid, forming carbon and carbon monoxide; from acetic acid, it is able to give ether or ethylene according to the conditions of the experiment; and from many oxygenated compounds (e.g. sugar, tartaric acid, &c.), with the production of charcoal masses. The formation of glyceric aldehydes and ketones by the action of sulphuric acid on glyceric alcohols is of considerable scientific interest and of the utmost importance in the history of organic chemistry.

It also acts in an opposite manner in certain cases, adding the elements of water to compounds; thus, nitriles are converted into acid-amides, and various acetylene derivatives may be caused to yield ketonic derivatives. As an oxidizing agent its application is limited. The transformation of pipetidine into pyridine by W. König, and the observation that antraquinone yields oxy-antraquinones when treated in the cold with strong sulphuric acid, and the recent introduction of fuming sulphuric acid for the oxidation of naphthalene to phthalic acid, a process of great value in the manufacture of artificial indigo, may be noted. But its chief employment is inorganic and has no resemblance to the properties of other acids when it reacts with aromatic hydrocarbon residues; these compounds being important either as a step towards the preparation of hydroxy-compounds, e.g. resorcin, the naphthols, alizarin, &c., or for which many of them do not possess a convenient soluble form.

Sulphates. — Sulphuric acid, being a dibasic acid, forms two series of salts with monovalent metals; an acid salt, MHSO\(_4\), and a basic salt, MSO\(_4\), the hydronio acid being employed in the manufacture of sulphur trioxide. When heated it loses water to form sodium pyrosulphate, NaHSO\(_4\), which on treatment with sulphuric acid yields normal sodium sulphate and sulphur trioxide. The normal sodium sulphate is the more important, and occur widely and abundantly distributed in the mineral kingdom; anhydrite, gypsum, angleseyite, barytes, celestite and kieserite (of the commonest occurrence in the United States). As the sulphates are soluble in water, and exhibit well crystallized forms. Of the most insoluble we may notice the salts of the metals of the alkaline earths, barium, strontium and calcium, barium sulphate, both the hydroxy and calcium sulphate sparingly but quite appreciably soluble. Lead sulphate is very slightly soluble in water, soluble in strong sulphuric acid, and almost insoluble in alcohol.

Sulphates may be detected by heating the salt with carbonate on charcoal in the reducing flame of the blowpipe; the black stain produced if the mass be transferred to a silver coin and then moistened. In solution, sulphates are always detected and estimated by the formation of a white precipitate of barium sulphate on treatment with barium chloride solution; the whole being made to react together in the presence of excess of barium chloride. This is the BaCI\(_2\) method. When the precipitation of barium chloride is slight, and the white precipitate is not formed, the BaO method is used. In this case the precipitate is not allowed to separate, but the excess of barium chloride is added until a white precipitate is formed, and the excess of BaO is determined by the reduction of barium chloride to sulphate. The precipitate is then washed, dried, and the barium in the precipitate estimated as sulphate.

Manufacture. — The first step in its manufacture is the combustion of sulphur. Formerly this was employed exclusively in the free state as brimstone, and was still employed in some countries, notably in the United States, but the great bulk of sulphuric acid is now made from metallic sulphides, especially those of iron and zinc. Most of the brimstone of trade at the present day comes from Sicily, Spain, and the United States, but in the United Kingdom, as playing an important part, and seems likely to oust the Sicilian sulphur. Free sulphur is also contained as "gas sulphur" in the "spontex" of gasworks, which are actually utilized for the manufacture of phytic acid by burning off the pure state from the "alkali waste" of the Leblanc process, but this "recovered sulphur" is too expensive to be burned for the purpose in quantity. In the United Kingdom much gas sulphur is used for the manufacture of sulphuric acid, together with a limited quantity of Sicilian sulphur for the production of sulphuric acid free from arsenic.

The largest single percentage of the sulphuric acid is made from pyrites, i.e. more or less pure disulphide of iron which occurs in large quantities in many countries. Great Britain produces very little of it, Ireland a little more, but of poor quality. Most of the pyrites of the United States, which can be made to yield a large proportion of pure iron pyrites for the production of sulphuric acid, is imported from Spain. Pyrites generally (not always) contains enough copper (say 3 or 4 %) to make its extraction from the residues ("cinders") worth while. The annual production of pyrites in the United States is nearly 15,000,000 tons, of which 7,000,000 tons are utilized for the production of sulphuric acid by the pyrites-burner method. Germany also contains large quantities of pyrites, and most of it is utilized for the production of sulphuric acid.

A very important source of sulphuric acid is the并不完全的句子，可能与实际内容相关且可能需要进一步的上下文才能完全理解。
The gas produced in the burning of sulphur ores, when issuing from the burner, holds in mechanical suspension a considerable quantity of "flue-dust," which must be removed as far as is practicable before the gas is subjected to further treatment. "Flue-dust" consists essentially of the salts of the respective sulphuric acids, and small quantities of the various metals occurring in the raw ore. All the thallium and selenium on the market is obtained from this source. Sometimes the burner-gas is employed directly for the distillation of the oxygen in the air to form "sulphite cellulose" from wood. When the gas is to be utilized for the manufacture of sulphuric acid the SO₃ must be combined with more oxygen to form SO₃ gas. This SO₃ gas is then connected. Until recently the only agent practically used for this purpose was furnished by the oxides of nitrogen; more recently other oxygen carriers, acting by "contact processes," have also been employed.

The production of sulphuric acid by the assistance of the oxides of the nitrogen of the nitrogenous carburettor gases is carried out in the "vitriol chambers." These are immense receptacles, mostly from 100 to 200 ft long, 20 to 30 ft wide, and 15 to 25 ft high, constructed of sheet-lead, the joints of the sheets being made by "burning" or autogenous soldering. Fusing them together by a blow-pipe without the aid of solder (which would be quickly destroyed by the reaction) the chambers must be supported on all sides by suitable wooden or iron framework, and they are always erected at a certain height over the ground, so that any leaks occurring can be easily detected. In practically all the chambers a single burner-gas line forms a set of a cubic capacity of from 100,000 to 200,000 cub. ft. The burner gas is introduced at one end, the waste gases issue from the other, and the movement of the gases is impelled partly by their own pressure, partly by the height of the chimney (or tower), or by mechanical means.

At the same time water is introduced in a number of places in the shape of steam or in the shape of liquid water. In consequence the SO₂ + H₂O = H₂SO₃. As this reaction of its own accord takes place only to a very small extent, an "oxygen carrier" is always introduced in the shape of the vapours of nitric acid or the lower oxides of nitrogen or both. This is used practically the whole of the SO₂ is ultimately converted into sulphuric acid, and at the same time the nitrogen oxides are always recovered with comparatively very slight losses and made to serve other purposes.

The reactions taking place in the vitriol chambers are very complicated, and have been explained in many different ways. The view hitherto accepted by most chemists is that developed by G. Lunge, according to which there are two principal reactions, succeeding each other, it may be in quite contiguous places, but under different conditions. Where the nitrous fumes prevail and there is less water present, sulphur dioxide combines with nitric acid and oxygen to form nitro-sulphuric acid, a crystalline substance of the formula SO₃(OH)(ONO). The reaction is therefore: SO₂ + O + HNO₃ = SO₃(OH)(ONO). The solid substance is, however, only formed in every fourth or fifth chamber of the apparatus consisting of sulphuric acid floating in the chamber and forming "nitrous vitriol." Wherever this nitrous vitriol comes into contact with liquid water, it is immediately converted into sulphuric acid, the mixture of mist, and practically as dilute sulphuric acid, it is decomposed into sulphuric and nitrous acid, thus: SO₃(OH)(ONO) + H₂O = H₂SO₄ + HONO₂. The re-formed nitric acid, although not so strong as nitric acid, is used to the same extent as nitric acid, and is used as an "oxygen carrier" in question, as the products of its spontaneous decomposition, when meeting with other compounds, always react like nitric acid itself and thus may transfer an indefinite quantity of oxygen to the corresponding quantities of SO₃ and H₂O, with the corresponding formation of H₂SO₄. This theory at once explains among other things, why the acid formed in the vitriol chambers always contains an excess of water (the second of the above-quoted reactions requiring the "mass action" of this excess), and why the external cooling produced by the contact of the chamber sides with the air is of great importance (liquid water in the shape of air-cooled "vitriol"").

In 1906 (in a paper published with Bert) to some extent modified his views, by introducing an intermediate compound, phosphotungstic acid, SO₄H₂O, which had been noticed by various chemists by its action on the phosphoric acid gas emitted in the formation of the blue colour to sulphuric acid. It is evident that the "nitrous gases" present in the vitriol chamber consist essentially of a mixture of SO₃ and SO₂. This SO₃ gas is further oxidized by NO from the excess of oxygen present. The NO (or (NO + O)NO) reacts with the SO₃, forming SO₃NH₂, which, being extremely unstable, is at once oxidized to SO₃NH₃ (nitro-sulphuric acid). The latter is now either converted into nitrogen by the gas issuing from the bottom of the tower, or it reacts with more SO₃ forming again sulphonitric acid: 2SO₃NH₂ + SO₃ = 2SO₃NH₃ + SO₃NH₂. The latter can also be converted into the nitric acid by the aid of NO and SO₃.

Whatever is the true theory of the vitriol-chamber process, there is no doubt about the way in which the reactions have to be carried out in practice. Since the reactions occur among gases and liquids in the nebulous state, vast spaces have to be provided in which the process may be carried out as completely as possible before the waste gases are allowed to escape into the outer air. These spaces cannot be constructed in any way other than is actually done; that is, by means of chimney-shaped chambers, together with about a third, or at least a fourth, of the oxygen originally present therein, such excess of oxygen being required to drive off to the outer air the nitrogen, which is obtained, rather than iron oxide, in a way that would be quickly destroyed by the acid liquids and gases.

When issuing from the chambers, the gases still contain the whole of the nitrous acid and a mixture of sulphuric acid and nitric acid. It is necessary to employ much more water than is required to form H₂SO₄; and this is the more necessary as strong sulphuric acid could not be formed in the absence of nitric acid, and thus withdraws these oxygen carriers from the gas-space of the chambers where the necessary reactions take place. It follows from this that the acid collecting at the bottom of the chambers must never exceed a certain concentration, say 70% of H₂SO₄, having a specific gravity of 1.615, but it is preferable to make it only 66 to 67% having a specific gravity of 1.57 to 1.58. On the steam required for the working of the chambers; and the acid issues from the apparatus in a "denitrated" and sufficiently concentrated state (78 to 80% H₂SO₄) to be used over again for absorbing nitrous vapours or any other purpose desired.

The process is, therefore, a continuous one, with the aid of the following cycle of operations is carried out. To begin with, in the burners pyrites (or, as the case may be, brimstone or blende) is partially oxidized to yield SO₂, and this is conveyed to the chambers; in the bottom of the tower, the SO₂ is absorbed with water, and the remaining gases containing the odour of SO₂ are conveyed back to the top of the tower and the recovery process begins again. The SO₂ is forced out of the acid by the steam, thereby liberating the SO₃ with which it is combined, and the acid which resembles the Glover tower, but is usually filled with coke, over which sulphuric acid of about 80% H₂SO₄ trickles down in sufficient quantity to retain the nitrous vapours. Ultimately the gas is drawn off by a chimney, or sometimes by mechanical means.
SULPHURIC ACID

with the nitrous vitriol. Although this method appears more troublesome, it allows the amount of nitre to be more easily and more accurately regulated. The size of the Glover towers, and more especially that of the Gay-Lussac towers, has been progressively increased, and thereby the cube of the lead chambers themselves has diminished to a much greater extent. By improved process the Faure and Kessler apparatus, which consists of a platinum pan, surmounted by a double-walled leaden hood, in such a manner that, while the hood is constantly cooled from the outside by water, the inner plate is heated sufficiently to cause the fumes thus produced to be carried away by a stream of air which is allowed to flow back into the pan. The majority of acid makers, however, prefer retorts made entirely of platinum, preferably provided with the Heraeus perforation with a dense, closely-woven covering of gold, including the top or "dome." The new Kessler furnace is a very ingenious apparatus, in which the fire from a gas-producer travels over the sulphuric acid contained in a trough made of Voltaic iron, and is employed by a number of perforated plates, over which fresh acid is constantly running down; the temperature is kept down by the production of a partial vacuum, which greatly promotes the volatilization of the water, whilst retarding that of the acid. This furnace is suitable for most acids, and, being unsuitable for platinum or platinum-gold stills on account of the crusts forming at the bottom of the retorts; and it is more and more coming into use both in Great Britain and on the Continent. A third consideration is the condensation of the vapours formed in the concentrating process; the further the concentration proceeds the more sulphuric acid they contain. Condensation is a comparatively easy task with the case of platinum apparatus, but with glass or porcelain beakers or retorts it presents great difficulties. In this respect the Kessler furnace has also proved to be very efficacious, so that it is at the present time considered the best apparatus for the concentration of sulphuric acid found in the trade.

The highest strength of sulphuric acid practically attainable by boiling down is 98% H₂SO₄, and this is only exceptionally reached, and then only by a method which involves the need for and the provision of a vacuum apparatus. The usual strength of the O.V. of commerce, mostly designated by its specific gravity as 168° Twaddell, is from 93 to 95, or at most 96% H₂SO₄. When attempts are made to push this higher, either through the medium of the vacuum apparatus, or simply by reducing the size of the tower is as strong as that which remains behind. Real "monohydrate" or acid approaching 100% can be made by Lunge's process of cooling strong O.V. down to 0° C. when H₂SO₄ crystallizes out, or by the addition of anhydrous SO₃ in the shape of fuming acids or a mixture of it.

Since the development of the contact processes the fuming acid has become so cheap that it is now exclusively used for the preparation of the acids applied to practical use.

Fuming or Nordhausen Oil or Vitriol, a mixture or chemical compound of H₂SO₄, with more or less SO₃, has been made for centuries by exposing pyritic ash to the influence of atmospheric agents, collecting the solution of ferrous and ferric sulphates, and then boiling it down into a hard mass ("vitriolite") and heating this to a low red heat in small earthenware retorts. Since about 1800 this industry had been confined to the north-west of Bohemia, and it survived until 1890, when it was entirely abandoned — not because its product had become any less necessary, but, quite on the contrary, because the enormously increasing demand for fuming sulphuric acid, which was then discovered to be useful in the manufacture of a variety of articles and alloys, and in the extraction of boric acid from the ore, made it absolutely necessary to supply the world with the original product from the vineyard of the Bohemian. Other sources of supply had accordingly to be sought, and they were found by going back to a reaction known long before, but the first time in which it was discovered by which the combination of SO₂ and O into SO₃ by means of spongy platinum. This reaction, now known by the name of the catalytic or contact process, was made the subject of a patent by Peregrine Phillips in 1831, and was tried later in many ways but had been always considered as useless for practical purposes until 1875, when it was simultaneously and independently taken up by Clemens Winkler in Freiberg, and by W. S. Squire and R. Messel in London. Both these inventors began in the same way, viz. by decomposing ordinary sulphuric acid by a high temperature into SO₃, O₂, and H₂O (the last of course being in the shape of steam), absorbing the water by sulphuric acid, and combining SO₂ and O to combine to SO₃ by means of moderately heated platinum in a fine state of division. Winkler showed that this division was best obtained by soaking asbestos with a solution of platinum chloride and then forming the asbestos into a kind of "pulverizer" or rather a specially active kind of "contact substance," prepared from platinum chloride at a low temperature. This revival of the synthetical production of SO₃, at a period when this article had suddenly become of great importance, caused the greatest excitement among chemists and led to numerous attempts in the same direction, some of which were at once sufficiently successful to enable them to work with the division. Progressive addition to the production of a mixture of SO₃ and O from sulphuric acid, as above described, was both too troublesome and costly, and after a number of experiments in other directions inventors went back to the use of the fuming acid. In the case of Winkler's apparatus, for a good many years the further development of this industry was surrounded by great mystery, but it is now known that a satisfactory process of manufacture of the acid was attained in several places, for instance, at Freiberg and in London, by the labours of the original inventors, Professor Winkler and Dr. Messel. These difficulties were mostly caused by the solid impurities.
SULPICIA—SULPICIUS RUFUS, PUBLIUS

contain in the burner-gases in the shape of flue-dust, especially the arsenic, which after a short time rendered the contact substance inapplicable. It is not certain how the difficulty arose from the fact that the reaction \( \text{SO}_4^2- + \text{O} = \text{SO}_3 \) is irreversible, the reverse reaction, \( \text{SO}_3 + \text{O} = \text{SO}_4^2- \) setting in but little above room temperature. This was due to the fact that the arsenic, though far from being so toxic as is known (so much secrecy having been observed), the best results obtained in various places, save one, did not exceed 67% of the theoretical quantity, the remaining 33% of \( \text{SO}_3 \) having to be considered as lost. The case was discussed in the first volume of the Journal of United States Geologists (1), and there is now known, the exception (undoubtedly the only one 1899, was the process discovered as early as 1889 by Dr R. T. J. N. Kietisch, of the Badische Anilin- und Soda-Fabrik at Ludwigshafen, but kept strictly secret until it was published in 1899. The principal features of this invention are, first, a much more thorough purification of the burner-gas than had been practised up to that time, both as to the increase of a million per annum of pyrites per annum. It is therefore not too much to say that, in all probability, the contact process will ultimately be employed generally for concentrated acids. Still, for the reasons given in the beginning of this article, this process is not likely to influence the ostrich trade, to a great extent. Since the Badische process has become known, several other new contact processes have come into the field, in some of which ferric oxide is employed as contact substance, but we must refrain from describing these in detail.

Medicine.—Sulphuric acid or oil of vitriol is a colourless oily-looking liquid incompatible with alkalis and their carbonates, lead and calcium. There are two medicinal preparations: (1) \( \text{HCl} \) acidum diutium dilutum, containing 13.5% of hydrogen sulphate, (2) \( \text{HCl} \) acidum sulphuricum aromaticum (elixir of vitriol), containing alcohol, spirit of cinnamon and ginger and 13.5% of hydrogen sulphate. When used in medicines the acid is rendered less powerful and irritating and caustic, acting by its powerful affinity for water and therefore dehydrating the tissues and causing them to turn black. It coagulates the albumen. Strong sulphuric acid is occasionally used as a medicinal article, and by surgeons in the treatment of malignant growths. It is difficult, however, to limit its action, and glacial acetic and nitric acids are preferable for this purpose. Considerable burns on the face or body may result from the application of sulphuric acid in the preparation olivewax. It is possible it may be of use in the distillation of any purifying or distilling apparatus. It is used in dilute form to distinguish the burns produced by this acid from those of other corrosive fluids. Intimately, dilute sulphuric acid is used in poisoning by alkalis as a neutralizing agent. Both it and the acetic or nitric acids are therefore intended by the last-named constituents, and would be useful in diarhoea of a serious type, being strongly recommended both as a prophylactic and as a treatment during epidemics of Asiatic cholera. Small doses of the acidic acid also serve as a prophylactic to those artisans who work in lead and as a treatment in lead poisoning in order to form an insoluble sulphate of lead. Sponging the body with very dilute solutions of sulphuric acid is useful to diminish the night-sweats of phthisis.

Toxicology.—Given in toxic doses or in strong solution, sulphuric acid is a severe gastro-intestinal irritant, causing intense burning pain, extending from the mouth to the stomach, and vomiting of matter. When taken internally, the onset of all its effects may be so rapid that death may take place in a couple of hours, owing to collapse, consequent on perforation of the walls of the oesophagus or stomach, or from asphyxia due to swelling of the glottis consequent on some of the acid having entered the larynx. Should the patient survive the first twenty-four hours death generally results later from stricture of the oesophagus or intestine, from destruction of the glands of the stomach or from excessive destruction of the stomach wall. Death is usually attended with an extreme thirst and the patient often requests half a teaspoonful of the strong acid, but recovery is recorded after half an hour having been swallowed. The poison consists in the presence of the irritating sulphuric acid, which in the eyes, skin, whiting, plaster, or any alkaline substance at hand, emetic. The stomach pump should not be used. Morphine may be given hypodermically to mitigate the pain. Should the patient survive have been made rapidly by him. The symptoms of sulphuric acid poisoning is bad, 60 to 70% of the cases proving fatal. The post-mortem appearances will be those of corrosive poisoning. The bucal mucous membrane will be greyish, brown or black in colour, due to the corrosive effects of the acid. SULPICIA, the name of two Roman poets. The earlier lived in the reign of Augustus, and was a niece of Messana, the patron of literature. Her verses, which were preserved with those of Tibullus and were for long attributed to him, are elegiac poems addressed to a lover called Cерinthus, possibly the Cornutus but very probably Th. Els. in two of his Elegies (bk. ii., 2 and 3; see Schanz, Gesch. d. röm. Litt., § 284; F. Pleaes, La Poésie lat., pp. 376–377 and references there given). The younger Sulpicia lived during the reign of Domitian. She is praised by Martial (x. 35, 38), who compares her to Sappho, as a model of wifely devotion, and wrote a volume of poems, describing with considerable freedom of language the methods adopted to retain her husband Calenus's affection. An extant poem (70 hexameters) also bears her name. It is in the form of a dialogue between Sulpicia and the muse Calliope, and is chiefly a protest against the banishment of the philosophers by the edict of Domitian (A.D. 94), as likely to throw Rome back into a state of barbarism. At the same time Sulpicia expresses the hope that no harm will befall Calenus. The muse reassures her, and prophesies the downfall of the tyrant. It is now generally agreed that the poem (the MS. of which was discovered in the monastery of Bobbio in 1493, but has long been lost) is not by Sulpicia, but is of much later date, probably the 4th century; according to some it is a 15th-century production, and not identical with the Bobbio poem.

Editions by O. Jahn (with Juvenal and Persius, revised by F. Bücheler, 1863) and in E. Bährn, De Sulpicio quaerat satura (1873), and in Bohn's Classical Library (Dec. 11, 1869) and Journal of Philology (1874), vol. v.; O. Ribbeck, Geschichte der römischen Dichtung (1892, vol. iii.; H. E. Butler, Persius, Augustus Poems (1900), p. 174; J. S. and Planck, Geschichte der römischen Litteratur (1900), p. 216); F. Jahn, Geschichte der röm. Literatur (Eng. trans., 1900), p. 233, 6. There are English translations by L. Evans in Bohn's Classical Library (prose, with Juvenal and Persius) and by J. Grainger (verse, 1759).

SULPICIUS RUFUS, PUBLIUS (c. 121–58 B.C.), Roman orator and statesman, legate in 89 to Cn. Pompeius Strabo in the eastern war, and in 88 tribune of the plebs. Soon afterwards Sulpicius, hitherto the orator, declared in favour of Marius and the popular party. He was deeply in debt, and it seems that Marius had promised him financial assistance in the event of his being appointed to the command in the Mithradatic War. To secure the appointment for Marius, Sulpicius brought in a franchise bill by which the newly enfranchised Italian allies and freedmen would have swapped the old electors (see further Rome, History, II. The Republic). The majority of the senate were strongly opposed to the proposals; a justitium (cession of public business) was proclaimed by the consuls, and Marius and Sulpicius got up a riot, and the consuls, in fear of their lives, withdrew the justitium. The proposals of Sulpicius became law, and, with the assistance of the new voters, the command was bestowed upon Marius, then a mere privatus. Sulpicius, who was then at Nola, immediately marched upon Rome. Marius and Sulpicius, unable to resist him, fled from the city. Marius managed to escape to Africa, but Sulpicius was discovered in a villa at Laurentum and put to death; his head was sent to Sulla and exposed in the forum. Sulpicius appears to have been originally a moderate reformer, who by force of circumstances became one of the leaders of a democratic revolt. Although he had impeached the turbulent tribune C. Norbanus (60 B.C.), he resisted the proposal of a second impeachment, and by popular decree, he did not hesitate to incur the displeasure of the Julian family by opposing the candidature for the consulship of C. Julius Caesar (Strabo Vopiscus), who had never been praetor and was consequently ineligible. His franchise proposals, as far as the Italians were concerned, were a necessary measure of justice; but they had been carried by violence. Of Sulpicius as an orator, Cicero says (Brutus, 53): "He was by far the most dignified of all the orators I have heard, and, so to speak, the most tragic; his voice was loud, but at the same time sweet and clear; his gestures were full of grace; his language was rapid and voluble, but not redundant or diffuse; he tried to imitate Crassus, but lacked his harm." Sulpicius left no written
speeches, those that bore his name being written by a certain P. Canutius (or Cannutius). He is one of the interlocutors in Cicero's *De oratore*.

**Sulpicius Rufus, Servius** (c. 106-43 B.C.), surnamed *Lemovia* from the tribe to which he belonged, Roman orator and jurist. He studied rhetoric with Cicero, and accompanied him to Rhodes in 78 B.C. Finding that he would never be able to rival his teacher he gave up rhetoric for law (Cic. *Brut.* 41). In 63 he was a candidate for the consulship, but was defeated by L. Licinius Murena (q.v.), whom he subsequently accused of bribery; in 51 he was successful. In the Civil War, after considerable hesitation, he threw in his lot with Caesar, who made him proconsul of Achaea in 46. He died in 43 while on a mission from the senate to Antony at Mutina. He was accorded a public funeral, and a statue was erected to his memory in front of the Rostra. Two excellent specimens of Sulpicius's style are preserved in Cicero (*Ad. Fam.* iv. 5 and 12). Quintilian (Instit. x. 1, 116) speaks of three orations by Sulpicius as still in existence; one of these was the speech against Murena, another *Pro or Contra Auidium*, of whom nothing is known. He is also said to have been a writer of erotic poems. It is as a jurist, however, that Sulpicius was chiefly distinguished. He left behind him a large number of treatises, and he is often quoted in theDigest, although the direct source is not named (fortified see Teuffel-Schwabe, *Hist. of Roman Lit.* 174, 4). His chief characteristics were lucidity, an intimate acquaintance with the principles of civil and natural law, and an unrivalled power of expression.

See R. Schneider, *De Servio Sulpicio Rufo* (Leipzig, 1834); O. Karlowa, *Römische Rechtgeschichte*, vol. i. (Leipzig, 1888); the chief ancient authority is Cicero.

**Sultan** (an Arabic word meaning "victorious" or "a ruler", *sultān*, dominion), a title of honour borne by a great variety of rulers of and varying powers and importance in Mahomedan Africa and the East. The word has thus no exact equivalent in English, and was early imported into the language in the Middle English form of *soudan* (from old Fr. *soudan*, *soudan*). This title is that conventionally applied by foreigners to the ruler of the Ottoman Empire, the sultan *par excellence*, whose proper style is, however, *padishah* (emperor) and "commander of the faithful" (see Amīr). The feminine form "*sultana*" is derived from the Italian fem. of *sultano*.

**Sultanpur**, a town and district of British India, in the Fyzabad division of the United Provinces. The town is on the right bank of the river Gumti, midway between Bareilly and Lucknow, on the Oudh & Rohilkhand railway. Pop. (1901), 9550.

The District of Sultanpur has an area of 1713 sq. m. The surface is generally level, being broken only by ravines in the neighbourhood of the rivers. The central portion is highly cultivated, while in the south are widespread arid plains and swampy *jhils* or marshes. The principal river is the Gumti, which passes through the centre of the district and affords a valuable highway for commerce. Minor streams are the Kandu, Pili, Tonsa, and Nandha, the last two being of some importance, as their channels form the outlet for the superfluous water of the *jhils*, draining into the Sai. There are no forests in the district, only stunted *dhak* woodlands used for fuel. In 1901 the population was 1,083,904, showing an increase of less than 1% in the decade. Sultanpur is a purely agricultural district with a very dense population. The principal crops are rice, pulses, wheat, barley, sugar-cane and a little poppy. The main line of the Oudh & Rohilkhand railway from Lucknow to Rae Bareli and Mogul Serai serves the south-western portion.

The most incident worthy of note in the history of the district since the British annexation of Oudo; one of the main functions of the native troops stationed at Sultanpur during the Mutiny. The troops rose in rebellion on the 9th of June 1857, and, after murdering two of their officers, sacked the station. Upon the restoration of order Sultanpur cantonment was strengthened by a detachment of British troops; but in 1861 it was entirely abandoned as a military station.

See *Sultanpur District Gazetteer* (Allahabad, 1903).

**Sumach**. The Sumach of commerce is the finely ground leaves of *Rhus coriaria*, a native of the North Mediterranean region from Portugal to Asia Minor; it is a shrub or low tree with hairy leaves composed of 11 to 15 elliptical leaflets with large blunt teeth, and large loose panicles of whitish-green flowers. Another species, *Rhus cotinus*, known as Venetian Sumach, also a native of southern Europe and Asia Minor, yields the yellow dye-wood known as young fustic; it is also known as the Smoke-plant or Wig-tree, from the feathery or hairy appearance of the leaf-stalks, which become elongated and hairy after the flowering. The genus *Rhus* is a member of the natural order Anacardiaceae and contains about 120 species of trees or shrubs mostly native in the temperature regions of both hemispheres. The leaves are alternate and simple or compound, with few to many entire-margined or serrated leaflets, and terminal or axillary panicles of small flowers with parts in fours or fives. The species are mostly poisonous, some being especially noxious. Such are *Rhus toxicodendron*, the North American poison ivy, a shrub climbing on rocks and trees by means of rootlets, and poisonous to the touch. *R. senecana*, the North American poison elder sumach or dogwood, also contains an extremely irritating poison. *R. vernicifera* is the Japan lacquer or varnish-tree. Several species are cultivated in the British Isles as store, greenhouse or hardy trees.

**Sumatra**, the westernmost and, next to Borneo, the largest of the Great Sunda Islands in the Malay Archipelago. It stretches N.W. to S.E. from Malacca Passage to Sunda Strait, between 5° 40' N. and 5° 59' S., and 95° 10' and 106° 3' 45' E. Its length is about 1100 m., its extreme breadth 250 m., and its area, including the neighbouring islands, except Banca and Biloton, is 178,338 sq. m. The northern half runs roughly parallel to the Malay Peninsula, from which it is separated by the Strait of Malacca, and the southern end is separated by the
narrow Sunda Strait from Java. Unlike Java, Sumatra has a series of considerable islands (Nias Islands, Mentawai Islands, &c.) arranged like outliers in front of the west coast, which faces the open Indian Ocean. The general physical features of the island are simple: a chain of lofty mountain ranges extends throughout the western part of the island, its western slopes descending rapidly towards the sea and the eastern part is a plain. Owing to this configuration of the island the rivers of the western side are comparatively short; only very few of them are large enough to be navigable. Those of the eastern slope, on the other hand, such as the Musi, Jambi, Indragiri, Kampar, Slak, Rokan, Panel, Bila, and Asahan, are longer, and with many of their affluents are navigable in their middle and lower courses over considerable stretches for craft drawing 6 to 10 ft. The Musi and Jambi are navigable for 577 and 497 m. respectively. As waterways all the rivers labour under the drawbacks of rapids, mud-banks at their mouths, banks overgrown with forest, sparse population, and currents liable to serious variations due to irregularity of supply from the mountains and sudden falls in their lower courses some of them form enormous intercommunicating deltas. The mountainous regions contain numerous lakes, many evidently occupying the craters of extinct volcanoes. When, as sometimes happens, two or three of these craters have merged into one, the lake attains a great size. Among the larger lakes may be mentioned Toba; Maninjau, west of Fort de Kock; Singkara, south-east of Fort de Kock; Korinchi, inland from Indrapura; and Ranus, in the south-west.

Orography.—In order to appreciate the orography of the island the following sections of Sumatra should be discriminated one from another: (1) The valley of the Achin or Aijieh River. (2) The plains around the lake of Toba, which are of varied level and physical character. Those on the north and north-east at an elevation of 4000 ft., having the character of steps, with scanty forest-cover, and, save in the narrow valleys and river-courses, are suitable for cattle-rearing. The plains on the east and west lie at a lower level and are eroded by larger rivers and swamps. The valleys are overgrown by sawahs and ladangs, or dry ricefields, and, near the rivers, planted with jagong (maize), coffee and fruits. Except on the south-east, where the elevation falls away to the east coast, Toba Lake is surrounded by steep shores. According to R. D. M. Verbeek, P. van Dyk, B. Hagen and W. Volz, the lake had its origin in the collapse of a volcano. (3) The valley of the Batang Toru, with the plateau of Sipirok in the east and the mountain chain three miles inland. On the south and south-east the valley is bounded by two volcanoes, Lubuk Raja and Si Buwali; whence were derived the volcanic tuffs of the valley and of the plateau of Sipirok, with the mafic lavas, which are drained by the Batang Toru and its affluents. The valley varies in breadth from 51 ft. to half a mile and less. Flowing in a deep bed cut in the tuff strata, the river is not navigable. (4) The longitudinal valley of the Batang Gadis, with its affluent the Angkola, and, in the south the valley of the Sipar, the upper course of the Rokan, between Lubuk Raja in the north and Mt Merapi in the south. This valley is 64 m. long, with a mean breadth of 5 to 6 ft. All the rivers of this valley, flowing in deep beds of eroded diluvial tuffs, with a fall as much as foundations of 5 to 660 ft., are more or less un navigable. The valley is bounded east and west by chains of plateau and Palaeozoic rocks. The bottom is in many parts the diluvial lake bottom or the river. (5) The section of middle Sumatra between the line of the three volcanoes, Singalang-Tandikat, Merapi, and Sago on the north, and that of the Dred Sondang, Batuah Selimbah, Korinchi and Tujuh on the south. This section is divided by the Medendi-bergen or middle chain into a northern half watered by the Ombilin or upper Indragiri with its affluents, and a southern half traversed by the Batang Hari or upper Jambi. Between these two volcanoes, which rise to 9500 ft. or more, there is a high plateau of volcanic formation, whose elevation declines in a direction from west to east from 2500 to 1650 ft., with the lake of Maninjau (about 40 sq. m.) filling the hollow of an old volcano, and with rivers which have eroded their beds in the tuffs to a depth of 300 ft. and more. South of the volcanoes the northern affluents of the Ombilin—the Sumpur, Sello and Sinarum—flow into one another in a north-west to south-east direction. Here, too, are found fertile tuffs, and the valleys are densely populated. The rivers, like those already characterized, are not available as waterways. Singkara Lake (44 sq. m.) is of origin similar to that of Maninjau. The Ombilin, issuing out of the lake on the east side and flowing through a plateau of Eocene sandstone, has on its banks the coalfields of Surie Durian, &c., but is not serviceable as a waterway for that part of Sumatra. The coal has to be transported by railway via Solok to Padang (Empuhaman), a port on the west coast. Solok lies on the Sumani, which, flowing from the south to the lake of Singkara, prolongs the valley of the Sumpur to the Medendi-bergen. Unlike the northern, the southern affluents of the Ombilin do not follow longitudinal valleys, the river lying in broad valleys and ranges of slate, limestone and sandstone. Here prevailing granite and diabase give rise to a complicated mountain system through which the rivers change their way in a curved and irregular course. South of the Medendi-bergen the southern affluents of the Batang Hari, the Seliti, Gumanti, Si Potar, Mamun and Pangang, at least these in the west, again run in longitudinal valleys. These affluents and the Batang Hari itself (except the part of it north of Mamun) are navigable for not more than 12 ft. (6) South Sumatra, so far as known, presents everywhere in its valleys the same character as that of the Batang Toru, Batang Gadis, and the valleys of the Rokan, Sumpur, and Maninjau. These valleys are divided into north and south by volcanoes which have here produced similar masses of tuff, with lakes and rivers of the same formation as in the north. Such are the valley of Korinchi, with the river of the same name, between the peaks of Korinchi and Mt Raja; the valleys of Serampe and Sungkai Tenang (as imperfectly known as that of the Korinchi), in which are to be sought the sources of the Tambesi and Aesi, both affluents of the Jambi; the longitudinal valley of

Ketua, in Lebong, flowing to the west coast, and of the upper Meunane. To the south of the Makaluk and the upper Komering, an affluent of the Musi, between Sebelat and Kabia. The Makaluk and Selabung drain into Lake Ranau, which on the south side is dammed by the volcano Seminung. The south side of the hinterland valley of the Meunane, which flows into the bay of the same name. Generally the lower valleys of the rivers lie at elevations of 500 to 1000 feet; higher up they rise to 2500 or 3000 feet; the mountain chains rise to 5500 feet; the highest point, 7000 feet from 6600 meters. The section of south Sumatra between the eastern chain of old rocks and the west coast with its numerous river mouths is formed of the alluvial deposits of the rivers. In the distance from the sea, older strata and eroding rocks underlie the alluvium. The strata near the mountain chains and volcanoes consist of diilluvial tuffs.

Older rocks are gneiss, schist and quartzite, the schist often containing gold. They probably belong to several geological periods, but all were folded and denuded before the Carboniferous beds were deposited. There are the back-arc basin, and the ocean flows at the levels of the old rocks. It lies unconformably upon the older rocks; and the limestone contains Fossilina, Philippias and Productus, indicating that it belongs to the Upper Carboniferous. These beds are found only in the eastern part of Sumatra. They consist mainly of sandstone, diabase and gabbro, and are sometimes folded, sometimes but little disturbed. No Permian beds are known, and for many years there were rocks which resembled Triassic clays and sandstones with Daonella have been found in the upper part of the basin of the Kwalu (East Sumatra). They rest unconformably upon the Carboniferous beds, and have themselves been tilted. A strong angle, and a strong bed, was recorded by Bücking. Tertiary deposits are very widely spread over the plains and low-lying country. They consist of breccias, conglomerates, sandstones, marls, and limestones, with seams of coal, the most valuable coal occurred in the Oecome beds. At the close of the Eocene period great eruptions of augite-anidesite took place from two fissures which ran along the west coast. The Melaye and Geurung are the oldest of the strata, and are old volcanic beds. The limestone of the east coast it sometimes yields petroleum. The Plioceene occurs chiefly in the low-lying land and is generally covered by drift and alluvium. Sometimes it contains thick seams of lignite or brown coal.

The present volcanoes lie along a line (with offshoots) which runs parallel to the west coast, but some distance to the east of the fissures from which the early Tertiary lavas were poured. Lava streams are seldom emitted from these volcanoes, the material erupted consisting chiefly of ash and scoriae, which are spread over a very wide extent of country. Augite-anidesite predominates, but basalt and rhyolite also occur.

Climate.—As throughout the whole of the Malay Archipelago, so in Sumatra, which lies about equally balanced on both sides of the equator, the temperature stands at a high level subject to but slight variations. The mean monthly temperature mounts only from 77 ° F. in January to 80-6 ° F. in May and August and October. In the distribution of the rainfall, as dependent on the direction of the winds, the following parts of Sumatra must be distinguished: (1) Punti—The Sumatra, on which, as on Banka and Billiton, the heaviest rainfall occurs during the north-west monsoon, the annual volume of rainfall increasing from 98-4 in. in the east to 139 in. in the west. Of the 139 in. of yearly rainfall, 91-7 in. are brought by the north-west and 47-3 in. by the south-east monsoon. (2) The west coast. Here the rainfall for the year increases from the southern and northern extremities towards the middle. Bengkulu, e.g. gets 126 in.; Singkawang (2°5' N.), 172 in.; and Padang 184 in. in the year. Here, too, the prevailing rainfall is brought by the north-west monsoon, but in this belt its prevalence is not so pronounced. Padang getting 94 in. of rain during the north-west monsoon. The west coast, in the middle of the rainy season, is washed by the withdrawal from the north-east monsoon towards the west coast. The higher stations of middle Sumatra, on the lee side of the western mountain chain, have a yearly rainfall of only 78-9 in. and 80-7 in. in the western parts. Sumatra is swept by a variety of winds. The south-east wind, which predominates. Blowing over land and in the direction of the longitudinal valleys, the south-east wind is comparatively dry, and thus helps the ripening of strawberries on the lowlands, but extends to some 6500 ft. above sea-level. The north-east wind does not extend above 9000 ft. The willows, Bos sundanus does not appear to find the least comfort in the forests in the lowlands, but extends to some 6500 ft. above sea-level. The range of the elephant does not extend above 9000 ft. The wild elephant is not abundant in Sumatra, but the elephant, altogether absent from Java, is represented in Sumatra by a species somewhat larger than the common Malayan deer is widely distributed, Cerus muntiacus less so. The orang-utan occurs, rarely, in the north-east. The siamang (Siamang, *Siamang* maculatus *Siamang* maculatus) is a small ape peculiar to the forests in the height of the Boxa-bolobes agilis is not so common. A fairly familiar form is the simipie (Simipius pongolus). The chigai (*Cercocerus cynomolus*) is the only ape found in central Sumatra in a tame state. The piglet (*Sus* domesticus) in the north of the island. The *Sus* domesticus is the only hare, the little hare found in the Malay Archipelago. The *Manis javanica* is the only representative of the Edentata. Some 350 species of birds are known, and the avifauna closely resembles that of the Malay Peninsula and Borneo, including few peculiar species.

Flora.—Rank grasses (*kalang, gloga*), which cover great areas in Java, have an even wider range in Sumatra, descending to within 50 ft. of sea-level; wherever a space is found in the forest, these aggressive grasses begin to take possession of the soil, and if once they are firmly rooted the woodland has great difficulty in reestablishing itself. Among the orders more strongly represented are Saururacae in the Diterandra section; *Bauhinia* section; *Hymenodendron* section; *Myrtaceae* in the *Myrtus* section; *Dipterocarpaceae*, *Nyctaginaceae*, *Begoniaceae*, *Acanthaceae*, *Annonaceae*, *Cucurbitaceae*, *Malvaceae*, *Gentianaceae*, *Combretaceae*, *Amaryllidaceae*, *Cyrtandraeae*, *Epiprionidae* and *Epiprionidae*. Many of the Sumatran forms which do not occur in Java are found in the Malay Peninsula. In the north the pine tree (*Pinus merkusii*) has advanced almost to the equator, and in the south a variety of species characteristic of the Australian region. The distribution of species does not depend on elevation to the same extent as in Java, where the horizontal zones are clearly marked; and there appears to be a tendency of all forms to grow at lower altitudes than in that island. A remarkable feature of the Sumatran flora is the great variety of trees that vie with each other in stature and beauty, and as a timber-producing country the Sumatran flora holds a position which is second to none in the archipelago. Forest products—gums and resins of various sorts, such as gutta-percha—are valuable articles of export. The process of reckless deforestation is perceptible in certain districts, the natives often destroying a whole tree for a plank of inferior quality. The principal cultivated plants, apart from sugar-cane and coffee, are rice (in great variety of kinds), the cocoonut palm, the areca palm, the sago palms, maize, yam, and sweet potatoes; and among the fruit trees the Indian tamarind, pomegranate, guava, papaw, orange and lemon. Even before the arrival of Europeans Sumatra was known for its pepper plantations; and these still form the most conspicuous feature of the south of the island. For the foreign market coffee is the most important of all the crops, the Padang districts being the chief seat of its cultivation. Benzoin was formerly obtained almost exclusively from Sumatra from the *Styrax benzoin*.}

**Population.**—The following tables give the area and estimated population of the several political divisions of Sumatra and of the island as a whole (excluding the small part belonging to the RIoow-Lingga residency):

SUMATRA

Of the total population, about 5000 are Europeans, 93,000 Chinese, 2500 Arabs, 7000 foreigners of other nations, and the rest natives. In 1905 the total population was given as 4,920,505.

The natives of the mainland of Sumatra are all of Malay stock (those of the north being the most hybrid), but it is doubtful to what extent Malay has here absorbed pre-Malay blood. The different tribes vary in language, customs and civilization. No race of true Negrito type has been found. The Kubus (q.v.), a savage forest people of the highlands, were believed by some to be Negrito owing to the frizzled character of their hair, but it appears certain that they are Malayan. The north of Sumatra is occupied by the Acehnese (q.v.), who have an extensive language, and the west of Lake Toba is the country of the Batass (q.v.) or Battaks. In the hill-country south of the lake are two forest tribes, Orang-ulu and Orang-lubu, pure savages of whom practically nothing is known, affiliated by most authorities to the Battaks. The plains east of this territory are occupied by the Siaks, and farther south on the east coast are the Jambis, both Malays. Above Padang are the several tribes of the prosperous and comparatively civilized Menangkobs (q.v.). The Korinchis live among the mountains south of Padang, and farther south on the east coast are the tribes called the Tiku, who are a peculiar tribe who employ a distinctive written character which they cut with a kris on bamboo or lontar. The same character is employed by their immediate neighbours to the south, the Pasumas, who bear traces of Javanese influence. In the extreme south are the Lampong people, who claim descent from the Menangkobs, but have also an admixture of Javanese blood. The inhabitants of the islands west of Sumatra are of mixed origin. Simalu is peopled partly by Achinese and partly by Menangkob settlers. They profess Mahomedanism but are practically savages. Nias (q.v.) has an interesting native population, apparently of pre-Malayan origin; and the Mortu and islands (q.v.) are inhabited by a race generally held to be a Polynesian settlement which has escaped fusion with Malay stock. As regards education and the spread of Christianity among the natives, the west coast division is far in advance of the rest of the island. Here about 32,000 natives profess Christianity and there are about 300 schools; elsewhere schools are comparatively few and the adhesion to Christianity very slight.

Administrative Divisions and Towns.—In the west coast lands East Sumatra is divided into 14 districts, each under a resident of the Dutch Government. Agriculture, timber, and coalfields have created populous settlements on the coast at Padang (the capital of the west coast, with 35,158 inhabitants in 1897, of whom 16,460 were Europeans), Prijam, Natau, Agung Puger, and Sinubong. Southwards are the towns of Perai Kock, Payokombo, &c. In the east coast land it is only at the mouths of rivers—Palembang at the mouth of the Musi, with 53,000 inhabitants, and Medan in Deli, the residence of the highest civil and military officials of the east coast, in which a fine government house has been erected—that considerable centres of population are to be found. Nine-tenths of the natives of Sumatra live by agriculture, the rest by cattle-rearing, fishing, navigation, and, last but not least, from the products of the forests; they are therefore little concentrated in towns.

The Dutch government of the west coast, extending along the shore of the Indian Ocean from the north of Acheh to the Siam frontier, has the principal offices and residences of the Padang lowlands, Tapanuli and the Padang highland. The governor has his residence at Padang, which is also the capital of the lowlands residency. Padang Sidempuan, the chief town of Tapanuli, lies inland, south of Mt Luba Raja. The town of Siboga has considerable commercial importance, the bay on which it stands being one of the finest in all Sumatra. Bukit Tianni, or, as it is commonly called, Fort de Kock, is the capital of the residency of the Padang highlands. To the government of the west coast belong the following islands: Simalu; Banjak Islands, a small limestone group, well wooded and sparsely peopled; Nias, formerly called Acheh; Bintuhan, a small island near Pulu Tiku, or Rat Island, in a low and swampy locality, and on an open roadstead. This was the chief establishment possessed by the Dutch in the island, but other noteworthy places are Moko-Moko, with the old British fort; Anna; Pasar Bintuhan, and Lais (Laye), the former seat of the British resident.

The residency of the Langkong districts is the southernmost in the island, being separated from Palembang by the Masui River. It is partly mountainous, partly so flat as to be under water in the rainy season. The most important places are Telok Betong, chief town of the residency; Mengkabang, with a Dutch trade, Lunung Sugki, Sukadana, Tanjung Karang, and Kota Agung.

The residency of Palembang consists of the former kingdom of Tapanuli, and various island districts, together forming a distinct monarchy. Between the mainland dependency of the Riau-Lingga residency and the residency of Palembang lies Jambi, an extensive sultanate, of which a portion belongs to the residency of Padang (called Jambi) a Dutch "comptroller," who represents the resident of Palembang; another portion is claimed by a quasi-independent native sultanate in the interior. Of this interior very little was known until the small outlying settlements of the Dutch Exploring and Royal Geographical Societies towards the end of the seventies, but in 1901 an armed Dutch expedition, necessitated by frequent disturbances, explored and surveyed the districts, and awarded the governor, however, another 50,000 inhabitants (2500 Chinese), extensive barracks, hospitals, &c., a mosque (1740), connected the forest in the Dutch Indies, and a traditional tomb of Alexander the Great. The residency of Riau, which embraces many hundreds of islands, great and small, also includes a portion of the Sumatra mainland, between the residencies of Palembang to the east and of Tapanuli to the west. It comprises the old kingdom of Indragiri, and lies on either hand of the river of that name.

The residency of the east coast was formed in 1873 of the territory of Siak and its dependencies and the state of Kampar. In includes perhaps the richest and best-developed districts of northern Sumatra, namely, Deli (with an assistant-resident), Langkat, Serdang, &c.—districts not so well known by the outside world, but practically the best 19th century famous among the chief tobacco-producing countries in the world. Belawan is the harbour to Deli, but the capital is Medan, where the sultan and the Dutch resident reside. Belawan is connected with Medan by a good, well-tarred road, and is connected with Singapore by a private company, almost entirely dependent for its earnings upon the numerous tobacco plantations, several of which belong to British and American interests, and are occupied by Japanese coolies, largely Chinese, and the Malays are comparatively few in number. The tobacco plantations of British North Borneo were nearly all started by planters from Deli.

The residency of Siau occupies the northern part of the island. No little progress has been made by the Dutch even in this war-ridden territory. There is a railway in the lower valley of the Achin River, connecting the capital, Kotaraja, and neighbourhood with Bintuhan, a good, free port, with Ian act trade, carried on by numerous steamers, both Dutch and foreign. Edi on the north-east coast, with another harbour, is capital of a sultanate which formerly owed allegiance to the sultan of Acheh, but was formed a political division of the government of Acheh since 1888, and the expedition restored order. Edi is a centre of the still extensive pepper trade, carried on mainly with the Chinese at Singapore and Palembang.

Products and Industry.—Forests and natural vegetation cover a much larger part of Sumatra than of Java. Whereas in Java tall timber on the mountains keeps to altitudes of not less than 3000 ft., the tall timber on the mountains of Sumatra commonly descends below 1500 ft., and in men and now a political division, is similarly managed. Tin is known, especially in Siak. Copper has been worked in the Padang highlands (most largely in the district of Lake Singkara) and also in Tin特区. Tin is produced in large quantities, and the export of this field increased from 1730 tons in 1892 to 78,500 metric tons in 1899. The profit on the working, which is carried on by the state, is large. Lignite of good quality is found in several localities. The production of vegetable oil, which was formerly carried on by great extent in the close of the 19th century: on the Lepan River in Langkat it mounted from 352,880 gallons in 1891 to 20,143,000 gallons in 1900. The oil of the palm oil is sent to Batavia, the capital, for refining, and has an extensive market, but the Achin government, has become one of the chief centres of the petroleum industry. The crude oil is conveyed in pipes to Aube Bay,
on the east coast, and refined in the island of Sumbanese, Arseneic, saltpetre, alum, naphtha and sulphur may be collected in the volcanic districts. A systematic mineralogical survey has been undertaken in central Sumbatra.

History.—As far as is known, Sumbatran civilization and culture are of Hindu origin; and it is not improbable that the island was the first of all the archipelago to receive the Indian immigrants who played so important a part in the history of the region. Certain inscriptions discovered in the Padang highlands seem to certify the existence in the 7th century of a powerful Hindu kingdom in Tanah Datar, not far from the site of the later capital of Menangkabo. In these inscriptions Sumatra is called the "S," and the individual inscriptions Sumatrenia is called the "W." The southern India influence still to be found in the island are extremely numerous, though far from being so important as those of Java. There are ruins of Hindu temples at Butar in Dili, near Pertibi, on the Panbij river at Jambi, in the interior of Palembang above Lahat, and in numerous other localities. One of the principal Hindu ruins is at Muara Takus on the Kampar river. The buildings (including a stupa 40 ft. high) may possibly date from the 11th century. At Pagar Rujung are several stones with inscriptions in Sanskrit and Menangkabo Malay. Sanskrit words occur in the various languages spoken in the island; and the Ficus religiosa, the sacred tree of the Hindu, is also the sacred tree of the Battas. At a later period the Hindu influence in Sumatra was strengthened by an influx of Hindus from Java, who settled in Palembang, Jambi and Indragiri, but their attachment to Sivaism prevented them from coalescing with their Buddhist brethren in the north. In the 13th century Mahomedanization began to make itself felt, and in course of time took a firm hold upon some of the most important states. In Menangkabo, for instance, the Arabic alphabet displaced the Kavi (ancient Javanese) character previously employed. Native chronicles describe Siva as the Great: and the Chinese dynasties boast its origin from a missionary of Islam. The town of Sumaderab was at that period the seat of an important principality in the north of the island, whose current name is probably a corruption of this word. There is a village called Suma near Pasi which possibly indicates the site.

Sumatra first became known to Europeans through the Portuguese, Diogo Lopes de Sequeira, in 1508. The Portuguese were the first to establish trading posts on the island, but at the end of the century they were driven out by the Dutch. At this time the most powerful native state in the island was Acheh (q.v.). Elsewhere Dutch sovereignty was gradually extended,—in 1664 over Indrapura; in 1666 over Padang, until by 1830 it was established over much of the southern part of the eastern lands, including Palembang. Meanwhile, in 1868 the British had acquired a footing in Benkulen, and between them and the Dutch there was always much jealousy and friction until in 1824 a treaty was made under which the British vacated Sumatra in favour of the Dutch, who reciprocated by giving up Malacca. In May 1825 Benkulen was taken over from the British. In the second half of the century the Dutch found a succession of armed expeditions necessary to consolidate their power. Thus in 1831 a revolt was suppressed in Palembang, and an expedition was sent to the Lampong districts. In 1833 Raja Rama of Lampang, ringleader of the revolt in Palembang, surrendered. In 1838 an expedition was sent against Sambal; the sultan was dethroned and a treaty made with his successor. In 1869 the British were invited to the Palembang residency. In 1863 there was an expedition against Nias, and in 1863 another against Ashan and Serdang (east coast). In 1873 war was declared against Achin. In 1876 there was an expedition against Kota Julo (east coast) and the emancipation of slaves was carried out on the west coast. In 1878 Benkulen was made a residency, and the civil administration of Achin and dependencies was entrusted to a governor. From 1883 to 1894 the government, with the help of missionaries, extended its authority over the south-east and south-west of the island, and also over some of the lands to the east and north of Toba lake, including the districts of Toba, Silindong and Tanah Jawa, and in 1895 over the southern part of the peninsula of Sumatra in Toba lake. Its jurisdiction was also extended over Tanjung Priok, where the frontier of the Dutch east coast of Sumatra. By military expeditions (1890-95) the Dutch influence on the Batang Hari, or Upper Jambi, was increased; and as also in 1899 in the Lima Kota in central Sumatra, included within the territory of Siak. The war in Achin did not materially retard the development of Sumatra, and although the titular sultan of Achin continued a desultory guerrilla warfare against the Dutch in the mountainous woodlands of the interior, the almost inaccessible Pasei country, really active warfare has long ceased. All along the main coasts of the former domains of Palembang, Sumatra, and north Sumatra have been established and military roads constructed; even in Pedir, on the north coast, until 1899 the most actively turbulent centre of resistance of the sultans' party, and still later only pacified in parts, Dutch engineers were able to build a highway to connect the west with the east coast, and other works have been successfully carried out. Practically the whole of the island is now more or less explored and under control.

The literature dealing with Sumatra is very extensive. Of the older works the best known is W. Marsden, History of Sumatra London, 1841. A full list of other authorities will be found in P. J. Veth's Aardrijkskundig Woordenboek van Nederl. Indië (1886). Among later works one of great importance is Midden-Sumatra; Reizen en Onderzoekingen door de Tanaband, 1829-1837; ed. by P. J. Veth. See also Brau de Saint-Pol Lias, I.d. de Sumatra (Paris, 1884); E. B. Kielstra, Beschrijving van de Afol van de Oost (1885-1886), and "Sumatra West-Kust van 1819-1825," in Bijdr. tot Land., etc., Kunde (1887); on the history of Palembang, west coast and the war in Achin, in Indisch militair Tijdschrift (1886-1889); Tijdschr. bat. Gen. (1887-1892). For topography and geography, see K. Fennema, Topographische en geologische Beschrijving van het Noordelijk gedeelte ... Westkust, etc.; J. van het Mijnwezen (1887); R. D. M. Verbeek, Topographische en geologische Beschrijving van een Deel van Sumatra's Westkust, with atlas (Batavia, 1883); similar work by Villers, of which the French edition (1892); D. Van der Stok, De Oost-Kust van Sumatra in de tijd van de Nederlanders, 1819-1825, in Batav. Tijdschr. Westkust, etc.; Volz, "Beiträge zur Geographie von Nord-Sumatra," Zeitschr. deutsch. geol. Gesell, (1899), vol. ii.; H. Büsing, "Zur Geologie der Sumatra-Inseln und der Inseln vor der Westküste," in Fortschritte d. Geol. 1899, vol. vii., with map and five plates (Leiden, 1904); D. J. Erb, "Beiträge zur Geologie und Morphologie der südlichen West-Küste von Sumatra," Z. Ges. Berlin (1907); J. F. Otto, Pfannenste- und Jügerlen auf Sumatra (Berlin, 1899); B. Hagen, "Die Gajo-Länder," Jahresb. Frankfurt v. G., etc., (1907); Climate: J. P. van der Stok, Regenmaeunungen und Atlas von Wind und Weather (Batavia, 1897). Consult further Tijd. Aardr. Gen., Tijd. Batav. Gen., Jaarb. van het Mijnwezen, and Koloniale Verslagen, passim. (See also MALAY ARCHIPELAGO).

Sumba (Tjendana, or Sandalwood), one of the Lesser Sunda Islands in the Dutch East Indies, lying south of Flores, from which it is separated by Sumba strait, about 10° S., 120° E. It has an area of about 4600 sq. m., consists of a plateau with an extreme elevation of about 3300 ft., and appears to be composed mainly of sedimentary rocks. It has a large Malay population (estimated at 200,000). Some trade is carried on in cotton, ponies, edible birds' nests, tortoiseshell, and various drugs and articles, among which is Waiangapu or Nangamessi on the north-east coast. Sumba is included in the Dutch residency of Timor, together with the lesser island of Savu, to the east. From this last island the sea is enclosed by Timor, Sumba and the islands between them, and Flores and the chain of islands east of it is called the Savu Sea.

1 Koto means the number of settlement or township, and a great many districts have been named from the number of kotaks they contain; e.g. the VII. Kotas, the VIII. Kotas, &c.
SUMBABA—SUMER AND SUMERIAN

SUMBABA (Dutch Soemba wa), one of the Little Sunda islands in the Dutch East Indies, east of Lombok, from which it is separated by the narrow Alas Strait. It has an area of 4300 sq. m., or, including the neighbouring islands, 5240 sq. m. The deep bay of Salé or Sumbawa on the north divides the island into two peninsulas, and the isthmus is further reduced by the narrower Bay of Chempi on the south. The eastern peninsula is deeply indented on the north by the Bay of Bima. Four mountain chains cross the island in a west to east direction. The northern, as in Bali and Lombok, is of volcanic origin. Tambora, forming a minor peninsula east of Sumbawa Bay, is said to have lost a third of its elevation in the eruption of 1815, but is still 9035 ft. high. In the southern chain is found a limestone formation analogous to that in Bali, Lombok and Java. Between these two chains are round hills consisting of lavas or sometimes of volcanic tuffs, covered with the long silvery grass which also clothes vast prairies in Java and Sumatra. There are no navigable streams. The climate and productions are not unlike those of Java, though the rains are heavier, the drought more severe, and the fertility less. Sulphur, arsenic, asphalt and petroleum exist. The natives live solely by agriculture. But out of a total population of about 75,000 there are 11,000 foreigners, living mostly by trade and navigation. The natives consist of Sumbawans proper, a people of Malay stock; of Buginese and Macassar immigrants, and of wild tribes of the mountains of whom nothing is known. Mahommedanism prevails throughout the island except among the mountain tribes.

Historically Sumbawa, with its four independent states, belongs to the confederated states of the government of Celebes and its dependencies, a situation to be explained by the fact of the old supremacy of the Macassaresi over Sumbawa, Flores and Sumba. The independent states are Sumbawa proper, Dompo, Sangar and Bima. Two other states on the northern part of the island were so far devastated by the Tambora eruption of 1815 that their territory, after lying for so long uninhabited, was in 1866 divided between the Sumbawa and Bima, the former lying in the south-western peninsula. The residence of the sultan is Sumbawa on the north coast. It is surrounded with a palisade and ditches. The inhabitants of this state employ sometimes the Malay and sometimes the Macassar character in writing. A considerable trade is carried on in the export of horses, buffaloes, goats, dinding (dried flesh), skins, birds’ nests, wax, rice, kattyang, sappanwood, &c. Sumbawa entered into treaty relations with the Dutch East India Company in 1674. Dompo is the western half of the eastern peninsula. The capital of the state, Dompo, lies in the heart of the country, on a stream that falls into Chempi Bay. Bada, the sultan’s residence, is situated on the south-western promontory of the island, and Bima the extreme east. Bima or Bodja, the chief town of the latter state, lies on the east side of the Bay of Bima; it has a stone-walled palace and a mosque, as well as a Dutch fort.

Sumbawang (p. 76), or Sumbawang, is a promontory on the northern coast of the island, now, however, considered a part of the town of Bima. Genoetsch, xxii.; Liggoet, “Anteekeningen betreffende den economischen Toestand en de Ethnographie van Sumbawang,” in Tijdschr. Bat. Gen. xxiii.

SUMBAL, or SUMBAL, also called Musk Root, a drug occasionally employed in European medical practice. It consists of the root of Perula sambul, Hook., a tall Umbelliferous plant found in the north of Bokhara, its range apparently extending beyond the Amur. It was first brought to Russia in 1833 as a substitute for musk; and in 1867 was introduced into the British pharmacopoeia. The root found in commerce consists of transverse sections an inch or more in thickness and from 1 to 3 or more inches in diameter. It has a dark thin papery bark, a spongy texture, and the cut surface is marbled with white and blackish or pale brown; it has a musky odour and a bitter aromatic taste. The action and uses of the drug are the same as those of asafoetida (q.v.) It owes its medicinal properties to a resin and an essential oil. Of the latter, it contains about 9% and of the latter 4%. The resin is soluble in water, and has a very smelly, but not fully developed until after contact with water.

Under the name of East Indian sambul, the root of Dorema ammonicum, Don., has occasionally been offered in English commerce. It is of a browner hue, has the taste of ammoniacum, and gives a much darker tincture than the genuine drug; it is thus easily detected. The name "sambal" (a word of Arabic origin, signifying a spike or ear) is applied to several fragrant roots in the East, the principal being Nardostachy shalalarnasi, D.C. (see SPIKE- NARD). West African sambul is the root of a species of Cyperus.

SUMER and SUMERIAN. The Babylonian name Shumer was used in the cuneiform inscriptions together with Akkad, for "mat Shumeri u Akkadi, "land of S. and A.," to denote Babylonian in general (see AKAAD). In the semi-Semitic ideographic documents the equivalent for Shumer is Ké-nu, which seems to be a combination of kén, "land," + gi, "reed," i.e. "land of reeds," and appropriate designation for Babylonia, which is essentially a district of reedy marshes formed by the Tigris and Euphrates. It was formerly thought that Shumer was employed especially to denote the south of Babylonia, while Akkad was used only of the north, but this view is no longer regarded as tenable. It is more probable that the expression Shumer designated the whole of Babylonia in much the same manner as did Akkad, and that the two words "Shumer and Akkad" were used together as a comprehensive term. That Shumer actually did mean all Babylonia appears evident from the biblical use of Shinar=Shumer to describe the district which contained the four chief Babylonian cities, viz. Babel, Erech, Accad and Calneh (Gen. x. 10), which, according to the Old Testament account, constituted the beginnings of Nimrod’s kingdom. The identity of Shinar and Shumer is also demonstrated by the Septuagint rendering of Shinar in Isaiah xi. 11 by "Babylonia." In short, there can be no doubt that the biblical name Shumer was practically equivalent to the mat Shumeri u Akkadi=non-Semitic form, Shemher, just as the non-Semitic word dimaru, "god," is equivalent to another form, dimir. Others have seen in the ancient Babylonian place-name Girsu an inversion of Su-gir=Su-Qir, which has also been identified with Shumer. In this connexion Hommel’s theory2 should be mentioned, that the word Shumer was a later palatalization of Ki-imir, "land of Imirr" = Shi-imirr, subsequently Shingi with palatalized k=s and elision of the final r. The form imir (imgar), however, as a place-name for Babylonia is uncertain. All that can be said at present about this difficult etymology is that in the non-Semitic Babylonian the name is represented by an ideographically indeterminate name which could also be indicated by the combination ng. Here we find Shumer, probably pronounced Shuwar, with a sound similar to that heard to-day in the Scottish Gaelic word lamh, “hand”; v. a sort of nasalized w. This gave rise to the later inaccurate forms: Greek, Senaar; Syriac, Sen’ar; and biblical Hebrew, Shinar=Shi’gar.

The so-called “Sumerian problem,” which has perplexed Assyriologists for many years, may be briefly stated as follows. In a great number of Babylonian inscriptions an idiom has long been recognized which is clearly not ordinary Semitic in character. This non-Semitic system, which is found in many instances, on alternate lines with a regular Semitic translation, in other cases in opposite columns to a Semitic rendering, and again without any Semitic equivalent at all, has been held by one school, founded and still vigorously defended by the distinguished French Assyriologist, Joseph Halevy, to be nothing more than a priestly system of cryptography based, of course, on the then current Semitic speech. This cryptography, according to some of the Halevyans, was read aloud in Semitic, but, according to other expositors, the system was read as an “ideophonic,” secret, and purely artificial language.

The opposing school (the Sumerists) insists that these

1 Hastings’s Dict. Bibb., iv. 503.
2 Ibid. i. 2240.
non-Semitic documents were evidently in an agglutinative language, naturally not uninfluenced by Semitic elements, but none the less essentially non-Semitic in origin and fundamental character. Scholars of this opinion believe that this language, which has been arbitrarily called "Akkaadin" in England and "Sumerian" on the European continent and in America, was primitively the speech of the pre-Semitic inhabitants of the Euphrates region who were conquered by the invading Semites. These invaders, according to this latter view, adopted the religious and cultural practices of the conquered Sumerians; and, consequently, the Sumerian idiom at a comparatively early date began to be used exclusively in the Semitic temples as the written vehicles of religious thought in much the same way as was the medieval Latin of the Roman Church. The solution of this problem is of vital importance in connexion with the early history of man's development in the Babylonian region.

The study of the Sumerian vocabulary falls logically into three divisions. These are (1) the origin of the cuneiform signs, (2) the etymology of the phonetic values, and (3) the elucidation of the many and varied primitive sign-meanings.

Previous to Professor Friedrich Delitzsch's masterly work, on the origin of the most ancient Babylonian system of writing, no one had correctly understood the facts regarding the beginnings of the cuneiform system, which is now generally recognized as having been originally a pure picture writing which later developed into a conventionalized ideographic and syllabic sign-list. In order to comprehend the mysteries of the Sumerian problem a thorough examination of the beginning of every one of these signs is, of course, imperative, but it is equally necessary that every phonetic Sumerian value and word-combination be also studied, both in connexion with the equivalent signs and with other allied phonetic values. This etymological study of Sumerian is attended with incalculable difficulties, because nearly all the Sumerian texts which we possess are written in an idiom which is quite evidently under the influence of Semitic. With the exception of some very ancient texts, the Sumerian literature, consisting largely of religious material such as hymns and incantations, shows a number of Semitic loanwords and grammatical Semitisms, and in many cases, although not always, is quite patent a translation of Semitic ideas by Semitic priests into the formal religious Sumerian language. Professor Paul Haupt may be termed the father of Sumerian etymology, as he was really the first to place this study on a scientific basis in his Sumerian Family Laws and Akkadian and Sumerian Cuneiform Texts. It is significant that all phonetic and grammatical work in Sumerian tends to confirm nearly every one of Haupt's views. Professors Peter Jensen and Zimmer have also done excellent work in the same field and, together with Haupt, have established the correct method of interpreting the Sumerian vocables, which should be studied only in relation to the Sumerian literature. Sumerian words should be compared with words in the idioms of more recent peoples, such as Turkish, in spite of many tempting resemblances. Until further light has been thrown on the nature of Sumerian, this language should be regarded as standing quite alone, a prehistoric philological remnant, and its etymology should be studied only with reference to the Sumerian inscriptions themselves. On the other hand, grammatical and constructional examination from outside the more modern agglutinative idioms, in order to establish the truly linguistic character of the Sumerian peculiarities and to dispel the Halévyan contentions that Sumerian is really not a language at all.

It is not surprising that Halévy's view as to the crypticographic nature of Sumerian should have arisen. In fact, the first impression given by the bewildering labyrinth of the Sumerian word-list is the conclusion that such a vocabulary could never have arisen in a regularly developed language. For example, anyone studying Brünnow's List will find the same sign denoting pages of meanings, many of which have apparently no connexion with any other meaning belonging to the sign in question. A great multiplicity of meanings is also attributed, apparently quite arbitrarily, to the same sign, sound-value or word. In these instances, however, we can explain the difficulty away by applying that great fundamental principle followed by the Semitic priests and scribes who played with and on the Sumerian idiom, and in the course of many centuries turned what was originally an agglutinative language into what has almost justified Halévy and his followers in calling Sumerian a cryptography. This principle is that of popular etymology, i.e., of sound-association and idea-association which has brought together in the word-lists many apparently quite distinct meanings, probably primarily for purposes of mnemonical aid. The present writer in his Materials for a Sumerian Lexicon has mentioned this ruling phenomenon again and again. A very few examples, however, will suffice here. Thus the word ag = the sign RAM = rámû, "love" (proper meaning) is associated with rōmmû, "to roar," for phonetic reasons only. The word a = the sign A = "water" (original meaning) can indicate anything whatever connected with the idea moisture. Thus, a = "water, moisture, weep, tears, inundate, irrigate," &c. The word a can also mean "shining, glistening," an idea evidently developed from the shining rippling of water. Note that in Turkish as means both "water" and "the lustre of a jewel," &c. The word a might possibly be "gems of the first water." The combination a-má-tu, literally "water enter ship," means abbâbû, "deluge," ordinarily, but in one passage a-má-tu is made the equivalent of šabbâbû, "flame," a pure pun on abbâbû, "deluge." Examples of this, the leading principle which was followed by the framers of the Sumerian system, might be cited almost ad infinitum.

Facts of this character taken by themselves would perhaps be sufficient to convince most philologists that in Sumerian we have an arbitrarily compounded cryptography just as Halévy believes, but these facts cannot be taken by themselves, as the evidences of the purely linguistic basis of Sumerian are stronger than these apparent proofs of its artificial character.

Briefly considered there are six most striking proofs that the Sumerian was based on a primitive agglutinative language. These may be tabulated concisely as follows:-

1. Sumerian presents a significant list of internal phonetic variations which would not have been possible in an arbitrarily invented language. Thus, taking the vowels alone; e =a by the principle of umlaut. Hence, we find the words ga and ge, as "for" for the same idea respectively. The vowel i could become e as de=di, &c. Consonantal variation is least common. Thus, b=m as bar=barn. Compare the modern Arabic pronunciation Maalbek for Baalbek. Perhaps the most interesting of these consonantal interchanges is that occurring between n and the sibilants sh and z; ner=sher; na=sa, which by some scholars has been declared to be phonetically impossible, but its existence is well established between the modern Chinese colloquial idioms. For example, Pekingese zhen, Hakka nziin, Fuchow ning, Ningpo zhein, and ying, Wonchoong song and nong all = "man." This demonstrates beyond a doubt the possibility of a strongly palatalized n becoming a palatal sibilant or vice versa, between which utterances there is but a very slight tongue movement.

The discussion of these phenomena brings us to another point which precludes the possibility of Sumerian having been merely an artificial system, and that is the undoubted existence in this language of at least two dialects, which have been named, following the inscriptions, the Eme-kû, "the noble or male speech," and the Eme-sal, "the woman's language." The existence and general phonetic character of the "woman's language" were first pointed out by Professor Paul Haupt,

2. Die Entstehung des ältesten Schriftsystems oder der Ursprung der Keilschrift in der Statthallie Mesopotamien (1897).
SUMMANUS

77

cited as being the basis of many of the Sumerian combinations. Deliberate inversion certainly occurs in the Sumerian documents, and it is highly probable that this was a priestly mode of writing, but never of speaking; at any rate, not when the language was in common use. It is not necessary to imagine, however, that these devices originated with the Semitic priesthood. It is quite conceivable that the still earlier Sumerian priesthood invented the method of orthographic inversion, which after all is merely an extreme development of the normal Sunnian inversion. The fact is, it is the sort of thing in people's minds when endeavouring to express itself in a manner out of the ordinary. For example, evident Sumerian inversions are Gibbi, "the fire god," for Bil-gi; ushar for Sem. sharru, "king," &c.

It is, moreover, highly probable that Sumerian had primitively a system of voice-tones similar to that now extant in Chinese. Thus, we find Sumerian ab, "dwelling," &c.; ab, "road," and -ab, a grammatical suffix, which words, with many others of a similar character, were perhaps originally uttered with different voice-tones. In Sumerian, the number of conjectural voice-tones never exceeds the possible number even... 

It is also clear that Sumerian was actually read aloud, probably as a ritual language, until a very late period, because we have a number of pure Sumerian words reproduced in Greek transliteration; for example, Delephai = Dilbat, "the Venus-star"; Illinos = the god Illi = Bél; iddi = itu, "month," &c.

In view of the many evidences of the linguistic character of Sumerian as opposed to the one fact that the language had engrailed upon it a great number of evident Semitisms, the opinion of the present writer is that the Sumerian, as we have it, is fundamentally an agglutinative, almost polythetic, language upon which a. m. j. j. h. was subsequently constructed pot-pourri of Semitic inventions was superimposed in the many centuries of accretion under Semitic influences. This view stands as a connecting link between the extreme idea of the Halévy school and the extreme idea of the opposing Sumerist school.

SUMMANUS, according to some, an old Sabine or Etruscan deity; the name, however, is Latin, formed by assimilation from sub-manus (cf. manu, Matuta), signifying the god of the time "before the morning." His sphere of influence was the nocturnal heavens, thunderstorms at night being attributed to him, those by day to Jupiter. Summanus had a temple at Rome near the Circus Maximus, dedicated at the time of the invasion of Italy by Pyrrhus, king of Epirus (278), when a terracotta image of the god (or of Jupiter himself) on the pediment of the Capitoline temple was struck by lightning and hurled into the river Tiber. Here sacrifice was offered every year to Summanus on the 20th of June, together with cakes called summanae. The name is often prefixed to a first wheel, supposed to be the bolical of the car of the god of the thunderbolt. In Plautus (Bacchides iv, 8, 54) Summanus and the verb summonare are used for the god of thieves and the act of stealing, with obvious reference to Summanus as a god of night, a time favourable to thieves and their business. The later explanation that Summanus is a contraction from Summus Manius (the highest of the Muses), and that he is to be identified with Dis Pater, is now generally rejected.

SUMMARY JURISDICTION

s.e. Provostum fulger; G. Wissowa, Religion und Kultur der Römer (1902); W. W. Fowler, The Roman Festivals (1899).

SUMMARY JURISDICTION. In the widest sense this phrase in English law includes the power asserted by courts of record to deal at
brevis manu with contempt of court without the intervention of a jury. Probably the power was originally exercisable only when the fact was notorious, i.e. done in presence of the court. But it has long been exercised as to extra curial contempt (see CONTEMPT or COURT). The term is also applied to the special powers given by statute or rules to the High Court of Justice and to county courts for dealing with certain classes of causes or matters by methods more simple and expeditious than the ordinary procedure of an action (see SUMMONS). But the phrase in modern times is applied almost exclusively to certain forms of jurisdiction exercised by justices of the peace out of general or quarter sessions, and without the assistance of a jury.

Ever since the creation of the office of justice of the peace (q.v.) the tendency of English legislation has been to enable them to deal with minor offences without trial. This was necessary, as Blackstone says, except in the case of contempt the common law is a stranger to trial without a jury, and because even when an offence is created by statute the procedure for trying must be by indictment and trial before a jury, unless by statute creating the offence or some other statute another mode of trial is provided. In one remarkable instance power is given by an act of 1725 (12 Geo. I. c. 29, s. 4) to judges of the superior courts summarily to sentence to transportation (penal servitude) a solicitor practising after conviction of barratry, forgery or perjury (Steph. Crim. 6th ed., 113). In other words all the summary jurisdiction of justices of the peace is the creation of statute. The history of the gradual development of the summary jurisdiction of justices of the peace is stated in Stephen's Hist. Crim. Law, vol. i. ch. 4. The result of legislation is that summary jurisdiction has been conferred by statutes and by-laws as to innumerable petty offences of a criminal or quasi-criminal character (most of which in French law would be described as contraventions), ranging through every letter of the alphabet. The most important perhaps are those under the Army, Game, Highway, Licensing, Merchant Shipping, Post Office, Public Health, Revenue, Acts.

A court of summary jurisdiction is defined in the Interpretation Act 1889 as "any justice or justices of the peace or other magistrate, by whatever name called, to whom jurisdiction is given by, or who is authorized to act under, the Summary Jurisdiction Acts, whether in England, Wales or Ireland, and whether acting under the Summary Jurisdiction Acts or any of them or any other act or by virtue of his commission or under the common law" (52 & 53 Vict. c. 63, s. 13 [11]). This definition does not apply to justices of the peace sitting to hold a preliminary inquiry as to indictable offences, or in the discharge of their quasi-administrative functions as licensing authority. The expression "Summary Jurisdiction Acts" means as to England and Wales the Summary Jurisdiction Acts of 1848 (11 & 12 Vict. c. 42) and 1870 (42 & 43 Vict. c. 49) and any act amending these acts or either of them. These acts define the procedure to be followed by justices in those cases in which they are empowered by statute to hear and determine civil or criminal cases without the intervention of a jury or the forms of an action or indictment at law or a suit in equity. Besides these two acts the procedure of the exercise of summary jurisdiction is also regulated by acts of 1857 (28 & 29 Vict. c. 1, c. 43), 1884 (47 & 48 Vict. c. 43) and 1899 (62 & 63 Vict. c. 22), and by the Summary Jurisdiction Process Act 1881 (44 & 45 Vict. c. 24). The act of 1848 repealed and consolidated the provisions of a large number of earlier acts. The act of 1857 provided a mode of appeal to the High Court by case stated as to questions of law raised in summary proceedings. The act of 1870 amended the procedure in many details with the view of uniformity, and enlarged the powers of justices to deal summarily with certain classes of offences ordinarily punishable on indictment. The act gives power to make rules regulating details of procedure.

The rules now in force were made in 1886, but have since been amended in certain details. The act of 1884 swept away special forms of procedure contained in a large number of statutes, and substituted the procedure of the Summary Jurisdiction Acts. The act of 1899 added the obtaining of property by false pretences to the list of indictable offences which could sub modo be summarily dealt with. The statutes above mentioned form a kind of code as to procedure and to some extent also as to jurisdiction.

As already stated, to enable a justice to deal summarily with an offence, whether created by statute or by-law, some statutory authority must be shown. A very large number of petty offences (contraventions) have been created (e.g. poaching, minor forms of vagrancy, nuisances of various descriptions, highway offences), and are not all being created (1) by legislation, or (2) by the by-laws of corporations made under statutory authority, or (3) by departments of state acting under such authority.

The two latter classes differ from the first in the necessity of proving by evidence the existence of the by-law or statutory rule, and if need be it is inutra vires.

In the case of offences which are primarily made punishable only on indictment, power to convict summarily is given in the following cases:

1. All indictable offences (except homicide) committed by children under seven and under twelve, if convicted before a summary court and not by parliamentary or delinquent act (1879, s. 10).

2. All indictable offences (except homicide) committed by young persons of twelve and under sixteen, if the young person consents to being told of his right to be tried by a jury (1879, s. 11; 1899, s. 2).

3. The indictable offences specified in sch. 1, col. 2 of the act of 1879 and in the act of 1899, if committed by adults, if they consent to being tried after being told of their right to be tried by a jury (1879, s. 12).

4. The indictable offences specified in sch. 1, col. 1 of the act of 1879 and the act of 1899, if committed by an adult who pleads guilty on due consideration that if he does so he will be summarily convicted (1879, s. 13).

5. Adults cannot be summarily dealt with under 3 or if the offence is punishable by law with penal servitude or imprisonment for two years or more, unless it is of a kind specified in the Schedule to the Summary Jurisdiction Act 1879, and they may be dealt with summarily only on the consent of the accused or the person having authority over him (1899, s. 14).

It will be observed that as to all the indictable offences falling under heads 1 to 4, the summary jurisdiction depends on the consent of the accused or person having authority over him, whereas in the case of summary conviction or indictment of the accused (1879, s. 14),

It will be observed that as to all the indictable offences falling under heads 1 to 4, the summary jurisdiction depends on the consent of the accused or person having authority over him, whereas in the case of summary conviction or indictment of the accused (1879, s. 14),

It will be observed that as to all the indictable offences falling under heads 1 to 4, the summary jurisdiction depends on the consent of the accused or person having authority over him, whereas in the case of summary conviction or indictment of the accused (1879, s. 14),

It will be observed that as to all the indictable offences falling under heads 1 to 4, the summary jurisdiction depends on the consent of the accused or person having authority over him, whereas in the case of summary conviction or indictment of the accused (1879, s. 14),

It will be observed that as to all the indictable offences falling under heads 1 to 4, the summary jurisdiction depends on the consent of the accused or person having authority over him, whereas in the case of summary conviction or indictment of the accused (1879, s. 14),

It will be observed that as to all the indictable offences falling under heads 1 to 4, the summary jurisdiction depends on the consent of the accused or person having authority over him, whereas in the case of summary conviction or indictment of the accused (1879, s. 14),

It will be observed that as to all the indictable offences falling under heads 1 to 4, the summary jurisdiction depends on the consent of the accused or person having authority over him, whereas in the case of summary conviction or indictment of the accused (1879, s. 14),

It will be observed that as to all the indictable offences falling under heads 1 to 4, the summary jurisdiction depends on the consent of the accused or person having authority over him, whereas in the case of summary conviction or indictment of the accused (1879, s. 14),

It will be observed that as to all the indictable offences falling under heads 1 to 4, the summary jurisdiction depends on the consent of the accused or person having authority over him, whereas in the case of summary conviction or indictment of the accused (1879, s. 14),

It will be observed that as to all the indictable offences falling under heads 1 to 4, the summary jurisdiction depends on the consent of the accused or person having authority over him, whereas in the case of summary conviction or induction of the accused (1879, s. 14).
Occasionally a warrant is issued in place of a summons in the first instance, in which case the information is likely to be more fully stated. The proceedings must be begun, i.e. by laying the information, not later than six months after the commission of the offence, unless by some particular statute another period is prescribed for the commencement of the action.

In a certain number of summary cases the accused is arrested under statutory authority without application to a justice, e.g. in the case of rogues and vagabonds and certain classes of offences committed on board a ship. In other cases the accused may be lawfully arrested without a warrant, or brought before the court in arrest, where he may be cross-examined. He may lawfully be arrested for a longer period of time, e.g. those of lunatics, if he is found in the jurisdiction of the court, i.e. before two or more justices, or in the regular place of meeting or some place temporarily appointed as the substitute for the regular court-house, or before a stipendiary magistrate. A summary conviction is a conviction in a lower court than the assize court, and the accused is brought before the court on arrest, and the court will not answer questions lawfully put to him by an inspector of the prison without endorsement, in the rest of England and Wales, and in Scotland, the Channel Islands and Isle of Man, after endorsement by a competent magistrate. The conviction is usually summarily, in the same court, by a justice of the peace or an inspector of the prison.

A warrant of arrest is executed by the constable or person to whom it is directed, and wherever or from whom the local jurisdiction of the issuing court; or a fresh pursuancy within the court may extend, summarily, where there is no without endorsement, in the rest of England and Wales, and in Scotland, the Channel Islands and Isle of Man after endorsement by a competent magistrate. The warrant may be issued in the summary court in a fresh jurisdiction, by a justice of the peace or an inspector of the prison.

The summons is obtained by writ of habeas corpus or by a writ of summons to the court by warrant, and a summary civil jurisdiction, e.g. as to certain civil debts recoverable summarily, or to make orders to do or to abstain from doing certain acts, e.g. with reference to nuisances and buildings, the procedure differs in certain details from that in criminal actions.

1. The summons is issued on a complaint which need not be in writing nor on oath, and not on an information, and warrants of arrest cannot be issued.

2. The evidence of the defendant and his or her spouse are the same as in civil actions.

3. The court's decision is by order and not by conviction. The order varies in form, but in the case of a conviction therewith is enforceable by distress and sale of the defendant's effects or by imprisonment, but only on proof that the defendant has had since the order means of paying and has refused or neglected to do so

4. Proceedings for the enforcement of local rates are not affected by the Summary Jurisdiction Acts except as to the power of summing to the High Court questions of law arising on a summons to enforce local rates. But all other points in the law as to such rates are sometimes but not quite accurately described as ministerial, for their powers of inquiry though limited are judicial and not ministerial.

Appeal.—The orders and convictions of a court of summary jurisdiction are in many cases appealable to quarter sessions. The right to appeal is always dependent on the specific provisions of a statute or rule of court. Some statutes or rules provide for appeal against an action on conviction (but not on plea of guilty) to imprisonment without the option of a fine, whether as punishment for an offence or for failure to do or abstain from doing any act, or for failure to pay money or find security or enter into recognizances or even to assert the appeals (1879, s. 19). The procedure on the appeals is regulated and made uniform by the acts of 1879, ss. 31, 32; and 1884. These provisions are supplementary of the particular provisions of many statutes authorizing an appeal.

The decisions of courts of summary jurisdiction on points of law arising in connexion with the proceedings are reviewable by the High Court under the acts of 1857 and 1879, but are occasionally corrected by the common law remedies of mandamus, prohibition, or certiorari. The application of the last-named remedy is restricted by the same statute to proceedings under the admiralty or police laws and orders of the High Court dealing with appeals, &c., from the decisions of justices in the exercise of their civil jurisdiction; but not when the subject-matter is a criminal cause or matter.

In proceedings between husband and wife for separation orders there is a special form of appeal on facts as well as to law to the probate, divorce and admiralty division of the High Court (Summary Jurisdiction [Married Women] Act 1895; Licensing Act 1902, s. 5).

SCOTLAND. Civil.—In the Court of Session there are certain forms of proceedings in summary cases, e.g. with reference to entails, custody of children, guardians and factors of minors and lunatics, which are applications for exercise of the nobile officium or extraordinary jurisdiction of the court (see Mackay, Court of Session Practice, 1914, p. 163). The appointment of such a person is given to justices of the peace as to the recovery of small debts.

Criminal and Quasi-criminal.—The only act relating to summary jurisdiction procedure common to England and Scotland is the Summary Jurisdiction (Scotland) Act 1881. Summary jurisdiction in Scotland depends chiefly upon the Summary Jurisdiction (Scotland) Acts 1864 and 1881. The acts follow, to some extent, the lines of the English statutes, but there are certain important differences, and some of the exceptions to the application of the summary jurisdiction are included in the definition of the court, as are stipendiary magistrates (1897, c. 48). The acts also apply to proceedings before church courts, or before burgesses, and to justices of the peace where they have by statute or by common law the power to try offenses or fines penalties. All proceedings for summary conviction or for recovery of a penalty must be by way of complaint according to one of the forms in the schedule to the act of 1864. The English summons and warrant are represented in Scotland by the warrant of citation and the warrant of apprehension. Where no punishment is fixed for a
statutory offence, the court cannot sentence more than a fine of £5 or sixty days' imprisonment, in addition to ordering caution to keep the peace. The jurisdiction of the ... English law called "libellus conventions." The antiquity and importance of the summons as a legal form in England is shown by the presence of the "summoner," or summoner of the ecclesiastical court, as one of the characters in the Assize Rolls, and in The History of Sir John Oldcastle, where the summoner was the substitute of the plaintiff issued from the bishop of Rochester's court. The term is used with reference to a demand for the attendance of a person in the high court of parliament. As regards English courts of justice it is equivalent to what in the civil and canon law and in Scots law, in which courts deriving their procedure from those sources, is known as "citation." That term is still preserved in English ecclesiastical courts and in matrimonial causes.

It is an essential principle of justice that a court should not adjudicate upon any question without giving the parties the opportunity of being heard and of bringing their witnesses before the court. The most usual term in English law for the process by which attendance is commanded or required is the "summons."  

Civil Proceedings.—In the High Court of Justice, civil actions are begun by obtaining from the officers of the court a document known as a writ of summons. In this document are stated the questions in controversy and the jurisdiction of the court to decide the question in the case; the matters in controversy must be of an amount exceeding £20. There is a short form of application to the Attorney General in England for a certificate as to the admissibility of the case for the purpose of obtaining a High Court summons, and the High Court summons is given as usual in the case of liquidated sums of money must be precise and particular. It is sealed and issued to the party suing it out, and served on the defendant by the officer of the court. It is a process by which the court instructs the defendant to appear and answer the claim, and to indicate the consequences of non-attendance, viz., adjudication in default.  

The procedure in the High Court and in some of the county courts is initiated by forms of summons different from the writ of summons. Of those issued in the High Court three classes merit mention: (1) the summons for determining interlocutory matters of practice and procedure arising in "a pending case or matter." These are now limited as far as possible to a general summons for directions, introduced in England by Lord Halsbury Lord Chief Justice, 1875, so as to discourage frequent and expensive applications to the masters or judges of the High Court on questions of detail. These summonses are sealed and issued on application at the offices of the High Court. The matters raised are dealt with by a master or judge in chambers summarily. In matters of practice and procedure there is no appeal from a judge at chambers without leave from him or from the court of appeal.

2. For determining certain classes of questions with more decision and less delay than is possible by the forms already mentioned. This kind of summons is known as an "originating summons," because under it proceedings may be begun without writ for certain classes of cases. The Law Reform Act, 1851, 2 & 3 Victorian (3), 3. The originating summons may be used in all divisions of the High Court, but is chiefly employed in the chancery division, where it is a great extent supersedes actions for the administration of trusts or of the title of property of the parties. It is a miscellaneous procedure similar to the action of origin in the chancery division. The evidence is usually written. In the chancery division where the questions raised are important the summons is adjourned into chambers after the evidence to the court of appeal from decisions on originating summonses.

The forms of summonses and the procedure thereon in civil cases in the High Court are regulated by the Rules of the Supreme Court 1883, 12 & 13 Vict. c. 86.  

3. Certain proceedings on the crown side of the king's bench division are begun by summons, e.g., applications for bail; and in certain of the actions of habeas corpus, prohibition and certiorari are asked for by summons as the full court is not in session. (See Crown Office Rules, 1906).

In the county courts an action is begun by plaint and summons. The power of summoning the defendant is limited to giving every form of county court action, and the default summons, which is an optional remedy of the plaintiff in actions for debts or liquidated demands exceeding £5, and in all actions for the price or hire of goods

1 A similar practice existed before 1853 under the powers given by 13 & 14 Vict. c. 86, but was very limited in its operation, as it applied only to the personal estate of a deceased person.
SUMMUM BONUM—SUMNER, C.

He graduated in 1830 at Harvard College, and in 1834 graduated at the Harvard Law School. Here, in closest intimacy with Joseph Story, he became an enthusiast in the study of jurisprudence: at the age of twenty-three he was admitted to the bar, and was contributing to the American Jurist, and editing law texts and Story's court decisions. What he saw of Congress during Lincoln's visit to Washington in 1864 filled him with loathing for politics as a career, and he returned to Boston resolved to devote himself to the practice of law. The three years (1837–1840) spent in Europe were years of fruitful study and experience. He secured a ready command of French, German and Italian, equalled by no American then in public life. He formed the acquaintance of many of the leading statesmen and publicists, and secured a deep insight into continental systems of government and of jurisprudence. In England (1838) his omnivorous reading in literature, history and jurisprudence made him persona grata to leaders of thought. Lord Brougham declared that he "had never met with any man of Sumner's age of such extensive legal knowledge and natural legal intellect." Not till many years after Sumner's death was any other American received so intimately into the best English circles, social, political and intellectual.

In his thirtieth year, a broadly cultured cosmopolitan, Sumner returned to Boston, resolved to settle down to the practice of his profession. But gradually he devoted less of his time to practice and more to lecturing in the Harvard Law School, to editing court reports and to contributions to law journals, especially historical and geographical lines, in which his erudition was unsurpassed. In his opinion the trial of the future would be conducted by himself and his friends, and he became despondent as to his future. It was in a 4th of July oration on "The True Grandeur of Nations," delivered in Boston in 1845, that he first found himself. His oration was a tremendous arrangement of war, and an impassioned appeal for freedom and for peace, and proved him an orator of the first rank. He immediately became one of the most eagerly sought orators for the lyceum and college platform. His lofty themes and stately eloquence made a profound impression, especially upon young men; his platform preachment imposing, for he was six feet and four inches in height and of massive frame; his voice was clear and of great power; his gestures unconventional and individual, but vigorous and impressive. His literary style was somewhat florid. Many of his speeches were monuments of erudition, but the wealth of detail, of allusion, and of quotation, often from the Greek and Latin, sometimes detracted from their effect.

Sumner co-operated effectively with Horace Mann for the improvement of the system of public education in Massachusetts. Prison reform and peace were other causes to which he gave ardent support. In 1847 the vigour with which Sumner denounced a Boston congressman's vote in favour of the Mexican War Bill made him the logical leader of the "Conscience Whigs," but he declined to accept their nomination for Congress. He took an active part in the organizing of the Free Soil party, in revolt at the Whigs' nomination of a slave-holding southerner for the presidency; and in 1848 was defeated as a candidate for the national House of Representatives. In 1851 control of the Massachusetts legislature was secured by the Democrats in coalition with the Free Soilers, but after filling the state offices with their own men, the Democrats refused to vote for Sumner, the Free Soilers' choice for United States senator, and urged the selection of some less radical candidate. A deadlock of more than three months ensued, finally resulting in the election (April 24) of Sumner by a majority of a single vote.

Sumner thus stepped from the lecture platform to the Senate, with no preliminary training. At first he prudently abstained from trying to force the issues in which he was interested, while he studied the temper and procedure of the Senate. In the closing hours of his first session, in spite of strenuous efforts to prevent it, Sumner delivered (Aug. 26, 1852) a speech, "Freedom national; Slavery sectional," which it was immediately felt marked a new era in American history. The conventions

sold or let to the defendant to be used in the way of his calling. It may also issue by leave of the judge or registrar in other cases, with the same effect. If no leave be had, the summons is not given even in cases where the claim is not for the price or hire of goods sold or let as above, if the affidavit of debt discloses that the defendant is a servant or partner of the plaintiff. The advantage of the written summons is that judgment is entered for the plaintiff without hearing unless the defendant gives notice of defence within a limited time. A default summons must as a rule be served personally on the defendant by a person of good character, but may be served by a bailli of the court and not by the party suing them out.

Justices of the peace have power to cause issue summons to persons accused of indictable offences, or of offences summarily punishable, for their attendance, for preliminary inquiry or summary trial according to the nature of the charge, and also to persons against whom a complaint of a civil nature within the justices' jurisdiction is made. On failure to attend on summons, attendance may be enforced by warrant; and in the case of indictable offences this is the course always adopted. The forms in use for indictable offences are scheduled to the Indictable Offences Act 1848, and those for other purposes to the Summons Act 1868. The summons is a writ of Summum Jurisdiction.) The attendance of witnesses before justices of the peace may be required by witness summons, enforced in the event of disobedience by arrest under warrant (see Witness).

The summons in civil proceedings, and the writ of subpoena, are usually served by a bailiff of the court and not by the party suing them out. In courts for the trial of indictable offences the attendance of the accused and of the witnesses is not secured by summons. Both officer and party can make an ex parte application, and the summons must be served with the writ of subpœna issued from the crown office of the High Court. Disobedience to the writ is punished as contempt of court.

Scotland.—Summons is a term confined in strictness to the books. The writ is called a summons. The summons is written in the sovereign's name, signed by a writer to the signet, citing the defendant to appear and answer the claim. The "will of the summons" is the conclusion of a writ, containing the will of the sovereign officer, accusing the defendant of some act or omission whose attendance is required. It is regulated by several acts, e.g. The Debtors (Scotland) Act 1838 (1 & 2 Vict. c. 114) and the Court of Session (Scotland) Act 1825, s. 53. Defects in the summons are cured by amendment or rectification of the summons by the Court of Session.

A privileged summons is one where the inducæ are shortened to six days against defenders within Scotland (Court of Session [Scotland] Act 1825, s. 53). Defects in the summons are cured by amendment or rectification of the summons by the Court of Session. The summonses go to the judge of the court, and are not like the English writ of summons, though it no longer states, as it once did, the grounds of action, now stated in the condescension and pursuer's pleas in law annexed to the summons. The form of the summons is given by the Court of Session (Scotland) Act 1850, s. 1 and schedule A. After the action has been set on foot by summons, the attendance of the parties and witnesses is obtained by citation. The Citation Amendment Acts 1871 and 1882 give additional facilities for the execution of citations in civil cases by means of registered letters, instead of by the old process known as "lock hole citation." In the act of 1871 the term "summons" is used to denote part of the process of inferior civil courts. In the sheriff court an action is now begun by writ (Sheriff Courts [Scotland] Act 1897), and not as formerly by petition or summons.

Ireland.—In Ireland summonses are used substantially for the same purposes and in the same manner as in England, but generally speaking under statutes and rules applying only to the parties. (W. F. C.)

SUMMUM BONUM (Lat. for "highest good"), in ethics, the ideal of human attainment. The significance of the term depends upon the character of the ethical system in which it occurs. It may be viewed as a perfect moral state: as pleasure or happiness (see Hedonism; Eudaemonism); as physical perfection; as wealth, and so forth. If, however, we abandon intuitional ethics, it is reasonable to argue that the term summum bonum ceases to have any real significance inasmuch as actions are not intrinsically good or bad, while the complete sceptic strives after no systematic ideal.

SUMNER, CHARLES (1811–1874), American statesman, was born in Boston, Massachusetts, on the 6th of January 1811.
of both the great parties had just affirmed the finality of every provision of the Compromise of 1850. Reckless of political expediency, Sumner moved that the Fugitive Slave Act be forthwith repealed; and for more than three hours he denounced it as a violation of the constitution, an affront to the public conscience, and an offence against the divine law. The speech provoked a storm of anger in the South, but the North was heartened to find at last a leader whose courage matched his conscience. In 1856, at the very time when "border ruffians" were drawing their lines closer about the doomed town of Lawrence, Kansas, Sumner in the Senate (May 19-20) laid bare the "Crime against Kansas." He denounced the Kansas-Nebraska Bill as in every respect a swindle, and held its authors, Stephen A. Douglas and Andrew P. Butler, up to the scorn of the world as the Don Quixote and Sancho Panza of the "harlot, Slavery." Two days later (May 22) Preston S. Brooks (1819-1857), a congressman from South Carolina, suddenly confronted Sumner as he sat writing at his desk in the Senate chamber, denounced his speech as a libel upon his state and upon Butler, his relative, and before Sumner, pinned on his desk, could make the slightest resistance, raised blow after blow upon his head, till his victim sank bleeding and unconscious upon the floor. That brutal assault cost Sumner three years of heroic struggle to restore his shattered health—years during which Massachusetts loyally re-elected him, in the belief that in the Senate chamber his vacant chair was the most eloquent pleader for free speech and free resistance to slavery. Upon his return, in 1859, the approaching presidential campaign of 1860 did not deter him from delivering a speech, entirely free from personal rancour, on "The Barbarism of Slavery"—to this day one of the most comprehensive and scathing indictments of American slavery ever presented.

In the critical months following Lincoln's election Sumner was an unyielding foe to every scheme of compromise. After the withdrawal of the Southern senators, Sumner was made chairman of the committee on foreign relations (March 8, 1861), a position for which he was pre-eminently fitted by his years of intimate acquaintance with European politics and statesmen. While the war was in progress his letters from Cobden and Bright, from Gladstone and the duke of Argyll, at Lincoln's request were read by Sumner to the cabinet, and formed a chief source of light as to political thought in England. In the turmoil over the "Trent" affair, it was Sumner's word that convinced Lincoln that Mason and Slidell must be given up, and that reconciled the public to that inevitable step. Again and again Sumner used the power incident to his chairmanship to block action which threatened to return the Union to war with England and France. Sumner openly and boldly advocated the policy of emancipation. Lincoln described Sumner as "my idea of a bishop," and used to consult him as an embodiment of the conscience of the American people.

The war had hardly begun when Sumner put forward his theory of reconstruction: that the seceded states by their own act had "become feto de se," had "committed state suicide," and that their status and the conditions of their readmission to membership in the Union lay absolutely at the determination of the government. There were two states which had never been states. He presented the initiative in Reconstruction to the Senate, and Lincoln, and later by Johnson, as an encroachment upon the powers of Congress. Throughout the war Sumner had constituted himself the special champion of the negro, being the most vigorous advocate of emancipation, of enlisting the blacks in the Union army, and of the establishment of the Freedmen's Bureau. The credit or the blame for imposing equal suffrage rights for negroes upon the Southern states as a condition of Reconstruction must rest with Charles Sumner more than with any other man. Needless of the teachings of science as to the slow evolution of any race's capacity for self-government, he insisted on putting the ballot forthwith into the hands of even the most ignorant blacks, lest their rights be taken from them by their former masters and the fruits of the war be lost. But it must be remembered that in Sumner's plan equal suffrage was to be accompanied by free homesteads and free schools for negroes.

In the impeachment proceedings against Johnson, Sumner was one of the president's most implacable assailants. Sumner's opposition to Grant's pet scheme for the annexation of San Domingo (1870), after the president mistakenly supposed that he had secured a pledge of support, brought upon him the president's bitter resentment. Sumner had always prized highly his popularity in England, but he unhesitatingly sacrificed it in taking his stand as to the adjustment of claims against England for breaches of neutrality during the war. Sumner laid great stress upon "national claims." He held that England's according the rights of belligerents to the Confederate states had doubled the duration of the war, entailing inestimable loss. He therefore insisted that England should be required not merely to pay damages for the havoc wrought by the "Alabama" and other cruisers fitted out for Confederate service in her ports, but that, for "that other damage, immense and infinite, caused by the prolongation of the war," the withdrawal of the British flag from this hemisphere could "not be abandoned as a condition or preliminary of such a settlement as is now proposed." (At the Geneva arbitration conference these "national claims" were abandoned.) Under pressure from the president, on the ground that Sumner was no longer on speaking terms with the secretary of state, he was deposed on the 10th of March 1871 from the chairmanship of the committee on foreign relations, in which he had served with great distinction and effectiveness throughout the critical years since 1861. Whether the chief cause of this humiliation was Grant's vindictiveness at Sumner's opposition to his San Domingo project or a genuine fear that the impossible demand, which he insisted should be made upon England, would wreck the prospect of a speedy and honourable adjustment with that country, cannot be determined. In any case it was a cruel blow to a man already broken by racking illness and domestic sorrows. Sumner's last years were further saddened by the misconstruction put upon one of his most magnanimous acts. In 1872 he introduced in the Senate a resolution providing that the names of battles with fellow citizens should not be placed on the regimental colours of the United States. The Massachusetts legislature denounced this battle-flag resolution as "an insult to the loyal soldiery of the nation" and as "meeting the unqualified condemnation of the people of the Commonwealth." For more than a year all efforts—headed by the poet Whittier—to rescind that censure were without avail, but early in 1874 it was annulled. On the 10th of March, against the advice of his physician, Sumner went to the Senate—it was the day on which his colleague was to propose the rescission resolution. He left for Kenilworth in the next day's mail. With these grateful words of vindication from Massachusetts in his ears Charles Sumner left the Senate chamber for the last time. That night he was stricken with an acute attack of angina pectoris, and on the following day he died.

Sumner was the scholar in politics. He could never be induced to suit his action to the political expediency of the moment. "The slave of principles, I call no party master," was the proud avowal with which he began his service in the Senate. For the tasks of Reconstruction he showed little aptitude. He was less a builder than a prophet. His was the first clear programme proposed in Congress for the reform of the civil service. It was his dauntless courage in denouncing compromise, in demanding the repeal of the Fugitive Slave Act, and in insisting upon emancipation, that made him the chief initiating force in the struggle that put an end to slavery.

See Sumner's Works (15 vols., Boston, 1870-1883), and Edward L. Pierce's Memoir and Letters of Charles Sumner (4 vols., Boston, 1877-1882). Brief biographies have been written by Anna L. Dawes (New York, 1892); Moorfield Storey (Boston, 1900); and George H. Haynes (Philadelphia, 1909).

SUMNER, CHARLES RICHARD (1790-1874), English bishop, was born at Kenilworth on the 22d of November 1790, and was educated at Eton and at Trinity College, Cambridge. He graduated B.A. in 1814, M.A. in 1817, and was ordained deacon
SUMNER, E. V.—SUMPTUARY LAWS

and priest. In the two winters of 1814-1816 he ministered to the English congregation at Geneva, and from 1816 to 1821 was curate of Highclere, Hampshire. In 1820 George IV. wished to appoint him canon of Windsor, but the prime minister, Lord Liverpool, objected; Sumner received instead a royal chaplaincy and librarianship, and other preferments quickly followed, till in 1826 he was consecrated bishop of Llandaff and in 1827 bishop of Winchester. In his long administration of his latter diocese he was most energetic, tactful and munificent. Though evangelical in his views he by no means confined his patronage to that school. In 1869 he resigned his see, but continued to live at the official residence at Farnham until his death on the 15th of August 1874. He published a number of charges and sermons, and The Ministerial Character of Christ Practically Considered (London, 1824). He also edited and translated John Milton's De doctrina christiana, which was found in the State Paper office in 1823, and formed the text of Macaulay's famous essay on Milton.

See the Life, by his son, G. H. Sumner (1876).

SUMNER, EDWIN VOSE (1707-1865), American soldier, was born at Boston, Massachusetts, and entered the United States army in 1819. He served in the Black Hawk War and in various Indian campaigns. In 1838 he commanded the cavalry instructional establishment at Carlisle, Pennsylvania. He took part in the Mexican War as a major, and for his bravery at Molino del Rey he received the brevet rank of colonel. In 1857 he commanded an expedition against the Cheyenne Indians. At the outbreak of the Civil War, four years later, Sumner had just been promoted brigadier-general U.S.A. and sent to replace Sidney Johnston in command on the Pacific coast. He thus took no part in the first campaign of the Civil War. But in the autumn he was brought back to the East to command a division, and soon afterwards, as a major-general U.S.V., a corps in the army that was being organized by McClellan. This corps, numbered II., retained its independent existence throughout the war, and under the command of Sumner, Couch, Hancock and Humphreys it had the deserved reputation of being the best in the Union army. Sumner, who was by far the oldest of the generals in the army of the Potomac, led his corps through out the peninsular campaign, was wounded during the Seven Days' Battle, and received the brevet of major-general U.S.A., and was again wounded in the battle of Antietam. When Burnside succeeded to the command of the army of the Potomac he grouped the corps in "grand divisions," and appointed Sumner to command the right grand division. In this capacity the old cavalry soldier took part in the disastrous battle of Fredericksburg, in which the II. corps suffered most severely. Soon afterwards, on Hooker's appointment to command the army, Sumner was relieved at his own request. He died suddenly, on the 21st of March 1869, while on his way to assume supreme command in Missouri.

SUMNER, JOHN BIRD (1780-1828), English archbishop, elder brother of Bishop Charles Sumner, was born at Kenilworth, Warwickshire, and educated at Eton and Cambridge. In 1802 he became a master at Eton, and in the following year he took orders. He was elected a fellow of Eton in 1817, and in 1818 the college presented him to the living of Maple Durham, Oxfordshire. After holding a prebendaryship of Durham for some years, he was consecrated bishop of Chester in 1828. During his episcopate many churches and schools were built in the diocese. His numerous writings were much esteemed, especially by the evangelical party, to which he belonged; the best and again wound in the battle of Antietam. When Burnside succeeded to the command of the army of the Potomac he grouped the corps in "grand divisions," and appointed Sumner to command the right grand division. In this capacity the old cavalry soldier took part in the disastrous battle of Fredericksburg, in which the II. corps suffered most severely. Soon afterwards, on Hooker's appointment to command the army, Sumner was relieved at his own request. He died suddenly, on the 21st of March 1869, while on his way to assume supreme command in Missouri.

1 George Cornelius Gorham (1787-1855) was refused institution by Bishop Phillpotts because of his Calvinistic views on baptismal regeneration. The court of arches upheld the bishop, but its decision was reversed by the privy council.
SUMPTUARY LAWS

(1) The Opillian law, 215 B.C., provided that no woman should possess more than half an ounce of gold, or wear a dress of different colors on the same day, or take part in a meal on occasions of public religious ceremonies. This law, which had been partly dictated by the financial necessities of the conflict with Hannibal, was repealed twenty years later, against the advice of Cicero. Like the law of 161 B.C., limited the sums to be spent on entertainments; it provided among other things that no flour should be served but a single hen, and that not fattened. (2) The Didian law, 143 B.C., extended to the whole of Italy the provisions of the Punic fleet. In 130 B.C. the decree passed in the Senate permitting the wearing of gold rings by men. But it appears from Tacitus (Ann. i. 5, where a speech is put into his mouth very much in the spirit of Horace's "Quid leges sine moribus vanae proficiunt?"

In modern times the first important sumptuary legislation was: in Italy that of Frederick II; in Aragon that of James I., in 1234; in France that of Philip IV; in England that of Edward II. and Edward III. In 1294 Philip IV. made provisions as to the dress and the table expenditure of the several orders of men in his kingdom. Charles V. of France forbade the use of long-pointed shoes, a fashion against which popes and councils had protested in vain. Under later kings the use of gold and silver embroidery, silk stuffs and fine linen wares was restricted to church officials. The effect of these rules was to stimulate the growth of the British wool industry and to permit the growth of the British clothmaking industry. In England we hear much from the writers of the 14th century of the extravagance of dress at that period. They remark both on the great splendour and conspicuousness of the apparel of the higher orders and on the fantastic and deforming fashions adopted by persons of all ranks. The parliament held at Westminster in 1363 made laws (37 Edw. III. c. 8-14) to restrain this undue expenditure and to regulate the dress of the several classes of the people. These statutes were repealed in the following year, but similar ones were passed again in the reign of Richard II. However, to have had little effect, for in the reign of Richard II. the sums increased upon the account of the cause of war. Another statute was passed in the year 1463 (3 Edw. IV. c. 5) for the regulation of the dress of persons of all ranks. In this it was stated that "the customs of the realm, as well men as women, wear excessive and inordinate apparel to the great displeasure of God, the enriching of strange realms, and the destruction of this realm." An act of 1444 had previously regulated the clothing, when it formed part of the wages, of servants employed in husbandry: a halfling or over was to have an allowance of 5s. a year for his clothing, a hind or prime, 25s. 4s. 5d. a year for clothes, 7s. 10s. 10s. 9d. in sums equivalent respectively to 50s., 40s., and 33s. 4d. of our money (Henry). Already in the reign of Edward II. a proclamation had been issued against the "outrageous and excessive multitude of meats and dishes which the great men of the kingdom had used, and still used, in their castles," as well as "persons of inferior rank imitating their example, beyond what their stations required and their circumstances could afford"; and the rule was laid down that the great men should have but two courses of flesh meat served up to their tables, and on fish days two courses of fish, each course consisting of but two kinds. In 1463 (temp. III.) the ordinances were attempted also to legislate against luxury in living, and in 1563, at the same time when costumes were regulated, it was enacted that the servants of gentlemen, merchants and artificers should have only one meal of fish or flesh in the day, and that their other food should consist of milk, butter and cheese. Similar acts to those above mentioned were passed in Scotland also. In 1433 (temp. James I.), by an act of a parliament which sat at Perth, the manners of living of all orders in Scotland was prescribed, and in particular the use of pies and baked meats, which had been only lately introduced into the country, was forbidden to all under the rank of baron. In 1457 (temp. James II.) an act was passed against "sumptuous clothing." A Scottish sumptuary law of 1621 was the last of the kind in Great Britain.

In Japan sumptuary laws have been passed with a frequency and minuteness of scope such as has no parallel in the history of the western world. At the beginning of the 11th century we find an Imperial edict regulating the size of a house and even imposing restrictions as to the materials of which it is to be built. But it was during the Tokugawa period that sumptuary legislation reached its fullest expression. All classes were subjected to austerities of dress, and to a careful regulation of the kindling of fires, every detail of a man's life was regulated down to the least particular—from the wearing of a beard or the dressing of the hair down to the cost of his wife's hairpins or the price of his child's doll.

A. Ferguson and others have pointed out that "luxury" is a term of relative import and that all luxuries do not deserve to be discouraged. Roscher has called attention to the fact that the nature of a sumptuaries law has changed in the course of time, a change due to a change in the character of the social classes affected. He endeavours to show that there are three periods in the history of luxury—one in which it is coarse and profuse; a second in which it sinizes mainly at comfort and elegance; and a third, propitious to periods of decadence, in which it is purifying and unnatural. The second of these began, in modern times, with the emergence of the Western nations from the medieval period, and in the ancient communities at epochs of similar transition. Roscher holds that the sumptuary legislation which regularly appears at the opening of this stage was then useful as promoting the reformation of habits. He remarks that the contemporary application of the stronger sate's laws resulted perhaps from two influences: firstly, the idea of the private man's right to regulate his own actions against the will of society; and secondly, the idea of the social policy that habits of wasteful expenditure and frequent and wanton changes of fashion should be discouraged. But such action looks more properly to the spiritual than to the temporal power. In ancient, especially Roman, life, when there was a confusion of the two powers in the state system, sumptuary legislation was more natural than in the modern world, in which those powers have been in general reality, though imperfectly, separated. Political economists are practically unanimous in their repudiation of the policy of legislative compulsion in these matters. In a well-known passage Adam Smith protests against the "imperariance and presumption of the minister's mind" in his attempt "to impose upon the private and public expense, being themselves always and without any exception the greatest spendthrifts in the society." Yet he does not seem to have availed from all attempts to influence through taxation the expenditure of the greater part of the people. The modern taxes on carriages, coats of arms, male servants, playing cards, &c., ought perhaps not to be regarded as resting on the principle of sumptuary laws, but only as means of proportioning taxation to the capacity of bearing the burden.

The loci classicus on Roman sumptuary laws are Celsus, Notae atticae, ii. 24, and Macrobius, Saturn. iii. 17. For Great Britain the earliest materials are in the "History of Husbandry and Huntingdon, During the Reign of Henry VII," ed. T. Arnold, 1879; W. Cunningham, Growth of English Industry and

SUN

Commerce; W. J. Ashley, Introduction to English Economic History and Theorizing England in the Fifteenth Century (1888). One of the best extant treatments of the whole subject is that by Roscher, in his essay, _Über den Luxus, republiert in seinen Ansichten der Volkswirtschaft auf dem geschichtlichen Standpunkt_ (J. K. L. 1898).

SUMTER, THOMAS (1736–1832), American soldier, was born in Hanover county, Virginia, on the 14th of July 1736. He served in the Virginia militia during the French and Indian War and was present at Braddock's defeat (1755). Some time after 1762 he removed to South Carolina. He is best known for his service during the War of Independence, but he saw little active service until after the fall of Charleston in May 1780. In July 1780 he became a brigadier-general of state troops. During the remainder of the war he carried on a partisan campaign, and earned the sobriquet of the "Gamcock." He fell in an attack upon Rocky Mount (Chester county) on the 1st of August 1780, but on the 6th defeated 500 Loyalists and regulars at Hanging Rock (Lancaster county), and on the 15th intercepted and defeated a convoy with stores between Charleston and Camden. His own regiment, however, was almost annihilated by Lieut.-Colonel Banastre Tarleton (1754–1833) at Fishing Creek (Chester county) on the 18th. A new force was soon recruited, with which he defeated Major James Wemys at Fishdam (Union county) on the night of the 8th–9th of November, and repulsed Tarleton's attack at Blackstock (Union county) on the 20th, when he was wounded. In January 1781 Congress formally thanked him for his services. He was a member of the state convention which ratified the Federal constitution for South Carolina in 1788, he himself opposing that instrument; of the national House of Representatives in 1789–1793 and again in 1797–1801, and of the United States Senate from 1801 to 1810.

At the time of his death at South Mount, South Carolina, on the 1st of June 1832, he was the last surviving general officer of the War of Independence.

SUMTER, a city and the county-seat of Sumter county, South Carolina, U.S.A., 42° 41' N. lat. by R. E. of S. of Columbia. Pop. (1900) 5673 (3160 negroes); (1910) 8109. Sumter is served by several divisions of the Atlantic Coast line and by the Southern railways. It is the seat of St Joseph's Academy (Roman Catholic) for girls. The region produces tobacco, vegetables and cotton, and there are various manufactories in the city. Sumter was founded in 1800 and was named in honour of General Thomas Sumter; it was first chartered as a city in 1887.

SUMY, a town of Little Russia, in the government of Kharkoff, 112 m. by rail N.W. of the city of Kharkof, founded in 1638. Pop. (1900), 28,519. It is an important centre for the trade of Great Russia with Little Russia—cattle and corn being sent to the north in exchange for manufactured and grocery wares. It has important sugar manufacture, and a technical school.

SUN (O. Eng. sunne, Ger. sonne, Fr. soleil, Lat. sol, Gr. ἡλίος, from which comes heliot—in various English compounds), the name of the central body of the solar system, the luminous orb from which the earth receives light and heat; (see SUNSHINE), hence by analogy other heavenly bodies which form the centre of systems of called suns.

To understand the phenomena of the sun, we should reproducible upon the earth; but this is clearly impossible since they take place at temperatures which volatilize all known substances. Hence our only guides are such general laws of mechanics and physics as we can hardly believe any circumstances will falsify. But it must be remembered that these require extrapolation from experience sometimes sufficiently remote, and it is possible they may lead to statements that are obscure, if not contradictory. The body of the sun must consist of uncombined gases; at the surface the temperature is some 200° C. above the boiling point of carbon, and is a little below what the hypothesis of the derivation of the sun's light and heat requires to exceed the critical point at which increase of pressure can produce the liquid state in any substance. But as the mean density exceeds that of water, and probably falls but little from the centre to the surface, these gases are gases only in the sense that if the pressure of neighbouring and outward parts gravitating towards the centre were relaxed, they would expand explosively, as air is happening in the eruptive phenomena. They have lost completely the gaseous characteristic of producing a spectrum, and radiate like incandescent solids. The surface region which yields a continuous spectrum is called the photosphere; it possesses optically a sharp boundary, which is generally a perfect sphere, but shows occasionally at the rim slight depressions or more rarely elevations. Enclosing the photosphere is a truly gaseous envelope which is called the chromosphere, and which shows a spectrum of bright lines when we can isolate its emission from that of the photosphere. This envelope is also sharply defined, but its normal appearance is compared to the sputters which blazes of grass show on the skyline of a hill, and it is disturbed by the outbursts, called prominences, of which details are given below. Outside this again is an envelope of matter of enormous extent and extreme tenuity, whether gaseous or partly minute liquid or solid drops, which is called the corona. It has no sharp boundary, its brightness diminishes rapidly as we recede from the limb, and such structure as it shows consists of long streaks or filaments extending outwards from the limb in broad curved sweeps. Finally there is the envelope of still vaster extent and of unknown constitution which gives the solisidal light (p.e.); its greatest extent is along the ecliptic, but it can also be certainly traced for 35° in a perpendicular direction. The lower gaseous cloaks absorb a large part of the light admitted by the photosphere, and especially at the limb and for the more refrangible rays the loss of intensity is very marked.

In the instant when a sharp image of the photosphere is seen or photographed, it shows a granulated appearance like white flakes stirred freely upon a dark ground. The figs. 1, 2, 3, 4 (plate) show enlargements from photographs by Hansky at Pulkowa (June 25, 1903); they are separated by intervals of 25 to 80 sec. The spots show with more or less completeness the granules in many of the granules, or more properly, clouds represented. Thus they exhibit at once general appearance and its changes. The diameters range from 400 m. or less up to 1200 m., and the speeds relative to the spot range up to 2 or 3 m. per second. M. Hansky believes these motions may be the consequences of matter rising from below and thrusting the surface groups aside. Usually the changes are such that it is impossible even to recognize the formations in successive photographs. Besides granulations the sun's disk shows, as a rule, one or more spots or groups of spots. Each spot shows with more or less completeness a ring-shaped penumbra enclosing a darker umbra; the umbra, which looks black beside the photosphere, is actually about as brilliant as limelight. In the neighbourhood surrounding the penumbra the granules appear to be packed more closely, forming brilliant patches called faculae. In the shape of a spot there is neither rule nor permanence, though those that are nearly circular seem to resist change better than the others. They arise from combinations of smaller spots, or from nothing, in a short period, say a day. They are never wholly quiescent. Bridges, more brilliant than the rest of the photosphere, form across them, and they may divide into two parts which separate from one another with great velocity. The largest spots are easily seen by the naked eye, if the brilliancy of the disk is veiled; the umbra may be many—ten or more—diameters of the earth in breadth. The length of their life is difficult to assign, because there is some tendency for a new group to arise where an old one has disappeared; but one is recorded which appeared in the same place for eighteen months; the average is perhaps two months. They are carried across the disk by the sun's rotation, partaking in the equatorial acceleration; they also show marked displacements of their own, whether with, or relative to, the neighbours. In the course of their life they usually outrun the average daily rotation appropriate to their latitude. Spots are rarely found on the equator, or
more than 35° N. or S. of it, and at 45° are practically unknown. Their occurrence within these zones follows statistically a uniform law (see Aurora). Other information about the spots is given below, in connexion with their spectra. It may be said that nothing definite has been established as to what they are. The statement known as A. Wilson's theory (1774), that they are hollows in the photosphere, long supposed to be proved by perspective effects as the spot approached the limb, is discredited by F. Howlett's careful drawings, which, however, do not establish the contrary. A conclusion it is necessary that the spot should be quiescent, show a well-developed and fairly symmetrical penumbra, and be observed near the limb and also near the centre, and these conditions are satisfied in so few cases as to withdraw all statistical force from the conclusion. Figs. 5, 6, 7, 8 (plate) are reproductions of the Greenwich photographs of the sun from the 30th of January to the 8th of February 1905. The first, taken alone, might seem to bear out Wilson's theory, but the others show that the penumbra is really very unsymmetrical and much broader on the side towards the limb, apart from anything which perspective may have to say. The photosphere does not rotate in one piece, lower latitudes outrunning higher. This was discovered by R. C. Carrington from observations of the spots, extending from 1833 to 1861, from which he determined also the position of the sun's axis. But conclusions from the spots are full of anomalies. E. W. Maunder and Mrs Maunder found that different spots in the same zone differ more than do the means for different zones, while a long-lived spot settles down to give more consistent results than are furnished by spots of one apparition. In the span of two complete sun-spot periods no evidence was found of periodic or other change with lapse of time. The problem still awaits complete discussion. The irregularities incidental to use of the spots are escaped by comparing the relative Doppler displacements of the same spectral line as given by the receding and advancing limbs of the sun. The observation is a delicate one, and was first successfully handled by N. C. Dunér in 1890. But his determinations, repeated recently (Adia specul. IV. vol. I., 1907) as well as those of J. Halm at Edinburgh (Adia Nach. vol. 173, 1907), are superseded by a photographic treatment of the problem by W. S. Adams (Astrophys. Journ., xxvi., 1907).

The diagram (fig. 9) shows Adams's value for the angular velocity \( \xi \) for different latitudes \( \phi \), the dots representing the actual observations. Fig. 10 shows the consequent distortion of a set of meridians after one revolution (at lat. 30°). An important feature added to the discussion by Adams is the different behaviour of spectral lines which are believed to originate at different levels. The data given above refer to the mean reversing layer. Lines of lanthanum and carbon which are believed to belong to a low level showed systematically smaller angular velocity than the average. This promises to be a fertile field for future inquiry. Pending more conclusive evidence from the spectroscope, the interpretation of the peculiar surface rotation of the sun appears to be that the central parts of the body are rotating faster than those outside them; for if such were the case the observed phenomenon would arise. For consider first a frictionless fluid. The equations of surfaces of equal angular motion would be of the form \( r = R (1 - \epsilon \cos \theta) \), where \( \epsilon \) is proportional to the square of the angular motion, supposed to be impressed to the pole from the equator along any meridian, the angular velocity would continually increase, at a rate which was greatest in the middle latitudes. This is exactly what the observations show. Now if the sun's state be supposed established in a frictionless fluid, the consideration of internal friction would simply extend the characteristics found at any spot to the neighbourhood, and therefore if the boundary were a sphere and so for a frictionless fluid an exception, it would cease to be an exception when we allow for viscosity. But this theory gives no clue to the results relating to hydrogen, which belongs to a high level, and which Adams has shown to move with an angular velocity decidedly greater than the equatorial angular velocity, and so to show no sign of falling off towards the poles.

It is useful to form a conception of the mechanical state within the sun's body. Its temperature must be dominated directly or indirectly by the surface radiation, and since the mechanical matter is gaseous and so open to redistribution, the state in the outer parts is true of density and pressure. It is true that within the body radiations must be stifled within a short distance of their source; none the less, they will determine a temperature gradient, falling from the centre to the borders, though for the most part falling very slowly, and we may ask what relative temperatures in different parts would maintain themselves if once established. Stefan's law of radiation according to the fourth power of the temperature is too difficult to pursue, but if we are content with cognate results we can follow them out mathematically in a hypothetical law of the first power. We then find that the density would increase as we go outwards, at first slowly, but finally with extreme rapidity, the last tenth of the radii comprising half the mass. The reason for such a density, if the body was practically nil, no matter how hot the centre was. Of course such a state would be statically unstable. It would never get established because currents would arise to exchange the positions of the hotter, less dense, inner parts and the cooler, more dense, outer ones. By this interchange the inner parts would be opened out and the total radiation raised. Since the only cause for these convection currents is the stational instability produced by radiation, and the rapid stifling of radiations within the body produces there a temperature gradient falling very slowly, they would be for the most part extremely slight. Only near the surface would they become violent, and only there would there be a rapid fall of temperature and density. Through the main body these would remain nearly constant. Indeed it seems that, in the final distribution of density throughout the part which is not subject to violent convection currents, it must increase slightly from the centre outwards, since the currents would cease altogether as soon as a uniform state was restored. In the outer strata a different state must prevail. Rapidly falling temperature must (and visibly does) produce furious motions which wholly outrun mere restoration of statical balance. Portions change places suddenly and so continually, that we may take it, where any average is reached, the energy is so distributed that there is neither gain nor loss when such a change occurs. This is the law of convective equilibrium. But in the sun's atmosphere gravitation alone is a misleading guide. Convective equilibrium, which depends upon it, gives far too steep a temperature gradient, for it yields a temperature of 6000° only 200 m. within the free surface, whereas the chromosphere is of an average thickness of 5000 m., and attains that temperature only at its base. Probably the factor which thus diminishes the effective

ENLarged Photographs of the Solar Surface. Taken by M. A. Hansky at the Observatory of Pulkowa (1905, June 25), at intervals from 25s. to 80s.
PHOTOGRAPHS OF THE SUN, TAKEN AT THE ROYAL OBSERVATORY, GREENWICH.

The pressure of radiation.

The radiations from the sun must be considered in two parts, corresponding respectively to the continuous spectrum and the line spectrum. The latter is considered below; it is indicative of the chemical elements from which the lines can proceed, and its state at the time of emission; the former is indicative only of the rate of loss of energy from the sun by radiation. The result of many and remarkable experiments in physical theory and experiment, known as the theory of the black body, or as black radiation. The “black body” is an ideal body with surface so constructed as to reflect no part of any radiations that fall upon it; in the case of such a body Kirchhoff and Balfour Stewart showed that unless energy were to be lost the rate of emission and absorption must be in fixed ratio for each specific wave-length.

The name has no reference to the appearance of the body to the eye; when emitting energy, its radiation will be of all wave-lengths, and if intense enough will appeal to the eye as luminous between about wave-lengths 7600 and 4000 tenth-metres; this intensity is a question of temperature, and as it is exquisitely inappropriate to speak of the bulk of the solar radiation as black, the term will speak instead of amorphous radiations from an ideal radiator. The ideal radiator is realized within any closed cavity, the walls of which are maintained at a definite temperature. The space filled with radiations corresponds to the radiating temperature, and these attain a certain equilibrium which permits the energy of radiation to be spoken of as a whole, as a scalar quantity, without express reference to the propagation or interference of the waves of which it is composed. It is then found both by experiment and by thermo-dynamic theory that in these amorphous radiations there is for each temperature a definite distribution of the energy over the spectrum according to a law very exactly represented by the equation in wave-lengths, length, and as to the form of the function ϕ, Planck has shown (Sitzungsber. Berlin Akad. S. 441) that an intelligible theory can be given which leads to the form 

\[ \phi(\nu) = c_1 \exp(c_2/\nu) - 1, \]

a form which agrees in a satisfactory way with all the experiments. Fig. 11 shows the resulting distribution of energy. The enclosed area for each temperature represents the total emission of energy for that temperature, the abscissae are the wave-lengths, and the ordinates the corresponding intensities of emission for that wave-length. It will be seen that the maximum ordinates lie upon the curve \( \lambda = \text{constant} \) dotted in the figure, and so, as the measure of the temperature of the radiator, the wave-length of most intense radiation shifts from the infra-red toward the continuous spectrum. When we speak of the sun’s radiation as a whole, it is assumed that it is of the character of the radiations from an ideal radiator at an appropriate temperature.

The first adequate determination of the character as well as amount of solar radiation was made by S. P. Langley in 1893 at Mount Whitney in California (4,000 ft.), with the bolometer, an exceedingly sensitive instrument which he invented, and which enabled him to feel his way thermally over the whole spectrum, noting all the chief Fraunhofer lines and bands, which were shown by sharp serrations, or more prolonged depressions of the curve which gave the emissions, and discovering the lines and bands of the invisible ultra-red portion. The bolograph thus obtained must be cleared of the absorption of the earth’s atmosphere, and that of the transmitting apparatus—a spectroscope and siderostat. The first in itself requires an elaborate study. The first essential is an elevated observatory; the next is a long series of bolographs taken at different times of the year and of the day, to examine the effect of interposing different thicknesses of air and its variation in transparency (chiefly due to water vapour). It is found that atmospheric absorption is generally larger in summer than in winter, a difference of 20% being found between March and August; morning hours show a rapid and often irregular increase of transparency, culminating shortly after noon, after which the diminution is slow and comparatively regular.

The resulting allowances and conclusion are illustrated in fig. 12, taken from an article by Langley in the Astrophysical Journal (1903), xvii. 2. The integrated emission of energy is given by the area of the (asterism) square, or, in other words, if one bolograph is that the “solar constant” is 2.54 calories. The meaning of this statement is that, away from the earth’s atmosphere, which wastes about one-half what is received, a square

---

(From Astrophysical Journal, xvii, by permission of the University of Chicago Press.)

**Fig. 12.**

centimetre, exposed perpendicularly to the sun’s rays, would receive sufficient energy per minute to raise 2.54 grams of water 1°C. C. Langley’s general determination of the constant was greater than this—3.0 to 3.5 calories; more recently C. G. Abbot at Mount Wilson, with instruments and methods in which Langley’s experience has been translated into greatly, having proved that one of Langley’s corrections was erroneously applied. The results vary between 1.89 and 2.22, and the variation appears to be solar, not terrestrial. The temperature of the sun’s surface, the rate of receiving energy at the rate of 1.47 kilowatts per square metre, or 1:70 horse-power per square yard. The corresponding intensity at the sun’s surface is 3.46×10^6 as great, or 6.79×10^6 kilowatts per square metre, or 600 horse-power per square yard! Enough to melt a thickness of 13.5 metres (=39 ft.) of ice, or to vaporize 1.81 metres (=5.92 ft.) of water per minute.

If we assume that the bolograph of solar energy is simply a graph of amorphous radiation from an ideal radiator, exactly as though it be, the constants of Planck’s formula determined terrestrially to apply to it, the hyperbola of maximum intensity is \( I = 2.941\times10^9 \), and as the sun’s maximum intensity occurs for about \( \lambda = 4000 \), we find the absolute temperature to be 5900° abs. If we calculate from the total energy emitted, and not from the position of maximum intensity, the same result is obtained within a few degrees. By way of temperature of the sun’s surface, is a convention, which sets aside some material factors. We may ask first whether the matter of which the surface is composed is such as to give an ideal radiator; it is impossible to answer this, for terrestrial experience is admitted to admit a departure from terrestrial exception, the estimated temperature is diminished only some 10%. A second question relates to the boundaries. The theory refers to radiation homogeneous at all points within a single closed boundary, maintained at uniform temperature; in the actual case we have a double boundary, one the sun’s surface, and the other infinitely remote, or, say, non-existent, and at zero temperature; not terrestrial. But the radiation of the sun at 2.5 microns is therefore inversely as the squares of the distance from the sun. Though there is no experiment behind this assumption it can hardly lead to error.

The question is more difficult. The temperature gradient at the confines of the photosphere must certainly ascend sharply at first. When we say the sun’s temperature is 6000°, of what level are we speaking? The fact is that radiation is not a superficial phenomenon. The solar spectrum is not a uniform glow, but a mosaic, so to speak, of a great many different phenomena. The temperature of the photosphere is so high that it is uncertain how it is maintained. The solar atmosphere is continually circulating, and it is not certain that the solar spectrum is not a more or less diffuse atmosphere. The help of theory and observation the part played by this atmosphere is tolerably precise. Its absorptive effects upon the radiations of the inner photosphere can be readily traced progressively from the centre to the rim of the sun’s disk, and it has been measured as a whole by Langley, W. E. Wilson and others, and for each separate wave-length by F. W. Very (Astrophys. Journ., vol. xvii). The entries in the table on following page express the reduction of intensity for different wave-lengths \( \lambda \), when the slit is set at a horizontal radius from the centre of the disk.

Building upon these results A. Schuster has shown (Astrophys. Journ., vol. xvi) that, if for the sake of argument the solar atmosphere be taken as homogeneous in temperature and quality, forming a sheet which itself radiates as a whole, the radiation of an unshielded ideal radiator at 6000° would give is represented well, both in sum and in the distribution of intensity with respect to wave-length, by another ideal radiator—now the actual body of
The energy which the sun pours out into space is, so far as we know, and except for the minute fraction intercepted by the disks of the planets, absolutely lost for the purposes of further mechanical effect. The amount is such that, supposing the average specific heat of the sun's body as high as that of iron, a general temperature of 2ø to 2.5ø C. In the lapse of empty 200 years ago, the sun's heat would have been greater than now by the factor 2ø to 3ø. The calculations of the solar temperature. It seems possible that n is not a large number, and if we take \( x \) equal, say, to 200, we come to the most recent estimate—the astronomical—of the date of the earth's glacial epoch, when the sun's radiation was certainly very much more intense than it is now, while this factor would differ materially from unity. Hence loss does not go on without regeneration, and we are apparently at a stage when there is an approximate balance between them. It is in fact an impossibility that loss should go on without regeneration, for if any part of the sun's body loses heat, it will be unable to support the pressure of neighbouring parts upon it; it will therefore be compressed, in a general sense towards the sun's centre, the velocities of its molecules will rise, and its temperature will again tend upwards. In consequence of the radiation of heat the whole body will be more condensed than before, but whether it is hotter or colder than before is not determined by the present method. The temperature is less than enough to restore an exact balance. If we are dealing with comparatively recent periods there is no evidence of progressive change, but if we go to remote epochs and suppose the sun to have once been diffused in a nebulous state, it is clear that its shrinkage, in spite of radiation, has left it hotter, so that the shrinkage has outrun what would suffice to maintain its radiation. It is equally clear that there is a point beyond which contraction cannot go, and, thereafter, if not before, the body will begin to grow colder. There is thus a turning-point in the life of every star. The movement towards a lower temperature will be offset by radiation until the process of radiation sets up, like other motions, overruns the contraction point, only however by a minute amount; the accumulated excesses from all past time now stored in the sun would maintain its radiation at its present rate for 2\( x \)3000 years, that is, for a few thousand years only.

There is a superior limit to the quantity of energy which can be derived from contraction. If we suppose the sun's mass once existed in a state of extreme diffusion, the energy yielded by collecting it into its present compact would not suffice to maintain its present rate of radiation for more than 17,000,000 years in the past; nor if its mean density were ultimately raised to eight times its present amount, for more than the same period in the future. This supposes the present density nearly uniform; if it is not uniform, any amount added to the former period is subtracted from the latter. A contraction of 0.5 or 0.6 of the sun's radius would maintain the present emission for 3500 years. Such a rate of change would be quite insensible, and we can affirm that for recent times there is no reason to look for any other factor than contraction; but for remote periods we cannot pass a strict judgment, for we have nothing quantitatively of the radiations from a nebulous body; and it is quite possible that the loss of radiant energy in this early stage was very small; but it is at least certain that in any previous inference that 17,000,000 years ago the earth itself was of its present dimensions, a comparatively old body with sea and living creatures upon it, and it is impossible to believe that the sun's radiations were wholly different; and if, but, if not, the same radiations have been maintained from some other source than contraction.

The fall of meteoric matter into the sun must be a certain source of energy; if considerable, this external supply would retard the sun's contraction and so increase the radiated amount. To bring about a reconciliation with geological theory, very nearly the whole amount must be thus supplied. It is easy to calculate that this would require a body 6000 miles in diameter to fall in on the line of density 2, over its whole surface in the course of the year. So far there is nothing impossible in the theory. But there are two fatal objections. The sun is a small target for a meteoric cloud of the probable size of Jupiter, and for an infinity of time before it reached its mark, a much greater amount would circulate round the sun in parabolas, and there is no evidence of it where it would often strike itself. But as the objects are out of the question, because no combinations of different elements are known to exist at a temperature 600ø.

A second objection is that it fails in its purpose, because 20,000,000 years ago it would give a sun quite as much changed as the contraction theory gave. If we examine chemical sources for maintenance of the temperature, complications are introduced, but the question is out of the question, because no combinations of different elements are known to exist at a total temperature of 600ø.

A source which seems plausible, perhaps the easiest to test, is the infrared energy of the structure of the elements' atomic rotation. It is no longer figured as indivisible, it is made up of more or less complex, and more or less permanent, systems in internal circulation. Now under the law of attraction according to the inverse square of the distance, or any other inverse power beyond the first, the energy of even a single pair of material points is unlimited, if their possible closeness of approach to one another is unlimited. If the energy of the sun were to change, it would change on the same principles, and no phenomena of radio-activity leave doubt about this, there is here an incalculable source of heat which takes the cogency out of any other objection. The sun's radiation. An equivalent statement of the same conclusion may be put thus: supposing a gaseous nebula is destined to condense into a sun, the elementary matter of which it is composed will develop in the course of time enough known terrestrial and solar elements, partaking with energy as it does so.

The continuous spectrum leads to no inference, except that of the temperature of the central globe; but the multitude of dark lines which it is crossed reveal the elements in the sun, in the truly gaseous clots which enclose it. A table of these lines is a physical document as exact as it is blank. The visual portion extends from 3700 to 7200 tenth-metres; the ultra-violet begins about 2970, beyond which point our atmosphere is almost perfectly opaque to it; the infra-red can be traced for more than ten times the visual length, but the temperature which indicates it is reduced to below 9870. The ultra-violet and the visual portions are recorded photographically; Rowland's classical work shows some 5700 lines in the former, and 14,200 in the latter, on a graduated scale of intensities from 1000 to 0, or 0000, for the faintest lines; between a quarter and a third of these lines have been identified, fully 2000 belonging to iron, and several hundred to water vapour and other atmospheric absorption. The infra-red requires special appliances; it has been examined visually by the help of phosphorescent plates (Beccquerel), and with special photographic plates (Abney); but the most efficient way is to use the bolometer or pyrometer; by this means some 500 or 600 lines have been mapped.

The first problem of the spectrum is to identify the effects of atmospheric absorption, especially oxygen, carbonic acid and water vapour; this is done by comparing the line of the sun at great and small zenith-distances, or by reducing the atmospheric effect by observing from a great elevation, as did P. J. T. C. Tanan from the summit of Mont Blanc, but the only unquestionable test is to find those lines which are not touched by Doppler effect when the reeding and advancing limbs of the sun are compared (Coru); by this method H. F. Newall has verified the presence of cyanogen in the photosphere, and it had previously served to disprove the solar origin of certain oxygen lines. In fact, doubt long surrounded the presence of oxygen in the sun, and was not set at rest until K. D. T. Rune and P. C. Pechers in 1896 identified an unmistakable oxygen triplet in the infra-red region of the spectrum, essentially in the vacuum tube, where the spectrum is very different from that of atmospheric absorptions. The absence of lines of oxygen in the spectrum of any element from the solar spectrum is no proof that the element is absent from the sun; apart from the possibility that the high temperature and other circumstances may show it transformed into some unknown mode, which is perhaps the explanation of the absence of nickel, the element of high atomic weight which we should expect it to be found only in the lowest strata of the sun's atmosphere, where its temperature is high enough to equalize it to the ground glass, and so an absorption line which it showed would be weak. This is particularly the case with lead and silver, and probably with mercury also. In Rowland's table lines from the arc-spectra of the following are identified. The order in which the lines are given is that of the arc-spectra, the lines of identified elements. Excepting strontium, those which are low upon the list are represented also by lines of small intensity. The chromosphere adds the three last of the list. The strongest lines, nickel, in the order named.
The spectrum taken near the limb of the sun shows increased general absorption, and also definite peculiarities of great interest in connexion with the spectra of the spots, which it will be convenient to describe first.

When the slit of the spectroscope is set across a spot, it shows, as may be expected, a general reduction of brightness as we pass from the photosphere to the umbra; and a still greater one as we pass to the umbral. This is not a uniform shade over the whole length of the spectrum, but shows changes in bands or flutings of greater or less darkness, which in places and at intervals have been resolved by Young, Dunér and other unques-
tionable observers into hosts of dark lines. Besides this the spectrum shows very many differences from the mean spectrum of the disk, the interpretation of which is at present far from clear. Generally speaking, the same absorption lines are present, but with altitudes of great heights, different from those of the disk; some of lines of certain elements are always seen fainter or thinner than on the photosphere, or even wholly obliterated; others sometimes show the same features, but not always; other lines of the same elements, perhaps not present at all in the disk, are now to be observed. Some of these differences in element of course are visible when the spot is absent, and sometimes such a bright line will correspond to a dark line on the photosphere; most generally the lines are intensified, general absorption is increased, and the individual lines strengthened, sometimes in both together, sometimes in one at the expense of the other; certain lines not seen in the photosphere show only across the umbra, others everywhere and of varying intensity. When the spectroscope was first introduced, it has been found G. E. Hale and W. S. Adams make its direction downward; but round the rim and on bridges the characteristic distortions due to the prominences are often observed. There appears to be some connection between prominences and the forms, prominences are sometimes found above the spots, and W. M. Mitchell records an eruptive prominence followed next day in the same place by the appearance of a small spot. It does not appear that the spectral lines follow in any way the sun-spot cycle. The radiation from a spot changes little as it approaches the sun’s limb; in fact Hale and Adams find that the absorption from the limb itself differs from that of the disk. The effect of the disk is an additional one that from a spot, the same lines being strengthened or weakened in exactly the same way, though in much less degree, with, however, one material exception: if a line is winged in the photosphere the wings are much less in the spot; and as the spot fills up the wings may be entirely obliterated. If the spot is separated from that of the chromosphere it appears that the lines of most frequent occurrence in the latter are those least affected in the spot, and the high level chromospheric lines not at all; the natural interpretation is that the spot is below the chromosphere. As to whether the spots are regions of higher or lower temperature than the photosphere, the best qualified judges are reserved or discouraged, but recent evidence seems to point very definitely to a lower temperature. Hale and Adams have shown that the spectrum contains, besides a strong line spectrum of titanium, a faint banded spectrum which is that of titanium oxide, and the at the same time it is clear that this line has been identified by A. L. Fowler as manganese hydride. The band spectrum, which corresponds to the compound or combination of the two elements, certainly belongs to a lower temperature than the line spectrum of titanium. These vapours of temperature low enough to give the banded spectra of this refractory metal, while only line spectra of sodium, iron and other elements at some moderate temperatures are found (see also Spectrohelioiaphy).

The chromosphere, which surrounds the photosphere, is a cloak of gases of an average depth of 5000 m., in a state of luminescence less intense than that of the photosphere. From the chromosphere the photosphere is viewed through it an absorption spectrum is shown, but when it is viewed separately a bright line spectrum appears. Most of the metallic vapours that produce absorption lines when added to the photosphere. The spectrum was made except during eclipses, when a flash spectrum of bright lines shines out for, say, five seconds after the continuous spectrum has disappeared, and again before it reappears (see Eclipse). F. W. Dyson has measured some eight hundreds lines in the lower chromosphere and identified them with emission spectra of the following elements: hydrogen, helium, carbon, with the cyanogen band, sodium, magnesium, aluminium, silicon, calcium, scandium, titanium, vanadium, chromium, manganese, iron, zinc, strontium, yttrium, cerium, lutecium, erbium, ytterbium, lead, europium, besides a few doubtful identifications; it is a curious fact that the agreement is with the spark spectra of these elements, while the photosphere shows exclusively or more definitely the arcs lines which were associated with greater temperature. In the higher chromosphere the following were recognized: helium and parahelium, hydrogen, strontium, calcium, indium, aluminium, magnesium, barium, yttrium.

In the higher chromosphere on occasions metallic gases are carried up to such a level that without an eclipse a bright line spectrum of many elements may be seen, but it is always possible to see those originating near the photosphere. The great extent of these lines makes it so as to weaken still further the continuous spectrum from the photosphere (now a mere reflection) the actual forms of the gaseous elements are revealed plainly in these bands. In the visual spectrum there are four hydrogen lines and one helium line in which the actual shapes may be examined. The features seen differ according to the line used, as the circumstances prevailing at different levels of the chromosphere call for one line with greater intensity. The helium formations do not reach the sun’s limb, and it is another puzzling detail that the spectrum of the disk shows no absorption line of anything like an intensity to correspond with the emission line of helium in the chromosphere. The prominences are of two kinds, quiescent and eruptive. Some of the former are to be seen at the limb on most occasions; they may hang for days or weeks in small groups; those which are left to the observer to classify are perhaps 20,000 m., and show the spectral lines of hydrogen and helium. Sometimes they float above the surface, sometimes they are connected with it by stems or branches, and they show delicate thin but continuous lines. The bright areas, generally focused in circular spots, are sometimes at the surface, sometimes, when they descend, in the form of elongated columns some 100 m. high. M. Mitchell watched one rise in 250 m. a second to the height of 70,000 m., and in five minutes after it had faded away and the region was quiet. This is remarkable for the velocity, as 70,000 m. in 250 m. represents 280,000 m. per second, a figure about six times the velocity of sound. These records which are not common, and are the only ones which are known, are the only ones which are known, must be examined scrupulously. We have seen above numerous applications of the Doppler effect. Two other causes of displacement—call for mention in their bear on the solar spectrum—pressure and anomalous dispersion. The pressure which produces a continuous spectrum in gases at a temperature of 6000° must be very great. Recent experiments on arc spectra at pressures up to 100 atmospheres by W. J. Humphreys and by W. H. Duffield show several suggestive peculiarities, though their bearing on solar phenomena is not yet determined. The lines are broadened (as was already known), the general intensity is much weaker. They are weakened and some strengthened, nor is the amount of broadening the same for all lines, nor is it always symmetrical, being sometimes greater on the red side; but besides the effect of pressure, it is probable that different lines with different differences again behave differently, and they may be arranged somewhat roughly in a few groups according to their behaviour; reversals are also effected, and correspond with the most intense part of the emission line. For example, in the iron three groups about wave-length 4500 are found by Duffield to be displaced respectively 0-17, 0-34, 0-17 tenth-metres, at 100 atmospheres. This shift, towards the red J. Larmor suggests is due to relaxation of the spring of the surrounding ether by the crowding of the molecules; a shift of 0-17 tenth-metres would, if interpreted by Doppler’s principle, have been caused by a relative motion of 250,000 m. per second. It is possible that these results may give a simple key to some puzzling anomalies, and on the other hand, they may throw a measure of uncertainty over absolute determination. The line-of-sight anomalons of anomalous dispersion are varied and interesting, and have recently had much attention given to them. W. H. Julius holds that this sole fact holds of 0-60 of the intensity is the intensity of some other line, including prominences, spots, faculae and fociuli, and even the eleven-year period. Though few follow him so far, an explanation of the principle will make it clear that there are numerous cases in which this is the case. Not all lines are removed from the spectrum. Theoretically anomalous dispersion is inseparable from absorption. When a system vibrating in a free period of its own encounters, say through the medium of an enveloping cloud, another system of vibrations, it is evident that two vibrations at right angles, the amplitude of the second vibration, the amplitude of the second vibration is incomparable, except when the periods approach equality. In such a case the two systems must be regarded as a single more complex one, and the absorbed becomes large, though remaining always finite, and the transmitted undergoes a remarkable change in
Apart then from absorption there will be a discontinuous change in brightness in the apparent disk at that value of the angular radius $d$ which corresponds to tangential emission from the upper limb of the sun. It is of course obvious that it is not possible to say whether such a region is an actuality in the sun, on the earth it is an exception and transient, but the greater the dimensions of the body the more probable is its occurrence. The theory can be applied to test certain facts cast by the moon, and to explain its different tints and colour. The greater $\mu$ is, the greater would be the value of $d$, the apparent angular radius, corresponding to horizontal emission from the upper limb, or such a region as the moon might reveal in its appearance.

Hence if the sun's diameter were measured through differently coloured screens, the violet disk must appear greater than the red. Now measures made by Auwers with the Cape heliometer showed the sun's diameter, at distance 1.8, to vary, and so it is possible that the rays reach us after issuing from a level where $\mu$ is sensibly different from unity. Presumably, then, the inner emissions are absorbed and those which reach us start from very remote parts of the sun's surface. The Sun's Distance.

The Sun's Diameter.

The Sun's Diameter.

The Sun's Diameter.
heterogeneous, and that in places where it would hardly be expected. The result is nearly the same as found at Greenwich alone, 8:806° ± 0·0026°, or a mean distance of 92,830,000 m. = 1·493X10¹⁴ cm. with an error of about 1:3 cm.

The greater distance enters into other relations, three of which permit of its determination, viz. the equation of light, the constant of aberration, and the parallactic inequality of the moon; the value of the parallax is found in the manner indicated the relations of the two first, but as this is better known than the sun's parallax, no disadvantage results. The equation of light is the time taken by light to traverse the sun's mean distance; it is found by the observed retardation or advancement of the eclipses of Jupiter's satellites according as Jupiter is approaching opposition or conjunction with a sun; a recent analysis shows that its value is 496-6", which lead to an equation of light of 9927-0", which, according to E. W. Brown's lunar theory would imply a parallax 8:778°.

The best discussion of the sun's apparent diameter has been made by G. F. J. Auwers, in connexion with his reduction of Stephenson's observations, and the result is 30·260" ± 0·004", which, according to Brown's lunar theory would imply a parallax 8:787°.

The Sun's Dimensions. 1874 and 1882. It was found that personality played an important part; the average effect might be 1", but frequently it reached 3", 4", 5", and even 6", with or without inconsistency, nor was any fixed for the same observer. Some 15,000 observations, from 1851 to 1883, taken by one hundred observers at Greenwich, Washington, Oxford and Neuchâtel, cleared up the question of persistence, and it was shown that could with probability be called progressive or periodic, particularly there was no sign of adhesion to the sun-spot period. Better determinations of the actual value came from the heliometer, and the mean of the observations of 1874 and 1875 of the solar diameter exceeded the equatorial by 0·038" ± 0·023".

The conclusion is that the photosphere is very sharply defined and shows no definite departure from a truly spherical shape. Using the observations of 1880, the resulting diameter of the sun is 664,000 m. = 1·390X10¹⁴ cm.

If we regard the sun as one of the stars, the first four questions we should seek to answer are its distance from its neighbours, proper motion, magnitude and spectral type. In some respects the systematic prosecution of these inquiries has only begun, and properly considered they involve vast resources of observation which will be of great value for the whole class of problems. It is not too far to treat them at any length, but it may be convenient to summarize some of the results. The sun's nearest neighbour is a Centauri, which is separated from it by 270,000 times the earth's distance from the sun. The sun would be within a year's journey of it. It is fairly certain that not more than six stars lie within twice this distance. No certain guide has been found to tell which stars are nearest to us; both brightness and large proper motion are indications of nearness, but proximity, are apparently without systematic average relation to parallax.

The sun's proper motion among the stars has been sought in the past as the assumption that the universe of stars showed as a whole no definite displacement of its parts, and, on this assumption, different methods of reduction which attributed apparent relative displacement of parts to real relative displacement of the sun agreed fairly well in concluding that the apex of the sun's way was directed to a point in right ascension 275°, declination +3° (F. W. Dyson and W. G. Thackeray), that is to say, not far from the star Vega in the constellation Lyra, and was moving thither at a rate of two and a half years. But recent observations by J. C. J. Adams and A. S. Eddington, confirmed by Dyson, show that there is better ground for believing that the universe is composed mainly of two streams of stars, one moving in the direction of Vega and the other in the opposite direction. Vet they are the motions of the same sense and magnitude on the average, than that the relative motions of the stars with one another are fortuitous (see STAR). This removes completely the ground upon which the discussion of the sun's Proper Motion has hitherto been calculated, and leaves the question wholly without an answer.

A star is said to rise one unit in magnitude when the logarithm of its brightness diminishes by 0·4. Taking as a star of magnitude 1 the star whose light is exactly one unit of the brightness of the sun, several estimates have been made which agree well together; whether direct use is made of known parallaxes, or comparison is made with the brightness of the sun, the result is the same. The brightness of the sun, therefore it may be assumed there is the same relation between magnitude and brilliancy (Gore), the result is found that the sun's magnitude is -26·5, or the sun is 10⁴ times as brilliant as a first magnitude star; it would follow that the sun viewed from a Centauri would appear as of magnitude 0·7, and from a star of average distance which has a parallax certainly less than 0·1", it would be at least fainter than the fifth magnitude, or, say, upon the boundary of the range of naked-eye visibility with increased prominence. These are the white stars, and the most prominent examples are Sirius, Vega and Procyon. It is commonly though not universally held that the difference between the white and yellow stars arises from their stages of development and that the former represent the earlier stage. This again is disputed, and there is indeed as yet slight material for a decisive statement.

Summary of Numerical Data.

Parallax: 8·806° ± 0·003° (Time taken by light to traverse this distance: 496-6β) 
Linear, 109X6 earth's equatorial diameter = 664,000 meters. 
Mass: 332,000 X mass of the earth. 
Mean density: 286X6 mean density of earth = 1.415. 
Equator: Inclination to ecliptic: 7° 15'. 
Longitude: at maximum opposition (1860-8), 7° 28'. 
Rotation period: latitude 0°: 24-64β. 
60°: 26-43β. 
90°: 29-56β. 
Solar constant, or units of energy received per minute per square centimetre at earth's mean distance: 2:1 calories. 
Effective temperature, as an ideal radiator or "black body": 6000° abs.

Bibliography. Nearly all the chief data respecting the sun have lately been and are still under active revision, so that publications have tended to fall rapidly out of date. The most important series is in the Astrophysical Journal, which is indispensable, and in itself almost sufficient; among other matter it contains all the publications of Mount Wilson Solar Observatory (Professor G. E. Hale), H. A. Rowland's Tables of Wave-Lengths, many theoretical papers, and some reproductions of important papers issued elsewhere. But there are also papers which cannot be disregarded in Monthly Notices and Memoirs of the Royal Astronomical Society, and in Astronomische Nachrichten. C. P. Langley's Researches on Solar Heat are published by the War Department (Signal Service, xv.) (Washington, 1884), and Gill's parallax researches in Cape Annals, vols. vii. Auwer's discussion of the sun's diameter is in the discussion of the transit of Venus in 1874, and the best single volume upon the whole subject is C. A. Young's The Sun, 2nd ed. (Inter. Sci. Series), and an excellent summary of solar spectroscopy, as far as rapid progress permits, is in Fresh's translation of Scheiner's Astronomical Spectroscopy (1894). Fresh's translation of 'Studien u. Versuche der Sonnenphysik' (1899), contains a great quantity of interesting matter carefully collected and discussed. For authoritative declarations upon the latest moon points the Transactions of the International Union for Solar Research (1880) may be consulted, vol. i, and the last two issues of the Annals des Ponts et Chaussées are published in 1906, and vol. ii. in 1908.

SUN-BIRD, a name more or less in use for many years, and now generally accepted as that of a group of over 100 species of small birds, but when or by whom it was first applied is uncertain. Those known to the older naturalists were for a long while referred to the genus Certita (TREE-CREEPER, g.v.) or some other group, but they are now fully recognized as forming a valid Passerine family Nectarinidae, from the name Nectarinia invented in 1881 by Illiger. They inhabit the Ethiopian, Indian, and Australian regions, and, with some notable exceptions, the species of the family Nectarinae are by range and habitat a little advanced, and a few are the most restricted in range of the whole group, and is perhaps curious that of the Indian region, but the fact of its being found there may be a reason for including that country within the region, just as the presence of another species in the Jordan valley induces zoographers to regard the Ghor as an outlying of the Ethiopian region. 1

1 Certainly since 1826 (cf. Stephens, Gen. Zoology, vol. xiv, pt. i, p. 292). W. Swinson (Nat. Hist. and Classif. Birds, i, 145) says they are "so called by the natives of Asia in allusion to their splendid and shining plumage," but gives no hint as to the nation or language from which the name is derived. A more remote derivation may be found in the Madagascan name of one given in 1858 by Flacourt as Seunanga. These specimens of the genus Nectarinia, which is perhaps outside of the Indian region, but the fact of its being found there may be a reason for including that country within the region, just as the presence of another species in the Jordan valley induces zoographers to regard the Ghor as an outlying of the Ethiopian region.
but their relations to the last require further investigation. Some of them are called “humming-birds” by Anglo-Indians and colonists, and with that group, which, as before indicated (see HUMMING-BIRD), belongs to the Picaricæ, the sun-birds, being true Passeres, have nothing to do. Though part of the plumage in many sun-birds gleams with metallic lustre, they owe much of their beauty to feathers which are not lustrous, though almost as vivid, and the most wonderful combination of the brightest colours—scarlet, purple, blue, green and yellow—is often seen in one and the same bird. One group, however, is dull in hue, and but for the presence in some of its members of yellow or flame-coloured precostal tufts, which are very characteristic of the family, might at first sight be thought not to belong to heron. Graceful in form and active in motion, sun-birds flit from flower to flower, feeding on small insects which are attracted by the nectar and on the nectar itself; but this is usually done while perched and rarely on the wing as is the habit of humming-birds. The extensible tongue, though practically serving the same end in both groups, is essentially different in its quasi-tubular structure, and there is also considerable difference between this organ in the Nectarineæ and the Meliphagæa. The nests of the sun-birds, domed with a penthouse porch, and pensile from the end of a bough or leaf, are very neatly built. The eggs are generally three in number, of a dull white covered with confluent specks of greenish grey.

The Nectarineæ form the subject of a sumptuous Monograph by G. E. Shelley (40, London, 1870—1880), in the coloured plates of which, where it is done to the varied duties which these gloriously arrayed little beings display, while almost every available source of information has been consulted and the results embodied. This author divides the family into three sub-families: Nectarineæ, consisting of a single genus and species peculiar to Madagascar; Nectarineæ, containing o genera, one of which, Cinnyris, has more than half the number of species in the whole group; and Anrochyeriæ (sometimes known as “spider-busters”), with 2 genera including 11 species—all large in size and plain in hue. To these he also adds the genus Promeropæ, composed of 2 species of South African birds, of very different appearance, whose affinity to the rest can as yet hardly be taken as proved. According to E. L. Layard, the habits of the Cape Promeropæ, its mode of nidification, and the character of its eggs are very unlike those of the ordinary Nectarineæ. In the British Museum Catalogue of Birds (ix., 1—126 and 291) H. J. Gadaw has more recently treated of this family, reducing the number of both genera and species, though adding a new genus discovered since the publication of Shelley’s work.

**SUN-BITTERN, the Eurypyga helias of ornithology, a bird that has long exercised systematists and one whose proper place can scarcely yet be said to have been determined to everybody’s satisfaction.**

According to Pallas, who in 1781 gave (N. nordl. Beyträde, vol. ii., pp. 48—54, pl. 3) a good description and fair figure of it, calling it the "Surnamische Sonnenvögel," Ardea helias, the first author to notice this form was Fermor, whose account of it, under the name of "Sonnenvogel," was published at Amsterdam in 1759 (Deser. Oe. de Sarinam, i. 192), but was vague and meagre. In 1772, however, Pallas satisfactorily figured and described it in his Observations sur la physique, Sci. (vol. v, pt. 1, p. 212, pl. 1), as the Petit paon des roseaux—by which name it was known in French Guiana. A few years later D’ Aubenton figured it in his well-known series (Pl. End., p. 782), and then in 1781 came Buffon (H.L.N., Oiseaux, vol. viii., pp. 169, 170, pl. xiv.), who, calling it “Le Caurâlé ou petit paon des roses,” announced it as hitherto undescribed and placed it among the Rallidiæ. In the same year appeared the above-cited paper by Pallas, who, notwithstanding his name above, was better informed as to its presence than his great contemporary, whose ignorance, real or affected, of his fellow-countryman’s province in the field is inexplicable; and it must have been by inadvertence that, writing “roses”

2 Ibid. (1883), pp. 62—69, pl. xvi.
3 According to M. J. Brisson (Ornithologie, ii. 400), this name was the invention of Réaumur. It seems to have become Anglicized.
4 This figure and description were repeated in the later, issue of this work in 1777 (vol. i. pp. 679—781, pl. 1).

**SUN-BITTERN** for “roseaux,” Buffon turned the colonial name from one that had a good meaning into nonsense. In 1783 Boddaert, equally ignorant of what Pallas had done, called it Scopolas solasærius, and in referring to it that genus he was followed by Latham (Synopsis, iii. 156), by Illiger (Ann. Nat. Hist., 3d ser. ii. 415), and by Illiger (Zool. Syst., 1784, p. 254), who introduced to English readers the ““Cautrale Snipe.” Thus within a dozen years this bird was referred to three perfectly distinct genera, and in those days genera meant much more than

**FIG. 1.**—Sun-Bittern (Eurypyga helias).

they do now. Not until 1811 was it recognized as forming a genus of its own. This was done by Illiger, whose appellation, Eurypyga has been generally accepted.

The sun-bittern is about as big as a small curlew, but with much shorter legs and a rather slender, straight bill. The wings are moderate, broad, and rounded, the tail rather long and pointed. The head is almost bare. The bill is fierce, but blackish, and the cere and legs are yellow. It has the habit of perching upon a branch, or a stick, and another under each eye, the chin and throat being also white. The rest of the plumage is not to be described in a limited space otherwise than generally, being variegated with black, brown, chestnut, bay, buff, grey and white—so mottled, speckled and belted either in wave-like or zigzag forms as somewhat to resemble certain moths. The bay colour forms two conspicuous patches on each wing, and also an antepenultimate bar on the tail, behind which is a subterminal band of black. The irides are red; the bill is greenish olive; and the legs are pale yellow. As in the case of most South American birds, very little is recorded of its habits in freedom, except that it frequents the muddy and wooded banks of rivers, feeding on small fishes and insects. In captivity it soon becomes tame, and has several times made its nest and reared its young (which, when hatched, are clothed with mottled down; Proc. Zool. Soc., 1866, p. 76, pl. ix. fig. 1) in the Zoological Gardens (London), where examples are generally to be seen and their plaintive piping heard. It ordinarily walks with slow and precise steps, keeping its body in a horizontal position, but at times, when excited, it will go through a series of fantastic performances, spreading its broad wings and tail so as to display their beautiful markings. This species inhabits Guiana and the interior of Brazil; but in Colombia and Central America occurs a larger and somewhat differently coloured form which is known as E. major.

For a long while it seemed as if Eurypyga had no near ally, but on the colonization of New Caledonia by the French, an extremely curious bird was found inhabiting most parts of that island, to which it is peculiar. This the natives called the Kagu, and it is the Rhinolophus jutatus of ornithology. Its original describers, MM. Jules Verreaux and Des Murs, regarded it first as a heron and then as a crane (Rev. et Mag. de Zoologie, 1860, pp. 439—441, pl. 21; 1862, pp. 142—144); but, on Mr George Bennett sending two live examples to the Zoological Gardens, Mr Bartlett quickly detected in them an affinity to Eurypyga (Proc. Zool. Soc., 1862, pp. 218, 219, pl. xx.), and in due time the naturalist’s investigation showed him to be right. The kagu, however, would not strike the ordinary observer as having much outward resemblance to the sun-bittern, of which it has neither the figure nor posture. It is rather a long-legged bird, about as large as an ordinary fowl, walking quickly
and then standing almost motionless, with bright red bill and legs, large eyes, a full pendent crest, and is generally of a light slate-colour, paler beneath, and obscurely barred on its longer wing-coverings and tail with a darker shade. It is only when it spreads its wings that these are seen to be marked and spotted with white, rust-colour, and black, somewhat after the pattern of those of the sun-bittern. Like that bird, too, the kagu will, in moments of excitement, give up its ordinary placid behaviour and execute a variety of violent gestures, some of them even of a more extraordinary kind, for it will dance round, holding the tip of its tail or one of its wings in a way that no other bird is known to do. Its habits in its own country were described at some length in 1863 by M. Jounin (Mém. Soc. Nat. Cherbourg, ix. 97 and 235), and in 1870 by M. Marie (Asters Soc. Linn. Bordeaux, xxvii. 323-326), the last of whom predicts the speedy extinction of this interesting form, a fate foreboded also by the statement of Messrs Layard (Ibis, 1882, pp. 534, 535) that it has nearly disappeared from the neighbourhood of the more settled and inhabited parts.

The internal and external structure of both these remarkable forms is now fully known and it appears that they, though separable as distinct families, Eurypterygidae and Rhinocetidae, must be deemed the relics of very ancient and generalized types more or less related to the Railidae (see Rail), and Pelecanidae (see Trumpeter). It is only to be remarked that the eggs of both Eurypteryx and Rhinocetes have a very strong rattle appearance—stronger even than the figures published (Proc. Zool. Soc., 1868, pl. 12) would indicate.

(A. N.)

SUNBURY, a borough and the county seat of Northumberland county, Pennsylvania, U.S.A., on the Susquehanna river about 53 m. by rail N. by E. of Harrisburg. Pop. (1900), 6810, of whom 197 were foreign-born; (1910 U.S. census) 13,770. It is served by the Pennsylvania, the Northern Central (controlled by the Pennsylvania) and the Philadelphia & Reading railways. Sunbury's principal industry is the manufacture of silk; the Pennsylvania railway has repair shops here. The total value of the borough's factory products increased from $1,868,157 in 1900 to $2,502,829 in 1905, or 38.8%. The borough stands on the site of the old Indian village, Shamokin, which was occupied by Delawares, Senecas and Tutelos, and was long the most prominent Indian village in the province; in 1747-1755 there was a Moravian mission here. Owing to the strategic importance of the place the provincial government erected Fort Augusta here in 1756; during the War of Independence many of the fugitives from the Wyoming Massacre tamed this fort. Sunbury was first surveyed in 1772 and was incorporated as a borough in 1797.

SUNBURY-ON-THEM, an urban district in the Uxbridge parliamentary division of Middlesex, England, 17 m. S.W. of St. Paul's Cathedral, London, on a branch of the London & South Western railway. Pop. (1901), 4544. It is a favourite riverside resort and has grown considerably as a residential district. The church of St Mary, Byzantine in style, dates from 1752. There are pumping works and filtration beds for the water-supply of London. To the north-east is Kempston Park, the manor-house of which was a royal residence early in the 14th century. The park is famed for its race-meetings, the principal fixture being the Jubilee Handicap, established in 1887. The manor was granted by Edward the Confessor to Westminster Abbey, and passed in the 13th century to the see of London and in the 16th to the Crown; but was not so held later than 1603.

SUN COPYING, or Photo COPYING, the name given to that branch of photographic contact printing which is carried out without the aid of a camera-made negative. It is now used very extensively for copying documents, especially the plans of architects and engineers.

The earliest discovered process, the ferroprussiate, is still the one most largely used, on account of its economy and permanence, combined with a simplicity of manipulation that renders it highly suitable for office use; it was invented in 1840 by Sir John Herschel. This method has the disadvantage that the copies are blue in colour, and, as it is a negative process, the black lines of the original become the white lines of the print; the development is by washing in water, so that the important feature of accuracy of scale is lost. The next step of importance was in 1864, when William Willis of Birmingham, the father of the inventor of the platinotype system of photographic printing, invented the aniline process. In this method a paper sensitized with bichromate of potassium is exposed to light, with the document (generally a tracing) in front of it; the unprotected lines are bleached out, but the protected ones remain and are developed by contact with vapour of aniline, a subsequent washing for the removal of chemicals completing the print. For twenty years this process was successfully used with little opposition other than that of the blue prints previously referred to, and of the Pellet process, which gave a blue line on a white ground, the inventor being associated throughout with the firm of Vincent Brooks, Day & Son; but since that time a large number of other methods have come into use, some requiring a paper negative in the first instance and some not, but all much aided by improved methods of applying electric light. The earliest of these improved systems utilizing electric light was that invented by Mr B. J. Hall, whose photo-copier consists of two semi-circular glasses forming a cylinder, which may be revolved, and through which an arc lamp travels, while the tracing and sensitized paper are strapped to its outer surface.

Between 1900 and 1908 attention was chiefly directed to overcoming the variation of scale that is inevitable in all systems that require a final washing in water either for development or for the removal of chemicals; and at least four excellent systems have arisen. While Mr F. R. Vandyke was perfecting the system which he patented in 1901 and which has been adopted by the Ordnance Survey Department at Southampton, Messrs Vincent Brooks, Day & Son were working along somewhat similar lines, the outcome of which was their "True-to-Scale Photo Litho" system. In both these methods a reversed positive print is secured on zinc, from which copies can be made in printer's ink of any colour by the usual lithographic method on almost any material that may be desired. The plates prepared by these methods are so sensitive to light that excellent results can be secured from drawings made even on semi-transparent material such as drawing paper, and of course the plates when made are capable of alteration or addition and can be stored for reprints.

An admirable process had since been invented by M.M. Dorel Freres of Paris, which is even more expedient, and boards in private cost is more suitable when only a small number of prints is required. In this case a large sheet of thin zinc is coated with chemically-treated gelatin, with the result that when a ferroprussiate print is pressed down on it either with the hand or by a roller the protected lines affect the gelatin in such a way that the parts that have been in contact with them receive a greasy ink while the remainder of the surface rejects it, so that a small number (not generally exceeding six) of very excellent prints can be secured. The inventors refrained from taking out a patent either in France or elsewhere, preferring to
work their invention as a secret process, but the formula appears either to have leaked out or to have been discovered, so that the process is, perhaps with slight variations, used under numerous names. With the aid of the various systems of rotary copiers, by which blue prints of almost any length can be secured, Dorel prints identical in scale with the originals have been made of the length of 22 ft. An interesting kindred process but with well defined variations is photographic lithography. For the technical and chemical details of the various methods reference may be made to Ferric and Heliographic Processes by G. E. Brown (Dawbarn & Ward).

(F. V. B.)

SUNDA ISLANDS, the collective name of the islands in the Malay Archipelago which extend from the Malay Peninsula to the Moluccas. They are divided into the Great Sunda Islands—i.e. Sumatra, Java, Borneo, Celebes, Banka and Billiton, with their adjacent islands—and the Little Sunda Islands, of which the most important are Bali, Lombok, Sumbawa, Flores, Sumba and Timor.

Sunda Strait is the channel separating Sumatra from Java and uniting the Indian Ocean with the Java Sea. It is 15 m. broad between the south-eastern extremity of Sumatra and the town of Anjer in Java. In the middle is the low-lying well-wooded island of Dwars-in-den-Weg ("right in the way"), otherwise Middle Island or Sungarian. In 1883 Sunda Strait was the scene of the most terrific results of the eruption of Krakatoa (g.v.), a volcanic island further west in the strait.

There are a few small islands and a great waste country in Bengal, India, forming the seaward fringe of the Gangetic delta. It has never been surveyed, nor has the census been extended to it. It stretches for about 165 m., from the mouth of the Hugli to the mouth of the Meghna, and is bordered inland by the three settled districts of the Twenty-four Parganas, Khulna and Backergunj. The total area (including water) is estimated at 63,26 sq. m. It is a water-logged jungle, in which tigers and other wild beasts abound. Attempts at reclamation have not been very successful. The future importance of the delta is not altogether removed. The characteristic tree is the sundari (Heritiera littoralis), from which the name of the tract has probably been derived. It yields a hard wood, used for building, and for making boats, furniture, &c. The Sundarbans are everywhere intersected by river channels and creeks, some of which afford water communication between Calcutta and the Brahmaputra valley, both for steamers and for native boats.

SUNDAY, or the LORD’S DAY (η τοῦ Ἑσυχία ἡμέρα, dies solis; ἡ κυριακή ἡμέρα, dies dominica, dies dominicus), in the Christian world, the first day of the week, celebrated in memory of the resurrection of Christ, as the principal day for public worship. An additional reason for the sanctity of the day may have been found in its association with Pentecost or Whit’sun. There is no evidence that in the earliest years of Christianity there was any formal observance of Sunday as a day of rest or any general cessation of work. But it seems to have from the first been set apart for worship. Thus according to Acts xx. 7, the disciples in Troas met weekly on the first day of the week for exhortation and the breaking of bread; i Cor. xvi. 2 implies an earlier habit of meeting together. The solemn commemorative character it had very early acquired is strikingly indicated by an incidental expression of the writer of the Apocalypse (i. 10), who for the first time gives it that name ("the Lord’s Day") by which it is almost invariably referred to by all writers of the century immediately succeeding apostolic times. Indications of the manner of its observance during this period are not wanting. Teaching of the Apostles (c. 14).

1 The Teutonic and Scandinavian nations adopt the former designation (Sunday, Sundag, Søndag, &c.), the Latin nations the latter (dimanche, domenica, domingo, &c.).
2 From an expression in the Epistle of Barnabas (c. 15), it would almost seem as if the Ascension also was believed by some to have taken place on a Sunday.
3 In the Epistle of Barnabas already referred to (c. 15) it is called “the eighth day”; “We keep the eighth day with joyfulness, the day also in which Jesus rose again from the dead.” Cf. Justin Martyr, Dial. c. Tryph. c. 138.

contains the precept: “And on the Lord’s day of the Lord (κυριακή κυριακῆ κυριου) come together and break bread and give thanks after confessing your transgressions, that your sacrifice may be pure.” Ignatius (Ad Magn. c. 9) speaks of those who he addresses as “no longer Sabatizing, but living in the observance of the Lord’s day both in work and in prayer, which also our life springing up again.” Eusebius (H. E. iv. 23) mentions that they wrote a letter of Dionysius of Corinth (A.D. 175) to Soter, bishop of Rome, in which he says: “To-day we have passed the Lord’s holy day, in which we have read your epistle”; and the same historian (H. E. iv. 26) mentions that Melito of Sardis (A.D. 170) had written a treatise on the Lord’s day. Pliny’s letter to Trajan in which he speaks of the meetings of the Christians “on a stated day” need only be alluded to. The first writer who mentions the name of Sunday as applicable to the Lord’s day is Justin Martyr; this designation (v. 20; cf. i. 59, v. 16) is to have come into general use in the Roman world shortly before Justin wrote. He describes (Apol. i. 67) how “on the day called Sunday” town and country Christians alike gathered together in one place for instruction and prayer and charitable offerings and the distribution of bread and wine; they thus meet together on that day, he says, because it is the first day in which God made the world, and because Jesus Christ on the same day rose from the dead.

As long as the Jewish Christian element continued to have an influence in the Church, a tendency to observe Sabbath as well as Sunday naturally persisted. Eusebius (H. E. iii. 27) mentions that the Ebionites continued to keep both days, and that there is abundant evidence from Tertullian onwards that so far as public worship and abstention from fasting are concerned the practice was widely spread among the Gentile churches. Thus we learn from Socrates (H. E. vi. c. 8) that in his time public worship was held in the churches of Constantineople on both days; the Apostolic Canons (can. 66 [65]) sternly prohibit fasting on Sunday or Saturday (except Holy Saturday), and the most important of the synods held by the early Church define a Sunday (v. 20; cf. ii. 59, xii. 21) as “to hold your solemn assemblies and rejoice every Sabbath day (excepting one), and every Lord’s day.” Thus the earliest observance of the day was confined to congregational worship, either in the early morning or late evening. The social condition of the early Christians naturally forbade any general suspension of work. Ireneaus (c. 140—202) is the first of the early fathers to refer to a tendency to make Sunday a day of rest in his mention that harvesting was forbidden by the Church on the Sabbath. Tertullian, writing in 202, says: “On the Lord’s day we ought always from all labor to lift up our hands, putting away even our business.” But the whole matter was placed on a new footing when the civil power, by the constitution of Constantine mentioned below, began to legislate as to the Sunday rest. The fourth commandment, holding as it does a conspicuous place in the decalogue, the precepts of which could not for the most part be regarded as of merely transitory obligation, and never of course escaped the attention of the fathers of the Church; but, remembering the liberty given in the Pauline writings “In respect of a feast day or a new moon or a Sabbath” (Col. ii. 16), they had determined to make the “Sabbath day” of the commandment as meaning the new era that had been introduced by the advent of Christ, and interpreted the rest enjoined as meaning cessation from sin. But when a series of imperial decrees had enjoined with increasing stringency an abstinence from labour on Sunday, it was inevitable that the Christian conscience should be roused on the subject of the Sabbath rest also, and in many minds the tendency would be such as finds expression in the Apostolic Constitutions (viii. 33): “Let the slaves work five days; but on the Sabbath day and the Lord’s day let them have their leisure.” The longer recension runs: “But let every one of you keep the Sabbath after a spiritual manner. And after the observance of the Sabbath let every friend of Christ keep the Lord’s day as a festival, the resurrection day, the queen and chief of all the days.” The writer finds a reference to the Lord’s day in the titles to Ps. vi. and xii., which are “set to the eighth.”
SUNDAY

leisure to go to church for instruction in piety." There is evidence of the same tendency in the opposite canon (29) of the council of Laodicea (363), which forbids Christians from Judaism and resting on the Sabbath day, and actually enjoins them to work on that day, preferring the Lord's day and so far as possible resting as Christians. About this time accordingly we find traces of a disposition in Christian thinkers to distinguish between a temporary and a permanent element in the Sabbath day precept; thus Chrysostom (10th homily on Genesis) discerns the fundamental principle of that precept to be that we should dedicate one whole day in the circle of the week and set it apart for exercise in spiritual things. The view that the Christian Lord's day or Sunday is but the Christian Sabbath transferred from the seventh to the first day of the week does not find categorical expression till a much later period, Alcuin being apparently the first to allege of the Jewish Sabbath that "ejus observationem mos Christianus ad diem dominican competentius transitullt" (cf. Decalogue).

**Law Relating to Sunday**

The earliest recognition of the observance of Sunday as a legal duty is a constitution of Constantine in 321 A.D., enacting that all courts of justice, inhabitants of towns, and workshops were to be at rest on Sunday (venerabilis die solis), with an exception in favour of those engaged in agricultural labour. This was the first of a long series of imperial constitutions, most of which are incorporated in the Code of Justinian, bk. iii. tit. 12 (De ferioriis). The constitutions comprised in this title of the code begin with that of Constantine, and thereafter provide that emancipation and manumission were the only legal proceedings permissible on the Lord's day (die dominico), though contracts and compromises might be made between the parties where no intervention of the court was necessary. Pleasure was forbidden as well as business. No spectacle was to be exhibited in a theatre or circus. If the emperor's birthday fell on a Sunday, its celebration was to be postponed. The seven days before and after Easter were to be kept as Sundays. In Cod. i. 4, 9, appears the regulation that prisoners were to be brought up for examination and interrogation on Sunday. On the other hand, Cod. iii. 12, 10, distinctly directs the torture of robbers and pirates, even on Easter Sunday, the divine pardon (says the law) being hoped for where the safety of society was thus assured. After the time of Justinian the observance of Sunday appears to have become stricter. In the West, Charlemagne forbade labour of any kind. A century later in the Eastern Empire No. liv, of the Leone constitutions abolished the exemption of agricultural labour contained in the constitution of Constantine; but this exemption was specially preserved in England by a constitution of Archbishop Mepham. The canon law followed the lines of Roman law. The decrees of ecclesiastical councils on the subject have been numerous. Much of the law is contained in the Decretals of Gregory, bk. ii. tit. 9 (De ferioriis), c. 1 of which (translated) runs thus: "We decree that all Sundays be observed from vespers to vespers (a vespera ad vesperam), and that all unlawful work be abstained from, so that in them trading or legal proceedings be not carried on, or any one condemned to death or punishment, or any oaths be administered, except for peace or other necessary reason." Works of necessity (especially in the case of perishable materials or where time was due important, as in fishing) were allowed, on condition that a due proportion of the gain made by work so done was given to the church and the poor. The consent of parties was insufficient to give jurisdiction to a court of law to proceed on Sunday, though it was sufficient in the case of a day sanctified by the ecclesiastical authority for a temporary purpose, e.g. a thanksgiving for vintage or harvest.

In England legislation on the subject began early and continues down to the most modern times. As early as the 7th century the laws of Ina, king of the West Saxons, provided that, if a "thowment" worked on Sunday by his lord's command, he was to be free and the lord to be fined 30s.; if a freeman worked without his lord's command, the penalty was forfeiture of freedom or a fine of 60s., and twice as much in the case of a priest. The laws of Æthelstan forbade marking, of Æthelred folkmoots and hunting, on the Sunday. In almost all the pre-Conquest compilations there are admonitions to keep the day holy. The first allusion to Sunday in statute law proper is in 1354 (25 Edw. III. c. 14 rep.), forbidding the sale of wool at the staple on Sunday. The mass of legislation from that date downwards may be arranged in the case of the question, probably, into five classes—ecclesiastical, constitutional, judicial, social and commercial. The terms "Sunday" and "Lord's day" are used in the statutes, but the term "Sabbath" occurs only in ordinances of the Long Parliament. "Sabbath-breaking" is sometimes used to describe a violation of the Sunday observance acts, but is objected to by Blackstone as legally incorrect. Good Friday and Christmas Day are as a rule in the same legal position as Sunday. In English law Sunday is reckoned from midnight to midnight, not as in canon law a vespera ad vesperam. The acts to be mentioned are still law unless the contrary is stated.

**Ecclesiastical.**—Before the Reformation there appears to be little or no statutory recognition of Sunday, except as a day on which trade was interdicted or national sports directed to be held. Thus the repealed acts of 1388 (12 Ric. II. c. 6) and 1409 (11 Hen. IV. c. 4) enjoined the practice of archery on Sunday. The church itself by provincial constitutions and other means declared the sanctity of the day, and was strong enough to visit with its own censures those who failed to observe Sunday. At the Reformation it was thought necessary to enforce the observance of Sunday by the state in face of the question, properly, whether the time as to the divine or merely human institution of the day as a holy day. Sunday observance was directed by injunctions as well as by statutes of Edward VI. and Elizabeth. The second Act of Uniformity of 1551 (5 & 6 Edw. IV. c. 1) enacted that all inhabitants of the realm were to endeavour themselves to resort to their parish church or chapel accustomed, or upon reasonable let thereof to some usual place where common prayer is used every Sunday, upon pain of punishment by the censures of the church. The same principle was re-enacted by the Act of Uniformity of 1558 (1 Eliz. c. 2), with the addition of a temporal punishment, viz. a fine of twelve pence for each offence. This section of the act is, however, no longer law, and it appears that the only penalty now incurred by non-attendance at church is the shadowy one of ecclesiastical censure. Protestant dissenters, Jews and Roman Catholics were in 1846 (q & 10, Vict. c. 59) exempted from the act, and the pecuniary penalties were abrogated as to all persons; but the acts as to Sundays and holy days are still binding on members of the Church of England [Marshall v. Graham, 1907, 2 K.B. 112].

An act of 1551 (5 & 6 Edw. VI. c. 3) directed the keeping of all Sundays as holy days, with an exception in favour of husbandmen, labourers, fishers and other persons in harvest or other time of necessity. Canon 13 of the canons of 1603 provides that "all manner of persons within the Church of England shall celebrate and keep the Lord's day, commonly called Sunday, according to God's holy will and pleasure and the orders of the Church of England prescribed in that behalf, that is, in hearing the word of God read and taught, in private and public prayers, in acknowledging their offences to God and amendment of the same, in reconciling themself to God and to all their neighbours, in holy works, and in oftentimes receiving the communion of the body and blood of Christ, in visiting the poor and sick, using all godly and sober conversation." The Long Parliament, by an ordinance of 1644, directed the Lord's day to be celebrated as holy, as being the Christian Sabbath. Ordinances of 1650, c. 9, and 1656, c. 15, contained various minute descriptions of crimes against the sanctity of the Lord's day, including "theherein as well as in the walking, The". These ordinances lapsed with the Restoration. The Act of Uniformity of 1661 (13 & 14 Car. II. c. 4) enforced the reading on every Lord's day of the morning and evening prayer according to the Book of Common Prayer on duty. This was previously enjoined by canon 14 of 1603. By the Church Building Act 1818, the bishop may direct a third service, morning or evening, in any church, where necessity, in his opinion, may require it (s. 65). By the Church Building Act 1838, he may order the performance of two full services, each if he so direct to include a sermon (s. 8). The Burial Laws Amendment Act 1880, which authorizes burials in churchyards of the Church of England without the use of the funeral
office of that church, does not allow such burials to take place on Sunday, Good Friday or Christmas Day if the parson of the church objects. Under the Metropolitan Police and Streets Acts, the Town Police Clauses Act 1847 and the Public Health Acts, street traffic may be regulated during the hours of divine service.

Constitutional.—Parliament has occasionally sat on Sunday in cases of great emergency, as on the demise of the Crown. Occasionally divisions in the House of Commons have taken place early on Sunday morning. The Ballot Act 1872 enacts that in reckoning time for election proceedings Sundays are to be excluded. A similar provision is contained in the Municipal Corporations Act 1882, as to proceedings under that act.

A general rule Sunday for the purpose of judicial proceedings is a dies non juridicus on which courts of justice do not sit (9 Car. & 10 Vict., c. 70, s. 6). By s. 6 of the Sunday Observance Act 1867 legal process cannot be served or executed on Sunday, except in cases of treason, felony or breach of the peace. Proceedings which do not need the intervention of the court are good, e.g. service of a citation or notice to quit or claim to vote. By s. 4 of the Indictable Offences Act 1848 justice may issue a warrant of apprehension or a search warrant on Sunday. The rules of the Supreme Court provide that the offices of the Supreme Court are not open on Sunday, and that no business is admissible to be reckoned in the computation of any limited time less than six days allowed for doing any act or taking any proceeding, and that, where the time for doing any act or taking any proceeding expires on Sunday, such act or proceeding is good if done or taken on the next day. In the divorce rules Sundays are excluded from compilation. In the county court rules they are excluded if the time limited is less than forty-eight hours, and the only county court process which can be executed on Sunday is a warrant of arrest in an Admiralty act.

Social.—Under this head may be grouped the enactments having for their object the regulation of Sunday travelling and amusements. The earliest example of non-ecclesiastical interference with recreation appears to be the Book of Sports issued by James I. in 1618. The Act impliedly allows sports other than the expected ones as long as only parishioners take part in them. In 1807 some lads were prosecuted at Streatham under this act for playing football in an adjoining parish, but the justices dismissed the charge, treating the act as obsolete. But in 1862 the Society for the Prevention of Cruelty to Animals instituted a prosecution under the act with the object of preventing extra-parochial rabbit-coursing on Sundays. The Game Act 1831 (1 & 2 Will. IV. c. 32, s. 2) makes it punishable to kill or take game, or to use a dog, net or other instrument (e.g. a snare), for that purpose on Sunday. The prohibition only applies to game proper and does not extend to rabbits.

There is no law in England against fishing on Sunday except as to salmon. Fishing for salmon on Sunday by means other than a rod and line is prohibited by the salmon Fishery Act 1861, and free passage for salmon through all cribs, &c., used for fishery is to be left during the whole of Sunday.

The Sunday Observance Act 1751 (21 Geo. III. c. 49), drawn by Dr Porteus, bishop of London, enacts that any place opened or used for public entertainment and amusement or for public debate upon any part of the Lord's day called Sunday, to which persons are admitted by payment of money or by tickets sold for money, is to be deemed a disorderly house. The keeper is to forfeit £200 for every day on which it is opened or used as aforesaid on the Lord's day, the manager or master of the ceremonies £100 and every doorkeeper or servant £50. The advertising or publishing any advertisement of such an entertainment is made subject to a penalty of £50. Proceedings under this act for penalties may be instituted by a common informer within six months of the offence. It was held in 1868 that a meeting the object of which was not pecuniary gain (though there was fee for admission), but an honest intention to introduce religious worship, though not according to any established or usual form, was not within the act. The hall used was registered for religious worship. On this principle, forms of worship such as Mormonism or Mahommedanism are protected. In 1875 actions were brought against the Brighton Aquarium Company and penalties recovered under the act. As doubts were felt as to the power of the Crown to remit the penalties in such a case, an act was passed in 1875 to remove such doubts and to enable the Crown to remit in whole or in part penalties recoverable for offences against the act of 1875.

The substantive effect of the act is to hit all Sunday exhibitions of amusements, and the decision as to where money is charged for admission. In 1875 it was decided that the chairman of a meeting held to hear a lecture was not liable as manager of the meeting, and the solicitor of the act did not come within the meaning of a company. A ruling that the hall for the meeting. In 1906 an attempt was unsuccessfully made to apply the act of 1871 to open-air meetings for rabbit-coursing. The rules for the government of theatres and places of public amusement (within the meaning of the Act of 1875) usually prohibit performances on Sundays. The lessees of certain places of public resort in London have in some cases obtained their licences from the London County Council on condition that they do not hold Sunday concerts, but the recent policy of the Council has been not to interfere with or restrict the giving of Sunday concerts unless they are given for private gain or by way of trade. The Council has no legal authority to dispense with the Sunday Observance Act 1867, which enforces penalties on giving entertainments to which persons are admitted by payment of money or by tickets sold for money. The law has been judicially interpreted, however, to mean that charges for reserved seats are not incompatible with free admission. In consequence of this ruling Sunday concerts have been regularly given at the Albert Hall, which is not under the licensing jurisdiction of the London County Council, and at the Queen's Hall and other theatres in London. The Act of 1875 also makes it a penal offence to sell any article for the purpose of enabling a person to enter a place kept for the purpose of entertainment on Sunday. In the case of the towns of Croydon and West Bromwich, the local authorities have decided that this subject between the advocates and opponents of Sunday music.

Bands play on Sundays in most of the parks in London, whether royal or under municipal control; and it is said that local authorities do not object to bands playing. In Sydney, bands are prohibited by law (e.g. the Sydney Municipal Act 1886, 6 Q.B.D. 708). Libraries, museums and gymnasiaums maintained by local authorities may, it would seem, be lawfully opened on Sundays, and the national galleries and museums are now so open for part of Sunday.

Commercial.—At common law a contract made on Sunday is not void, nor is Sunday trading or labour unlawful, and enlistment of a soldier on a Sunday has been held valid. At an early period, however, the legislature began to impose restrictions, at first by making Sunday trade impossible by closing the places of ordinary business, later by declaring certain kinds of trade and labour illegal, still later by attempting to prohibit all trade and labour. 28 Edw. III. c. 14 (1354, now repealed) closed the wool market on Sunday. An act of 1448 (27 Hen. VI. c. 5) prohibits fairs and markets on Sunday (necessary victual only excepted), unless on the four Sundays in harvest, and execution (repealed in 1837). An act of 1842 (4 Edw. IV. c. 7 (164) repeals the provision of March 26, 1716, remaining the shoemakers of London from carrying on their business on Sunday. An act of 1627 (3 Car. I. c. 7) imposes a penalty of 20s. on any carrier, wagoner or drover travelling on the Lord's day, and a penalty of 6s. 8d. on any butcher killing or selling on that day. The act does not apply to stage coaches. Both this and the act of 1625 were originally passed only for a limited period, but by subsequent legislation they have become perpetual. Next in order is the Sunday Observance Act 1677 (29 Car. II. c. 7), "An act for
Ward, 2 Will. the for few districts he Sunday The day which in exercising dwelling were ordinary markets to forceable in (but pain exposed offending exercise labourer dead dressing work of ordinary clauses Sunday). The day; 1907, St. Geo. the day, 1762. bread of hawkers for hawkers 13 22, 1836. Certain in 1.30 dressing land, 1761, Lords & Westminster, Act 34. 1871, the workshops, the day, 1877, or & to 109). The act of 1871 does not apply 1.22. A good many bills have been introduced with respect to Sunday trading. Most have been directed to the closing of public houses on that day; but the Shop Hours Bill introduced in 1907 contained clauses for closing shops on Sundays, with the exception of certain specified trades. The result of the act of 1871 in London has been in substance to make the Lord’s Day act a dead letter as to Sunday trading. The commissioner of police rarely if ever allows a prosecution for Sunday trading. Sunday markets are usual in all the poorer districts, and shopkeepers and hawkers are allowed freely to ply their trades for the sale of eatables, temperance drinks and tobacco. But the conditions

It is curious that by an order in council of Hen. VI. to regulate the sanctity of St Martin-le-Granth it was provided that all artificers dwelling within the said sanctuary (as well bakers as others) keep holy the Sundays and other great festival days without breach or exercising their craft as do the citizens of London (Gomme, Government of London, 1907, p. 329).

SUNDAY

of licences for the sale of intoxicants and for refreshment houses are strictly confined with respect to Sunday. In districts where the town councils have control of the police, prosecutions for Sunday trading are not infrequent; but they seem to be instituted rather from objection to the annoyance caused by street traders from religious scruples. The limitation of the time for prosecution to ten days, and the necessity of the previous consent of the chief constable, have a great effect in restricting prosecutions. In most districts there is a distinct disposition to refrain from enforcing the strict letter of the older law, and to permit the latitude of what is described as the "Continental Sunday," except in the case of businesses carried on to interfere with the public comfort. In most districts libelarity in administration has progressed pari passu with a change in public opinion as to the uses to which Sunday may properly be put; it is becoming less of a holy day and more of a holiday.

There is great activity among those interested in different theories as to the proper use of Sundays. On the one side, Lord’s day observance societies and the organizations concerned in the promotion of "temperance" (i.e. of abstinence from alcoholic drinks) have been extremely anxious to enforce the existing law against Sunday trading and against the sale of intoxicants. Lord’s day societies have endeavored to obtain legislation against the sale of any alcohol on Sundays. On the other side, the Sunday League and other like organizations have been active to organize lectures and concerts and excursions on Sundays, and to promote so far as possible every variety of recreation other than attendance at the exercises of any religious body. Travelling and boating on Sunday are now freely resorted to, regardless of any restrictions in the old acts, and railway companies run their trains at all hours, the power to run them being given by their special acts. Tramcars and omnibuses run freely on Sundays, subject only to the restrictions, if any, which may in London ply for hire on Sundays (1 & 2 Will. IV. c. 22).

Besides the general act of 1677, there are various acts dealing with special trades; of these the Licensing Acts and the Factory and Workshop Acts are the most important. By the Licensing Acts, 1872 and 1874, premises licensed for the sale of intoxicating liquors by retail are to be open on Sunday only at certain hours, varying according as the premises are situate in the metropolitan district, a town or populous place, or elsewhere. The hours may be varied to suit the premises. For the purposes of a person dealing in the liquor trade who is interested in the premises, the Act of 1877 is described as "the most extraordinary Act ever passed by the House of Commons and has frequently received judicial construction. The use of the word "ordinary" in section 1 has led to the establishment by a series of decisions of the principle that the word denotes the ordinary calling of the person doing it is not in the act. The therefore of a Sunday on a horse-dealer would not be enforceable by him and he would be liable to the penalty, but these restrictions are not applicable to a person dealing in fish. Certain acts have been held to fall within the exception as to works of necessity and charity, e.g., baking provisions for customers (but not baking bread in the ordinary course of business), running stage-coaches, or hiring farm-labourers. The legislature has also inter- vened to obviate some of the inconveniences caused by the act. By 10 Will. III. c. 13 (1698) mackerel was allowed to be sold before and after service. By 11 Will. III. c. 16 (1699), forty watermen were ruled "to be at liberty to trade on Thanes day" (July 1701), licensed coachmen or chairmen might be hired on Sunday. By an act of 1794 (34 Geo. III. c. 61), bakers were allowed to bake and sell bread on Saturdays, but all remaining provisions of the law are the acts of 1762 (2 Geo. III. c. 15 s. 7), allowing fish carriages to travel on Sunday in London and Westminster; 1827 (8 Geo. IV. c. 75), repealing s. 2 of the act of 1677 as far as regards Thanes boroughs, and 1835 (9 & 10 Will. IV. c. 37) allow bakers out of London, and of 1836 & 8 (Will. IV. c. 37) allow bakers out of London, to carry on their trade up to 1.30 p.m. Since 1871, by an act annually continued (34 & 35 Vict. c. 87), no prosecution or proceeding for penalties under the act of 1877 can be instituted except with the consent in writing of the chief officer of a police district or the consent of the two justices or a stipendiary magistrate, which must be obtained before beginning the prosecution, i.e., the applying for a summons (Thorpe v. Priestnall, 1897, 1, Q.B. 159). The act of 1871 does not apply to breaches of the Bread Acts (R. v. Mead, 1903, 2 K.B. 212).

A good many bills have been introduced with respect to Sunday trading. Most have been directed to the closing of public houses on that day; but the Shop Hours Bill introduced in 1907 contained clauses for closing shops on Sundays, with the exception of certain specified trades. The result of the act of 1871 in London has been in substance to make the Lord’s Day act a dead letter as to Sunday trading. The commissioner of police rarely if ever allows a prosecution for Sunday trading. Sunday markets are usual in all the poorer districts, and shopkeepers and hawkers are allowed freely to ply their trades for the sale of eatables, temperance drinks and tobacco. But the conditions

1 The act 1 James I. c. 9 (now repealed) appears, however, to have provided for closing ale-houses in most cases, except in usual working days.
the subject. That of 1457, c. 6, ordered the practice of archery on Sunday; that of 1526, c. 3, allowed markets for the sale of flesh to be held on Sunday at Edinburgh. Then came a long series of acts forbidding the profanation of the day, especially by salmon-fishing, holding fairs and markets, and working in mills and salt-panes. The act of 1577, c. 70, and 1661, c. 18, prohibited handy labouring and working, and trading on the Sab-
bath. Under the act of 1579 the House of Lords in 1837 held that it was illegal for barbers to shave their customers on Sun-
days, although the deprivation of a shave might prevent decently disposed men from attending religious worship, or associating in a becoming manner with their families and friends through want of personal cleanliness. The later legislation introduced an exception in favour of duties of necessity and mercy, in accordance with ch. 21 of the Confession of Faith (1666, c. 5).

In more modern times the exigencies of travelling have led to a still further extension of the exception. In these acts the word Sabbath is generally used as in the Commonwealth ordinances. The Sabbath Observance Acts were frequently confirmed, the last time by the Scots parliament in 1697. The Scottish Episcopalian Act 1711 (4 Ann. 10) contains a proviso that all the laws made for the frequenting of divine service on the Lord's day commonly called Sunday shall be still in force and executed against all persons who shall be found to come to some assembly or public assembly of religious worship allowed and permitted by this act. The Scots acts were held by the High Court of Justiciary in 1870 to be still subsisting, as far as they declare the keeping open shop on Sundays an offence by the law of Scotland (Baring v. Maxwell, 1 Cooper's Reports, 499), but all except those of 1759 and 1661 above specified were repealed in 1866. The Licensing (Scotland) Act 1903 provides by the scheduled forms of certificate for the closing on Sunday of public-houses, and proclaims licensed for the sale of excisable liquor, and in the case of inns and hotels forbids the sale of intoxicants except for the accommodation of lodgers or travellers. There has been litigation as to the legality of running tram-cars on the Sabbath.

By the Herring Fishery (Scotland) Act 1815, s. 11, herring nets set or hauled on the coast or within two leagues thereon on Sundays are forfeited. By the Salmon Fisheries (Scotland) Act 1868, s. 15, fishing for salmon on Sunday, even where the river is out of season and line, is an offence, as is taking or attempting to take or assisting in fishing for salmon. As to contracts and legal process, the law is in general accordance with that of England.

Sundays. The acts are not void, apart from statute, simply because they are made on Sunday. Diligence cannot be executed but a warrant of imprisonment or meditatio fugae is “exercisable.”

Ireland.—In Ireland an act of 1695 (2 Will. III. c. 17) covers the same ground as the English act of 1677, but the acts referred to under England do not apply. An act of 1851 (14 & 15 V. c. 93, s. 11) provides for the issue and execution of warrants for indictable offences and search-warrants on Sundays. But proceedings for the peace taken on Sunday are void. The Irish act of 1787 against killing game on Sunday (27 Geo. III. c. 35, s. 4) includes rabbits and quail, landrail or other wild fowl. The Sunday closing of public-houses with exemptions as to certain cities and as to railway stations, packet-boats and canals, is enforced by legislation of 1787, continued annually until 1866 and then made perpetual with certain modifications (1886, c. 39, s. 1), and in the case of six-day licences by acts of 1876, 1877 and 1880.

In 1893 a race-course used for Sunday racing was closed by interdict. The nuisance to the Sunday peace and quiet of the neighbourhood and the services of the adjacent churches. Where railway trains are run on Sundays one cheap train each way is to be provided (7 & 8 Vict. c. 85, s. 10; repealed in 1883 as to Great Britain).

British Colonies.—The English law as to Sunday observance was the original law of the colonies acquired by settlement, and in many of them so much of it as does not relate to the Church of England is left to operate without colonial legislation. In other colonies it is supplemented or superseded by colonial acts of their own. In New Zealand the towns and cities, and selling and all exercise by a man of his ordinary vocations or business, either by himself or his employees on the Lord's day, except in cases of works of necessity or mercy. In New Zealand an act of 1884 (c. 24, s. 16; amended 1906, c. 36) prohibits the carrying on Sunday of any trade or calling, but the exceptions are numerous, and, besides works of necessity or charity, include driving live stock, sale of medicines, sale or delivery of milk, hairdressing or shaving before 9 a.m., driving public or private carriages, keeping livery stables, working railways, ships and boats, and letting boats for hire, and work in connection with post offices and telegraph offices and with daily newspapers.

Foreign Countries.—Consequent on the introduction of a Weekly Rest Day Bill (which obtained a second reading) in the English House of Lords in 1908, a parliamentary paper was published in 1909 (cd. 4568) containing “Reports from His Majesty's Representatives Abroad as to Legislation in Foreign Countries Respecting a Weekly Rest Day.” The principal points are summarized below.

Legislation is embodied in laws of 1895 and 1905, which prohibit any industrial work on Sunday, rest on that day beginning not later than 6 a.m., and lasting for not less than twenty-four hours. Permission is given for absolutely necessary work, provided the employer submits to the authorities a list giving the names of the persons employed, and the place, duration and nature of their employment. Sunday work is permitted in certain indus-
tries, such as shops for retailing food, occupations in which place, season, the habits of the public, &c., make observance impossible, and in such the weekly day of rest must be given in rotation to the employees of a compensating holiday instead.

Sunday rest in Belgium are contained in the Trade Regulations (Gewerbeerleidung) of the 26th of July 1900, according to which manufacturers cannot compel workmen to work on Sundays, whereas employers may do so. In the commercial and trading businesses may assistants, apprentices or workmen be employed at all on Christmas Day, Easter Sunday and Whitsunday, or on other Sundays and holidays more than five hours. The regula-
tions do not apply to hotels, cafés, &c., or to theatres or other places of amusement, or to means of communication. Infringement of the regulations is punishable by a fine, not exceeding 600 marks or imprisonment.

By a law of 1901 and others of 1903 and 1906 all industrial work is prohibited on Sundays and St Stephen's Day (the patron saint of Hungary). Certain categories of industries are exempted on account of necessity or the needs of the consuming public, independent small craftsmen who work at home without assistants are also exempted. The law is enforced by the police and infringement is punished by fine.

Sunday rest in France is given by a law of the 7th of July 1907. Exceptions to the law are river, lake and maritime navigation; agricultural, hunting and fishing industries; state railways and tramways and state public services and industrial undertakings.

The act of 1901 provides for a weekly Sunday rest on the 3rd day of each week, and a subvention of the 4th day. The state legislatures, consequently there exists considerable diversity of legislation on the subject, ranging from the old Quaker laws of the state of Pennsylvania of the beginning of the 18th century to the modern regulations of the Far Western agricultural and mining states. . . . There is no state, however, where it is specifically laid down that an employee who is forced to work
SUNDERLAND, 3rd EARL OF—SUNDERLAND, 2nd EARL OF

on Sunday shall receive another equivalent day of rest." (Report of H.M. Ambassador to the U.S. vide supra.) In Massachusetts, which may be fairly taken as representing the Eastern states, public service corporations, such as railway, street railway, steamboat, telegraph, telephone, electric lighting, water and gas companies, are permitted to serve the public in the usual manner. Public parks and baths are open. Tobacco may be sold by licensed innholders, common victuallers, druggists and news-dealers. Bake shops may be open during certain hours. All other shops must be closed. Saloons are closed, and liquor can be served only to the guests of licensed innholders. Horses, carriages, boats and yachts may be let for hire. All games and entertainments, except licensed sacred concerts, are prohibited. In Connecticut Sunday recreation is still prohibited, but electric and steam cars are allowed to run. Sunday is a close time for game and birds (15). In many of the Western states base-ball, games and various entertainments for pay are permitted, and in some saloons are open. In many but not all the states such persons as by their religion are accustomed to observe Saturday are allowed to pursue their ordinary business on Sunday. In Delaware and Illinois barbers may not shave customers on Sundays; and in Georgia guns and pistols may not be fired (1858). In North Dakota the fines for Sabbath-breaking have been raised.

SUNDERLAND, CHARLES SPENCER, 3rd EARL OF (c. 1674—1722), English statesman, was the second son of the 2nd earl, but the death of his elder brother Henry in Paris in September 1688 he became heir to the peerage. Called by John Evelyn "a youth of extraordinary hopes," he completed his education at Utrecht, and in 1695 entered the House of Commons as member for Tiverton. In the same year he married Arabella, daughter of Henry Cavendish, 2nd duke of Newcastle; she died in 1698 and in 1700 he married Anne Churchill, daughter of the famous duke of Marlborough. This was an important alliance for Sunderland and for his descendants; through it he was introduced to political life and later the dukedom of Marlborough came to the Spencer family. He succeeded to the peerage in 1702, the earl was one of the commissioners for the union between England and Scotland, and in 1705 he was sent to Vienna as envoy extraordinary. Although he was tiring with republican ideas and had rendered himself obnoxious to Queen Anne by opposing the grant to her husband, Prince George, through the influence of Marlborough he was foisted into the ministry as secretary of state for the southern department, taking office in December 1706. From 1708 to 1710 he was one of the five whigs, called the Junta, who dominated the government, but he had many enemies, the queen still disliked him, and in June 1710 he was dismissed. He was granted a pension of £1000 a year, but this he refused, saying "if he could not have the honour to serve his country he would not plunder it."

Sunderland continued to take part in public life, and was active in communicating with the court of Hanover about the steps to be taken in view of the approaching death of the queen. He made the acquaintance of George I., in 1706, but when the elector became king the office which he secured was the comparatively unimportant one of lord-lieutenant of Ireland. In August 1715 he joined the cabinet as lord keeper of the privy seal, and after a visit to George I. in Hanover he secured in April 1717 the position of secretary of state for the northern department. He retained until March 1718, when he became first lord of the treasury, holding also the post of lord president of the council. He was now prime minister. Sunderland was especially interested in the proposed peerage bill, a measure designed to limit the number of members of the House of Lords, but this was defeated owing partly to the opposition of Sir Robert Walpole. He was still at the head of affairs when the South Sea bubble burst and this led to his political ruin. He had taken some part in launching the scheme of 1720, but he had not profited financially by it; however, public opinion was roused against him and it was only through the efforts of Sir Robert Walpole that he was acquitted by the House of Commons, when the matter was investigated. In April 1721 he resigned his offices, but he retained his influence with George I. until his death on the 19th of April 1722.

Sunderland inherited his father's passion for intrigue, while his mother's love of repelling, but he played his hand among his associates for disinterestedness and had an alert and discerning mind. From his early years he had a great love of books, and he spent his leisure and his wealth in forming the library at Althorp, which in 1703 was called "the finest in Europe." In 1749 part of it was removed to Blenheim.

The earl's second wife having died in April 1716, after a career of considerable influence, but in which he had shown signs of moral decay, he married an Irish lady of fortune, Judith Tichborne (d. 1749). By Lady Anne Churchill he had three sons and two daughters. Robert (1701—1729), the eldest son, succeeded as 4th earl, and Charles (1700—1749) the second, but both of them died without issue. In 1733 Charles inherited the dukedom of Marlborough and he then transferred the Sunderland estates to his brother John, father of the 1st Earl Spencer (see MARLBOROUGH, EARLS AND DUKES OF).

For the career of Sunderland see W. Cox, Memoirs of Marlborough (1847—1848); Earl Stanhope, History of England (1853), and I. S. Leadam, Political History of England, 1702—1760 (1900).

SUNDERLAND, ROBERT SPENCER, 2nd EARL OF (1640—1702), English politician, was the only son of Henry Spencer (1620—1645), who succeeded his father, William, as 3rd Baron Spencer of Wormleighton in 1646. This barony had been bestowed in 1603 upon Sir Robert Spencer (d. 1617), the only son of Sir John Spencer (d. 1600) of Althorp, Northamptonshire, who claimed descent from the baronial family of Despenser. The first baronet of the family were Sir John Spencer (d. 1522) of Snitterfield, Warwickshire, a wealthy grazier. His descendant, Sir Robert Spencer, the 1st baron, was in 1663, "reputed to have by him the most money of any person in the kingdom." Sir Robert's grandson, Henry, the 3rd baron, was created earl of Sunderland in June 1643, and was killed at the battle of Newbury when fighting for the king a little later in the same year. He married Dorothy (1617—1684), daughter of Robert Sidney, 2nd earl of Leicester. She was the Sacharissa of the poems of her admirer, Edmund Waller, and for her second husband she married Sir Robert Smythe. Their son Robert, the 2nd earl, was educated abroad and at Christ Church, Oxford, and in 1665 married Anne (d. 1715), daughter of John Digby, 3rd earl of Bristol; she was both a beauty and an heiress, and is also famous for her knowledge and love of intrigue. Having passed some time in the court circle, Sunderland was successively ambassador at Madrid, at Paris and at Cologne; in 1678 he was again ambassador at Paris. In February 1679, when the country was agitated by real or fancied dangers to the Protestant religion, the earl entered political life as secretary of state for the northern department and became at once a member of the small clique which was responsible for the exclusion of James, duke of York, from the throne, and made overtures to William, prince of Orange, and consequently in 1681 he lost both his secretarship and his seat on the privy council. Early in 1683, however, through the influence of the king's mistress, the duchess of Portsmouth, Sunderland regained his place as secretary for the northern department, the chief feature of his term of office being his rivalry with his brother-in-law, George Savile, marquess of Halifax. By this time he had made his peace with the duke of York, and when in February 1685 James became king, he retained his position of secretary, to which he was appointed by the new lord president of the council. He carried out the wishes of the new sovereign and after the intrigues of a few months he had the satisfaction of securing the dismissal of Lawrence Hyde, earl of Rochester, from his post as lord treasurer. He was a member of the commission for ecclesiastical causes, and although afterwards he claimed that he had used all his influence to dissuade James from removing the tests, and in other ways illegally favouring the Roman Catholics, he signed the warrant for the committal of the seven bishops, and appeared as a witness against them. It should be mentioned that while Sunderland was thus serving James II., he was receiving a pension from France, and through his wife's lover, Henry Sidney, afterwards earl of Romney, he was furnishing William of Orange with particulars about affairs in England.
SUDBURY, Sunderland. In the last months of James’s reign he was obviously uncomfortable. Although he had in 1687 openly embraced the Roman Catholic faith, he hesitated to commit himself entirely to the acts of the fierce devotees who surrounded the king, whom he advised to reverse the arbitrary acts of the last year or two, and in October 1688 he was dismissed by James with the remark of ‘you will become more faithful to your next master than you have been to me.’

Sunderland now took refuge in Holland, and from Utrecht he sought to justify his recent actions in A letter to a friend in the country. He had been too deeply involved in the arbitrary acts of James II. to find a place at once among the advisers of William and Mary, and he was excepted from the act of indemnity of 1690. However, in 1691, he was permitted to return to England, and he declared himself a Protestant and began to attend the sittings of parliament. But his experience was invaluable and soon he became prominent in public affairs, a visit which William III. paid him at Althorp, his Northamptonshire seat, in 1691, being the prelude to his recall into the royal counsels. It was his advice which led the king to choose all his ministers from one political party, to adopt the modern system, and he managed to effect a reconciliation between William and his sister-in-law, the princess Anne. From April to December 1697 he discharged the duties of lord chamberlain, and for part of this time he was one of the lords justices, but the general suspicion with which he was regarded terrified him, and in December he resigned. The rest of his life was passed in seclusion at Althorp, where he died on the 28th of September 1702. The earl was a great gambler, but he was wealthy enough also to spend money on improving his house at Althorp, which he beautified both within and without. His only surviving son was Charles Spencer, 3rd earl of Sunderland (q.v.).

Lord Sunderland possessed a keen intellect and was consumed by intense restless; but his character was wanting in steadfastness, and he yielded too easily to opposition. His aridotism in intrigue and his fascinating manners were exceptional even in an age when such qualities formed part of every statesman’s education; but the characteristics which ensured him success in the House of Lords and in the royal closet led to failure in his attempts to understand the feelings of the mass of his countrymen. Consistency of conduct was not among the objects which he aimed at, nor did he shrink from thwarting in secret a policy which he supported in public. A large share of the discredit attaching to the measures of James II. must be assigned to the earl of Sunderland.

The best account of Sunderland is the article by T. Seccombe in the Dict. Nat. Bio., which gives a full bibliography.

SUDBURY, Sunderland, a seaport and municipal, county and parliamentary borough of Durham, England, at the mouth of the river Wear, on the North-Eastern railway, 281 m. N. by W. from London. Pop. (1801), 131,686; (1901) 146,977. The borough includes the township of Bishopwearmouth, to the south of Sunderland proper, which lies on the south bank of the river; and that of Monkwearmouth, on the north bank. Adjacent to Monkwearmouth on the north-west is the extensive urban district of Southwick, within the parliamentary borough. A great cast-iron bridge crosses the river with a single span of 236 ft. and a height of 100 ft. above low water. It was designed by Rowland Burdon, opened in 1796, and widened under the direction of Robert Stephenson in 1858. The only building of antiquarian interest is the church of St Peter, Monkwearmouth, in which part of the tower and other portions belong to the Saxon building attached to the monastery founded by Benedict Bishop in 674. The church of St Michael, Bishopwearmouth, is on an ancient site, but is a rebuilding of the 10th century. There is a large park at Roker on the north-east of the town, a favourite seaside resort, and (among other parks) that at Bishopwearmouth contains a bronze statue of Sir Henry Havelock, who was born (1793) at Ford Hall in the neighbourhood.

The prosperity of Sunderland rests on the coalfields of the neighbour-
which dropped to £4 in 1590. Bishop Morton incorporated Sunderland in 1634, stating that it had been a borough from time immemorial under the name of the New Borough of Wearnemouth. This charter lapsed during the Civil Wars, when the borough was sold with the manor of Houghton-le-Spring for £3875, £8, 6d. Nevertheless the inhabitants retained their rights. Sunderland became a parliamentary borough returning two members in 1825. The charter of 1634 granted a market and annual fair which are still held. The charter of Bishop Hugh provided for pleas between burgesses and foreign merchants, and directed that merchandise brought by sea should be landed before sale, except in the case of salt and herrings. Bishop Hatfield gave a lease of the fisheries in 1538. In the 16th century commissions were held touching salmon-fisheries and obstructions in the Wear, while Bishop Barnes (1577-1587) appointed a water-bailiff for the port, and licensed the building of wharves for the sale of coal. During the 17th century Sunderland was the seat of a vice-admiralty court for the county palatine and in 1669 letters patent permitted the erection of a pier and lighthouse as the harbour was "very commodiously situate for the shipping of vast quantities of sea-coles plentifully gotten and wrought there."

See William Hutchinson, History and Antiquities of the County Palatine of Durham (Newcastle, 1785-1794); J. W. Summers, History and Antiquities of Sunderland (Sunderland, 1850); Victoria County History, Durham.

**Sundew**, in botany, the popular name for a genus of plants known as Drosera (Gr. ἄγγελος, dew; Fr. rosée, Ger. Sonnenhut) so called from the drops of viscid transparent glittering secretion borne by the tentacles which cover the leaf-surface. It is a cosmopolitan genus of slender glandular herbs, with leaves arranged in a basal rosette or alternately on an elongated stem, and is represented in Britain by three species, which are found in spongy bogs and heaths.

The common sundew (D. rotundifolia) has extremely small roots, and bears five or six radical leaves horizontally extended in a rosette around the flower-stalk. The upper surface of each leaf is covered with gland-bearing filaments or "tentacles," of which there are on an average about two hundred. Each gland is surrounded by a large dew-like drop of the viscid secretion. A small fibro-vascular bundle (6, fig. 3, B), consisting mainly of spiral vessels, runs up through the stalk of the tentacle and is surrounded by a layer of elongated parenchyma cells outside of which is the epidermis filled with a homogenous fluid tinted purple by a derivative of chlorophyll (cytophylly). The epidermis bears small multicellular prominences. The glandular head of the tentacle contains a central mass of spirally thickened cells (tracheids) in immediate contact with the upper end of the fibrovascular bundle. Around these is a layer of large colourless thin walled cells which reaches the surface at the base of the head and acts as absorbing cells. Outside these (the outer one the epidermis) filled with purple fluid.

Insects are attracted by the leaves; a fly alighting on the disk, or even only touching one or two of the exterior tentacles, is immediately entangled by the viscid secretion; if the blade or the leaf may even become almost cup-shaped; and the insect, bathed in the abundant secretion which soon closes up its tentacles, is drowned in about a quarter of an hour. The leaves clasp also, for a much shorter time, over inorganic bodies.

The bending of the tentacle takes place near its base, and may be excited (1) by repeated touches, although not by gusts of wind or drops of rain, thus saving the plant from much useless movement; (2) by contact with any solid, even though insoluble and of far greater minuteness than could be appreciated by our sense of touch—a morsel of human hair weighing only 736 of a grain, and this

---

**Fig. 2.—Leaf of Sundew, enlarged, with the tentacles on one side inflected over a bit of meat placed on the disk.**

**Fig. 3.—Glands of Sundew magnified.**

A, External aspect with drop of secretion; B, Internal structure. largely supported too by the viscid secretion, sufficing to induce movement; (3) by the absorption of a trace of certain fluids, mostly nitrogenous. During the inflexion of the tentacle, and even before it touches the stimulating object, the secretion of the gland increases in quantity, and, instead of remaining neutral, becomes acid. The secretion contains a digestive enzyme which renders soluble the nitrogenous substances of the insect's body; these are then absorbed through thin-walled cells at the base of the gland. After absorption the tentacles recurve and the leaf assumes its normal appearance.

Closely allied to Drosera is Drotophyllum plantains, which catches such vast numbers of flies in a state of nature that the Portuguese cottagers call it the fly-catcher, and hang up branches of it in their houses for this purpose. Its long narrow leaves are covered with stalked glands, which resemble in the main the tentacles of Drosera, save in that they are incapable of movement, and that the gland is less viscid; the leaves of the main the tentacles of Drosera, save in that they are incapable of movement, and that the gland is less viscid; the leaves of the gland to wet the insect, which, creeping onward, soon clogs its wings and dies. There are, moreover, many minute colourless sessile glands, which, when stimulated by the absorption of nitrogenous matter, excrete an acid digestive secretion similar to that of the sundew, by means of which the body of the captured insect is digested and absorbed.

**Fig. 4.—Part of Leaf of Drotophyllum plantains.** (X 7.)
SUNDSVALL, a seaport of Sweden in the district (län) of Västernorrland, on a wide bay of the Baltic, at the north of the Selanger River, 360 m. N. by W. of Stockholm, the terminus of a branch from Anga on the northern railway. Pop. (1900), 14,531. It was rebuilt in brick and stone after a destructive fire in 1888. In the town and its vicinity are numerous steam saw-mills, besides wood-pulp factories, steelworks, brickworks, engineering shops, breweries and joineries, but Sundsvall owes its chief importance to its export trade in timber (6 to 7 million cub. ft. annually), the bulk of which goes to Germany, France and Great Britain. It also exports wood-pulp, iron and fish. There is a special trade with Finland. The harbour, which is usually closed by ice from about the middle of December to the second week in May, is sheltered against the east winds by a group of islands.

SUNFISH, a name chiefly and properly applied to a marine fish (Orthagonicus) of the order Plecognathi, which by its large size, grotesque appearance and numerous peculiarities of organiza-
tion has attracted the attention equally of fishermen as of naturalists. Only two species are known, the rough or short sunfish (O. mola), which is found in all seas of the temperate and tropical zones; and the smaller and scarcer smooth or oblong sunfish (O. truncatus), of which only a small number of specimens have been obtained from the Atlantic and Indian oceans.

Sunfishes have the appearance of tailless fish. This is due to the extreme shortening of the caudal region which is sup-
ported by only a few short vertebrae; the caudal fin is absent, what appears to be a tail being formed by the confluence of dorsal and ventral fins: pelvic fins are also wanting. The anterior parts of the dorsal and ventral fins are high and broad, similar to each other in size and triangular in form. The head is com-
pletely merged in the trunk, the boundary between them being indicated only by a very small and narrow gill-opening and a comparatively small pectoral fin. This fin can be of but little use in locomotion, and the horizontal and vertical movements of the fish, as well as the maintenance of its body in a vertical position, are evidently executed by the powerful dorsal and anal fins. The small mouth, situated in front of the head, is armed with an undivided dental plate above and below, similar to but weaker than the teeth of the goby-fish (Diodon).

Sunfishes are truly pelagic, propagating their species in the open sea, and only occasionally approach the coast. During the stormy season they live probably at some depth, but in calm, bright weather they rise and rest or play on the surface with their dorsal fin high above the water. This habit has given rise to the popular name "sunfish," a term also sometimes applied to the basking-shark. In some years the rough sunfish is by no means scarce on the south coast of England and on the Irish coasts, where it appears principally in the summer months. The usual size is from 3 to 4 ft. in length, but this species attains to 7 ft. and more. One of the largest specimens (shown in the figure) was caught near Portland (Dorsetshire) in 1846, and is now in the British Museum; its length is 7 ft. 6 in. The sunfish has no economic value, and is rarely, if ever, eaten.

Whilst the rough sunfish has a granulated, rough, shagreen-like skin, the second species (O. truncatus) has the surface of the body smooth and polished, with its small dermal scutes arranged in a tesselated fashion. It is oblong in shape, the body being much longer than it is deep. The sides are finely ornamented with transverse silvery, black-edged stripes running downwards to the lower part of the abdomen. It has not been found to exceed 2 ft. in length. Only a few specimens have been captured on the coasts of Europe, at the Cape of Good Hope and off Mauritius.

SUNFLOWER. The common sunflower, known botanically as Helianthus annuus, a member of the natural order Compositae, is a native of the western United States. It is an annual herb with a rough hairy stem 3 to 12 ft. high, broad coarsely toothed rough leaves 3 to 12 in. long, and heads of flowers 3 to 6 in. wide in wild specimens and often a foot or more in cultivated. Double forms are in cultivation, one (globosus fistulosus) having very large globular heads. The plant is valuable from an economic as well as a decorative point of view, and not only the heads, but as fodder, the flowers yield a yellow dye, and the seeds contain oil and are used for food. It is cultivated in Russia and other parts of Europe, in Egypt and India and in several parts of England hundreds of plants are grown on sewage farms for the seeds. The yellow sweet oil obtained by compression from the seeds is considered equal to olive or almond oil for table use. Sunflower oilcake is used for stock and poultry feeding, and largely exported by Russia to Denmark, Sweden and elsewhere.

The genus Helianthus contains about fifty species, chiefly natives of North America, a few being found in Peru and Chile. They are tall, hardy annual or perennial herbs, several of which are well known in gardens where they are of easy cultivation in moderately good soil. H. decapetalus is a perennial about 5 ft. high with solitary heads about 2 in. across in slender twiggy branchlets; H. multiflorus is a beautiful species with several handsome double varieties; H. orygalis is a graceful perennial 6 to 10 ft. high, with drooping willow-like leaves and numerous comparatively small yellow flower-heads. H. atrorubens, better known as Harpaliu rigidu, is a smaller plant, 2 to 3 ft. high, the flower heads of which have a dark red or purple disk and yellow rays. There are many fine forms of this now, of which grow 6 to 9 ft. high and have much larger and finer flowers than the type. Other fine species are H. giganteus, 10 to 12 ft.; H. laetiflorus, 6 to 8 ft. and H. mollis, 3 to 5 ft. H. tuberosus is the Jerusalem artichoke.

Since the word "sunflower," or something corresponding to it, existed in English literature before the introduction of Helianthus annuus, or, at any rate, before its general diffusion in English gardens, it is obvious that some other flower must have been intended. The marigold (Calendula officinalis) is considered by Dr. Prior to have been the plant intended by Ovid (Met. iv. 269-270)—

"... Ilia suum, quamvis radice tenetur,
Vertitur ad solem; mutataque servat amorem "—

and likewise the solsaece of the Anglo-Saxon, a word equivalent to solsequium (sun-following). But this movement with the sun is more imaginary than real, the better explanation for the application of the name to a flower being afforded by the resemblance to "the radiant beams of the sun," as Gerard expresses it. The rock-rose (Helianthemum vulgare) was also termed sunflower in some of the herbs from its flowers opening only in the sunshine. Actinella grandiflora, a pretty perennial 6 to 9 in. high, from the Colorado mountains, is known as the Pigmy sunflower.
SUNNIA—SUNNITES

SUNNIA (Colovar; mod. Cape Colonna), a cape at the southern extremity of Attica, with a temple of Poseidon upon it, which serves as a landmark for all ships approaching Athens from the east. The rocky promontory on which the temple stands was fortified by a wall with towers, in 413 B.C., as a protection against the Spartans in Decela; but it was soon afterward seized by a body of fugitive slaves from the Laurium mines. In the 4th century it was still kept up as a fortress. The temple was shown by an inscription found in 1898 to be dedicated to Poseidon, not, as formerly supposed, to Athena, the remains of whose temple are to be seen about a quarter of a mile away to the north-east; they are of a peculiar plan, consisting of a hall with a colonnade on two sides only. The extant temple on the promontory was probably built in the time of Pericles. It took the place of an earlier one, of similar proportions but built of tufa or “poros” stone. There are still standing nine columns of the south side and two of the north of the peripteral, and one of the outer and an inner column of the prosomas. They are built of local white marble, which has suffered much from the weather. In form they resemble those of the Parthenon and Theseum, but they have only sixteen fluting. Recent excavations have revealed porticoes, a gateway and other buildings, and also the remains of several colossal early statues, the best preserved of which is now in the museum at Athens. The site of Cape Colonna is extolled by Byron, and is the scene of Falconer’s “Shipwreck." (E. Gr.)

SUNNIA, or INDIA HEMP (Crotalaria juncea), a plant which is a native of India and Ceylon. It frequently receives other names, e.g. false hemp, brown hemp, Bombay hemp, Jubbulpore hemp, sana, &c. The plant is an annual, requires a light soil, and is easily cultivated. The ground is ploughed two or three times, and from 80 to 100 lb of seed are sown broadcast. The seedlings quickly appear above the surface, but it is about four months before the plant begins to flower. Sometimes the seed is sown in October for the winter crop, and sometimes in May or June for the summer crop. When the seeds are sown in May, the bright yellow flowers appear in August, when the plant may be gathered. It is not unusual, however, to defer this operation until the seed is ripe, especially if the fibre of great strength is desired. The stems may be pulled up, as is the case with flax, or they may be cut down. Different opinions exist as to whether the stems should be steepled immediately after they are pulled, or left to dry and then steepled: in the wet districts they are taken direct to the water. Since the root ends are much thicker and coarser than the tops, it is common to place the bundles erect, and to immerse the root ends in about a foot of water. Afterwards the bundles are totally immersed in the ponds, and in two to four days the fibre should be ready for stripping. There is the same danger of over-retting and under-retting as in other fibres, but when the retting is complete, the workmen enter the ponds, take up a handful of stems, and sow them upon the surface of the water until the fibre becomes loose. After the fibre has been peeled off it is hung over poles to dry. When intended for cloth it is combed in order to remove any foreign matter, but if it is intended to be used for rope or similar purposes, the fibres are simply separated and the woody matter combed out with the fingers. The fibre is of a light grey colour, and has an average length of 3 to 4 ft. It is extensively used for rope and cordage and also for paper-making in its native country, but it has made little, if any, progress in this country. According to Warden, the fibre was tried in Dundee in the beginning of the 19th century. About 1820 the price of India hemp bagging, as quoted in the Dundee Advertiser, was 1½d. per yard below hemp bagging, and 4½d. a yard below tow warp bagging.

It is stated in Sir G. Watt’s Dictionary of the Economic Products of India that a cord 8 in. in size of best Peters burg hemp broke with 14 tons, 8 cwt. 1 qr., while a similar rope of sown only gave way with 7 tons, 16 cwt. 1 qr. Ruxton’s experiments with ropes made from this and other fibres appear on p. 607 of the above work. The ropes were tested in the fresh state, and also after having been immersed in water for 110 days. His results, reproduced in the following table, show the comparison.

<table>

It would appear that, after maceration, neither ordinary hemp nor sunn hemp can compare with jute for strength.

SUNNITES, literally, "those of the path," *sunnā*, i.e. followers of the Prophet’s directions, the name of one of the two main divisions of Islam, the other being the Shi’ites (q.v.). The Sunnites, who accept the orthodox tradition (*sunnā*) as well as the Koran as a source of theologico-juridical doctrines, predominate in Arabia, the Turkish Empire, the north of Africa, Turkestan, Afghanistan and the Mahomedan parts of India and the east of Asia; the Shi’ites have their main seat in Persia, where their confession is the state religion, but are also scattered over the whole sphere of Islam, especially in India and the regions bordering on Persia, except among the nomad Tatars, who are all nominally Sunnite. Even in Turkey there are many native Shi’ites, generally men of the upper classes, and often men in high office (see generally MAHOMMEDAN RELIGION).

Orthodox Islam preserves unchanged the form of doctrine established in the 10th century by Abū l-Hasan al-Asbā’ī (see ASBA’I). The attacks of rationalism, aided by Greek philosophy, were repelled and vanquished by the weapons of scholastic dialectic borrowed from the enemy; on most points of dispute discussion was forbidden altogether, and faith in what is written in Koran and tradition was enjoined without question as to how these things were true (būla kaijū). Freer allegorical views, however, were admitted on some specially perplexing points, such as the doctrine of the eternity of the Koran, the crude anthropomorphisms of the sacred text, &c.; and, since Mo’tazīlī (*Mu’tazīlī*) views had never taken deep root among the masses, while the caliphs required the help of the clergy, and from the time of Motawakkīl (a.d. 847) became ever more closely bound to orthodox views, the freethinking tendency was thoroughly put down, and to the present day no rationalizing movement has failed to be crushed in the bud. Philosophy still means no more than scholastic dialectic, and is the humble servant of orthodoxy, no man venturing on devious paths except in secret. In the years 1572–1578 the Afghan Šāhīd ud-Dīn, a professor in the Azhar mosque at Cairo, attempted to read Avicenna with his scholars, and to exercise them in things that went beyond theology, bringing, for example, a globe into the mosque to explain the form of the earth. But the other professors rose in arms, forbade him to enter the mosque, and in 1579 procured his exile on the pretex that he entertained democratic and revolutionary ideas. Thus the later movements of thought in Islam never touch on the great questions that exercised Mahomedanism in its first centuries, e.g. the being and attributes of God, the freedom of the will, sin, heaven and hell, &c. Religious earnestness, ceasing to touch the higher problems of speculative thought, has expressed itself in later times exclusively in protest against the extravagances of the dervishes, of the worship of saints, and so forth, and has thus given rise to movements analogous to Puritanism. That even in early times the masses were never shaken in their attachment to the traditional faith, with all its crude and grotesque conceptions, is due to the zeal of the umma (clergy). Mahomedanism has no priest-hood standing between God and the congregation, but Koran and Sunna are full of minute rules for the details of private
SUNNITES

civil life, the knowledge of which is necessarily in the hands of a class of professors, theologians. These are the "ulema (q.v.), "knowers," theology being briefly named "the knowledge" ('ilm). Their influence is enormous and hardly has a parallel in the history of religions. For it is not supported by temporal agencies like the spiritual authority of the Christian priesthood in theirognos, and is a public act of knowledge. Among the ignorant masses, who do nothing without consulting their spiritual advisers. When the vigorous Spanish sultan Manṣūr b. Abī 'Amīr proposed to confiscate a religious foundation and the assembled ulema refused to approve the act, and were threatened by his vizier, one of them replied, "All the evil you say of us applies to yourself; you seek unjust gains and support your injustice by threats; you take bribes and practise ungodliness in the world. But we are guides on the path of righteousness, lights in the darkness, and bulwarks of Islam; we decide what is just or unjust and declare the right; through us the precepts of religion are maintained. We know that the sultan will soon think better of the matter; but, if he persists, every act of his government will be null, for every treaty of peace and war, every act of sale and purchase, is valid only through our testimony."

With this answer they left the assembly, and the sultan's apology overtook them before they had passed the palace gate. The same consciousness of independent authority and strength still survives among the ulema. Thus the sheikh ul-Islam 'Abbasī (who was deposed by the professed ulema as the head of the religion and judged the first of the present presidency a sharp conflict with 'Abbās Pasha, viceroy of Egypt, who asked of him an unlegal opinion in matters of inheritance. When bribes and threats failed, the sheikh was thrown into chains and treated with great severity, but it was the pasha who finally yielded, and 'Abbās was recalled to honours and rich rewards.

The way in which the ulema are recruited and formed into a hierarchy with a vigorous esprit de corps takes an instructive light on the whole subject before us. The brilliant days are past when the universities of Damascus, Bagdad, Nishāpur, Cairo, Kairawan, Seville, Cordova, were thronged by thousands of students of theology, when a professor had often hundreds or even, like Bukhārī, thousands of hearers, and when vast estates in the hands of the clergy fed both masters and scholars. Of the great universities but one survives—the Azhar mosque at Cairo—where thousands of students still gather to follow a course of study which gives an accurate picture of the Mahommedan ideal of theological education.

The students generally begin their course in early youth, but seldom in later years. Almost all come from the lowest orders, a few from the middle classes, and none from the highest ranks of society—a fact which in itself excludes all elements of free and refined education. These sons of poor peasants, artisans or tradesmen are already disposed to narrow fanaticism, and generally take up study as a means of livelihood rather than from genuine religious interest. The scholar appears before the president's secretary with his poor belongings tied up in a red handkerchief, and after a brief interrogatory is entered on the list of one of the four orthodox rites—Shafi'ite, Hanifi, Maķkite and Hanbalite (see MAHOMMEDAN LAW). If he is lucky he gets a sleeping-place within the mosque, a chest to hold his things, and a daily ration of bread. The less fortunate must shift to live outside as best they can, but are all day in the mosque, and are selected in the presence of the sheikh and his assistants to the pillars of the great court and the students crouch on mats at their feet. The beginner takes first a course in the grammar of classical Arabic, which is called, and is known, in Arabic, tajwīd. The rules of grammar are read out in the memorial verses of the Ajrīmiya, and the teacher adds an exposition, generally read from a printed commentary. The student's chief task is to know the rules by heart, without help; but the other parts of the Ottoman Empire, 8 from North Arabia, 1 from the government of Bagdad, 12 from Kurdistan, and 7 from India with its thirty million Sunnites.

Except in India, where it is controlled by the government, the learning seems to have been raised by Russian and Western scholars. The madrasa is here a college, generally attached to a mosque, with lands whose revenues provide the means of instruction and in part also lod and residence for scholars and teachers.
the organization of the priestly and judicial persons trained in the schools is a compromise between what theological principles dictate and what the state demands. Neither Koran nor Sunna distinguishes between temporal and spiritual powers, and no such distinction was known as long as the caliphs acted in all things as successors of the prophets and heads of the community of the faithful. But, as the power of the 'Abbasids declined (see article Caliphate, ad fin.) and external authority fell in the provinces into the hands of the governors and in the capital into those of the amir al-omarā, the distinction became more and more palpable, especially when the Buyids, who were disposed to Shi'ite views, proclaimed themselves sultans, i.e. possessors of all real authority. The theologians tried to uphold the orthodox theory by declaring the sultanate to be subordinate to the imāmate or sovereignty of the caliphs, and dependent on the latter especially in all religious matters; but their artificial theories have never modified facts. The various dynasties of sultans (Buyids, Ghaznevis, Seljuks, and finally the Mongols) never paid heed to the caliphs, and at length abolished them; but the fall of theocracy only increased the influence of the clergy, the expounders and practical administrators of that legislation of Koran and Sunna which had become part of the life of the Mahomedan world. The Mengeluke in Egypt tried to uphold the caliphate as the result of the Islamic law, and to render possible the idea of a person who is not only the legal but the spiritual successor of the caliph. Thus in India too the sultan was something perhaps to his spiritual title. But among his own subjects he is compelled to defer to the ulemā and has no considerable influence on the composition of that body. He nominates the Sheikh ul-Islam or mufti (q.v.) of Constantinople (grand mufti), who is his representative in the imāmate and issues judgments in points of faith and law from which there is no appeal; but the nomination must fall on one of the mollahs, who form the upper stratum of the hierarchy of ulemā. And, though the various places of religious dignity are conferred by the sultan, no one can hold office who has not been examined by learned ulemā, so that the corporation is self-propagating, and palace intriguers, though not without influence, can never break through its iron bonds. The deposition of 'Abd ul-Aziz is an example of the tremendous power that can be wielded by the ulemā at the head of their thousands of pupils, when they choose to stir up the masses; nor would Mahmūd II. in 1826 have ventured to enter on his struggle with the janissaries unless he had had the hierarchy with him.

The student who has passed his examinations at Constantinople or Cairo may take up the purely religious office of wakil (pensionary or worship) or khaṭṭīb (preacher) at a mosque. These offices, however, are purely ministerial, and not necessarily limited to students, and give no place in the hierarchy and no particular consideration or social status. On the other hand, he may become a judge or cadi. Every place of any importance has at least one cadi, who is nominated by the government, but has no further dependence upon the Russians gained preponderating influence the khan of Khwarazm also proclaimed himself Sultan in the East.

2 Mollah is the Perso-Turkish pronunciation of the Arabic mualī, literally "patron," a term applied to heads of orders and other religious dignitaries of various grades.

3 Called in Constantinople süfî, Persian šāhīkha, burned up, secti, with zeal or love to God.

4 In Egypt before the time of Sa'd Pasha (1854-1863) the local judges were appointed by the chief cadi of Cairo, who is sent from Constantinople. Since then they have been nominated by the Egyptian government.

on it, and is answerable only to a member of the third class of the ulama, viz. the mufti or pronouncer of fatwas. A fatwa is a decision according to Koran and Sunna, but without reasons, on an abstract case of law which is brought before the mufti by appeal from the cadi's judgment or by reference from the cadi himself. For example, a dispute between master and slave may be found by the cadi to turn on the general question, "Has Zaid, the master of 'Amr, the absolute right to dispose of his slave's earnings?" When this is put to the mufti, the answer will be simply "Yes," and from this decision there is no appeal, so that the mufti is supreme judge in his own district. The grand mufti of Constantinople is, as we have seen, nominated by the sultan, but his hold on the people makes him quite an independent power in the state; in Cairo he is no longer nominated by the government, but each school of law chooses its own shiek, who is also mufti, and the Şafīite is head mufti because his school is official in the Turkish Empire.

All this gives the judges great private and political influence. But the former is tainted by venality, which, aggravated by the scantiness of judicial salaries or in some cases by the judge having no salary at all, is almost universal among the administrators of justice. Their political influence, again, which arises from the fusion of private and public law in Koran and Sunna, is highly inconvenient to the state, and often becomes intolerable now that relations with Western states are multiplied. And even in such distant parts as Central Asia the law founded on the conditions of the Prophet's lifetime proves so unsuited to modern life that cases are often referred to civil authorities rather than to canonical jurists. Thus a customary law (urf) has there sprung up side by side with the official sacred law (shari'a), much to the displeasure of the mollahs. In Turkey, and above all in Egypt, it has been found necessary greatly to limit the sphere and influence of the canonical jurists and to introduce a more independent power in the state; in Cairo he is no longer nominated by the government, but each school of law chooses its own shiek, who is also mufti, and the Şafīite is head mufti because his school is official in the Turkish Empire.
SUNSHINE

have tended to bring them closer to one another, we still find
that of the thirty-six chief orders three claim an origin from the
caliph Abü Bekr, whom the Sunnites honour, and the rest from
Alī, the idol of the Shi'ītes.1 Mystic absorption in the being
of God, with an increasing tendency to pantheism and ascetic
practices, are the main scope of all Šī'īism, which is not neces-
sarily confined to members of orders; indeed the secret practice
of contemplation of the love of God and contempt of the world
is sometimes viewed as specially meritorious. And so ultimately
the word ściī has come to denote all who have this religious
direction, while those who follow the special rules of an order
are known as dervishes (beggars, in Arabic ṣfārādī, slang ṣfārī
—originally designating only the mendicant orders).
In Persia at the present day a ściī is much the same as a free-
thinker.2

SUNSHINE. As a meteorological element sunshine requires
some conventional definition. There is uninterrupted continu-
ance of gradation from the burning sunshine of a tropical noon
to the pale luminosity that throws no shadow, but just identifies
the position and shape of the sun through the thin cloud of
northern skies.

The Campbell-Stokes Sunshine Recorder.—In the British Isles
the sun is allowed to be its own timekeeper and the shadow of
a specially prepared card used as the criterion for bright sunshine.
The practice arose out of the use of the sunshine recorder which
depends upon the glowing effect of a glass sphere in the sun's
rays. The original form of the instrument was suggested by
J. F. Campbell of Islay in 1857. He used a glass sphere within
a hemispherical bowl of wood. The scorching of the wood along
successive lines of the bowl as the sun alters its declination from
solstice to solstice leaves a rugged monument of the duration
and intensity of the sunshine during the half-year, but does not
lend itself to numerical measurement. The design of a metal
frame to carry movable cards and thus give a decipherable
record of each day's sunshine is due to Sir G. G. Stokes. The
excursions of the sun to the north and south of the equator are
limited by the tropical circles, and the solar record on the hemi-
spherical bowl will be confined within a belt 23° 27' north and
south of the plane through the centre parallel to the equator
or perpendicular to the polar axis. Thus a belt 46° 54' in angular
width will be suitable for a sunshine recorder for any part of
the world. Whatever place be chosen for the observation the
same belt will do if it is set up perpendicular to the earth's
polar axis. But there can be no record if the sun is below the
horizon; hence any part of the belt projecting above the horizon
is not only useless for recording but is liable to shadow a part
of the belt where there might be a record. Hence to meet the
requirements of a particular locality the belt as set up round the
polar axis should be cut in two by a horizontal plane through
the middle of the half projecting above the horizontal removed.
Reversed it makes a half belt, exactly similar to what is left,
and thus each complete belt is cut by a horizontal plane through
the centre into two frames suitable for sunshine recorders for
the particular locality.

The cutting of the belt may, of course, vary between the direct
transverse cut along the polar axis which gives a half-ring belt
for a recorder to project a point on the equator, and the cut perpendicular to the polar axis which
divides the belt into two similar rings suitable for recording the
sunshine at the poles. Clearly, when the belt is so cut that two
complete rings are formed, a continuous record of sunshine
throughout the twenty-four hours may be expected, so that for
the polar circles the cut will run diagonally between opposite
points of the extreme circles of the sun's records. As examples
of the cutting of the belt for different latitudes we may put side
by side the recorder as used in temperate latitudes (fig. 1) and

FIG. 1.—Campbell-Stokes Sunshine Recorder.

the special form designed in the Meteorological Office, London,
for use on the National Antarctic Expedition, 1901–1904 (fig. 2).
A belt cut for a particular latitude is serviceable for some 10°

Antarctic Sunshine Recorder, to carry 24-hour record.

FIG. 2.—Antarctic Sunshine Recorder, to carry 12-hour record.

on either side of that latitude if the cards are not trimmed too
closely to the cutting of the belt. The belt must always be
adjusted round the parallel to the polar axis. If the cut of the
belt is too oblique for the latitude of the place where it is exposed,
and the cards are cut strictly to the belt, the northern side of the
cut will be below the horizon and the southern side above it,
some sunshine may be lost near sunrise or sunset in the winter because there is no card to receive it. The part projecting above the horizon in summer will partly shadow the globe, and faint sunshine may be lost, for at most only half the globe can be solarized at sunset. But the loss due to this cause is unimportant.

Stokes designed the complete belt to use successively three cards of different shape for different times of the year. The equinoctial card forms a portion of a cylinder round the polar axis for spring and autumn, the summer card and the winter card each forms a part of a cone making a vertical angle of 16° with the polar axis as indicated in fig. 3.

Adjustments.—The adjustments of the instrument are to set the belt so that its axis is parallel to the polar axis and symmetrically adjusted with reference to the meridian of the place, and to set the sphere so that its centre coincides precisely with the centre of the belt. No one of the three adjustments is easy to make or to test because neither the centre of the sphere nor the centre (nor indeed the axis) of the belt can be easily identified. For an instrument for testing these adjustments see Quart. Journ. Roy. Met. Soc., xxxii., 249.

Instruments differ according to the means provided for mounting or adjusting the positions of the belt or sphere, and in that known as the Whipple Casella instrument the fixed belt is replaced by a movable card holder. The chief advantage of Stokes's specification is the simplicity of the use of the instrument when once it has been properly adjusted and fixed.

It is essential that the glass sphere and refractive index to give an image of the sun on the prepared card or within the 20th of an inch of it nearer the centre. It is also essential that the cards used should not only be of suitable material but also of the right dimensions for the bowl. The colour and material of the cards were selected by Stokes in consultation with Warren De la Rue, who was at that time his colleague on the Meteorological Council, and the cards used by the meteorological office are still supplied by Messrs De la Rue & Co. Accuracy in the comparative measurements of sunshine by this method depends upon the proper adjustment of the dimensions of the different constituent parts of the recorder and accordingly the following specification of standard dimensions has been adopted by the meteorological office.

The Time Scale.—On the time scale of the equinoctial card twelve hours are represented by 9:00 in.

The Bowl.—The diameter of the bowl, measured between the centres of the 6 o'clock marks on a metal equinoctial card of thickness 0.02 in. when in its place, is to be 5.73 in. (± 0.01 in.). The distance between the exposure edges of the upper winter flange and the lower summer flange must not be less than 2.45 in., nor exceed 2.50 in. The distances from the middle line on the equinoctial card to the middle lines on the summer and winter cards are to be 0.70 in. (± 0.02 in.). The inclination of the summer card, in place, to the winter card, in place, is to be 30° = 1°, symmetrically arranged with regard to the equinoctial card. The section of the supporting surface by a plane through the polar axis is to be as in fig. 3.

The Sphere.—The material for the sphere must be "crown" glass, colourless, or of a very pale yellow tint. The diameter 4 in. The weight between 2.02 and 3.02 lb. The focal length from the centre of the sphere to the geometrical focus for parallel rays should be between 2.96 in. and 2.99 in.

Measurement of the Sunshine Record.—It was mentioned that the Campbell-Stokes recorder involves a conventional definition of sunshine. The recorded day of sunshine is less than the actual time during which the sun is above the horizon by about twenty minutes at sunrise and sunset on account of the want of burning power of a very low sun. Some further convention is necessary in order to obtain a tabulation of the records which will serve as the basis of a comparison of results for climatological purposes. The spot which is scorched on the card by the sun is not quite limited to the image of the sun, and a few seconds of really strong sunshine will produce a circular burn which is hardly distinguishable in size from that of a minute's record. (See fig. 4.) Consequently with intermittent sunshine exaggeration of the actual duration of burning is very probable. Strictly speaking measurements ought to be between the diameters of the circular ends of the burns, but the practice of measuring all the trace that can be distinctly recognized as scorched has become almost universal in Great Britain, and appears to give a working basis of comparisons.

Other Types of Sunshine Recorder.—There are, however, various other conventions as to sunshine which are used as the basis of recorders of quite different types. The Jordan recorder uses ferrocyanide paper and the sun keeps the time of its own record by the traverse of a spot of light over the sensitive paper, arranged as a cylinder about a line parallel to the polar axis. The effect thereby recorded is a photochemical one, and the composite character of the sun's radiation, modified by the elective absorption of the atmosphere makes the relation of the record to that of the sun's scorching power dependent upon atmospheric conditions and therefore on different occasions, so that the two records give different aspects of the solar influence. Other recorders use the thermal or photographic effect.
of the sun's rays and record duration by a clock instead of allowing the sun to keep its own time. In the Marvin sunshine recorders of the United States weather bureau an electrical contact is made by the thermal effect of the sun and the duration of the contact is recorded. An instrument which gives a corresponding result is described by W. H. Dines (Quart. Journ. Roy. Meteor. Soc. xxvi. 243). These define sunshine by the effect necessary to produce or maintain a certain thermal effect, but the definition once accepted there is no uncertainty as to the record. The Calender sunshine recorder1 gives a record of the difference of temperature of two wires, one solarized and the other not, and it is therefore a continuous record of the thermal effect of solar and terrestrial radiation. It is vastly more complicated than that of other instruments (see fig. 5), but the interpretation of the record in terms suitable for meteorological or climatological purposes is a special study, which has not yet been attempted. In a somewhat similar way information about the duration and intensity of sunshine with an abundance of detail can be obtained from the record upon photographic paper passing under an aperture in a drum which revolves with the sun, as in the Lander recorder, but the study of such details has not been begun.

Sunshine Records for the British Isles.—The interest in the sunshine recorders is more widely extended in the British Isles than elsewhere, and it is, so far as the public are concerned, the most important meteorological element, but it is singular that up to the present a knowledge of the total amount of sunshine recorded during the day, the week, the month or the year is all that is apparently required. Except for the observatories in connexion with the meteorological office and a few others the distribution of sunshine during the day is not taken out, so that we are still some distance from attacking the problems presented by the finer details of solar records. Fig. 6 shows the average duration of bright sunshine for each hour of the day for each month at Valencia. The expectation of sunshine is greatest at 1 p.m. and 2 p.m. in May, while there is a well-marked secondary maximum in September.

Exposure.—We now consider what the daily sunshine record for a particular station means. An ideal exposure has an uninterrupted view of those parts of the horizon in which the sun rises or sets; and elsewhere the view of the sun must not be obstructed by the ground, buildings, trees or any other obstacle; but ideal exposures are not always to be obtained. In mountainous districts particularly it may be impossible to find a site in which the sun is not obstructed for an appreciable part of the day. In these circumstances it becomes a question whether the amount of sunshine recorded should be referred to the maximum possible for an uninterrupted horizon or the maximum possible for the particular exposure. The answer to the question really depends upon the purpose for which the information is wanted. As a climatological factor of the locality the shadow cast by the surrounding hills is of importance, it is part of the difference between the fertility of the southern and northern slopes of hill country. This importance is, of course, in many respects

---

---

Sunshine in the Antarctic Regions.—It is clear that so far as concerns the zone from 50° to 60° N. in this particular region, the annual amount of sunshine diminishes as one goes northward. It would, however, not be safe to conclude that this diminution in the aggregate duration of sunshine is above the horizon as one proceeds northward. At least the corresponding statement would not be true of the southern hemisphere. No doubt
the frequency of cloud and the consequent loss of duration of sunshine would increase for corresponding latitudes from the tropical anticyclone southward, but beyond the region of minimum pressure at the winter quarters of the "Discovery" in latitude 77° 51' S., longitude 166° 45' E., the amount of bright sunshine recorded during the two years 1902 and 1903 was remarkably large. The total for 1903 equaled that for Scilly, and in December of that year an average of 16 hours per day was registered.

FIG. 8.—Sunshine in the British Isles in May and June 1909.

**Sunshine Results for Other Parts of the World.**—Maps showing the average annual distribution of sunshine over Europe and North America are given in Bartholomew's *Physical Atlas*, vol. iii. Atlas of Meteorology. Over Europe the largest totals, over 2750 hours per annum, are shown over central Spain. In North America, values exceed 3250 hours per annum in the New Mexico region. For other parts of the world the information available is not sufficiently extensive for the construction of charts.

**Effect upon Sunshine Records of the Smoke of Great Cities.**—Much discussion has taken place from time to time as to whether the climate of a locality can be altered by artificial means. Questions have been raised as to the effect of forests upon rainfall, as to the indirect effect of irrigation or the converse process, the obliteration of natural irrigation by blown sand, and as to the possibility of producing, arresting or modifying rainfall by the discharge of explosives.

The one question of the kind to which the sunshine records give an absolutely incontrovertible answer is as to the effect of the smoke of great cities in diminishing the sunshine in the immediate neighbourhood. This may be illustrated by the figures for sunshine during the winter months off Bunhill Row, E.C., in the middle of London, Westminster, Kew and Cambridge. **Monthly Average Duration of Bright Sunshine derived from Observations extending over Twenty Years.**

This is not a question which comes out merely by taking averages. The answer can be seen directly by comparing the daily cards (see fig. 10, Sunshine Cards for Cambridge, Westminster and Bunhill Row for December 1904). Thus it appears that the direct effect of the local contamination of the London atmosphere results in the
diminution of the recorded sunshine for the whole year by 37%, and it is clear that the contamination extends in some degree as far as Kew, where the loss amounts to about 10%. There is evidence of various kinds to show that the effect of the smoke cloud of cities

SUNSTONE, a felspar exhibiting in certain directions a brilliant spangled appearance, which has led to its use as an ornamental stone. The effect appears to be due to reflections from enclosures of red haematite, in the form of minute scales, which are hexagonal, rhombic or irregular in shape, and are disposed parallel to the principal cleavage-plane. These enclosures give the stone an appearance something like that of aventurine (q.v.), whence sunstone is known also as "aventurine-felspar." It is not common, the best-known locality being Tvedestrand, near Arendal, in south Norway, where masses of the sunstone occur embedded in a vein of quartz running through gneiss. It is found also near Lake Baikal, in Siberia, and at several localities in the United States, notably at Middletown, Delaware county, Pennsylvania, and at Statesville in North Carolina. The felspar which usually displays the aventurine appearance is oligoclase (q.v.), but the effect is sometimes seen also in orthoclase (q.v.): hence two kinds of sunstone are distinguished as "oligoclase sunstone" and "orthoclase sunstone." The latter has been found near Crownpoint and at several other localities in the state of New York, as also at Glen Riddle in Delaware county, Pennsylvania, and at Amelia Court House, Amelia county, Virginia.

SUNSTONE (Heatstroke; Insolation; Thermic Fever; Siriasis), a term applied to the effects produced upon the central nervous system, and through it upon other organs of the body, by exposure to the sun or to overheated air. Although most frequently observed in tropical regions, this disease occurs also in temperate climates during hot weather. A moist condition of the atmosphere, which interferes with cooling of the overheated body, greatly increases the liability to suffer from this ailment.

Sunstroke has been chiefly observed and investigated as occurring among soldiers in India, where formerly, both in active service and in the routine of ordinary duty, cases of this disease constituted a considerable item of sickness and mortality. The increased attention now paid by military authorities to the personal health and comfort of the soldier, particularly as regards barrack accommodation and dress, together with the care taken in adjusting the time and mode of movement of troops, has done much to lessen the mortality from this cause. It would appear that, while any one exposed to the influence of strong solar heat may suffer from the symptoms of sunstroke, there are certain conditions which greatly predispose to it in the case of individuals. Causes calculated to depress the health, such as previous disease, particularly affections of the nervous system—anxiety, worry or overwork, irregularities in food, and in a marked degree intertemperance—have a powerful predisposing influence, while personal uncleanliness, which prevents among other things the healthy action of the skin, the wearing of tight garments, which impede the functions alike of heart and lungs; and living in overcrowded and insanitary dwellings have an equally hurtful tendency.

While attacks of sunstroke are frequently precipitated by exposure, especially during fatigue, to the direct rays of the sun, in a large number of instances they come on under other circumstances. Cases are of no infrequent occurrence among soldiers in hot climates when there is overcooling or bad ventilation in their barracks, and sometimes several will be attacked in the course of a single night. The same remark applies to similar conditions existing on shipboard. Further, persons whose occupation exposes them to excessive heat, such as stokers, laundry workers, &c., are apt to suffer, particularly in hot seasons. In the tropics Europeans, especially those who have recently arrived, are more readily affected than natives. But natives are not exempt.

The symptoms of heatstroke, which obviously depend upon the disorganization of the normal heat-regulating mechanism, as well as of the functions of circulation and respiration, vary in their intensity and likewise to some extent in their form. Three chief types of the disease are usually described.

1. Heat Syncope.—In this form the symptoms are those of exhaustion, with a tendency towards fainting or its actual occurrence. A fully developed attack of this description is usually preceded by sickness, giddiness, some amount of mental excitement followed by prostration, and then the passage and then the perspiration which there are pallor and coldness of the skin, a weak, quick and interminent pulse, and gasping or sighing respiration. The pupils are often contracted. Death may quickly occur; but if timely treatment is available recovery may take place.

2. Heat Apoplexy or Asphyxia.—In this variety the attack, whether preceded or not by the premonitory symptoms already mentioned, is usually sudden, and occurs in the form of an apoplectic seizure, with great vascular engorgement, as seen in the flushed face, congested eyes, quick full pulse and stertorous breathing. There is usually insensibility, and convulsions are not infrequent. Death often occurs very sudden. This form, however, is also amenable to treatment.

3. Thermic Fever.—This variety is characterized chiefly by the excessive development of fever (hyperpyrexia), the temperature of the body rising to 105° or 106°, and at some portion of the body remaining so high. Among other symptoms are those of exhaustion, with a tendency towards fainting or its actual occurrence. A fully developed attack of this description is usually preceded by sickness, giddiness, some amount of mental excitement followed by prostration, and then the passage and then the perspiration which there are pallor and coldness of the skin, a weak, quick and interminent pulse, and gasping or sighing respiration. The pupils are often contracted. Death may quickly occur; but if timely treatment is available recovery may take place.

Besides these, other varieties depending on the prominence of certain symptoms are occasionally met with. The chief changes in the body after death from heatstroke are those of anaemia of the brain and congestion of the lungs, together with softness of the heart and of the muscular tissues generally. The blood is dark and fluid and the blood corpuscles are somewhat altered in shape. Attacks of sunstroke are upon the whole, more fatal to Europeans, especially upon the nervous system. A liability to severe headache, which in many cases would seem to depend upon a condition of chronic meningitis, epileptic fits, mental irritability and depression of the disposition are among the more important. It is often observed that heat in any form is ever afterwards ill borne, while there also appears to be an abnormal susceptibility to the action of stimulants. The mortality from sunstroke is estimated at from 40 to 50%.

Treatment.—Should be adopted to prevent attacks in the case of those who must necessarily be exposed to the sun. These consist in the wearing of loose clothing, with the exception of the head-dress, which ought to be worn close to the head, in due attention to the function of the skin, and in the avoidance of alcoholic and other excesses. Cold water may be drunk in small quantities at frequent intervals. Sweat in the face, after exposure, is not recommended. The treatment of a patient suffering from an attack necessarily depends upon the form it has assumed. In all cases he should if possible be at once removed into a shaded or cool place. Where the symptoms are mostly those of shock and there is a
SUPERANNUATION—SUPERINTENDENT

Tendency to death from heart failure, rest in the recumbent position, the use of the moderate stimulants, such as ammonium carbonate, &c., together with friction or warm bath applied to the extremities, are the means to be adopted. Where, on the other hand, the symptoms are those of apoplexy or of hyperpyrexia, by far the most successful results are obtained by the use of cold (the cold affusion, rubbing the surface with ice, emenata of ice-cold water). The effect is a marked lowering of the temperature, while at the same time a stimulus is given to the respiratory function. Mustard or turpentine applied to the nape of the neck or other hot adjutant. Should the temperature be lowered in this way but unconsciously still persist, removal of the hair and blisting the scalp are recommended. The subsequent treatment will depend upon the nature of the resulting symptoms, but change to a cool climate is often followed by marked benefit.

SUPERANNUATION (formed on the basis of “annual,” “annuity,” from the Late Lat. superannatus, one who has lived beyond the year, super, above, and annus, year, Fr. superanumer, to grow very old), properly a disqualification or relief from office or service on account of old age, infirmity, or of passing the limit of age fixed for service, hence the pension or allowance granted in respect of service at the expiry of the term or the retirement (see Pension). Educationally the term is specifically used of the removal of a backward pupil, who would otherwise remain in a class or form below that which his age demands.

SUPERcargo, a term in maritime law (adapted from the Span. sobrecargo, one over or in charge of a cargo) for a person employed on board a vessel by the owners of the cargo to manage their trade, or sell the merchandise at the ports to which the vessel is sailing, and buy and receive goods for shipment homewards. He has control of the cargo unless expressly or impliedly limited by his contract or agreement. He differs from a factor, who has a fixed place of residence at a port or trading place, by sailing from port to port with the vessel to which he is attached.

SUPEREROGATION (Late Lat. supererogatio, payment beyond what is due or asked, from super, beyond, erogare, to pay out, expend, ex, out, rogare, to ask), the performance of more than is asked for, the action of doing more than duty requires. In the theology of the Roman Church, “works of supererogation,” those which are performed beyond what is required by God, thus forming a reserve store of works of merit which can be drawn upon for the dispensation of those whose works fall short of the standard required.

SUPERINTENDENT, a term which, apart from its general use for an official in charge, has a distinct religious connotation, being applied, e.g. to the head of a Sunday school and to the chief minister in a Methodist circuit. In its most important historical sense it refers to certain ecclesiastical officers of reformed churches of the Lutheran model.

At the Reformation the question of the ordering and constitution of the churches was urgent. The greatest confusion prevailed: the priests were often dissolute, the people were ignorant, and meanwhile nobles were seizing the Church lands. Luther and Melanchthon would have preferred to retain the old episcopal control, and to have charged the bishops with the duty of making the necessary alterations in the ecclesiastical constitution. For, while they taught that in spiritual powers all ministers were equal, they recognized the propriety of allowing administrative distinctions. But the bishops were unwilling to come to any terms with the Reformers, and hence became superintendents to certain officers of the new order. The name of superintendant was then given to a class of men who discharged many of the functions of the older bishops, while bearing a character which in several respects was new. Only in Denmark was the name of bishops reserved for the new officers after the Lutheran model had been adopted and the older bishops had been deposed and imprisoned. It is still used there, though no claim is made that it is the sign of formal apostolical succession. In Scotland the First Book of Discipline provided not only for ministers, teachers, elders and deacons, but also for superintendents and readers. The superintendents (who were appointed because of the scarcity of Protestant pastors) took charge of districts corresponding in some degree with the episcopal dioceses, and made annual reports to the general assembly of the ecclesiastical and religious state of their provinces, in the churches of which they also preached.

The distinctive character borne by the new officers was determined by the cardinal principles which Luther had laid down in his work regarding the religious functions of the state. He conceived of the state as the delegated power of God, and as being set to direct and control the external fortunes of the Church. He hoped that righteous magistrates would at all times form a sound court of appeal in times of ecclesiastical disorder, and that they would guard the interests of truth and justice more securely than had been done under papal jurisdiction. The superintendents who now had to undertake large administrative responsibilities in the Church were therefore to be appointed by the civil power and to be answerable to it. They were to stand as intermediaries between the prince or magistrates on the one hand, and the ministers in their districts on the other.

In his earlier writings Luther had laid his main emphasis on the spiritual priesthood of all believers. Every sincere Christian was declared free, not only to preach, but also to administer the sacraments and to rebuke evil livers. The differences in office and function between the members implied no difference in rank, for the members of Christ’s Church were all members of His body, and Luther believed that they would all be ruled into true order and charity by the Head. But he became dismayed by the Peasants’ War, and his faith in the virtues of the average man never recovered itself. The concept was seen in his later writings, where he expresses his conviction that men need to be directed and restrained from without, and he looks to the state to undertake this duty. In the last resort the civil magistrates must take control of the Church. His vindication for thus subordinating the ecclesiastical to the civil lay in his assumption that the rulers of a Christian land would themselves be Christian, and that it was the Christian duty of the Church to render obedience to those who had been ordained of God to bear rule. He, and the rest of the Reformers, were firm believers in a visible Catholic Church as were any of those of whom he speaks as “the adherents of the old religion,” and Luther, always conservative in feeling, clung to an alliance with the state and denied that the repudiation by the Reformers of papal authority had severed them from the visible Church.

The character of the office and duties of the superintendent were not everywhere the same. Luther shrank from imposing any stereotyped forms and asked that the special circumstances of each separate district should be consulted. He hoped that as few changes as possible would be made, and trusted that what was devolved down would be done decently and well. But the civil authorities, when they started to reorganize the Church in their respective dominions as they thought best, was not felt to present any great difficulties in the free towns, for institutions of self-rule had there grown strong and schemes of ecclesiastical readjustment were speedily drawn up. Richter and Sehling1 have published a number of these ordinances, and they show that as a rule one of the city clergy was appointed superintendent by the city fathers and set in a position of administrative authority over all the churches within their jurisdiction. They were invited in as expressing their good will. Great difficulties presented themselves in the territories of the German princes, and in the case of Saxony Luther proposed to the elector that his first step should be to send out a commission of investigation which should report on the moral and spiritual condition of his principality, district by district. His proposal was carried out, and Luther himself became one of the visitors (1527–1528). He found the people in a state of such religious indifference and ignorance, and the clergy living often in such grossness, that his faith in their fitness to govern themselves ecclesiastically sank even lower than before, and he resisted all schemes for self-government such as had been proposed by Francis Lambar.

The church organization which he devised for Saxony provided

1 In their works on Die evangelischen Kirchenordnung des 16ten Jahrhunderts (Weimar, 1846; and Leipzig, 1902–1904).
no place for democratic or representative elements; the grasp of the state must at all times be felt. The superintendent must speak at all times as a minister of the state, and the state must be represented in the synod to which he makes his first report, for upon the synod there must sit not only the pastors but also a delegate from every parish. If any appeal should be made from the decisions of the synod it must be heard in the court of the state, and from the decision of that court, which is final, itself, it must be appealed to the juss episcopole, the right of oversight of the churches. Luther proposed that he should exercise this right by appointing a consistorial court composed in part of theologians and in part of canon lawyers, and it was thus that in 1542 the Wittenberg ecclesiastical consistory was formed. Other principalities adopted the model, so that the institution became common throughout the Lutheran churches.

In this scheme the superintendent (or superintendant) was charged with such part of the duty of the older bishops as had been purely administrative. He must concern himself with the discharge of their duties by the pastors of the churches, as well as with their character and demeanour. He must supervise their conduct of public worship, as well as give them licence to preach. He must take cognizance of their ministry to the indigent in their parishes, and of their management of the schools. He must further direct the studies of candidates for the pastoral office. He was answerable to the state for the conduct of the synod and for reports on the state of his province and those authorities had final power in the matters referred to. If those matters, however, presented technical difficulties, they could be referred to the consistorial courts.

The appointment of such a superintendent would seem to have been found in the decisions of Prince John of Saxony about 1537. He assigns the duties of the office, and commends the new-school teaching of the pastors under him, faithfully to warn them of all errors, and, in case they prove obstinate, to report them to the electoral court. He must further give close attention to the due observance of the marriage laws, for in this matter the previously appointed visitors to the principality had reported grave laxity. The title of this office was not new, but was taken over from the later Scholastics, who had employed it as a suitable translation of the words kirchenordnung, a phrase which had come into the church.

In the case in which the old bishops were retained in Lutheran communities their tenants held office directly from the state.

Some of the smaller principalities appointed but a single superintendant, the later, who was also the pastor, being answerable to a consistory, sat as spiritual member on the territorial council, whilst in towns the superintendent was summoned to the town council when matters of a secular nature arose. In larger states there were various classes of superintendants with their respective duties severally assigned.

In modern times the functions of the superintendent have been somewhat confused in consequence of the introduction into Lutheran Church theory of inconsistent elements of Presbyterian and synodal type.

J. T. M. Lindsay, History of the Reformation (1906), i, 400-416; and the articles "Kirchenordnung" and "Superintendent" in Herzog-Hauck's Realencyklopädie für protestantische Theologie und Kirche.

SUPERIOR, the most north-westerly of the Great Lakes of North America, and the largest body of fresh water in the world, lying between 46° 30' and 48° N., and 89° 30' and 92° W. It is the largest body of inland water in the state of Minnesota, and S. by Wisconsin and Michigan. It has deep, extremely cold, clear water, and high and rocky shores along a large portion of its coast. Its general form is that of a wide crescentic convex towards the north, but its shores are more irregular in outline than those of the other lakes. Following the curves of its axis from west to east the lake is about 383 m. long, and its greatest breadth is 160 m. Its maximum recorded depth is 1308 ft., and its height above mean sea level is 602 ft., or about 21 ft. above that of lakes Michigan and Huron, to which it is joined at its eastern extreme by a narrow connecting arm. In large streams of 200 rivers, and drains a territory of 48,600 sq. m., the total area of its basin being 80,400 sq. m. The largest river which empties into it is the St Louis, at its western end. The principal rivers on the north shore are the Pigeon, which forms the international boundary line, the Kamissakwa, the Nipigon, which drains the lake of the same name and together with the lake is about 200 m. long, the Pic, the White and the Michigan. No large rivers empty into Lake Superior from the south. There are not many islands in the lake, the largest among them being Isle Royal, by far the largest in the eastern part; St Ignace, in the northern part, off the mouth of the Nipigon River; Grand Island between Pictured Rocks and Marquette; Manitou Island, east of Keweenaw Point, and the Apostle Group, to the north of Chequamegon Bay.

The boundary between the United States and Canada runs up the middle of the outlet of the lake and follows a median line approximately to about mid-lake; thence it sweeps north-westward, so as to include Isle Royal within the territory of the United States, and continues near the north shore, to the southwest of Pigeon River, which it follows westward, leaving the whole west end of the lake in United States territory.

Lake Superior lies in a deep rift in rocks principally of Archean and Cambrian age, of the Laurentian, Huronian and Keweenaw formations, rich in minerals that have been extensively worked. The lake is, as it were, surrounded by iron, which is the probable cause of very strong magnetic fields of influence. Native silver as well as silver ores exist around Thunder Bay, native copper was formerly worked on Isle Royal, and rich copper mines are worked on the south shore, while nickel abounds in the north-western part. The Archean belt produces a picturesque coast-line, the northern part particularly being indented by deep bays surrounded by high cliffs, mostly burnt off and somewhat desolate; the islands also rise abruptly to considerable heights, the north shore furnishing the boldest scenery of the Great Lakes. On the south coast, opposite the broadest part of the lake, are precipitous walls of red sandstone, extending about 14 m., famous as the Pictured Rocks, so called from the effect of wave action on them. There are no appreciable tides and little current. A general set of the water towards the outlet exists, especially on the southern shore. From the Apostle Islands to the eastward of Keweenaw point this current has great width, and towards the eastern end of the lake spreads out in the shape of a fan, a branch passing to the northward and westward reaching the north coast. Autumn storms raise dangerous seas. The level varies with the season, and also from year to year, the maximum variation, covering a cycle of years, being about 5 ft. The discharge of the lake is computed to be 75,200 cubic ft. per second at mean stage of water.

The season of navigation, controlled by the opening and closing of the Sault Ste Marie canals, averages about eight months—from the middle of April to the middle of December. The season has been extended for a few days, in both spring and autumn, by the use of ice-breaking tugs at Fort William and Port Arthur, this service being organized by the government particularly to facilitate the movement of grain from the Canadian North-west. (The lake never freezes over, though the temperature of the water does not, even in summer, rise far above freezing point. The bays freeze over and there is border ice, often gathered by wind into large fields in the bays and extremities of the lake.)

Lake Superior is fairly well provided with natural harbours, and works of improvement have created additional harbours of refuge at various points. Marquette, Mich., Presque Isle Point, Mich., Agate Bay, Minn., Grand Marais, Minn., and Ashland, Wis., are harbours which have protective breakwaters across their mouths. Duluth, Superior, Port Wing, Wis., Ontonagon, Mich., and Grand Marais, Mich., are harbours with entrances formed by parallel breakwaters running along the beach, and are no longer supplied with natural harbours. The traffic on Lake Superior grows constantly in volume, the increase in tonnage of each year over that of the preceding year having, for 50 years past, averaged 20%. The freight carried into and out of the lake, as gauged by
SUPPERIOR—SUPPLY AND TRANSPORT

The statistics gathered at the Sault Canal offices, aggregated in 1907
over $8,000,000 (short) tons. The principal freight shipped east-
ward consists of flour, wheat and other grains, through Duluth-
Superior to the United States. Fort William, the
Arthur from the Canadian prairies; copper ore from the mines on
the south shore; iron ore in immense quantities from both shores,
the principal ore shipping ports being Ashland, Two Harbors,
Marquette, Superior, and captive ore bringing into the
tributary rivers. West-bound freight consists largely of coal
for general distribution and for terminal railway points.

The fishing industry of Lake Superior is important, the total tonnage of salmon-trout
(Salvelinus namaycush, Walb), ranging from 10 to 50 lb in weight,
being gathered from the individual fishermen by steam tenders and
shipped by rail to city markets. The river Nixon, on the north
shore, is the chief salmon-trout stream (Salvelinus nuttallii.
Mitchell) of unusual size; and all rivers and brooks falling into the
lake are trout streams.

Directions for Lake Superior and the St. Mary’s River, U.S. Hydro-
graphic Office publication No. 108 A. (Washington, 1906), with
supplements.

(W. P. A.)

SUPPERIOR, a city, a port of entry and the county-seat of
Douglas county, Wisconsin, U.S.A., about 140 m. N. by E. of
Minneapolis and St. Paul. Superior is on both sides of Lake
Superior, connected directly opposite Duluth, Minnesota, with
which it is connected by ferry and by railway and
road bridges.

The harbour, which has been improved by the Federal govern-
ment, is formed by two narrow strips of sandy land, known as
Minnesota and Wisconsin Points, which extend several miles
across the head of the lake from the Minnesota and Wisconsin
stores respectively and almost meet in the centre. The body
of water thus formed, Superior and Allouez bays, varies in
width from 1 to 12 m., and is 9½ m. long. St Louis Bay, on
the west, is about 1½ by 4 m. The city is situated on gently
rising ground facing the bays, and has 20 m. and Allouze-front.

The second port of Superior at different times and in
different places is responsible for the large area covered by
the city (36½ sq. m.) and its appearance is that of three distinct
towns. The intervening portions have however been platted and
are now largely settled. Superior is the seat of a state normal
school (1866), which occupies a splendidly equipped building,
and, in addition to the ordinary normal courses, has departments
of kindergarten training, manual training and domestic science.
The city is the see of a Roman Catholic bishop. Superior has a
cheap fuel supply and power is furnished by electricity gene-
rally connected to the several towns.

1905 the value of its factory
products was $6,556,081. Flour is the principal product, and
shipbuilding is important. Among steel ships, the type known as
the “whaleback” originated here; and iron and wooden
ships, launches and small pleasure craft are also made. Other
manufactures are railway cars, casks, cooperage, saw and planing
mill products, furniture, wooden ware, windmills, gas-engines,
and mattresses and wire beds. Superior is an important
grain market. Much iron and copper ore is shipped from the
Duluth-Superior harbour; and large quantities of coal, brought
by lake boats, are distributed from here throughout the American
and Canadian markets. The total tonnage of Duluth-
Superior Harbour was estimated in 1908 to be exceeded in the
United States only by that of New York and that of Philadelphia.

Pier Esprit Radisson and Medard Chouart des Grosel-
liers probably visited the site of Superior in 1662, and it is prac-
tically certain that other French coureurs-des-bois were here
at different times before Daniel Greysolon, Sieur Du Lhut
(Duluth), established a trading post in the neighbourhood about
1678. About 1820 the Hudson’s Bay Company established a
post here, but there was no permanent settlement until after
the middle of the 19th century. Attention was directed to
the site by a survey made by George R. Stantz, a government
surveyor, in 1852, and in 1853 a syndicate of capitalists, at
the head of which was William Wilson Corcoran, the wealthy
banker, associated with whom were Senators Stephen A. Douglas (from whom the county was named), R. M.
T. Hunter and J. B. Bright, Ex-Senator Robert J. Walker,
Congressmen John C. Breckinridge and John L. Dawson,
and, by necessity, largely Southern politicians and members of
Congress, bought lands here. A settler of the name of Superior
was among them. The proprietors secured in 1856 the construc-
tion of a military road to St Paul, Minnesota, 160 m. long. The town
grew rapidly, and in 1856–1857 had about 2500 inhabitants.
The panic of 1857 interrupted its growth, and the population
fell so that in 1860 there were only a few hundred settlers
on the town-site. The Civil War increased the depression,
and the lands of those who had taken part against the Union
were confiscated. In 1862 a series of stockade was built as
a protection from the Indians. Within the area under the govern-
ment of the town of Superior, consisting of the land granted
with the county, West Superior was platted in 1883 and South
Superior soon afterwards. A village government was estab-
lished in September 1887, including the three settlements men-
tioned, and in April 1889 Superior was chartered as a city.
The harbour was surveyed in 1823–1825 by Lieut. Henry Wolsey
Bayfield (1795–1885) of the British Navy. In 1860–1861
it was resurveyed by Captain George G. Meade, who was engaged
in the work at the outbreak of the Civil War. A branch of
the Northern Pacific railway was built to Superior in 1881.

SUPPÉ, FRANZ VON (1820–1895), Austrian musical com-
poser, whose real name was Francesco Ezechielle Ermenegildo
Suppé-Demelli, was born at Spalato, in Dalmatia, in 1820, and
died at Vienna in 1895. Originally he studied philosophy at
the university of Padua, but on the death of his father devoted
himself to music, studying at the Vienna conservatoire. He
began his musical career as a conductor in one of the smaller
Viennese theatres, and gradually worked his way up to be one
of the most popular composers of ephemeral light opera of
the day. Outside Vienna his works never won much success.
Of his sixty comic operas Patinites (Vienna, 1870; London,
1871) were the most successful. Suppé’s work was one of
only enjoyed moderate favour. Suppé’s overture to Dichter
und Bauer is his most successful orchestral work. He also
wrote some church music.

SUPPLY (through Fr. from Lat. supplyre, to fill up), pro-
vision; more particularly the money granted by a legislature to
carry on the work of government. In the United Kingdom the
granting of supply is the exclusive right of the House of
Commons, and is carried out by two committees of the House,
one of supply and the other of ways and means (see Parlia-
mment). In the United States supply originates in the House of
Representatives (see United States: Appropriation).

In Scotland commissioners of supply were officers appointed to
assess and collect the land tax offered as surplus to the sovereign.
Under the Lands Valuation (Scotland) Act 1854 all owners of
property of a certain value were qualified as commissioners of
supply. Their duties were also enlarged to comprising the granting of
appropriation, or the legal application of the proceeds of customs,
bating food, forage and stores for men and horses. In modern
history these supplies have become more and more varied as
weapons developed in complexity, power and accuracy of
workmanship. In proportion, the branches of an army which are
charged with the duties of "supply and transport " have become
specialized as regards recruiting, training and organization.

The predatory armies of the middle ages not only lived upon
the country they traversed, but enriched themselves with the
plunder they obtained from it, and this method of subsisting and paying an army reached its utmost limits in the Thirty Years' War. During the last stages of this war Germany had been so thoroughly devastated that the armies marched hither and thither like packs of hungry wolves, every soldier accompanied by two or three non-combatants—camp followers of all sorts, mistresses, ragged children and miserable peasants who had lost all and now sought to live by robbing others under the protection of arms. An English officer of the time wrote that twelve years before the peace of Westphalia, reported that at Bacharach-on-Rhine he had found "the poor people dead with grass in their mouths," and that a village at which he stayed "had been pillaged eight-and-twenty times in two years, and twice in one day."

From these horrors there followed a revulsion to the other extreme. Unless ordered by higher authority for political reasons to sack a particular town or to pillage a particular district, the soldiers were rigidly kept in hand, rationed by their own supply officers and hanged or flogged by the men if an outbreak of the old vices made the example necessary. After 1648 there were very few districts in Middle Europe that could support an army for even a few days, and the burden of their sustenance had to be distributed over a larger area. Thus, at the mere rumour of an army's approach, the peasantry fled with all their belongings into the fortified places, armies soon came to be supplied from "magazines," which were filled either by contract from the home country or by inducing the peasantry—by means of good conduct and cash payments—to bring their produce to market. These magazines were placed in a strong place, and if the town was not available, a traverse had to be undertaken to meet the demand. Moreover, soldiers in Marlborough's time were not as easily obtained as in the Thirty Years' War, and they had to be housed and fed comfortably enough to make it worth their while to stay with the colours instead of deserting. From these and similar conditions there grew up a system of supply and transport usually called the "magazine system," under which an army was bound, under penalty of dissolution, to go no farther than seven marches from the nearest fortress, two days from the nearest field bakery, and so on. When an 18th-century army foraged for itself it was because the regular supply service was interrupted, i.e. when it was in extremis. But the relative rarity of wars in the 18th century, the habit of demanding nothing from the inhabitants of the country traversed by an army, and the virtual exclusion of the people from the prince's quarrels, gave Europe a century's respite in which to recover from the drain of the Thirty Years' War. And therefore, when the French Revolution came, the attempts of the armies of old Europe to suppress it without robbing a single Frenchman of a loaf of bread proved futile, and soon the national army of the Revolution traversed the country unencumbered by tents, magazines and supply trains, swept over southern Germany and Italy. The Revolutionary armies differed indeed from those of the old wars in this, that they did not devastate wantonly, nor did they murder for the sake of loot. But they were merciless in their exactions, and, moreover, the tides of their invasions flowed in particular channels, so that the greater part of the invaded country escaped. This had a considerable, sometimes even a predominant, influence on the strategy pursued, a retreat along their own lines of communication being often in fact avoided by the French as being the worst fate that could befall them. Napoleon, however, systematized the wasteful and irregular requisitioning that his predecessors had introduced, and in his hands the supply service, like all else connected with the art of war, underwent a thorough reform. His strategy in the offensive passed through two distinct stages—

(a) the swift and sudden descent into the theatre of war, and
(b) the close grouping of his armies in view of the decisive blow.

The first stage was characterized by extraordinarily swift movement, complete independence of all trains (other than the reserves of ammunition) and thorough exploitation of the food resources of the traversed zone. If the troops suffered, as well as the inhabitants, this did not shake the emperor's purpose in the slightest. If all the disorders which are the natural consequence of ill-regulated requisitioning—that is, marauding—cost the army 50,000 men, he had foreseen the loss and taken 50,000 men more than he needed for the battle. But the second stage, which as a rule involved three or four days' occupation, without considerable movement, of a restricted area, required other measures of supply. In this the army lived upon magazines which were filled from the captured supply trains from the available supplies in the area, and from the resources accumulated in requisitioned vehicles close to the head of the routes followed in the first period. These resources were collected in the towns within this concentration area, and placed "out of reach of an insult" (that is, made safe against raiders) with a garrison and field works to supplement the town walls and gates. From this centre of operations Napoleon never allowed himself to be severed, whereas to the preservation of the route between France and that centre of operations he gave with Napoleonic arrogance, to a military advantage (other than the existence of railways) with much less than Napoleonic severity. Their system has been accepted as the best for European warfare by all the great powers, whose organizations and methods of transporting and issuing supplies are the same in principle.

This principle is based on the Napoleonic distinction between supplies required during an advance and those required during a concentrated halt. The British Field Service Regulations (1809), pt. ii., lay it down that "the system of subsistence should be elastic and readily adaptable to every situation as it arises, and that it must always be based on the rule that "all mobile supplies are to be regarded as a reserve" for use when neither local nor line-of-communication resources are available. As a general rule local resources should be used before the line of communication is called upon, and last of all the call is made on the mobile supplies in the hands of the fighting units. During a strategical concentration or a long halt "the resources of the immediate neighbourhood cannot be expected to support the troops. At such times they may be supplied from field dépôts established at convenient centres, and filled with supplies that are obtained by purchase or requisition and collected by requisition or hired (civilian) transport." During an advance, on the other hand, "by far the most advantageous method is for the troops to be rationed by the inhabitants on whom they are billeted . . . This method should be employed whenever possible."

The extent to which it can be employed varies considerably with the place and the season, but the British and all continental armies have their own "rules of thumb" or rough generalizations based on experience. General Lewal (Stratégie de marche, p. 47) says that in a country of 20 inhabitants to the square kilometre, or 180 to the square mile, 1,000 men can be subsisted for one day on an area of 22 square
kilometres or 5/8 square miles, or 1200 per square mile. General Napoleon, in his Sadowa gives 36 square miles as sufficient for the maintenance of an army corps (30,000–35,000) or about 1100 men to the square mile during the assembly period, but only on condition of helping out local resources by special supplies from the base. The British Field Service Regulations state that ordinary agricultural districts of Western Europe, not previously traversed by troops, will support a force of twice the strength of the population, and for wheat at a maximum. This would mean using fourteen rations from each inhabitant, but the incidence of the burden is spread over several days. A practical rule therefore would seem to be, in a district of 200 inhabitants to the square mile, to allot 1400 men per square mile for a flying passage of one day and 400 for a stay of one week, the resources of the country being more thoroughly and systematically exploited in the latter case. A British division (combatant column only) closing up to half its marching depth at the end of the day would require 12 square miles, and as its depth would be about 51 miles, its front or width would perhaps extend for only a mile on either side of the road. It is quite possible to move two divisions for several consecutive days on the same road, living on the country exclusively, subject to the condition that the second should halt on the areas which the first has passed through without stopping. In continental armies the rule is, in fact, "one army corps (= 2 British divisions) on one road." During the period of concentration, however, even if in movement, a modern army will necessarily be supplied in somewhat the same way as Napoleon's. The billets will be allotted "without subsistence," so the regimental officers will be called upon to ration their men, while all around the occupied towns and villages the supply officers and their mounted escorts will requisition food and vehicles to bring the food into the concentration area. In view of this, "supply officers will be sent on with cavalry or mounted brigades to investigate the resources of the country ahead of the main body, and if possible to collect supplies at suitable points." Only commissioned officers and, as a rule, only those officers to whom the power is expressly delegated are entitled to carry out requisitions, though in an emergency a commander of any rank may obtain from any inhabitant articles of the requisition. It is quite impossible to move two divisions for several consecutive days on the same road, living on the country exclusively, subject to the condition that the second should halt on the areas which the first has passed through without stopping. In continental armies the rule is, in fact, "one army corps (= 2 British divisions) on one road." In continental armies the rule is, in fact, "one army corps (= 2 British divisions) on one road."
European, and to a large extent in other warfare, horseless transport by far the most generally used. Mechanical transport (generally either traction engines with trucks or motor lorries) is, however, superseding to a still greater extent horseless transport. The vehicle usually employed for military transport is the "General Service Wagon," a heavily-built springless four-wheeled vehicle drawn by six or four horses according to circumstances, with a weight of up to and over the allowances of a load of 30 cwt. There are also four-horse "limbered wagons" consisting of body and limber, weighing 13 cwt. empty and 43 cwt. fully loaded, and lighter two-wheeled carts which can take 3 cwt. empty or 15 cwt. load.

As regards organization and functions, road transport is used on the line of communications to supplement the railway, and consists of the General Service Corps or of civilian personnel under A.S.C. control. Transport with the field units is, as has been said, divided into first line, which accompanies the fighting troops, and second line, which finds them. The former is used exclusively by the A.S.C. (or regimental details in the case of regimental transport) and composed of regulation-pattern carts and wagons. The first-line vehicles include ammunition wagons and carts, tool carts, engineer vehicles and medical vehicles. All baggage and store and supply wagons, as well as a proportion of medical, ammunition and engineer vehicles, form the second line.

SUPRA-PERENAL EXTRACT. The extract of the suprarenal gland is one of the most valuable remedies recently introduced in medicine. Feeding with the fresh gland of sheep was at first practised, but the sterilized glycerin preparation known as supra-renal extract is now used, the dose being 5 to 15 minims. The active principle of the gland, best known as adrenaline or epinephrine, occurs only in the medulla of the gland. It forms minute white crystals, soluble in weak solutions of hydrochloric acid. The U.S.P. contains a desiccated preparation, Glandulae suprarenales siccae. Adrenaline is most frequently used in 1% solutions of the chloride.

Adrenaline has no action on the unbroken skin, but locally astringent properties, as well as the tonic and stimulant properties, are shown. On the other hand, the heart, when exposed, is much affected by adrenaline, owing to its powerful constriiction of the capillaries by stimulating the muscular fibres of the vessel walls. It acts rapidly in a similar manner when hypodermically injected. The vessels of the uterus are strongly acted upon by it, but the effect on the cerebral vessels is slight, and the pulmonary vessels are unaffected. The heart is slowed and the systole increased. Adrenaline stimulates the salivary glands. It also produces a temporary glycosuria. In poisonous doses it causes haemorrhages into the visera and oedema of the lungs.

In Addison's disease the use of supra-renal extract has been beneficial in some cases, but its effects in the cases of haemorrhage. For this purpose it is given in conjunction with local anaesthetics such as cocaine in order to produce bloodless operations on the eye, nose and elsewhere. It is also useful in haemorrhage from small vessels, when used as a在我的 bloodspot, as in epistaxis. In menorrhagia and menorrhagia it is also of use in surgical shock and in chlorform syncope an injection of adrenaline often saves life through the rise of blood pressure produced. An attack of bronchial asthma may be treated by an hypodermic injection of adrenaline solution. It should never be used in the treatment of haemoptysis. Similar commercial products on the market are hemins, renadrenaline, supraprene, adrenalin, paramepine and renostypting. Supra-nial snuff containing the dry extract with menthol and boracic acid is of use in hay fever. Rhizodine is of this type. Suppositories containing supra-renal extract are used to effect heating of the lower haemorrhage.

The chemistry of adrenaline has been mainly elucidated by the investigations of Pauli, Jowett and Bertrand; Jowett proposing a constitution (see annexed formula) which was early accepted in codification. Many substances having related constitutional constitutions have been synthetized, and it has been found that they resemble adrenaline in increasing the blood pressure. For example, the corresponding ketone, adrenaline obtained in 1904 by Stolz is active, and the methyl derivative (obtained by Schöpf) has an even greater activity, without destroying the potency. It seems that the para-hydroxyl group is essential. For instance, para-hydroxyphenylalanine, HO-CH(OH)-CH(NH_2)\_2, which is one of the active bases of ergot, clove, and cinchona bark, is not active. (Chem. Ber., 1909, 32, 95, pp. 1123, 1720; K. W. Rosenmund, Ber., 1909, 29, 278.) as does also its dimethyl derivative homoverine, an alkaloid found in the leaf of Rauwolfia (C. Ber., 1909, 29, 1393.). Adrenaline is optically active, the naturally occurring isomer being the laevorotatory form. It seems that, like nicotine, the laevo base has a much greater physiological activity than the dextro.

SUPREME COURT OF JUDICATURE, in England, a court of law established by the Judicature Act 1873, by section 3 of which it was provided that the high court of chancery, the courts of king's bench, common pleas, and exchequer, the high court of admiralty, the court of probate and the divorce court, should be united under this name. By section 4, the Supreme Court was to consist of two divisions, one to be called the "high-court of justice" and the other the "court of appeal." See further under JUDICATURE ACTS, and also the articles under the headings of the different courts enumerated above.

The Supreme Court of the United States is the head of the judicial branch of the Federal Government. It is established by article iii. of the Constitution, which states that the "judicial power of the United States shall be vested in one Supreme Court, and in such inferior courts as the Congress may from time to time ordain and establish." (s. i.) Section ii. states that the "judicial power shall extend to all cases in law and equity arising under this Constitution, the laws of the United States, and treaties made, or which shall be made, under their authority; to all cases affecting ambassadors, other public ministers and consuls; to all cases of admiralty and maritime jurisdiction; and on questions of public policy arising under such regulations as the Congress shall make." The Supreme Court of the United States also occupies the unique position of being guardian of the Constitution. It has to decide whether a measure passed by the legislative powers is unconstitutional or not, and it may thus have to veto the deliberate resolutions of both houses of Congress and the president.

See UNITED STATES.

SURABAYA (Dutch Soerabaja), a seaport of Java, in the eastern division of the island, on the narrow Surabaya strait, which separates the island of Madura from Java, and at the mouth of the Kali Maea river. Pop. (1900), 146,944. (Europeans 106; Chinese 38; Dutch 1.) This arrorable or "the real medina" of Java. Its town. Its roadstead is sheltered by Madura, and it has important dockyards. It is also the headquarters of the military authorities for East Java, and has artillery workshops. Railways running north-west, south-west and south give it connections throughout the island. In the old town, with its partly demolished fortifications, houses, shops and warehouses are more closely packed and the streets are narrower than in most East Indian towns, and, although a considerable number of Europeans live in this quarter, the outlying quarters, such as Simpang (where is the government house) and Tuntungan, are preferable for residence.

SURAJ-UD-DOWLAH (d. 1757), ruler of Bengal. The date of his birth is uncertain, but is generally placed between 1729 and 1736. His name was Mirza Mahommed, and he succeeded his grandfather Aliverdi Khan as nawab of Bengal on the 4th of April 1756. He was a cruel and profligate fanatic. Being offended with the English for giving protection to a native chief who had escaped with treasure from Dacca, he attacked and took Calcutta on the 18th of June 1756. He then permitted the massacre known in history as "The Black Hole of Calcutta" (see CALCUTTA). This atrocious act was soon avenged. Calcutta was retaken by Clive and Admiral Watson on the 2nd of January 1757, and on the 23rd of June, Suraj-ud-Dowlah, routed at Plassey, fled to Rajmahal, where he was captured. He was put to death on the 4th of July 1757 at Murshidabad, by order of Miran, son of Mir Jafar, who had conspired against Suraj-ud-Dowlah and had been present at Plassey without taking part in the battle.
SURAT, a city and district of British India in the northern division of Bombay. The city is on the site where the English first established a factory on the mainland, and so planted the seed of the British Empire in India. Local traditions fix the establishment of the modern city in the last year of the eighteenth century, and in 1814 the Portuguese traveller Barbosa described it as an important seaport, frequented by many ships from Malabar and all parts. During the reigns of Akbar, Jahangir and Shah Jahan it rose to be the chief commercial city of India. By the end of the 16th century the Portuguese were undisputed masters of the Surat seas. But in 1612 Captain Best, and after him Captain Downton, destroyed the Portuguese naval supremacy and obtained an imperial firman making Surat the seat of a presidency under the English East India Company, while the Dutch also founded a factory.

In 1664 Sir George Oxenden defended the factory against Sivaji with a bravery that deserves to rank with Clive's defence of Arcot. The prosperity of the factory at Surat received a fatal blow when Bombay was ceded to the Company (1668) and shortly afterwards made the capital of the Company's possessions and the chief seat of their trade. From that date also the city began to decline. At one time its population was estimated at 800,000, by the middle of the 19th century the number had fallen to 80,000; but in 1901 it had risen again to 119,306. Surat was taken by the English in 1759, and the conquerors assumed the undivided government of the city in 1800. Since the introduction of British rule the district has remained comparatively tranquil; and even during the Mutiny peace was not disturbed, owing in great measure to the loyalty of the leading Mahomedan families.

The city is situated on the left bank of the river Tapti, 14 m. from its mouth, and has a station on the Bombay, Baroda & Central India railway, 167 m. north of Bombay. A moat indicates the dividing-line between the city, with its narrow streets and handsome houses, and the suburbs, mostly scattered among cultivated lands; but the city wall has almost disappeared. On the river frontage rises the irregular picturesque fortress built about 1540. A fire and a flood in 1837 destroyed a great number of buildings, but there remain several of interest, such as the mosque of Nav Saiyid Salih, with its nine tombs, the Saiyid Edroos mosque (1634) and the ornate Mirza Sami mosque and tombs (1661). The principal monuments are the tombs of English and Dutch merchants of the 17th century, especially that of the Oxenden brothers. Surat is still a centre of trade and manufacture, though some of its former industries, such as ship-building, are extinct. There are cotton mills, factories for ginning and pressing cotton, rice-clearing mills and paper mills. Fine cotton goods are woven in hand-looms, and there are special manufactories of silk brocade and embroidery. The chief trades are organized in guilds. There are many wealthy Parsees, Hindu and Mahomedan merchants.

The District of Surat has an area of 1653 sq. m., and the population in 1901 was 617,079, showing a decrease of 2% in the decade. The district has a coast-line of 80 m., consisting of a barren stretch of sand drift and salt marsh; behind this is a rich, highly-cultivated plain, nearly 60 m. in breadth, at the mouth of the Tapti, but narrowing to only 15 m. in the southern part, and on the north-east are the wild hills and jungle of the Dans. The principal crops are millets, rice, pulses, cotton and a little wheat. After Surat city the chief centre of trade is Bulsar. The district is traversed by the main line of the Bombay & Baroda railways with a branch along the Tapti to Nadiad, and the Indian Peninsular Railway in Khandesh. Near the coast, under the influence of the sea breeze, an equable temperature prevails, but 8 to 11 m. inland the breeze ceases to blow. The coast also possesses a much lighter rainfall than the interior, the annual average ranging from 30 in. in Olpad to 72 in Chikhli, while at Surat city the average is 39 in.

The Surat Agency consists of three native states: Dhampur (q.v.), Bansda (q.v.) and Sachin, together with the tract known as the Dans. Total area, 1660 sq. m.; pop. (1901), 179,975. Sachin has a revenue of £17,000 and its chief is a Mahomedan.

SURFACE (Lat. super, whence the Fr. sur, above or upon, and base, q.v.), i.e. upper base, the term in architecture applied to what, in the fittings of a room, is called the chair-rail. It is also used to distinguish the cornice of a pedestal or podium and is separated from the base by the dado or plate.

SURBITON, an urban district in the Kingston parliamentary division of Surrey, England, 13 m. S.W. of Charing Cross, London; and the London & South-Western Railway. Pop. (1891), 12,178; (1901), 15,017. It has a frontage upon the right bank of the Thames, with a pleasant esplanade. The district is largely residential. Surbiton is the headquarters of the Kingston Rowing Club and the Thames Sailing Club.

SURETY, in law, the party liable under a contract of guarantee (q.v.). In criminal practice sureties bound by recognizance (q.v.) are a means of obtaining compliance with the order of a court of justice, whether to keep the peace or otherwise.

SURFACE, the bounding or limiting parts of a body. In the article Curve the mathematical question is treated from an historical point of view, for the purpose of showing how the leading ideas of the theory were successively arrived at. These leading ideas apply to surfaces, but the ideas peculiar to surfaces are scarcely of the like fundamental nature, being rather developments of the former set in their application to a more advanced portion of geometry; there is consequently less occasion for the historical mode of treatment. Curves in space are considered in the same article, and they will not be discussed here; but it is proper to refer to them in connexion with the other notions of solid geometry.

In plane geometry the elementary figures are the point, the line and the plane; and we then have the curve, which may be regarded as a singly infinite system of points, and also as a singly infinite system of lines. In solid geometry the elementary figures are the point, the line and the plane; we have, moreover, first, that which under one aspect is the curve and under another aspect the developable (or torse), and which may be regarded as a singly infinite system of points, of lines or of planes; and secondly, the surface, which may be regarded as a doubly infinite system of points or of planes, and also as a special triply infinite system of lines. The tangents lines of a surface are a special complex.) As distinct particular cases of the first figure we have the plane, which is the special case of the second figure the ruled surface, regulus or singly infinite system of lines; we have, besides, the congruence or doubly infinite system of lines and the complex or tripoly infinite system of lines. And thus the crowds of theories arise which have hardly any analogues in plane geometry; the relation of a curve to the various surfaces which can be drawn through it, and that of a surface to the various curves which can be drawn upon it, are different in kind from those which in plane geometry most nearly correspond to them—the relation of a system of points to the different curves through them and that of a curve to the systems of points upon it. In particular, there is nothing in plane geometry to correspond to the theory of the curves of curvature of a surface. Again, to the single theorem of plane geometry, that a line is the shortest distance between two points, there correspond in solid geometry two extensive and difficult theorems—that of the geodesic lines on a surface and that of the minimal surface, or surface of minimum area, for a given boundary. And it would be easy to say more in illustration of the great extent and complexity of the subject.

In Part I. the subject will be treated by the ordinary methods of analytical geometry; Part II. will consider the Gaussian treatment by differentials, or the E, F, G analysis.

Part I.

Surfaces in General; Torse, etc.

1. A surface may be regarded as the locus of a doubly infinite system of points—that is, the locus of the system of points determined by a single equation 

\[ U = (x^2 + y^2 + z^2)^{\frac{1}{2}} \]

between the cartesian co-ordinates (to fix the ideas, say rectangular co-ordinates) \( x, y, z \); or, if we please, by a single homogeneous relation 

\[ U = (x^2 + y^2 + z^2 + w^2)^{\frac{1}{2}} = 0 \]

between the quadricular co-ordinates \( x, y, z, w \).
The degree \( n \) of the equation is the order of the surface; and this definition of the order agrees with the geometrical one, that the order of the surface is equal to the number of the intersections of the tangent line with the surface. To make the foregoing point definition of the surface, we might develop the notions of the tangent line and the tangent plane; but it will be more convenient to consider the surface \textit{ab initio} from the more general point of view in its relation to the point, the line and the plane.

2. Mention has been made of the plane curve and the cone; it is proper to recall that the \textit{order} of a plane curve is equal to the number of the intersections of it with the tangent line at any point of the plane (the curve), and that its \textit{class} is equal to the number of tangents to the curve which pass through any given point of the plane. The cone is a figure correlative to the plane curve; corresponding to the plane of the curve we have the vertex of the cone, to its tangents the generating lines of the cone, and to its points the tangent planes to the cone; with a given point of view we may consider the generating lines of the cone as corresponding to the points of the curve and its tangent planes as corresponding to the tangents of the curve. From this point of view we define the \textit{order} of the cone as equal to the number of its intersections (generating lines) by an arbitrary plane through the vertex, and its \textit{class} as equal to the number of these tangent planes which pass through any given point of the cone. As a plane curve has singularities (singular points and singular tangents) so a cone has singularities (singular generating lines and singular tangent planes).

3. In order now a surface in connection with an arbitrary line. The line meets the surface in a certain number of points, and, as already mentioned, the \textit{order} of the surface is equal to the number of these intersections. We have therefore with the line a certain number of tangents to the surface, and the \textit{class} of the surface is equal to the number of these tangent planes.

But, further, through the line imagine a plane; this meets the surface in a number of points, and, as we have seen, through the point of contact passes a tangent line which is equal to each other. It may be noticed that for a general surface \((x, y, z, w)^n = 0\), of order \( n \) without point singularities the rank is \( n \); but that the class of the surface is equal to \( n(n-1)/2 \) (what is in fact the case) that the circumscribed cone has singularities, for otherwise its class, that is the class of the surface, would be \( 0(n-1)/2 \), which is not \( n(n-1)/2 \); in other words, the tangent plane of the point of contact of the tangent plane have been assumed as known, but they require to be further explained.

4. In reference to the original point definition of the surface. Speaking generally, we may say that the points of the surface consecutive to a given point on it lie in a plane which is the tangent plane at the given point, and conversely the given point is the point of contact of this tangent plane. This tangent plane is a tangent line touching the surface at the point of contact. Hence we see at once that the tangent line is any line meeting the surface in two consecutive point, or what is the same thing, the point of the surface is a general point of the tangent line as two intersections and in \( n-2 \) other points. But, from the foregoing notion of the tangent plane as a plane containing the point of contact and the consecutive points of the surface, the passage to another point of contact, and the tangent plane, can be made.

A plane in general meets the surface of the order \( n \) in a curve of that order without double points; but the plane may be such that the curve has a double point, and when this is so the plane is a tangent plane having the double point for its point of contact. The double point is either an accnode (isolated point), then the surface at the point in question is convex towards (that is, concave away from) the plane, or it is flat, then the surface in the tangent plane is an \( n-1 \) curve and the plane is tangent to the surface along the line of intersection of the tangent plane and the surface. In the first case there is only one tangent plane, viz., in the point of contact, which gives a plane double point as two intersections, and in \( n-2 \) other points; that is, we have the preceding definition of the tangent line.

5. The complete enumeration and discussion of the singularities of a surface is a question of extreme difficulty which has not yet been solved. A plane curve has point singularities and line singularities; corresponding to these we have for the surface isolated point singularities and isolated plane singularities, but also in the plane curve there are besides the singularities on or torse circumscribed to the surface, and it is among these that we have the non-special singularities which play the most important part in the theory. Thus the plane curve and the surface may be considered to be the same, and the order \( n \), has the non-special line singularities of inflexions and double tangents; corresponding to this the surface represented by the general equation \((x, y, z, w)^n = 0\), of any given order \( n \), has singularities of the isolated line singularities, but the continuous singularities of the spinode curve or torse and the node-couple curve or torse. A plane may meet the surface in a curve or plane, and it is easy to see that in each case there is a singly infinite system of such singular tangent planes, and the locus of the points of contact is the curve, the envelope of the tangent planes the torse. The reciprocal of the surface is therefore defined by the tangent planes; the surface may intersect or touch itself along a curve in such wise that, cutting the surface by an arbitrary plane, the curve of intersection has at each intersection of the plane with the curve on the surface \((1)\) a double point (node) or \((2)\) a cusp. Observe that these are singularities not occurring in the surface represented by the general equation \((x, y, z, w)^n = 0\); of any order; observe also that in this curve a tangent plane or tangent line is defined by cutting the surface by a plane on the surface, and in this way a different definition of the tangent plane must be modified. A tangent plane is a plane such that there is in the plane section a double point in addition to the nodes or cusps at the intersections with the singular lines of the surface.

6. As regards isolated singularities, it will be sufficient to mention the point singularity of the conical line (or cun-node) and the corresponding plane singularity of the conic of contact (or conic trope). In the former case we have a triple curve and a cone, instead of lying in a tangent plane, lie on a quadric cone, having the point for its vertex; in the latter case we have a plane touching a quadric cone in a conic trope, and such a plane must be taken to be the surface enveloped by the polar planes (in regard to a given quadric surface) of the points of the original surface; the surface is thus a cuneo surface in reference to the reciprocal relations of its order, \( n \), class, singularities, etc.

In either case we have a series of unaccented letters and a corresponding series of accented letters, and the relations between them are such that we may in any equation interchange the accented and the unaccented letters; in some cases an unaccented letter may be equal to the corresponding accented letter. Thus, let \( n' \) be as before the order and the class of the surface, but, instead of being continuous to the surface, let it be the order of the plane section and \( a' \) the order of the circumscribed cone; also let \( S, S' \) be numbers referring to the singularities. The form of the equations \( n'' = n'(n'-1)/2; \quad n'' = n'(b-1)/2 \), where the tangent planes of the tangent plane have been assumed as known, but they require to be further explained.

7. In reference to a curve in space in the same manner as a cone corresponds to a plane curve; although capable of representation by an equation \( U = (x, y, w)^n = 0 \), and so of coming under the foregoing point definition of a developable surface, it is an entirely distinct geometric concept. We may indeed, give surface, regard it as a surface characterized by the property that each of its tangent planes touches it, not at a single point, but along a line; this is equivalent to saying that it is the envelope, not of a single, but of an infinite system of tangent planes, or the equivalent of an \( n \) curve, which has been defined to be a singly infinite system of planes. But it is perhaps easier to regard it as the locus of a singly infinite system of lines, each line meeting the consecutive line, or, what is the same thing, the lines being tangent to the line it determines. And in general these lines are through two consecutive lines, or, what is the same thing, an osculating plane of the curve, whence also the tangent plane intersects the surface in the general line of contact, with a residue in the curve of the order \( n-2 \). The curve is said to be the edge of the surface which it encloses, and it is a cuspidal curve thereof; that is to say, any plane section of the developable has at each point a point of contact with the surface, or rather an infinite number; a sheet of paper bent in any manner without crumpling gives a developable.

1 In a plane curve the only singularities which need to be considered are those that present themselves in Pliicker's equations, for every higher singularity whatever is equivalent to a certain number of nodes, cusps, inflexions and double tangents. As regards a surface, no such reduction of the higher singularities has as yet been made.
but we cannot with a single sheet of paper properly exhibit the form in the neighbourhood of the edge of regression: we need two sheets connected along a plane curve, which, when the paper is bent, becomes a complete edge of regression and appears as a cuspal curve on the surface.

It may be mentioned that the condition which must be satisfied in order that the surface be determinate is $H(U) = 0$; that is, the Hessian or functional determinant formed with the second differential coefficients of $U$ must vanish in virtue of the equation $\frac{\partial U}{\partial x} = 0$, or, what is the same thing—$H(U)$ must contain $U$ as a factor. If in cartesian co-ordinates the equation is taken in the form $z = \frac{x}{a} = 0$, then the condition is $r = \frac{s}{a} = 0$ identically, where $a, b, c$ denote as usual the second differential coefficients of $a$ in regard to $x, y$ respectively.

Or consider the surface as the locus of a singly infinite system of lines, where the consecutive lines do not intersect; this is a true surface, for there is a doubly infinite series of tangents to each surface throughout the system. If $n$ is the rank of the lines, there is a tangent plane at the point on the line, and in such wise that, as the tangent plane turns about the line, the point of contact moves along the line.

The complex intersection of the surface is the tangent plane is made up of the unit line counting once and of a residual curve of the order $n - 1$. A quadratic surface is a regulus in a two-fold manner, for there are on the surface two systems of lines each of which passes through a point. A cubic surface may be a regulus (see below, par. 11).

**Surfaces of the Orders 2, 3 and 4.**

10. A surface of the second order or a quadratic surface is a surface such that every line meets it in two points, or—what comes to the same thing—such that every plane section thereof is a conic or quadric curve. Such surfaces have been studied in detail; we have the ellipsoid, the hyperboloid of two sheets, the hyperboloid of one sheet, the elliptic paraboloid and the hyperbolic paraboloid (see Geometry: § Analytical). A particular case of the ellipsoid is the sphere; in abstract geometry this is a quadric surface passing through a given quadric curve, the circle at infinity. The tangent plane of a quadric surface meets it in a quadric curve having a node, that is, in a pair of lines; hence there are on the surface two singly infinite sets of lines. Two lines of the same set do not meet, but each line of the one set meets each line of the other set; the surface is thus a regulus in a two-fold manner. The lines are real for the hyperboloid of one sheet and the elliptic paraboloid; for the other forms of surface they are imaginary.

11. We have next the surface of the third order or cubic surface, which has also been very completely studied. Such a surface may have 27 lines (as related cases with higher points of higher singularity), or it may have a nodal line; we have thus 21 or 22 cases. In the general case of a surface without any singularities, the order, rank and class are $a = 3, b = 6, c = 6$. If, however, we take a line of the general cubic surface lying through 15 planes, we have 45 lines, which are three tangent planes. Observe that the tangent plane is a plane meeting the surface in a curve having a node. For a surface of any given order $n$ there will be a certain number of planes each meeting the surface in a curve with $n$ nodes, that is, triple tangent planes; and, in the particular case where $n = 3$, the cubic curve with 3 nodes is of course a set of 3 lines; it is found that the number of triple tangent planes is, as just mentioned, $= 45$. This would give 135 lines, but through each line we have 5 such planes, and the number of lines is thus $= 27$. The theory of the 27 lines is an important one; we may state that we can, in thirty-six ways, select a system of $6\times 6$ lines, or "double sextet," such that no two of the lines are the same intersect each other, but that each line of the one set intersects each line of the other set.

A cubic surface having a nodal line is a ruled surface or regulus; in fact any plane through the nodal line meets the surface in a node, a line and a plane curve; and there is thus on the surface a singly infinite set of lines. These are called the regulus or ruled surface.

12. As regards quartic surfaces, only particular forms have been much studied. We have the surface at seven points (cnicnodes); an instance of such a surface is Fresnel's wave surface, which has 4 real cnicnodes in one of the principal planes, $4\times 2$ imaginary ones in the other two principal planes, or 9 imaginary ones in all 16 cnicnodes; the same surface has also $4+12$ imaginary planes each touching the surface along a circle (cnicnodes) in all 16 cnicnodes. It was easy by a mere homographic transformation to pass to the more general surface called the tetrahedroid; but this was itself only a particular form of the general surface of the fourth order, the general curves and 16 cnicnodes first studied by Kummer. Quartic surfaces with a smaller number of cnicnodes have also been considered.

Another very important form is the quartic surface having a nodal curve and a ruling, the so-called anallagmatic surface, or the Dupin cyclide (which includes the particular form called Dupin's cyclide). These correspond to the bicuspidate curve of plane geometry. Other forms of quartic surface might be referred to.

**Congruences and Complexes.**

13. A congruence is a doubly infinite system of lines. A line depends on four parameters or can be determined so as to satisfy four conditions; if only two conditions are imposed on the line we have a doubly infinite system of lines known as a congruence. For example the lines meeting each of two given lines form a congruence. It is hardly necessary to remark that, imposing on the line one more condition, we have a ruled surface or regulus; thus we can in an infinity of ways separate the congruence into a singly infinite system of regula or of torses (see below, par. 16).

Considering in connexion with the congruence two arbitrary lines, there will be in the congruence a determinate number of lines which are, for example, concurrent or co-planar, or make up a given surface, or are ruled and so forth. The order of the congruence is the number of number of congruence lines which is the class of the congruence. In other words, the order of the congruence is equal to the number of congruence lines lying in an arbitrary plane, and its class to the number of congruence lines passing through an arbitrary point.

The following systems of lines form each of them a congruence: (A) lines meeting each of two given curves; (B) lines meeting a given plane, each through a given point; (C) lines through a given surface; (D) lines touching each of two given surfaces; (E) lines touching a given surface twice, or, say, the bitangents of a surface.

The last case is the most general one; and conversely for a given congruence there will be in general a surface having the congruence lines for bitangents. This surface is said to be the focal surface of the congruence; the general surface with 16 cnicnodes first presented itself in this manner as the focal surface of a congruence. But the focal surface may degenerate into the forms belonging to the other cases A, B, C, D, E.

A complex is a simply infinite system of lines—for instance, the tangent lines of a surface. Considering an arbitrary point in connexion with the complex, the complex lines which pass through the point form a cone; considering a plane through the point, the complex lines of the plane envelop a curve. It is easy to see that the class of the curve is equal to the order of the cone; in fact each of these numbers is equal to the number of complex lines which lie in an arbitrary plane and pass through an arbitrary point of that plane; and we then have the equation of complex = order of curve; rank of complex = class of curve = order of cone; class of complex = class of cone. It is to be observed that, while for a conic there is in general a surface having the congruence lines for bitangents, for a complex there is not in general any surface having the complex lines for tangents; the tangent lines of a surface are thus only a special form of complex. The theory of complexes first presented itself in the researches of Malus on systems of rays of light in connexion with double refraction.

14. Analytical theory as well of congruences as of complexes is just as easily carried out by means of the six co-ordinates $a, b, c, f, g, h$. viz. there are co-ordinates $(a, b, c, f, g, h)$ connected by the equation $a b c + f g h + a f h + b g h + c f g + a b h + c f g + a b h + c f g + a f g = 0$, and therefore such that the ratios $a : b : c : f : g : h$ of any system of lines have thus a congruence of the order $n$ represented by a single homogeneous equation of that order $(a, b, c, f, g, h) = 0$ between the six co-ordinates; two such relations determine a congruence. But we have now to consider the case when $a, b, c, f, g, h$ are all zero, which presents itself in regard to curves in space; it is not every congruence which can be represented completely and precisely by two such equations (see Geometry: § Line).

For such a curve $a b c = 0$ represents a congruence of the first order or linear congruence; such congruences are interesting both in geometry and in connexion with the theory of forces acting on a rigid body.

**Curves of Curvature; Asymptotic Lines.**

16. The normals of a surface form a congruence. In any congruence the lines consecutive to a given congruence line do not
in general meet this line; but there is a determinable number of consecutive lines which do meet it; or, attending for the moment to only one of these, say the congruence line is met by a consecutive congruence-line. In particular, each normal is met by a consecutive normal; if it be met by a normal, the third equation which determines the normal is,

That is, we have a singly infinite system of normals each meeting the consecutive normal, and so forming a torse; starting from different normals successively, we obtain a singly infinite system of normals. Each of these will meet a consecutive normal, and, using in the construction first the one and then the other of these, we obtain two singly infinite systems of tores each intersecting the given surface at right angles. In other words, if in place of the normal we consider the point on the surface, we obtain on the surface two singly infinite systems of curves such that for any curve of either system the normals at consecutive points intersect the normal of the torse intersected, each normal the tores of the two systems intersect each other at right angles; and therefore for each point of the surface the curves of the two systems intersect each other at right angles. The two systems of curves are said to be the curves of curvature on the surface.

The normal is met by the two consecutive normals in two points which are the centres of curvature for the point on the surface; these lie on the line of the point or on opposite sides, and the surface has at this point in question like curvatures or opposite curvatures in the two cases respectively (see above, p. 17).

In immediate connexion with the curves of curvature we have the so-called asymptotic curves (Haupt-tangentenlinien). The tangent plane at a point of the surface cuts the surface in a curve; if we start from a normal of the surface, two directions of passage to a consecutive point, or, say, two elements of arc; and, passing along one of these to the consecutive point, we obtain the curve of curvature, or, as we say, obtain on the surface a curve. Starting successively from different points of the surface we thus obtain a singly infinite system of curves; or, using first one and then the other of the two directions of arc, we obtain a curve of curvature, or, as we say, a curve of curvature proceeding along the direction in the several tangent lines at the point. If, and, if the direction PP is given, the property given is constructed by successive elements of arc for the required geodetic line.

Considering the geodetic lines which proceed from a given point P of the surface, any particular geodetic line is or is not again intersected by the consecutive generating line; if it is thus intersected, the generating line is a shortest line on the surface up to, but not beyond, the point at which it is first intersected by the consecutive generating line; if it is not intersected, it continues a shortest line for the whole course.

In the analytical theory both of geodetic lines and of the curves of curvature, and in other parts of the theory of surfaces, it is very convenient to consider the three coordinate co-ordinates x, y, z. We have the surface given as functions of two independent parameters p, q; the form of these functions of course determines the surface, since by the elimination of p, q from the three equations we obtain the equation in the two variables x, y, z.

We have for the geodetic lines a differential equation of the second order between p and q; the general solution contains two arbitrary constants, and is thus capable of representing the geodesics. If p, q, r, s are the first and the second differential coefficients of z in regard to x, y, respectively, the equation (as first shown by Lagrange) is

\[
\frac{\partial}{\partial x} (1+p^2) + \frac{\partial}{\partial y} (1+q^2) = 0,
\]

The Minimal Surface.

24. This is the surface of minimum area—more accurately, a surface such that, for any indefinitely small closed curve which can be drawn on it round any point, the area of the surface is less than the second and third equations of the given singular set of surfaces. If, to fix the ideas, f_1, f_2, f_3 are taken to denote each a rational and integral function of x, y, z, then two surfaces of the same set will not intersect each other, and through a given point of the surface, there will pass one, and only one, surface of the set which will be determined as a point of intersection of three surfaces belonging to the three sets respectively; moreover, the whole space will be divided by the three sets of surfaces into a triply infinite system of elements, each of them being a parallelepiped.

Orthotomic Surfaces; Parallel Surfaces.

20. The three sets of surfaces may be such that the three surfaces through any point of space whatever intersect each other at right angles; and they are in this case said to be orthotomic. The term is for any other surfaces almost through the closed curve. In this theory is chiefly due, to the case in question: assuming that the equations \( p=f(x, y, z), q=g(x, y, z), r=f(x, y, z) \), which express curves of that of surfaces, we have in the restricted sense p, q, r as the curvilinear-coordinates of the point.

An interesting special case is that of confocal quadric surfaces. The general equation of a surface confocal with the ellipsoid

\[
\frac{x^2}{a^2} + \frac{y^2}{b^2} + \frac{z^2}{c^2} = 1 = \frac{x^2}{a^2 + b^2} + \frac{y^2}{b^2 + c^2} + \frac{z^2}{c^2 + a^2} = 1;
\]

and, if in this equation we consider x, y, z as given, we have for a cubic equation with three real roots p, q, r, and thus we have through the point three real surfaces, one an ellipsoid, one a hyperboloid of one sheet, and one a hyperboloid of two sheets. In the case of the plane, it is connected with that of curves of curvature by Dupin's theorem. Thus in any system of orthotomic surfaces each point of one of the three sets is intersected by the surfaces of the other two sets, and the surfaces of the other two sets are called confocal surfaces of the first kind, depending on the square root of a sextic function.

Curvilinear Co-ordinates.

19. The expressions of the co-ordinates x, y, z in terms of p, q may contain a parameter r, and, if this is regarded as a given constant, these expressions will as before refer to a point on a given surface. If it be required to represent the curvilinear co-ordinates x, y, z will be the co-ordinates of a point in space, determined by means of the three parameters p, q, r; these parameters are said to be the curvilinear co-ordinates, or (in a general sense) the co-ordinates of the point. We arrive otherwise at the notion by taking p, q, r each as a given function of x, y, z; say we have p = f(x, y, z), q = g(x, y, z), r = h(x, y, z), which equations of course lead to expressions for p, q, r each as a function of x, y, z. The first equation determines a singly infinite set of surfaces; for any given value of p we have a surface; and similarly the second and third equations determine a singly infinite set of surfaces. If, to fix the ideas, f_1, f_2, f_3 are taken to denote each a rational and integral function of x, y, z, then two surfaces of the same set will not intersect each other, and through a given point of the surface, there will pass one, and only one, surface of the set which will be determined as a point of intersection of three surfaces belonging to the three sets respectively; moreover, the whole space will be divided by the three sets of surfaces into a triply infinite system of elements, each of them being a parallelepiped.
of necessity a single curve: it may be, for instance, a skew polygon of four or more sides.

The partial differential equation was dealt with in a very remarkable manner by Riemann. From the second form given above it appears that we have \( \sqrt{\xi^2 + \eta^2} = \text{constant} \) as a complete differential, or, putting this \( = \xi, \eta \), we introduce into the solution a variable \( \psi \) which combines with \( x \) in the forms \( x = \xi, \eta \). The boundary conditions have to be satisfied by the determination of the conjugate variables \( \eta, \xi \) as functions of \( z, x \); \( z, x \); or, say, of \( Z, x \), respectively, and by writing \( S, S' \) to denote \( x + iy, x - iy \), we obtain finally two of the differential equations of the first order in \( S, S', \eta, \xi, \eta, \xi \), and the results are completely worked out in some very interesting special cases.

(A. C. A.)

PART II.

We proceed to treat the differential geometry of surfaces, a study founded on the consideration of the expression of the lineal element in terms of two parameters, \( u, v \),

\[ ds^2 = Edu^2 + 2Fdudv + Gdv^2, \]

\( u = \text{const}, v = \text{const}, \) being thus systems of curves traced on the surface. This method, which may be said to have been inaugurated by Gauss in his classical paper published in 1828, *Disquisitiones generales circa superficies curvas*, has the great advantage of dealing in the most natural way with all questions connected with geodesics, geodesic curvature, geodesic circles, &c. In short, all relations of lines on a surface which can be formulated without reference to anything external to the surface are established. It is not always possible to deduce the properties of the surface from the properties of the curves which represent it on the surface, but it can be at once generalized in their application holding good for any other surface which has the same expression for its lineal element; e.g., relations involving great circles and small circles on a sphere furnish us with corresponding relations for geodesics and geodesic circles on any syndetic surface of constant specific curvature.

1. Gauss begins by introducing the conception of the integral curve (curvatura integra) of any portion of a surface. This he defines to be the area of the corresponding portion of a sphere of unit radius, traced out by a radius drawn parallel to the normal at each point of the surface; i.e., it is \( \int ds/RR' \) where \( R, R' \) are the principal radii of curvature. The quotient obtained by dividing the integral curvature of a small portion of the surface round a point by the area of that portion, that is \( 1/RR' \), he naturally calls the measure of curvature or the specific curvature at the point in question.

He proceeds to establish his leading proposition, that this specific curvature is a constant for a given point in surface, 

\[ \frac{\xi}{P} = \text{constant} \]

or, 

\[ \xi = \text{constant} \times \frac{P}{\xi}. \]

This, as we shall see, is the expression of the fundamental property of the geodesics on such surfaces. The following are some of the well-known classes for which this integral has been obtained: (1) quadrics; (2) developable surfaces; (3) surfaces of revolution.

In a later part of the 19th century a special study of the geometry of the lines of curvature and the geodesics on quadrics, and were rewarded by the discovery of many wonderfully simple and elegant analogies between the properties of geometrical and the systems of confocal conics and their tangents in \( \text{plano} \). As explained above, the lines of curvature on a quadric are the systems of orthogonal curves formed by its intersection with the two systems of confocal quadrics. Jacobi showed that the interpretation of the first integral of the equation for geodesics on a central quadric is, that along a geodesic \( \phi = \text{constant} \), \( \phi \) denoting the perpendicular let fall from the centre on a plane through the tangent plane at the point of intersection, the element of the geodesic, the envelope of all geodesics having the same \( \phi \) being a line of curvature. In particular, all geodesics passing through one of the real umbilics (the four points where the indicatrix is a circle) have the same \( C \).

Michael Roberts pointed out that it is an immediate consequence of the equation \( \phi = \text{constant} \), that if two umbilics, \( A \) and \( B \) (selecting two not diametrically opposite), be joined by geodesics to any point \( P \) on a given line of curvature, they may be made angles with such line of curvature, and consequently that, as \( P \) moves along a line of curvature, either \( PA + PB \) or \( PA - PB \) remains constant.

Or, conversely, that the locus of a point \( P \) on the surface, for which the sum of the difference of the geodesic distances \( PA \) and \( PB \) is constant, is a line of curvature. It follows that if the ends of a string be fastened at the two umbilics of a central quadric, and a style move on the surface keeping the string always stretched, it will describe a line of curvature.

Another striking analogy is the following: As in \( \text{plano} \), if a variable point or an ellipse be joined to the two focal \( S \) and \( H \),
tan $\frac{1}{2}$ PSH $=\tan \frac{1}{2}$ PHS = const, and for the hyperbola tan $\frac{1}{2}$ PSH $=\tan \frac{1}{2}$ PHS $=\cos t$, so for a line of curvature on a central quadric, if $P$ be joined to two umbilics $S$ and $H$ by geodetics, either the product or the ratio of the tangents of $\frac{1}{2}$ PHS and $\frac{1}{2}$ PHS will be constant.

Chasles proved that if an ellipse be intersected in the point $A$ by a confocal hyperbola, and from any point $P$ on the hyperbola tangents $PT$, $PT'$ be drawn to the ellipse, then the difference of the arcs of the ellipse $TA$, $TA'$ = the difference of the tangents $PT$, $PT'$; and subsequently Graves showed that if from any point $P$ on the outer of two confocal ellipses tangents be drawn to the inner, then the excess of the sum of the tangents $PT$, $PT$ over the intercepted arc $TT'$ is constant. Precisely the same theorems hold for a quadric replacing the confocals by lines of curvature and the rectilinear tangents by geodetic tangents. Hart still further developed the analogies with confocal conics, and established the following: If a geodetic polygon circumscribe a line of curvature, and all its vertices but one move on lines of curvature, this vertex will also describe a line of curvature, and when the lines of curvature all belong to the same system the perimeter of the polygon will be constant.

2. Geodetics on Developable Surfaces.—On these the geodetics are the curves which become right lines when the surface is unrolled into a plane. From this property a first integral can be immediately deduced.

3. Geodetics on Surfaces of Revolution.—In all such the geodetics are the curves given by the equation $r \sin \phi = \text{const}$, $r$ being the perpendicular on the axis of revolution, $\phi$ the angle at which the curve crosses the meridian.

The general problem of the determination of geodetics on any surface can be treated by a method in connection with that of "parallel" curves. By "parallel" curves are meant curves whose geodetic distances from one another are constant—in other words, the orthogonal trajectories of a system of geodetics. Applying this method the determination of a system of parallel curves comes first, and the determination of the geodetics to which they are orthogonal follows as a deduction. If $\phi (u, v) = \text{const}$ be a system of parallel curves, it is shown that $\phi$ must satisfy the partial differential equation

$$E \left( \frac{\partial^2 \phi}{\partial u^2} \right)^2 - 2F \left( \frac{\partial^2 \phi}{\partial u \partial v} \right) + G \left( \frac{\partial^2 \phi}{\partial v^2} \right)^2 = \text{EG} - \text{F}^2.$$  

If $\phi (u, v, a) = \text{const}$ be a system of parallel curves satisfying this equation, then $a \partial \phi/\partial a = \text{const}$ is proved to represent the orthogonal geodetics. The same method enables us to establish a result first arrived at by Jacobi, that whenever a first integral of the differential equation for geodetics can be found, the final integral is always reducible to quadratures. In this method $\phi$ corresponds to the characteristic function in the Hamiltonian dynamics, the geodetics being the paths of a particle confined to the surface when no extraneous forces are in action.

The expression for the lineal element on a quadric in elliptic co-ordinates suggested to Liouville the consideration of the class of surfaces for which this equation takes the more general form $ds^2 = (U - V)(Uu^2d\alpha^2 + Vv^2d\beta^2)$, where $U$, $V$ are functions of $u$, and $V, V$, functions of $v$ and $w$, in this class, the first integral of the equation of the parallels is immediately obtainable, and hence that of the corresponding geodetics. It is to be remarked that for this general class of surfaces the theorems of Chasles and Graves in these points, and the lineal element denoted by a point whose geodetic distance from a given point is constant; and, second, the curves of constant geodetic curvature.

On certain surfaces the curves which satisfy one of these conditions also satisfy the other, but in general the two curves must be carefully distinguished. The property involved in the second definition is more intrinsic, and we shall therefore, following Liouville, call the curves possessing it geodetic curves.

It may be noted that geodetic circles, except surfaces of constant specific curvature, do not return back upon themselves like circles in plane. As a particular instance, a geodetic on an ellipsoid (which is, of course, a geodetic circle of zero specific curvature), starting from a point, returns back upon itself in the same direction. Gauss showed from the fundamental property of a geodetic that this curve resembles the plane circle in being everywhere perpendicular to its radius. In the same way it holds that the curve described by a point the surface (or difference) of whose geodetic distances from two given points (foci) is constant, resembles the ellipse (or hyperbola) in the property that it bisects at every point the external (i.e., internal) angle between the geodetic focal radii, and, as a consequence, that the curves on an oval answering to confocal ellipses and hyperbolas intersect at right angles. The equation for the first integral of this element enables us to discuss geodetic circles on surfaces of constant specific curvature; for we have seen that if we choose as parameters geodetics and their orthogonal trajectories, the equation becomes $ds^2 = du^2 + Pdu^2$; and since $(RR')^2 = P^2 + P'd$, and here $(RR')^2 = P^2 + P'd$, it follows $P = A \cos u + B \sin u$, or $P = A \cosh u + B \sinh u$, according as the surface is synclastic or anticlastic. If a geodetic circle (curve $k^2$) is chosen for the starting curve $u = 0$, and if $v$ be made the length of the arc $OY$ intercepted on this circle by the curve $u = \text{const}$ (see fig. 1), then $A$ and $B$ can be proved to be independent of $u$ and $P = \cos u + A \sin u$ for a synclastic surface, and $P = A \cosh u + B \sinh u$ for an anticlastic surface. It follows from the expression for the geodetic curvature $r = \frac{1}{2}dP/du$ that in both classes of surfaces all the other orthogonal circles $u = \text{const}$ will be geodetic circles. It also appears that on a synclastic surface of constant specific curvature all the geodetics normal to a geodetic circle converge to a point on either side as on a sphere, and can be described with a stretched string taking either of these points as centre, the length of the string being $a \tan \theta = \text{see fig. 2}$. These normals will be all cut orthogonally by an equator, that is, by a geodetic circle of zero curvature.

For anticlastic surfaces, however, we must distinguish two cases. If the curvature $k^2$ of the geodetic circle $> a^2$, the geodetic normals meet a point on the concave side of the geodetic circle, and can be described as on the synclastic by a stretched string, the length of the string being $a \tan \theta = \text{fig. 4}$. But in this case the geodetic normals have no such property (see fig. 3). If on the other hand the curvature of the geodetic circle be $< a^4$, the normals do not meet on either side, but do possess an equator, and at this equator the geodetic normals come nearer together than they do anywhere else (see fig. 4).

On a synclastic surface of constant specific curvature $a^2$, two near geodetics proceeding from a point always meet again at the geodetic
distance \( r_a \); and more generally for any synclastic surface whose specific curvature at every point lies between the limits \( a^2 \) and \( b^2 \) a near geodetics proceeding from a point always such again at a geodetic distance intermediate in value between \( r_a \) and \( r_b \). On an anticlastic surface two near geodetics proceeding from a point never meet again.

**Fig. 5.**

\[ z = \omega \sin \phi, \quad \varphi = \cos \phi + \log \tan \frac{\phi}{2}. \]

This surface can be conformably represented as a plane map by choosing \( x' = \omega \) where \( \omega \) is the longitude of the point and \( y' = \omega \sin \phi \). It will then be found that \( ds = dx' / \sqrt{y'} \), where \( ds = \text{linear element on the surface, } dx' = \text{same on the map} \). It easily appears that geodetic circles on the surface are represented by circles on the map, the angle \( \psi \) at which these circles cut the base depending only upon the curvature of the geodetic circle, cos \( \psi \) being equal to \( p^2 \). As a particular case it follows that the geodetics on the surface are represented by those special circles on the map whose centres lie on the base (see fig. 6). The geodetic lines passing through \( P \) and \( Q \) on the surface is represented by the logarithm of the anharmonic function \( AP : BO' \), where \( P'Q' \) are the representing points on the map, \( A' \) the points in which the circle on the map passes through \( P' \) and \( Q' \) and has its centre on the base cuts the base. The perimeter \( l \) of a geodetic circle of curvature \( p^3 \) turns out to be \( 2 \pi \sqrt{\ln (a^2 - \rho^2)} \), and its area \( (\pi^2 - \pi) \rho^2 \).

**Fig. 6.**

The geometry of coaxial circles in plane accordingly enables us to demonstrate anew by means of the theorems of the present theory that we have shown to hold good in all anticlastic surfaces of constant curvature. Thus the system of geodetics cutting orthogonally a geodetic circle \( C \) will be represented by the hyperboloidal system of lines cutting a given circle \( C \) orthogonally, i.e., by a coaxial system of circles. We know that the other orthogonal trajectories of this last system are another coaxal system, and therefore, going back to the pseudosphere, we learn that the lines represented by these geodetics can be drawn normal to a geodetic circle, all the orthogonal to this system are geodetic circles. It is to be noted that while every point on its surface is represented on the map, the converse does not hold. It is only points lying above the line \( y' = a \) which have their prototypes on the surface, the portion of the plane below this line not answering any prototypes on the surface.

**Representations of Figures on a Surface by Corresponding Figures on a Plane; Theory of Maps.**

The most valuable methods of effecting such representation are those in which small figures are identical in shape with the figures which they represent. This property is known to belong to the representation of a spherical surface by Mercator's method as well as to those of a cylindrical surface by stereographic projection. The problem of effecting this "conformable" representation is easily seen to be equivalent to that of throwing the expression for the lineal element into what is known in the theory of heat conduction by the isotropical formalism \( ds = \sqrt{\Delta x^2 + \Delta y^2} \). We shall always choose for the representing point on the plane that whose rectangular co-ordinates are \( z = u, \ y = v \). A curious investigation has been made by Beltrami—when it is possible to represent a surface on a plane in such a way that the geodetics on the surface shall correspond to the right lines on the plane (as, for example, holds true when a spherical surface is projected on a plane by lines through its centre)? He has proved that the only class of surfaces for which such representation is possible is the class of uniform specific curvature.

Just as the intrinsic properties of a synclastic surface of uniform specific curvature are reducible to those of a particular surface of this type, so the sphere, so we can deal with an anticlastic surface of constant specific curvature, and reduce its properties to a particular anticlastic surface. A convenient surface to study for this purpose is that known as the pseudosphere, formed by the revolution of the tractrix (an involute of the catenary) round its base (see fig. 5). Its equations are \( r = a \sin \varphi, \quad \varphi = \cos \varphi + \log \tan \frac{\varphi}{2} \). This surface can be conformably represented as a plane map by choosing \( x' = \omega \sin \varphi \), where \( \omega \) is the longitude of the point and \( y' = \omega \sin \varphi \). It will then be found that \( ds = dx' / \sqrt{y'} \), where \( ds = \text{linear element on the surface, } dx' = \text{same on the map} \). It easily appears that geodetic circles on the surface are represented by circles on the map, the angle \( \psi \) at which these circles cut the base depending only upon the
surface, and two systems on the second, such that the equation for the lineal element, when referred to these, may have an identical form for the two surfaces. The problem is now to select these corresponding elements. Now, let us consider the curve $u$ the specific curvature on each surface, and choose for $v$ the function $du/du$ which denotes the rate of increase of $u$ along a direction normal to the curve $u = const$. Then, since at corresponding points both $u$ and $v$ will be the same for one surface as for the other, if the surfaces are applicable, $E$, $F$, and $G$, in the equation $ds^2 = Edu^2 + 2Fdu dv + Gdv^2$, must be identical for the two surfaces. Clerk Maxwell has put the geometrical relation which exists between two applicable surfaces following this idea. If any two such surfaces, $P$ and $P^\prime$, be such, it is always possible to draw two elements through $P$ parallel to conjugate semi-diameters of the indicatrix of the corresponding element on $P^\prime$, that will be parallel to conjugate semi-diameters of the indicatrix at $P^\prime$. The curves made up of all these elements will divide the two surfaces into small parallelograms, the four parallelograms having $P$ as a common vertex being identical in size and shape with the four having $P^\prime$ as vertex. Clerk Maxwell regards the surfaces as made up in the limit of these small parallelograms. Now, in order to render these surfaces ready for application, the first step would be to alter the angle between two of the planes of the parallelograms at $P$, so as to make it equal to that between the corresponding planes at $P^\prime$. If this be done, it is readily seen that all the angles between the other planes at $P$ and $P^\prime$, corresponding to those at $P$, will be altered also. The curves which thus belong to the conjugate systems common to the two surfaces may be regarded as lines of bending.

2. Any surface of uniform specific curvature, whether positive or negative, may be obtained in two methods similar to these for the same uniform specific curvature in an infinite variety of ways. For if we arbitrarily choose two points, $0$ and $O'$, one on each surface, and two elements that touch the surfaces, making $O$ and $O'$ corresponding points and the other curves passing through these elements. This follows from the form of the equation of the lineal element, which is for synclastic surfaces $ds^2 = ds' + d^2$ sin($\varphi(s-a)$) $d\varphi$, and for anticlastic surfaces $ds^2 = ds' + d^2$ cos($\varphi(s-a)$) $d\varphi$. This is therefore identical for the two surfaces in question. Again, a ruled surface may evidently be deformed by first rotating round a generator, the portion of the surface lying to one side of this generator, then round the other side, but each generator, the portion of the surface lying to one side, and so on. It is clear that in such deformation the rectilinear generators in the old surface remain the rectilinear generators in the new; it is only necessary to note that areas and volumes of the surfaces can be constructed which shall be applicable, yet so that the generators will not correspond. For, do a hyperboloid of one sheet in the manner described, turning the portions of the surface round the rectilinear generators of one system, and then do the hyperboloid, using the generators of the other system. The two surfaces so obtained are, of course, applicable to one another, yet so that their generators do not now correspond. Conversely Barden has shown that any surfaces in such a manner applicable, without correspondence of generators, must be both applicable to the same hyperboloid of one sheet. The alysseide is a good example of this, revolving a portion of a ruled surface in this case the right circular conoid, the generators of the conoid coinciding with the meridians of the alysseide.

3. As instances of surfaces applicable to themselves, we may take surfaces of uniform specific curvature, which are thus applicable, without correspondence of generators. Two surfaces in such a manner applicable, having given a screw motion round a fixed axis, or, which comes to the same thing, the surface made up of a system of helices starting from the points of a given curve all turning along the same axis in the same direction, will in the end be identical between the successive threads. The applicability of such a surface to itself, if given a screw motion round the axis, is evident from the law of its formation.

A possible small variational $\varepsilon, \eta, \xi$ of the points of the surface when it is subject to a small inextensible deformation are conditioned by the equation $dx dy + dy dz + dz dx = 0$, or making $x$ and $y$ the independent variables, $d^2 x + d^2 y + d^2 z = 0$. From this it follows that the three equations must separately hold $\frac{d^2 x}{d\xi^2} + \frac{d^2 y}{d\eta^2} + \frac{d^2 z}{d\varepsilon^2} = 0, \frac{d^2 x}{d\eta^2} + \frac{d^2 z}{d\varepsilon^2} = 0, \frac{d^2 y}{d\varepsilon^2} + \frac{d^2 z}{d\eta^2} = 0$. Accordingly, the determination of a possible small deformation of a given surface is subject to the application of the same definite functions $\varepsilon, \eta, \xi$ of the variables $x$ and $y$ to satisfy these equations. Changing the co-ordinates to $\alpha$ and $\beta$ where $\alpha = const., \beta = const.$, are the curves of inflexion on the surface, the solution of the equations can be found by supposing that of the equation $d^2 x = 0$ when $\lambda$ is a function of $\alpha$ and $\beta$ depending on the form of the surface. The last equation can be integrated, and the possible deformation determined in the case of a spherical surface, or of any surface of uniform specific curvature. It is easily shown that if we have determined the displacements for any surface $S$ we can do so for any surface obtained from $S$ by a linear transformation of the variables.

For $x = ax = by = cz + d$, $y = ax = by = cz + d$, $z = ax = by = cz + d$, then the displacements $\varepsilon = \frac{A}{2} + B + C$, $\eta = -A + B + C$, $\xi = A + B + C$, then $\frac{\partial A}{\partial a} + \frac{\partial B}{\partial b} + \frac{\partial C}{\partial c} = 0$. Accordingly the known solution for a surface furnishes us with a solution for any quadric. Moutard has pointed out a curious connexion between the problem of small deformation and that of the applicability of two infinitely different surfaces.

$d^2 x + d^2 y + d^2 z = 0$, that if $k$ be any constant, $d^2 x + d^2 y + d^2 z = 0$.

Consequently, if we take two surfaces such that for the first $X = x + k$, $Y = y + k$, $Z = z + k$, then

$X = x - k$, $Y = y - k$, $Z = z - k$,

and for the second

$2X - y + z = 2X - y + z = 0$,

and therefore the new surfaces are applicable.

5. Jellett and Clerk Maxwell have shown by different methods that, if a curve on a surface be held fixed, there can be no small deformation, except this curve be a curve of inflexion. This may be also proved thus: There can be no displacement of the tangent planes along the fixed curve, for, at any point of the curve the geodesic curvature cannot alter; but in present case the ordinary curvature of the curve is also fixed, therefore their ratio is constant, so that $\kappa/\rho = -\sin \theta d\theta = 0$, where $\theta$ is the angle which the osculating plane makes with the tangent plane; therefore unless sin $\theta = 0$, as it is along a curve of inflexion, $d\theta = 0$, and therefore the tangent plane at each point is unaltered. Hence it can be shown that along the given curve not only $\kappa$ is zero, but also their differential coefficients of all orders, and therefore no displacement is possible.

The question has been much discussed: Can a closed synthetic surface be deformed into a new one, such as to be a prevalent opinion amongst mathematicians that such deformation is always impossible, but we do not think any unimpeachable demonstration of this has yet been given. It is certain that a complete spherical surface does not admit of inextensible deformation, for if it did it would follow from Gauss's theorem that the new surface would have a uniform specific curvature. Now, it is not difficult to prove that the only closed surface possessing this property is the sphere itself, provided that the given surface is such that all their tangent planes lie entirely outside them. We can then, by the method of linear transformation already given, extend the theorem of impossibility of deformation to any ellipsoid.

The theorem is that if $S$ be the given surface of constant specific curvature $\kappa$, we may, suggest, be established by means of the following two propositions, which hold for integration on any coordinate system, being the perpendicular from the origin on the tangent plane:

$\int (R + n/R) ds = 2 \int pds/R'$

$2 \int ds = \int p(1 + R)/R ds$.

Now multiply both sides of the first equation by the constant $\sqrt{R'}$, and subtract the second, and we get:

$\int (R/R + 1/R') ds + \int p(R/R - 1/R') ds = 0$

which is impossible unless $R' = R$ everywhere, since in accordance with the proviso $p$ is everywhere positive.

Theorems (1) and (2) are deduced by Jellett by means of the calculus of variations in his treatise on the subject. They may also be very simply proved thus: Draw normals to the surface along the contours of the small squares formed by lines of curvature, and let these meet successive parallel surfaces at distances $d\lambda$, then the volume bounded by two parallel surfaces

$\int dS \int_0^\lambda \sin (n + 1/R)(1 + n/R) ds$

and for outer surface $S = \int_0^{R'} \sin (1 + 1/R') ds$.
SURGE—SURGERY

Hence equating coefficients of the powers of \( n \):

\[
\int \left( \frac{2}{(1 + R/1/R)S} \right) = \frac{2}{R},
\]

and

\[
\int 1 = \int R = \frac{R}{1/R + 1/R}.S
\]

References to the original memoirs will be found in Salmon's "Arithmetical Geometrical and Algebraical Propositions for Dimensions", Frost's "Solid Geometry and, more completely, in Darbois's "Lesons sur la théorie générale des surfaces."

SURGE, in meteorology, an irregular fluctuation of the barometer, extending over a long period (e.g. a month), in contradistinction to the shorter fluctuations, covering two or three days, caused by alternating conditions of high and low pressure. The cause of surges is not understood.

SURGERY (Fr. chirurgie, fro Gr. χειρουργός, i.e. hand-work), the art of the surgeon (chirurgien), connected specially with the cure of diseases or injuries by operative manual and instrumental treatment.

History.—Surgery in all countries is as old as human needs. A certain skill in the stanching of blood, the extraction of arrows, the binding up of wounds, the supporting of broken limbs by splints, and the like, together with an instinctive reliance on the healing power of the tissues, has been common to men everywhere. In both branches of the Indo-European stock surgical practice (as well as medical) reached a high degree of perfection at a very early period. The controversy whether the Greeks got their medicine (or any of it) from the Hindus (through the medium of the Egyptian priest-hood), or whether the Hindus owed that high degree of medical and surgical knowledge and skill which is reflected in Charaka (1st century A.D.) and Suśruta (2nd century) (commentators of uncertain date on the Yajur-Veda) to their contact with Western civilization after the campaigns of Alexander. The evidence in favour of the former view is ably stated by Wise in the Introduction to his "History of Medicine Among the Asians" (London, 1868). The correspondence between the "Susruta" and the Hippocratic Collection is close, the latter being related to the ethics of medical practice; the description, also, of lithotomy in the former agrees almost exactly with the account of the Alexandrian practice as given by Celsus. But there are certainly some dexterous operations described in Suśruta (such as the rhinoplastics) which were of native invention; the elaborate and lofty ethical code appears to be of pure Brahmanical origin; and the copious materia medica (which included arsenic, mercury, zinc, and many other substances of permanent value) does not contain a single article of foreign source. There is evidence also (in Arrian, Strabo and other writers) that the East enjoyed, under the pressure of medical and surgical wisdom at the time of Alexander's invasion. We may give the first place, then, to the Eastern branch of the Indo-European stock in a sketch of the rise of surgery, leaving as insoluble the question of the date of the Sanskrit compendiums or compilations which pass under the names of two representative persons, Charaka and Suśruta (the dates assigned to these ranging as widely as 500 years on each side of the Christian era).

The Suśruta speaks throughout of a single class of practitioners who undertook both surgical and medical cases. Nor were there any fixed degrees or orders of skill within the profession; even lithotomy, which at Alexandria was assigned to specialists, was to be undertaken by any one, the leave of the raja having been first obtained. The only distinction recognized between medicine and surgery was in the inferior order of barbers, nail-trimmers, ear-borers, tooth-drawers and phlebotomists, who were outside the Brahmanical caste.

Suśruta describes more than one hundred surgical instruments, made of steel. They should have good handles and firm joints, be well polished, and sharp enough to divide a hair; they should be perfectly clean, and kept in a box made of wood. They included various shapes of scalpels, bistouries, lances, scarifiers, saws, bone-nippers, scissors, trocars and needles. There were also blunt hooks, loops, probes (including a caustic-holder), directors, sounds, scoops and forceps (for polypus, &c.), as well as catheters, syringes, a rectal speculum and bougies. There were fourteen varieties of bandage. The favourite form of splint was made of thin slips of bamboo bound together with string and cut to the length required. Wise says that he had frequented "this admirable splint," particularly for fractures of the thigh, humerus, radius and ulna, and it was subsequently adopted in the English army under the name of the "patent ratten-cane splint."

Fractures were diagnosed, among other signs, by crepitus. Dislocations were elaborately distinguished and classified, and given the treatment was by traction and countertraction, circumduction and other dexterous manipulations. Wounds were divided into incised, punctured, lacerated, contused, &c. Cuts of the head were particularly recommended. When a patient was about to be operated upon, he was asked whether he knew his disease; and to a great height, the magnet being used for iron particles under certain specified circumstances. Inflammations were treated by the usual antiphlogistic regimen and appliances; venesection was applied in several cases, and antiphlogistic dressings, and leeches were more often resorted to than the lancet; cupping also was in general use. Poulticing, fomenting and the like were done at present. Amputation was done now and then, notwithstanding the want of a good control over the haemorrhage; boiling oil was applied to the stump, with pressure by means of a cup-formed bandage, pitch being sometimes added. Tumours and enlarged lymph glands were cut out, and an arthritic salve applied to the raw surfaces to prevent recurrence. Abdominal dropsy and hydrocele were treated by tapping with a trocar; and varieties of hernia were understood, ventral hernia being removed by operation on the first day, or, if the patient was healthy, two or three days after the operation. The ligature on the continuity of an artery, as well as on the cut end of it in a flap, is the one thing that a modern surgeon will miss somewhat protected, though in the ancient surgery of the Hindus the background to the latter was doubtless their want of familiarity with the arterial circulation and with the arterial ligature. Besides the operation already mentioned, the abdomen was opened by a short incision or by the old operation, which is the middle line for the purpose of removing intestinal concretions or other obstruction (laparotomy). Only a small segment of the bowel was exposed at one time; the concretion when found was removed and the incision was then closed. The intestines were dried and kept up by balsamic and antiphlogistic substances. The tumours, which were considered of no use without experience and manual skill in operations; the different surgical operations were shown to the student upon the skin of a dead cow laid on a table covered with a sheet of calico; tapping and puncturing were practised on a leathen bag filled with water or soft mud; scarifications and bleeding on the fresh hides of animals from which the hair had been removed; puncturing and other operations upon the skin of dead animals; bandaging was practised on flexible models of the human body; sutures on leather and cloth; the plastic operations on dead animals; and the application of caustics and cauteries on living animals. A knowledge of anatomy was held to be necessary, but it does not appear that it was systematically acquired by dissection. Superstitions and theurgical ideas were diligently kept up so as to impress the vulgar. The whole body of teaching, itself the slow growth of much close observation and profound thinking during the vigorous period of Indo-Aryan progress, was given out in later times as a revelation from heaven, and as resting upon an absolute authority. But this authority was in the main derived from a purely arbitrary or conventional physiology (wind, bile and phlegm); and the whole elaborate fabric of rules and directions, great though its utility must have been for many generations, was in the quick succession of reason and freedom, and became inevitably stiff and decrepit.

The Chinese appear to have been far behind the Hindus in their knowledge of medicine and surgery, notwithstanding that China profited at the same time as Tibet by the missionary propagation of Buddhism. Surgery, in particular, had hardly developed among them beyond the merest rudiments, owing to their religious respect for dead bodies and their unwillingness to draw blood or otherwise interfere with the living structure. Their anatomy and physiology have been from the earliest times unusually fanciful, and their surgical practice has consisted almost entirely of external applications. Tumours and boils were treated by scarifications.
or incisions. The distinctive Chinese surgical invention is acupuncturing, or the insertion of fine needles, of hardened silver or gold, for an inch or more (with a twisting motion) into the seats of pain or inflammation. Wise says that "the needle is allowed to remain in that part several minutes, or in some cases of neuralgia for days, with great advantage"; rheumatism and chronic gout were among the localized pains so treated. There are 367 points specified where needles may be inserted without injuring great vessels and vital organs.

Cupping-vessels made of cow-horn were found in ancient Egyptian tombs and the walls of temples are figures of patients bandaged, or undergoing operation at the hands of surgeons. In museum collections of Egyptian antiquities there are lanceets, forceps, knives, probes, scissors, &c. Ebers interprets a passage in the papyrus discovered by him as relating to the operation of cataract. Surgical instruments for the ear are figured, and artificial teeth have been found in mummies. Mummies have also been found with well-set fractures. Herodotus describes Egypt, notwithstanding its fine climate, as being full of medical practitioners, who are called "surgeons." These "surgeons" were celebrated, and practised at the court of Cyrus.

Greek Surgery.—As in the case of the Sanskrit medical writings, the earliest Greek compendiums on surgery bear witness to a long organic growth of knowledge and skill through many generations. In the Homeric picture of society the surgery is that of the battlefield, and it is of the most meagre kind. Achilles is concerned about the restoration to health of Machaon for the reason that his skill in cutting out darts and applying salves to wounds was not the least valuable service that a hero could render to the Greek host. Machaon probably represents an amateur, whose taste had led him, as it did Melampus, to converse with centaurs and to glean some of their traditional wisdom. Between that primitive state of civilization and the date of the first Greek treatises there had been a long interval of gradual progress.

The surgery of the Hippocratic Collection (age of Pericles) bears every evidence of finish and elaboration. The two treatises on fractures and on dislocations respectively are hardly surpassed in some ways by the writings of the present mechanical age. Of the four dislocations of the shoulder the displacement downwards into the axilla is given as the most common. The case are described. The depressed of the femur were backwards on to the dorsal illi and forwards on to the obturator region. Fractures of the spino processes of the vertebræ are described, and caution advised against trusting these fissures not to fracture the spine itself. Tubercles (spathura) are given as one of the causes of spinal curvature, an anticipation of Pott's disease. In all matters of dislocations there is the same fidelity to the true practice; the most noteworthy point is that shortening was by many regarded as inevitable after simple fracture of the femur. Fractures and dislocations were the most complete chapters of the Hippocratic surgery; the whole doctrine and practical art of them had arisen (like sculpture) with no help from dissection, and obviously owed its excellence to the opportunities of the palaestra. The next most elaborate chapter is that on wounds and injuries of the head, which refers them to a minute subdivision, and includes the depressed fracture and the contrecoup. Trephining was the measure most commonly resorted to, even where there was no compression. Nerve injuries and internal and intestinal injuries are among the other parts discussed. Ruptures, piles, rectal polypi, fistula in ano and prolapsus ani were among the other conditions treated. The amputation or excision of tumours does not appear to have been undertaken so freely as in Hindu surgical practice; nor was lithotomy performed except by a specially expert person now and then. The diagnosis of empyema was known, and the treatment of it was by an incision in the intercostal space and evacuation of the pus. Among their instruments were forceps, probes, directors, syringes, rectal speculums, catheter and various kinds of cautery.

Between the Hippocratic era and the founding of the school of Alexandria (about 300 B.C.) there is nothing of surgical progress to dwell upon. The Alexandrian epoch stands out prominently by reason of the enthusiastic cultivation of human anatomy—there are allegations also of vivisection—at the hands of Herophilus (335-280 B.C.) and Erasistratus (280 B.C.). The substance of this movement appears to have been precision of diagnosis (not unattended with pediatric minuteness), boldness of operative procedure, subdivision of practice into a number of specialties, but hardly a single addition to the stock of physiological or pathological ideas, or even to the traditional wisdom of the Hippocratic time. "The surgeons of the Alexandrian school were all distinguished by the nicety and complexity of their dressings and bandages, of which they invented a great variety." Herophilus boldly used the knife even on internal organs such as the liver and spleen, which latter he regarded "as of little advantage in the economy of the body." The retention of urine by a particular kind of catheter, which long bore his name. Lithotomy was much practised by a few specialists, and one of them (Ammonius Lithotomos, 287 B.C.) is said to have used an instrument for breaking the stone in the bladder into several pieces when it was too large to remove whole. A sinister story of the time is that concerning Antiochus, son of Alexander, king of Syria (150 B.C.), who was done to death by the lithotomists when he was ten years old, under the pretense that he had stone in the bladder, the instigator of the crime being his guardian and supplanter Diodotus.

The treatise of Celsus, De re medica (regius of Augustus), reflects the state of surgery in the ancient world in a period of several centuries: it is the best record of the Alexandrian practice itself, and it may be taken to stand for the Roman practice of the period following. Celsus was of a family of physicians of note, and had contact with many of the Romans of the republic, notably by Cato the Elder (235-149 B.C.), who himself practised on his estate according to the medical observations... His medical observations are given in De re medica. In reducing dislocations he made use of the following incantation: "Huat hanat ista pista sista damato damnaestut." The first Greek surgeon who established himself in Rome is said to have been Archagathus, whose fondness for the knife and cautery at length led to his expulsion by the populace. It was in the person of Asclepiades, the contemporary and friend of Cicero, that the Hellenic medical practice acquired a permanent footing in Rome. He confined his practice mostly to medicine, but he is credited with practising the operation of tracheotomy. He is one of those whom Tertullian quotes as practising vivisections for the gratification of the Greeks. The first Roman surgeon whose name is of any repute was Herophilus (De anima, 8th book). The next great name is Celsus, who devotes the 7th and 8th books of his De re medica exclusively to surgery. There is not much in this beyond the precepts of the Brahmanical Sastras and the maxims and rules of Greek surgery. Plastic operations for the restoration of the nose, lips and ears are described at some length, as well as the treatment of hernia by taxis and operation; in the latter it was recommended to apply the actual cautery, and that the operation was attended on by the son of the host. The celebrated description of lithotomy is that of the operation as practised long before in India and at Alexandria. The incision is made in the sinus of the umbilicus or anus, the sinus of the thoracic wall resection of the rib is mentioned. Trephining has the same prominent place assigned to it as in the Greek surgery. The resources of contemporary surgery may be seen in the account in De re medica of the cure of a stricture in the urethra when the urethra was blocked by a calculus. Amputation of an extremity is described in detail for the first time in surgical literature. Mention is made of a variety of ophthalmic operations, which were done by specialists after the Alexandrian fashion.

Galen's practice of surgery was mostly in the early part of his career (b. A.D. 130), and there is little of special surgical interest in his writings, great as their importance is for anatomy, physiology and the general doctrines of disease. Among the operations credited to him are resection of a portion of the sterna for caries and ligature of the temporal artery. It may be assumed that surgical practice was in a flourishing condition all through the period of the empire from the accounts preserved by Orisbasius of the great surgeons Antyllus, Leonides, Rufus and Heliodorus. Antyllus (A.D. 300) is claimed by Häser as one of the greatest of the Alexandrian surgeons of the Roman Empire. Heliodorus (A.D. 300) is attributed to Häser as "a brilliant example of the surgical skill during the empire." The same surgeon treated stricture.
of the urethra by internal section. Both Leonides and Antyllus removed glandular swellings of the neck (strumae); the latter ligatured vessels before cutting them, and gives directions for avoiding the carotid artery and jugular vein. Flap-amputations were practised by Leonides and Heliodorus. But perhaps the most striking illustration of the advanced surgery of the period is the freedom with which bones were resected, including the long bones, the lower jaw and the upper jaw.

Whatever progress or decadence surgery may have experienced during the next three centuries is summed up in the authoritative Byzantine, treatise of Paulus of Aegina (A.D. 650). Of his seven books the sixth is entirely devoted to operative surgery, and the fourth is largely occupied with surgical diseases. The importance of Paulus for surgical history during several centuries on each side of his own period will appear from the following remarks of Francis Adams (1796–1861) in his translation and commentary (ii. 247):—

"This book (bk. vi) contains the most complete system of operative surgery which has come down to us from ancient times . . . Haly Abbas (d. A.D. 904) in the 9th book of his Practica copies almost everything from Paulus. Albucasis [Abulcasir] (10th century A.D.) gives more detailed matter on surgery than any other Arabic author who comes down from ancient times. He dedicates for whole chapters to Paulus. In the Continens of Rhazes, that precious repository of ancient opinions on medical subjects, if there be any surgical matter not to be found in our author it is mostly derived from the Arabic authors. Other authors have, although we will occasionally have to explain their opinions upon particular subjects, no one has treated of surgery in a systematic manner. . . . He who would learn everything else connected with medicine, is defective in his accounts of surgical operations; and the descriptions which he does give of them are almost all borrowed from our author. The accounts of fractures and dislocations given by Hippocrates and his commentator Galen may be pronounced almost complete; but the information which they supply upon most other surgical subjects is scanty."

Paulus’ sixth book, with the valuable commentary of Adams, brings the whole surgery of the ancient world to a focus. Paulus is credited with the principle of local depletions against general, with the lateral operation for stone instead of the mesial and with understanding the merits of a free external incision and a limited internal, with the diagnosis of aneurism by anastomosis, with an operation for aneurism like that of Antyllus, with amputation of the cancerous breast by crucial incision, and with the treatment of fractured patella.

The Arabian have hardly any greater merit in medicine than that of preserving intact the bequest of the ancient world. Arabian.

To surgery in particular their services are small—first, because their religion proscribed the practice of anatomy, and, secondly, because it was a characteristic of their race to accept with equanimity the sufferings that fell to them, and to decline the means of alleviation. The great names of the Arabian school, Avicenna (980–1037) and Averroes (1126–1198), are altogether unimportant for surgery. Their one distinctively surgical writer was Abulcasir (d. 1212), who is chiefly celebrated for his free use of the actual cautery and by cautica. He showed a good deal of character in declining to operate on goitre, in resorting to tractionotomy but sparingly, in refusing to meddle with cancer, and in evacuating large abscesses by degrees.

For the five hundred years following the work of Paulus of Aegina there is nothing to record but the names of a few practitioners at the court and of imitators or compilers. Meanwhile in western Europe (apart from the Saracen civilisation) a medical school had grown up at Salerno, which in the 10th century had already become famous. From them the "Regimen sanitatis," so, a work used by the laity for several centuries, and the Centurie of Soro, which circulated among the profession. The decline of the school dates from the founding of a university at Naples in 1224. In its best period princes and nobles resorted to it for treatment from all parts of Europe. The hôtel dieu of Lyons had been founded in 560, and that of Paris a century later. The school of Montpellier was founded in 1025, and became the rallying point of Arabian and Jewish learning. A good deal of the medical and surgical practice was in the hands of the religious orders, particularly of the Benedictines. The practice of surgery by the clergy was at length forbidden by the Council of Tours (1163). The surgical writings of the time were mere reproductions of the classical or Arabian authors. One of the first to go back to independent observation and reflection was William of Saliceto, who belonged to the school of Bologna; his work (1275) advocates the use of the knife in many places where the actual cautery was used by ancient prescription. A greater name in the history of medieval surgery is that of his pupil Lanfranchi of Montpellier. (e.g., treating of the political troubles) first to Lyons and then to Paris. His distinction between arterial and venous haemorrhage, and is said to have used the ligature for the former. Contemporary with him in France was Henri de Mondeville (hermondeville) of the school of Montpellier, whose teaching is best known through that of his more famous pupil Guy de Chauliac; the Chirurgie of the latter bears the date of 1363, and marks the advance in precision which the revival of anatomy by Mondino had made possible. Eighteen years before Lanfranchi came to Paris a college of surgeons was founded there (1170) by Pithard, who had accompanied St Louis to Palestine and was his surgeon. The college was under the protection of St Cosmas and St Damianus, two practitioners of medicine who suffered martyrdom in the reign of Diocletian, and it became known as the Collège de St Côme. From the time that Lanfranchi joined it it attracted many pupils. It maintained its independent existence for several centuries, alongside the medical faculty of the university; the corporations of surgeons in other capitals, such as those of London and Edinburgh, were modelled upon it. The 14th and 15th centuries are almost entirely without interest for surgical history. The dead level of tradition is broken first by two men of originality and genius—P. Paracelsus (1493–1541) and Paré, and by the revival of anatomy at the hands of Andreas Vesalius (1514–1564) and Gabriel Fallopius (1523–1562), professors at Padua. Apart from the mystical form in which much of his teaching was cast, Paracelsus has great merits as a reformer of surgical practice. Paracelsus.

"The high value of his surgical writings," says Häszer, "has been recognized at all times, even by his opponents." It is not, however, an innovator in operative surgery, but rather as a direct observer of natural processes, that Paracelsus is distinguished as an "hospitals gangrene," for example, is perfectly true to nature; his numerous observations on syphilis are also sound and sensible; and he was the first to point out the connexion between cretinism of the offspring and goitre of the parents. He gives most prominence to the healing of wounds. His special surgical treatises are Die kleine Chirurgie (1528) and Die grosse Wand-Arcei (1536–1537)—the latter being the best known of his works. Somewhat later in date, and of much greater concrete importance for surgery than Paracelsus, is Ambroise Paré (1510–1590). He began life as an apprentices to a barber-surgeon in Paris and as a pupil at the hôpital dieu. His earliest opportunities were in military surgery during the campaign of Francis I in Piedmont. Instead of treating gunshot wounds with hot oil, according to the practice of the day, he had the temerity to trust to a simple bandage; and from that beginning he proceeded to many other developments of rational surgery. In 1545 he published at Paris La Méthode de traiter les plaies faites par hâquebude et autres bastons à feu. The same year he began to attend the lectures of Sylvius, the Paris teacher of anatomy, to whom he became a protégé, and his next book was an Anatomie (1550). His most memorable service was to get the use of the ligature for large arteries generally adopted, a method of controlling the haemorrhage which made amputation on a large scale possible for the first time. Like Paracelsus, he writes in the language of the people, while he is free from the encumbrance of mystical theories, which detract from the merits of his fellow reformer in Germany. It is only in his book on monsters, written towards the end of his career, that he shows himself to have been by no means free from superstition. Paré was adored by the army and greatly esteemed by successive
The 18th century marked the establishment of surgery on a broader basis than the skill of individual surgeons of the court and army, and on a more scientific basis than the rule of thumb of the multitude of barber-surgeons and other inferior orders of practitioners. In Paris the Collège de St Côme gave way to the Academy of Surgery in 1731, with Petit as director, to which was added at a later date the École Pratique de Chirurgie, with François Chopard (1743–1795) and Pierre Desault (1744–1795) among its first professors. The Academy of Surgery set up a very high standard from the first, and exercised great exclusiveness in its publications and its honorary membership. In London and Edinburgh the development of surgery proceeded less academically, and with greater scope for individual effort. Private dissecting rooms and anatomical theatres were started, of which perhaps the most notable was Dr William Hunter’s (1728–1783) school in Great Windmill Street, London, inasmuch as it was the first perch of his more famous brother John Hunter (1728–1793). In Edinburgh, Alexander Monro (1697–1767), first of the name, became professor of anatomy to the company of surgeons in 1719, transferring his title and services to the university the year after; as he was the first systematic teacher of medicine or surgery in Edinburgh, he is regarded as the founder of the Academic medical school of that city. In both London and Edinburgh a company of barbers and surgeons had been in existence for many years before; but it was not until the association of these companies with the study of anatomy, comparative anatomy, physiology and pathology that the surgical profession began to take rank with the older order of physicians. Hence the significance of the eulogy of a living surgeon on John Hunter: “More than any other man he helped to make us gentlemen” (Hunterian Oration, 1677). The state of surgery in Germany may be inferred from the fact that the long list of distinguished surgeons of the century—of the likes of Albrecht von Haller (1708–1777), whose office was “professor of theoretical medicine”—in the Prussian army it fell to the regimental surgeon to shave the officers. At Berlin a medic chirurgical college was founded by Surgeon-General Ernst von Holtzendorff (1688–1751) in 1714, to which was joined in 1726 a school of clinical surgery at the Charité. Military surgery was the original purpose of the school, which still exists, side by side with the surgical clinics of the faculty, as the Friedrich Wilhelm’s Institut. In Vienna, in like manner, a school for the training of army surgeons was founded in 1785—Joseph’s Hospital for the poor. The first systematic teaching of surgery in the United States was by Dr Shippen at Philadelphia, where the medical college towards the end of the century was largely officered by pupils of the Edinburgh school. A great part of the advance during the 18th century was in surgical pathology, including Petit’s observations on the formation of thrombi in severed vessels, Hunter’s account of the reparative process, Benjamin Bell’s classification of ulcers, the observations of Duhamel and others on the formation of callus and on bone repair in general, Pott’s distinction between spinal curvature from causes or abscess of the vertebrae and kyphosis from other causes, observations by various surgeons on chronic disease of the hip, knee, and other joints, and Cheselden’s description of neuroma. Among the great improvements in surgical procedure we have Cheselden’s operation of lithotomy (six deaths in eighty cases), Sir Caesar Hawkins’s (1711–1786) cutting gorget for the same (1753), Hunter’s operation (1775) for popliteal aneurism by tying the femoral artery in the canal of the triceps where its walls were sound (‘excited the greatest wonder,’ Assalini), Petit’s, Desault’s and Percival Pott’s (1747–1768) treatment of fractures, Gimbernat’s (Barcelona) operation for strangulated femoral hernia, Pott’s history for fistula, Charles White’s (1728–1813, Manchester) and Henry Park’s (1754–1831, Liverpool) excision of joints, Petit’s invention of the screw-tourniquet, the same surgeon’s operation for lacrimal fistula, Chopart’s partial amputation of the foot, Desault’s hangade for fractured clavicle, William Bromfield’s (1712–1792) artery hook, and William Cheselden’s (1688–1752) operation of iridectomy. Other surgeons of great versatility and general merit were Sharp of London, Benjamin Gooch (fl. 1772) of Norwich, William Hey (1736–1819) of Leeds, David and Claude Nicolas Le Cat (1705–1768) of Rouen, Raphaël Sabatier (1732–1811), Georges de La

Two things gave surgical knowledge and skill in the 19th century a character of scientific or possible cumulative truth and a wide diffusion through all ranks of the profession. The one was the founding of museums of anatomy and surgical pathology by the Hunters, Guillaume Dupuytren (1777-1835), Jules Cloquet (1790-1843), J. F. Blumenbach (1752-1840), John Barclay (1758-1826), and a great number of more modern anatomists and surgeons; the other was the method of clinical teaching, exemplified in its highest form of constant reference to principles by Thomas Lawrence (1711-1785) and James Syme (1790-1870).

In surgery the discovery of the anaesthetic properties of ether, chloroform, mephylene, &c., was of incalculable service; while the conservative principle in operations upon diseased or injured parts, and especially what may be called the hygienic idea (or, more narrowly, the antiseptic and aseptic principles) in the conditions governing surgery, were strikingly beneficial.

The following were among the more important additions to the resources of the surgical art: the thin thread ligature for arteries, introduced by Lord Byron (1788-1824); the cannula for the removal of dropsy fluid by Jean Amussat (1796-1856) [1829]; the practice of drainage by Pierre Marie Chassaing (1805-1879) [1859]; aspiration by Philippe Perlecan (1747-1829) and recent improvers; the plaster-of-Paris bandage or other immovable application for simple fractures, club-foot, &c. (an old Eastern practice recommended in Europe about 1814 by the English consul at Basra); the re-breaking of badly set fractures by Jean-Jacques Morelot (1778-1856) [1828]; the generation of resection of joints (Sir William Fergusson (1808-1877), Syme and others); tenotomy by Jacques Delpech (1777-1832) and Louis Strome heterosexuals (1804-1876) [1834]; operation for ophthalmia by Johann Friedrich Gottlob Meckel (1772-1828) [1816]; cure of the subcutaneous abscess by Yon (1806); the adoption of the hot water bag for aneurism by the memorial by John Abernethy (1764-1831) [1806]; ligature of the subclavian in the third portion by Astley Cooper (1768-1841) [1806], and in its first portion by Colles; crushing by dislocation of the olecranon by Dupuytren (1790-1867) [1856]; cure of ovarian dropsy by removing the cyst (since perfectly perfected); discovery of the ophthalmoscope, and many improvements in ophthalmic surgery by Alfred von Graefe (1830-1899) and others; application of the laryngoscope in operations on the larynx by Jean Czermak (1828-1873) [1860] and others; together with the additions to the resources of auricular surgery and dentistry; the discovery of the stethoscope in the first quarter of the 19th century besides those mentioned are: Antonio Scarpa of Italy (1747-1812); Alexis Boyer (1757-1833); Felix Larrey (1766-1842)—to whom Napoleon left a legacy of a hundred thousand francs, with the request that his name be placed on the monuments of Philibert Roux (1780-1854), Jacques Lisfranc (1790-1847), Alfred Louis Velpeau (1795-1868), Joseph Malaga (1806-1865), Auguste Nidalon (1807-1873)—all of the French school; of the British school, John Bell (1753-1820), Charles Bell (1774-1842), Allan Burns (1781-1813), Robert Liston (1794-1847), James Wardrop (1782-1860), Astley Cooper, Henry Clive (1750-1827), Benjamin Travers (1756-1835), Benjamin Breckly (1784-1840), Harward Stanly (1783-1862) and George Guthrie (1785-1856) in the United States, V. Mott, S. D. Gross and others; in Germany, Kern and Schuh of Vienna, Von Walther and Textor of Wurtzburg, Chelius, Hessebach and the two Langenbecks,—Konrad (1776-1851) and Bernhard (1803-1887).

Modern Practice of Surgery. A great change has taken place in the practice of surgery since the middle of the 19th century, in consequence of the new science of bacteriology, and the introduction of aseptic methods, due to the teaching of Lord Lister.

It had long been known that subcutaneous injuries followed a far more satisfactory course than those with wounds, and the history of subcutaneous infections endured was by the use of various dressings, empirically to prevent the evils which were matters of common observation during the healing

1 The Royal College of Surgeons in London was established in 1800, the title being changed in 1843 to Royal College of Surgeons of England.

2 For the surgery of any particular region or organ, reference should be made to the article on that region or organ.
SURGERY

its irritating properties and the difficulty of finding the exact strength in which to use it; he feared to use it too strong, lest it should impair the vitality of the tissues and thus prevent healing; and he feared to use it too weak, lest its antiseptic qualities should be insufficient for the object in view. As dressings for wounds he used various chemical substances, which, being mixed with carbolic acid, were intended to give off a certain quantity of carbolic acid in the form of vapour, so that the wound might be constantly surrounded by an antiseptic wall. Many organs in the body, however, at the same time, not interfere with its healing. At first, although he prevented pyaemia in a marked degree, he, to a certain extent, irritated the wounds and prevented rapid healing. He began his historic experiments in Glasgow and continued them on his removal to the chair of clinical surgery in Edinburgh. After many disappointments, he gradually perfected his method of performing operations and dressing wounds, which was somewhat as follows.

A patient was suffering, for instance, from disease of the foot necessitating amputation at the ankle joint. The part to be operated on was enveloped in a towel soaked with a 5% solution of carbolic acid. The towel was applied two hours before the operation, with the object of destroying the putrefactive organisms present in the skin. The patient was placed on the operating table, and brought under the influence of chloroform; the limb was then elevated to empty it of blood, and a tourniquet was applied round the limb below the knee. The instruments to be used during the operation had been previously purified by lying for half an hour in a flat porcelain dish containing carbolic acid (1 in 20). The sponges lay in a similar carbolic solution. Towels soaked in the same solution were laid over the table and blankets near the part to be operated upon. The hands of the operator, as well as those of his assistants, were thoroughly cleansed by washing them in carbolic solution, free use being made of a nail brush for this purpose. The operation was performed under a cloud of carbolized watery vapour (1 in 30) from a steam-spray-producer. The visible bleeding points were first ligated; the tourniquet was removed; and any vessels that had escaped notice were secured. The wound was stitched, a drainage-tube made of red rubber being introduced at one corner to prevent accumulation of discharge; a strip of "protective"—oiled silk coated with carbolized dextrin—was washed in carbolic lotion and applied over the wound. A double ply of carbolic gauze was soaked in the lotion laid over the protective, overlapping it freely. A dressing consisting of eight layers of dry gauze was placed over all, covering the stump and passing up the leg for about six inches. Over that a piece of thin mackintosh cloth was placed, and the whole arrangement was fixed with a gauze bandage. The mackintosh cloth prevented the carbolic acid from escaping and at the same time caused the discharge from the wound to spread through the gauze. The wound itself was shielded by the protective from the vapour given off by the carbolic gauze, whilst the surrounding parts, being constantly exposed to its activity, were protected from the intrusion of septic contamination. And these conditions were maintained until sound healing took place. Whenever the discharge reached the edge of the mackintosh the case required to be dressed, and a new supply of gauze was applied round the stump. Whenever the wound was exposed for dressing the stump was enveloped in the vapour of carbolic acid by means of the steam-spray-producer. At first a syringe was used to keep the surface constantly wet with lotion and then a hand-spray. These dressings were repeated at intervals until the wound was healed. The drainage-tube was gradually shortened, and was ultimately removed altogether.

The object Lister had in view from the beginning of his experiments was to place the open wound in a condition as regards the entrance of organisms as nearly as possible like a truly subcutaneous wound, such as a contusion or a simple fracture, in which the unbroken skin acted as a protection to the wounded tissues beneath. The introduction of this practice by Lister effected a complete change in operative surgery. The dark times of suppurring wounds, of foul discharges, of secondary haemorrhage, of pyaemic abscesses and hospital gangrene constitute what is now spoken of in surgery as the pre-Listerian era.

As years went on, surgeons tried to simplify and improve the somewhat complicated and expensive measures and dressings and chemists were at pains to supply carbolic acid in a pure form and to discover new antiseptics, the great object being to get a non-irritating antiseptic which should at the same time be a powerful germicide. Iodoform, oil of eucalyptus, salicylic acid, boracic acid, mercuric iodide, and corrosive sublimate were used.

For some years Lister irrigated a wound with carbolic lotion during the operation and at the dressings when it was exposed, but the introduction of the spray displaced the irrigation method. All these different procedures, however, as regards both the antiseptic used and the best method of its application in oily and watery solutions and in dressings, were subsidiary to the great principle involved—namely, that putrefaction in a wound can be prevented and that, if it is prevented, local irritation, in so far as it is due to putrefaction, is obviated and septicemia and pyaemia cannot occur. Alongside of this great improvement the immense advantage of free drainage was universally acknowledged. Moreover, surgeons at once began to take greater care in securing the cleanliness of wounds, and some of them, Lawson Tait and Bantock, for example, produced such excellent results by the adoption merely of methods of strict cleanliness, and became so aggressive in their championship of them, that many of the older practitioners were bewildered and unable to decide as to where truth began and where it ended in the new doctrine. But though the actual methods, as taught and practised by Lister, have, with the spray-producers, passed away and given place to new, still the great light which he shed in the surgical world burns as brightly as ever it did, and all the methods which are practised to-day are the direct results of his teaching.

By 1885 the carbolic acid spray, which to some practitioners had apparently been the embodiment of the Listerian theory and practice, was beginning to pass into desuetude, though for a good many years after that time certain surgeons continued to employ it during operation, and during the subsequent dressings of the wound. Surgeons who, having had practical experience of the unhappy course which their operation-cases had been apt to run in the pre-Listerian days, and of the vast improvements which ensued on their adoption of the spray-and-gauze method in its entirety, were, not unnaturally, reluctant to operate except in a cloud of carbolic vapour. So, even after Lister himself had given up the spray, its use was continued by many of his disciples. It was in the course of 1888 that operating surgeons began to neglect the letter of the antiseptic treatment and to bring themselves more under the broadening influence of its spirit. Certain adventurous and partially unconvinced surgeons began to give up the carbolic spray gradually, by imparting a smaller percentage of carbolic acid to the vapour, until at last the antiseptic disappeared altogether, apparently without detriment to the excellence of the results obtained. But while some surgeons were thus ceasing to apply the antiseptic spray to the wound during operation, others were pouring mild carbolic lotion, or a very weak solution of corrosive sublimate (an extremely potent germicide) over the freshly-cut surfaces. These measures were in turn given up, to the advantage of the patient; for it was hardly to be expected that a chemical agent which was strong enough to destroy or render inert septic micro-organisms in and about a wound would fail to injure exposed and living tissues. Eventually it became generally admitted that if a surgeon was going to operate upon the depths of an open abdomen for an hour or more, the chilling and the chemical influences of the spray must certainly lower the vitality of the parts exposed, as well as interfere with the prompt healing of the wounded surfaces. With the spray went also the "protective," the paraffin gauze, and the mackintosh sheeting which enveloped the bulky dressing.
Aseptic Surgery.

Years before this happened, in the address on surgery given at the Cork meeting of the British Medical Association, Sir William (then Mr) Savory had somewhat severely criticized the rigid exclusiveness of the members of the spray-and-gauze school; the sum and substance of the address was that every careful surgeon was an anti-septic surgeon, and that the success of the Listerian surgeon did not depend upon the spray or the gauze, or the two together, but upon cleanliness—that the surgeon’s fingers and instruments and the area operated on must be surgically clean. Though precise experiments show that it is impossible for the surgeon to remove every trace of septicity from his own hands and from the skin of the operator, or to use instruments which are certainly germless, and alcohol and turpentine, with possibly the help of some mercuretic germicide, he can, for all practical purposes, render his hands safe. Recognizing this difficulty many surgeons prefer to operate in thin rubber gloves which can, for certain, by boiling, be rendered free of all germs; others, in addition, put on a mask, sterile overalls, and india-rubber shoes. But these excessive refinements do not seem to be generally acceptable, whilst the results of practice show that they are by no means necessary.

The careful, the antiseptic surgeon of 1885 is to-day represented by the careful, the aseptic surgeon. The antiseptic surgeon was wrestling with the Listerian antiseptic system. But though the pendulum has swung so far in the direction of aseptic surgery, a very large proportion of operators still adhere to the antiseptic measures which had proved so highly beneficial. The judicious employment of weak solutions of carbolic acid, or of mercuretic salts, and the application of unirritating dressings of an anti-septic nature cannot do any harm, and, on the other hand, they may be of great service in the case of there having been some flaw in the carrying out of what should have been an absolutely aseptic operation.

A great change has taken place in connexion with the use of soft india-rubber drainage-tubes. In former years most surgeons placed one or more of these in the dependent parts of the area of operation, so that the blood or serum oozing from the injured tissues might find a ready escape. But to-day, except in dealing with a large abscess or other septic cavity, many surgeons make no provision for drainage, but, bandaging the part beneath a pad of aspetic wool, put on so much pressure that any little leakage into the tissues is quickly absorbed. If a drainage-tube can be dispensed with, so much the better, for if it is not actually needed its presence keeps up irritation and delays prompt healing. But inasmuch as a tube if rightly placed in a deep wound is an insur- ance against the occurrence of "tension," and as it can easily be withdrawn at the end of twenty-four hours (even if it has served no useful purpose), it is improbable that the practice of drainage of freshly made cavities will ever be entirely given up. If the tube is removed after twenty-four hours its presence can have done no harm and sometimes the large amount of fluid which it has drained from the wound affords clear evidence that its use has saved the patient discomfort and has probably expedited his recovery. For septic cavities drainage-tubes are still used, but it must be remembered that the tube cannot remain long in position without causing and keeping up irritation; hence, even in septic cases, the modern surgeon discards the tube at the earliest possible moment. If after he has taken it out septic fluids collect, and the patient’s temperature rises, it can easily be taken out. But it is better to take out the tube too soon than to leave it in too long; this remark applies with special force to the treatment of abscess of the pleural cavity (Bier’s treatment) in the case of which a drainage-tube has almost certainly to be employed.

Poultices are now never used: they were apt to be foul and offensive, and were certainly septic and dangerous. If moisture and warmth are needed for a wound they can be obtained by the use of a fold of clean lint, or by some aseptic wool which has been wrung out in a hot solution of boracic or carbolic acid, and applied under some waterproof material, which effectually prevents evaporation and chilling. There was no special virtue in poultices made of linseed meal or even of scraped carrot: they simply stored up the moisture and heat. They possessed no possible advantage over the modern fomentation under oil-silk.

Much less is heard now of so-called "bloodless" operations. The bloodlessness was secured by the part to be operated on—an arm, for instance—being raised and compressed from the fingers to the shoulder by successive turns of an india-rubber roller-bandage (Esmarch’s), the main artery of the limb being then compressed by the application of an elastic cord above the highest turn of the bandage. The bandage being removed, the operation was performed through bloodless tissues. But when it was completed the elastic cord removed from around the upper part of the limb, a reactionary flow of blood took place into every small vessel which had been previously squeezed empty, so that though the operation itself had actually been bloodless, the wound could not be closed because of the occurrence of unusually free haemorrhage or troublesome oozing. A further objection to the application of such an elastic roller-bandage was that septic or tuberculous material might by chance be squeezed from the tissues in which it was perhaps harmlessly lying, forced into the blood vessels, and so widely disseminated through the body. Esmarch’s bandage is therefore but little used now in operative surgery. Instead, each bleeding point at an operation is promptly secured by a small pair of nickel-plated clip-forceps, which generally have the effect, after being left on for a few minutes, of completely and permanently arresting the bleeding. These clips were specially introduced into practice by Sir Spencer Wells, and it is no unusual thing for a surgeon to have twenty or thirty pairs of them at hand during an extensive operation. Seeing how convenient, not to say indispensable, they are in such circumstances, the surgeon of to-day wonders how he formerly managed to get on at all without them.

A great change in the treatment of pressure congestion is carried out by gently assisting the return of venous blood from a part of the body without in any way checking the arterial flow. In the case of tuberculous disease of the knee-joint, for instance, an elastic band is gently placed round the thigh for several hours a day, and in disease of the wrist or elbow the girth is applied round the arm. The skin below becomes flushed, and the arterial blood which, as shown by the pulse, is still flowing into the affected part, is compelled to linger in the affected tissues, giving the serum and the white corpuscles time to exert their beneficial influence upon the disease. In the case of tuberculosis, or, septic, affections of the lymphatic glands of the neck, or of other parts where the constriction cannot be conveniently obtained, effective congestion can be secured by the use of cupping glasses. And if so be that suppuration is taking place in the interior of an inflamed gland, the cupping-glasses can be applied after a small puncture has
been made into the softened part of the gland. In this way the whole of the broken-down material can be got away without the necessity of making an actual incision or of resorting to scraping. The method of inducing hyperaemia should be so conducted as to give the patient no pain whatever; it must not be carried on an extirpative surgery.

By means of the Röntgen or X-rays (see X-Ray Treatment) the surgeon is able to procure a distinct shadow-portrait of deeply-placed bones, so that he can be assured as to the presence or absence of fracture or dislocation, or of outgrowth of bone, or of bone-containing tumours. By this means also he is able to locate with absolute precision the situation of a foreign body in the tissues—of a coin in the windpipe or gullet, of a broken piece of a needle in the hand, of a splinter cf glass in the foot, or of a bullet deeply embedded in soft tissues or bone. This effect may be obtained upon a fluorescent screen or printed in a permanent form upon glass or paper. The shadow is cast by a 10- or 12-in. spark from a Crookes vacuum tube. The rays of Röntgen find their way through dead and living tissues which are far beyond the reach of the rays of ordinary light, and they are thus able even to reveal changes in the deeply placed hip-joint which have been produced by tuberculous disease. In examining an injured limb it is not necessary to take off wooden splints or bandages except in cases where the latter have been treated with plaster of paris, or where fragments of bone or other foreign bodies obstruct the rays and throw a shadow. Thus the rays may pass through an ordinary uric acid calculus in the kidney or bladder; but if it contains salts of lime, as does the mulberry calculus (oxalate of lime), a definite shadow is cast upon the screen. The value of the X-rays is not limited to the elucidation of obscure problems such as those just indicated: they are also of therapeutic value; for example, in the treatment of certain forms of skin disease, as well as of cancer.

Too much, however, must not be expected from them. For the treatment of a patch of tuberculous ulceration (lupus), or for a superficial cancerous sore (epithelioma), they may be of service, but in the treatment of a deeply-seated malignant growth—as a cancer of the breast—they have not proved of value. Moreover, the X-rays sometimes cause serious burns of the skin; and although this happens less often now than was previously the case, still the frequent application of the rays is apt to be followed by cutaneous warty growths which are apt in turn to develop into cancer. In many cases in which the X-rays are used a more prompt and efficient means of treatment would probably be by excision. One great advantage which operative treatment by the knife must always have over the treatment by X-rays is that the secondary implication of the lymphatic glands can be dealt with at the same time. And this, in many cases, is a matter of almost equal importance to that of removal of the cancer itself.

The employment of radium in surgery is still in its infancy. Doubtless radium is a very powerful agent, but even if it were found of peculiar value in treatment its cost would, for the present, put it out of the reach of most practitioners. Probably it will be found useful in the treatment of naevus, rodent ulcers and superficial malignant growths. As to what influence radium may have in the treatment of deeply-seated cancers it is as yet impossible even to guess. For those sad cases, however, which the practical surgeon is reluctantly compelled to admit as being beyond the reach of his operative skill, the influence of radium should be tried with determination and thoroughness. The therapeutic influence of radium may eventually be found to be great, or it may be disappointing. The fact that under direct royal patronage an institution has been established in London for the investigation of the physical and therapeutic value of this newly discovered agent should satisfy every one that its properties will be duly inquired into and made known without mystery or charlatanism and absolutely in the interest of the people. But in the meanwhile too much must not be expected from it as a surgical agent.

(E. O. *)

SURGICAL INSTRUMENTS AND APPLIANCES. The purpose of this article is to give an account of the more important surgical Instruments that are now in general use, and to show by what modifications, and from what discoveries in science, the present methods of an operation have come to be what they are. The good surgeon is careful to use the right sort and pattern of instrument, and the chief fact about the surgery of the present day, that it is aseptic or antiseptic, is recorded in the make of surgical instruments and in all the installation of an operating-theatre. Take, for instance, a scalpel and a saw that are figured in Ambroise Paré's (1570-1596) surgical writings. The scalpel folds into a handle like an ordinary pocket-knife, which alone was enough in those days to keep it from being aseptic. The handle is most elegantly adorned with a little winged female figure, but it does not commend itself as likely to be surgically clean. The saw, after the same fashion, has a richly chased metal frame, and, at the end of the handle, a lion's head in bold relief, with a ring through its mouth to hang it up by. It may be admirable art, but it would harbour all sorts of germs. If one contrasts with these artistic weapons the instruments of 1850, one finds no such adornment, and for general finish Savigny's instruments would be hard to beat; but the wooden or ivory handles, cut with finely scored lines like the cross-hatching of an engraving, are not more likely to be aseptic than the handles of Paré's instruments. At the present time, instead of such handles as these, with blades riveted into them, scalpels are forged out of one piece of steel, their handles are nickel-plated and perfectly smooth, that they may afford no crevices, and may be boiled and immersed in carbolic lotion without tarnishing or rusting; the scalpel has become just a single, smooth, plain piece of metal, having this one purpose that it shall make an aseptic wound. In the same way the saw is made in one piece, if this be possible; anyhow, it must be, so far as possible, a simple, smooth, unrusting metal instrument, that can be boiled and laid in lotion; it is a foreign body that must be introduced into tissues susceptible of infection, and it must not carry infection with it.

Or we may take, at different periods of surgery, the various kinds of ligature for the arrest of bleeding from a divided blood-vessel. In Paré's time (he was the first to use the ligature in amputation, but the existence of some sort of ligature as
old as Galen) the ligature was a double thread, *bon fil qui soit en double;* and he employed a forceps to draw forward the cut end of the vessel to be ligatured. From the time of Ambroise Paré to the time of Lord Lister no great improvement was made. In the middle of last century it was no uncommon thing for the house-surgeon at an operation to hang a leash of waxed threads, silk or flax, through his button-hole, that they might be handy during the operation. Then came Lord Lister's work on the absorbable ligature; and out of this and much other experimental work has come the present use of the ligature in its utmost perfection—a thread that can be tied, cut short, and left in the depth of the wound, with absolute certainty that the wound may at once be closed from end to end and nothing more will ever be heard of the ligatures left buried in the tissues. The choice of materials for the ligature is wide. Some surgeons prefer catgut, variously prepared; others prefer silk; for certain purposes, as for the obliteration of a vessel not divided but tied in its course for the cure of aneurism, use is made of kangaroo-tendon, or some other animal substance. But whatever is chosen is made aseptic by boiling, and is guarded vigilantly from contamination on its way from the sterilizer into the body of the patient. The old ligatures were a common cause of suppuration. Therefore the wound was not closed along its whole length, but the ligatures were left long, hanging out of one end of the wound, and from day to day were gently pulled until they came away. Certainly they served thus to drain the wound, but they were themselves a chief cause of the suppuration that required drainage.

Sutures, like ligatures, were a common cause of suppuration in or around the edges of the wound. Therefore, in the hope of avoiding this trouble, they were made of silver wire, which was inconvenient to handle, and gave pain at the time of removal of the sutures. At the present time they are of silkworm-gut, catgut, silk or horsehair; they are made aseptic by boiling, and can be left any number of days without causing suppuration and can then be removed without pain.

Next may come the consideration of surgical dressings. In the days when inflammation and suppuration were almost inevitable, the dressings were usually something very simple, that could be easily and frequently changed—ointments, or wet compresses, to begin with, and poultices when suppuration was established. It is reported of the great Sir William Fergusson that he once told his students, "You may say what you like, gentlemen, but after all, there's no better dressing than cold water." This is not the place to try to tell the long history of the quest after a perfect surgical dressing, and the advance that was begun when Lord Lister invented his carbolic paste. The work was done slowly in the international unity of science during many years. The perfect, antiseptic dressing must fulfill many requirements: it must be absorbent, yet not let its medicament be too quickly soaked out of it; and it must be antiseptic, yet not virulent or poisonous. Of the many gauzes now available, that which is chiefly used is one impregnated with a double cyanide of zinc and mercury. Its pleasant amethystine tint has no healing virtue, but is used to distinguish it from other gauzes—carbized gauze, tinted straw-colour; iodoform gauze, tinted yellow; sublituate, blue; chinosol, green. The chinosol gauze is especially used in ophthalmic surgery; for general surgery the cyanide gauze is chiefly employed. The various preparations of absorbent wool (i.e. wool that has been freed of its grease, so that it readily takes up moisture) are used not only for outside dressings, but also as sponges at the time of operation, and have to a great extent done away with the use of real sponges. The gauzes in most cases are used not dry, but just wrung out of carbolic lotion, that their antiseptic influence may act at once.

The whole subject of surgical instruments may be considered in more ways than one. It may be well, for the sake of clearing the ground, to take first some of the more common instruments of general surgery, and then to note the working out, in the operations of surgery, of the three great principles—the use of anaesthetics, the use of antiseptic or aseptic methods, and the surgical uses of electricity.
on one side, near the point. Thus they enter the skin very easily, like a miniature knife, and the minute wound they make is not a hole, but a tiny slit that is at once drawn together and, as it were, obliterated by the tying of the suture. Or, for another simple instrument in universal use, take the catch-forceps that is used for taking hold of a bleeding point till it is ligatured. This forceps is as old as the time of Paré, but he made use of a very heavy and clumsy pattern. Up to the last few years the artery-forceps was made with broad, curved, fenestrated blades, with the catch set close to the blades. At the present time the forceps in general use, named after Dr Féau in France and after Sir Spencer Wells in England, is made with very narrow grooved blades, and the catch is placed not near the blades, but near the handles; thus it takes a surer hold, and can be set free when the ligature is tied by a moment’s extra pressure on the handles.

Among other instruments in universal use are divers forms of retractors, for holding gently the edges of a wound: the larger patterns are made with broad, slightly-concave, highly-polished surfaces, that they may, so far as possible, reflect light into the wound. Among tourniquets, the old and elaborate Petit’s tourniquet, which was a band carrying a pad screwed down over the main artery of the limb, has given place to the elastic tourniquet with Esmarch’s bandage. For example, in an amputation, or in an operation on a joint or on a vessel or a nerve in a limb, the limb is raised, and the Esmarch’s elastic bandage is applied from below upward till it has reached a point well above the site of the operation; then an elastic tourniquet is wound round the limb at this point, the bandage is removed, and the limb is thus kept almost bloodless during the operation.

It is not possible to describe here the many forms of other ordinary instruments of general surgery—probes, directors, scissors, forceps, and many more—nor those that are used in operations on the bones. Nor again can the numerous instruments used in special departments of surgery be discussed in detail. But, with regard to the special surgery of the eye, and of the throat and ear, it is to be noted that the chief advance in treatment arose from the invention of the present instruments of diagnosis, and that these are of comparatively recent date. The ophthalmoscope was the work of Helmholtz. The laryngoscope was invented by Manuel Garcia in the middle of the 19th century; and the use of a frontal mirror, for focussing a strong light on the membrana tympani, in the examination of the ear, was in use somewhat earlier. Before the ophthalmoscope it was impossible to study the internal diseases of the eye; before the laryngoscope the diseases of the larynx were invisible, and were mainly a matter of guess-work, and of vague and often futile treatment. Before the use of the frontal mirror the diseases of the ear were hardly studied, in that sense in which they are studied now. The wonderful advance of the special departments of surgery was, of course, the result of many forces, but one of the chief of these forces was the invention of proper instruments of diagnosis. The textbooks that were written immediately before those instruments became available were not far in advance of Ambrose Paré, so far as these special departments are concerned.

It may be well next to consider in what ways the conduct of an operation is influenced by those two great discoveries of anaesthetics, and the more gradual development of the principles of antisepsic and aseptic surgery; with special reference to the use of the instruments of surgery. The jubilee year of anaesthesia was 1896; the first use of nitrous oxide was on the 11th of December 1844; the first operation under ether was on the 30th of September 1846; the first use of chloroform was on the 4th of November 1847. The choice of the anaesthetic, or of some combination of anaesthetics, that is best suited to each particular case, is a matter of careful consideration; but, on the whole, the tendency in England is to keep to the use media between the more general use of chloroform in Scotland and the more general use of ether in the United States. Of the methods of administering chloroform there is no need to say much; by some anaesthetists no instrument is used save a fold of lint or some such stuff, or a piece of flannel made into a sort of cone or mask. Use is generally made of a modification of "Junker’s inhaler," whereby the vapour of chloroform is administered by means of a hand-ball. For the administration of ether some form of Clover’s inhaler is generally used, whereby the ether in a small metal chamber passes as vapour into an indiarubber bag, and there is combined with the patient’s breath in proportions determined by the anaesthetist throughout the operation. The metal chamber is so designed that by turning it the exact proportion of ether to air is fixed in accordance with the requirements of the case. Of late years, by the use of an iron cylinder of nitrous oxide, connected by a tube with a Clover’s inhaler, it is possible to begin with nitrous oxide, and to go on, without interruption, with ether. More recently an admirable method has been devised of administering nitrous oxide with the admixture of air or of oxygen in such a way that the anaesthesia produced by the gas may be maintained for time enough to allow of an operation of some length.
The series of discoveries which, in its application to surgery, has brought about the present antiseptic and aseptic methods of operation, is concerned both with the sterilization of instruments, water, and with their preparation for use. The mere sterilization, by boiling or by steaming, of all instruments and dressings, is enough to ensure their freedom from the ordinary micro-organisms, but the surgeon cannot boil or steam either himself or his patient. The preparation, therefore, of the surgeon's hands, and of the skin over the area of operation, is made not only by scrubbing with soap and hot water, but by careful use of antiseptic lotions. Again, ligatures and sutures, which must be kept in stock ready for use, are kept, after careful sterilization, in antiseptic lotion, or are again sterilized immediately after an operation. Again, all towels used at an operation must be prepared, either by sterilization or by immersion in antiseptic lotion.

Beside anaesthetics and antiseptics, there is a third series of discoveries that has profoundly influenced surgery—the use of the forces of electricity. The uses of electricity are fivefold.

1. The Galvano-Cautery.—The original form of the cautery, the fer ardent of Paré's time, for the arrest of haemorrhage after amputation, was a terrible affair. Happily for mankind, his invention of the ligature put an end to this use of the cautery, but it was still used in a small number of other cases. Subsequently André Paquelin (b. 1836) invented a very ingenious form of cautery, a series of metal blades or points of different shapes and sizes, that could be fitted to a handle: these points were hollow inside, and were filled with fine platinum gauze, and, by means of a bottle and hand-bellows, they could be kept heated with benzene-vapour. Thus, when they had once been raised to a glowing heat by holding them over a spirit-lamp, they could be kept at any desired heat. This instrument is still in use for a few cases where very rapid and extensive cauterization is necessary. But for all finer use of actual heat the galvano-cautery alone is needed. It consists of very minute points of platinum, with a suitable trigger-handle, connected with a battery or (by means of a converter) with the ordinary house supply of electricity. In this way it is possible to apply a glowing point with a fineness and accuracy of adjustment that were wholly impossible with Paquelin's cautery.

2. Electrolysis.—This method is of great value, in suitable cases, for the arrest or obliteration of small growths. The passage of the electric current between needles introduced into the skin brings about a gradual shrinking or cicatrization of the tissues subjected to it, without the production of any unsightly scar.

3. Electro-Motor Power.—During recent years the use of a small electro-motor machine has come into the practice of surgery for certain operations on the bones; especially for the operation for disease involving the mastoid bone. It is, of course, a better method for the use of a fine drill or burr, for example, than the "dental engine," where the power is generated by a pedal演员 wheel, and it will probably come into wide use both for dental surgery and for those operations of general surgery that require very gradual and delicate removal of small circumscribed areas of bone, especially of the cranial bones.

4. The X-Rays.—This was the most unexpected and, as it were, the most sensational discovery that has been bestowed on physicians and surgeons since the discovery of anaesthetics, is now used over a very wide and varied field of practice. Its value does not stop at the detection and localization of foreign bodies; indeed, this is but a small part of its work. It is used constantly for cases of actual or suspected fracture or dislocation; for cases of congenital or acquired deformity: for cases involving difficulties of diagnosis between a swelling of the bone due to inflammation and a swelling due to a fungus; and for the observation of cases of spinal disease, hip disease and the like. Moreover, it has been found possible, by Dr Hugh Walsham, and others to obtain pictures of the thoracic organs that are a very valuable guide in many obscure cases of disease of the lungs or of the heart, and in many cases of thoracic aneurism or of intra-thoracic tumour. Every year the number and the range of the uses where the X-rays are helpful for diagnosis and for treatment become greater; and it is impossible to say at what point the surgical value of this discovery will find its limits. Beyond these uses, it is probable that the X-rays will maintain and extend the importance and value that they already have in the direct treatment of certain cases of disease of the skin (see X-Ray Treatment).

5. The Electric Light.—The use of this to light up the field of operation is of the greatest importance. It is especially valuable in those operations in the eye, nose, and throat, where the light has to be brought to a very delicate point. The Oleophot is the most convenient for this purpose. With it, in the hands of a skilled operator, it is possible to inspect the interior of the bladder, and in many cases to make an exact diagnosis under circumstances where otherwise it would be impossible. Another instance of the value of the electric light in diagnosis is given by the trans-illumination of the facial bones in cases of suspected disease of the central cavity of the superior maxillary bone. A small glow-lamp is held in the opened mouth, in a darkened room, and by a comparison of the shadows on the two or under the face, thus trans-illuminated, an exact diagnosis can often be obtained as to the presence or absence of pus in this central cavity. Again, a small glow-lamp, duly sterilized, is often of great value in deep operations on the abdominal cavity.

The bactericidal properties of light have long been demonstrated by Bisé and others. Professor Niels Finsen of Copenhagen first used the ultra-violet rays of solar light in the treatment of skin diseases,
notably of lupus. He later invented the lamp which bears his name. The original Finsen lamp comprised a volatile arc of 60 to 80 amperes round which four tubes collected the light by quartz lenses, the light being cooled by passing through water and the tubes being surrounded by a water-jacket. The usual exposure was one hour. In the Finsen-Reyn modification now used, a single collecting tube fitted on an adjustable stand is placed in front of a scissors arc lamp consuming 20 amperes. The rays are cooled and water-jacketed as in the original. A suitable quartz compressor with a chamber containing circulating water is pressed upon the skin of the part to be treated and held at right angles to the impinging rays. The time of exposure is now reduced to forty-five minutes.

Radium when used in surgery is applied by means of applicators, either having the fixed salts on square or oblong metallic plates or cloth or by applicators having free radium in sealed metal tubes. These tubes are sometimes buried in the tissues. Sometimes a method of "screening" is adopted in order to modify the intensity of the radiation. This is done by enveloping the tubes containing the radium in cases of silver, lead or nickel of various thicknesses. In this, known as the method of Dr Dominici, the α and β rays are intercepted by the metal screens and the highly penetrative rays only applied to the morbid tissues.

The illustrations in this article are by permission of Messrs Allen & Hanbury, London, and that of the radium applicators, by permission of Messrs Siemens Brothers, London.

SURIFICATE, or MEERKAT (Suricata tetradactyla), a small South African mammal of the civet family, ranging from Cape Colony to Algoa Bay. The head and body are about 14 in. long, and the tail half as much; the fur is long and soft, light grazed grey in colour, and banded with black on the lower part of the back. Meerkats are sociable animals, living in holes in the rocks on the mountains, and burrowing in the sandy soil of the plains. They form amusing pets, and in a wild state, writes Mrs A. Martin, they feed chiefly on "succulent bulbs, which they scratch up with the long, curved, black claws on their fore-feet. They are devoted sun-worshippers and in the early morning, before it is daylight, they emerge from their burrows and walk in rows till their divinity appears, when they bask joyfully in his beams."

SURINAM TOAD (Pipa americana), an agnostic tailless Batrachian, rendered famous by its mode of reproduction, first observed in 1710 by the Dutch anatomist F. Rinicus. It inhabits South America and the west coast of the Amazon, and is thoroughly aquatic. In its extremely flattened head it is paralleled by two other vertebrates only, which, curiously, inhabit the same parts of South America, viz. the Silurid fish Aspredo batracus and the Chelonian Chelys matamata; the end of the snout and the angles of the jaws bear several lappets, the fingers terminate in a star-shaped appendage, the toes are very broadly webbed and the eyes are minute and without lids.

The eggs are carried on the back by the mother, and the skin thickens and grows around the egg until each is enclosed in a dermal cell, which is finally covered by a healthy lid believed to be formed by a secretion of the skin or else to represent the remains of the gelatinous capsule which at first surrounded the eggs. These, which may number about one hundred and measure five to seven millimetres in diameter, develop entirely within these pouches, and the young hop out in the perfect condition, without a vestige of a tail. Pairing takes place in the water, the male clasping the female round the waist. The way in which the eggs reach the back of the female has been observed in specimens kept in the London Zoological Gardens. During oviposition the cloacas projects from the vent as a bladdery-like pouch, which is inverted forwards, between the back of the female and the breast of the male, and by means of this ovi-POSITOR the eggs are evenly distributed over the whole back. How the eggs are fertilized has not been ascertained.

SURMA, or BARAK, a river of Assam, India. It is one of the two chief rivers of the province, watering the southern valley of the Brahmaputra waters the northern and larger valley. It rises in the Barall range to the north of Manipur, its sources being among the southern spurs of Tripo. Thence its course is south with a slight westerly bearing, through the Manipur hills to British territory. The name of Barak is given to this part of the river, in Manipur and Cachar. A short distance below Badarpur in Cachar it divides into two branches. One of these, which passes Syhet, is called Surma. The other is called Kusira till it subdivides into (a) a branch called Bhitiana Kahnì, which joins the Surma near Ajimganji, and (b) a branch which resumes the name of Barak and joins the Surma near Habiganj. At Bhairab Bazar in Mymensingh the Surma unites with the old Brahmaputra and becomes known as the Meghna. The river is navigable by steamers as far as Silchar in the rains. Total length about 500 m.

The SURMA VALLEY AND HILL DISTRICTS DIVISION is a division of the province of Eastern Bengal and Assam. It includes the five districts of Syhet Cachar, Lushai hills, Naga hills, and Khasi and Jaintia hills, with a total area of 25,481 sq. m. and a population in 1901 of 3,084,527.

SURFACE-WATER (Latin: superficium), is the part of a watercourse, lake, river, or standing water, which is exposed at low water; the part below the surface, yet above the bed of the stream and often covered with water, is called the sub-surface.

SURPLICE—SURPlice.

Fig. 19.—Radium Applicators.
SURRENDER—SURRENTUM

137

that this was, in all main particulars, the custom so early as the 14th century.

The older history of the surplice is obscured by lack of exact information. Its name is derived, as Durandus and Gerland also affirm, from the fact that it was formerly put on over the fur garments which used to be worn in church and at divine service as a protection against the cold. It has been maintained that the surplice was known in the 5th century, the evidence being the garments worn by the two clergies in attendance on Bishop Maximian represented in the mosaics of S. Vitale at Ravenna; in this case, however, the dalmatic has been confused with the surplice. In all probability the surplice is no more than an expansion of the ordinary liturgical alb, due to the necessity for wearing it over thick furs. It is first mentioned in the 12th century, in a canon of the synod of Coyaza in Spain (1090) and in an ordinance of King Edward the Confessor. In Rome it was known at least as early as the 12th century. It probably originated outside Rome, and was imported thence into the Roman use. Originally only a choir vestment and peculiar to lower clergy, it gradually—certainly no later than the 13th century—replaced the alb as the vestment proper to the administering of the sacraments and other sacerdotal functions.

In the Oriental rites there is no surplice, nor any analogous vestment. Of the non-Roman Churches in the West the surplice has continued in regular use only in the Lutheran churches of Denmark, Norway and Sweden, and in the Church of England (see below).

Church of England.—The surplice was prescribed by the second Prayer-Book of Edward VI., as, with the tippet or the acedemical hood, the sole vestment of the minister of the church at “all times of their ministration,” the rochet being practically regarded as the episcopal surplice. Its use was furiously assailed by the extemore Reformers but, in spite of their efforts, was retained by Elizabeth’s Act of Uniformity, and enforced by the advertisements and injunctions issued under her authority, which ordered the “massing vestments”—chasubles, albs, stoles and the like—to be destroyed. It has since remained, with the exception of the cope (q.v.), the sole vestment authorized by law for the ministers, other than bishops, of the Church of England (for the question of the vestments prescribed by the “Ornaments Rubric” see VESTMENTS). Its use has never been confined to clerics in holy orders, and it has been worn since the Reformation by all the “ministers” (including vicars-choral and choristers) of cathedral and collegiate churches, as well as by the fellows and scholars of colleges and choirs. The distinctive mark of the clergy (at least of the more dignified) has been the tippet or scarf above mentioned, a broad band of black silk worn stole-wise, but not to be confused with the stole, since it has no liturgical significance and was originally no more than part of the clerical outdoor dress (see STOLE). The surplice was formerly only worn by the clergy when conducting the service, being exchanged during the sermon for the “black gown,” i.e. either a Geneva gown or the gown of an academic degree. This custom has, however, as a result of the High Church movement, fallen almost completely obsolete. The “black gown,” considered wrongly as the ensign of Low Church views, survives in comparatively few of even the “evangelical” churches; it is still, however, the custom for preachers of university sermons to wear the gown of their degree.

The traditional form of the surplice in the Church of England is that which survived from pre-Reformation times, viz. a wide-sleeved, very full, plain, white linen tunic, pleated from the yoke, and reaching almost, or quite, to the feet. Towards the end of the 17th century, when large wigs came into fashion, it came for convenience to be constructed gown-wise, open down the front and buttoned at the neck, a fashion which still partially survives, notably at the universities. In general, however, the tendency has been, under continental influence, to curtail its proportions. The ample vestment with beautiful falling folds has thus in many churches given place to a scanty, unplasted garment scarce reaching to the knee. In the more “extreme” churches the surplices are frank imitations of the Roman cassock (W. A. P.)

SURRENDER, in law, a mode of alienation of real estate.

It is defined by Lord Coke to be “the yielding up of an estate for life or years to him that hath an immediate estate in reversion or remainder” (Coke upon Littleton, 337 b). It is the converse of release, which is a conveyance by the reversoner or remainderman to the tenant of the particular estate. A surrender is the usual means of effecting the alienation of copyholds. The surrender is made to the lord, who grants admissitance to the purchaser, an entry of the surrender and admittance being made upon the court rolls. Formerly a devise of copyholds could only have been made by surrender to the use of the testator’s will followed by admittance by the devisee. The Wills Act of 1837 now allows the devisee of copyholds without surrender, though admissitance of the devisee is still necessary. A surrender must, since the Real Property Act 1845, be by deed, except in the case of copyholds and of surrender by operation of law. Surrender of the latter kind generally takes place by merger, that is, the combination of the greater and less estate by descent or by other means without the act of the party (see REMAINDER). In Scots law surrender in the case of a lease is represented by renunciation. The nearest approach to surrender of a copyhold is resignation in remanentiam (to the lord) or resignation in faveore (to a purchaser). These modes of conveyance were practically superseded by the simpler form introduced by the Conveyancing Act 1874.

SURRENTUM (mod. Sorrento, q.v.), an ancient town of Campania, Italy, situated on the N. side of the promontory which forms the S.E. extremity of the Bay of Naples. The legends indicate a close connexion between Lipara and Surrentum, as though the latter had been a colony of the former; and even through the Imperial period Surrentum remained largely Greek. Before the Roman supremacy it was one of the towns subject to Surrentum, and shared its fortunes (to the Social War; it seems to have joined in the revolt of 90 B.C. of the Stabiae; and was reduced to obedience in the following year, when it seems to have received a colony. Its prosperity dates from the imperial period, when Capreae was a favourite residence of Augustus and Tiberius. Numerous sepulchral inscriptions of Imperial slaves and freedmen have been found at Surrentum. An inscription shows that Titus in the year after the earthquake of A.D. 79 restored the horologium of the town and its architectural decoration. A similar restoration of an unknown building in Naples in the same year is recorded in an inscription from the last-named town (cf. A. Sogliano in Notizie degli Scavi, 1904, p. 363). The most important remains of Surrentum are those of Athena and of the Sirens (the latter the only one in the Greek world in historic times); the former gave its name to the promontory. In antiquity Surrentum was famous for its wine (oranges and lemons which are now so much cultivated there not having been introduced into Italy in antiquity), its fish, and its red Campanian vases; the discovery of coins of Massilia, Gaul and the Balearic Islands here indicates the extensive trade which it carried on. The position of Surrentum was very secure, it being protected by deep gorges, except for a distance of 300 yds. on the south-west where it was defended by the walls, and the north-west by those of Athena and of the Sirens. The arrangement of the modern streets preserves that of the ancient town, and the disposition of the walled paths which divide the plain to the east seems to date in like manner from Roman times. No ruins are now preserved in the town itself, but there are many remains in the villa quarter to the east of the town on the road to Stabiae, of which traces still exist, running much higher than the modern road, across the mountain; the site of one of the largest (possibly belonging to the Imperial house) is now occupied by the Hotel Victoria, under the terrace of which a small theatre was found in 1855; an ancient rock-cut tunnel descends hence to the shore. Remains of other villas may be seen, but the most important ruin is the reservoir of the (subterranean) aqueducts just outside the town on the east, which had no less than twenty-seven chambers each about 90 ft. by 20 ft. Greek and Oscan tombs
have also been found. Another suburb lay below the town and on the promontory on the west of it; under the Hotel Sirena are substructions and a rock-hewn tunnel. To the north-west on the Cape, the Sorrento has been built, the so-called Regina Giovanna, with baths, and in the bay to the south-west was the villa of Polluis Felix, the friend of Statius, which he describes in Silvae ii. 2, of which remains still exist.

Farther west again are villas, as far as the temple of Athena on the promontory named after her at the extremity of the peninsula (now Punta Campanella). Neither of this nor of the famous temple of the Sirens are any traces existing.

See J. Beloch, 

SURREY, EARLDOM OF. There is some doubt as to when this earldom was created, but it is unquestionably of early origin. A Norman count, William de Warenne (c. 1030–1088), is generally regarded as its first holder and is thought to have been made an earl by William II. about 1088. William and his successors were styled earls of Surrey or Ears Warenne indifferently, and the family became extinct when William, the 3rd earl, died in 1148. The second family to hold the earldom of Surrey was descended from Isabel de Warenne (d. 1190), daughter and heiress of Earl William, and her second husband Hamelin Plantagenet, d. 1216, and his brother Richard de Warenne, 2nd Earl of Surrey. Hamelin took the name of Warenne and was recognized as earl of Surrey or Earl Warenne, and his descendants held the earldom until Earl John died without legitimate issue in 1347.

The earldom and estates of the Warennes now passed to John's nephew, Richard Fitzalan, earl of Arundel (c. 1307–1376), being forfeited when Richard's son, Richard, was beheaded for treason in 1307. Then for about two years there was a duke of Surrey, the title being borne by Thomas Holand, earl of Kent (1374–1400), from 1397 until his deposition in 1399. In 1400 Richard Fitzalan's son, Sir Thomas Fitzalan (1381–1415), was restored to his father's honours and became earl of Arundel and earl of Surrey, but the latter earldom reverted to the Crown when he died. In 1415 John Mowbray (1444–1476), afterwards duke of Norfolk, was created earl of Surrey, but the title became extinct on his death.

The long connexion of the Howards with the earldom of Surrey began in 1483 when Thomas Howard, afterwards duke of Norfolk, was created earl of Surrey. Since that time, with the exception of brief periods when some of its holders were under arrest, the earldom of Surrey was always held by the dukes of Norfolk. The courtesy title of the duke's eldest son is earl of Surrey.

See the articles WARENNE, EARLS; and ARUNDEL, EARLS OF; also G. E. C. (okayne), Complete Peerage, vol. vii. (1896).

SURREY, HENRY HOWARD, EARL OF (1518–1547). English poet, son of Lord Thomas Howard, afterwards 3rd duke of Norfolk, and his wife Elizabeth Stafford, daughter of the duke of Buckingham, was born probably in 1518. He succeeded to the courtesy title of earl of Surrey in 1524, when his father became duke of Norfolk. His early years were spent in the various houses belonging to the Howards, chiefly at Kennington, in the county of Oxford. This was concluded at the earliest possible date, in February 1532, but in consequence of the extreme youth of the contracting parties, Frances did not join her husband until 1535. In October Surrey accompanied Henry VIII. to Boulogne to meet Francis I., and, rejoining the duke of Richmond at Calais, he proceeded with him to the French court, where the two Englishmen were lodged with the French royal princes. Surrey created for himself a reputation for wisdom, soberness and good learning, which seems curious in view of the events of his later life.

In 1535, while in Spain, he made the project of a contract between him and the princess Mary was revived in a correspondence between Pope Clement VII. and the emperor Charles V., but definitely rejected by the latter. Surrey only returned to England in the autumn of 1535, when the duke of Richmond was recalled to marry his friend's sister, Mary Howard. Surrey made his home at his father's house of Kenninghall, and here was a witness of the final separation between his parents, due to the duke's relations with Elizabeth Holland, who had been employed in the Howards' nursery. Surrey took his father's side in the family disputes, and when Kenninghall was purchased for him in 1535. In May 1536, he discharged his father's functions of earl marshal at the trial of his cousins Anne Boleyn and Lord Rochford. In the autumn of that year he took part with his father in the bloodless campaign against the rebels in Yorkshire and Lincolnshire, in the "Pilgrimage of Grace." Although he had supported the royal cause, insinuations were made that he secretly favoured the insurgents. Hasty in temper, and by no means friendly to the Seymour faction at court, he struck a man who repeated the accusation in the park at Hampton Court. For breaking the peace in the king's domain he was arrested in 1541, but released in time to exchange for the petition of the young man's father, he was not compelled to appear before the privy council, but was merely sent to reside for a time at Windsor. During this imprisonment and the subsequent retirement at Kenninghall, he had leisure to devote himself to poetry. He was again received into favour. In May 1540 he was one of the champions in the jousts celebrated at court. The fall of Thomas Cromwell a month later increased the power of the Howards, and in August Henry VIII. married Surrey's cousin, Catherine Howard. Surrey was knighted early in 1541, and soon after he received the order of the Garter, made a grand councilor of the realm, and re-formed his connection with his father, grand seneschal of the university of Cambridge. He apparently preserved the royal favour after the execution of Catherine Howard (at which he was present), for in December 1541 he received the grant of certain manors in Norfolk and Suffolk. In 1542 he was imprisoned in the Fleet for a quartar with a certain John Leigh, but on appeal to the privy council he was sent to Windsor Castle, and, after being bound over to keep the peace with John Leigh under a penalty of 10,000 marks, he was soon liberated.

Shortly after his release he joined his father on the Scottish expedition. They laid waste the country, but retreated before the earl of Huntly, taking no part in the victorious operations that led up to Solway Moss. To this year no doubt belong the poems in memory of Sir Thomas Wyatt. His ties with Wyatt, who was fifteen years his elder and of opposite politics, seem to have been rather literary than personal. He appears to have entered into closer relations with the younger Wyatt. In company with "Mr Wyatt," he amused himself by breaking the windows of the citizens of London on the 2nd of February 1543. For this he was accused by the privy council, a second charge being that he had been present at the meet in Lent. In prison probably he wrote the satire on the city of London, in which he explains his escapade by a desire to rouse Londoners to a sense of their wickedness. In October he joined the English army co-operating with the imperial forces in Flanders, and on his return in the next month brought with him a letter of high commendation from Charles V. In the campaign of the next year he served as field marshal under his

1 The only authority for the date of his birth is the legend Salt. superest. Aetatis XXIX. on a portrait of Henry Howard at Arundel Castle.
father, and took part in the unsuccessful siege of Montreuil. In August 1545 he was sent to the relief of Edward Paynings, then in command of Boulogne, and was made lieutenant-general of the English possessions on the Continent and governor of Boulogne. Here he gained considerable successes, and insisted on the retention of the town in spite of the desire of the privy council that it should be surrendered to France. A reverse on the 7th of January at St Étienne was followed by a period of inaction, during which Suffolk was in the Dutch service.

Suffolk had always been an enemy to the Seymours, whom he regarded as upstarts, and when his sister, the duchess of Richmond, seemed disposed to accept a marriage with Sir Thomas Seymour, he wrote to her insinuating that this was a step towards becoming the mistress of Henry VIII. By his action in thwarting this plan he increased the enmity of the Seymours and added his sister to the already long list of the enemies which he had made by his haughty manner and brutal frankness. He was now accused of quartering with his own the arms of Edward the Confessor, a proceeding which, if true, was, only permissible for the heir to the crown. The details of this accusation were false; moreover, Suffolk had long quartered the royal arms with his own without offence. The charge was a pretext covering graver suspicions. Suffolk had asserted in the presence of a certain George Blage, who was inclined to the reforming movement, that on Henry’s death, his father, the duke of Norfolk, as the premier duke in England, had the obvious right of acting as regent to Prince Edward. He also boasted of what he would do when his father had attained that position. All of this was construed into a plot on the part of his father and himself to end in March Suffolk and the prince. The duke of Norfolk and his son were sent to the Tower on the 12th of December 1546. Every effort was made to secure evidence. The duchess of Richmond was one of the witnesses (see her depositions in Herbert of Cherbury, Life and Reign of Henry VIII., 1649) against her brother, but her statements were too doubtful to add anything to the formal indictment. On the 25th of January 1547 Suffolk defended himself at the gaolhall on the charge of high treason for having illegally made use of the arms of Edward the Confessor, before judges selected for their known hatred of himself. He was condemed by a jury, packed for the occasion, to be hanged, drawn and quartered at Tyburn. This sentence was commuted to transportation to Tower Hill on the 19th of the month, and was buried in the church of All Saints, Barking. His remains were afterwards removed by his son the earl of Northampton to Framlingham, Suffolk. His father, who was charged with complicity in his son’s crime, was, as a peer of the realm, not amenable to a common jury. The consequent delay saved his life. He was imprisoned during the whole of the reign of Edward VI., but on Mary’s accession he was set free, by an act which also assured the right of the Howards, as descendants of the Mowbray family, to bear the arms of the Confessor.

Surrey’s name has been long connected with the “Fair Geraldine,” to whom his love poems were supposed to be addressed. The story is recorded in the last section of Thomas Nashe, The Unfortunate Traveller, or Life of Jack Wilton (1594), according to which Surrey saw a magic glass in the Netherlands the face of Geraldine, and then traced those features to the challenge placed by a woman in one of the fields of the lady. At Florence he held a tournament in her honour, and was to do the same in other Italian cities when he was recalled by order of Henry VIII. The legend, deprived of its more glaring discrepancies with Surrey’s life, and revived by Drayton’s England’s Heroicall Epistles (1598). Geraldine was the daughter of the earl of Kildare, Lady Elizabeth Fitzgerald, who was brought up at the English court in company with the princess Elizabeth, afterwards Mary, Queen of Scots (see Lives of the Fitzgeralds, 1874). She was ten years old when in 1537 Surrey addressed to her the sonnet “From Tuscanie came my ladies worthy race,” and another one “And游击队 in your pleasures in exile,” are addressed to her wife, to whom, at any rate in his later years, he seems to have been sincerely attached.

His poems, which were the occupation of the leisure moments of his short and crowded life, were first printed in Songs and Sonettes written by the right honorable Lord Henry Howard late Earl of Surrey, and afterwards (another collection followed) in July 1557, and others in 1559, 1565, 1567, 1570, 1580, and 1587. Although Surrey’s name, probably because of his rank, stands first on the title-page, Wyatt was the earlier in point of time and more original. The courtiers, who had stuck close to the king’s contributions are distinguished by their impetuous eloquence and sweetness. He revived the principles of Chaucer’s versification, which his predecessor had allowed to fall on a weak syllable, nor did he permit weak syllables as rhymes. His chief innovation as a poet lies outside the form, for the earlier volumes of his Poetical Works, the first and fourth books of the Aenidae into blank verse—the first attempt at blank verse in English—was published separately by Tottel in the same year with the title of Certain Bookes of Virgiles Aenidae turned into English meter. It has been suggested that in this matter Surrey was influenced by the translation of Virgil published at Venice by Ippolito de’ Medicis in 1541, but there is no direct evidence that such was the case. His sonnets are in various schemes of verse, and are less correct in form and more loosely constructed than those of Wyatt. They commonly consist of three quatrains with independent rhymes, terminating with a rhyming couplet. But his sonnets, which had the least value of the poems left to him, are still more free from the form, and his lyrics in various measures, served as models to more than one generation of court poets. Both in form and substance Surrey and his fellow poets were largely indebted to Italian predecessors of his, but the English were the first in originals. The tone of the love sentiment was new in English poetry, very different in its earnestness, passion and fantastic extravagance from the lightness and gaiety of the Chaucerian school.

SURREY, a south-eastern county of England bounded N. by the Thames, separating it from Buckinghamshire and Middlesex, E. by Kent, S. by Sussex, and W. by Hampshire and Berkshire. The county Northemlyly includes the tidal portion of the Thames (south of the Thames) on the north-east. The area is 758 sq. m. The north Downs are a picturesque line of hills running east and west through the county somewhat south of the centre (see Downs). Leith Hill, south-west of Dorking (805 ft.), is the highest summit, and commands a prospect unrivalled in the south of England; Holmbury Hill close by reaches 857 ft., and the detached summit of Hindhead above Haslemere in the south-west reaches 895 ft. At Guildford the Wey breaches the hills; and at Dorking the Mole. These are the chief rivers of the county; they reach the Thames near Weybridge and at East Molesey respectively. The county is divided into two districts, the north and south respectively, the latter including the largest part of the county. Surrey is thus almost entirely in the Thames basin. In the south-east it includes headstreams of the Eden, a tributary of the Medway; and in the south a small area drains to the English channel. Three types of scenery appear—that of the hilly southern district; that of the Thames, with its richly-wooded banks; and, in the north-west, that of the sandy heath-covered district, abundant in conifers, which includes the healthy open tracts of Bagshot Heath and other commons, extending into Berkshire and Hampshire. Possessing these varied attractions, Surrey has become practically a great residential district for those who must live in the neighbourhood of London.

Geology.—The northern portion of the county, in the London basin elevation, belongs to the London Clay, with its Upper Eocene deposits, the London Clay, the lowest of which is generally the London Clay of the Lower Eocene, stretching (with interruptions) from London to Farnham; this is fringed on its southern edge by the underlying Woolwich beds of the same group,

SURREY 139
which also appear in isolated patches at Headley near Leatherhead; and the thatchets at the base crop out between Beddington, Banstead and Leatherhead. The north-western portion of the county, which is called the South Surrey or South-West area, is in the Upper Eocene, Bagshot Sands: the Fox hills and the black Chobham Ridges are formed of the upper series of the group, which rests upon the Wey valley clay. The district has been called the Bagshot Heath by Blaisey and Firbright commons, while eastwards the commons of Chobham, Woking and Esher belong to the lower division of the group. To the south of the Eocene formations the smooth rounded outliers of the clay hills extend to and surround the centre of the county from Farnham to Westerham (Kent). From Farnham to Guildford they form a narrow ridge called the Hog’s Back, about half a mile in breadth with a higher northern escarpment embracing the towns of Barnet and Harrow. Between East and Guildford the northern dip decreases and the outcrop widens, throwing out picturesque summits, frequently partly wooded, and commanding wide and beautiful views of the Weald. The Wealden clay is well known as firestone, and quarried and mined for this purpose and for hearthstone near Godstone, crops out underneath the Chalk along the southern escarpment of the Downs. The Gault, a dark blue sandy clay, rests beneath the Upper Greensand and is the bottom of the long narrow valley which separates the chalk Downs from the well-marked Lower Greensand hills. The Lower Greensand includes the subordinated diatomaceous beds of the Folkestone that here are lavishly near the claystone for commercial purposes; the Sandgate beds, to which the well-known fuller’s earth of Nutfield belongs, and the Hythe beds, which contain the Kentish Rag, a sandy chloritic limestone used for building purposes. This formation is comical of this series locally called Bargete stone. To this formation belong the heights of Leith Hill, Hindhead and the Devil’s Punchbowl, Holmbury Hill. Between the Lower Greensand and the Wealden clay the Weald clay is frequently covered with a few feet of loam. The Weald Clay itself consists of a blue or brown shaly clay, amid which are deposited river shels, plants of tropical origin and reptilian remains. The Weald Clay is much worked for clay pitting by the Wealden Sandstone, 90 ft. thick, is a small area in the south-eastern corner of the county. Bordering the Thames there are terraced deposits of gravel and loam.

Agriculture.—Between one-half and three-fifths of the area of the county, a low proportion, is under cultivation, and of the land that is in permanent pasture there are considerable varieties of soil, ranging from plastic clay to calcareous earth and bare rocky heath. The plastic clay is well adapted for wheat, but only extensively grown on the London Clay. A considerable area is occupied by market gardens on the alluvial soil along the banks of the Thames, especially in the vicinity of London. In early times the market gardeners were Flemings, who introduced the culture of asparagus at Ruislip and of carrots at Chertsey. Rhodendrons and azaleas are largely grown in the north-western district of the county. In the neighbourhood of Mitcham various medicinal plants are cultivated, especially lavender, marjoram, rosemary, liquorice, hyssop, &c. The calcareous soil in the neighbourhood of Farnham is well adapted for hops, but this crop in Surrey is of minor importance. There is a large market for hops at Woking. Such crops as oak, chestnut, ash, beech, sycamore, birch are extensively planted; alder and willow plantations are common; and the Scotch fir propagates naturally from seed on the commons in the north-west. The extent of pasture land is not great, with the exception of the Isle of Wight, which is entirely devoted to pasturage. Dairy-farming is a more important industry than cattle-rearing, large quantities of milk being sent to London.

Manufactures and Communications.—The more important manufactures are chiefly confined to London and its immediate neighbourhood. The rivers Mole and Wandle, however, supply power for a variety of manufactures, such as oil, paper and sheet-iron mills. Communications include the navigation of the Thames and the Medway, and the Basingstoke canal, communicating with the Wey from Frimley and Woking. Owing to its proximity to London the county is served by many lines of railway, the companies being the London & South Western, London Brighton & South Coast and the South-Eastern & Chatham.

Population and Administration.—The area of the ancient county is 485,122 acres, with a population in 1901 of 2,012,774. The population of the counties of Surrey and Middlesex (1,698,032) is equal to 13 per cent. of the population of England and Wales, as also in 1841. The population of the county has doubled between 1871 and 1901. Under the provisions of the Local Government Act 1888, part of the county was transferred to the county of London. Thus the area of the ancient county remains 55,461 acres, with a population in 1901 of 675,774. The area of the administrative county is 461,807 acres. The county contains 14 hundreds. Croydon (pop. 133,895) is a county borough, and the ancient city of London (pop. 1,325,098) is a Metropolis County Borough. The counties of Croydon, Epsom (109,915), Esher and The Dittons (94,899), Farnham (91,377), Frimley (84,094), Hambledon (146,094). The following are urban districts: Barnes (17,668), Carshalton (67,576), Caterham (64,906), Chertsey (12,762), Effingham (8,783), Egham (7,249), Ewell (10,915), Esher (15,958), Kingston (34,475), Reigate (25,906), Richmond (31,672), Wimbledon (41,652). The following are rural districts: Barnes, Carshalton, Leatherhead, Malden and Morden. There are six parliamentary divisions—North Western or Chertsey, Mid or Epsom, Kingston, North Eastern or Woking, South Eastern or Croydon, South Western or Guildford, and West or Woking. The borough of Croydon returns one member. Surrey is in the south-eastern circuit, and assizes are held at Guildford and Kingston alternately. The administrative county has one court of quarter sessions, but the liberty of Chertsey has a separate court of sessions. The county is divided into 10 hundreds, and the hundreds of Croydon, Godalming, Guildford, Kingston, Reigate and Richmond have separate commissions of the peace, and Croydon and Guildford have in addition separate courts of quarter sessions. The county is constituted of fourteen hundreds, and has jurisdiction over certain parishes adjacent to London. All those civil parishes within the county of Surrey, of which any part is within 12 m. of, or of which no part is within 12 m. from, Charing Cross, are in the metropolitan police district. The total number of civil parishes is 144. The ancient county contains 230 ecclesiastical parishes or districts, wholly or in part situated in the dioceses of Rochester, Winchester, Canterbury, Oxford, and Chichester.

History.—The early history of this county is somewhat uncertain. Ethelward, in the Anglo-Saxon Chronicle for 823, places it in the "Medii Angli" or "Medii Saxones." Its position between the Weald and the Thames decided its northern and southern borders, and the Kentish boundary probably dates from the battle of Wibbandune between Ethelbert of Kent and Cæwan of Wessex, which traditionally took place at Wimborne, though this is disputed. The western border, like the southern, was a wild uncultivated district; no settled boundary probably existing at the time of the Domesday Survey. The number of hundreds at that time was fourteen as now, but the hundred of Farnham was not so called till the time of Wim- bledon. "The hundred of Wimborne" is one of the largest; and the present hundred of that name. There is no record of Surrey ever having been in any diocese but Winchester, of which it was an archdeaconry in the 12th century. At the time of the Domesday Survey there were four deaneries: Croydon, Southwark, Guildford and Ewell. Croydon was a peculiar of Canterbury, in which diocese it was included in 1291. In the time of Henry VIII., Croydon was comprehended in the deanery of Ewell, some of its rectories being included in the deanery of Southwark. The old deanery of Guildford was included in the modern one of Stoke. In 1577, Southwark, with some parishes, was transferred to the diocese of Rochester. In the 17th century Surrey was under the overlordship of Wulfhere, king of Mercia, who founded Chertsey abbey, but in 823, when the Mercians were defeated by Egbert of Wessex, it was included in the kingdom of Wessex, as the Anglo-Saxon Chronicle relates.

Surrey was constantly overrun by Danish hordes in the 9th century and until peace was established by the accession of Canute. In 857 a great national victory over the Danes took place at Ockley near Leith Hill. Surrey is not of great historical importance, except its northern border, the southern part having the forest of Weybridge and the Thankful, impassable for an army. Guildford, though the county town, and often the seat of the court under John and Henry III., was of little importance beside Southwark, the centre of trade and commerce, the residence of many ecclesiastical dignitaries, a frequent point of attack on London, and a centre for rebellions and riots. The Norman army traversed and ravaged the county in their march on London, a large portion of the county having been in the hands of Edward and Harold, fell to the share of William himself; his most important tenants in chief being Odo of Bayeux and Robert of Gloucester. At the time of the Barons’ War the bishopric was divided—de Clare marching with Montfort, and de Warenne supporting the king. In the Peasants’ Rising of 1381,
and during Jack Cade's Rebellion in the next century, Southwark was invaded, the prisons broken open and the bridge into London crossed. London was unsuccessfully attacked from the Surrey side in the Wars of the Roses; and was held for three days and pillaged during a rising of the southern counties under Mary. During the fears of invasions from Spain, levies were held in readiness in Surrey to protect London; and it was an even more important bulwark of London in the Civil War, on account of the powder mills at Chilworth and the cannon foundries of the Weald. In common with the southern counties, a distinctively Surrey accent still is in sympathetic use. Sir Richard Onslow and Sir Poyning's More were the most prominent local leaders. Farnham Castle and Kingston, with its bridge, were several times taken and held during the war by the opposing parties, and in the later part of the war, when the parliament and army were treating, three of the line of forts defending London were on the Surrey side, from which the army entered London.

The last serious skirmish south of the Thames took place near Ewell and Kingston, where the earl of Holland and a body of the Royalists were routed. This was the last real fighting in the county, though it was often a centre of riot; the most serious being those of 1830, and of the Chartists in 1848, who chose Kennington Common as their meeting-place. The Moors of Loselay and the Onsloes were among the most famous county families under the Tudors, as at the time of the Civil War; the Onsloes being even better known later in the person of Sir Arthur Onslow, Speaker of the House under George I.

The earliest industries in Surrey were agricultural. The stone quarries of Limpsfield and the chalk of the Downs were early used, the latter chiefly for lime-making. Fuller's earth was obtained from Reigate and Nutfield; and the facilities afforded by the many small streams, and the excellent sheep pasture, made it of importance in the manufacture of cloth, of which Guildford was a centre. Glass and iron were made in the Weald district, whose forests produced the necessary charcoal for smelting. Chiddingfold is mentioned in 1266 for its glass-making, and was one of the chief glass-producing districts in late Tudor times. The iron-works of Surrey were of less importance, and much later in development than those of Kent and Sussex, owing to the want of good roads or waterways, but the increasing demand for ordnance in the 16th century led to the spread of iron industry northward; the most considerable works in Surrey being those of Viscount Montague at Haslemere. Chilworth, which was famous for its powder mills in the 16th century, remains a seat of the industry. Southwark and its neighbouring hood early became a suburb of London and a centre of trades which were crowded out of London. The earliest Delft ware manufactary in England was at Lambeth, which maintains its fame as a centre of earthenware manufacture. The beautiful encaustic tiles of Chertsey Abbey are thought to have been made in English monasteries and date from the 13th century. Although the county was doubtless represented in the representative councils of the reign of Henry III., the first extant returns of two knights of the shire are for the parliament of 1290. The Reform Bill of 1832 gave Surrey four members; dividing the county into east and west divisions. Several boroughs were disfranchised then and in 1867, when East Surrey was again divided into east and mid divisions, on account of the growth of London suburbs, two more members being added at the same time. In 1855 all old boroughs and divisions were superseded; the county being divided into the electoral divisions of Chertsey, Guildford, Reigate, Epsom, Kingston and Wimbledon, each returning one member. Finally, in 1888, the new county of Surrey annexed large portions of Surrey along the northern border.

Antiquities.—The only ecclesiastical ruins worthy of special mention are the picturesque walls of Newark Priory, near Woking, founded for Augustinians in the time of Richard Coer de Lion; and the Early English crypt and part of the refectory of Waverley Abbey, the earliest house of the Cistercians in England, founded in 1128. The church architecture is of a very varied kind, and has no peculiarly special features. Among the more interesting churches are Albury (the old church), near Guildford, the tower of which is of Saxon or very early Norman date; Beddington, a fine example of Perpendicular, containing monuments of the Carew family; Chaldon, remarkable for its fresco wall-paintings of the 12th century, discovered during restoration in 1870; Compton, which, though mentioned in Domesday, possesses little of its original architecture, but is worthy of notice for its two-storeyed chantry and its carved wooden balustrade surmounting the pointed transitional Norman arch which separates the nave from the chancel. Leigh, Perpendicular, possessing some very fine brasses of the 13th century; Lingfield, Perpendicular, containing ancient tombs and brasses of the Cobhams, and some fine stalls (the church was formerly collegiate); Ockham, chiefly Decorated, with a lofty embattled tower, containing the mausoleum of Lord Chancellor King (d. 1754), with full-length statue of the chancellor by Rysbrack; Stoke d'Abernnon, Early English, with the earliest extant English brass, that of Sir John d'Abernnon, 1277, and other fine examples. Churches at Guildford, Reigate and Woking are also noteworthy. A few early examples are Farnham, occupied as a palace by the bishops of Winchester; the most interesting of Blois, and restored by Henry III.; and Guildford, with a strong quadrangular Norman keep. Of ancient domestic architecture examples include Beddington Hall (now a female orphan asylum), the ancient mansion of the Carews, rebuilt in the reign of Queen Anne, and in modern times, but retaining the hall of the Elizabethan building; Crowhurst Place, built in the time of Henry VII., the ancient seat of the Gaynesfords, and frequently visited by Henry VIII.; portions of Croydon Palace, an ancient seat of the archbishops of Canterbury; the gate tower of Esher Place, built by William of Wykeham, bishop of Winchester, and repaired by Cardinal Wolsey; Archbishop Abbot's hospital, Guildford, in the Tudor style; the fine Elizabethan house of Losley near Guildford; Smallsfield Place near Reigate, now a farmhouse, once the seat of Sir Edward Bysse (c. 1615–1679), garter king-at-arms; Sutton Place near Woking, dating from the time of Henry VIII., possessing curious mouldings and ornaments in terra-cotta; and Ham House, of red brick, dating from 1610.

SURROGATE (from Lat. surrogare, to substitute for), do a deputy of a bishop or an ecclesiastical judge, acting in the absence of his principal and strictly bound by the authority of the latter. Canon 32 of the canons of 1603 lays down the qualifications necessary for the office of surrogate and canon 127 the regulations for the appointment to the office. At present the chief duty of a surrogae is in England is the granting of marriage licences, but judgments of the arches court of Canterbury have been delivered by a surrogae in the absence of the official principal. The office is unknown in Scotland, but is of some importance in the United States as denoting the judge to whom the jurisdiction of the probate of wills, the grant of administration and of guardianship is confined. In some states he is termed surrogae, in others judge of probate, register, judge of the orphans' court, &c. His jurisdiction is local, being limited to his county.

SURTEES, ROBERT (1734–1814), antiquary and topographical historian, was the son of Robert Surtees of Mainsforth, Durham. He was educated at Christ Church, Oxford, and after studying law without being called to the bar he settled on the family estate at Mainsforth, which he inherited on his father's death in 1802, and where he lived in retirement for the rest of his life, devoting himself to the study of local antiquities and collecting materials for his History of Durham. This
book was published in four volumes, the first of which appeared in 1816, and the last in 1840, after the author’s death. The work contains a large amount of an episcopal and antiquarian information; it is written in a readable style, and its learning is enlivened by humour. Surtees had also a gift for ballad writing, and he was so successful in imitating the style of old ballads that he managed to deceive Sir Walter Scott himself, who gave a place in his Minstrelsy of the Scottish Border to a piece by Surtees called “The Death of Featherstonehaugh,” under the impression that it was ancient. Surtees, who in 1807 married Anne Robinson, died at Mainsforth on the 11th of February 1834. As a memorial of him the Surtees Society was founded in 1834 for the purpose of publishing and collecting unedited manuscripts bearing on the history of the border country.

SURTEES, ROBERT SMITH (1803–1864), English novelist and sporting writer, was the second son of Anthony Surtees of Hamsterley Hall, a member of an old Durham family. Educated to be a solicitor, Surtees soon began to contribute to the Sporting Magazine, and in 1831 he published a treatise on the law relating to horses and particularly the law of warranty, entitled The Horseman’s Manual. In 1832 and 1833, he helped to found the Horseman’s Journal, of which he was the editor for the next five years. To this periodical he contributed between 1832 and 1834 the papers which were afterwards collected and published in 1838 as Jorrocks’s Jaunts and Jollities. This humorous narrative of the sporting experiences of a cockney grocer, which suggested the more famous Pickwick Papers of Charles Dickens, is the work by which Surtees is chiefly remembered, though his novel Handley Cross, published in 1843, in which the character of “Jorrocks” is re-introduced as a master of fox-hounds, also enjoyed a wide popularity. The former of these two books was illustrated by “Thix” (H. K. Browne), and the latter, as well as most of Surtees’s subsequent novels, by John Leech, whose pictures of “Jorrocks” are everywhere familiar and were the chief means of ensuring the lasting popularity of that humorous creation. In 1838, on the death of his father, Surtees, whose elder brother had died in 1831, inherited the family property of Hamsterley Hall, where he lived for the rest of his life. The later novels by Surtees included Hildesdon Hall (1849), in which “Jorrocks” again appears; Hawbuck Grange (1847); Mr sponge’s sporting tour (1853); ask mamma (1859); Mr facey Romford’s hounds (1863). The last of these novels appeared after the author’s death, which occurred on the 16th of March 1864. In 1841 he married Elizabeth Jane, daughter of Addison Fenwick of Bishopwearmouth, by whom he had one son and two daughters, the younger of whom, Eleanor, in 1855 married John Prenedest Vereker, afterwards 5th Viscount Gort.

SURVEYING, the technical term for the art of determining the position of prominent points and other objects on the surface of the ground, for the purpose of making therefrom a graphic representation of the area surveyed. The general principles on which surveys are conducted and maps computed from such data are in all instances the same; certain measures are made on the ground, and corresponding measures are projected on paper on whatever scale may be a convenient fraction of the natural scale. The method of surveying varies with the magnitude of the survey, which may embrace an empire or represent a small plot of land. All surveys rest primarily on linear measurements for the direct determination of distances; but linear measurement is often supplemented by angular measurement which enables distances to be determined by principles of geometry over areas which cannot be conveniently measured directly, such, for instance, as hilly or broken ground. The nature of the survey depends on the proportion which the linear and angular measures bear to one another and is almost always a combination of both.

History.—The art of surveying, i.e. the primary art of map-making from linear measurements, has no historical beginning. The first rude attempts at the representation of natural and artificial features on a ground plan based on actual measurements of which any record is obtainable were those of the Romans, who certainly made use of an instrument not unlike the plane-table for determining the alignment of their roads. Instruments adapted to surveying purposes were in use many centuries earlier than the Roman period. The Greeks used a form of log line for recording the distances from point to point along the coast, while making their slow voyage from the Indus to the Persian Gulf three centuries B.C.; and it is improbable that the adaptation of this form of linear measurement was confined to the sea alone. Still earlier (as early as 1600 B.C.) it is said that the Chinese knew the value of the loadstone and possessed some form of magnetic compass. But there is no record of their methods of linear measurements, or that the distances and angles measured were applied to the purpose of map-making (see COMPASS and MAP). The earliest maps of which we have any record were based on inaccurate astronomical data; and it was not till several centuries, when the Arabs made use of the Astrolabe (q.v.), that nautical surveying (the earliest form of the art) could really be said to begin. In 1450 the Arabs were acquainted with the use of the compass, and could make charts of the coast-line of those countries which they visited. In 1498 Vasco da Gama saw a chart of the coast-line of India, which was shown him by a Gujarati, and there can be little doubt that he benefited largely by information obtained from charts which were of the nature of practical coast surveys. The beginning of land surveying (apart from small plan-making) was probably coincident with the earliest attempts to discover the size and figure of the earth by means of exact measurements, i.e. with the inauguration of geodesy (see GEODESY and Earth, Figure of the), which is the fundamental basis of all scientific surveying.

Classification.—For convenience of reference surveying may be considered under the following heads—involving very distinct branches of the art dependent on different methods and instruments:

1. Geodetic triangulation.
2. Levelling.
3. Nautical surveys.

1. Geodetic Triangulation

Geodesy, as an abstract science dealing primarily with the dimensions and figure of the earth, may be found fully discussed in the articles GEODESY and Earth, Figure of the; but, as furnishing the basis for the construction of the first framework of triangulation on which all further surveys depend (which may be described as its second but most important function), geodesy is an integral part of the art of surveying, and its relation to subsequent processes requires separate consideration. The part which geodetic triangulation plays in the general surveys of civilized countries which require closely accurate and various forms of mapping to illustrate their physical features for military, political or fiscal purposes is best exemplified by reference to some completed system which has already served its purpose over a large area. That of India will serve as an example.

The great triangulation of India was, at its inception, calculated to satisfy the requirements of geodesy as well as geography, because the latitudes and longitudes of the points of the triangulation had to be determined for future reference by process of calculation combining the results of the triangulation with the elements of the earth’s figure. The latter were not then known with much accuracy, for so far geodetic operations had been mainly carried on in Europe, and additional operations nearer the equator were much wanted; the survey was conducted with a view to supply this want. The necessity for accuracy in the triangulation was therefore great.

Primarily a network was thrown over the southern peninsula. The triangles on the central meridian were measured with extra care and checked by base-lines at distances of about 2° apart in
latitude in order to form a geodetic arc, with the addition of astronomically determined latitudes at certain of the stations. The base-lines were measured with chains and the principal angles with a 3-ft. theodolite. The signals were carried of stones or poles. The chains were somewhat rude and their units of length had not been determined originally, and could not be afterwards ascertained. The results were good of their kind and sufficient for geographical purposes; but the central meridional arc—the 'great arc'—was eventually deemed inadequate for geodetic requirements. A superior instrumental equipment was introduced, with an improved

**GEODETIC**

---

**FIG. 1.**

**modus operandi**, under the direction of Colonel Sir G. Everest in 1832. The network system of triangulation was superseded by meridional and longitudinal chains taking the form of gridirons and resting on base-lines at the angles of the gridirons, as represented in fig. 1. For convenience of reference and nomenclature the triangulation west of meridian 92° E. has been divided into five sections—the lowest a trigon, the other four quadrilaterals distinguished by cardinal points which have reference to an observatory in Central India, the adopted origin of latitudes. In the north-east quadrilateral, which was first measured, the meridional chains are about one degree apart; this distance was latterly much increased and eventually certain chains—as on the Malabar coast and on meridian 84° in the south-east quadrilateral—were dispensed with because good secondary triangulation for topography had been accomplished before they could be begun.

All base-lines were measured with the Colby apparatus of compensation bars and microscopes. The bars, 10 ft. long, were set up horizontally on tripod stands; the microscopes, 6 in. apart, were mounted in pairs revolving on a vertical axis and were set up on tripods fitted to the ends of the bars. Six bars and five central and two end pairs of microscopes—the latter with their vertical axes perforated for a look-down telescope—constituted a complete apparatus, measuring 63 ft. between the ground pins or registers. Compound bars are more liable to accidental changes of length than simple bars; they were therefore tested from time to time by comparison with a standard simple bar; the microscopes were also tested by comparison with a standard 6-in. scale. At the first base-line the compensated bars were found to be liable to sensible variations of length with the diurnal variations of temperature; these were supposed to be due to the different thermal conductivities of the brass and the iron components. It became necessary, therefore, to determine the mean daily length of the bars precisely, for which reason they were systematically compared with the standard before and after, and sometimes at the middle of the base-line measurement throughout the entire day for a space of three days, and under conditions as nearly similar as possible to those obtaining during the measurement. Eventually thermometers were applied experimentally to both components of each compound bar, when it was found that the diurnal variations in length were principally due to difference of position relatively to the sun, not to difference of conductivity—the component nearest the sun acquiring heat most rapidly or parting with it most slowly, notwithstanding that both were in the same box, which was always sheltered from the sun's rays. Happily the systematic comparisons of the compound bars with the standard were found to give a sufficiently exact determination of the mean daily length. An elaborate investigation of theoretical probable errors (p.e.) at the Cape Comorin base showed that, for any base-line measured as usual without thermometers in the compound bars, the p.e. may be taken as \( \pm 0.5 \) millionths of the length, excluding unascertainable constant errors, and that on introducing thermometers into these bars the p.e. was diminished to \( \pm 0.55 \) millionths.

In all base-line measurements the weak point is the determination of the temperature of the bars when that of the atmosphere is rapidly rising or falling; the thermometers acquire and lose heat rapidly, and thus much more accurately than the chain or their bulbs are outside, and more slowly if inside the bar. Thus there are always errors and its effects are only eliminated when the rises and falls are of equal amount and duration; but as a rule the rise generally predominates on the first day of the station and is less on the second; but lagging may cause more error in a base-line measured with simple bars than all other sources of error combined. In India the probable average lagging of the standard-bar thermometer was estimated as \( \pm 0.01 \) degree centigrade, corresponding to an error of 0.0001 in the length of a base-line measured with iron bars. With compound bars lagging would be much the same for both components and its influence would consequently be eliminated. Thus the iron perfect base-lines seem to require compensation bars with thermometers attached to each component; then the comparisons with the standard need only be taken at those times when the temperature is constant, and there is no lagging.

**The plan of triangulation** was broadly a system of internal meridional and longitudinal chains with an external border of oblique curves, following the well-known course of the primary geodetic base lines. The design of each chain was necessarily much influenced by the physical features of the country over which it was carried. The most difficult tracts were plains, devoid of any commanding points of view; in some parts covered with forests and jungles almost impenetrable, in other parts covered with towns and villages and unobstructed trees. In such tracts triangulation was impossible except by the use of theodolites, raising them to a sufficient height to overtop at least the earth's curvature, and then either increasing the height to surmount all obstacles to mutual vision, or clearing the lines. Thus in hilly and mountainous country the largest possible geodetic chain was made "double" throughout, i.e. formed of polygonal and quadrilateral figures to give greater breadth and accuracy; but in forest and close country they were carried out as series of single triangles, to give the maximum of labour and expense. Syntheses were carried out by restricting the angles between the limits of 30° and 90°. The average side length was 30 m. in hill country and 11 in the plains; the principal length of the chain from the Malabar coast to the Himalayan peaks was 10,000 ft., and the triangulation to the Himalayan peaks there were sides exceeding 200 m. Long sides were at first considered desirable, on the principle that the fewer the links the greater the accuracy of a chain of triangulation, but this did not hold true, for the triangles on long sides could only be obtained under exceptionally favourable atmospheric conditions. In plains the length was governed by the height to which towers could be conveniently raised to surmount all obstacles on the ground. In Indian plains refraction is much more frequent than in European countries, and a simple matter in hills and close country, is often difficult in plains and close country. In the early operations, when the great arc was being carried across the wide plains of the Gangetic valley, which are covered with villages and hamlets and other object of interest, there was no need for the support of the small reconnaisance theodolites, with a sufficiency of poles and bamboo to form a scaffolding of the same height for the observer. Other masts 70 ft. high, with arrangements for displaying blue lights by night at 90 ft. were erected at the spots where station sites were wanted. But the cost of transport was great, the rate of progress was slow, and the results were unsatisfactory. Eventually a method of touch rather than sight was adopted, feeling the ground to search for the obstacles to be avoided, rather than attempting to look over them: the "rays" were traced either by a minor triangulation, or by a traverse through the station, the theodolite was carried up under such conditions that the "rays" could be put to the sides of the station, the "rays" being indicated by red flags. The first method gives the direction of the new station most accurately; the second searches the ground most closely; the third is suited for tracks of uninhabited forest in which it is the practice to put a party of soldiers in advance. Any points may be built at the intersection of the two trial rays leading up to it. As a rule it has been found most economical and expeditious to search for obstacles at a distance, and to store the theodolite on the height, to survey the curvature, and to remove the trees and other obstacles on the line.

Each principal station has a central masonry pillar, circular and 3 ft. high, in diameter, in which are housed the theodolite and level, and around it a platform 14 to 16 ft. square for the observatory tent, observer and signalers. The pillar is isolated from the platform, and when solid carries the station mark—a dot surrounded by a circle—on the upper surface at the very top, on a vertical stone or the rock in situ, in the normal of the upper mark; but, if the height is considerable and there is a liability to deflection, the pillar is constructed with a central vertical shaft to enable the
SURVEYING

Theodolite to be plumbwed over the ground level mark, to which access is gained by means of a ladder in the theodolite shed. An extra precaution against deflection was neglected and the pillars were built solid throughout, whatever their height; the surveying platforms, being usually constructed of sun-dried bricks or stones and then left to harden during the hot days of the summer season, which thus became deflected during the rainy seasons that intervened between the periods during which operations were arrested or were temporarily suspended. Large theodolites were invariably employed. Repeating circles were highly thought of by French geodesists at the time when the operations in India were begun; but they were not used in the surveys of the turbid atmosphere. In the latter theodolites, the heads were somewhat similar to the astronomer's alt-azimuth instrument, but with larger azimuthal and smaller vertical circles, also with a greater base to give stability. Theodolites were also employed with two and four horizontal arcs.

The azimuthal circles had mostly diameters of either 36 or 24 in., the vertical circles having a diameter of 15 in. In all the theodolites the base was a triform tripod resting on three levelled foot-screws, and the circles are read by microscopes; but in different instruments the fixed and the rotatory parts of the body varied. In some the vertical axis was fixed on the tripod and projected upwards; in others it revolved in the tripod and projected downwards. In the former the azimuthal circle was fixed to the triform, while the theodolite pillars, the microscopes, the clamps and the tangent screws were attached to the tripod, while in the latter the microscopes, clamps and tangent screws were fixed to the triform, while the telescope pillars and the azimuthal circle were attached to a plate fixed at the head of the rotary vertical axis.

Cairns of stones, poles or other opaque signals were primarily employed, the angles being measured by day only; eventually it was found that the atmosphere was often more favourable for observing at night, and by the former methods signals were readily visible well into view by refraction by night which might be invisible or only seen with difficulty by day. Lamps were then introduced of the simple open type, atmospheric conditions allowing. But the stones, which have been discarded, were sometimes used for the purpose of checking the accuracy of the opposed angles. The introduction of luminous signals not only rendered the night more accessible to the observer, but made it possible to check the accuracy of the operations, enabling work to be done during the dry and healthy season of the year, when the atmosphere is generally hazy and dusty laden, instead of being restricted as formerly to the rainy and unhealthy season, when distant opaque objects are best seen. A higher degree of accuracy was also secured, for the luminous signals were invariably displayed through diaphragms of appropriate aperture, truly centred over the station mark; and, being seen in parallactic refraction, the observer could give his attention to the azimuth, whereas opaque signals are always dim in comparison and are liable to be seen extinguently when the light falls on one side. A signal-lining instrument, which usually consisted of two opal glass discs, was sometimes used, and a pair of heliottopes—one for single, two for double refraction—according to the sun's position—and a lamp, throughout the night and day. Heliottopes were also employed at the observing stations for checking the observations. The theodolites were invariably set up under tents for protection against sun, wind and rain, and centred, levelled and adjusted for the runs of the microscopes. Then the signals were observed in regular rotation round the horizon, alternately from right to left and vice versa; after the prescribed minimum number of rounds, either two or three, had been thus measured, the telescope was turned 180°, both in altitude and azimuth, changing the position of the face of the vertical circle relatively to the observer, and further rounds were measured; additional measures of single angles were taken at each interval of 90°, and of double refractions at intervals of 36°.

As the microscopes were invariably equidistant and their number was always odd, either three or five, the readings taken on the azimuthal circle during the telescope pointings to any object in the two positions of the vertical circle were made on twice as many equidistant graduations as the number of microscopes. The theodolite was then shifted bodily in azimuth, by being turned on the ring on the head of the stand, which would be sufficient, and new graduations under the microscopes at the telescope pointings; then further rounds were measured in the new positions, face right and vice versa. This process was repeated as often as had been previously prescribed. The operation of obtaining the position angles by equal arcues bringing equidistant graduations under the microscopes during the successive telescope pointings to one and the same object. By means of all the microscopes the instrumental error of graduation was eliminated, the numerous graduations that were used tending to eliminate accidental errors of division, and the numerous rounds of measures to minimize the errors of observation arising from atmospheric irregularities.

Under this system of procedure the instrumental and ordinary errors are practically cancelled and any remaining error is most probably due to refraction, measurement inaccuracy and to light grazing the surface of the ground. The three angles of every triangle were always measured.

The apparent altitude of a distant point is liable to considerable variations in the course of the day, due to the influence of changes in the density of the lower strata of the atmosphere. Terrestrial refraction is capricious, more particularly when one is concerned with higher objects, such as hill tops and the tops of buildings, where the light is divergent to the horizon, passing through a medium which is liable to extremes of refraction and condensation, under the alternate influence of the sun's heat radiated from the surface of the ground and of chilled atmospheric vapour. When the back and forward vertical angle of a pair of stations are equidistantly refraacted, their difference gives an exact measure of the difference of height. But the atmospheric conditions are not uniform, and the earth's atmosphere is a sphere on long rays which graze the surface of the ground, and the ray between two reciprocating stations is liable to be differently refraacted at its extremities, each end being influenced in a greater degree by the conditions prevailing around it, and by the height at a distance; thus instances are on record of a station A being invisible from another B, while B was visible from A.

When the great arc was entered the plains of the Gangetic valley, simultaneous reciprocal verticals were at first adopted with the hope of eliminating refraction; but it was soon found that they did not do so sufficiently to justify the expenditure of the time involved. Vertical Angles.

Afterwards the back and forward verticals were observed as the stations were visited in succession, the back angles at as nearly as possible the same time of the day as the forward angles, and always during fine weather. "Time" refers to the mean sun's motion, which begins about an hour after apparent noon and lasts from two to three hours. The apparent zenith distance is always greatest then, but the refraction is a minimum only at stations which are situated between Tropic of Cancer and 20° of latitude. The refraction is liable to pass through zero and attain a considerable negative magnitude during the heat of the day, for the lower atmosphere is then less dense and the rays are refracted straighly above and the rays are refracted downwards. On this account the greatest positive refractions are also obtained—maximum values, both positive and negative, usually occurring, the former by the inverse method of observing. The time of day at which the refraction is zero varies during the seasons; during the months of March and April, 18,000 ft., broadly varying inversely as the temperature and directly as the pressure, but much influenced also by local climatic conditions.

In measuring the vertical angles with the great theodolites, graduation errors were regarded as insignificant compared with errors arising from uncertain refraction; thus no arrangement was put forward for correcting out the errors in the vertical angles that were undertaken. The values actually met with were found to range from +1·21 down to −0·09 parts of the contained arc on plains; the normal "coefficient of refraction" for free rays between hill stations 800 ft. above the level of the sea, which diminished to 0·08 above 18,000 ft., broadly varying inversely as the temperature and directly as the pressure, but much influenced also by local climatic conditions.

In the ordnance and other surveys the bearings of the surrounding stations are determined by visual observations, but from the "included angles" in the Indian survey. Triangulation observations of every angle are tabulated vertically in as many columns as the number of circle settings face left and face right, and the mean for each setting is taken. For several years the general mean of these was adopted as the final result; but subsequently a "concluded angle" was obtained by combining the angle means with weights inversely proportional to \(\beta + \delta^2 - \gamma\), being a value of the e.m.t.\(^1\) of graduation derived empirically from the difference between the general mean and the mean for each setting, \(o\) the e.m.t. of observation deduced from the differences between the theoretical and the observed values for the respective means, and \(n\) the number of measures at each setting. Thus putting

\[
C = M + \left(\varphi + \varphi_0\right) + \left(\varphi + \varphi_0\right)
\]

and

\[
\varphi = \varphi_0 + \varphi_0
\]

\(C - M\) vanishes when \(n\) is constant; it is inapplicable when \(g\) is much larger than \(\varphi\); it is significant only when the graduation errors are more minute than the errors of observation; but it was always good enough not to exceed \(0·14\) with the system of two rounds of measures and 0·05° with the system of three rounds.

The weights of the concluded angles thus obtained were employed in the primary reductions of the angles of single triangles and poligons which were made to satisfy the geometrical conditions

1 The theoretical "error of mean square" = 1·48 X "probable error."
of each figure, because they were strictly relative for all angles measured with the same instrument and under similar circumstances, and conditions. In these cases it was not always the case that the angles were original, but in the final reductions, when numerous chains of triangles composed of figures executed with different instruments and under different circumstances, it may become necessary to modify the original weights, on such evidence of the precision of the angles as might be obtained from other and more reliable sources than the actual measures of the angles. This treatment will now be described.

Values of theoretical error for groups of angles measured with the same instrument and under similar conditions may be obtained in three ways: (1) from the squares of the reciprocals of the weights as deduced as above from the measures of such angle, (ii) from the magnitudes of the excess of the sum of the angles of each triangle above 180° + the spherical excess, and (iii) from the magnitude of the corrections which it is necessary to apply to the angles of polygonal figures and networks to satisfy the several geometrical conditions.

Every figure, whether a single triangle or a polygonal network, was made consistent by the application of corrections to the observed angles to satisfy its geometrical conditions. The three angles of every triangle having been observed, their sum had to be made 180° ± the spherical excess of the triangle. The angles should be identical, whatever the route through which it was computed. These are called the triangular, central, tolo-partial and side conditions; they present n geometrical equations, which contain t unknown quantities, the excesses of the observed angles, t being always >n. When these equations are satisfied and the deduced values of errors are applied as corrections to the observed angles, the figure becomes consistent. Primarily the equations were treated by a method of successive approximations; but afterwards they were all solved simultaneously by the so-called method of minimum squares, which leads to the most probable of any system of corrections.

The angles having been made geometrically consistent inter se in each figure, the side-lengths are computed from the base-line onwards by Legendre's theorem, each angle being diminished by one half the spherical excess of the triangle to which it appertains. The theorem is applicable without sensible error to triangles of a much larger size than any that are ever measured.

A station of origin being chosen of which the latitude and longitude are known astronomically, and also the azimuth of one of the stations in succession, for all the stations of the triangulation, Azimuth of

Sides of

Triangles.

Longitude of latitude and the reverse azimuths are calculated in Stations: for determining the triangulation, Azimuth of by Puissant's formulae (Traité de géodésie, 3rd ed., Paris, Sides.

1842).

Problem.—Assigning the earth to be spheroidal, let A and B be two stations on its surface, and let the latitude and longitude of A be known, also the azimuth of B at A, and the distance between A and B at the mean sea-level; we have to find the latitude and longitude of B.

The following symbols are employed: a the major and b the minor semi-axis; e the excentricity, \( \frac{c^2-a^2-b^2}{a^2} \); p the radius of curvature to the meridian in latitude \( \lambda \), \( d(1-e) \) ; \( \frac{\pi}{2} \) the normal to the meridian in latitude \( \lambda \), \( a(1-e^2) \); \( \lambda \) and L the given latitude and longitude of A; \( \lambda + \Delta \lambda \) and \( L + \Delta L \) the required latitude and longitude of B; A the azimuth of B at A; B the azimuth of A at B; \( \Delta L = B = (\lambda + \Delta \lambda) - \Delta L \) the distance between A and B. Then, all azimuths being measured from the south, we have

\[ \Delta \theta = \cos A \tan \lambda \cos 1'' \]

\[ \frac{\cos^2 A \sin A \tan \lambda \cos 1''}{\cos^2 A \sin A \tan \lambda \cos 1''} \]

where \( \Delta \theta \) is the algebraic difference of the angles of the triangles, \( A \) is the angle at A, and \( \lambda \) is the latitude of the station. The values of the angles of the triangles are computed for the given latitudes and longitudes of the stations, and are used in the following manner:

1. \( \frac{\cos^2 A \sin A \tan \lambda \cos 1''}{\cos^2 A \sin A \tan \lambda \cos 1''} \)
2. \( \frac{\cos^2 A \sin A \tan \lambda \cos 1''}{\cos^2 A \sin A \tan \lambda \cos 1''} \)
3. \( \frac{\cos^2 A \sin A \tan \lambda \cos 1''}{\cos^2 A \sin A \tan \lambda \cos 1''} \)
4. \( \frac{\cos^2 A \sin A \tan \lambda \cos 1''}{\cos^2 A \sin A \tan \lambda \cos 1''} \)

By means of these equations, the azimuths of the stations are computed from the given latitudes and longitudes.

Each \( \Delta \) is the sum of four terms symbolized by \( \delta_{1,2}, \delta_{3}, \delta_{4}, \delta_{5}, \delta_{6}, \delta_{7}, \delta_{8}, \delta_{9}, \delta_{10}, \delta_{11} \), the calculations are so arranged as to produce these terms in the order \( \delta_{1}, \delta_{2}, \delta_{3}, \delta_{4} \), each term entering as a factor in calculating the following term. The arrangement is shown below in equations in which the symbols \( P, \cos, \cot, \tan, \sec \), \( \Delta, \delta \) represent the factors which depend on the adopted geodetic constants, and vary with the latitude; the logarithms of their numerical values are tabulated in three auxiliary tables for Further calculations, see the Appendix Surveying.

\[ \delta_{1} = \frac{P \cos \lambda \cot \lambda \sec \lambda}{2} \tan \lambda \sin 2A \cos A \cos 1'' \]

\[ \delta_{2} = \frac{P \cos \lambda \cot \lambda \sec \lambda}{2} \tan \lambda \sin 2A \cos A \cos 1'' \]

\[ \delta_{3} = \frac{P \cos \lambda \cot \lambda \sec \lambda}{2} \tan \lambda \sin 2A \cos A \cos 1'' \]

\[ \delta_{4} = \frac{P \cos \lambda \cot \lambda \sec \lambda}{2} \tan \lambda \sin 2A \cos A \cos 1'' \]

The calculations described so far suffice to make the angles of the several trigonometric figures consistent inter se, and to give preliminary values of the lengths and azimuths of the sides, and the latitudes and longitudes of the stations, Reduction of the results are amply sufficient for the requirements of the topographer and land surveyor, and they are published in preliminary charts, which give full numerical details of latitude, longitude, azimuth and side-length, and of height also, for each portion of the triangulation—secondary as well as principal—as executed year by year. But on the completion of the several chains of triangles further reductions became necessary, to make the triangulation everywhere consistent inter se and the verificatory base-lines, so that the lengths and azimuths of common sides and the latitudes and longitudes of common stations should be identical at the junctions of chains and that the measured and computed lengths of the base-lines should also be identical.

As an illustration of the problem for treatment, suppose a triangulation of two dimensional and two dimensional consisting of seventy-two single triangles with a base-line at each corner as shown in the accompanying diagram (fig. 2); suppose the angles of elevation of each triangle to have been measured and made consistent. Let A be the origin, with its latitude and longitude given, and also the length and azimuth of the adjoining base-line. With these data processes of calculation are carried through the triangulation to obtain the lengths and azimuths of the other stations from the latitudes and longitudes of the stations, say in the following order: from A through B to E, through F to E, through F to D, through F and E to C, and through D and C. Then there are two values of side, azimuth, latitude, and longitude of each base-line, right and left, or right and left, and are verified by the left-hand chain via F; similarly there are two sets of values at C; and each of the base-lines at B, C and D has a calculated as well as a measured value. This is the most important absolute errors are present for dispersion over the triangulation by the application of the most appropriate correction to each angle, and, as a preliminary to the determination of these corrections, equations must be constructed between each of the absolute errors and the unknown errors of the angles from which they originated. For this purpose we have the equation:

\[ D = \delta_{1} + \delta_{2} + \delta_{3} + \delta_{4} + \delta_{5} + \delta_{6} + \delta_{7} + \delta_{8} + \delta_{9} + \delta_{10} + \delta_{11} \]

where \( \delta_{1} \) is the angle at A, \( \lambda \) and \( \lambda' \) be the most probable values of the angles of the triangles, \( \Delta \lambda = \lambda' - \lambda \) the difference between A and B, and \( \Delta L = \lambda' - \lambda \) the difference between A and B. Then, all azimuths being measured from the south, we have

\[ D = \delta_{1} + \delta_{2} + \delta_{3} + \delta_{4} + \delta_{5} + \delta_{6} + \delta_{7} + \delta_{8} + \delta_{9} + \delta_{10} + \delta_{11} \]

where \( \delta_{1} \) is the angle at A, \( \lambda \) and \( \lambda' \) be the most probable values of the angles of the triangles, \( \Delta \lambda = \lambda' - \lambda \) the difference between A and B, and \( \Delta L = \lambda' - \lambda \) the difference between A and B.
SURVEYING

ii. One of the unknown quantities in every triangle, as \( x \), may be eliminated from each of the three circuits, and base-line equations be substituted in the analogous \(-y\) for the difference \(-y\) for the difference between \( x \) and \(-y\). This process being made the minimum. Then the equations take the form \((a-b)+x=(a-b)+x\) for the minimum which involves becomes
\[
\begin{align*}
0 & = 
\sum_{n} \left( y_n + z_n \right) - \sum_{n} \left( y_n + z_n \right) + \sum_{n} \left( y_n + z_n \right) - \sum_{n} \left( y_n + z_n \right)
\end{align*}
\]
Thus we have now to find only eleven values of \( x \) by a simultaneous solution of so many equations, instead of thirty-one from eight equations; but we arrive at more complex expressions for the angular errors as follows:
\[
\begin{align*}
y_n & = y_n + \theta_n + \phi_n - \left( y_n + \theta_n + \phi_n \right)
\end{align*}
\]

The second method has invariably been adopted, originally because it was supposed that, the number of the factors \( \lambda \) being reduced by about \( n \) of the straight-line equations, a great saving of labour would be effected. But subsequently it was ascertained that in this respect there is little to choose between the two methods for the elimination of errors, and as many factors are introduced as there are equations, the factors for the triangular equations may be readily eliminated at the outset. Then the really severe calculations will be restricted to the solution of the simultaneous equations containing the factors for the circuit and base-line equations as in the second method.

In the preceding illustration it is assumed that the base-lines are errorless as compared with the triangulation. Strictly speaking, however, the base-line and the angular errors are in almost all cases of the same order, and it is the former which are due to the summation in forming the coefficient of \( \theta \).

The angular errors \( x \), \( y \), and \( z \) must now be introduced, in place of \( \theta \) and \( \lambda \), into the general expression, which will then take different forms, according as the route adopted for the line of traverse was the zigzag or the direct. In the former, the number of stations on the traverse is obtained by the number of triangles, whether or not a common numerical notation may be adopted for both the traverse stations and the collateral triangles; but the angular errors of every triangle enter the general expression in the form in which \( \mu = \mu \sin \phi \); and the upper signs of \( \phi \) is taken if the triangle lies to the left, the lower it to the right, of the line of traverse. When the direct traverse is adopted, there are only as many Traverse stations as triangles, and therefore only half the number of \( \mu \) and \( \phi \)'s to determine; but it becomes necessary to adopt different numerations for the stations and the triangles, and the form of the coefficients of the angular errors alternates in successive triangles. Thus, the \( p \) th triangle has no side on the line of the traverse but only one angle at the \( p \) th station, the form is
\[
+ \phi_1 x_1 + \gamma_1 x_2 + \cdots + \gamma_{n} x_{n}
\]
If the \( p \) th triangle has a side between the \( p \) th and the \( q \) th stations of the traverse, the form is
\[
+ \phi_1 x_1 + \gamma_1 x_2 + \cdots + \gamma_{n} x_{n} - \theta_1 y_1 - \theta_2 y_2 - \cdots - \theta_{n} y_{n}
\]

The eighteenth century and base-line equations of condition having been duly constructed, the next step is to find values of the angular errors which will satisfy these equations, and be the most probable of any system of values that will do so, and at the same time will not disturb the existing harmony in each of the seventy-two triangles. Harmony is maintained by introducing the equation of condition \( x = y = z = w \) for every triangle. The most probable results are obtained by the method of minimum squares, which may be applied in the following way.

i. A factor \( \lambda \) may be obtained for each of the eighty-three equations under the condition that
\[
\sum_{u} x^2 + \sum_{v} y^2 + \sum_{w} z^2 = E
\]

\[\frac{x}{u} + \frac{y}{v} + \frac{z}{w}\] is made a minimum,
number of "side" and other geometrical equations of condition, which entered irregularly and caused great entanglement. Equations 9 and 10 of the illustration are of a simple form because they have a primary geometric condition to maintain, the triangle, which is not only expressed by the simple and symmetrical equation $x+y+z=\omega$, but—what is of much greater importance—recur in a regular order of sequence that materially facilitates the general solution. Thus, though the calculations must in all cases be very numerous and laborious, rules can be formulated under which they can be well controlled at every stage and eventually brought to a successful issue. The other geometrical conditions of networks are expressed by equations which are not merely of a more complex form but have no regular order of sequence, for the networks present a variety of forms; thus their introduction would cause much entanglement and confusion, and greatly the labour of the calculations and the chances of failure. Wherefore, therefore, any compound figure occurred, only so much of it as was required to form a chain of single triangles was employed. The figure having previously been marked probable errors of the angles, what part was employed, but the selection was usually made so as to introduce the fewest triangles. The triangulation for final simultaneous reduction was thus made to consist of chains of single triangles only; but all the included angles were "fixed" simultaneously. The excluded angles of compound figures were subsequently harmonized with the fixed angles, which was readily done for each figure per se.

This departure from rigorous accuracy was not of material importance, for the angles of the compound figures excluded from the simultaneous reduction had already, in the course of the several independent figural reductions, received their share of influence on the included angles. The figural adjustments had, however, introduced new relations between the angles of different figures, causing their weights to increase aequitas parsibus with the number of geometrical conditions satisfied in each instance. Thus, suppose $w$ to be the average weight of the $i$ observed angles of any figure, and $n$ the number of geometrical conditions presented for satisfaction; then the average weight of the angles after adjustment may be taken as $w_i=\frac{w}{n}$, the factor thus being $1+\frac{i}{n}$ for a triangle, $1+\frac{i}{n}$ for a hexagon, $2$ for a quadrilateral, $2+\frac{i}{n}$ for the network around the Sironj base-line, &c. In framing the normal equations between the indeterminate factors $x$ for the final simultaneous reduction, it would have greatly added to the labour of the subsequent calculations if a separate weight had been given to each angle, as was done in the primary figural reductions; this was obviously unnecessary, for theoretical requirements would now be amply satisfied by giving equal weights to all the angles of each independent figure. The mean weight that was finally adopted for the angles of each group was therefore taken as $w_i=\frac{1}{n}$, $x_i$.

The second of the two processes for applying the method of minimum squares had been adopted, the values of the errors $\varepsilon$ and $\gamma$ in the angles, determining to any, the $i$th triangle were finally expressed by the following equations, which are derived from (10) by substituting $w$ for the reciprocal final mean weight as above determined:—

$$\begin{align*}
\varepsilon &= w_i (2z - a_i - b_i) / n_i \\
\gamma &= w_i (2z - a_i - b_i) / n_i
\end{align*}$$

The following table gives the number of equations of condition and unknown quantities—the angular errors—in the five great sections of the triangulation, which were respectively included in the simultaneous general reductions and relegated to the subsequent adjustments of each figure per se:—

The corrections to the angles were generally minute, rarely exceeding the probable errors of the angles themselves, and thereby applicable without taking any liberties with the facts of observation.

Azimuth observations in connexion with the principal triangulation were determined by measuring the horizontal angle between a referring mark and a circumpolar star, shortly before and after the close of the triangle, and finally at both stations. In order to eliminate the error of the star's place, systematic changes of "face" and of the zero settings of the azimuthal circle were made as in the measurement of the principal angles; conditions of the reductions referred to the station through the triangulation, for comparison with the principal azimuth. A table was prepared of the differences (observed at the origin—computed from a distance) between the primary and the geodetic azimuths; the differences were assumed to be mainly due to the local deflections of the plumb-line and only partially to error in the triangulation, and each was multiplied by the factor $p$.

The tangent of latitude of comparing station may be taken as $t=\tan \phi$, the factor thus being $1+\frac{i}{n}$ for a triangle, $1+\frac{i}{n}$ for a hexagon, $2$ for a quadrilateral, $2+\frac{i}{n}$ for the network around the Sironj base-line, &c. The corrections to the angles were generally minute, rarely exceeding the probable errors of the angles themselves, and thereby applicable without taking any liberties with the facts of observation.
SURVEYING

cannot be separately ascertained they are always assumed to be equal; the hypothesis is sufficiently exact for practical purposes when both verticals have been measured under similar atmospheric conditions. The refractions being taken equal, the observed value is substituted for the true in (14) to find \( S \), and the difference of height is calculated by (16); the third term within the brackets of (14) is usually omitted. The mean value of the refraction is deduced from the formula

\[
E = \frac{d}{2} - D = \frac{d}{2} - D
\]

An approximate value is thus obtained from the observations between the pairs of reciprocating stations in each district, and the corresponding mean "coefficient of refraction," \( \phi + C \), is computed for the district, and is employed when heights have to be evaluated from observations at a single station only. When either of the vertical angles is an elevation, \( -E \) must be substituted for \( D \) in the above expressions.\(^1\)

2. LEVELLING

Levelling is the art of determining the relative heights of points on the surface of the ground as referred to a hypothetical surface which cuts the direction of gravity everywhere at right angles. When a line of instrumental levels is begun at the foot of a hill, a series of heights is determined corresponding to what would be found by perpendicular measurements upwards from the surface of water communicating freely with the sea in underground channels; thus the line traced indicates a hypothetical prolongation of the surface of the sea inland, which is everywhere conformable to the earth's curvature.

The trigonometrical determination of the relative heights of points at known distances apart, by the measurements of their mutual vertical angles—is a method of levelling. But the method to which the term "levelling" is always applied is that of direct determination of differences of height from the readings of the lines at which graduated staves, held vertically over the points, are cut by the horizontal plane which passes through the eye of the observer. Each method has its own advantages. The former is less accurate, but best suited for the requirements of a general geographical survey, to obtain the heights of all the more prominent objects on the surface of the ground, whether accessible or not. The latter may be conducted with extreme precision, and is specially valuable for the determination of the relative levels, however minute, of easily accessible points, however numerous, which succeed sea-level, at short intervals apart; thus it is very generally undertaken pari passu with geographical surveys to furnish lines of level for ready reference as a check on the accuracy of the trigonometrical heights. In levelling with staves the measurements are always taken from the horizontal plane which passes through the eye of the observer; but the line of levels which it is the object of the operations to trace is a curved line, everywhere conforming to the normal curvature of the earth's surface, and deviating more and more from the plane of reference as the distance from the station of observation increases. Thus, either a correction for curvature must be applied to every staff reading, or the instrument must be set up at equal distances from the staves; the curvature correction, being the same for each staff, will then be eliminated from the difference of the readings, which will thus give the true difference of level of the points on which the staves are set up.

Levelle has to be repeated frequently in executing a long line of levels—say seven times on an average in every mile—and must be conducted with particular attention to the observations of the height of the perpendicular to the instrument. Instrumental errors arise when the visual axis of the telescope is not perpendicular to the axis of rotation, and when the focusing tube does not move truly parallel to the visual axis on a change of focus. The latter may be corrected, and the former avoided, by placing the instrument at equal distances from the staves; and as this procedure has also the advantage of eliminating the corrections for both curvature and refraction, it should invariably be adopted.

Errors of staff readings should be guarded against by having the staffs graduated on both faces, but differently figured, so that the observer may not be biased to repeat an error of the first reading in the second. Accurate sightings are taken both when the spirit-level and applying corresponding corrections to the staff readings, or be eliminated by setting the bubble to the same position on its scale at the readings of the second staff as at that of the first, or by correcting the instrument from the observer.

Certain errors are liable to recur in a constant order and to accumulate to a considerable magnitude, though they may be too minute to be noticed, provided that any single station, as a rule, contains only one face painted white with black divisions; feet, tenths and hundredths—from 0 to 10, the other black with white divisions from 55 to 75. Deflection from horizontality may either be measured and allowed for, or be eliminated by making the instrument and the spirit-level uniform; or the instrument, or the line of observation, or both, may be carried over a land crossing from one district, to another, the levelling in each being independently from the same line of survey, or from the same reference staffs stationary. In levelling, the right hand side of the staff is always taken to the east, and the observer, when at a considerable distance, will often fall endwise on the bubble of the level, illuminating the outer edge of the rim at the nearer end and the inner edge at the farther end, and so biasing the observations. When levels of this kind are taken, the observer should be a little more distant from the centre of the bubble, which will introduce a tendency to raise the south or depress the north ends of lines of level in the northern hemisphere. On long lines, therefore, a measurement of a line can be made, and the latter is carried over to the next line, or over the right hand side of the staff, from coast to coast in such a manner that the level of any common crossing point may be found by several independent lines. These points there are 166 in England, Scotland and Wales; the discrepancies found with them were adjusted simultaneously by the method of minimum squares.

The sea-level is the natural datum plane for levelling operations, more particularly in countries bordering on the ocean. The earliest surveys of coasts were made for the use of navigators and, as it was considered very important that the charts should everywhere show the minimum depth of water which a vessel would meet with, low water of spring-tides was adopted as the datum. But this does not answer the requirements of a land survey, because the tidal range between extreme high and low water differs greatly at different points on coast-lines. Thus the generally adopted datum plane for land surveys is the mean sea-level, which, if not absolutely uniform all the world over, is much more nearly so than low water. Tidal observations have been taken at nearly fifty points on the coasts of Great Britain, which were connected by levelling operations; the local levels of mean sea were found to differ by larger magnitudes than could fairly be attributed to errors in the lines of level, having a range of 12 to 15 in. above or below the mean of all points on the open coast, and more in tidal rivers.\(^2\) But the general mean of the coast stations for England and Wales was practically identical with that for Scotland. The observations, however, were seldom of longer duration than a fortnight, which is insufficient for an exact determination of even the short period components of the tides, and ignores the annual and semi-annual components, which occasionally attain considerable magnitudes. The mean sea-levels at Port Said in the Mediterranean and at Suez in the Red Sea have been found to be identical, and a similar identity is said to exist in the levels of the Atlantic and the Pacific Oceans; on the opposite coasts of the Isthmus of Panama. This is in favour of a uniform level all the world over; but, on the other hand, lines of level carried across the continent of Europe make the mean sea-level of the Mediterranean at Marseilles and Trieste from 2 to 5 ft. below that of the North Sea and the Atlantic at Amsterdam and Brest—a result which is in tidial estuaries and rivers the mean water-level rises above the mean sea-level as the distance from the open coast-line increases; for example, in the Mississippi River, which has a fall of 10 in. in 42 m. between Sagar (Saugor) Island at the mouth of the river and Diamond Harbour, and a further rise of 20 in. in 43 m. between Diamond Harbour and Kidderpore.

\(^1\) In topographical and levelling operations it is sometimes convenient to apply small corrections to the formula \( S = \frac{d}{2} - D \) for the precision of the instrument, \( \phi + C \), and the correction for curvature, and also for deflection from horizontality. Putting \( d \) for the distance, \( r \) for the earth's radius, and \( \kappa \) for the coefficient of refraction, and expressing the distance and radius in miles and the correction to height in feet, the correction for curvature is \( \frac{1}{2} k r^2 \); the correction for deflection from horizontality is \( \frac{1}{2} k r^2 \); the correction for both curvature and refraction is \( \frac{1}{2} k r^2 \).

\(^2\) In tidal estuaries and rivers the mean water-level rises above the mean sea-level as the distance from the open coast-line increases; for example, in the Mississippi River, which has a fall of 10 in. in 42 m. between Sagar (Saugor) Island at the mouth of the river and Diamond Harbour, and a further rise of 20 in. in 43 m. between Diamond Harbour and Kidderpore.
it is not easy to explain on mechanical principles. In India various tidal stations on the east and west coasts, at which the mean sea-level has been determined from several years' observations, have been connected by lines of level run along the coasts and across the continent; the differences between the results were in all cases due with greater probability to error generated in levelling over lines of great length than to actual differences of sea-level in different localities.

The sea-level, however, may not coincide everywhere with the geometrical figure which most closely represents the earth's surface, but may be raised or lowered, here and there, under the influence of local and atmospheric conditions, presenting an equipotential surface—an ellipsoid or spheroid of revolution slightly deformed by bumps and hollows—which II. Bruns calls a `geoid.' Archdeacon Pratt has shown that, under the combined influence of the positive attraction of the Himalayan Mountains and the negative attraction of the Indian Ocean, the sea-level may be some 500 ft. higher at Karachi than at Cape Comorin; but, on the other hand, the Indian pendulum operations have shown that there is a deficiency of density under the Himalayas and an increase under the bed of the ocean, which may wholly compensate the effect of the mountain masses and deficiency of the ocean, and leave the surface undisturbed. If any bumps and hollows exist, they cannot be measured, instrumentally; for the instrumental levels will be affected by the local attractions precisely as the sea-level is, and will thus invariably show level surfaces even if considerable deviations from the geometrical figure.

3. Topographical Surveys

The skeleton framework of a survey over a large area should be triangulation, although it is frequently combined with traversing. The method of filling in the details is necessarily influenced to some extent by the nature of the framework, but it depends mainly on the magnitude of the scale and the requisite degree of minutiae. In all instances the principal triangles and circuit-traverses have to be broken down into smaller ones to furnish a sufficient number of fixed points and lines for the subsequent operations. The filling in may be performed wholly by linear measurements or wholly by direction intersections, but is most frequently effected by both linear and angular measures, the former taken with chains and tapes and offset poles, the latter with small theodolites, sextants, optical squares or other reflecting instruments, magnetized needles, prismatic compasses and plane tables. In the scale of a large and local triangulation, linear and angular measures are usually recorded on the spot in a field-book and afterwards plotted in office; when small they are sometimes drawn on the spot on a plane table and the field-book is dispensed with.

In every country the scale is generally expressed by the ratio of some fraction or multiple of the smallest to the largest national units of length, but sometimes by the fraction which indicates the ratio of the length of a line on the paper to that of the corresponding line on the ground. The latter form is obviously preferable, being international in character and dependent on the various units of length and planes of the nation's survey. The survey of Great Britain and Ireland and the Indian survey the double unit of the foot and the Gunter's link ( = 0.066 of a foot) are employed, the former invariably in the triangulation, the latter generally in the traversing and filling in, because of its convenience in calculations and measurements of area, a square chain of 100 Gunter's links being exactly one-tenth of an acre.

In the ordnance survey all linear measures are made with the Gunter's chain, all angular with small theodolites only; neither magnetized nor reflecting instruments nor plane tables are ever employed, except in hill sketching. As a rule the filling in is done by triangle-chaining only; traverses with theodolite and chain are occasionally resorted to, but only when it is necessary to work round woods and hill tracts across which right lines cannot be carried. Detail surveying by triangles is based on the points of the minor triangulation. The sides are first chained perfectly straight, all the points where the lines of interior detail cross the sides being fixed; the alignment is effected with a small theodolite, and marks are established at the crossing points and at any other points on the sides where they may be of use in the subsequent operations. The surveyor is given a diagram of the triangulation, but no side lengths, as the accuracy of his chaining is tested by comparisons with the triangulation. All the operations are carried across the intermediate detail between the points established on the sides; they constitute the principal "cutting up or split lines"; their crossings of detail are marked in turn and the process is repeated until a sufficient number of lines and marks have been established on the ground to enable all houses, roads, fences, streams, railways, canals, rivers, boundaries and other details to be conveniently and economically represented. The total length of the lines laid out and the number of points marked is a sufficient number of lines and bars have been established on the ground to enable all houses, roads, fences, streams, railways, canals, rivers, boundaries and other details to be conveniently and economically represented. The total length of the lines laid out and the number of points marked is.

As when a trinomontational station, the theodolite is set for the reading of with the telescope pointing to the north, and at every "forward" station of the traverse the circle is set to the same reading when the telescope is pointed at the back station as when the telescope is pointed at the back.

3. Topographical Surveys

The plotting is done from the field-books of the surveyors by a separate agency. Its accuracy is tested by examination on the ground of all the necessary addenda are made. The examiner— who should be surveyor, plotter and draughtsman—verifies the accuracy of the detail by intersections and productions and occasional direct measurements, and generally endeavours to cause the detailed work to be done in the field to a higher standard of accuracy than might be obtained by direct measurement. He fixes conspicuous trees and delineates the roads, footpaths, rocks, precipices, steep slopes, embankments, &c., and supplies the requisite information regarding minor objects to enable a draughtsman to make a perfect representation according to the scale of the map. In examining a coast-line he delineates the foreshore and sketched the structure of the stratified rocks, tidal rivers and estuaries, and marks and points out the highest points to which the ordinary tides flow.

The examiner on the 25 1/44 in. scale ( = 1') is required to give all necessary information regarding the parcels of ground of different character, and the topographical detail itself. It is for the draughtsman to define the limits of each on a separate tracing if necessary. He has also to distinguish between turnpike, parish and occupation roads, to collect all names, and to furnish notes of military, baronial and antiquities, with a map of the civil and ecclesiastical. All the topographical information is drawn in the final maps. The latter are subject to a double examination—first in the office, secondly on the ground; they are then handed over to the officer in charge of the levelling to have the levels and contour lines inserted, and finally to the hill sketchers, whose duty is to make an artistic representation of the features of the ground.

In the Indian survey all filling in is done by plane-tabling on a basis of points previously fixed; the methods differ simply in the extent to which linear measures are introduced to supplement the direction rays of the plane-table. When the scale of the survey is small, no measure is introduced, the filling in is usually done wholly by direction intersections, which fix all the principal points, and by eye-sketching; but as the scale is increased linear measures with chains and offset poles are introduced to supplement the eye, and large objects, such as roads, are represented on the final sheets by linear measurements for the convenience of the draughtsman, when these are more convenient for employment than the spherical, having been first drawn; the plane-table is then ready for use. Operations are begun at a fixed point by aligning with a string fixed to the point, which is a relaying on the line of the table on that of the station. The magnetic needle may now be placed on the table and a position assigned to it for future reference. Rays are drawn from the station point on the table to the object to be represented, the compass being set to the angles and bearings found by the theodolite; the table is then taken to other fixed points, and the process of ray-drawing is repeated at each; thus a number of objects, some of which may become available as stations of observation, are fixed. Additional stations may be established by setting up the
table on a ray, adjusting it on the back station—that from which the ray was drawn—and then obtaining a cross intersection with the sight rule laid on some other fixed point, also by interpolating between three fixed points situated around the observer. The magnetic needle may not be relied on for correct orientation, but is of service in enabling the table to be set so nearly true at the beginning. It is therefore possible, by careful setting, to ensure that in the setting is indicated by the rays from the surrounding fixed points intersecting in a small triangle instead of a point, and a slight change in azimuth suffices to reduce the triangle to a point, which will indicate the position of the station exactly. Azimuthal error being less apparent on short than on long lines, interpolation is best performed by rays drawn from near points, and checked by rays drawn to distant points, as the latter show most strongly any possible error of the primary magnetic setting. In this way, and by self-verificatory traverses on the back ray between fixed points, plane-table stations are established over the ground at the commencement of the traverse. One of the advantages of this method is that ray, from these stations all surrounding objects which the scale permits of being shown are laid down on the table, sometimes by rays only, sometimes by a single ray and a measured distance. The general configuration of the ground is delineated simultaneously. In checking and examination various methods are followed. For large scale work in plains it is customary to run arbitrary lines across it and make an independent survey of the belt of ground to a distance of a few chains on either side for comparison with the original survey; the smaller scale hill topography is checked by examination from commanding points, and also by traverses run across the finished work on the table.

4. GEOGRAPHICAL SURVEYING

The introduction by mechanical means of superior graduation in instruments of the smaller class has enabled surveyors to effect good results more rapidly, and with less expenditure. The introduction of mechanical devices in the field, than was formerly possible. The 12-in. theodolite of the present day, with micrometer adjustments to assist in the reading of minute subdivisions of angular graduation, is found to be equal to the old 24-in. or even 36-in. instruments. New Methods for the measurement of bases have largely superseded the laborious process of measurement by the alignment of "compensation" bars, though not entirely independent of them. The Jäderin apparatus, which consists of a wire 25 metres in length stretched along a series of cradles or supports, is the simplest means of measuring a base yet devised; and experiments with it at the Pulkova observatory show it to be capable of producing most accurate results. But there is a measurable defect in the apparatus, owing to the liability of the wires to change in length under variable conditions of temperature. It is therefore considered necessary, where base measurements for geodetic purposes are to be made with scientific exactness, that the Jäderin wires should be compared before and after use with a standard measurement, and this standard is best attained by the use of the Brunner, or Colby, bars. The direct process of measurement by means of these bars involves errors which are not present when the ends of a shorter line, the length of which has been exactly determined, the base is extended by a process of triangulation.

There are vast areas in which, while it is impossible to apply the elaborate processes of first-class or "geodetic" triangulation, Secondary it is nevertheless desirable that we should rapidly acquire such geographical knowledge as will enable us to lay down political boundaries, to project roads and railways, and to attain such exact knowledge of special localities as will further military ends. Such surveys are called by various names—military surveys, first surveys, geographical surveys, etc., but in practice they are all undertaken with the same end in view, i.e. the acquisition of a sound topographical map on various scales, and as that end serves civil purposes as much as military, it seems appropriate to designate them geographical surveys only.

The governing principles of geographical surveys are rapidity and economy. Accuracy is, of course, a recognized necessity, but the term must admit of a certain elasticity in geographical work which is inadmissible in geodetic or cadastral functions. It is obviously foolish to attempt to meet the requirements of a perfectly accurate geographical survey in the unpeopled sand wastes which border the Nile valley, for instance (albeit those deserts may be full of topographical detail), as in the valley itself—the great centre of Egyptian cultivation, the great military highway of northern Africa. On the other hand, the most careful accuracy attainable in the art of topographical delineation is requisite in illustrating the nature of a district which immediately surrounds what may prove hereafter to be an important military position. And this, again, implies a class of technical accuracy which is quite apart from the rigid attainment of an ideal geographical survey, and demands a much higher intelligence to compass.

The technical principles of procedure, however, are the same in geographical as in other surveys. A geographical survey must equally start from a base and be supported by triangulation, or at least by some process analogous to triangulation, which will furnish the necessary skeleton on which to adjust the topography so as to ensure a complete and homogeneous map.

This base may be found in a variety of ways. If geodetic triangulation exists in the country, that triangulation should of course be used, as it affords a wide extent of secondary determinations, the fixing of peaks and points in the landscape far away to either flank, which will either give the data for further extension of geographical triangulation, or which may even serve the purposes of the map-maker without any such extension at all. In this manner the Indus valley series of the triangulation of India has furnished the basis for surveys across Afghanistan and Baluchistan to the Oxus and Persia.

Should no such preliminary determinations of the value of one or two starting-points be available, and it becomes necessary to measure a base and to work ab initio, the Jäderin wire apparatus may be adopted. It is cheap (cost about £50), and far more accurate than the process of measuring either by any known "subtense" system (in which the distance is computed from the angle subtended by a bar of given length) or by measurement with a steel chain. This latter method may, however, be adopted so long as the base can be levelled, repeated measurements obtained, and the chain compared with a standard steel tape before and after use.

The initial data on which to start a comprehensive scheme of triangulation for a geographical survey are: (1) latitude; (2) longitude; (3) azimuth; and (4) altitude, and this data should, if possible, be obtained pari passu with the measurement of the base.

The transit theodolite, fitted with a micrometer eyepiece and extra vertical wires, is the instrument par excellence for work of this nature; and it possesses the advantages of portability and comparative cheapness.

The method of using it for the purposes of determining values for (1) and (3), i.e. for ascertaining the latitude of one end of the base and the azimuth of the other end from it, are fully explained in Major Talbot's paper on "Military Azimuth and the Principle of the French Chain" (Co. Chief Geographical, 1889), which is not a theoretical treatise, but a practical illustration of methods employed successfully in the geographical survey of a very large area of the Indian trans-frontier districts. It should be noted that these observations are not merely of an initial character. They should be constantly repeated as the survey advances, and under certain circumstances (referred to subsequently) they require daily repetition.

The problems connected with the determination of (2) longitude have of late years occupied much of the attention of scientific surveyors. No system of absolute determination is accurate enough for combination with triangulation, as affording a check on the accuracy of the latter, and the spaces in the world across which geographical surveying has yet to be carried are rapidly becoming more and more subjected to any liability to error so great as is invariably involved in such determinations. It is true that absolute values derived from the observation of lunar distances, or occultations, have often proved to be the highest values, and there remains a degree of uncertainty in the form of triangulation more trustworthy for ascertaining differential longitude than any comparison between the absolute determination of any two points. The system of differential determination is necessary it should be made once, with all possible care, and the value obtained should be carried through the whole scheme of triangulation. It rests with the surveyor to decide at what point of the general survey this value can best be introduced, provided he
can estimate the probable longitudinal value of his initial base within a few minutes of the truth. A final correction in longitude is constant, and can be easily applied. With reference to such determinations of longitude, Major J. S. Goodspeed in 1881 for determining the parallaxes in declination and right ascension of a heavenly body and its application to the prediction of occultations" (Roy. Geog. Soc. Journ. for June 1896) will afford the observant reader ample information.

But the recognized method of obtaining a longitude value in recent geographical fields is by means of the telegraph—a method not only quick and accurate but it so y be applied with advantage even to the checking of long lines of triangulation or triangulation control. No effort should be spared to introduce a telegraphic longitude value into any scheme of geographical survey. One involves a large initial expenditure, but if an instrument is applied to the field in the manner as one by one they are passed by the moving force, it has been found to yield results which are quite sufficiently accurate and would be very serviceable in the absence of any subsequent system of triangulation which may be extended through the country traversed, without serious discrepancies in compilation. It is, however, obvious that as accuracy depends very largely on the exact determination of those points at which the beds are passed through; as for instance, on the route between Seistan and Herat, where the initial data for the Russo-Afghan boundary delimitation was secured with a precision which was not more recently on the boundary surveys of western Abyssinia.

When an active enemy is in the field, and topographical operations are consequently restricted, it is usually possible to obtain the necessary condition without the aid of the ordinary called "military surveyor," and he may, in favourable circumstances, combine his work with that of the topographical engineer. In such circumstances, observations which are fixed, and in a widely extended position held by the enemy. The application of the camera and of telephotography to the evolution of a map of the enemy's position is well understood in Russia's "Photographie Militaire" ("Military Topography"), as it is in Russia, and we must in future expect that all advantages of an expert and professional map of the whole theatre of war will be thrown open to the hands of the general who is best supplied with professional expertise, the deliberate reconnaissance, graphic surveying and military surveying are convertible terms, and it is important to note that both equally require the services of a trained topographer. The combined use of the camera and the telegraph during the war between Russia and Turkey (1877–78) upwards of a hundred professional geographical surveyors were pressed into military service, besides the regular survey staff which is attached to every army corps. The results have been largely compiled from eight different series; every pass and every notable feature of the Balkans and Rhodope Mountains was accurately surveyed, as well as the plains intervening between the Balkans and Constantinople. Surveys on a scale which averaged about 1. m. were carried up to the very gates of the city.

The use of the camera as an accessory to the plane table (i.e., the art of photo-topography) has been applied almost exclusively to geographical or exploratory surveys. The camera is specially prepared, resting on a graduated horizontal plate which is read with verniers, and with a small telescope which is described vertically, is fixed in the local plane of the camera, which is also fitted with a magnetic needle and a scale so placed that the magnetic declination, the declination of the intersection of the cross wires are all photographed on the plate containing the view (slightly overlapping each other) is taken at each station, and the angular distance between each is measured on the horizontal projection from these perspective views involves plotting the skeleton triangulation, as obtained from the primary triangulation, with the theodolite (which precedes the photographic survey), or from the horizontal plate of the camera. With several stations plotted, the view from each of them of a certain portion of the country may be projected on the plane of the map, and salient positions in perspective may be fixed by intersection.

The field work of modern work is primarily in execution of a triangulation by the usual methods which would be adapted to any ordinary topographical survey. To this is added a second and very important operation, which is executed pari passu with the photography for the purpose of the position of the camera stations. From such stations alone the topographical details are finally secured with the aid of the photographs. Great care is taken to bring the camera to the tacheometer at each station, and to the tacheometer with the azimuths. Occasionally a hill can be reached in the course of the day's march, or during a day's halt, which will materially assist to consolidate and strengthen the survey. It may, however, frequently be impossible to maintain a consistent series of triangulation for the "control" (to use an American expression) of the topography, even when the configuration of the land surface is favourable. In such circumstances the method of observing azimuths to points situated approximately in the center of the portion to be triangulated, and of determining the exact position of those points, in latitudes and longitudes, as one by one they are passed by the moving force, has been found to yield results which are quite sufficiently accurate and would be very serviceable in the absence of any subsequent system of triangulation which may be extended through the country traversed, without serious discrepancies in compilation. It is, however, obvious that as accuracy depends very largely on the exact determination of those points at which the beds are passed through; as for instance, on the route between Seistan and Herat, where the initial data for the Russo-Afghan boundary delimitation was secured with a precision which was not more recently on the boundary surveys of western Abyssinia.
of the final topography are drawn. The principal trigonometrical points are plotted on both these boards by their co-ordinates, and the camera stations either by their co-ordinate values or by intersecting two circles that appear on the camera planes, or more rarely, are plotted by intersection. The horizontal projection of a panorama consisting of any given number of plates is a regular geometrical figure. The radius of the inscribed circle whose radius is the focal length of the camera. Having correctly plotted the position of one plate, or view, with reference to the projected camera station by means of the anamorphosed circular coordinate or by intersection of the corresponding circles, it is possible to plot the position of the rest of the series, with reference to the camera station and the orienting triangulation point, by the angular differences which are dependent upon the amount of the horizontal alternations of the figure. Having secured the correct orientation of the horizontal plan, direction lines are drawn from the plotted camera station to points photographed, and the position of the geographical features is fixed by intersection from two or more camera stations.

The plane-table is the instrument, par excellence, on which the geographical surveyor must depend for the final mapping of the physical features of the country under survey. The methods of adapting the plane-table to geographical requirements differ with those varying climatic conditions which characterize the various parts of the world. In the tropics, or in the regions bordering seas and oceans, where the earth's rotation is of great effect, the plane-table is adapted with apparatus which will allow greater accuracy, and the surveyor can work under these conditions with his camera. In the high mountains and in regions with extreme climates, the plane-table is used in a modified form, or with other apparatus for increasing the certainty and the accuracy of observations. Thus, in the Himalayas, the plane-table is adapted to the atmospheric conditions, and it is, therefore, possible to work in the upper regions. The Indian plane-table is the simplest possible construction, and it is never used in connexion with the stadia for ascertaining the distances of points and features of the ground (as is the case in America); and in place of the complicated American alidade, with its telescope and vertical arc, a simple sight rule is adopted, with a clinometer for the measurement of vertical angles. The Indian plane-table approximates closely in general construction to the Compass, or Compass Survey, of America, which is specially constructed for exploratory surveys.

The scale on which geographical surveys are conducted is necessarily small. It may be reckoned at 1 : 500000 to 1 : 125000, or from 1 in. = 8 m. to 1 in. = 2 m. The 1 in. = 1 m. scale is the normal scale for rigorous topography, and although it is impossible to fix a definite line beyond which geographical scales merge into topographical (for instance, the 1 in. scale is classified as geographical in America whenever the continuous line system contour of ground representation gives place to hachuring), it is convenient to assume generally that geographical scales greater than 1 in. = 1 m. are called topographical.

On the smaller scales of 1 : 50000 or 1 : 250000 an experienced geographical surveyor, in favourable country, will complete an area of mapping from day to day which will practically cover a large portion of the surface of the globe. He will, in the course of five or six months of continuous travelling (especially if provided with the necessary "control") cover an area of geographical scale from 1 in. to 10 m., and introduce on the small scale of his survey, which may be reckoned at tens of thousands of square miles. But inasmuch as everything depends upon his range of vision, and the constant occurrence of suitable features from which to extend it, there is obviously no guiding rule by which to reckon his probable out-turn.

The same uncertainty which exists about "out-turn" manifestly exists about "cost." The normal cost of the 1 in. rigorous topographical survey in India, when carried over districts which present an average of hills, plains and forests, may be estimated as between 35 to 40 shillings a square mile. This comparison is not between the rigorous plane-table style of surveying over districts which probably present far more facilities for surveying than India does, but where cheap native labour is unknown. The geographical surveyor is simply a topographer employed on a smaller scale survey. His equipment and staff are somewhat less, but, on the other hand, his travelling expenses are greater. It is found that, on the whole, a fair average for the cost of geographical survey work by applying the square of the unit of scale as a factor to 1 in. survey is 4 shillings per quarter mile of survey (i.e. 4 m. to the in.), should be one-sixteenth of the cost per mile of the 1 in. survey over similar ground. A geographical reconnaissance of the scale of 1 : 500000 is placed in the hands of the topographer, and it is submitted to the surveyor, together with the results of the interferometric photographic work, and is then estimated as a basis for the future survey.
right angles as the figure has sides, less four; the second is linear, viz., the algebraical sum of the $x$ co-ordinates and that of the $y$ co-ordinates above mentioned. The astronomical test is this: at any station of the traverse the azimuth of a referring mark may be determined by astronomical observations; the inclination of the line of the origin is given by the traverse; the two should differ by the convexity of the meridians of the station and the origin. In practice the angles of the traverse are usually adjusted to satisfy their special geometrical and astronomical tests in the first instance, and then the co-ordinates of the stations are calculated and adjusted by corrections applied to the longest, that the angles may be least disturbed, as no further corrections are given them.

The exact value of the convergence, when the distance and azimuth of the second astronomical station from the first are known, is that of $B-(x+\alpha)$ of equation (5); but, as the first term is sufficiently for the traverse, we have

$$\text{convergence} = x \tan \frac{\alpha}{2} \cot \frac{\beta}{2},$$

substituting $x$, the co-ordinate of the second station perpendicular to the meridian of the origin, for $c \sin \alpha$.

The co-ordinates of the principal stations of a trigonometrical survey are usually the spherical co-ordinates of latitude and longitude; those of a traverse survey are always rectangular, plane for a small area but spherical for a large one. It is often, for purposes of comparison and check at stations common to surveys of both descriptions, to convert either rectangular co-ordinates into latitudes and longitudes, or vice versa, in order that the traverse survey may be represented by proportion over the co-ordinates of the traverse stations, if desired, or adjusted in the final mapping. The latter is generally all that is necessary, more particularly when the traverses are referred to successive trigonometrical stations, as origins, as the operations are being extended, in order to prevent any large accumulation of error. Similar conversions are also frequently necessary in map projections.

The method of effecting them will now be indicated.

Let $A$ and $B$ be any two points, $A_d$ the meridian of $A$, $B_d$ the parallel of latitude of $B$; then $A_b$, $B_b$ will be their differences in latitude and longitude; from the line between $A$, $B$, $A_B$, $B_B$ will be the arc $AB$, the difference of longitude, $\omega$; also let $\lambda_A$, $\lambda_B$ and $\lambda_{AB}$ be the latitudes of $A$, $B$, and the point $P$, $\rho_B$ the radius of curvature of the meridian, and $\rho_A$ the normal terminating in the axis minor for the latitude $\lambda_A$; and

$$\begin{align*}
\lambda_{AB} &= \lambda_A + \lambda_{B} - \lambda_{AB} + \lambda_{B}(-\frac{\pi}{2}) + \frac{\pi}{2} \\
\lambda_{AB} &= \lambda_A + \frac{x}{\cos \frac{\beta}{2}} - \frac{\pi}{2} + \frac{\pi}{2}.
\end{align*}$$

(19)

And, when the longitude and latitude are given, we have

$$\begin{align*}
\eta &= \frac{s}{2} \sin 2 \beta \\
y &= \rho_A \cos \eta - \rho_B \sin \eta \\
x &= \cos \cos (\lambda_A + y + y) \cot \frac{\beta}{2}.
\end{align*}$$

(20)

When a hill peak or other prominent object has been observed from a number of stations whose co-ordinates are already fixed, the converging rays may be projected graphically, and from an examination of their several intersections the most probable position of the object may be obtained almost as accurately as by calculations by the method of least squares, which are very laborious and out of place for the determination of a secondary point. The following is a description of the application of this method to points on a plane surface in the calculations of the ordnance survey. Let $s_1$, $s_2$, be stations where the traverses or co-ordinates, $x$, co-ordinates, and $y$, are parallel, to the meridian of the origin are given; let $a_1$, $a_2$, be the bearings of the direction-inclinations with the meridian of the origin of any point $P$, as observed at the several stations; and let $p$ be an approximate position of $P$, with co-ordinates $x_p$, $y_p$, as determined by graphical projection on a district map or by rough calculation. Construct a diagram of the rays converging around $P$, by taking a point to represent $p$ and drawing two lines through at right angles to each other to indicate the directions of north, south, east and west. Calculate the distances $\tan (y_p - y_1)$ and with compare with $x_p - x_1$; the difference will show how far the direction of the ray from $a_1$ falls to the east or west of $p$. Or calculate $x_p - x_2$ and $y_p - y_2$ to find how far the direction falls to the north or south of $p$. Set off the distance on the corresponding axis of $p$, and through the point thus fixed draw the direction $a_1$ with a common protractor. All the other rays around $p$ may be drawn in like manner; they will intersect each other in a number of points, the centre of which may be adopted as the most probable position of $P$. The co-ordinates of $P$ will then be readily obtained from those of the points of the distances on the meridian and perpendicular. In the annexed diagram (fig. 6) $P$ is supposed to have been observed from five stations, giving as many intersecting rays, $(1, 1)$, $(2, 2)$, etc., there are ten points of intersection, the mean point of which gives the true position of $P$, of assumed position being $p$. The advantages claimed for the method are that, the bearings being independent, an erroneous bearing may be redrawn without disturbing those that are correct; similarly new bearings may be introduced without disturbing previous work, and observations from several stations may be readily utilized, whereas, when calculation is resorted to, observations in excess of the minimum number required are frequently rejected because of the labour of computing the authorities.

6. NAUTICAL SURVEYING

The great majority of nautical surveys are carried out by H.M. surveying vessels under the orders of the hydrographer of the admiralty. Plans of harbours and anchorages are also received from H.M. ships in commission on foreign stations, but surveys of an extended nature can hardly be executed except by a ship specially fitted and carrying a trained staff. The introduction of steam placed means at the disposal of nautical surveyors which largely modified the conditions under which they had to work in the earlier days of sailing vessels, and it has enabled the ship to be used in various ways previously impracticable. The heavy draught of ships in the present day, the growing increase of ocean and coasting traffic all over the world, coupled with the desire to save distance by rounding points of land and other dangers as closely as possible, demand surveys on larger scales and in greater detail than was formerly necessary; and to meet these modern requirements a large number of the vessels which are continually being called for. Nautical surveys vary much in character according to the nature of the work, its importance to navigation, and the time available. The elaborate methods and rigid accuracy of a triangulation for geodetic purposes on shore are unnecessary,
and are not attempted; astronomical observations at intervals in an extended survey prevent any serious accumulation of errors consequent upon a triangulation which is usually carried out with instruments, of which an 8-in. theodolite is the largest size used, whilst 5-in. theodolites generally suffice, and the sextant is largely employed for the minor triangulation. The scales upon which nautical surveys are plotted range from \( \frac{1}{3} \) in. to 2 or 3 in. to the mile in coast surveys for the ordinary purposes of navigation, according to the requirements; for detailed surveys, two scales of from 6 to 12 in. is usually adopted, but in special cases scales as large as 60 in. to the mile are used.

The following are the principal instruments required for use in the field: Theodolite, 5 in., fitted with large telescope of high power, with coloured shades to the eye-piece for observing the sun for true bearings. Sextant, 8 in. observing, stand of brass, eight, box, and two or three pocket, are usually supplied to surveying vessels. Sounding sextants, differing from ordinary sextants in being lighter and handier. The arc is cut only to minutes, reading to large angles of as much as 140°, and fitted with a tube of bell shape so as to include a large field in the telescope, which is of high power. Measuring chains 100 ft. in length. Ten-foot pole for coast-lining, is similar to the foregoing frames, 15 in. by 24 in., covered with canvas painted white, with a broad vertical black stripe in the centre and fixed on the pole 10 ft. apart. Station-pointer, an instrument in constant requisition either for sounding, coast-lining, or topographical plotting, which enables an observer's position to be fixed by taking two angles between three objects suitably situated. The movable legs being set to the observed angles, and placed on the position of the fixed extremities of the three legs are brought to pass through the points observed. The centre of the instrument then indicates the observer's position. Hollows, for reflecting the rays of the sun from distant stations to indicate their position, are invaluable. The most convenient form is Galton's sun-signal; but an ordinary swing mirror, mounted to turn horizontally, will answer the purpose, the flash being directed from a hole in the centre of the mirror for topographical purposes. Prismatic compass, patent logs (taffrail and hawse). Lucas wire sounding machine (large and small size), and James's submarine senery are also required. For chart-room use are provided a graduated brass scale, steel straight-edges and beam compasses of different lengths, rectangular vanecluse or ivory protractors of 6-in. and 12-in. length, and semicircular brass protractors of 10-in. radius, a box of good mathematical drawing instruments, lead weights, drawing boards and mounted paper. Every survey must have fixed objects which are first plotted on the sheet, and technically known as "points." A keen eye is required for natural marks of all kinds, but these must often be supplemented by whitewash marks, cairns, tripods or bushes covered with white canvas or calico, and flags, white or black according to background. On low coasts, flax or seaweed 80 ft. high must sometimes be erected in order to get the necessary range of vision, and thereby avoid the evil of small triangles, in working through which errors accumulate so rapidly. A barling spar 35 ft. in length, securely stayed and carrying as a guide a line of somewhat lighter spar, lengthened by a long bamboo, will give the required height. A fixed beacon can be erected in shallow water, 2 to 3 fathoms in depth, by constructing a tripod of spars about 45 ft. long. The heads of two of them are lashed together, and the heels kept open at a fixed distance by a plank about 27 ft. long, nailed on at about 5 ft. above the heels of the spars. These are taken out by three hooks, and the third tripod leg lashed in position on the boat, the heel in the opposite direction to the other two. The first two legs, weighted, are let go together; using the third leg as a prop, the tripod is secured into position and secured by guys to anchors, and by additional weights slipped down the legs. A vertical pole with bamboo can now be added, its weighted heel being on the ground and lashed to the fork. On this a flag 14 ft. square may be hoisted. Floating beacons can be made by filling up the gaps between two 27-gallon casks, connected by nailing a piece of thick plank at top and bottom. A barling spar passing through holes cut in the planks between the casks, projecting at least 20 ft. below and above 10 ft. above, is tucked in the upper and below the lower plank. To the upper part of the spar is lashed a bamboo, 30 to 35 ft. long, carrying a black flag 12 or 16 ft. square, which will be visible for a quarter of a mile in clear weather. The ends of a span of 3-in. chain are secured round the spar above and below the casks with a long link travelling upon it, to which the cable is attached by a slip, the end being carried up and lightly stopped to the bamboo below the flag. The flag's pole is open by its own stiffening, and is fitted to the casks for convenience in slipping and picking up. The beacon is moored with chain and rope half as long as the depth of water. Beacons have been moored by sounding line in as great depth as 3000 fathoms with a weight of 100 lb.

There is nothing in a nautical survey which requires more attention than the "fix"; a knowledge of the principles involved is essential in order to select properly situated objects. The method of fixing by two angles between three fixed points is generally known as the "two-circle method," but there are really three circles involved. The "station-pointer" is the instrument used for plotting fixes. Its construction depends upon the fact that angles subtended by the chord of a segment of a circle measured from any point in its circumference are equal. The lines joining three fixed points form the chords of segments of three circles, each of which passes through the observer's position and two of the fixed points. The more rectangular the angle at which the circles intersect each other, and the more sensitive they are, the better will be the fix; one condition is useless without the other. A circle is "sensitive" when the angle between the two objects responds readily to any small movement of the observer towards or away from the centre of the circle passing through the observer's position and the two objects. This is most markedly the case when one object is very close to the observer and the other very distant, but not so when both objects are distant. Speaking generally, the sensibility of angles depends upon the relative distance of the two objects from the observer, as well as the absolute distance of the nearer of the two objects. The accompanying diagram A, B, C are the objects, and X the observer. Fig. 7 shows the circle passing through C, B and X, cutting the circle ABX at a good angle, and therefore fixing X independently of the circle CAX, which is less sensitive than either of the other two. In fig. 8 the two first circles are very sensitive, but being nearly tangential they give no cut with each other. The third circle cuts both at right angles; it is, however, far less sensitive, and for that reason if the right and left hand objects are both distant the fix must be bad. In such a case as this, because the angles CXB, BXA are both so sensitive, and the accuracy of the fix depends on the precision with which the angle CAX is measured, that angle should be observed direct, together with one of the other angles composing it. Fig. 9 represents a case where the points are badly disposed, approaching the condition known as "on the circle," passing through the three points. All three circles cut one another at such a fine angle as to give a very poor fix. The centre of the station-pointer could be moved considerably without materially affecting the coincidence of the legs with the three points. To avoid a bad fix the following rules are safe:

1. Never observe objects of which the central is the furthest unless it is very distant relatively to the other two, in which case the fix is admissible, but must be used with caution.

2. Choose objects disposed as follows: (a) One outside object distant and the other two near, the angle between the two near
objects being not less than 30° or more than 140°. The amount of the angle between the middle and distant object is immaterial.

(b) The three objects nearly in a straight line, the angle between any two being not less than 30°. (c) The observer's position being inside the triangle formed by the objects.

A fix on the line of two points in transit, with an angle to a third point, becomes more sensitive as the distance between the transit points increases relatively to the distance between the front transit point and the observer; the nearer the angle to the third point approaches a right angle, and the nearer it is situated to the observer, the better the fix. If the third point is at a long distance, small errors either of observation or plotting affect the result largely. A good practical test for a fix is afforded by noticing whether a very slight movement of the centre of the station-pointer will throw one or more of the points away from the leg. If it can be moved without appreciably disturbing the coincidence of the leg and all three points, the fix is bad.

Tracing-paper answers exactly the same purpose as the station-pointer. The angles are laid off from a centre representing the position, and the lines brought to mark the legs of the triangles, and the angles are not so accurately measured with a small protractor. Nevertheless this has often to be used, as when points are close together on a small scale the central part of the station-pointer will often hide them and prevent the use of the instrument. The use of tracing-paper permits any number of angles to different points to be laid down on it, which under certain conditions of fixing is sometimes a great advantage.

Although marine surveys are in reality founded upon triangulation and measured bases of some description, yet when plotted irregardless of the system of triangles is not always apparent. The triangulation ranges from the rough triangle of a running survey to the carefully formed triangles of detailed surveys. The measured base for an extended survey is provisional only, the scale resting ultimately mainly upon the astronomical positions observed at its extremes. In the case of a plan the base is absolute. The main triangulation, of which the first triangle contains the measured base as its known side, establishes a series of points known as main stations, from which and to which angles are taken to fix other stations. A sufficiency of secondary stations and marks enables the detail of the chart to be filled in between them. The points embracing the area to be worked on, having been plotted, are transferred to field boards, upon which the detail of the work in the field is plotted; when complete the work is traced and re-transferred to the plotting-sheet, which is then inked in as the finished chart, and if of large extent it is graduated on the gnomonic projection on the astronomical positions of two points situated near opposite corners of the chart.

The kind of base ordinarily used is one measured by chain on flat ground, of 3 to 13 m. in length, between two points visible from one another, and so situated that a triangulation can be readily extended from them to embrace other points in the survey forming well-conditioned triangles. The error of the chain is noted before leaving the ship, and again on returning, by comparing its length with the standard length of 100 ft. marked on the ship's deck. The correction so found is applied to obtain the final result. If by reason of water intervening between the base stations it is impossible to measure the direct distance between them, it is permissible to deduce it by traversing.

A Masthead Angle Base is useful for small plans of harbours, &c., when circumstances do not permit of a base being measured on land, or when the visibility between stations is the most favourable condition for employing this method. Theodolite reading of the masthead with its elevation by sextant observed simultaneously at each base station (the mean of several observations being employed) gives the necessary data to calculate the distance between the base stations from the two distances resulting from the elevation of the masthead and the simultaneous theodolite-angles between the masthead and the base stations. The height of the masthead may be temporarily increased by securing a spar to extend 30 ft. or so above it, and the exact height from truck to netting is found by tripping up the end of the measuring chain. The angle of elevation should not be diminished below about 1° from either station.

Base by Sound.—The interval in seconds between the flash and return of the flash or echo, called, when measured with a watch or pocket chronometer, multiplied by the rate per second at which sound travels (corrected for temperature) supplies a means of obtaining a base which is sometimes of great use when other methods are not available. This method is well adapted for ship base, and guns or small brass Cohorn mortars are fired alternately from either end, and repeated several times. The arithmetical mean is not strictly correct, owing to the retardation of the sound on its outward and return journey, but when traveling with it; the formula used is therefore \( T = \frac{2t}{1 + \frac{t}{T}} \), where \( T \) is the mean interval required, \( t \) the interval observed one way, \( r \) the interval the other way. The method is not a very accurate one, but is sufficient so when the scale is finally determined by astronomical observations, or for sketch surveys. The measurement should be taken across the wind if possible, especially if guns can only be fired from one end of the base. Sound travels about 1090 ft. per second at a temperature of 62° F., and increases at the rate of 1.15 ft. for each degree above that temperature, decreasing in the same proportion for the figures below 32°.

Base by Angle of Short Measured Length.—An angle measured by sextant between two well-defined marks at a carefully measured distance apart, placed at right angles to the required base, will give a good for a small and regular base.

Astronomical Base.—The difference of latitude between two stations visible from each other and nearly in the same meridian, which is given approximately by the use of the sextant and extended triangulation; the only drawback to it is the effect of local attraction of masses of land in the vicinity on the pendulum, or, in other words, on the mercury in the artificial horizon. The ship's dead reckoning should be checked to test the effect of any error in the astronomical observations. The observation spots would not necessarily be actually at the base stations, which would probably be situated on summits at some little distance in order to command distant views. In each case each observation spot would be connected with its corresponding base station by a subsidiary triangulation, a short base being measured for the purpose of making the ship at anchor off the observation spot frequently affords a convenient means of effecting the connexion by a masthead angle base and simultaneous angles. If possible, the observation spots should be east or west of the mountain stations from which the true bearings of the stations A and B can be deduced.

If the base stations A and B are so situated that by reason of distance or of high land intervening they are invisible from one another, but both visible from some main station C between them, when the main triangulation is completed, the ratio of the sides AC, BC can be determined. From this ratio and the observed angle ACB, the angles ABC, BAC can be found. The true bearing of the lines AC or BC being known, the true bearing of the base stations A and B can be deduced.

Extension of Base.—A base of any description is seldom long enough to plot directly, and in order to diminish errors of direction, which are necessary, an extension should be worked inwards. A short base measured on flat ground will give a better result than a longer one measured over inequalities, provided that the triangulation is carefully extended by means of judiciously chosen angles, great care being taken to select suitable centres of each station. To facilitate the extension of the base in as few triangles as possible, the base should be placed so that there are two stations, one on each side of it, subtending angles at them of from 30° to 100°, and the distances between which, on being calculated in the triangles of the quadrilateral so formed, will constitute the first extension of the base. Similarly, two other stations placed one on each side of the last two will form another quadrilateral, giving a yet longer side, and so on.

The angles to be used in the main triangulation scheme must be very carefully observed and the theodolite placed exactly over the centre of the station. Main angles are usually repeated several times by resetting the vernier at intervals equidistant along the arc, in order to eliminate instrumental errors as well as errors of observation. The selection of an object suitable for a zero is very important. In plotting the points, if possible, main station at some distance, but not so far or so high as to be easily obscured, well defined, and likely to be permanent. Angles to secondary stations and other marks need not be repeated so many times as the more important angles, but it is well to check all angles once at least. Rough sketches from all stations are of great assistance in identifying objects from different points of view, the angles being entered against each in the sketch.

False Station.—When the theodolite cannot for any reason be placed over the centre of a station, if the distance measured
and the theodolite reading of it be noted, the observed angles may be reduced to what they would be at the centre of the station. For stations derived from the theodolite in practice, a simple rule to meet all cases is of great assistance to avoid the possibility of error in applying the correction with its proper sign. This may very easily be found as follows, without having to bestow a moment's thought beyond applying the rule, which is a matter of no small gain in time, when a large number of angles have to be corrected.

RESULTS.—Put down the theodolite reading which it is required to correct (increased if necessary by 360°), and from it subtract the theodolite reading of the centre of the station. Call this remainder θ. With the angle under construction (the sides of the triangle) it is-as a "course" and the number of feet from the theodolite to the station as a "distance," enter the traverse table and take out the greatest, or least, or lesser of the two (when 225° and 315°, or between 225° and 135°, and the lesser increment for other angles. The accompanying diagram (fig. 10) will assist in referring to the "table of subtended angles by various lengths at different distances" (using the distance of the object observed) and find the corresponding correction in arc, which mark + or − according as θ is under or over 150°. Apply this correction to the observed (corrected) angle. A "table of subtended angles" is unnecessary if the formula

\[ \text{Angle in seconds} = \frac{\text{number of feet subtended} \times 34}{\text{distance of object in sea-miles}} \]

Convergence of Meridians.—The difference of the reciprocal true bearings between two stations is called the "convergence." In Converting the reciprocal bearings in sea-miles to degrees, divide the number by 180. In south latitude the greater of the two, and in south latitudes the northerly bearing. The Mercatorial bearing between two stations is the mean of their reciprocal true bearings.

After a preliminary run over the ground to note suitable positions for main and secondary stations on prominent headlands, islands and summits not too far back from the coast, and, if no former survey exists, to make the same time a rough record of the position and general aspect of the object to be surveyed from the other land and from the short side. In open country the selection of stations is comparatively an easy matter, but in country densely wooded the time occupied by a triangulation is mainly governed by the judicious selection of stations quickly reached, sufficiently elevated to command distant views, and situated on summits capable of being readily cleared of trees in the required direction, an all-round view being, of course, desirable but not always attainable. The positions of secondary stations will also generally be decided upon during the preliminary reconnaissance. The object of these stations is to break up the large primary triangulations into triangles of smaller size, dividing up the distances between the primary stations into suitable lengths; they are selected with a view to greater accessibility than the latter, and should therefore usually be near the coast and at no great elevation. Upon shots from these will depend the position of the greater number of the coast-line marks, to be erected and fixed as the detailed survey of each section of the coast is taken in hand in regular order. The nature of the base to be used, and its position in order to fulfil the conditions specified under the head of Bases must be considered, as otherwise the triangulation may be falsified. It is immaterial at what part of the survey the base is situated, but if it is near one end, a satisfactory check on the accuracy of the triangulation is obtained by comparing the length of a side at the other extreme of the survey, derived by calculation through the whole system of triangles, with its length deduced from a check base measured in its vicinity. It is generally a saving of time to measure the base at some anchorages or harbour that requires a large scale plan. The triangulation involved in extending the base to the station will thus be made from an initial triangulation so as thus to be utilized for both purposes, and the triangulation is being calculated and plotted the survey of the plan can be proceeded with. True bearings are observed at both ends of the survey and the results subsequently compared. Astronomical observations for latitude are obtained at observation spots near the extremes of the survey and the meridian distance run between them, the observation spots being connected with the primary triangulation; they are usually disposed at intervals of from 100 to 150 m., and thus errors due to a triangulation carried out with theodolites of moderate diameter do not accumulate to any serious extent. If the survey is greatly extended, intermediate observation spots afford a satisfactory check, by comparing the positions as calculated in the triangulation with those obtained by direct observation.

Calculating the Triangulation.—The triangles as observed being tabulated, the angles of each triangle are corrected to bring their angles to 180°, using as much as as one minute, but under favourable conditions they may be much less. In distributing the errors we must consider the general skill of the observer, the size of his theodolite relatively to the distance, and the astronomical observations the observer has made; failing any particular reason to assign a larger error to one angle than to another, the error must be divided equally, and we find that a mistake of as much as one minute in the result may be considered as accidental. The bearing of the first side is then compared with the bearing obtained by direct observation at that end of the survey. The difference is principally due to accumulated errors in the triangulation; half of the difference is then applied to the bearing of each side. Convert these true bearings into Mercatorial bearings by applying half the convergence between each pair of stations. With the lengths of the connecting sides found from the measured base and their Mercatorial bearing, the position of a station is determined to a line in the sea. The bearing is then corrected to middle latitude sailing. Taking the observed astronomical positions of the observation spots and first reducing their true difference longitude to departure, as measured on a spheroid from the formula

\[ \text{Dep.} = \text{T. D. long.} \times \text{ft. in } 1 \text{ m. of lat.} \]

and adding the correction for the difference in latitude, then with the d. lat. and dep. the Mercatorial true bearing and distance between the observation spots is calculated by middle latitude sailing, and compared with that by triangulation and measured base. To adjust any discrepancy, it is necessary to consider the probable error of the observations for latitude and meridian distance; within these limits the astronomical positions may safely be altered in order to obtain the results; it is more important to bring the measurements into close agreement than the distance. From the amended astronomical positions the Mercatorial true bearings and distance between them are recalculated. The difference between this true bearing and the bearing derived from the triangulation by middle latitude sailing must be applied to the bearing of each side to get the final corrected bearings, and to the logarithm of each side of the triangulation as originally calculated must be added or subtracted the difference between the logarithms of the distances of the amended positions of the observation spots and the same distance by triangulation.
of the sides and their lengths ultimately depend almost entirely upon the astronomical observations at the extremities of the survey; the observed true bearings and measured base are consequently modified; this is especially true when the survey is altogether a pattern of irregular triangles, for here it is evident that, generally speaking, and therefore, that the nearer together the observation spots, the greater effect will a given error in the astronomical positions have upon the length and direction of the sides of the triangulation and upon all that depends thereon. It is evident, therefore, that the existence of observation spots may cause very false results, which may often account for discrepancies when situated on opposite sides of a mountainous country.

Great care is requisite in projecting on paper the points of a survey. The paper should be allowed to stretch and shrink as it pleases until it comes to a stand, being exposed to the air for four or five hours daily, and finally well flattened before being placed on a table with drawing boards placed over it heavily weighted. If the triangulation has been calculated beforehand throughout, and the lengths of all the different sides have been found, it is more advantageous to begin plotting by distances rather than by chords. The main stations are thus got down in less time and with less trouble, but these are only a small proportion of the points to be plotted, and long lines must be ruled between the stations as zeros for plotting other points by chords. In ruling these lines care must be taken to draw them exactly through the centre of the pricks denoting the stations, but, however carefully drawn, there is liability to slight errors, and these should be as small as they can possibly be, but as a general rule, any error in the absolute bearings of the stations between which the zero line is drawn. In plotting by distances, therefore, all points that will subsequently have to be plotted by chords should lie well within the area covered by the main triangulation. Three distances must be measured to obtain an intersection of the arcs cutting each other at a sufficiently broad angle; the plotting of the main stations once begun must be completed before distortion of the paper can occur from change in the humidity of the atmosphere. Plotting, whether by distance or by chords, must be begun on as long a side as possible, so as to plot forwards, or with decreasing distances. In plotting by chords it is important to remember in the selection of lines of reference or zero lines, that it should be preferred that which makes the smallest angle with the line to be projected from it, and of the angular points those nearest to the object to be projected from them.

Irregular Methods of Plotting.—In surveys for the ordinary purposes of navigation, it frequently happens that a regular system of triangulation cannot be carried out, and recourse must be had to a system of irregular triangulation. This is especially true in determining chartwork in coast survey, where a good deal of accuracy is often essential, and with proper care excellent results may be obtained. A few examples will illustrate some of the methods used, but circumstances vary so much in every survey that it is only possible to state a few general propositions for the guidance of the surveyor, and to improvise methods. Fixing a position by means of the "back-angle" is one of the most ordinary expedients. Angles having been observed at A, B, and C, a station D, and certain other fixed points of the survey, C and D for instance, if A is shot up from B, at which station angles to the same fixed points have been observed, then it is not necessary to visit those points to fix A. For instance, in the triangle ABC, two of the angles have been observed, and therefore the third angle at C is known (the three angles of a triangle being equal to 180°), and it is called the "calculated or back-angle from C." A necessary condition is that the receiving angle at A, between angles at A and B, should be known with sufficient accuracy to give a good cut; also the points from which the "back-angles" are calculated should not be situated at too great distances from A, relatively to the distance between A and B. A station may be plotted by laying down the line to it from some other station, and then placing on tracing-paper a number of the angles taken at it, including the angle to the station from which it has been shot up. If the plotting of the second line has been done in the proper way, the position is obtained, its accuracy being much strengthened by being able to plot on a line to it, which, moreover, forms a good zero line for laying off other angles from the station when plotted. Surveyors refer the known stations to the unknown station on the line to it, which to the other will afford a check. A well-defined mountain peak, far inland and never visited, when once it is well fixed is often invaluable in carrying on an irregular triangulation, as it may remain visible when all other original points of the survey have disappeared, and "back-angles" from it may be continually used for plotting on true bearing lines of it. In plotting the true bearing of such a peak, the convergence must be found and applied to get the reversed bearing, which is also true bearing down through it; or the reversed bearing of any other line already drawn through it, when bearing is known, it may simply be laid down with that at a zero. A rough position of the spot from which the true bearing was taken must be had, and this corrected in the appropriate proportion for the convergence. Fig. 11 will illustrate the foregoing remarks. A and B are astronomical observation spots at the extremities of a survey, with which the high, inaccessible peak C is visible. D, E, F are intermediate stations; A and D, B and C, D and E, E and F, F and B being respectively visible from each other. G is visible from A and D, and C is visible from all stations. The latitudes of A and B, and meridian distance between them being determined, and the true bearing of C being observed from both stations, is projected at all the stations. Calculating the spherical correction (from the formula, correction = d. cos² mid. lat.) and adding it to the true (or chromometric)

---

**Fig. 11.** Difference longitude between A and B to obtain the spherical d. long.; with this spherical d. long. and the d. lat., the Mercatorian true bearing and distance is found by middle latitude sailing (which is an equally correct but shorter method than by the foregoing method). The distances usual between observation spots in nautical surveys. The convergency is also calculated, and the true bearing of A from B, B from C, C from D, and A from C, is found. The angle ABC is the difference between the calculated bearing of B and the observed bearing of C from A; similarly angle B is the difference between calculated bearing of A and observed bearing of C from B. Another way is All have been also calculated, the side AC is found. Laying down AC on the paper on the required scale, D is plotted on its direct shot from A, and on the angle back from C, calculated in the triangle ACD. G is plotted on the direct shots from A and D, and the angle between them calculated either in the triangle ACG or GCD. The perfect intersection of the three lines at G assures these four points being correct. E, F and B are plotted then laid down from a meridian drawn and angle ABC is calculated, relying on the angle A the difference between the calculated bearing of B and the observed bearing of C from A; similarly angle B is the difference between calculated bearing of A and observed bearing of C from B. If the discrepancy is but small, it will be a strong presumption in favour of the substantial accuracy of the work. If the calculated true bearing of B from A be now laid down, it is very unlikely that the line will pass through B, but this is due to the discrepancy which must always be expected between astronomical positions and triangulation. If some of the stations between A and B require to be placed somewhat closer to one another, it may be desirable to obtain fresh true bearings of C instead of carrying on the original bearing means of the calculated angle. In all cases of irregular plotting the ship is very useful, especially if an irregular triangle is being run, and angles are observed from the bow. Floating beacons may also assist an irregular triangulation.

Surveys of various degrees of accuracy are included among sketch surveys. The roughest description is the ordinary running survey, when the work is done by the ship steaming along the coast, fixing points, and sketching a coast-line. This is done at a great distance from the coast, and her position upon her courses and distances as registered by patent log, necessarily regardless of the effect of wind and current and errors of steereage. At the other extreme comes the modified running survey, which in point of practical accuracy falls little short of that attained by irregular triangulation. Some of these modifications will be briefly noticed. A running survey of a coast-line between two harbours, that have been surveyed independently and astronomically fixed, may often be carried out
by fixing the ship on the points already laid down on the harbour surveys and shooting up prominent intermediate natural objects, assisted possibly by theodolite lines from the shore stations. Theodolite-lines to the ship at any of her positions are particularly valuable, because the visual angle can be very accurately placed and will increase the value of any such work. A sketch survey of a coast upon which it is impossible to land may be well carried out by dropping beacons at intervals of about 10 m., well out from the land and placed abreast prominent natural objects called the "breemarks," which must be capable of recognition from the beacons anchored off the next "breemark" on either side. The distance between the beacons is found by running a patent log by both ways, noting the time occupied by each run; if the current has remained constant, a tolerably good result can be obtained. At any time between the points of intersection of the second and the two "breemarks," an "intermediate" mark, and any other natural object which will serve as "points." At the second beacon; angles are observed between the first beacon and the same objects as before. Plotting on the line of the two beacons as a base, all the points observed can be pricked in on two shots. At a position about midway between the beacons, simultaneous angles are observed to all the points and laid off on tracing-paper, which will afford the necessary check, and the foundation is thus laid for filling in the detail of coast-line, through angles and soundings only being made to the beacons or shore in any detail desired. Each section of coast is complete in itself on its own base; the weak point lies in the junction of the different sections, as the patent log bases can hardly be expected to agree precisely, and the scales of adjacent sections may thus be slightly different. This is obviated, as far as possible, by fixing on the points of one section and shooting up those of another, which will check any great irregularity of scale creeping in. The bearing is preserved by getting occasional true bearing lines at the beacons of the most distant point visible. Space does not permit this duty to be done upon the coast, and the precautions that are necessary to secure the best results the method is capable of; it can only be stated generally that in all cases of using angles from the ship under weigh, several assistants are necessary, so that the principal angles may be taken simultaneously, the remainder being connected immediately afterwards with zeros involving the smallest possible error due to the ship not being absolutely stationary, these zeros being included amongst the primary angles. When close to a beacon, if its bearing is noted and the distance in feet obtained from its edge, the bathymetrical soundings only are made towards the beacon and the angles are in this manner obtained. Astronomical positions by twilight stars keep a check on the work.

**Sketch Surveys by Compass Bearings and Vertical Angles.**—In the case of an island culminating in a high, well-defined summit visible from all directions, a useful and accurate method is to steam round it at a sufficient distance to obtain a true horizon, stopping to make as many stations as may be desirable, and fixing by compass bearing of the summit and its vertical angle. The height is roughly obtained by shooting in the summit, from two positions on a patent log base whilst approaching it. With this approximate height and Lecky's vertical danger table, each station may be plotted on its bearing of the summit. From these stations the island is shot in by angles between its tangents to the summit, and angles to any other natural features, plotting the work as we go on any convenient scale which must be considered only as provisional. On completing the circuit of the island, the true scale is found by measuring the total distance in miles on the plotting-sheet from the first to the last station, and dividing it by the distance in miles between them as shown by patent log. The final height of the summit bears to the round height used in plotting the direct proportion of the provisional scale to the true scale. This method may be utilized for the sketch survey of a coast where there are well-defined peaks of sufficient height. This method has the advantage of being independent of the soundings and running survey. From positions of the ship fixed by bearings and elevations of one peak, another farther along the coast is shot in and its height determined; this second peak is then used in its turn to fix the position of the next, and so on. The results, however, are not without their limitations; the soundings are liable to error, there is no guarantee that the Lecky's tables will show what effect an error of say 1° in altitude will produce for any given height and distance, and the limits of distance must depend upon this consideration.

**Surveys of Banks out of Sight of Land.**—On striking shoal soundings unexpectedly, the ship may either be anchored at once and the sounding be taken, or the ship may be steered, or the sounding be measured, usingprismatic compass and masthead wheel; or if the shoal is of large extent and may be prudently crossed in the ship, it is a good plan to get two beacons laid down on a bearing from one another and patent log distance of 4 or 5 m. With another beacon (or mark boat, carrying a large black bag on a bamboo 30 ft. high) fixed on this base, forming an equilateral triangle, and the ship anchored as a third, the soundings will be obtained by shooting in succession, working off to the station-pointer. The ship's position is determined by observations of twilight stars.

In a detailed survey the coast is sketched in by walking along it, fixing by theodolite or sextant angles, and plotting by tracing-paper or station-pointer. A sufficient number of fixed marks along the shore afford a constant check on the minor coast-line stations, which should be plotted on, or checked by, lines from one to the other wherever possible to do so. If impracticable to fix in the ordinary way, the ten-foot pole may be used to traverse from one fixed point to another. With a coast fronted by broad drying, coral reef or flats over which it is possible to walk, the distances between any two coast-line stations may be found by measuring at one of them the angle subtended by a known length placed at right angles to the line joining the stations. There is far less liability to error if the work is plotted at once on a spot on field board with the fixed points pricked through and circled in upon it; but if circumstances render it necessary, the angles being registered and sketches made of the bits of coast between the fixes on a scale larger than that of the chart, they may be plotted afterwards; to do this satisfactorily, however, requires the surveyor to appreciate instinctively exactly what angles are necessary at the time. It is with the high-water line that the coast-liner is concerned, delineating its character according to the Admiralty symbols. The officer sounding off the coast is responsible for the position of the dry line at low-water, and on large scales this would be sketched in from a small boat at low-water springs. Heights of cliffs, rocks, islets, &c., must be inserted, either from measurement or from the formula,

\[
\text{height in feet} = \text{angle of elevation in seconds} \times \text{distance in miles} / 34
\]

and details of topography close to the coast, including roads, houses and enclosures, must be shown by the coast-liner. Rocks above water or breaking should be fixed on passing them. Coast-line may be sketched from a boat pulling along the shore, fixing and shooting up any natural objects on the beach from positions at anchor.

The most important feature of a chart is the completeness with which it is sounded. Small scale surveys on anything less than one inch to the mile are apt to be very misleading; sounding, such a survey may appear to have been closely sounded, but in reality the lines are so far apart that they often fail to disclose indications of shoal-water. The work of sounding may be proceeded with as soon as sufficient points for fixing are plotted; but off an intricate coast it is better to get the coast-line done first. The lines of soundings are run by the boats parallel to one another and perpendicular to the coast at a distance apart which is governed by the scale; five lines to the inch is about as close as they can be run without overcrowding; if closer lines are required the scale must generally be increased. The distance apart will vary with the depth of water and the nature of the coast; a rocky coast with shallow water off it and projecting points will need much closer examination than a steep-to coast, for instance. The line of prolongation of a point under water will require special care to ensure that the fathom lines being drawn correctly. If the soundings begin to decrease when pulling off-shore it is evidence of something suspicious, and intermediate lines of soundings or lines at right angles to those previously run should be obtained; whenever possible lines of soundings should be run on transit lines; these may often be picked up by fixing when on the required line, noting the angle on the protractor between the line and some fixed mark on the field board, and then placing the angle on the sextant, reflecting the mark and noting what objects are in line at that angle. On
large scale surveys whitewash marks or flags should mark the ends of the lines, and for the back transit marks natural objects may perhaps be picked up; if not, they must be placed in the required positions. The boat is fixed by two angles, with an occasional third angle as a check; the distance between the fixes is dependent upon the scale of the chart and the rapidity with which the depth alters; the 3, 5, and 10 fathom lines should always be fixed, allowing roughly for the tidal reduction. The nature of the bottom must be taken every few casts and recorded. It is best to plot each fix on the sounding board at once, joining the fixes by straight lines and numbering them for identification. The tidal reduction being obtained, the reduced soundings are written in the field-book. In undercurrents, to prevent the soundings from revolting, a line should be used. The boat is then placed in its proper position on the board between the fixes. Suspicious ground should be closely examined; a small nun buoy anchored on the shoal is useful to guide the boat while trying for the least depth. Sweeping for a reported pinnacle rock may be resorted to when sounding fails to discover it. Local information from fishermen and others is often most valuable as to the existence of dangers. Up to depths of about 15 fathoms the hand lead-line is used from the boats, but beyond that depth the small Lucas machine for wire effects a great saving of time and labour. The deeper soundings of a survey are usually obtained from the ship, but schooners with wire sounding machines may assist very materially. By the aid of a steam winch, which by means of an endless sounding line hauls a 100-lb lead forward to the end of the lower boom rigged out, from which it is dropped by a slipping apparatus which acts on striking the water, soundings of 40 fathoms may be picked up from the sounding platform aft, whilst going at a speed of 4½ knots. In deeper water it is quicker to stop the ship and sound from aft with the wire sounding machine. In running long lines of soundings on and off shore, it is very essential to be able to fix as far as the land as possible. Angles will be taken from aloft for this purpose, and a few floating beacons dredged in judiciously chosen positions will often help to clear the trouble. A single fixed point on the land used in conjunction with two beacons suitably placed will give an admirable fix. A line to the ship or her smoke from one or two theodolite stations on shore is often invaluable; if watches are compared, observations may be made at stated times and plotted afterwards. True bearings of a distant fixed object cutting the line of position derived from an altitude of the sun is another means of fixing a position, and after dark the true bearing of a light may be obtained by the time azimuth and angular distance of a star near the prime vertical, or by the angular distance of the Pole Star from the horizon.

A very large percentage of the bugsbeaws to navigation denoted by vigias1 on the charts eventually turn out to have no existence, but before it is possible to expunge them a large area has to be examined. No-bottom soundings are but little use, but the evidence of positive soundings should be conclusive. Submarine banks rising from great depths necessarily stand on bases many square miles in area. Of recent years our knowledge of the angle of slope that may be expected to occur at different depths has been much extended. From depths of 50 fathoms the slope is so gradual that a bank could hardly approach the surface less than such a sounding; therefore anywhere within an area of at least 150 sq. m. all round a bank rising from these depths, a sounding must show some decided indications of a rise in the bottom. Under such circumstances, soundings at intervals of 7 m., and run in parallel lines 7 m. apart, enclosing areas of only 50 sq. m., between any four adjacent soundings, should effectually clear up the ground and lead to the discovery of any shoal; and in fact the soundings might even be more widely spaced. From depths of 1500 and 1000 fathoms, shoals can scarcely occur within 45 m. and 2 m. respectively; but as the depth decreases the angle of slope rapidly increases, and a shoal might occur within three-quarters of a mile or even half a mile of such a sounding as 500 fathoms. A full appreciation of these facts will indicate the distance apart at which it is proper to place soundings in squares suitable to the general depth of water. These soundings will soon show in which direction to proceed for the search if any irregularity of depth is manifested. When once a decided indication is found, it is not difficult to follow it up by paying attention to the contour lines as developed by successive soundings. Discouraged water, ripplings, fish jumping or birds hovering about may assist in locating a shoal, but the submarine sentry, with a head at a depth of 40 fathoms is here invaluable, and may save hours of hunting. Reports being more liable to errors of longitude than of latitude, a greater margin is necessary in that direction. Long parallel lines east and west are preferable, but the necessity of turning the ship might make this impossible. The wind and wind direction to wind at every sounding makes it desirable to run the line both with the wind abeam, which tends to disturb the dead reckoning least. A good idea of the current may be obtained from the general direction of the ship’s head whilst sounding considered with reference to the strength and direction of the wind, and it should be allowed for in shaping the course to preserve the parallelism of the lines, but the less frequently the course is altered the better. A good position in the morning should be obtained by pairs of stars on opposite bearings, the lines of position of one pair cutting those of another pair nearly at right angles. If the observations of the sun at two sunrises, or any number of observations of the sun about every two hours throughout the day, preferably whilst a sounding is being obtained and the ship stationary, evening twilight stars give another position.

Tides.—The datum for reduction of soundings is low-water ordinary springs, the level of which is referred to a permanent bench mark in order that future surveys may be reduced to the same datum level. Whilst sounding is going on, the position of the survey lines will soon show in which direction to proceed for the search if any irregularity of depth is manifested. When once a decided indication is found, it is not difficult to follow it up by paying attention to the contour lines as developed by successive soundings. Discouraged water, ripplings, fish jumping or birds hovering about may assist in locating a shoal, but the submarine sentry, with a head at a depth of 40 fathoms is here invaluable, and may save hours of hunting. Reports being more liable to errors of longitude than of latitude, a greater margin is necessary in that direction. Long parallel lines east and west are preferable, but the necessity of turning the ship might make this impossible. The wind and wind direction to wind at every sounding makes it desirable to run the line both with the wind abeam, which tends to disturb the dead reckoning least. A good position in the morning should be obtained by pairs of stars on opposite bearings, the lines of position of one pair cutting those of another pair nearly at right angles. If the observations of the sun at two sunrises, or any number of observations of the sun about every two hours throughout the day, preferably whilst a sounding is being obtained and the ship stationary, evening twilight stars give another position.

Tidal Streams and Surface Currents are observed from the ship or boats at anchor in different positions, by means of a current log; or the course of a buooy drifted by the current may be followed by sending a boat out at regular intervals. The most noticeable is the high-water at full and change, called the “establishment,” and the heights to which spring and neap tides respectively rise above the datum are also required. It is seldom that a sufficiently long observation is preserved for subsequent harmonic analysis, and therefore the graphical method is preferred; an abstract form provides for the projection of high and low waters, lunar tidal intervals, moon’s meridian passage, declination of sun and moon, apogee and perigee, and mean time of high-water following superior transit, and of the highest tide in the twenty-four hours. A good portable automatic tide gauge suitable for all requirements is much to be desired.

A good portable automatic tide gauge suitable for all requirements is much to be desired.

Deep-sea Current Meter.

The instrument is first lowered to the required depth, and when ready is put into action by means of a heavy weight, or messenger, travelling down the supporting line and striking on a metal plate, thus closing the jaws of the levers and enabling the instrument to begin working. The rudder is then free to revolve inside the framework and take up the direction of the current; the small levers, which revolve on a pin, are operated by the motions, while the compass needle is released and free to take up the north and south line. On the despach of a second messenger, the lever, acting on the lever of the side, opens the jaws of the levers as soon as the machine is open, every part of the machine is simultaneously locked. Having noted the exact time of starting each of the messengers, the time during which the instrument has been working at the required depth, and from this the velocity of the current can be calculated, the number of revolutions having been recorded, while the direction is shown by the angle between the compass needle and the direction of the rudder.

Mark each object in fig. 12. AA are the jaws of the levers through which the first messenger passes and strikes on the metal plate B. The force of the blow is sufficient to press down, thus bringing the jaws close together as possible, and the corresponding direction of the current is marked by B. On the head of the first opens the levers again and prevents their closing, thus keeping all parts of the machine locked. C is the rudder which takes up the direction of the current when the lever is opened. D is a set of small levers on the rudder in connexion with AA. The
outer end on the tail of the rudder fits into the notches on the outer ring of the frame when the machine is locked and thus keeps the rudder fixed, but when the first messenger has started the machine by pressing down B and opening the levers AA, this small lever is raised and the rudder can revolve freely. EE are four small cones which revolve on their axis in a vertical plane, similar to an anemometer; the axis is connected by a worm screw to geared wheels which register the number of revolutions up to 5000, corresponding to about 4 nautical miles. There is a small lever in connection with AA which prevents the cones revolving when the machine is locked, but allows them to revolve freely when the machine is in action. Below the rudder-post is a compass-bowl F, which is hung in gimnals and capable of removal. The needle is so arranged that it can be lifted off the pivot by means of a lever in connection with AA; when the lever is in action the needle swings freely on its pivot, but, when the levers are locked it is raised off its pivot by the inverted cup-piece K placed inside the triple claws on the top of the compass and screwed to the lever, thus locking the needle without chance of moving. The compass bowl should be filled with fresh water before lowering the instrument into the sea, and the top screwed home tightly. The needle should be removed and carefully dried after use, to prevent corrosion. The long arm G is to keep the machine steady in one direction; it works up and down a jackstay which passes between two sheaves at the extremity of the long arm. This also assists to keep the machine in as upright a position as possible, and prevents it from being drifted astern with the current. A weight of as much as 8 or 10 cwt. is required at the bottom of the jackstay in a very strong current. An elongated weight of from 60 to 80 lb. must be suspended from the eye at the bottom of the meter to help to keep it as vertical as possible. On the outer part of the horizontal notched ring forming the frame, and placed on the side of the machine opposite to the projecting arm G, it has been found necessary to bolt a short arm supported by stays from above, from which is suspended a leaden counterpoise weight to assist in keeping the apparatus upright. This additional fitting is not shown in fig. 12. A 4-in. phosphor-bronze wire rope is used for lowering the machine; it is rove through a metal sleeve H and india-rubber washer, and spliced round a heart which is attached to metal plate B. The messengers are fitted with a hinged joint to enable them to be placed round the wire rope, and secured with a screw bolt. To obtain the exact value of a revolution of the small cones it is necessary to make experiments when the actual speed of the current is known, by immersing the meter just below the surface and taking careful observations of the surface-current by means of a current leg or weighted pole. From the number of revolutions registered by the meter in a certain number of minutes, and taking the mean of several observations, a very fair value of a revolution during the day can be deduced. On every occasion of using the meter for under-current observations the value of a revolution should be re-determined, as it is apt to vary owing to small differences in the friction caused by want of oil or the presence of dust or grit; while the force of the current is probably another important factor in influencing the number of revolutions recorded.

The features of the country should generally be delineated as far back as the skyline viewed from seaward, in order to assist the navigator to recognize the land. The summits of hills and conspicuous spurs are fixed either by lines to or by angles at them; their heights are determined by theodolite elevations or depressions to or from stations whose height above high-water is known. As much of the ground as possible is walked over, and its shape is delineated by contour lines sketched by eye, assisted by an aneroid barometer. In wooded country much of the topography may have to be shot in from the ship; sketches made from different positions at anchor along the coast with angles to all prominent features, valleys, ravines, spurs of hills, &c., will give a very fair idea of the general lie of the country.

Circum-meridian altitudes of stars on opposite sides of the zenith observed by sextant in the artificial horizon is the method adopted wherever possible for observations for latitudes. Arranged in pairs nearly the same altitude north and south of zenith, the mean of each pair should give a result from which instrumental and personal errors and errors due to atmospheric conditions are altogether eliminated. The mean of several such pairs should have a probable error of not more than $\pm 1\degree$. As a rule the observations of each star should be confined to within 5 or 6 minutes on either side of the altitude, which will allow of from fifteen to twenty observations. Two stars selected to "pair" should pass the meridian within an hour of each other, and should not differ in altitude more than $2\degree$ or $3\degree$. Artificial horizon roof error is eliminated by always keeping the same end of the roof towards the observer; when observing a single object, as the sun, the roof must be reversed when half way through the observations. The observations are reduced to the meridian by Raper's method. When pairs of stars are not observed, circum-meridian altitudes of the sun alone must be resorted to, but being observed on one side of the zenith only, none of the errors to which all observations are liable can be eliminated.

Sets of equal altitudes of sun or stars by sextant and artificial horizon are usually employed to discover chronometer errors. Six sets of eleven observations, a.m. and p.m., observing both limbs of the sun, should give a result which, under favourable conditions of latitude and declination, might be expected to vary less than two-tenths of a second from the normal personal equation of the observer. Stars give equally good results. In high latitudes sextant observations diminish in value owing to the slower movement in altitude. In the case of the sun the chronometers are compared with the "standard" at apparent noon; the comparisons with the chronometer used for the observations on each occasion of landing and returning to the ship are worked up to noon. In the case of stars, the chronometer comparisons on leaving and again on returning are worked up to an intermediate time. A convenient system, which retains the advantage of the equal altitude method, whilst avoiding the necessity of waiting some hours for the p.m. observation, is to observe two stars at equal altitudes on opposite sides of the meridian, and, combining the observations, treat them as relating to an imaginary star having the mean R.A. and mean declination of the two stars selected, which should have nearly the same declination and should differ from $4\degree$ to $8\degree$ in R.A.

The error of chronometer on mean time of place being obtained, the local time is transferred from one observation spot to another by the ship carrying usually eight box chronometers.

The best results are found by using travelling rates, which are deduced from the difference of the errors found on leaving an observation spot and returning to it; from this difference is eliminated that portion which may have accumulated during an interval between two determinations of error at the other, or any intermediate observation spot. A travelling rate may also be obtained from observations at two places, the meridian distance between which is known; this rate may then be used for the meridian distance between places observed at during the passage. Failing travelling rates, the mean of the harbour rates at either end must be used. The same observer, using the same instrument, must be employed throughout the observations of a meridian distance.

If the telegraph is available, it should of course be used. The error on local time at each end of the wire is obtained, and a number of telegraphic signals are exchanged between the
observers, an equal number being transmitted and received at
either end. The local time of sending a signal from one place
being known and the local time of its reception being noted,
the difference is the meridian distance. The retardation due to the
time occupied by the current in travelling along the wire is elimi-
ated by sending signals in both directions. The relative personal
measurement of the observers at either end, both in their observa-
tions for time, and also in receiving and transmitting signals,
is eliminated by changing ends and repeating the operations.
If this is impracticable, the personal equations should be deter-
mined and applied to the results. Chronometers keeping solar
time at one end of the wire, and sidereal time at the other end,
materially increase the accuracy with which signals can be
exchanged, for the same reason that comparisons between sidereal
clocks at an observatory are made through the medium of a
solar clock. Time bearings are means of the extant to be
readily obtained, and within such small limits of error, by skilled
observers, that in hydrographic surveys it is usually employed;
but if transit instruments are available, and sufficient time
may be devoted to erecting them properly, the value of the
work is greatly enhanced in high latitudes.

True bearings are obtained on shore by observing with theo-
dolite the horizontal angle between the object selected as the
zero and the sun, taking the latter in each quadrant
as defined by the cross-wires of the telescope. The
altitudes may be read on the vertical arc of the theo-
dolite; except in high latitude, where the observer with
sextant and artificial horizon are necessary, unless the
precise errors of the chronometers are known, when the time
may be obtained by carrying a pocket chronometer to the station.
The sun should be near the prime vertical and at a low altitude;
the theodolite must be very carefully levelled, especially in
the position with the telescope pointing towards the sun. To elimi-
nate instrumental errors the observations should be repeated with
the vernier set at intervals equidistant along the arc, and a.m. and
p.m. observations should be taken at about equal altitudes.

An observation is obtained by measuring with a sextant
the angle between the sun and some distant well-defined object
making an angle of from 100° to 120° and observing the altitude
of the sun at the same time, together with that of the terrestrial
object. The sun's altitude should be low to get the best results,
and both limbs should be observed. The sun's true bearing
is calculated from its altitude, the latitude, and its declination;
the horizontal angle is applied to obtain the true bearing of the
zero. On shore the theodolite gives the horizontal angle direct,
but with sextant observations it must be deduced from the
angular distance and the elevation.

(London, 1898); Shortland, Nautical Surveying (London, 1890).

"SURVILLE, CLOTILDE DE," the supposed author of the
Poesies de Clotilde. The generally accepted legend gave
the following account of her. Marguerite Eléonore Clotilde de
Vallon Chalis, dame de Surville, was born in the early years
of the 15th century at Vallon. In 1421 she married Bérenger
de Surville, who was killed at the siege of Orleans in 1428. Her
husband's absence at the war inspired her heroic verses and his
death her elegiac poems. The last of her poems is a chant royal
addressed to Charles VIII.

In 1503 Charles Vanderbourg published as the Poesies de
Clotilde some forty poems dealing with love and war. The
history given in the introduction of the discovery of the manu-
script was evidently a fable, and the poems were set down by
most authorities as forgeries, especially as they contained many
anachronisms and were written in accordance with modern laws
of prosody. The manuscript had been in the possession of
Jean François Marie, marquis de Surville, an émigré who returned
to France in 1795 to raise an insurrection in Provence, and had
paid the penalty with his life. In 1863 Antoine Macé made
further inquiries on the subject, and discovered letters from
Vanderbourg to Surville's widow. This correspondence makes it
clear that Vanderbourg was innocent of forgery and believed that
the poems were of 15th-century date, and that the anachronisms
of matter and form were due to retouching by Surville. But the
researches of M. Macé interested local antiquarians, and
documentary evidence was produced that the wife of Bérenger
de Surville was Marguerite Chalis, not Clotilde, and that the
marriage dated only from 1428. Moreover Bérenger's
white death at the siege of Orleans was one of the leading motives
of the book, lived for twenty years after that date. Friends
of M. de Surville also disclosed the fact that the marquis had
contributed archaic poetry to a Lausanne journal.

SUS, a province of southern Morocco, once an independent
kingdom, and still too unruly to be opened to Europeans, who
have nevertheless for centuries past made efforts to secure a
foothold. Its principal towns are Taradant, Iihig (the old
capital), and Glimin on the Wad Nun. Taradant, the present
capital, flourished in the 12th century on account of the neigh-
bouring copper-mines. Saltpetre is now the only important
product. Forts might be opened at Agadir Ighir (once occupied
by the Portuguese for thirty years as Santa Cruz), Massa, Ifni,
Arkob and Assaka at the mouth of the Wad Nun. As a fortified
district, all kinds of natural riches are attributed to Sus, but
it may be assumed that they are exaggerated. Europeans land
at their peril, since the coast is by imperial order closed to trade,
and custom-house being provided. Most of the business of Sus
is carried on at great fairs lasting eight or fifteen days, during
which time all roads of approach are guaranteed safe by the
tribesmen that trade may be uninterrupted. Caravans from
Sus laden with copper-ware, olive oil, butter, saffron, wax, skins,
dates, dried roses, &c., are sent to Marrakesh, four days' journey
from Taradant. Susa are well known in the north of Morocco
as able tradersmen and clever metal workers. They live frugally,
and are only prodigal in powder and human life. Their language
is almost exclusively Shihah, a dialect of Berber. (K.A.M. *)

SUSA (Biblical, Shashan), the capital of Susiana or Elam
and from the time of Darius I. the chief residence of the Achem-
ianen kings. It had been the centre of the old monarchy of
Elam and had undergone many vicissitudes before it fell into
the hands of the Persians (see ELAM). The site, fixed by the
explorations of W. K. Loftus, lies in the plain, but within sight
of the mountains, between the courses of the Kerka (Chosaepes)
and the Dizful, on the banks of the Tigris. The
Shaur, a small tributary of the Dizful, washes the eastern base
of the mounds of Shush, and seems to be the representative of
the ancient Ulai or Eulaeus. Thus the whole district was fruit-
ful and well watered; the surrounding rivers with their canals
gave protection and a waterway to the Persian Gulf; while
the position of the town between the Semitic and Iranian lands
of the empire was convenient for administrative purposes. Susa
therefore became a vast and populous capital; Greek
writers assign to it a circuit of 15 or 20 m.

The remains include four mounds, of which one is the site of
the citadel called Memnon by the Greeks, while another
(the Apadana to the east of it) represents the palace of Darius I.
and Artaxerxes II. Mmnon. This latter has been excavated by
M. Dieulafoy and the enamelled bricks with which its walls
were adorned are now in the Louvre. South of these two mounds
is the site of the royal Elamite city. The fourth mound, covering
the remains of the poorer houses, is on the right bank of the river
between the Shaur and the Kerka. J. de Morgan's excava-
tions (since 1897) have been principally in the citadel mound,
which measures roughly 1500 ft. by 825 ft. and is 125 ft. high.
The two lowest strata belong to the old town, and the first
is on the Dizful, on the banks of the river, with yellow bricks decora-
ted with geometrical patterns and animal or vegetable figures
in black and brown-red. Some of it is similar to the prehistoric

XXVI. 6
pottery of Egypt. The pottery of the second neolithic stratum is much inferior. Above these strata come the remains of Elamite and early Babylonian civilization with inscribed objects, the oldest of which exhibit the pictorial characters out of which the cuneiform were evolved. Under the foundations of the temple of In-Susinak (in the north-west part of the mound) a vast quantity of bronze objects has been discovered, for the most part earlier than the 10th century B.C. Among the monuments brought to light in other parts of the mound are the obelisk of Manisuta (see BABYLONIA), the stela of Naram-Sin and the code of Hammurabi, along with a great number of historically valuable boundary stones. The objects which have yielded, besides Persian remains, Greek pottery and inscriptions of the 4th century B.C., numerous coins of the Kammaskires dynasty and other kings of Elymais in the Seleucid era, and Parthian and Sassanian relics. In the Sassanian period the city was razed in consequence of a revolt, but rebuilt by Sapor (Shapur) II.; the walls were again destroyed at the time of the Mahomedan conquest, but the site, which is now deserted, was a seat of sugar manufacture in the middle ages.

SUSA (fr. Souse), a city of Tunisia, on the Gulf of Hammatem, in 35° 49' N., 10° 30' E., 36 m. by rail. E. by N. of Kairawan, of which it is the port, and 93 m. S. by E. by rail of Tunis. Susa, which occupies part of the site of the ancient Hadrumetum, is built on the site of a hill sloping seawards, and is surrounded by a crenellated wall, strengthened by towers. Recesses in the inner side of the wall are used as shops and warehouses. The kasbah, or citadel, built on the highest point within the town, was thoroughly restored by the French after their occupation of the country in 1881, and serves as military headquarters for the district, the camp for the troops being outside the walls west of the citadel. The native town has been little changed since the French occupation, but north of the port a European quarter has been created, and here are public buildings such as law courts, a museum and a town-hall. The museum contains many archaeological treasures, notable mosaics and sculptures. The most interesting buildings in the old town are the Kasser-Ribat and the Kaswati-el-Kubbah. The Kasser-Ribat is a square fortress with a high tower and seven bastions. Its date is uncertain, but is not later than the 9th century. The Kaswati-el-Kubbah (Café of the Dome) is a curious house, square at the base, then cylindrical, and surmounted by a fluted dome. It was probably a church during the Byzantine period. Another domed building, now used as oil-mills, dates from Roman and Byzantine times. In the Bab-el-Gharbi (West Gate) a Roman sarcophagus of marble has been built into the wall, and serves as a drinking fountain. The grand mosque is in the north-east part of the town. The ancient harbours are silted up, but vestiges of the Roman breakwaters may be seen. The modern port, completed in 1901, enables steamers drawing 21 ft. to lie at the quays. Exports are chiefly phosphates and other minerals, olive oil, esparto and cereals; imports: cotton goods, building material, &c. The population, less than 10,000 at the time of the French occupation, had increased in 1907 to over 25,000, of whom 1500 were French and 4000 other Europeans, chiefly Italians and Maltese.

Susa, the Arab town which succeeded Hadrumetum (q.v.), was fortified by Aghlabite rulers of Kairawan in the 9th century A.D. It shared the general fortunes of Tunisia and became a noted haunt of pirates, who RAIDed the coast of Italy. In 1537 it was unsuccessfully besieged by the marquis of Terra Nova, in the service of Charles V., but in 1539 was captured for the emperor by Andrea Doria. As soon as the imperial forces were withdrawn it became again the seat of Turkish piracy. The town was attacked by the French and the Knights of St John in 1779, and by the Venetians in 1764. It remained, however, in the possession of the bey of Tunis.

Some 35 m. due south of Susa, and half way on the road to Sfax is El Jem, the site of the city of Thysdrus. Of the ancient city there are scarcely any remains save the amphitheatre—a magnificent ruin which still resembles the theater of Dionysus. The site of the ancient theater is marked by a rock-cut amphitheatre, three open arcades crowned by a fourth storey with windows. The first and second arcades are Corinthian; the middle one Composite. Each of these galleries has sixty-four columns and supports arches. Constantly used as a fortress since the Arab invasion, the amphitheatre suffered much, and in 1697 the bey of Tunis made a great breach in its western end to prevent it being again used for this purpose. The building is now in ruins, but the standing solitary in a desolate district—is grandly impressive. Its major axis is 488 ft., its minor axis 406 ft. (The figures of the Colosseum are 615 and 510 respectively.)

SUSA (anc. Segusio, q.v.), a city and episcopal see of Piedmont, Italy, in the province of Turin, from which it is 33 m. W. by rail. Pop. (1901), 3607 (town); 5023 (commune). It is situated on the Dora Riparia, a tributary of the Po, 1625 ft. above sea-level, and is protected from the northern winds by the Rocciamelone. Among the most important buildings of Susa is the first palace or convent of the Cistercian order, which was founded in 1070 by Oldericus Manfredi II. and the countess Berta, and in 1772 raised to be the cathedral. It has a fine brick campanile and brick decoration, and contains a bronze triptych of 1358 in niello, with the Virgin and Child. In the Valle di Susa, about 14 m. east of it, towards Turin, near S. Ambrogio di Torino, is the monastery of S. Michele with a Romanesque church, situated on a rocky mountain (968-1002).

After the time of Charlemagne a marquisate of Susa was established; and the town became in the 11th century the capital of Adefalda, countess of Savoy, who was mistress of the whole province of Piedmont. On his retreat from Legnano in 1176 Barbarossa set fire to Susa; but the town became more than ever important when Emmanuel Philibert fortified it at great expense in the 16th century. It was, however, dismantled by Napoleon I. in 1796.

SUSARION, Greek comic poet, a native of Tripodiscus in Megaris. About 350 B.C. he transplanted the Megarian comedy (if the rude extempore jests and buffoonery deserve the name) into the Attic dème of Icaria, the cradle also of Greek tragedy and the oldest seat of the worship of Dianysus. According to the Parian Chronicle, there seems to have been a competition on this occasion, in which the prize was a basket of figs and an amphora of wine. Susarian's improvements in his native farces did not include a separate actor or a regular plot, but probably consisted in substituting metrical compositions for the old extempore effusions of the chorus. These were intended for recitation, and not committed to writing. But such performances did not suit the taste of the Athenians, and nothing more is heard of them until eighty years after the time of Susarion. U. von. Wilamowitz-Moellendorf (in Hermes, ix.) considers the so-called Megarian comedy to have been an invention of the Athenians themselves, intended as a satire on Megarian coarseness and vulgarity. The lines attributed to Susarion (in Meineke, Poetarum comicorum graecorum fragmenta) are probably not genuine.

SUSO [SEUSE], HEINRICH (1300-1366), German mystic, was born of good family at Überlingen on Lake Constance on the 21st of March, in all probability in the year 1300; he assumed the name of his mother, his father being a Herr von Berg. He was educated for the Church, first at Constance, then at Cologne, where he came under the influence of the greatest of the German Augustinian mystics, Master Eck. He subsequently entered a monastery in Constance, where he submitted himself to the severest trials of asceticism. In 1335 he wandered through Swabia as a preacher, and won all hearts by his gentle, persuasive eloquence; the effusive lyricism of his language made him an especial favourite among the nuns. About 1348 he seems to have settled in Ulm, where he died on the 25th of January 1366. Suso's first work, Das Büchlein der Wahrheit, was written in Cologne about 1329; setting out from Eckart's doctrines, he presents the mystical faith from its speculative or theoretical side; whereas
in *Das Büchlein der einew Weisheit*, written some years later in Constance, he discusses the practical aspects of mysticism. The latter work, which Suso also translated into Latin under the title of *Horologium sapientiae*, has been called the finest fruit of German mysticism. Suso is the poet of the early mystic movement, "the Minnesinger of Gottessinner." But his faith is purely medieval in tone, inspired by the romanticism of the age of chivalry; the individualism, the philosophic insight and the anti-Catholic tendencies which made the mystic movement in its later manifestations so important a forerunner of the Reformation are absent.

Suso's works were collected as early as 1482 and again in 1512; recent editions: Heinrich Suso's *Leben und Schriften*, ed. by M. Dippel (1854); Suso, *Deutsche Schriften*, F. H. S. Denike (1878-1880, not completed), and Deutsche Schriften, by K. Bihlmeyer (2 vols., 1907). See also W. Preger, *Die Briefe Heinrich Susos* (1867); W. Preger, *Geschichte der deutschen Mystik* (1882), vol. ii.; J. Jäger, *Heinrich Suso aus Schwaben* (1894).

**SUSPENsURA,** the architectural term given by Vitruvius (v. 10) to the hollow space under the floor of a Roman bath, in which the smoke from the furnace passed to the vertical flues in the wall (see HYPOCAUST).

**SUSSEX, EARLS OF.** The early history of the earldom of Sussex, a title that has been borne at different periods by several English families, is involved in some obscurity, owing to the fact that under the Norman kings the titles of earls were often indifferently derived from a county, from its chief town, or from the earl's principal residence, although the distinctive mark of an earldom is the right of war. In 1086, by the charter of H. de Redon, the pleas of a county (see EARL). Thus in the 12th century the same person is sometimes found described as earl of Sussex, sometimes as earl of Chichester, and sometimes as earl of Arundel, while the inclusion of the counties of Sussex and Surrey under the jurisdiction of a single sheriff led at one time, as will be seen, to a further confusion between the earldoms of those counties. The difficulty is, again, increased by the Crown's admission in 1433 that the possession of the castle of Arundel carried with it the right to the title of earl of Arundel, though later investigations have shown that in 1563 this claim was proved the invalidity of the claim, and Mr J. H. Round and other modern authorities maintain that inasmuch as Norman earls were earls of counties, the earldom of Arundel was strictly that of Sussex.

On the other hand G. E. Cockayne (Complete Peerage, i. 138, 139) holds that Roger de Montgomery, who received grants from William the Conqueror of a large part of the county of Sussex, including the city of Chichester and the castle and honour of Arundel, besides lands in Shropshire with the castles of Shrewsbury and Montgomery, but who does not appear to have held "the third penny" of any county, carried the title of earl of Montgomery. This Roger de Montgomery was considered by Dugdale, a 17th-century authority, to have been earl of Sussex.

However Roger's titles may have been, they were forfeited to the Crown when his son Robert was attainted in 1302, and the forfeited estates were conferred by Henry L. on his second wife Adelicia, who after Henry's death married William de Albinia, or d'Aubigny. This Roger was created earl of Sussex by King Stephen, and the "third penny" of that county was confirmed to him by an instrument of the reign of Henry II., in which however, he is styled earl of Arundel, a designation by which he was more generally known. His grandson William, 3rd earl of Sussex, was one of King John's sureties for the observance of Magna Carta; and the earldom remained in his family till 1243, when it reverted to the Crown on the death of Hugh de Albinia, 6th earl of the line (see ARUNDEL, EARLS OF). This Hugh married Isabel, daughter of William de Warenne, earl of Surrey, who was killed by him nearly forty years, during which time she held the estates of the earldom of Surrey in dower; after her death in 1282 her brother John de Warenne, earl of Surrey, was in various writs described as "earl of Surrey and Sussex," the same style being also used by his grandson and successor, another John de Warenne (1286-1347), though it is not clear that either of these Warennes had any right to the Sussex title, the confusion having perhaps arisen through both counties being under the jurisdiction of one sheriff. In any case the earldom of Sussex, if vested in the younger Warenne, reverted to the Crown on his death without legitimate issue in 1347, when his estates devolved on his nephew Richard Fitzalan, earl of Arundel. Since the death of the last earl of the de Albini line in 1343 the earldoms of Arundel and Sussex had been separate.

For nearly two hundred years, from 1347 to 1529, the title of earl of Sussex did not exist in the English peerage. In 1529, however, it was conferred on Robert Radcliffe, Radclyffe or Ratcliffe (c. 1483-1542), who had been made Viscount Fitzwalter in 1525. Radcliffe was a son of John Radcliffe, Baron Fitzwalter (c. 1492-1545), and a grandson of Sir John Radcliffe of Attleborough in Norfolk, who became Baron Fitzwalter by right of his wife Elizabeth. The younger John Radcliffe shared in the conspiracy of Perkin Warbeck and was beheaded for high treason in 1496. The attainer being reversed in 1506, his son Robert became Baron Fitzwalter in 1506 and was soon a prominent person at the court of Henry VIII. In 1529 he was created earl of Sussex and in 1540 he was appointed great chamberlain of England. He died on the 26th of November 1542, when his son Henry (c. 1506-1557) became the 2nd earl. Henry's son, Thomas Radcliffe (see below), became the 3rd earl. Thomas was created Baron Radcliffe in 1583 by his uncle, John Radcliffe, the 5th earl of Sussex, by whom he succeeded, and was assassinated in the murder of his sister-in-law Elizabeth in Ireland. His son Robert (c. 1569-1629), the 5th earl, was a soldier and a patron of men of letters. When Robert's son, Edward, the 6th earl (c. 1592-1641), died, the title became extinct, but the barony of Fitzwalter passed to the family of Mildmay, which held it until 1756, when it fell into abeyance.

In 1644 Thomas Savile (c. 1590-1659), son of John Savile, 1st Baron Savile of Pontefract (1506-1630), was created earl of Sussex. Having been elected to the House of Commons as member for Yorkshire in 1624, Savile became an opponent of King Charles I. In 1634, after the execution of Charles I., the Saviles and the Wentworths having long being a feature of the history of Yorkshire, and attaching himself to the Duke of Buckingham, he was created Viscount Castlebar in the peerage of Ireland in 1628, and two years later succeeded to his father's English peerage. His growing enmity to Strafford led him into violent opposition to the government as the earl's power increased, and in 1640 he entered into correspondence with the Scots, to whom he sent a promise of support to which he forged the signatures of six peers. He was appointed lord president of the council of the north in succession to Strafford in 1642, but in May 1643 he was captured by Lord Byron, and, later, was retained in the Tower, in whose interest he exerted his influence in Yorkshire in a manner that brought upon him the displeasure of the parliament in 1642. His efforts to exonerate himself led to his being suspected by the Royalists, and to his arrest, while his residence, Howley Hall, was sacked by Newcastle, the Royalist general. Having been pardoned by Charles, whom Savile attended at Oxford, he was created earl of Sussex in 1644; but his efforts to promote peace on terms distasteful to the king brought him again into disfavour, and in 1645 he was imprisoned and accused of high treason. Escaping from this charge on the ground of his privilege as a peer, he went to London and again ingratiated himself with the popular party. Intriguing simultaneously with both parties, he continued to play a double game with considerable skill, although he suffered imprisonment in 1645 for accusing Holles and Whitelocke of treachery in negotiations with the king, and was heavily fined. After this he retired into private life at Howley Hall, where he died about 1659.

He was succeeded in the earldom of Sussex by his son James, on whose death without issue in 1671 the title became extinct. It was revived in 1684 in favour of Thomas Lennard, 13th Baron Dacre, whose wife Ann (d. 1722) was a daughter of the famous duchess of Cleveland by King Charles II., and again became extinct at this nobleman's death in 1715.
was next conferred in 1717 on Talbot Vevloton, 2nd Viscount de Longueville and 16th Baron Grey de Ruthyn (c. 1602–1731), from whom it descended to his sons successively, becoming once more extinct on the death of the younger of these, Henry, 3rd earl of Sussex of this creation, in 1799.

In 1801 Prince Augustus Frederick (1773–1843) the sixth son of George III., was created duke of Sussex. Spending his early years abroad, the prince was married in Rome in 1793 to Lady Augusta (d. 1830) daughter of John Murray, 4th earl of Dunmore. The ceremony was repeated in London and two children were born, but under the Royal Marriages Act of 1772 the Court of Arches could not declare them illegitimate. The children took the name of d’Este. The son, Sir Augustus Frederick d’Este (1794–1848), became a colonel in the British army. In 1843 he claimed his father’s honours, but the House of Lords decided against him. He died unmarried. The daughter, Augusta Emma (1801–1866) married Sir Thomas Wilde, afterwards Lord Truro.

Unlike his brothers the duke of Sussex was a man of liberal ideas; he favoured the abolition of the slave trade, the repeal of the corn laws, and the removal of the civil disabilities of Roman Catholics, Dissenters, and Jews. His second wife, Countess of Oxford, his second wife, Sir George Buggin, was created duchess of Inverness in 1840. He died at Kensington Palace on the 21st of April 1843.

The old title of earl of Sussex was revived in 1874 when it was conferred upon Prince Albert, the third son of Queen Victoria, who at the same time was created duke of Connaught and Strathearn.

Sussex, Thomas Radclyffe [or Ratcliffe], 3rd Earl of (c. 1525–1583), lord-tenant of Ireland, eldest son of Henry, 2nd earl of Sussex (see Sussex, Earls of), by his first wife, Elizabeth, daughter of Thomas Howard, 2nd duke of Norfolk, was born at London and afterwards in 1542 was styled Viscount Fitzwalter. After serving in the army abroad, he was employed in 1553 in negotiating a marriage between Edward VI. and a daughter of Henry II., king of France. His prominence in the kingdom was shown by his inclusion among the signatories to the letters patent of the 16th of June 1553 setting the crown on Lady Jane Grey; but he nevertheless won favour with Queen Mary, who employed him in arranging her marriage with Philip of Spain, and who raised him to the peerage as Baron Fitzwalter in August 1555.

Returning to England from a mission to the emperor Charles V. in April 1556, Fitzwalter was appointed lord deputy of Ireland. The prevailing anarchy in Ireland, a country which, nominally subject to the English Crown, was torn by feuds among its practically independent native chieftains, rendered the task of the lord deputy one of no ordinary difficulty; a difficulty that was increased by the ignorance of English statesmen concerning Ireland and Irish conditions, and by their incapacity to devise or to carry into execution any consistent and thoroughgoing policy for bringing the half-conquered island under an orderly system of administration. The measures enjoined upon him by the crown and government, the entire reversal of the partial attempts that had been made during the short reign of Edward VI. to promote Protestantism in Ireland, and the "plantation" by English settlers of that part of the country then known as Offaly and Leix. But before Fitzwalter could give his attention to such matters he found it necessary to make an expedition into Ulster, which was being kept in a constant state of disturbance by the Highland Scots from Kintyre and the Islands who were making settlements along the Antrim coast in the district known as the Gylness (glen), and by the efforts of Shane O'Neill to convert into effective sovereignty the chiefship of his clan which he had recently wrested from his father, Conn, 1st earl of Tyrone. Having defeated O'Neill and his allies the MacDonnells, the lord deputy, who by the death of his father in February 1557 became earl of Sussex, returned to Dublin, where he summoned a parliament in June of that year. Statutes were passed declaring the legitimacy of Queen Mary, reviving the laws for the suppression of heresy, forbidding the immigration of Scots, and vesting in the earl of Sussex all the properties which were now the King's County and Queen's County, which were then so named after Philip and Mary respectively. Having carried this legislation, Sussex endeavoured to give forcible effect to it, first by taking the field against Donough O'Connor, whom he failed to capture, and afterwards against Shane O'Neill, whose lands in Tyrone he ravaged, restoring to their nominal rights the earl of Tyrone and his reputed son Matthew O'Neill, baron of Dunganon (see O'Neill). In June of the following year Sussex turned his attention to the west, where the head of the O'Briens had ousted his nephew Conor O'Brien, earl of Thomond, from his possessions, and was about to pay allegiance to the Crown of Rome in order to open its gates to him, restored Thomond, and proclaimed The O'Brien a traitor. In the autumn of 1558 the continued inroads of the Scottish islanders in the Antrim glens called for drastic treatment by the lord deputy. Sussex laid waste Kintyre and some of the southern Hebridean isles, and landing at Carrickfergus he fired and plundered the settlements of the Scots on the Antrim coast before returning to Dublin for Christmas.

In the metropolis the news reached him of the queen's death. Crossing to England, he took part in the coronation of Queen Elizabeth's coronation in January 1559; and in the following July he returned to Ireland with a fresh commission, now as lord lieutenant, from the new queen, whose policy required him to come to terms if possible with the troublesome leaders of the O'Neills and the MacDonnells. Shane O'Neill refused to meet Sussex without security for his safety, and having established his power in Ulster he demanded terms of peace which Elizabeth was unwilling to grant. Sussex failed in his efforts to bring Shane to submission, either by open warfare or by a shameful attempt to procure the Irish chieftain's assassination. He was preparing for a fresh invasion at the request of the earl of Kildare, who was commissioned by Elizabeth to open negotiations with O'Neill, the result of which was that the latter repaired to London and made formal submission to the queen. Shane's conduct on his return to Ireland was no less rebellious than before, and energetic measures against him became more imperative than ever. Having obtained Elizabeth's sanction, Sussex conducted a campaign in the summer of 1563 with Armagh as his temporary headquarters; but except for some indecise skirmishing and the seizure of many of O'Neill's cattle, the operations led to no result and left Shane O'Neill with his power little diminished. His continued failure to effect a purpose for the accomplishment of which he possessed inadequate resources led Sussex to pray for his recall from Ireland; and his wish was granted in May 1564. His government of Ireland had not, however, been wholly without fruit. Sussex was the first representative of the English Crown who enforced authority to any considerable extent beyond the limits of the Pale; the policy of planting English settlers in Offaly and Leix was carried out by him in 1562 with a certain measure of success; and although he fell far short of establishing an English garrison in Ulster, the expedition of 1566 made its influence felt in remote parts of the island, such as Thomond and the Glynnes of Antrim, where the independence of the native septs had hitherto been subjected not even to nominal interference. His letters from Ireland display a just conception of the problems with which he was confronted, and of the methods by which their solution should be undertaken; and his failure was due, not to lack of statesmanship or of executive capacity on his own part, but to the insufficiency
of the resources placed at his command and want of insight and persistence on the part of Elizabeth and her ministers.

On his return to England, Sussex, who before leaving Ireland had to endure the indignity of an inquiry into his administration instigated by his enemies, threw himself into opposition to the earl of Leicester, especially in regard to the suggested marriage between that nobleman and the queen. He does not appear to have on that account incurred Elizabeth's displeasure, for in 1566 and the following year she employed him in negotiations for bringing about a matrimonial alliance which he warmly supported, namely, the proposal that she should bestow her hand on the archduke Charles. When this project fell to the ground Sussex returned from Vienna to London in March 1568, and in July he was appointed lord president of the north, a position which threw on him the responsibility of dealing with the rebellion of the earls of Northumberland and Westmorland in the following year. The weakness of the force at his disposal rendered necessary at the outset a caution which engendered some suspicion of his loyalty; and this suspicion was increased by the counsel of moderation which he urged upon the queen; but in 1570 he laid waste the border, invaded Scotland, and raided the country round Dumfries, reducing the rebel leaders to complete submission. In July 1572 Sussex became lord chamberlain, and he was henceforth in frequent attendance on Queen Elizabeth, both in her progress through the country and at court, until his death on the 9th of June 1583.

The earl of Sussex was one of the great nobles of the Elizabethan period. Though his loyalty was questioned by his enemies, it was as unwavering as his patriotism. He was a courtier; he excelled in diplomacy; he was a man of cultivation and even of scholarship, a patron of literature and of the drama on the eve of its blossoming into the glory it became soon after his death. He was twice married: first to Elizabeth, daughter of Thomas Wriothesley, earl of Southampton; and secondly to Frances, daughter of Sir William Sidney. His second wife was the foundress of Sidley Sussex College at Cambridge, which she endowed by her will, and whose name commemorates the father and the husband of the countess. The earl left no children, and at his death his titles passed to his brother Henry (see Sussex, Eares, 09).

SUSSEX, a southern county of England, bounded N. by Surrey, N.E. by Kent, S. by the English Channel, and W. by Hampshire. The area is 1,459-2 sq. m. The extreme length from E. to W. is 78 m., while the breadth never exceeds 28 m., but the county is not wholly on the southward slope, for in the middle northern district it contributes a small drainage area to the Thames basin, and the river Medway rises in it. A line of hills known as the Forest Ridges forms the watershed. Its direction is E.S.E. from the northern part of the county to the coast at Fairlight Down east of Hastings, and it reaches a height of about 800 ft. in the neighbourhood of Crowborough. The salient physical feature of the country, however, is the hill range called the Downs (see Downs). Entering in the west, where its summit is about 80 m. from the sea, and extending for some 50 m., gradually approaching the coast, and terminating in the bold promontory of Beachy Head near Eastbourne. The average height is about 500 ft., though some summits exceed 700, and Ditchling Beacon is over 800. The portion of the county north of the South Downs is called the Weald (q.v.). It was formerly covered with forest, and this part of the county is still well wooded. About 1660 the total area under forest was estimated to exceed 200,000 acres, but much wood was cut to supply the furnaces of the ironworks which formed an important industry in the county down to the 17th century, and survived even until the early years of the 19th.

The rivers wholly within the county are small. All rise in the Forest Ridges, and all, except the Rother, which forms part of the boundary with Kent, and falls into the sea below Rye, breach the South Downs. From east to west they are the Cuckmere, rising near Heathfield; the Ouse, Adur and Arun, all rising in the district of St. Leonard's Forest; and having at their mouths the ports of Newhaven, Shoreham and Littlehampton respectively. The natural trench known as the Devil's Dike is a point greatly favoured by visitors from Brighton. The coast-line is practically coextensive with the extreme breadth of the county, and its character greatly varies. The sea has done great damage by incursion at some points, and has receded in others, within historic times. Thus what is now marshland or "Levels" round Pevensey was formerly an island-studded bay. In the east Winchelsea and Rye, members of the Cinque Ports, and great medieval towns, are deprived of their standing, the one wholly and the other in part, since a low flat tract interposes between their elevated sites where formerly was a navigable inlet. Yet the total submergence of the site of Old Winchelsea was effected in the 13th century. The site of the ancient cathedral of Selsey is a mile out at sea. Between 1292 and 1340 upwards of 5500 acres were submerged. In the early part of the 14th century Pagham Harbour was formed by a sudden irruption of the sea, devastating 2700 acres, since reclaimed. There is reason to believe that the whole coast-line has subsequently been slightly raised. These changes are reflected in the numerous alterations recorded in the course of time in the rivers passing through the county. Thus the Adur was diverted by a great storm on the 12th of October 1250, before which date it entered the sea 12 m. to the east. The outlet of the Ouse was at Seaford until 1570, and that of the Adur formerly shifted from year to year, ranging east and west over a distance of 2 m. Submerged forests are found off the shore and eastward points. Long stretches of firm sand, and the mild climate of the coast, sheltered by the hills from north and east winds, have resulted in the growth of numerous watering-places, of which the most popular are Brighton, Hastings, Eastbourne, Bexhill, Seaford, Shoreham, Worthing, Littlehampton, Saltdean and Bognor.

Geology.—The disposition of the rock formations of Sussex is simple. The South Downs consist of chalk, which extends from Beachy Head by Seaford, Brighton, Lewes, Steyning and Goodwood to the western border. The dip of the chalk is southerly, while a more or less escarpment faces the north. From the summit of the elevated area to the northern limit of the district the chalk is low; and here it is occupied mainly by the Wealden Beds and the Weald Clay; at the foot of the escarpment it constitutes the Gault and Upper Greensand, while between these formations and the more elevated area to the south, the Chalk is usually represented by the Greensand. The southern and eastern portion of this latter district is particularly remarkable; for at one time there is no doubt that the Chalk, Greensand and Gault covered the entire area in the form of an uplifted dome, but denudation has removed the Chalk and most of the other formations as far as the North Downs; exposing the under strata of the Old Red Sandstone, and the Wealden Beds, which are of very different character. The oldest rocks thus brought to light along the crest of the anticline are the Purbeck Beds, small patches of shale and limestone, with flints, which are partly covered by the Wealden Beds. A deep boring (909 ft.) at Netherfield, passed through Portlandian Beds and Kimmeridge Clay into Oxford Clay, but these do not appear anywhere at the surface. Above the Purbeck Beds, and covering all the modern portion of the county from the coast at Bexhill and Rye to Horsham, are sands and clays of the Lower Wealden or Hastings Beds. This includes the following local subdivisions, in ascending order; the Fairlight Clay, Ashdown Sand, Wadhurst Clay, Tunbridge Wells Sand, Greensand Clay and Upper Tunbridge Wells Sand (with Tilgate stone at the top and Cuckfield Clay at the base). The Weald Clay occupies a belt of lower ground
on the south and west of the Hastings Sands, it consists of blue and mottled clays with thin sand layers and beds of hard limestone, the "Sussex marble" with the shells of Paludina. The Horsham Stone is another local hard bed. Near Tilgate the remains of Ignavodon have been found. The oldest formation. Bordering the outcrop of the Weald Clay is the Lower Greensand; it appears a little north of Eastbourne and passes thence through Ringmer, Storrington, Pulborough, Petworth, Midhurst and Lindrum. It contains the following well-marked divisions: Upper Weald Beds (sandstone, sandstone and chert), Sandgate Beds and Folkestone Beds. The Eocene strata slanting south of the Downs and west of Brighton—with the exception of some outliers of Reading Beds, known as the Chalk—extend the Weald Clay as far west as the Hampshire border. London Clay (with hard "Boghor Rock"), the Bagshot and Bracklesham Beds; the last-named formation is very fossiliferous in the bay of Wadhurst. The Serpentinite on the Weald is quite distinct from the much of the low ground west of Brighton; these include glacial deposits with large boulders, raised beaches, brick earth and gravels, marine and estuarine, and the interesting Coombe rock or Brighton Elephant Bed, a coarse rubble of chalk waste formed late in the Glacial period, well exposed in the cliff at Black Rock east of Brighton, where it rests on a raised beach. The natural gas of Heathfield comes from the Lower Wealden and Purbeck Beds. The Weald Clay was formerly iron ore.

Climate and Agriculture.—The climate of the coast district is mild, equable and dry, while that of the Wealden shows greater extremes of temperature, and is rather wetter. The mean daily range at Heathfield in the Weald is 18°F. in summer and 2°F. on the coast. The influence of the sea in modifying the temperature of the coast district is specially noticeable in the autumn months, when the temperature is higher than in the Weald and other parts of the county. The districts are not very suitable for market gardens and for growing fruit trees. The fig gardens of West Tarring are celebrated. About seven-tenths of the total area is arable and pasture. The rest is woods and heaths in the north of Sussex. Sussex is still one of the best-wooded counties in England. The acreage under grain crops shows a large decrease; nearly the whole of it is occupied by oats and wheat. The acreage under green crops is mainly devoted to turnips and other food for cattle, and to the supply of vegetables for the London market. The growing of hops has not kept pace with that in the neighbouring county of Kent. Cattle are kept in increasing numbers both for breeding and for dairy purposes. South Downs White is the best milk breed, and Sussex and Hampshire Black are the best dairy breeds. The county is famed for black-faced sheep and Sussex is famed for a special breed of black-faced sheep. The numbers, however, show a steady decrease. Poultry farming is largely carried on in some parts of the county. The cultivation of hops, by which land descends to the youngest son, prevailed to an extraordinary degree in Sussex, and no fewer than 140 manors have been catalogued in which it was found. Gavelkind tenure existed in Rye, in the large manor of Brede, and in Courntard manor (in Brede parish).

Other Industries.—The manufacturing industries are meagre. The London, Brighton & South Coast Railway Company has large works at Brighton. At Heathfield in 1901 the development of the field directory is a further indication of the growth of the company, which is still at its highest point. There are a number of important, including cord, herrings, mackerel, sprats, plaice, soles, turbot, shrimps, crabs, lobsters, oysters, mussels, oysters and cuttlefish. There are thousands of acres of salt marshes. When he visited the county in 681, taught the people the art of net-fishing. At the time of the Domesday survey the fisheries were extensive, and no fewer than 285 salines (saltworks) existed. The customs of the Rye district were preserved to 1576, in 563.202. The earliest statement as to the population is made by Bode, who describes the county as containing in the year 681 land of 7000 families; allowing ten to a family (not an unreasonable estimate), the whole population would be 70,000. In 1593 the county is stated to have contained 21,517 houses. If seven were allowed to a house at that date, the total population would be 150,759. It is curious, therefore, to observe that in 1801 the population was only 85,114, and in 1901 it stood at 695,202. The reasons for this decrease have been stated, but the work of the census probably accounts for the small increase of population during several centuries, although after the massacre of St Bartholomew up to 250,000 people were expelled in 1586, 10 years after the revocation of the Edict of Nantes, many more refugees were added to the county.

An act of Henry VII. (1504) directed that for convenience the county court should be held at Lewes as well as at Chichester, and this apparently gave rise to the division of Sussex into east and west parts, each of which is an administrative county. East Sussex has an area of 628,879 acres, and West Sussex of 603,602 acres. The division includes the county boroughs of Brighton and Hastings. East Sussex contains the municipal boroughs of Bexhill (pop. 12,213), Brighton (123,475), Eastbourne (43,344), Hastings (65,528), Hove (39,110), and Worthing (29,444). The ancient county of this division are Battle (996), Burgess Hill (4888), Cuckfield (1813), East Grinstead (6094), Haywards Heath (3717), Newhaven (8772), Portslade-by-Sea (5417), Seaford (3555) and Uckfield (2895). In West Sussex the municipal boroughs are Arundel (2750), Chichester a city (12,244) and Worthing (20,015). The urban districts are Bognor (6180), Horsham (9446), Littlehampton (7365), Shoreham (3868) and Southwick (3566). The ancient county, which is wholly in the diocese of Chichester, contains 373 ecclesiastical parishes or districts, wholly or in part. The total number of civil parishes is 338. Sussex is divided into the following parliamentary divisions: northern or East Grinstead, eastern or Rye, southern or Eastbourne, mid or Lewes, western or Chichester, north-western or Horsham, each returning one member: and contains the parliamentary boroughs of Brighton, returning two members, and Hastings, returning one.

History.—Apart from conclusions to be drawn from prehistoric remains, the history of Sussex begins in 477, when the Saxons landed in the west of the county under Ella and his three sons, and built up the kingdom of the South Saxons (see Sussex, Kin and Family). They took the Roman city of Regulam, which became Chichester, afterwards westward, into the forest of Andred. The Roman fortress of Anderida, the site of the castle of Pevensey, also fell to the Saxons. Ella became the most influential of the contemporary Saxon chiefs, and was, according to Bede, the first Bretwald. After his time the kingdom of Sussex gradually declined, and fell entirely under the dominion of Wessex in 823. Interesting Saxon remains are found in numerous cemeteries, and scattered burial places along the south slopes of the Downs. The cemetery on High Down hill, where weapons, ornaments and vessels of various kinds were found, and the Chantry hoard of coins, are among the most noticeable relics. A coin of Offa of Mercia, found at Beddingham, recalls the charter of Archbishop Wilfred in 825, in which Offa's connexion with the monastery in that place is recorded. From 895 Sussex suffered from constant raids by the Danes, till the accession of Canute, after which arose the two great forces of the house of Godwine and of the Normans. Godwine was probably a native of Sussex, and by the end of the Conqueror's reign a third part of the county was in the hands of his family. Norman influence increased after 1066, when the Conqueror died, and the barons of Hastings, Rye, Winchelsea, Selsey and Shoreham, who were kept by the Normans so long as the abbey of the Norman abbey of Fécamp, while the Norman chaplain of Edward the Conqueror, Osbern, afterwards bishop of Exeter, held the estate of Bosham.

The county was of great importance to the Normans; Hastings and Pevensey being on the most direct route for Normandy. William was accordingly careful to secure the lines of communication with London by placing the lands in the hands of men bound by close ties to himself, such as his half-brother, the count of Mortain, who held Pevensey, and his son-in-law, William of Warre, who held Winchelsea. The warrens and large tracts of lands held by the Church and the Crown, the five rapanies of Sussex were held by these and three other Norman tenants-in-chief: William de Braose, the count of Eu, and Roger, earl of Montgomery, who held respectively Bramber, Hastings and Arundel. The honour of Battle was afterwards made into a rape by the Conqueror, and provides one of the arguments in favour of the theory of the Norman origin of these divisions of the county. The county was divided into five (afterwards six) strips, running north and south, and having each a town or center of military, commercial and maritime importance. These were the rapes, and each had its sheriff, in addition to the sheriff of the whole county. Whether the origin of the rapes, as districts, is to be found in the Icelandic territorial division hreppr (repeated in the New English Dictionary), or in the Saxo rap, a rope, or is of Norman origin, as lords
SUSSEX

they undoubtedly owed their existence to the Normans. The holdings—which had been scattered under the Saxons, so that one man’s holding might be in more than one rape—were now determined, not by the manors in which they lay, but by the borders of the rape. Another peculiarity of the division of land in Sussex is that, apparently, each hide of land had eight instead of the usual four virgates.

The county’s boundary was long and somewhat indeterminate on the north, the Crown owning dense forest of Andredswald, which was uninhabited till the 11th century. Evidence of this is seen in Domesday Book by the survey of Worth and Lodsworth under Surrey, and also by the fact that as late as 1834 the present parishes of north and south Amersham in Sussex were part of Hampshire. At the time of the Domesday Survey Sussex contained sixty hundreds, which have been little altered since. A few have been split up into two or three, making seventy-three in all; and the names of some have changed, owing probably to the meeting-place of the hundred court having been altered. These courts were in private hands in Sussex; either of the Church, or of great barons and local lords. The county court was held at Lewes and Shoreham until the Great Inquest, when it was moved to Chichester. After several changes the act of 1504 arranged for it to be held alternately at Lewes and Chichester. There was no gaol in the county until 1487; that at Guildford being used in common by Surrey and Sussex, which were under one sheriff until 1597.

Private jurisdictions, both ecclesiastical and lay, played a large part in the county. The chief ecclesiastical franchises were those of the archbishop of Canterbury, of the bishop of Chichester, of the Saxon foundation of Bosham, where Bishop Wilfrid had found the only gleam of Christianity in the county, and of the totive abbey of Battle, founded by the Conqueror. This abbey possessed, besides land in many other counties, the “Lowy of Battle,” a district extending, for 3 m. round the abbey. The see of Chichester was co-extensive with the county, and has altered little. It is one of the oldest bishoprics, having been founded by Wilfrid at Selsey; the seat was removed to Chichester by William I. Among the lay franchises, the most noticeable are those of the Cinque Ports and of the honor of Pevensey, named the honor of the Eagle from the lords of L’Aigle or Aguila.

Sussex, from its position, was constantly the scene of preparations for invasion, and was often concerned in rebellions. Pevensey and Arundel play a great part in rebellions and forfeiture during the troubled times of the early Norman kings. In the barons’ wars the county was a good centre for the king’s forces; Lewes being in the hands of the king’s brother-in-law, John de Warenne, earl of Surrey, Pevensey and Hastings in those of his uncle, Peter of Savoy. The forces of the king and of De Montfort met at Lewes, where the famous battle and “Mise of Lewes” took place. The corrupt and burdensome administration of the county during the 13th and 14th centuries, combined with the constant passage of troops for the French wars and the devastating plagues of the 14th century, were the causes of such rebellions as the Peasants’ Rising of 1381 and Jack Cade’s Rebellion in 1450. In the former Lewes Castle was taken, and in the latter we find such men engaged as the abbot of Battle and the prior of Lewes. During Elizabeth’s reign there was again constant levying of troops for warfare in Flanders and the Low Countries, and preparations for defence against Spain. The sympathies of the county were divided during the Civil War, Arundel and Chichester being held for the king; and Lewes and the Cinque Ports for the parliament. Chichester and Arundel were besieged by Waller, and the Roundheads gained a strong hold on the county, in spite of the loyalty of Sir Edward Ford, sheriff of Sussex. A royalist gathering in the west of the county in 1645 caused preparations for resistance at Chichester, of which Algernon Sidney was governor. In the same year the “Clubmen” rose and endeavoured to compel the armies to come to terms. Little active part in the national history fell to Sussex from that time till the French Revolution, when numbers of volunteers were raised in defence. At the outbreak of war with France in 1793 a camp was formed at Brighton; and at Eastbourne in 1803, when the famous Martello towers were erected.

The parliamentary history of the county began in 1290, for which year we have the first extant return of knights of the shire for this county, Henry Hussey and William de Etchingham, representatives of two well-known Sussex families, being elected.

Waste and localistic reform was effected by the Redistribution Act of 1832, when Bramer, East Grinstead, Seaford, Steyning and Winchelsea were disfranchised after returning two members each, the first being classed among the worst of the “rotten” boroughs. Before 1832 two members each had been returned also by Arundel, Chichester, Hastings, Horsham, Lewes, Midhurst, New Shoreham (with the rape of Bramber) and Rye. Arundel, Horsham, Midhurst and Rye were each deprived of a member in 1832, Chichester and Lewes in 1867, and Hastings in 1885. Arundel was disfranchised in 1868, and Chichester, Horsham, Midhurst, New Shoreham and Rye in 1885.

In the 13th century the duke of Newcastle was all-powerful in the county, where the Pelham family had been settled from the time of Edward I; the earl of Chichester being the present representative of the family. Among the oldest county families of Sussex may be mentioned the Ashburnhams of Ashburnham, the Gages of Firle and the Bartelots of Stopham.

The industries of Sussex, now mainly agricultural, were once varied. Among those noted in the Domesday Survey were the herring fisheries, the salt pans of the coast and the wool trade; the South Down sheep being noted for their wool, at home and in the Levant as early as the 13th century. The iron mines of the county, though not mentioned in Domesday, are known to have been worked by the Romans; and the smelting and forging of iron was the great industry of the Weald from the 13th to the 18th century, the first mention of the trade in the county being in 1266. In the 15th century ordnance for the government was made here. Some old banded guns with the name of a Sussex maker on them may be seen at the Tower of London. The first cast-iron cannon made in England came from Buxted in Sussex, and were made by one Ralph Hogge, whose device can be seen on a house in Buxted. The large supply of wood in the county made it a favourable centre for the industry, all smelting being done with charcoal till the middle of the 18th century. In the time of Henry VIII. the destruction of the forest for fuel began to arouse attention, and enactments for the preservation of timber increased from this time forward, till the use of pit-coal for smelting was perfected, when the industry moved to districts where coal was to be found. Camden, Thomas Fuller, and Drayton in his Polycion refer to the busy and noisy Weald district, and lament the destruction of the trees. The glass-making industry, which had flourished at Chiddingfold in Surrey, and at Wesborough Green, Loxwood and Petworth in Sussex, was destroyed by the prohibition of the use of wood fuel in 1615. The timber trade had been one of the most considerable in early times; the Sussex oak being considered the finest shipbuilding timber. Among the smaller industries weaving and fulling were also to be found, Chichester having been noted for its cloth, also for malt and needles.

Antiquities.—From early times castles guarded three important entries from the coast through the South Downs into the interior provided by the valleys of the Ouse, the Adur and the Arun. These are respectively at Lewes, Bramber and Arundel. These are now in ruins and have little fighting, do not compare in grandeur with the third, which is still the residence of the Dukes of Norfolk. More famous than these are the massive remains, in part Norman but mainly of the 13th century, of the stronghold of Pevensey, within the walls of Roman Anderida. Other ruins are those of the finely situated Hastings Castle; the Norman remains at Knep near West Grinstead; the picturesque and remarkably perfect moated fortress of Bodiam, of the 14th century; and Hurstmonceaux Castle, a beautiful 15th-century building of brick. Specimens of ancient domestic architecture are fairly numerous; such are the remnants of old
palaces of the archbishops of Canterbury at Mayfield and West Tarring; Amberley Castle, a residence until the 16th century of the bishops of Chichester; and the Elizabethan mansions of Parham and of Danny at Hursstpierpoint. There are many fine residences dating from the 18th century or later; Goodwood is perhaps the most famous. Here and elsewhere are fine collections of paintings, though the county suffered a loss in this respect through the partial destruction by fire of the modern castle of Knapp in 1904.

Monastic remains are few and generally slight. The ruins of Battle Abbey near Tunbridge Wells, and of Battle Abbey, may be noticed. There are numerous churches, however, of great interest and beauty. Of those in the towns may be mentioned the cathedral of Chichester, the churches of Shoreham and Rye, and the mother church of Worthing at Broadwater. Construction of pre-Norman date is seen in the churches of Bosham, Sombiting and, most notably, Worth. There is very rich Norman work of various dates in the church of St Nicholas, Steyning. Several perfect specimens of small Early English churches are found, as at West Tarring, and at Climping near Littlehampton. Perhaps the most interesting church in the county is the magnificent Decorated fragment at Winchelsea; another noteworthy church of this period is at Etchingham, near the eastern border. The church of St Denis, Midhurst, is mainly Perpendicular; but this style is not otherwise predominant. The large church at Fletching, of various styles, contains the tomb of Gibbon the historian. At Cowfold, south-east of Horsham, is a great Carthusian monastery, founded in 1277. The iron memorial slabs occurring in several churches recall the period of the iron industry in Sussex.

**SUSSEX, KINGDOM OF SUTHERLAND, EARLS OF**

Sutheird's return to Sussex was the beginning of a new chapter in Sussex history. The king's exactions in relieving a famine which occurred in Sussex the king granted to him eighty-seven hides in and near the peninsula of Selsey which, with a lapse until 709 after Wilfrid's retirement, remained the seat of the South Saxon bishopric until the Norman Conquest. Shortly afterwards, however, Ethelwald was slain and his kingdom ravaged by the exiled West Saxon prince Ceddwalla. The latter was eventually expelled by two princes named Berthun and Andhun, who thereupon assumed the government of the kingdom. In 868 the South Saxons attacked Hlothhere, king of Kent, in support of his nephew Eadric, but soon afterwards Berthun was killed, and the kingdom subjugated for a time by Ceddwalla, who had now become king of Wessex.

Of the later South Saxon kings we have little knowledge except from occasional charters. In 692 a grant is made by a king called Nothelm to his sister, which is witnessed by two other kings called Nunna and "Uattuss." Nunna is probably to be identified with Nun, described in the Chronicle as the kinman of Ine of Wessex who fought with him against Gereht, king of the West Welsh, in 710. According to Bede, Sussex was subject to Ine for a number of years. A grant, dated by Birch about 725, is made by Nunna to Eadforth, bishop of Selsey, and to this too "Uattuss" appears as a witness. In 722 we find Ine of Wessex at war with the South Saxons, apparently because they were supporting a certain Aldbyrht, probably an exile from Wessex. An undated grant is made by Nunna about this time, which is witnessed by a King Ethelberht. After this we hear nothing more until shortly before 755, when a grant of land is made by a king named Aelfwald with two other kings, Aelwald and Osric, as witnesses. In 765 and 770 grants are made by a King Osmund, the latter of which is witnessed by Offa of Mercia. Offa also appears as witness to two charters of an Ethelberht, king of the South Saxons, and in 732 he grants land himself in Sussex, with Oswald, duw of the South Saxons, as a witness. It is probable that about this time Offa definitely annexed the kingdom of Sussex, as several persons, Osmund, Ethelwald and Osric, who had previously used the royal title, now sign with that of duw. In 825 the South Saxons submitted to Egbert, and from this time they remained subject to the West Saxon dynasty. The earldom of Sussex seems later to have been held sometimes with that of Kent.

**AUTHORITIES.**—See T. W. Hobsford, History, Antiquities and Topography of Sussex (Lewes, 1838); J. Dallaway, History of the Western District (London, 1838); J. M. Moore, Lower History of Sussex (Lewes, 1870), Churches of Sussex (Brighton, 1872) and Worthies of Sussex (Lewes, 1869); Sussex Archaeological Society's Collections; W. E. Baxter, Domedog Book for . . . Sussex (Lewes, 1875); E. D. Hughes, Life of William Berkeley (London, 1888); Sussex Dialect (Brighton, 1884) and Sussex Songs and Music (Brighton, 1885); A. J. C. Hare, Sussex (London, 1894).

**SUSSEX, KINGDOM OF (546-Soce, i.e. the South Saxons),** one of the kingdoms of Anglo-Saxon Britain, the boundaries of which coincided in general with those of the modern county of Sussex. A large part of that district, however, was covered in early times by the so-called Saxon Shore. According to the traditional account given in the Anglo-Saxon Chronicle, it was in 477 that a certain Ella (Ella) led the invaders ashore at a place called Cymenes or and defeated the inhabitants. A further battle at a place called Mearcreses burne is recorded under the year 485, and in the annal for 491 we read that Ella and Cissa his son sacked Anderida and slew all the inhabitants. Ella is the first king of the invading race whom Bede describes as exercising supremacy over his fellows, and we may probably regard him as an historical person, though little weight can be attached to the tradition by which he is represented.

The history of Sussex now becomes a blank until 607, in which year Ceolwulf of Wessex is found fighting against the South Saxons. In 618 Wilfrid of York, on his expulsion from Northumbria by Egfrith, retired into Sussex, where he remained until 686 converting its pagan inhabitants. According to Bede, Ethelwald, king of Sussex, had been previously baptized in Mercia at the suggestion of Wulfhere, who presented him with the Isle of Wight and the district about the Meon. After Wilfrid's exertions in relieving a famine which occurred in Sussex
of 1715. This Earl, who took the name of Sutherland instead of that of Gordon, was succeeded by his grandson William (1708-1750), a very humane, who helped to suppress the rebellion of 1745. William, the next earl, died without male issue in 1766. This Earl’s daughter Elizabeth (1705-1839) claimed the peerage, and although her title thereto was contested by Sir Robert Gordon, Bart., a descendant of the first Gordon earl, it was confirmed by the House of Lords in 1771.

Established in the possession of the title and the vast estates of the earldom, the countess of Sutherland was married in 1785 to George Granville Leveson-Gower (1758-1833), who succeeded her father as second marquess of Stafford in 1803. In addition to the vast estates of the earldom, and the Bridgewater Canal and estates from his maternal uncle, Francis Egerton, 2nd Duke of Bridgewater, and these properties, together with his wife’s estates, which included almost the whole of the county of Sutherland, made him a "leviathan of wealth," as he is called by Charles Greville.

In 1833 he created duke of Sutherland. Leveson-Gower was a member of parliament from 1778 to 1784 and again from 1787 to 1798 and was British ambassador in Paris from 1790 to 1792. From 1790 to 1810 he was joint postmaster-general. He inherited the estates of the Duke of Sutherland and the London residence of the dukes of Sutherland. As a landlord he greatly improved his estates in Staffordshire and Shropshire and then turned his attention to those of his wife in Sutherlandshire. He was responsible for the construction of about 450 m. of road and of many bridges, but his policy of removing a large number of his tenants from the interior to the coast aroused bitterness and criticism. However, he reduced rents and brought thousands of acres into cultivation. He died at Dunrobin Castle on the 5th of July 1833.

His eldest son, George Granville (1786-1861), became the 2nd Duke. The 2nd Duke’s wife, Harriet Elizabeth Georgiana (1806-1868), a daughter of George, 6th Earl ofCarlisle, was one of Queen Victoria’s most intimate friends. She was mistress of the robes to the queen, whose refusal to part with her in 1839 led to a ministerial crisis. Some of her letters are published in Stafford House Letters, edited by her son Lord Ronald Gower (1801).

George Granville William, the 3rd Duke (1828-1892), spent large sums in improving his estates. His wife Anne (1830-1883), daughter of John Hay, Maclean, was created countess of Crichton in 1881, and the earldom descended to her younger son, Lord Francis Leveson-Gower, who became earl of Ellesmere in 1846. The 2nd Duke’s wife, Harriet Elizabeth Georgiana (1806-1868), a daughter of George, 6th Earl of Carlisle, was one of Queen Victoria’s most intimate friends. She was mistress of the robes to the queen, whose refusal to part with her in 1839 led to a ministerial crisis. Some of her letters are published in Stafford House Letters, edited by her son Lord Ronald Gower (1801).

In 1892 Crichton Leveson-Gower (b. 1851), who had been M.P. for Sutherlandshire, became 4th Duke of Sutherland. His wife, Millicent Fanny, daughter of the 4th Earl of Rosslyn, became well known in literary as well as in social and philanthropic circles.

See Sir Robert Gordon and George Gordon, Genealogical History of the Earldom of Sutherland (Edinburgh, 1813); and also the article Stafford, Earls and Marquesses of.

SUTHERLANDSHIRE, a northern county of Scotland, bounded N. and W. by the Atlantic, E. by Caithness, S.E. by the North Sea and S. by the shire of Ross and Cromarty. It has an area of 1,207, 846 acres or 2,028 sq. m., being the fifth largest shire in Scotland. The western and northern shores are much indented and terminate at many points in precipices and rugged headlands. The mountains are distinguished by grandeur of outline. Ben More (3,573 ft.) in Assynt is the highest in the shire, and next to it in height is Ben Clitherick (3,954 ft.). Ben Hope (Icelandic Hög, haven, 3,040 ft.) in the north, is noted as the only place in Great Britain where the Alpine Alpine Rubella is found, and also for its fauna, ptarmigan being common, and even the wild cat and golden eagle occurring at rare intervals. Other lofty hills include Findochan (wart mountain, 2980 ft.) in the north-west; Ben Hee (3864 ft.), the highest point in Reay Forest; the serrated ridge of Quinag (2653) and Glaive (2541) north, and the cone of Canisp (2779) south of Loch Assynt; the precipitous Carn Stackie (2630) in Durness; Ben Arkle (2580) and Ben Stack (2564), frowning above Loch Stack; the fantastic peaks of Ben Loyal (the hill of the young calves, or deer, 2504 ft.) in Tongue; and Suilven (2390). The greater part of the mountainous region consists of wild and desolate moorlands. The chief river is the Oykell, which, rising in Coniveall (3273 ft.), a peak of Ben More, flows south and then south-east for 33 m. to Dornoch Firth, forming the major part of the southern boundary of the shire. Its principal left-hand tributaries, the Kyle of Tongue and the Oykell, also join from the south. Dornoch Firth are the Helmsdale (22 m.), issuing from Loch an Ruathair; the Brora (28 m.), rising in Mt Uaran and preserving in its name (bridge river) the fact that its bridge was the only important one in the county; and the Fleet (17), the head of the estuary of which was embanked for 1000 yds. in 1813 by Thomas Telford, whereby a considerable tract of rich alluvial land was reclaimed from the sea. The longest rivers flowing to the north coast are the Dionard (1.4) to Kyle of Durness, the Naver (27) to Torridon Bay, and the Halladale (22), rising in Assynt. The beds of these drain the basins of the sea to the east of Portskerry. Much of the surface in the vicinity of Assynt is honeycombed with lakes and tarns, but the only large lake is Loch Assynt, which is 1/2 m. long, lies 215 ft. above the sea, has a drainage area of 43 sq. m., and a greatest depth of 282 ft., and empties into the sea by the Inver. Other lakes are Loch Croach, little more than 1 m. long by 1/ m. wide, in which the ratio of the area of islands to the total area of the loch is greater than in any other British lake; Loch Shin (17 m. long); Loch Loyal (4 m.); Loch Hope (6 m.); Loch Naver (6 m.); and Loch More (4 m.). The principal inlets of the sea are, on the north coast, Kyle of Tongue, on the east shore of which stands Tongue House, once the property of the Roy family, now a seat of the Duke of Sutherland—Loch Eriboll and Kyle of Durness; on the west, Lochs Inchard, Laxford (salmon fjord), Caithness, Glendhu, Glencoul, Eddarachlis Bay and Loch Inver; and, on the south-east, Loch Fleet. There are many waterfalls in the county. Those of Escullan, near the head of Glencoul, are among the finest in Great Britain. There are three principal capes—Strathy Point on the north; Cape Wrath at the extreme north-west; and Ry Stor, near which is the Old Man of Stoer, a detached pillar of rock about 250 ft. high. On its seaward face Cape Wrath, (a corruption of the Icelandic krav, turning-point) rises in precipices to a height of 300 ft. The gneiss rocks are scored with pink granite. Sunken reefs keep the sea almost always in tumult. Of the larger islands Handa, usually visited from Scourie on the west coast, has magnificent cliff scenery, distinguished for its beautiful coloration, its caverns and the richness and variety of the bird life, especially on the north-west, where the Torridonian sandstone rocks are 406 ft. high. The cave of Smoo (Icelandic smaga, hole: same root as smuggle) on the north coast, 1 m. east of Durness, is the most famous cavern in the north coast, Kyle of Tongue: on the west coast of which stands Tongue House; the entrance hall, 33 ft. high and 20 ft. wide, opens from the inner chamber, 70 ft. long by 30 ft. wide, by a ledge of rock beneath which pours a stream that descends as a cataract from a hole in the roof, 80 ft. above. Behind the waterfall is the third chamber, 120 ft. long by 8 ft. wide, which can only be seen by artificial light.

Geology.—A very irregular line from Loch Eriboll on the north coast to the neighbourhood of Cromalt near the southern boundary separates the two rock groups that form the foundation of the major portion of the county. On the western side of this line are the ancient gneisses and schists (the Lewisian gneiss); these are penetrated by innumerable basic and acid dikes which generally have a north-west to south-east trend. On the eastern side of the line, occupying the whole of the remaining area except the eastern fringe of the county, is a younger series of metamorphic rocks, the Moine schists. Resting with marked unconformability upon the old gneisses near Cape Wrath, at R.Stor, Quinag, Canisp and Suidven are the dark red conglomerates, breccias and sandstones of Torridonian.
The Sutlej, serpulite good when 1891 In in under reclamation. Assynt a of evicted fortieth on of along Firth, robin striking schists by it rock, "(3) of the agricultural rest, of west Scotland great and of the north-east extent, of the Mesozoic scale; of the Cambrian Lewisian rocks, of the Torridonian limestone and of the Lewisian quartzite. These masses of granite appear in the eastern shorthorn area. Between the River Firth, the Sutlej rises E.S.E. of the Manaswar lakes in Tibet, at an elevation of about 15,200 ft., threads its way through the gorges of the Himalayas with heights of 20,000 ft. on either side, crosses Bashahr and the Simla hill states, and enters the British district of Hoshiarpur. Thence it flows through the plains of the Punjab, receives the Beas in Kapurthala state, and joins the Chenab near Madawala. From that point the whole river bears the name of Panjnad (“five rivers”) until it falls into the Indus near Mithankot after a course of 900 m. In the time of Ranjit Singh the Sutlej formed the boundary line between the Sikh and British dominions, and the Sikh states south of the river still bear the title of Go-Sutlej.

The Sutlej supplies two systems of irrigation works: the Sirhind canal, which draws off the whole of the cold season supply of the Sutlej at Rupar, 100 m above its junction with the
SUTLER—SUTTON, T. 171

Beas; and the inundation canals of the Upper and Lower Sutlej, Ferozepur and Bahawalpur, which come below the junction. 

SUTLER, a camp-follower who sells provisions, liquor and other things to an army in the field, in camp or in quarters. The word was one of the numerous naval and military terms adapted in English from the Dutch, where it appears as soeteelaar or soetebaar. It meant originally one who does dirty work, a drudge, a scullion, and is derived from soelen, detoil, fully, a camp-follower, common "suds," hot soapy water, "seethe," to boil, and "sadden."

SUTRI (anc. Sutrum), a town and episcopal see of Italy, in the province of Rome, 4 m. W.N.W. of the railway station of Capranica, which is 36 m. from Rome; 955 ft. above sea-level. Pop. (1901), 2701. The town is picturesquely situated on a narrow hill, surrounded by ravines, a narrow neck on the west alone connecting it with the surrounding country. There are some remains of the ancient city walls of rectangular blocks of tufa on the southern side of the town, and some rock-cut sermons in the cliffs below them. The cathedral is modern, but the crypt, with twenty columns, is old, and the campanile dates from the 13th century. In the cliffs opposite the town on the south is the rock-cut church of the Madonna del Parto, developed, no doubt, out of an Etruscan tomb, of which there are many here; and close by is a rock-hewn amphitheatre of the Roman period, with axes of 55 and 44 yds., now most picturesque.

The position of Sutri was important, commanding as it did the road into Etruria, the latter Via Cassia; and it is spoken of by Livy as one of the keys of Etruria, Nepet being the other. It came into the hands of Rome after the fall of Veii, and a Latin colony was established there; but it was abandoned in 356, but was recovered and recolonized in 383 (?). It was besieged by the Etruscans in 311-10 B.C., but not taken. With Nepet and ten other Latin colonies it refused further help in the Hannibalic War in 209 B.C. Its importance as a fortress explains, according to Festus, the proverb Sutrium ere, of one who goes on important business, as it occurs in Plautus. It is mentioned in the war of 41 B.C., and received a colony of veterans under the triumvir (Colonia coniuncta Italia Sutrina). Inscriptions show that it was a place of some importance under the empire, and it is mentioned as occupied by the Lombards.

See G. Dennis, Cities and Cemeteries of Etruria, i. 62 (London, 1883).

SUTTEE (an English corruption of Sanskrit sati, "good woman" or true "wife"), the rite of widow-sacrifice, i.e. the burning the living widow on the funeral pyre of her husband, as practised among certain Hindu castes. As early as the Atharva Veda the rite is mentioned as an "old custom," but European scholars have shown that the text of the still earlier Rig Veda had been corrupted, probably willfully, by the Hindu priesthood, and that there was no injunction that the rite should be observed. The directions of the Rig Veda seem to have involved a merely symbolic suttee: the widow taking her place on the funeral pile, but being recalled to "this world of life" at the last moment by her brother-in-law or adopted child. The practice was sporadically observed in India when the Macedonians reached India late in the 4th century B.C. (Diod. Sic. xix. 33-34); but the earlier Indian law books do not enjoit it, and Manu simply commands the widow to lead a life of chastity and asceticism. About the 6th century A.D. a recrudescence of the rite took place, and with the help of corrupted Vedic texts it soon grew to have a full religious sanction. But even so it was not general throughout India. It was rare in the Punjab; and in Malbar, the most primitive part of southern India, it was forbidden. In its medieval form it was essentially a Brahminic rite, and it was where Brahminism was strongest, in Bengal and along the Ganges valley and in Oudh and Rajputana, that it was most usual.

The manner of the sacrifice differed according to the district. In south India the widow jumped or was forced into the fire-pit; in western India she was placed in a grass hut, supporting the corpse's head with her right hand while her left held the torch; in the Ganges valley she lay down upon the already lighted pile, while in Nepal she was placed beside the corpse, and when the pile was lighted the two bodies were held in place by long poles pressed down by relatives. The earliest attempt to stop suttee was made by Akbar (1542-1605), who forbade compulsion, voluntary suttees alone being permitted. Towards the end of the 18th century the British authorities, on the initiative of Sir C. Malet and Jonathan Duncan in Bombay, took up the question, but nothing definite was ventured on till 1839 when Lord William Bentinck, despite fierce opposition, carried in council on the 4th of December a regulation which declared that all who abetted suttee were "guilty of culpable homicide." Though thus illegal, widow-burning continued into modern days in isolated parts of India. In 1905 those who assisted at a suttee in Behar were sentenced to penal servitude.

Widow sacrifice is not peculiar to India, and E. B. Tylor in his Primitive Culture (ch. 11) has collected evidence to support a theory that the rite existed among all primitive Aryan nations. He thinks that in enjoining it the medieval priesthood of India were making no innovation, but were simply reviving an Aryan custom of a barbaric period long antedating the Vedas. See also Jakob Grimm, Verbrechen der Leichen.

SUTTNER, BERTHA, BARONESS VON (1843— ), Austrian writer, was born at Prague on the 9th of July 1843, the daughter of Count Franz Kinsky, Austrian field marshal, who died shortly after her birth. On her mother's side she was descended from the family of the German poet, Theodor Körner. After receiving a careful education she travelled abroad and resided for a long period in Paris and in Italy. In 1876 she married the novelist, Freiherr Arthur Gundaccar von Suttner (1850-1902), and for the next nine years lived with him at Tiflis in the Caucasus. After 1885 she resided at Schloss Harmsdorf, near Eggenburg, in Lower Austria. The Baroness von Suttner, a fertile writer, has produced numerous tales, books on social science and romances, among which the best known are Inven- torium einer Seele (1882), Die Waffen nieder (1884), Honna (1894), La Traviata (1898), Schad der Qual (1899), Martha's Große Hochzeit (1900), Die Heimgesinnten (1901), Die Herbortin (1904), a collection of essays, and a one time secretary to Alfred Nobel, and as a champion of the "brotherhood of nations," had much influence on him and others; and in this connexion has published Krieg und Frieden (1896), Das Maschinen-Zeitalter, Zukunft-Vorlesungen über unsere Zeit (1899) and Die Haager Friedenskonferenzen (1900). In 1905 she was awarded a Nobel prize of £5000 for her endeavours in the cause of peace.

Her Memoiren, full of interesting autobiographical matter, were published at Stuttgart in 1908.

SUTTON, SIR RICHARD (d. c. 1524), the founder, with William Smyth, bishop of Lincoln, of Brasenose College, Oxford, and the first lay founder of any college, is said to have come of a good north-country family, the Suttons of that ilk, near Macclesfield, Cheshire. Little is known of his life, but he was a barrister, and in 1407 a member of the privy council. In 1513 he became steward of the monastery of Sion, a house of Brigitine nuns at Isleworth. How Smyth and Sutton came to plan a college is not known, but in 1508 we find Edmund Croston, or Crofon, bequeathing £6, 13s. 4d. towards the building of "a college of Brasynnose" if the projects of "the bishop of Lincoln and master Sutton" were carried into effect within a stipulated period. In the same year Sutton obtained a ninety-two year lease of Brasenose Hall and Little University Hall for £3 per annum, and from that time until the end of his life he was occupied in purchasing estates with which he might endow the new college. He is thought to have contributed to the funds of Corpus Christi College, Oxford, as well. He was knighted some years before his death, which occurred about 1524.

SUTTON, THOMAS (c. 1532-1611), founder of Charterhouse school and hospital, was the son of an official of the city of Lincoln, and was educated at Eton College and probably at Cambridge. He then spent some time travelling in Europe and appears to have acted as secretary to two or three English noblemen. He became a soldier, and in 1590 was with the troops engaged in suppressing the rising in the north of England; in 1570 he was
made master and surveyor of the ordnance in the northern parts of the realm and in this capacity he took part in the siege of Edinburgh Castle by the English in May 1573. Sutton obtained great wealth by the ownership of coal mines in Durham and also by his marriage in 1582 with Elizabeth (d. 1602), widow of John Dudley of Stoke Newington. His wish to devote some of his money to charitable purposes led him in 1611 to purchase for £13,000 the Charterhouse (q.v.) from Thomas Howard, earl of Suffolk. On this spot Sutton erected the hospital and school which he had originally intended to build at Hallingbury, Essex. Sutton died at Hackney on the 13th of December 1621 and was buried in the chapel in the Charterhouse. His wealth was left for charitable uses, but in 1613 James I. ordered his executors to make an allowance to his natural son, Roger Sutton.

**SUTTON**, an urban district in the Epsom parliamentary division of Surrey, England, 11 m. S. of London by the London Brighton & South Coast railway. Pop. (1891), 13,977; (1901), 17,223. It is pleasantly situated at the edge of the Downs, and is in favour as an outer residential district of London. The manor, according to Domesday, belonged to the abbey of Chertsey at the Conquest and continued so until the dissolution of the monasteries by Henry VIII.

**SUTTON COLDFIELD**, a municipal borough in the Tamworth parliamentary division of Warwickshire, England, 7 m. N.E. from Birmingham on branches of the London & North-Western and Midland railways. Pop. (1901), 14,264. The town, which lies high in a hilly situation, is the centre of a residential district for persons having their business offices in Birmingham, Walsall, and other towns. The church of the Holy Trinity, Early English arches, was restored in 1879, contains a fine Norman font and the tomb of Bishop Vesey. On the picturesque park near the town, 2400 acres in extent, the inhabitants have the right of grazing horses and cattle at a small fee. This, with the Crystal Palace gardens, forms a recreation ground for the people of Birmingham. In the vicinity are New Hall, an interesting mansion of the 13th century, with a hall of the 16th, used as a boys' school; and Peddimore Hall, a moated mansion of the ancient family of Arden, of which there are slight remains. The town is governed by a mayor, 6 aldermen, and 18 councillors. (Area, 12,828 acres.)

The church of St Mary Magdalene of the 12th and 14th centuries was restored in 1868. There are collieries and lineworks in the vicinity. Cotton hosiery and thread are the principal manufactures.

**SUVÁROV**, ALEXANDER VASILEVICH, COUNT (1720-1800), Russian field marshal, was born at Moscow on the 24th of November 1729, the descendant of a Swede named Suvar who emigrated to Russia in 1622. He entered the army as a boy, served against the Swedes in Finland and against the Prussians during the Seven Years' War. After repeatedly distinguishing himself in battle he was made a colonel in 1762. He next served in Poland, dispersed the Polish forces under Pulaski, stormed Cracow (1768) and was made a major-general. In his first campaigns against the Turks in 1773-74, and particularly in the battle of Kösudzki in the latter year, he laid the foundations of his reputation. In 1775 he suppressed the rebellion of Pugachev, who was decapitated at Moscow. From 1777-1785 he served in the Crimea and the Caucasus, becoming lieutenant-general in 1780, and major-general in 1783, on the conclusion of his work there. From 1787 to 1791 he was again fighting the Turks and won many victories; he was wounded at Kinburn (1787), took part in the siege of Ochakov, and in 1788 won two great victories at Focsani and on the Rinnik. For the latter victory, in which an Austrian corps under Prince Josias of Saxe-Coburg participated, Catherine II. made him a count with the name Rimmenski in addition to his own name, and the emperor Joseph II. created him a count of the Holy Roman Empire. On the 2nd of December 1799 Suvarov was made field marshal in Berlin, and the same year he was allowed some of the expenditure which that followed the capture equals in horror such events as the "Spanish Fury" and the fall of Magdeburg. He was next placed at the head of the army which subdued the Poles, and repeated the triumph, and some of the cruelties, of Ismail at Warsaw. He was now made a field marshal, and was retained in Poland till 1795, when he returned to St Petersburg. But his sovereign and friend Catherine died in 1796, and her successor Paul dismissed the veteran in disgrace. Suvárov then lived for some years in retirement on his estate of Konchausky, near Moscow. He criticized the new military tactics and dress of the French, and, in his old age and the same year in which he reached the ears of Paul. His conduct was therefore watched and his correspondence with his wife, who had remained at Moscow—for his marriage relations had not been happy—was tampered with. On Sundays he tolled the bell for church and sang among the rustics in the village choir. On week days he worked among them in a smock frock. But in February 1799 he was summoned by the tsar to take the field again, this time against the French Revolutionary armies in Italy.

The campaign (see FRENCH REVOLUTIONARY WARS) opened with a series of victories (Cassano, Troyes, Novi) which induced the French government to desperate straits and drove every French soldier from Italy, save for the handful under Moreau, which maintained a foothold in the Maritime Alps and around Genoa. Suvárov himself was made a prince. But the later events of the eventful year went uniformly against the allies. Suvárov's lieutenant Korsakov was defeated by Masséna at Zürich, and the old field marshal, seeking to make his way over the Swiss passes to the Upper Rhine, had to retreat to the Vorarlberg, where his army, much shattered and almost destitute of horses and artillery, went into winter quarters. Early in 1800 Suvárov returned to St Petersburg in disguise. Paul refused to give him an audience, and, worn out and ill, he died a few days afterwards on the 18th of May 1800 at St Petersburg. Lord Whitworth, the English ambassador, was the only person of distinction present at the funeral. Suvárov lies buried in the church of the Annunciation in the Alexandro-Nevskii monastery, the simple inscription on his grave being, according to his own direction, "Here lies Suvárov." But within a year of his death the tsar Alexander I. erected a statue to his memory in the Field of Mars, St Petersburg.

His son Arkadi (1785-1811) was a general officer in the
Russian army during the Napoleonic and Turkish wars of the early 19th century, and was drowned in the river Rimnik in 1811. His grandson Alexander Arkadievich (1804–1882) was also a Russian general.

Among the Russians the memory of Suvorov is cherished to this day. A great captain, viewed from the standpoint of any age of military need for leadership, and, especially for the capital of the Russian nation, for the character of his leadership responded to the character of the Russian soldier. In an age when war had, become an act of diplomacy he restored its true significance as a war of conquest. He redefined the role of the general as not only on the achievement of the objective in hand, and he spared his own soldiers as little as he showed mercy to the population of a fallen city. He was a man of great simplicity of nature, modest, and he could not be a private army, sleeping on straw and contending himself with the humblest fare. But he had himself passed through all the gradations of military service; moreover, his education had been of the rudest kind. His gifts were considerable; he was known as a man of ability and action for ignorant favourites and ceremonial carpet-knights. But his drolleries served, sometimes to hide, more often to express, a soldierly genius, the effect of which the Russian army has not outgrown. If the tactics of the Russians in the war of 1905-06 reflected too literally some of the maxims of Suvorov's Turkish war, the spirit of self-sacrifice, resolution and indifference to losses there shown was a precious legacy from those wars. Dragomirov (g.v.) avowed that his teaching was based on Suvorov's practice, which he held to be representative of the truths of war and of the military qualities of the Russian nation.

Suvorov's activities are described in Kriegsgeschichte der Grafen Suvorow (Gotha, 1796-1799); F. von Smitt, Suvorows Leben und Heerzüge (Vilna, 1833-1834) and Suvorov und Polens Untergang (Leipzig, 1858); Von Reckling-Bibelberg, Der Zag Suvorow, ein Ehrengast der Könige (Zlatarevo, 1851); H. van de Sande (London, 1890); G. von Fuchs, Suvorows Korrespondenz, 1799 (Glogau, 1835); Suvorou en Italie, by Gachot, Masséna's biographer (Paris, 1903); and the standard Russian biographies of Polevoi (1853; German, Mitau, 1853; Rybkin (Moscow, 1874) and A. Asliev (Vilna, 1899).

SUWALKI, a government of Russian Poland, of which it occupies the N.E. corner, extending to the N. between East Prussia and the Russian governments of Vilna and Grodno, with the government of Kovno on the N. Its area is 4846 sq. m. It includes the east of the low Baltic swelling (800 to 1000 ft. above the sea) and is studded with lakes. Its northern slopes descend to the valley of the Niemen, while in the south it falls away gently to the marly tract of the Bogatyr river. Rivers flow there in deep-cut gorges and hollows, diversifying the surface. The Niemen forms its eastern and northern boundary and has many affluents from both slopes of the swelling. The Augustow canal connects the navigable Hancza, a tributary of the Niemen, with a tributary of the Biebrza, which belongs to the basin of the Vistula, and an active traffic is carried on by this canal. Forests cover about one-fourth of the area. Tertiary and cretaceous strata occupy large areas, and the entire surface is covered with Post-Tertiary deposits. The bottom moraine of the great ice-sheet of North Germany, containing scratched boulders and furrowed by depressions having a direction N.E. and S.S.W., extended over immense tracts of the ridge of the lake-districts and its slopes, while limited spaces are covered with well-washed glacial sands and gravel. On the northern slopes of the coast-ridge, the boulder-clay being covered with lacustrine deposits, there are in many places areas of fertile soil; and in the southern parts of the province the boulder-clay is stony, and sometimes covered with gravel. Still, nearly nine-tenths of the surface are suitable for cultivation.

The population in 1906 was estimated at 633,900. The majority (82·7%) are Lithuanians, mostly in the north; there are 21·5% Poles (and Mazury chiefly in the town); 6·5% Jews; 2·5% Russians and 4·2% others. The chief towns of the seven districts into which the government is divided are Suwałki, Augustowo, Kalwaria, Mariampol, Seiny, Wilkowiski (or Volkovyski) and Wladislavow. The principal crops are rye, wheat, oats, barley and potatoes, which are largely exported to Prussia for use in the distilleries. Bee-keeping is widely spread, and about 40,000 lb of honey are obtained every year. The weaving of linen, woolen cloth and fishing-nets is extensively carried on in the villages as a domestic industry, and in small factories. A large number of the inhabitants are compelled to seek work in winter in other parts of the empire. The felling of timber, which is floated down the Niemen, gives occupation to many.

SUWALKI, a town of Russian Poland, capital of the government of the same name, situated at the source of the Hancza, a tributary of the Niemen, 65 m. by rail N.W. of Grodno. Pop. 27,165. In the 15th century it was a small village amid forests, possessed of some rights granted by the lord in timber, grain, flax, linen, wool, and to a certain extent, to the king's taille of 3% in money. It was granted a town charter in 1450 and has a market in 1465. It fell into decay after the abolition of the taille in 1795. Its manufactures are flax, linen, worsted, wollen cloth and other manufactured goods.

SUYUTI [Abu-l Fadl Abd ur-Rahman ibn Abi Bakr Jalal ud-Din us-Suyuti (1445-1505), Arabic encyclopaedic writer, was the son of a Turkish slave woman. His father, who was of Persian descent, had been cadi in Suuyut (Upper Egypt) and professor in Cairo, but died before his son was six years old. The boy's training was taken in hand by a Sufi friend of the father. He was precocious and is said to have known the Koran by heart before he was eight years old. In 1462 he was already a teacher; in 1464 he made the pilgrimage to Mecca; in 1472 he became a professor, and in 1486 was promoted to a chair in the mosque of Bihars. Here, however, he provoked a revolt among the students and in 1501 was discharged for maladministration of trust funds. Two years later he was offered the same post again, but declined, and worked in seclusion at Raua, an island of the Nile, and there died in 1505. He was one of the most prolific writers of the East, though many of his works are only pamphlets and some are mere abridgments of the work of others.

We know of 563 separate titles of his works, and over 316 exist in the libraries of Turkey. He was given a permit to publish the Nebi Nasir, in the career of the Koran, published with an analysis by A. Spranger (Calcutta, 1852-1854) and often in Cairo; the commentary on the Koran, known as the Tasfir al-Jaldain, begun by Jalal ud-Din al-Maqrizi (1389-1465) and finished by Suyut, published in the East; and the history of the caliphs, published at Calcutta (1858) and elsewhere.

Suzerainty. "Suzerain," a term of feudal law, is now used to describe persons or states in positions of superiority to others. Its etymology, according to Professor W. W. Skeat (Eymological Dictionary), is as follows: "A coined word; made from French suz., Latin suusum suum suus, signifying 'his'; in the same way as sovereign is made from Latin super; it corresponds to a Low Latin type suzeranus." Another form of the word is suzerain (F. Godfroy, De l'Ancienne langue francaise). Suzerain has been defined as "Qui possede un fief dont d'autres feifs relevent" (Liittré and Dictionnaire de l'académie francaise). C. Loyseau, in his Traité des seigneuries (3rd ed., 1610, p. 14), explains that there are two kinds of public seigneuries, that is, sovereign seigneurs, possessing sumsum imperium, and suzerains, "Les suzeraines sont celles qui ont puissance supérieure mais non suprême." Elsewhere he says that suzerainy is a form of public seigneuries which has been " usurpée par les particuliers pour laquelle exprimer il nous a fallu forger un mot exprès, et l'appeller suzeraineté, mot qui est aussi étrange comme celle espèce de seigneuries est absurde " (p. 11). Loyseau adds, "Seigneurie suzeraine est dignité d'un fief ayant justice " (p. 35). Bouquet (Nouveau dictionnaire de droit) defines suzerain as " supérieur, celui dont un fief relevait;" Rogulau (Glossaire du droit francais), " supérieur en quelque charge ou dignité autre que le roi. " The name does not occur in the Consuetudines feudorum, or in Hotoman's De verbis feudalibus commentarius. It was rare in feudal times in England. But it was used in France to describe a feudal lord, the supreme suzerain being the king. Merlin, under suzeraineté, shows that the word was not used by all feudal writers in the same sense. (See also Chas. Butler's note to Coke on Litt. 101 a.)

In modern times the term has come to be used as descriptive of relations, ill-defined and vague, which exist between powerful and dependent states; its very indefiniteness being its recommendation. According to feudal law the vassal owed certain duties to the lord; he promised fidelity and service; and the lord was bound to perform reciprocal duties, not very
SUZERAINITY

clearly defined, to the vassal—Dominus vassallo confregit et amicitiam dicuit. The relation between a lord and his vassals, implied in the oath of fealty, has been extended to states of unequal power: it has been found convenient to designate certain states as vassal states, and their superiors as suzerains. Originally and properly applicable to a status recognized by feudalism, the term vassal state has been used to describe the subordinate position of certain states once parts of the Ottoman Empire, and still loosely connected therewith. Such are Egypt and Bulgaria. Rumania, Servia and Montenegro, once vassal states, may now be regarded as independent. The relations of these states to the Ottoman Porte are very varied. Egypt has been variously described as a vassal state or as a protectorate. But all of these pay tribute to the sultan, or in some way acknowledge his supremacy (Emanuel Ullmann, Völkerecht, § 16): M. de Martens (Traité de droit international, 1883, i. 333 n.) thus defines the term: "La suzeraineté est la souveraineté limitée exercée par le pouvoir suprême d'un état sur un gouvernement mi-souverain," a definition applicable to protectorates, with which it is often confounded. Thus Mommsen (History of Rome) indiscriminately describes the supremacy of Rome over Armenia as "suzerainity" or "protectorate." To emphasize the vague use of the word in modern diplomacy may be quite misleading; it was concluded by Lord Kimberley, which Mr Chamberlain in the correspondence as to South Africa mentioned with approval: "Superiority over a state possessing independent rights of government subject to reservations with reference to certain specified matters" (1899 [C. 9027], p. 28).

M. Gaillard (Le Protectorat international) distinguishes suzerainty from protectorate in these respects: (a) suzerainty proceeds from a concession on the part of the suzerain (p. 112); (b) the vassal state is bound to perform specific services; and (c) the vassal state has larger powers of action than those belonging to a protected state; (d) there is reciprocity of obligation. According to M. F. Despagnet the term suzerain is applicable to a case in which a state concedes a fief, in virtue of its sovereignty (Éssai sur le protectorat international, p. 46), reserving to itself certain rights as the author of this concession.

Another writer draws these distinctions: (a) a state connected by protectorship with another previously enjoyed autonomy; the vassal state did not; (b) the protected state retains its nationality and its internal administration; the vassal state acquires a distinct nationality; (c) the establishment of a protectorate modifies few of the institutions of the protectorate state except as to foreign relations; the establishment of a suzerainty changes the institutions of the vassal state; (d) the protected state exercises its internal sovereignty & peu près pleinement; the vassal state remains subordinate in several respects; (e) while the protected state has the right to be assisted in case of war by the protecting state, but is not bound to defend the latter, the vassal state is bound to aid its suzerain (Thomacoff, De la Souveraineté du protectorat. See also Hachenburger, De la Nature juridique du protectorat.

W. E. Hall thus defines vassal states: "States under the suzerainty of others are portions of the latter which during a process of gradual disruption or by the grace of the sovereign have acquired certain of the powers of an independent community, such as that of making commercial conventions, or of conferring their exequatur on foreign consuls. Their position differs from that of the foregoing varieties of states (protectorates, &c.), in that a presumption exists against the possession by them of any given international capacity (International Law, 4th ed., p. 31).

Another suggested distinction is this: Suzerainty is title without corresponding power: protectorate is power without corresponding title (Professor Freund, Political Science Quarterly. 1899, p. 28).

On the whole, usage seems to favor this distinction: while a protectorate flows from or, is a reduction of, the sovereignty of the protected state, suzerainty is conceived as derived from, and a reduction of, the sovereignty of the dominant state.

As to the power of making treaties, a vassal state cannot, as a rule, conclude them; such power does not exist unless it is specially given. On the other hand, a protected state, unless the contrary is stipulated, retains the power of concluding treaties (Bry, p. 204).

It is sometimes said that a protected state, unlike a vassal state, has the right of sending representatives to foreign states. But such distinctions are of doubtful value: the facts of each case must be considered (Ullmann, § 26).

There is one practical difference between the two relations: while the protecting and protected states tend to draw nearer, the reverse is true of the suzerain and vassal states; a protectorate is generally the preliminary to incorporation, suzerainty to independence. Sometimes the suzerain and vassal states are formed as protectorates. But the vassal state forms part of the territory of the suzerain; a proposition which is true for some purposes, but not for all.

All definitions of suzerainty are of little use. Each instrument in which the word is used must be studied in order to ascertain its significance. Even in feudal times suzerainty might be merely nominal, an instance in point being the suzerainty or over-lordship of the papacy over Naples. In some cases it may be said that suzerainty brings no practical advantages and implies no serious obligations. Among the instances in which the term has been applied it has been used as a synonym for protectorate (March 1896, Treaty, Peace of Paris, 1856 (arts. 21 and 22), recognizing the suzerainty of Turkey over the Danubian principalities Moldavia and Wallachia, modifying the "sovereignty" of Turkey recognized by the Treaty of Adrianople. "Les principautés de Valachie et de Moldavie continueront à jouir, sous la suzeraineté de la Porte et sous la garantie des Puissances contractantes, des privilèges et des immunités dont elles sont en possession." The convention of the 19th of August 1858 (Hertael x. 1592) organized the then principalities "under the suzerainty of the sultan" (art. 1). The internal government was to be exercised by a hospodar, who received his investiture from the sultan, the sign of vassalship, it has been said (Thomacoff, p. 45). The autonomy of these vassal states has been fully recognized by the Treaty of Berlin of 1878 (art. 1). In the Interpretation Act, 1889, s. 18 (5), "suzerainty" is used to describe the authority of the sovereign over native princes.

The word suzerain is used in the Pretoria convention of the 3rd of August 1881 between the British government and the late South African Republic. The convention (by its preamble) granted to the inhabitants complete self-government, "subject to the suzerainty of her Majesty," and this suzerainty was formally referred to in the articles. Even when the convention was being negotiated doubts arose as to its meaning, and legal authorities were divided as to its effect (see speech of Lord Cairns, Hansard, 260, p. 261; Lord Selborne, 260, p. 390; answer of attorney-general 260, 1534). It was doubtful whether territory could be ceded by the Crown of its own authority; and if the power existed the cession could, it was said, be made only by virtue of clear words. From the articles substituted in the London convention of the 27th of February 1884 for those of 1881, the word "suzerainty" was omitted. Fresh doubts arose as to the effect of this omission; and a correspondence on the subject took place between the British government and the government of the republic before the outbreak of hostilities in South Africa, the former maintaining that the preamble of 1881, by which alone any self-government was granted, was still in force, and therefore that the suzerainty—whatever it involved—remained; the Transvaal government, on the other hand, contending that the suzerainty had been abolished by the substitution of the 1884 convention for the 1881. Writers on international law differ greatly as to the exact position of the South African republic under the later convention. Some considered it an independent sovereign state (Mr Taylor (A Treatise of International Public Law, p. 174) treats the Transvaal after the convention of 1884 as a "neutralized state only part sovereign." Other writers describe the relation as that of a protectorate (see Professor J. Westlake, Revue de droit international, 1896, p. 268 seq.; International Law, pt. 1, p. 27). Professor de Louther defines it as "une servitude du droit des gens (servitus juris gentium), et qui diffère de la servitude du
SVANE—SVERDRUP

droit privé en ce qu'elle ne constitue pas un droit réel (jus in re aliena) mais un droit entre deux personnes de droit international (subjecta juris gentium)" (Revue de droit international, 1899, p. 330). Dr F. Von Lützow (Das Völkerrecht, p. 331) treats the South African republic as an example of a half sovereign state. M. Gairal describes it as a vassal state. Probably the soundest opinion is that the British Crown reserved no other rights than those expressly stated in the treaty. Furthermore, it is probable that the clergy did much to increase the welfare and independence of the Danish Church in difficult times, while his representations to the king that Danish theology was not likely to be promoted by placing Germans over the heads of native professors bore good fruit. Svane died on the 26th of July 1668, in his 62nd year.

See Dotlev Gotthard Zwergius, Sjælendes klæreris (Copenhagen, 1754).

SVANETIA, a mountainous district on the south slopes of the Caucasus, immediately underneath the loftiest glaciated peaks of the middle of the system. It extends over the upper valleys of the Rioni, Ingur and Tkhenis-iskhali, and is included in the modern government of Kutais. The Svanetians belong to the Georgian race. (See Caucasus and Caucasia.)

SVENDBORG, a seaport of Denmark, capital of the omil (county) of its name, on the south shore of the island of Fünen. Pop. (1901), 11,543. The situation is pleasant. The narrow Svendborg Sund separates Fünen from the lesser islands of Taasinge and Turø, of which the former rises to 245 ft. Land from the town there is also elevated ground, the Ovnhøj. The harbour is accessible to vessels drawing 20 ft. There are tobacco and earthenware manufactories, host-building yards, and distilleries. Butter is the principal export, and petroleum, coal and iron the imports. Neighbouring to the town are the mined coal of Orkil, the watering-place Christiansminde, and the extensive orchards of Gammel Hesthove, where wine is produced.

SVENDSEN, JOHANN SEVERIN (1840— ), Norwegian composer, was born in Christiania on the 30th of September 1840. He learnt the elements of music and violin-playing from his father, and after serving for some time in the army, and later touring as violinist with a troupe of instrumentalists, he entered the conservatorium at Leipzig through the aid of the king of Sweden. After another tour, which extended to the British Isles, Svendsen spent a year in Paris, and in 1871-1872 was leader of the once famous Euterpe concerts in Leipzig. In 1871 he married an American, and from 1872 to 1877 he conducted the Christiania Musical Society, while in 1877-1879 he lived in Rome, London and Paris. In 1883 Svendsen became court kapellmeister at Copenhagen. Probably we have to go back to Schubert to find a composer whose Opus 1 has attained the wide popularity of Svendsen's A minor string quartet, while his beautiful octet, Opus 3, added to his fame. Though Svendsen was at one time intimate with Wagner, the latter does not seem to have influenced his music, which includes two symphonies, a violin concerto, and a romance for violin, as well as a number of Norwegian rhapsodies for the orchestra.

SVERDRUP, JOHAN (1816—1892), Norwegian statesman, was born at Jarlsberg on the 30th of July 1816. His father, Jakob Sverdrup, was a land steward, and the founder of the first school of agriculture in Norway. Johan entered the Storting in 1830, sitting first for Lærvik, and then for the district of Akershus, and was its president from 1871 to 1884; during the whole of the dispute over the prerogative of the Crown. He built up a strong political party, which, relying for support chiefly on the Norwegian peasantry, was determined to secure strict constitutional government and practically to destroy the power of the king. Under his leadership the opposition, in 1872, secured the passing of a bill for the admission of the ministers to the Storting, which bill was passed by a large majority. The independence of the cabinet on a majority in that assembly. King Charles XV. refused his sanction to this bill, and on its third passing in 1880 Oscar II. opposed his veto, at the same time claiming his right to the absolute veto. Sverdrup then proposed the proclamation of the law in defiance of the king's action. The
retirement of Frederik Stang removed Sverdrup's chief political opponent from the field. He was aided in his campaign by Bjoernstjerne Bjornson and, after a series of political crises he became prime minister in June 1884. But when he became prime minister he soon found himself at issue with Bjornson on church matters. Inspired chiefly by his nephew Johan he secured the refusal of a pension to the novelist Kielland because of his anti-clerical views, and he further wished to give the parish councils the right to strike off the voting list persons who had broken away from church discipline. Therefore, although during his term of office no fewer than eighty-nine measures, many of them involving useful reforms, became law, he failed to satisfy the expectations of moderate Liberals, and it was only by appeal to the moderate Liberals. He was compelled to retire in 1880, and died on the 17th of February 1892 at Christiania.

SWABIA, Suevia or Suevia (Ger, Schwaben), one of the stem-duchies of medieval Germany, taking its name from the Suevi, a tribe which inhabited the district in the first century of the Christian era. Dwelling in the angle formed by the Rhine and the Danube, they were joined by other tribes, and were called Almannia, whilst the district was called Almannia, until about the 11th century, when the form Swabia began to prevail, and at length Suevia to the Rhine, and Almannia to the Danube, the former, turned under Frankish rule, and governed by dukes who were dependent on the Frankish kings. In the 7th century the people were converted to Christianity, bishoprics were founded at Augsburg and Constance, and in the 8th century abbys at Reichenau and St Gall. The Almanni had gradually thrown off the Frankish yoke, but in 730 Charles Martel again reduced them to dependence, and his son Pippin the Short abolished the tribal dukedom and ruled the duchy by two counts palatine, or Kammerbolten. The duchy, which was divided into gau or counties, took about this time the extent which it retained throughout the middle ages, and was bounded by the Rhine, the lake of Constance, the Lech and Franconia. The Lech, separating Almannia from Bavaria, did not form, either ethnologically or geographically, a very strong boundary, and there was a good deal of inter-communion between the two races. During the later and weaker years of the Carolingian rule the counts became almost independent, and a struggle for supremacy took place between them and the bishops of Constance. The chief family in Almannia was that of the counts of Raetia, who were sometimes called the Almanni, and one of whom, William, was called duke of the Almanni. Burkhard was killed in 811, and two counts palatine, Bertold and Erchanger, were accused of treason, and put to death by order of the German king Conrad I. In 917, Burkhard, count in Raetia, took the title of duke, and was recognized as such by King Henry I., the Fowler, in 919. His position was virtually independent, and when he died in 926 he was succeeded by Hermann, a Franconian noble, who married his widow. When Hermann died in 948 Otto the Great gave the duchy to his own son Ludolf, who had married Hermann's daughter Ada; but he reduced the ducal privileges and appointed counts palatine to watch the royal interests. Ludolf revolted, and was deposed, and other dukes followed in quick succession. Burkhard II., son of Burkhard I., ruled from 934 to 973, Ludolf's son, Otto, afterwards duke of Bavaria, to 982, and Conrad I., a relative of Duke Hermann I., until 997. Hermann II., possibly a son of Conrad, succeeded, and, dying in 1003, was followed by his son Hermann III. During these years the Swabians were loyal to the kings of the Saxon house, probably owing to the influence of the bishops. Hermann III. had no children, and the succession passed to Ernest, son of his sister Elisabeth and Ernest I., margrave of Austria. Ernest held the duchy for his son until his own death in 1015, when Gisela undertook the government, and was married a second time, to Conrad, duke of Franconia, who was afterwards the German king Conrad II. When Ernest came of age he quarrelled with his step-father, who deposed him, and, in 1030, gave the duchy to Gisela's second son, Hermann IV. and, on his death in 1058, to Henry, his own son by Gisela. In 1045 Henry, who had become German king as Henry III., granted Almannia to Otto, grandson of the emperor Otto II. and count palatine of the Rhine, and, in 1048, to Otto, count of Schwentfurt. Rudolph, count of Rheinfelden, was the next duke, and in 1077 he was chosen German king in opposition to the emperor Henry IV., but found little support in Swabia, which was given by Henry to his faithful adherent, Frederick I., count of Hohenstaufen. Frederick had to fight for his position with Bertold, son of Duke Rudolph, and the duke's son-in-law, Bertold II., duke of Zähringen, to whom he ceded the Breisgau in 1056. Frederick II. succeeded his father in 1102, and was followed by Frederick III., afterwards the emperor Frederick I. The emperors were rulers of the duchies of Franconia, Hesse, and Swabia, where they received steady support, although ecclesiastical influences were very strong. In 1152 Frederick I. gave the duchy to his kinsman, Frederick, count of Rothenburg and duke of Franconia, after whose death in 1167 it was held successively by three sons of the emperor, the youngest of whom, Philip, was chosen German king in 1198. During his struggle for the throne Philip purchased support by large cessions of Swabian lands, and the duchy remained in the royal hands during the reign of Otto IV., and came to Frederick II. in 1214. Frederick II. made it his own in 1235, to his son Conrad, whose son Conradin, setting out in 1266 to take possession of Sicily, pledged his Swabian inheritance to Ulrich II. count of Württemberg. The duchy was ripe for dissolution and, after Conradin's death, in 1268, the chief authority in Swabia fell to the counts of Württemberg, the margraves of Baden, the counts palatine of Tübingen, the counts of Hohenzollern and others.

When the emperor Maximilian I. divided Germany into circles in 1512, one, which was practically coterminous with the duchy, was called the Swabian circle. The area, which was formerly Swabia, is now covered by the kingdoms of Württemberg and Bavaria, the grand-duchy of Hesse and the western part of the kingdom of Bavaria. Although the name Swabia is occasionally used in a general way to denote the district formerly occupied by the duchy, the exact use of the name is now confined to a Bavarian province, with its capital at Augsburg.

See J. Leichtlen, Schwaben unter den Römer (Freiburg, 1825); J. C. v. Plater, Pragmatische Geschichte von Schwaben (Heilbronn, 1823, continuation to 1496, 1827).

SWABIAN LEAGUE. An association of the great cities, principally in the territory which had formed the old duchy of Swabia. The name, though usually given to the German federation of 1488, is applicable also to several earlier leagues (e.g. those of 1331, 1370). The Swabian cities had attained great prosperity under the protection of the Hohenstaufen emperors, but the extinction of that house in 1268 was followed by disintegration. Cities and nobles alike, now owing allegiance to none but the emperor, who was seldom able to defend them, were exposed to the aggression of ambitious princes.

In 1331, twenty-two Swabian cities, including Ulm, Augsburg, Reutlingen and Heilbronn, formed a league at the instance of the emperor Louis the Hutten to return for their support promised not to mortgage any of them to a vassal. The count of Württemberg was induced to join in 1340. Under Charles IV. the lesser Swabian nobles began to combine against the cities, and formed the Schlegelerbund (from Schlegel, a maul). Civil war ensuing in 1367, the emperor, jealous of the growing power of the cities, endeavoured to set up a league under his own control, for the maintenance of public peace (Landfriedenbund, 1370). The defeat of the city league by Eberhard II. of Württemberg in 1372, the murder of the captain of the league, and the breach of his obligations by Charles IV., led to the formation of a new league of fourteen Swabian cities led by Ulm in 1376. This league triumphed over the count of Württemberg at Reutlingen in 1377, and the emperor having removed his ban, it assumed a permanent character, set up an arbitration court, and was rapidly extended over the Rhineland, Bavaria and Franconia. In 1382 an alliance was made at Eihingen with the archduke of Austria, and through his mediation with the
three chief knightly associations of Swabia. The new king, Wenceslaus, hoped at first, like his father Charles, to check the federal movement by associating all estates of the realm under his own lead in Landfriedensbeischaffungen, but such a compact made at Heidelberg in 1384, although renewed at Mergentheim three years later, was a mere makeshift. The struggle between burghers and nobles was precipitated by the inclusion of the urban members of the Swiss confederation in the league in 1385 and the overthrow of Archduke Leopold of Austria by the latter at Sedlmeyr in the following year. A quarrel between the latter of Bavaria and the archbishop of Salzburg gave the signal for a general war in Swabia, in which the cities, weakened by their isolation, mutual jealousies and internal conflicts, were defeated by Count Eberhard II. at Dössingen (Aug. 24, 1388), and were severally taken and devastated. Most of them quietly acquiesced when Wenceslaus proclaimed a Landfriede at Eger in 1389 and prohibited all leagues between cities. The professed aims of the cities which had formed this league of 1376 were the maintenance of their imperial status (Reichtumsmittelbarkeit), security against sale or mortgage and against excessive taxation, the protection of property, trade and traffic, and the power to suppress disturbances of the peace. There is no trace of cooperation with the Hanseatic towns. The league necessarily opposed the pretensions of the emperors and the electoral princes, especially as set forth in the Golden Bull, and in accordance with the growing spirit of civil freedom demanded a share in the government, but that there was any widespread conscious desire for a fundamental change in the constitution, for the abolition of aristocratic privilege or for a republic, as certain historians maintain, is improbable.

For nearly a century there was no great effort at federation among the Swabian cities, attention being diverted to the ecclesiastical controversies of the time, but there were partial and short-lived associations, e.g. the league of twelve Swabian cities in defence of their liberties in 1392, the Marbach league in 1405 against the German king, Rupert, and in 1441 the union of twenty-two cities (in 1446 thirty-one) headed by Ulm and Nuremberg, for the suppression of highway robbery. This latter union in 1446 formed a standing army and waged war on a confederation of princes led by Albert Achilles, afterwards elector of Brandenburg (q.v.).

The growing anarchy in Swabia, where the cities were violently agitated by the constant infringement of their liberties (e.g. the annexation of Regensburg by Bavaria in 1489), induced Frederick III., who required men and money for the Hungarian War, to conciliate the cities by proposing a scheme of pacification and reform. His commissioner, Count Hugo of Werdenberg, met the Swabian estates at Esslingen and laid before them a plan probably drawn up by Bertold, elector of Mainz, and on the 14th of February 1458 the Great Swabian League was constituted. There were four constituent parties, the archduke Sigismund of Austria, Count Eberhard V. (afterwards duke) of Württemberg, who became the first captain of the league, the knightly league of St. George, and lastly twenty-two Swabian imperial cities. The league received a formal constitution with a federal council consisting of three colleges of nine counsellors each, a captain and a federal court with judicial and executive powers. The armed force which was to police Swabia consisted of 12,000 foot and 1200 horse, each party contributing one-fourth. The league gained strength by the speedy accession of Augsburg and other Swabian cities, the margraves of Brandenburg and Baden, the four Rhinen electors, i.e., and in 1490 of Maximilian, king of the Romans, whom the league had helped to rescue from the hands of the Netherlands in 1488. It did not render him the support he expected in his foreign policy, but it performed its primary work of restoring and maintaining order with energy and efficiency. In 1492 it compelled Duke Albert of Bavaria to renounce Regensburg; in 1519 it expelled the turbulent duke, Ulrich of Württemberg, who had seized Reutlingen, and it sold his duchy to Charles V.; and in 1523 it defeated the Franchonian knights who had taken up arms with Franz von Sickingen. In 1525, Truchsess, the league captain, aided by the forces of Trier and the palatinate, overthrew the rebel peasants of Königshofen on the Tauber and at Ingolstadt.

The league, which had been several times renewed, expired on the 2nd of February 1534, its dissolution being due to internal dissensions regarding the reformation. Futile attempts were made to renew it, in 1535 by the Bavarian chancellor, Eck, and in 1547 by Charles V.

See E. Osann, Zur Geschichte des schwäbischen Bundes (Giessen, 1861); K. Klüpfel, "Der schwäbische Bund" (in Hitl. Taschenbuch, 1883-1884), Urkunden zur Geschichte des schwäbischen Bundes (Stuttgart, 1846-1853). (A. B. Go.)

SWADLINCOTE, a town in the southern parliamentary division of Derbyshire, England, 15 m. S.S.W. of Derby, and 4 m. S.E. of Burton-upon-Trent, on the Midland railway. Pop. (1901), urban district of Swadlincote district, 18,014. This includes the civil parishes of Swadlincote, Church Gresley and Stanton and Newhall, which together form a large industrial township, mainly devoted to the manufacture of earthenware and fireclay goods. There are collieries in the neighbourhood.

SWAFFHAM, a market town in the south-western parliamentary division of Norfolk, England; 111 m. N.N.E. from London by the Great Eastern railway. Pop. of urban district (1901), 3371. The town lies high, in an open, healthy district. The church of St Peter and St Paul is Perpendicular, a handsome cruciform structure with central tower, and has a fine carved roof of wood. The town, which has a town-hall and assembly rooms, possesses iron foundries and a considerable agricultural trade, with cattle fairs. At Castle Acre, 4 m. N., are the picturesque ruins of a Cluniac priory, founded shortly after the Conquest by William de Warren. These comprise portions of the church, including the fine west front, arcaded, with three Norman doors and a Perpendicular window, with the chapter-house, cloisters and conventual buildings. The majority of the remains are Norman or Perpendicular. The castle of the same founder has left little but its foundations, but it was erected within the protection of a remarkable series of earthworks, which remain in good condition. These are apparently in part Roman, in part earlier. The site, on which Roman coins, pottery and other remains have been discovered, was on an ancient trackway running north and south. It may be noted that de Warren founded a similar castle and priory at Lewes in Sussex. The church of St James, Castle Acre, contains good Early English and Perpendicular work.

SWAHILI (Wa-Swahili, i.e. coast people, from the Arabic zaahir, coast), a term commonly applied to the inhabitants of Zanzibar and of the opposite mainland between the parallels of 2° and 9° S., who speak the KI-Swahili language. The Swahili are essentially a mixed people, the result of long crossing between the negroes of the coast and the Arabs, with an admixture of slave blood from nearly all the East African tribes. Among Swahili are found every shade of colour and every type of physique from the full-blooded negro to the pure Semite. Usually they are a powerfully built, handsome people, inclined to stoutness and with Semitic features. They number about a million. They figured largely in the history of African enterprise during the 19th century. The energy and intelligence derived from their Semitic blood have enabled them to take a leading part in the development of trade and the industries, as shown in the wide diffusion of their language, which, like the Hindustani in India and the South American in South America, has become the principal medium of intercourse between a large area of Africa south of the equator. During his journey from the Indian Ocean to the Atlantic (1873-1874) Commander V. Lovett Cameron found that a knowledge of this language enabled him everywhere to dispense with the aid of an interpreter, as it was understood by one or more persons in all the tribes along the route. Owing to this circumstance the Swahili have been found invaluable assistants in every expedition from the eastern seaboard to the interior after they began to be
employed by J. H. Speke and Richard Burton as porters and escorts in 1857. The language is somewhat archaic Bantu, much mixed with Arabic, while Indian, Persian and even English, Portuguese and German words have contributed to the vocabulary. Many of these words have since been published, and into it portions of the Bible have been translated by Bishop Steere.1 The Swahili are Mahomedans, but in disposition are genuine negroes. Christian missions among them have met with little success.

SWALLOW (A. S. swælwe, Icel. swalda, Du. swaluw, Ger. Schwebe), the bird which of all others is recognized as the harbinger of summer in the northern hemisphere. The name Hirundo rustica of Linnaeus is now employed for the common chimney-swallow of Europe, which has been divided into many races and subspecies. In summer it ranges all over Europe, and in Asia extends to Manchuria and China; in winter it migrates south, reaching India, Burma, the Malay Peninsula and the whole of Africa. The common swallow of North America, usually called the barn-swallow, is H. erythrogaster, but in summer it also reaches Alaska and Greenland and extends across to Lake Balikal. The winter migration extends to Burma for the Asiatic swallows and to South Brazil for those of America.

In all some twenty-seven species of Hirundo are recognized, the range of the genus being practically worldwide. It is usually considered, to its summer haunts, after its winter sojourn in southern lands, and generally reaching England about the first week in April, the English swallow at once repairs to its old quarters, nearly always around the abodes of men; and, about a month later, the site of the nest is chosen, resort being had in most cases to the very spot that has formerly served the same purpose—the old structure, if still remaining, being restored and refurnished. So trustful is the bird that it commonly establishes itself in any of men's works that will supply the necessary accommodation, and a shed, a barn, or any building with an open roof, a chimney-dovey or for a support for the nest, or even the room of an inhabited house— if chance should give free access thereto—to say nothing of extraordinary positions, may be the place of its choice. Wheresoever placed, the nest is formed of small lumps of moist earth, which, carried to the spot in the bird's bill, are duly arranged and modelled, with the aid of short straws or slender sticks, into the required shape. This is generally that of a half-saucer, but it varies according to the exigencies of the site. The materials dry quickly into a hard crust, which is lined with soft feathers, and therein are laid from four to six eggs, bluish-black, speckled with grey and orange-brown deepening into black. Two broods are usually reared in the season, and the young on leaving the nest soon make their way to some leafless bough, whence they try their powers of flight, at first accompanying their parents in short excursions on the wing, receiving from them the food which they are as yet unable to capture, until able to shift for themselves. They collect in flocks, often of many hundreds, and finally leave the country about the end of August or early in September, to be followed, after a few weeks, by their progenitors. They moult their feathers in their winter quarters, and this outward change is accompanied by the profoundest arguments against the popular belief (which, curious to say, is still partly if not fully entertained by many who should know better) of their becoming torpid in winter, for a state of torpidity would suspend all animal action.2 The crest at the forehead and throat, the shining steel-blue upper plumage, and the dusky white—in some cases reddening so as almost to vie with the frontal and gular patches—of the lower parts are well known to every observer; and this is the markedly forked tail, which is become proverbial of this bird.

Taking the word swallow in a more extended sense, it is used for all the members of the family Hirundinidae, excepting a few to which the name martin (q.v.) has been applied, and this family includes about seventy species, which have been placed in four genera, and differ in different genera. The true swallow has very many affinities, some of which range almost as widely as itself does, while others seem to have curiously restricted limits, and much the same may be said of several of its more distant relatives. But altogether the family forms one of the most circumscribed and therefore one of the most natural groups of Oscines, having no near allies: for, though in outward appearance and in habits it bears a striking resemblance to swifts (q.v.), the latter belong to a different order, and are not Passerine birds at all, as their structure, both internal and external, proves. It has been sometimes stated that the Hirundinidae have their nearest relations in the flycatchers (q.v.); but it must be quite obvious that the supposition that they are allied to the Amelidiæ (cf. WAXWING), though possibly better founded, has not been confirmed. An affinity to the Indian and Australian Artamus (the species of which genus are often known as wood-swallows or swallow-shrikes) has also been suggested, but has not been accepted.

A. N.]

SWALLOW-HOLE, in physical geography the name applied to a cavity resulting from the solution of rock under the action of water, and forming, or having at some period formed, the entrance to a subterranean stream-channel. Such holes are common in calcareous (limestone or chalky) districts, or along the line of outcrop of a limestone belt among non-calcareous strata. They are known as caves, swallow-holes, subterranean butter-tubs, and by other local names, and sometimes as potato-holes; the last term, however, is also synonymous with Giant's Kettle (q.v.). See CAVE.

SWAMMERDAM, JAN (1637-1680), Dutch naturalist, was born on the 12th of February 1637 at Amsterdam, the son of an apothecary and naturalist. He was destined for the Church; but he preferred the profession of medicine, taking his doctor's degree at Leiden in 1667. Having necessarily to interest himself in human anatomy, he devoted much attention to the preservation and better demonstration of the various structures, and he devised the method of studying the circulatory system by means of injections. He also spent much time in the study of insects, investigating the subject of their metamorphosis, and in this and other ways laying the beginnings of their natural classification, while his researches on the anatomy of mayflies and bees were also of great importance. His devotion to science led to his neglect of practice; his father, resenting this, stopped all supplies and thus Swammerdam experienced a period of considerable privation, which had the most unfortunate consequences to his health, both bodily and mental. In 1675 his father died, leaving him an adequate fortune, but the mischief was irreparable. He became a hypochondriac and mystic, joined the followers of Antoïette Bourignon, and died at Amsterdam on the 15th of February 1680.

His Allgemeine Verhandelung van bloedloose dierijen appeared at Utrecht in 1669, and his Bildia naturae, sive Historia insectorum in certis classes reducita was published after his death by H. Boerhaave in 1724-1728. He is the author of Miraculum naturae, seu Uteri mihi corporis fabrica (Leiden, 1672).

SWAN, JOHN MACALLAN (1847-1910), English painter and sculptor, received his art training first in England at the Worcester and Lambeth schools of art and the Royal Academy schools, and subsequently in Paris, in the studies of J. L. Gérôme and E. Frémiet. He began to exhibit at the Academy in 1878, and was elected associate in 1894 and academician in 1905. He was appointed a member of the Dutch Water-Colour Society in 1885; and associate of the Royal Society of Painters in Water Colours in 1896 and full member in 1899. A master of all, water-colour and pastel mediums, an accomplished

1 An enormous amount of labour has been bestowed upon the Hirundinidae by R. Bowdich's Descriptive List of the Birds of the British Isles, x. 85-210, and in the finely-illustrated Monograph which he and C. W. Wyatt have published (2 vols. 4to, London, 1885-1894).

2 The language was first reduced to writing by the Arabs, who still use the Arabic character. But the European missionaries have reported the progress of the syntax somewhat suited for the transliteration of most African, and especially of the Bantu, tongues.

3 See John Hunter's Essays and Observations in Natural History, edited by Sir R. Owen in 1864 (ii. 280). An excellent bibliography of the torpidity controversy, up to 1878, is given by Professor Coues (Birds of the Colorado Valley, pp. 378-390), who seems still to hang on the ancient faith in "hibernation."
SWAN, SIR J. W.—SWAN

painter and a skilful draughtsman, he ranks also as a sculptor of distinguished ability. He has treated the human figure with notable power, but it is by his representations of the larger wild animals, mainly the felidae, that he chiefly established his reputation; in this branch of practice he has scarcely a rival. His picture "The Prodigal Son," bought for the Chantrey collection in 1859, is in the National Gallery of British Art. He was awarded first class gold medals for painting and sculpture in the Paris Exhibition, 1900. He died on the 14th of February, 1904.

SWAN, SIR JOSEPH WILSON (1828- ), English physicist and electrician, was born at Sunderland on the 31st of October 1828. After serving his apprenticeship with a chemist in his native town, he became first assistant and later partner in a firm of manufacturing chemists in Newcastle. Among its operations this firm included the manufacture of photographic plates, and thus Swan was led to one of the advances in photography as to which his name is chiefly associated, the invention of an extremely rapid dry plate, which were the outcome of an original observation made by him on the effect of heat in increasing the sensitiveness of a gelatino-bromide of silver emulsion. In 1861 he patented the first commercially practicable process for carbon printing in photography. This depended on the fact that when gelatine is exposed to light in the presence of bichromate salts it is rendered insoluble and non-absorbent of water. Swan took a surface of gelatine, dusted over with lampblack and sensitized with bichromate of ammonium, and exposed it to light below a photographic negative; the result was to make the gelatine from the surface downwards insoluble to a depth depending on the intensity, and therefore penetration, of the light which had reached it through the negative. In this operation the surface of the gelatine was also rendered insoluble, and it therefore became necessary to get at its back in order to be able to wash away the portions that still remained soluble; this was effected by cementing the insoluble surface to a fresh sheet of paper by means of indiarubber solution, and then detaching the original support. It thus became possible to reach the soluble portions with water and to obtain a representation of the picture, though reversed as to right and left, in relief on the pigmented gelatin. This process has been simplified and improved by subsequent workers, but in its essential features it forms the basis of some of the methods of photographic reproduction most widely used at the present day. But Swan's name deserves remembrance even more in connexion with the invention of the incandescent electric lamp than with improvements in photographic technique. He was one of the first to undertake the production of an electric lamp in which the light should be produced by the passage of an electric current through a carbon filament, and he was almost certainly far ahead, in point of time, of any other worker in the same field in realizing the conditions to be met and the difficulties to be overcome. So far back as 1860 he constructed an electric lamp with a carbon filament, which was formed by packing pieces of paper or card with charcoal powder in a crucible and subjecting the whole to a high temperature. The carbonized paper thus obtained he mounted in the form of a fine strip in a vacuous glass vessel and connected it with a battery of Grove's cells, which though not strong enough to raise it to complete incandescence, were sufficient to make it red-hot. This was substantially the method adopted by Edison nearly twenty years later, after various fruitless efforts to make a practical lamp with a filament of platinum or a platinum alloy, had convinced him of the unsuitability of that metal for the purpose—a conclusion which Swan had reasoned out for himself many years before. By the time Edison had hit upon the idea of carbonizing paper or bamboo by heat to form the filament Swan had devised the further improvement of using cotton thread "parchmentized" by the action of sulphuric acid, and it was by the aid of such carbon filaments that on the 20th of October 1880 he gave at Newcastle the first public exhibition on a large scale of electric lighting by means of glow lamps. In another method devised by him for the manufacture of filaments, collodion was squirted into a coagulating solution and the tough threads thus obtained carbonized by heat. He also devoted attention to apparatus for measuring electric currents, to the improvement of accumulators and to the conditions governing the electro-deposition of metals. He was elected a fellow of the Royal Society in 1854, and served as president of the Institution of Electrical Engineers in 1896-1897 and of the Chemical Society in 1901. In the last named year he received the honorary degree of D.Sc. from Durham University, and he was knighted in 1904.

SWAN (A. S. swan and swon, Icel. swur, Du. swaan, 'Ger. Schwan'), a large swimming-bird, well known from being kept in a half-domesticated condition throughout many parts of Europe, whence it has been carried to other countries. In England it was far more abundant formerly than at present, the young, or cygnets, being highly esteemed for the table, and it was under especial enactments for its preservation, and regarded as a "bird royal" that no subject could possess without licence from the Crown, the trading of which, however, was accompanied by the condition that every bird in a "game" (to use the old legal term) of swans should bear a distinguishing mark of ownership (cyginitata) on the bill. Originally this privilege was conferred on the larger freeholders only, but it was gradually extended, so that in the reign of Elizabeth upwards of 400 distinct swan-marks, being those of private persons or corporations, were recognized by the royal swanherd, whose jurisdiction extended over the whole kingdom. It is impossible here to enter into further details on this subject, interesting as it is from various points of view. It is enough to remark that all the legal protection afforded to the swan points out that it was not indigenous to the British Islands, and indeed it is stated (though on uncertain authority) to have been introduced to England in the reign of Richard Cœur de Lion; but it it now so perfectly naturalized that birds having the full power of flight remain in the country. There is no evidence to show that its numbers are ever increased by immigration from abroad, though it is known to breed as a wild bird not farther from the British shores than the extreme south of Sweden and possibly in Denmark, whence it may be traced, but with considerable vacuities, in a south-westerly direction from the Danube and the western part of Central Asia. In Europe, however, no definite limits can be assigned for its natural range, since birds more or less reclaimed and at liberty consort with those that are truly wild, and either induce them to settle in localities beyond its boundary, or of themselves occupy such localities, so that no difference is observable between them and their untamed brethren. From its breeding-grounds, whether they be in Turkestan, in south-eastern Europe or Scania, the swan migrates southward towards winter, and at that season may be found in north-western India (though rarely), in Egypt, and on the shores of the Mediterranean.

The swan just spoken of is by some naturalists named the mute or tame swan, to distinguish it from one to be presently mentioned, but it is the swan simply of the English language

1 Here, as in so many other cases, we have what may be called the "name game" of descriptive nomenclature, by which, while it which it bore when alive was of Teutonic origin.
2 The king and the Companies of Dyers and Vintners still maintain their swans on the Thames, and a yearly expedition is made in the month of August to take up the young birds—thence called "swan-upping" and corruptly "swan-hopping"—and mark them. The largest swannery in England, indeed, the only one worthy of the name, is that belonging to Lord Hambleden on the river called the Fleet, lying inside the Chelsh Bank on the coast of Dorset, where from 700 to double that number of birds may be kept—a stock doubtless too great for the area, but very small when compared with that of the Danube swanherds, which are retained for the benefit of the whole country. The swanpit at Norwich seems to be the only place now existing for fattening the cygnets for the table—an expensive process, but one fully appreciated by those who have tasted the results. The English swan, with its distinctive colors and resonant tones, has been, unfortunately, but admirably treated by Serjeant Manning (Penny Cyclopædia, xxiii. 271, 272).
SWANAGE

and literature. Scientifically it is usually known as Cygnus olor. Its large size, its spotless white plumage, its orange-red bill, surmounted by a black knob (technically the "betry") larger in the male than in the female, its black legs and stately bearing, evidence the swan's presence on a grand scale. Indeed, it is a member of the family Anatidae. The young swans, or cygnets, are not readily apparent in the water, but their distinctive presence is evident from their unique appearance, almost every one. When left to itself its nest is a large nest of aquatic plants, often piled to the height of a couple of feet and possibly some six feet in diameter. In the midst of this is a hollow which contains the eggs, generally from five to nine in number, of a greyish-olive colour. The period of incubation is between five and six weeks, and the young when hatched are clothed in sooty-grey down, which is succeeded by feathers of sooty-brown. This suit is gradually replaced by white, but the young birds are more than a twelve-month old before they lose all trace of colouring and become wholly white.

It was, however, noticed by Plot (N.H. Staffordshire, p. 228) more than 200 years ago that certain swans on the Trent had white cygnets; and it was subsequently observed of such birds that both parents and progeny had legs of a paler colour, while the young had not the "blue bill" of ordinary swans at the same age that has in some parts of the country given them a name, besides offering a few other minor differences. These, being examined by W. Yarrell led him to announce (Proc. Zool. Society, 1858, p. 319), as "a new species," them forming a distinct species, C. immutabilis, to which the English name of "Polish" swan had already been attached by the London poulterers, but which is now regarded merely as a variety, not in any way specially associated with Poland but possibly a dimorphic form.

The whooper, whistling or wild swan1 of modern usage, Cygnus cygnus, which was doubtless always a winter-visitor to Britain, though nearly as bulky and quite as purely white in external plumage, is at once recognizable from the species which has been half domesticated by its wholly different but equally graceful carriage, and its bill—which is black at the tip and lemon-yellow for a greater or lesser length of the position. This latter character is a distinguishing mark of most of Iceland, eastern Lapland and northern Russia, whence it wanders southward in autumn, and the musical tones it utters (contrasting with the silence that has caused its relative to be often called the mute swan) have been celebrated from the time of Homer to our own. Otherwise in a general way there is little difference between the habits of the two, and very closely allied to the whooper is a much smaller species, with very well marked characteristics, known as Bewick's Swan, C. bewickii. This was first indicated as a variety of the last by P. S. Pallas, but its specific validity is now fully established. Apart from size, it may be easily distinguished by the whooper by the bill having only a small patch of yellow, which inclines to an orange rather than a lemon tint; while internally the difference of the vocal organs is well marked, and its cry, though melodious enough, is unlike. It is known incidentally that the Bewick’s swan is a much better flier than the whooper, but its winter infrequently occurs in Britain.

Both the species last mentioned have their representatives in North America, and in each case the transatlantic bird is considerably larger than that of the Old World. The first is the trumpeter-swam, C. buccinator, which has the bill wholly black, and the second the C. columbianus—greatly resembling Bewick's Swan, but with the coloured patches on the bill of less extent and deepening almost into scarlet. South America produces two very different birds commonly regarded as swans, Cygnus melancoryphus, the black-necked swan, and that which is called Coscoroba. This latter, though not in the same extent as the first, is the smallest species known—pure white in colour except the tip of its primaries, but having a red bill and red spots on the feet. It is found in the interior of the continent and was first observed by Capt. Cook in 1778, and rediscovered by Mr Gibson in 1820. The tussle between the sexes in the nest is very noisy. The wings are much smaller than those of the Bewick's swan, and its general appearance more like that of a goose.

1 M. Gerbe, in his edition of Degland's Ornithologie Européenne (ii. 477), makes the amusing mistake of attributing this name to the pourleurs (furlers) of London, and of reading it Cygne du pôle (polar, and not Polish, swan).

12 Perhaps original wild-fowlers "elk," which perhaps may be cognate with the Icelandic Alft and the Old German Elbs or Elps (cf. Gesner, Ornithologia, pp. 385, 389), though by modern Germans Elbschwan seems to be used for the preceding species.

13 Or, "a loquacious bird," from the Latin, suggesting the idea of being a noisy animal, which is evident from the account given of its habits.

14 Or, "a loud trumpet-call," and that it swims with the neck curved and the wings raised after the true swan model. P. Forster's Mammalia und Vögel des Ost Indien (Amsterdam, 1726). The incidents of the voyage are related in Deel iii. Hoofde, iv. (which has for its title Description of Banda, pp. 68-71).
of St Mary has a massive tower possibly of pre-Norman date; there is a town-hall, an institute with library and lecture hall, and memorials to a victory gained by King Alfred over the Danes in the bay in 877, and to Albert, Prince Consort. A large export trade is carried on in stone from the Purbeck quarries.

SWANSEA, a municipal, county and parliamentary borough, market town, and seaport of Glamorganshire, South Wales, finely situated in an angle between lofty hills, on the river Tawe or Tawel. Part of its scene on Swansea Bay, and the lofty record of the Bristol Channel, 201 m. W. of London by rail and 453 m. W.N.W. of Cardiff. The Great Western main line has a junction within the borough at Landore, whence a branch runs into a more central part of the town. The Vale of Neath branch of the same railway and the Rhondda & Swansea Bay railway (now worked by the Great Western) have terminal stations near the docks on the other (eastern) side of the river, as also has the Midland railway from Hereford and Brecon. All these lines approach the town from the north and east through an unattractive industrial district, but the central Wales branch of the London & North-Western railway from Craven Arms in entering it on the west passes through some beautiful woodlands and then skirts the bay, having parallel to it for the last 3 m. the light (passenger) railway which runs from Swansea to Mumbles Pier. The older part of the town, being the whole of the municipal borough previous to 1836, occupies the west bank of the Tawe near its mouth and is now wholly given up to business. Stretching inland to the north along the river for some 3 m. through Landore to Morriston, and also eastwards along the sea margin towards Neath, is the industrial quarter, while the "residential part occupies the sea front and the slopes of the Town Hill (580 ft. high) to the west, stretching out to the pleasant suburb of Sketty. The east side of the river (known as St Thomas's and Port Tennant) is approached from the west by a road carried over the North Dock Lock and the river by two girder drawbridges, each of which has a double line of roadway (on which tramways are laid), two footpaths and a line of railway. All the main thoroughfares are spacious, and in two or three instances even imposing, but most of the residential part consists of monotonous stuccoed terraces. The climate is mild and relaxing and the rainfall averages about 40 in.

Public Buildings, &c.—The old castle, first built by Henry de Newburgh about 1099, has entirely disappeared; but of the new castle, which was probably intended only as a fortified house, there remain the great and lesser halls, a tower and a so-called keep with the curtain wall connecting them, its chief architectural feature being a fine embattled parapet with an arcade of pointed arches in a style similar to that of the episcopal palaces of St Davids and Llandeilo built by Henry Gower (d. 1347), bishop of St Davids, to whom the building of the new "castle" is also ascribed. Part of it is now used as the headquarters of the 4th Welsh (Howitzer) Brigade R.F.A. Possibly some traces of St Davids Hospital, built by the same prelate in 1331, are still to be seen at Cross Keys Inn. The parish church of St Mary was entirely rebuilt in 1805-1808. It previously consisted of a tower and chancel (with a fine Decorated window) built by Bishop Gower, the piers of the chancel arch being partly built on earlier Norman work, the Herbert Chapel (originally St Ann's) of about the same date as the chancel and rebuilt in the early part of the 18th century, and a nave built in 1739. Of the earlier work there remains the door of the chancel (built into a wall) 12 ft. by 7 ft., a Pavilion, carved with a representation of the resurrection, in memory of Sir Hugh Johnys (d. c. 1463) and his wife, and three canopied altar tombs—one with the effigy of a priest and another with effigies of Sir Matthew Craddock and his wife. Within the parish of St Mary was St John's, the church of a small parish of the same name lying to the north of St Mary's and once owned by the Knights Hospitallers. This church, which was entirely rebuilt in 1820, was renamed St Matthew in 1880, when a new St John's was built within its own parish. There are 26 other churches and 10 mission rooms belonging to the Church of England, besides 2 Roman Catholic churches, a synagogue and 84 Nonconformist, 31 Welsh and 53 English and 20 mission rooms, but all are modern buildings. There are 9 ecclesiastical parishes and parts of two or three others, all in the diocese of St Davids. The Royal Institution of South Wales, founded in 1835, is housed in a handsome building in the Ionic style erected in 1838-1839 and possesses a museum in which the geology, mineralogy, botany and antiquities of the district are well represented, there being a fine collection of neolithic remains from the Gower Caves and from Merrthyr Mawr. Its library is rich in historical and scientific works relating to Wales and Welsh industries and contains the collection of historical MSS. made by Colonel Grant-Francis, some time its honorary librarian, but one of its most valued possessions is the original contract of affiance between Edward II. (when prince of Wales) and Isabella. Its art gallery has many prints and drawings of great local interest and here the Swansea Art Society holds its annual exhibition. The Swansea Scientific Society also meets here. In its early days the institution was the chief centre of scientific activity in South Wales, those associated with it worked including L. W. Dillwyn, James Motley, Dr Gutch and J. E. Bicheno, all botanists, J. Gwyn Jeffreys, conchologist, Sir W. R. Grove and the 1st Lord Swansea, the last three being natives of the town.

The free library and art gallery of the corporation, a four-storeyed building in Italian style erected in 1887, contains the library of the Rev. Rowland Williams (one of the authors of "Essays and Reviews"), the rich Welsh collection of the Rev. Robert Jones of Rotherithe, a small Devonian section (presented by the Swansea Scientific Society) containing about 2500 prints and engravings, intended to be mutually illustrative, given by the Swansea portrait-painter and art critic, John Deffris Francis, from 1876 to 1881, to receive whose first gift the library was established in 1876. It also contains a complete set of the patent office publications.

The grammar school founded in 1682 by Hugh Gore (1613-1691), bishop of Waterford, is now carried on by the town council under the Welsh Intermediate Education Act of 1889, and there is a similar school for girls. The technical college is also carried on by the town council, the chief features of its building having been designed by Sir Aston Webb. An attracting college for school-mistresses, established by the British and Foreign School Society in 1872, was transferred to the town council in 1908.

The other public buildings of the town include the gildhall and law courts, in the Italian style with Corinthian pillars and pilasters, built in 1847 and internally remodelled in 1901; a prison and workhouse, both remarkably modern and of the same period (1886); the Albert Hall for concerts and public meetings (1864); the Royal Metal Exchange (1897); harbour trust offices (1904); a central post office (1901) and two theatres. The bencovolent institutions include the general hospital, founded in 1817, removed to the present site in 1867, extended by the addition of two wings in 1878 and of an eye department in 1890; a convalescent home for twenty patients from the hospital only (1903); the Royal Cambrian Institution for the Deaf and Dumb, established in 1847 at Aberystwyth, removed to Swansea in 1850, and several times enlarged, so as to have at present accommodation for eighty patients; the Welsh National Institution for the Blind, established in 1865 and now under the Board of Education; the Swansea and South Wales Nursing Institute (1873), providing a home for nurses in the intervals of their employment; a nursing institution (1902) for nursing the sick poor in their own homes, affiliated with the Queen's Jubilee Institute of London; the Sailors' Home (1864); a Sailors' Rest (1885); and a Mission to Seamen's Institute (1904).

On the other side of the Tawe are many acres of parks and open spaces, the chief being Llewyn Park of 42 acres in the north of the town near Morrison, Victoria Park (16 acres) and recreation ground (8 acres) abutting on the harbour, in the south; the privately owned football field between them, Cwmdonkin (13 acres) commanding a fine panoramic view of the bay, and Brynmill (9 acres) with a disused reservoir constructed in 1837 and now converted into an ornamental lake. Some of the most interesting features of Swansea are the Cwmdonkin, a good collection of waterfowl in Brynmill, and a small aviary of the rarer British birds in Victoria Park, which also has a meteorological station in connexion with the meteorological office,
SWANSEA

and a statue of Mr. William Thomas of Lan erected in 1905 in appreciation of the work done by him in preserving and obtaining in 1878 a statutory connexion with the town. Hence there are the statutes of J. Henry Vivian and of his son Henry Hussey Vivian (created Lord Swansea in 1873) each in his turn the 'copper king.' The corporation consists of the lord mayors, the two aldermen, and 26 members elected annually by the corporation of Swansea. The trustees are conservators of the river Tawe and parts of Swansea Bay, and have the charge and management of the town hall, and their powers were incorporated by the Harbour Act of 1854. There are 9 private graving docks.

The total exports (foreign and coastwise) from Swansea during 1929 amounted to 4,832,496 tons, of which coal and coke were 3,655,050 tons; patent fuel, 679,002 tons; tin, terne and black plates, 348,240 tons; iron and steel and their manufactures, 38,438 tons; various chemical and medicinal products, 37,100 tons; copper, zinc and silver, 22,633 tons, including the year amounting to 809,201 tons, of which 172,319 tons of grain and other agricultural produce, 136,620 tons of framed, 145,255 tons of pig-iron and manufactured iron and steel, 47,210 tons of iron ore, 121,168 tons of copper, silver, lead, tin and nickel with their ores and alloys, 63,009 tons of zinc, its ores and alloys, 41,029 tons of sulphur ore, phosphates and other substances, 105,095 tons of slag and cold blast (called "the metallurgical capital of Wales") is the chief seat of the copper, spelter, tin-plate and patent fuel industries, and has within a compass of 4 m. over 50 different works of 36 varieties (exclusive of collieries) for the treatment or manufacture of copper, gold, silver, lead, sulphate of copper, spelter, tinplates, steel and iron, nickel and cobalt, yellow metal, sulphuric acid, hydrochloric acid, crocoite, alkali, galvanised sheets, patent fuel as well as engineering works, iron foundries, large flour and provender mills, fuse works and brick works. Copper smelting, which during most of the 19th century was the chief industry, has not maintained its relative importance, though Swansea is still the chief smelting port of the world.

The town is lighted with gas supplied by a gas company first incorporated in 1830 and by electricity supplied by the corporation. There is a good system of electrically worked tramways, 51 miles being in working order, but the whole worked by the company. The town obtains its chief supply of water from moorlands situated on the Old Red Sandstone formation in the valley of the Cray, a tributary of the Usk, and the water, which is at a higher level than the town, is conveyed by a tunnel of 30,000,000 gallons capacity and has been constructed at a cost of £547,759, under parliamentary powers obtained in 1892, 1902 and 1905. The water is brought to the town in a conduit consisting of 23 m. of iron pipes and 3 m. of tunnel into a service reservoir of 3,000,000 gallons capacity made on the Town Hill at an elevation of 580 ft. above sea-level. There is a further supply obtained from three reservoirs of a combined capacity of 51,000,000, constructed in 1866, 1874 and 1880 respectively in the Llwi and adjoining valleys, in the drainage area of the Loughor, about 10 m. to the north of Swansea.

Harbour and Commerce.—Swansea owes its commercial prosperity to its great natural advantages as a harbour and its situation with regard to the trade of the three counties which it is the natural port of shipment. It is the most westerly port of the Bristol Channel and the nearest to the open sea, only 35 m. from the natural headland, and is sheltered anchorage under the Mumbles Head at all states of the tide.

The modern development of the port dates from about the middle of the 18th century when the town began to be extensively supplied by the Llansamlet and copper smelting (begun at Swansea in 1717, though at Neath it dated from 1834) assumed large proportions. The coal was conveyed to the works and for shipment to a wharf on the east bank, on the banks of mules and small precipices by 1820, and a trawling was especially by a private canal. The common quay was on the west bank; all ships coming in had to lie in the river bed or in a natural tidal basin known as the east basin. In 1794 the Act of Parliament allowed the trustees were appointed who cleared and deepened the river bed and built a long pier on either side of it; in 1796 the approach to the port was made safer by means of an improved light on Mumbles Head. A canal connecting the tidal part of the river Neath with the mouth of the Taw, made in 1789, was in 1824 connected with the Vale of Neath canal by means of aaqueduct across the Neath river, when also a small dock, Port Tennant (so named after the its owner or its previous owners), was opened near the mouth of this canal and this continued to be used till 1880. Meanwhile in 1798 the whole coalfield of the Swansea Valley was connected with the port by a canal 162 m. long through the village of Westland, a new harbour was opened in 1822; then in 1834 the river was diverted eastward into a new channel (called the New Cut) and its old channel was locked and floated, thereby forming the North Dock with an area of 113 acres and a half-tide basin 500 ft. wide. The New Valley was completed in 1837, a connecting lock with this dock, and on the island between the dock and the New Cut are patent fuel works, copper ore yards and other works. The Western Docks, the Mumbles and South Dock, begun in 1847 under powers obtained that year by a private company, transferred in 1857 to the harbour trustees and opened in 1859, is mainly used for shipping coal and for discharging timber and fish. Lying parallel to the seafront and to the west of the entrance channel from which it runs at right angles, it has an area of 13 acres with a half-tide basin of 4 acres and a lock 300 ft. long by 60 ft. wide. The next dock, the east end, lies at the mouth of Fabian's Bay, inside the harbour mouth, was utilized for the construction of the Prince of Wales's Dock (authorized 1874, opened October 1881, extension opened 1883). This dock, which is 22,000 ft. long and 7000 ft. wide, and it is connected with the Tennant canal. The very rapid increase in the demand for anthracite coal (for the shipment of which Swansea has practically a monopoly) soon necessitated still another dock. This was begun in 1875, the dock, which lies farther east and has an entrance direct from the bay. By means of the embankment made in connexion with it, 400 acres were reclaimed from the sea. It has an area of 69 acres, its length 2168 ft. and its width 230 ft., and it has a depth of 32 ft. of water, or inner cell. The total dock area of Swansea has thus been increased to about 147 acres with a half-tide basin 900 ft. wide. By 1928 the adjacent railways (which exceed 20 m.) are owned and administered by a harbour trust of 26 members, of whom one is the owner of the Briton Ferry estate (Earl Jersey), 4 represent the lordship of the seigniory of Gower (the slate of the former family of the counts of Gower), 12 are trustees of local charities and 9 are elected annually by the corporation of Swansea. The trustees

From 1535 to 1832 (with the exception of 1638-1650), Swansea was associated with the other boroughs of Glamorgan in sending one representative to Parliament. In 1658 Cromwell gave the town the right of separately returning a member of its own, but this right lapsed with the Restoration. In 1832 John's, St Thomas and parts of the parishes of Llansamlet and Llangyfelach were added to the parliamentary borough of Swansea, to which along with the boroughs of Neath, Aberavon, Kenfig and Loughor a separate representative was given. In 1836 the municipal borough was made coextensive with the parliamentary borough and continued so till 1868, when some further additions were made to the latter, with which the municipal borough of Neath was also united. Meanwhile in 1885 the parliamentary constituency was made into two divisions with a member each, namely Swansea Town consisting of the original borough with St John's, and Swansea District consisting of the remainder of the borough with the four contributory boroughs. In 1888 Swansea was made a county borough and in 1000 the various parishes constituting it were consolidated into the civil parish of Swansea. Its total area is 5104 acres. The corporation consists of 10 aldermen and 50 councillors. The assizes and quarter sessions for Glamorgan are held at Swansea alternately with Cardiff. The borough has a separate commission for a peace, and, since 1891, a court of quarter sessions.

The population of the old borough was 6090 in 1801 and 13,256 in 1831; after the first extension it amounted to 24,604 in 1841. The population in 1901 was 94,537. Of those who were three years of age and upwards, nearly 67 % were returned as speaking English only, 20% as speaking both English and Welsh, and 3% as speaking Welsh only.

History.—No traces of any Roman settlement have been discovered at Swansea, though there seems to have been a small one at Oystermouth, 5 m. to the south, and the Via Britannica, which led from London to Dinas on the northern part of the present borough, where a large quantity of Roman coins was found in 1835. The name Swansea stands for Swynniy's "ey" or inlet, and may have been derived from King Swynw Forkeard, who certainly visited the Bristol Channel
and may have established a small settlement at the estuary of the Tawè. The earliest known form of the name is Svey-
nesse, which occurs in a charter granted by William earl of
Warwick some time previous to 1184; in King John’s charter
(1215) it appears as Swaynehes, and in the town seal, the
origin of which is supposed to date from about the same period,
it is given as “Sweye.” An attempt has been made to derive
the name from Sein Henydd, the Welsh name of a Gower castle
which has been plausibly identified with the first castle built
at Swansea, but that derivation is etymologically impossible.
The Welsh name, Aber Tawè, first appears in Welsh poems of
the beginning of the 13th century. The town grew up round
the castle which Henry de Beauchamp (or Beaumont) on
his conquest of Gower about 1099, built on the west bank of
the river. The castle passed with the lordship or seigniory of
Gower, of which it was the caput, into the hands of the De
Braose family in 1203 (by grant from King John) and eventually
it came by marriage to the Somersets and is still held by
the dukes of Beaufort, whose title of barons de Gower dates from
1306. The castle was frequently attacked and on several
occasions more or less demolished, in the 12th and 13th cen-
turies. In the last year of the 12th century, the Earl of
Hereford, in the capacity of Dyvorser, it was visited by King
John in 1210 and probably by Edward II. In 1326, for,
after its capture, the encampment rolls were found de-
posited in the castle and were thence removed to Hereford.
It was finally destroyed by Glendower, was a "ruinous build-
ing" when seen by Leland (1536) and has since wholly disap-
ppeared. In the Civil War the town was royalist till the autumn
of 1645 when Colonel Philip Jones, a native of the adjoining
parish of Llanglyfelach and subsequently a member of Crom-
well’s upper house, was made its governor. Cromwell stayed
in the Welsh name, Aber Tawè, for several years in Welsh poems
and Ireland respectively, and later showed it exceptional favour
by giving it a liberal charter and parliamentary representation.
The town claimed to be a borough by prescription, for its
only known charters of incorporation are those of Cromwell
and James II., which were never acted upon. It probably
received its first grant of municipal privileges from William
3rd earl of Warwick some time before 1184. By a charter of
1215 (confirmed by Henry II. in 1234, by Edward II. in 1312
and Edward III. in 1332), John himself granted the burgesses
the right of trading, free of all customs dues, throughout the
wholesomeness of the land, and their lord the Tag of Emo.
This grant was extremely limited to the seigniory. By 1305 the burgesses had be
come so powerful as to want a more liberal grant of privileges from their then seigneur William de Braose (fourth in descent from his namesake to whom Gower was granted by King John in 1203), and he bound himself to pay £500 to the king and 500
marks to any burgess in the event of his infringing any of the rights contained in it. By this charter the burgesses acquired the right of nominating annually two of their number for the office of portreeve so that the lord’s steward might select one of them to exercise the office, an arrangement which continued till 1835; the bailiff’s functions were defined and curtailed, and the lord’s chancery was to be continually kept open for all requiring writs, and in Gower—not wherever the lord might happen to be. A patent of murage and pavage—from which it may probably be inferred that Swansea was a walled town—
was granted by Edward II. in 1317 and another by Edward
III. in 1338. Cromwell’s charter of 1655, though reciting that “time out of mind” Swansea had been “a town corporate,” incorporated it anew, and changed the title of portreeve into
mayor, in whom, with twelve aldermen and twelve capital bur-
gesses, it vested the government of the town. The mayor,
ex-mayor and one selected alderman were to be justices of the
peace with exclusive jurisdiction and the mayor was the coroner.
Four annual fairs were appointed, namely on the 8th of May,
2nd of July, 15th of August and 8th of October—the first, how-
ever, being the only new one. In 1658 the protector by another
charter granted the town independent representation in par-
liament. At the Restoration, Cromwell’s charters lapsed, but
in 1665 James II. granted another charter which contained the
arbitrary proviso that the king by order in council might
remove any officer or members of the corporation. This charter
was not adopted by the burgesses.
De Braose’s charter of 1305 bears some evidence to the im-
portance of the shipping of Swansea even at that date, for
by it there was granted or confirmed to the burgesses the right
to take from the lord’s woods’ sufficient timber to make four
great ships at a time and as many small vessels as they wished.
Coal was even then worked in the district. Cromwell in his
charter of 1655 recognized Swansea as “an ancient port town
and her town and city situate on the sea coast towards France conve-

tient for shipping and resisting foreign invasions.” Its status
was only that of a “creek” in the port of Cardiff till 1685,
when it was made an independent port with jurisdiction over
Newton (now Porthcawl), Neath or Briton Ferry and South
Burry, its limits being defined in 1847 as extending from Nash
Point on the east to Whitford Point on the west, but in 1904
Port Talbot, which was included in this area, was made into
a separate port.
From about 1768 to 1830 Swansea had a somewhat famous
apottery. Beginning with earthenware which twenty years
later was improved into “opaque china,” it produced from
1814 to 1823 superior porcelain which was beautifully decorated
with landscapes, birds, butterflies and flowers and is much prized
by connoisseurs. During a short period (1845-1850) an imita-
tion of Etruscan ware was also produced with figures of rich
red colour over a body of black.

SWANWICK, ANNA (1833-1890), English writer and philan-
thropist, was the youngest daughter of John Swanwick of
Liverpool, and was born on the 22nd of June 1833. She
was educated partly at home and partly at one of the fashionable
boarding-schools of the day, where she received the usual edu-
cation of accomplishments. Dissatisfied with her own intel-
lectual attainments she went in 1859 to Berlin, where she
took lessons in German, Greek and Hebrew. On her return to
London she continued these pursuits, along with the study
of mathematics. In 1853 appeared her first volume of transla-
tions, Selections from the Dramas of Goethe and Schiller. In 1857 she
published a translation of Schiller’s Jungfrau von Orleans;
this was followed in 1859 by Faust, Tasso, Iphigenie and Egmont.
In 1878 she published a complete translation of both parts of
Faust, which appeared with Retch’s illustrations. It passed
through several editions, was included in Bohn’s series of trans-
lations, and ranked as standard work. It was at the sug-
gestion of Baron Bunsen that she first tried her hand at trans-
lation from the Greek. In 1865 she published a blank verse
translation of Aeschylus’s Trilogy, and in 1873, a complete
edition of Aeschylus, which appeared with Flaxman’s illus-
trations. Miss Swanwick is chiefly known by her translations,
but she also published some original work. In 1886 appeared
Books, our Best Friends and Deadliest foes; in 1888, An Utopian
Dream and How it may be Realized; in 1892, Poets, the Interpre-
ters of their Age; and in 1894, Evolution and the Religion of
the Future. Miss Swanwick was interested in many of the
social and philanthropic movements of her day. In 1861 she
signed John Stuart Mill’s petition to parliament for the political
enfranchisement of women. She helped in the higher education
movement, took part in the foundation of Queen’s and Bed-
ford Colleges, and continued to take a sympathetic interest in
the movement which led to the opening of the universities to
women. Her work was acknowledged by the university of Aberdeen,
which bestowed on her the degree of L.L.D. She died in
November 1899.
See Memoir, by Miss Bruce (1904).

SWARTZ, OLOF (1760-1818), Swedish botanist, was born
in 1760. He commenced his botanical studies in Upsala, under
Linnaeus and Thunberg, and began early to make excursions. He made a voyage to America in 1783, visited England in 1788, returned to Sweden in 1789, and was made professor of natural history in Stockholm. He was the author of many systematic works, and largely extended our knowledge of both flowering plants and cryptogams. He died in 1818.

SWAT, a tract on the Peshawar border of the North-West Frontier province, consisting of the valley of the Swat river above its confluence with the Panjorka. This valley is some 70 m. long, varying from 10 m. to a few hundred yards in breadth; it is intersected by ravines and glens, which bring down the drainage of the ranges on either side. Only a portion of the valley which lies beyond the Peshawar frontier hills, and which is reached by the Malakand, the Shakhtot and other passes from the south, is SWAT. To the east are the independent hill tracts of Kohistan and Buner, all bordering the Indus, and to the west are Dir and Bajour.

The Swat river rises among snow mountains in the Kohistan, not far from the source of the Gilgit river. After flowing due south for nearly 70 m., it turns to the west and is joined by the Panjorka. It then passes through the Mohmand country, and on entering Peshawar district spreads out to the southeast in many channels which ultimately fall into the Kabul river. Total length about 400 m. In British territory its waters have been utilised by a series of canals to irrigate an area of about 160,000 acres; and the system is now being extended by means of a tunnel through the Malakand range, which will tap the river of much higher up.

Swat was better known to the ancients, and to the warriors of Baber's time, than it was to us until the frontier risings of 1895-97 gave British surveyors the opportunity of visiting the country. The ancient name of the river was Suastos, and that of the Panjorka was Ghoura, under which names they figure in the history of Alexander's campaign. The site of the city Massaga, the capital of the Assakeni, is supposed to be near the modern Manglaur. But since the adoption of the Khyber as the main high road from Kabul to Ind and the Swat routes had passed into oblivion. Only the lower portion of the Swat valley, where the river intervenes between Malakand and the passes leading to Dir from the Panjorka, is of military significance. The upper valley is closely gripped between mountain spurs stretching southwards from the Hindu Koh, rising to 1,500 ft. on one side and 19,000 ft. on the other, leaving but a narrow space between their rugged summits and the banks of the river. The valley, narrow though it is, and traversed by the worst conceivable type of hill tracks, contains many villages or hamlets, and is pretty thickly populated. The district has come into prominence of recent years, on account of its lying on the direct road to Chitrall.

The Swatis are a clan of Yusafzai Pathans numbering 40,000 fighting men but are of weakly and thin physique, due to the malaria with which the valley is saturated. They are divided into three main clans, the Baizais, Ranizais and Khwaz-ozais. They had not much name for valour, but they opposed a stout resistance to Sir Robert Low's advance over the Malakand Pass in 1893 to the relief of Chitrall; and again in 1897, under the influence of fanaticism, they showed desperate bravery in the attack on the Malakand and British garrison and their Mohommedans, and have earned the reputation of being the most bigoted of all the Afghan tribes. For many years they were under the religious dominance of the Akhund of Swat, Abdul Ghafur, who, born in 1794, obtained ascendance by means of his ascetic practices, ruled practically undisputed in Swat for the last 30 years of his life, and died in 1877. The Akhund, after his experience of the British strength in the Umbeyla Campaign of 1863, always exerted his influence in favour of peace with the British government, though in his earlier days he was sometimes troublesome. He was succeeded by his son Mian Gul, who never possessed the same influence as his father.

SWATOW (also Shaowow), a port of China, in the province of Kwang-tung, opened to foreign trade in 1860. The population is upwards of 60,000. The town is situated at the mouth of the main branch of the river Han, which 30 miles inland flows past the great city of Chi'achow Fu or Tai-chu (Tie-chu), while the surrounding country is more populous and full of towns and villages than any other part of the province. The climate is good, but being situated at the southern end of the plateau, the town is exposed to the full force of the typhoons, and much destruction is occasionally wrought. English merchants settled on Double Island in the river as early as 1826; but the city, which is built on ground but recently recovered from the sea, was formerly a mere fishing village. The trade of the port has rapidly increased. In 1869 the total value of the trade was £4,800,000, in 1884 £5,519,772, and in 1904 £7,063,579. The surrounding country is a great sugar-cane district producing annually about 2,400,000 cwt. of sugar, and there is an extensive refinery in the town employing upwards of 600 workmen and possessing a reservoir for 7,000,000 gallons of water. Next in value comes the manufacture of bean-cake, which is also imported in large quantities from Niuchwang, Chifu, Shanghai, Amoy and Hong-Kong. Among the leading exports are tea (since about 1872); grass-cloth, manufactured at Swatow from so-called Taiwan hemp (the fibre of the Boehmeria nivea from Formosa); pine-apple cloth, manufactured in the villages about Chieh-Yang (a town 22 m. distant); oranges, for which the district is famous; cheap fans; and pewter, iron and tin wares. Swatow is also a great emigration port and for the scene of many kidnapping adventures on the part of foreigners in the early days. Their outrages gave rise to much hostile feeling towards foreigners who were not allowed to enter the city of Chi'achow Fu until the year 1861. Of the whole foreign trade of the port upwards of 83% is in British bottoms, the trade with Hong-Kong being of especial importance.

About 1865 the whole Swatow district was still divided into a number of "independent townships, each ruled by its own headmen, and the population was described in the official gazetteer, as generally rebellious and wicked in the highest degree. Mr Forrest, British consular agent, relates that in that year he was witness to the preparations for a fight between the people living on the opposite sides of the estuary, which was only prevented by a British war- vessel. The T'ai-p'ings swept over the country, and by their ravages and plundering did much to tame the independence of the clans. The punishment inflicted in 1869 by Commander Jones on the inhabitants of Otingpui (Ou-ting-pel), about 8 m. from Swatow, for the attack they had made on the boats of H.M.S. "Cockchafer," showed the Chinese authorities that such piratical villages were not so easily subdued. Within the last year or two, the native of Chi'achow Fu) was sent to reduce the district to order, and he carried out his instructions with remorseless rigour.

SWAZILAND (native name Pungwane), a country of British South Africa bounded S., W. and N. by the Transvaal, E. by the Portuguese possessions at Delagoa Bay and the Ingwavuma division of Zululand. It lies between the Drakensberg and Lebombo Mountains and is separated from the Indian Ocean by low land varying in width from 30 to 50 m. It has an area of 65,548 sq. m. (being somewhat larger than Yorkshire). The height of the mountains (1904), of 9,545, and 9,896 ft. whites were whites. The natives are nearly all Amaswazi Bantus, commonly called Swazis, and are closely allied to the Zulus.

Spurs from the Drakensberg occupy a large part of the country, which may be divided into three parallel belts running north and south. The western belt is that of the Maputulu and the northern belt of the Komati (g.v.) and the Umbeloi. The Umbeloi has two chief headstreams, the Black and the White Umbeloi, the White branch being the more southerly. The climate is warm but healthy wave in some of the river valleys. The flora and fauna differ in no
SWAZILAND

185

essential respects from the corresponding regions of the Transvaal and Zululand (see those articles).

Towns and Communications.—The seat of the administration is Embaabaana (Mbabane), a town on a northern tributary of the Usutu (60 m.), and the capital of the Swaziland Colony and administration of the Tugela Valley, about 18 m. east of Johannesburg. It replaced (1904) the former capital of Bremersdorp situated in the middle veld 23 m. south-east of Embaabaana, and destroyed by Boer forces during the war of 1899-1901. The settlement of Mbabane was named after the British explorer Sir Henry Mares, who, long runs through Portuguese territory to the Swaziland border at Umbelizoe Poort. This line is the eastern link in the direct railway connexion designed to make the Tombozi (the Swazi) fertile. On it has been constructed.

There is telegraphic connexion with the Transvaal.

Industry and Trade.—The soil is generally fertile. On the high veld, where green herbage is found all the year round, large numbers of sheep and cattle are pastured. This region serves as a winter grazing ground for sheep from the Transvaal. The middle veld is suitable for grain crops as well as bananas, sugar, coffee, tea and other semi-tropical produce. Millet, maize, pumpkins and ground-nuts are extensively cultivated. On the low veld cotton is grown, but the variety is scanty and the price low.

Besides agriculture the only considerable industries are gold, tin and coal mining. The goldfields, situated in the north-western part of the country, are a continuation of the De Kaap (Barberton) field. Theyield of gold, however, is by no means such as to be of great extent. Up to the outbreak of the Anglo-Boer War in 1899 the value of the gold exported from Swaziland was about £300,000. Gold mining re-started on a small scale in 1904. The output for 1906-1907 was 63,000 t., and in 1908-1909, 102,000 t. was successfully in the neighbourhood of Embaabaana, casseriterite to the value of £45,000 being exported in 1905-1907. The output for 1908-1909 was valued at £36,000. Anthracite coal occurs in quantity on the eastern part of the country.

Administration, &c.—Swaziland forms a crown colony under the government of the High Commissioner for South Africa. It is administered by a resident commissioner. Legislation is by ordinance. Roman-Dutch common law prevails except when modified by statute. The costs of Swaziland are met from the general revenue of the country.

The chiefs are customarily respected as the heads of the four groups of the nation. The administration has a few schools, and the education is largely received.

History.—The Abaswe tribe is believed to have occupied the country now known as Swaziland from the period of the invasion of South East Africa by the Bantu peoples. They were formerly called Ba-Rapuza or Barabuza after a chief under whom in the 18th century they acquired homogeneity. In the early part of the 19th century they fell under the domination of the newly constituted Zulu nation. In 1843, the year in which the British annexed Natal and with it a part of the country hitherto ruled by the Zulus, the Barabuza, under a chief named Swazi, took advantage of the comparative weakness of the Zulu power, achieved independence and founded the present state. According to Kanes, the custom they adopted the name of their deliverers. The Boers of the Transvaal began to move into the regions adjacent to Swaziland and in 1855 the Swazis in order to get a strip of territory between themselves and the Zulus, whose power they still dreaded, ceded to the Boers the narrow strip of land north of the Pongola river now known as the Piet Retief district. The Zulus under Cetywayo claimed the ceded district as their own, and the Swazis as their subjects and for over ten years no white farmers were able to settle in the district. With the Boers the Swazis remained on friendly terms and this friendship was extended to the British on the occupation of the Transvaal in 1877. In 1879 they joined the British in the attack on the Bapedi chief Sikukuni, whom they looked upon as an ally of the Zulus.

They captured from Sikukuni certain "rain medicine," the possession of which has since greatly increased the prestige of the paramount chief of the Swazis among the Kafirs of South Africa. On the retrocession of the Transvaal in 1881 the independent status of the Swazi nation was recognized by the Boers. The Pretoria convention of that year defined the boundaries of the country. By the London convention of 1884 the Transvaal again recognized the independence of Swaziland. Immediately afterwards, however, the Boers began a series of efforts to obtain control of the country. In 1886 the governor of Natal received a paper from Umbandine (Mbandini), the paramount chief of the Swazis, stating that Piet Joubert had called on him and requested to sign a paper saying that "he and all the Swazis agreed to go over and recognize the authority of the Boer government, and have nothing more to do with the English. On his refusal the Boers reply to him, why then refuse to sign the paper? You know we defeated the English at Majuba." The Boers further added that if the Swazis were relying on the British, they were leaning on a broken reed, and would find themselves left in the lurch. Umbandine followed up this communication with a request for British protection, but without result. Later on, in 1887, both Boers and gold prospectors of all nationalities were overrunning his country, and Umbandine asked for a British resident. This request was also refused. The Boers now determined to adopt towards Swaziland the policy which had proved so successful in Zululand, and endeavoured to force them to cede valuable parts of their territory. A considerable body of British soldiers was sent to within the Swazi territories and proclaimed "The Little Free State." Umbandine was then at length induced to ask the Transvaal for annexation.

The Transvaal applied in 1889 to Great Britain for permission to accede to this request, but the British government replied that the only intervention to which they would consent must be a dual one. Consequently a joint commission was appointed to visit Swaziland and report on the condition of things there. Sir Francis de Winton, the British commissioner, who was accompanied by Generals Joubert and Smit on behalf of the Transvaal, reported that Umbandine had already granted to the British crown certain concessions, such as postal, telegraphic, banking, customs, &c., to the Transvaal, and concessions of land mining and grazing rights to various adventurers. Umbandine had in short granted concessions of every conceivable character, including exemption from taxation. A charter of self-government had also been granted (1888) to the whites in the country. In the circumstances de Winton considered a British protectorate inadvisable and impracticable. A dual control was arranged in 1890, but the convention then signed proved abortive owing to the objection of the Transvaal to join the South African Customs Union. In 1893 a further convention was drafted, but after negotiations between Lord Carnarvon, high commissioner for the Transvaal, and President Kruger, the result of which was that the administration of Swaziland, with certain reservations as to the rights of the natives, was made over to the South African Republic. In the following year six Swazi envoys visited England for the purpose of asking Queen Victoria to take Swaziland under her protection. In view, however, of the arrangement come to, this petition had to be refused. In 1894 a convention was signed between Great Britain and the Transvaal, and the Boers, in spite of the Swazi opposition, assumed administration of the country. The Boers' object in intriguing to acquire Swaziland was not merely that of obtaining that country; they desired also to annex the coast lands to its east and thus obtain—at Kosi Bay—a seaport of their own. This object they might have attained if they had agreed to de Winton's proposals, but Great Britain in view of the increasingly hostile attitude...
SWEARING—SWEATING-SICKNESS

assumed by the Transvaal government now intervened and by
annexing in 1884 Transvaal, the region in question, blocked
the Boers' further progress towards the sea (see SOUTH AFRICA:
History).

Swaziland suffered during the struggle between the Transvaal
and Great Britain as to its destiny. Umbandine died in 1889
and had various successors. Ilavanu, installed by the Boers
as paramount chief in 1894, was a sanguinary despot and
was compelled to flee in 1899. The principal convention
for which Umbandine was defeated, however, his widow Naba
Taiben, known to Europeans as the queen regent. She more
than once appealed to the British to cause the Boers to respect
the terms of the conventions, and before the outbreak of the
Anglo-Boer war in 1899 she took the side of the British.

On the annexation of the Transvaal in 1901 the queen regent asked
that Swaziland might be annexed also. On the cessation of hostilities a British special commissioner was sent into the
country—then in a condition bordering on anarchy—and a pro-
visional administration established. In June 1903 an order in
Council formally conferred the government of the country on
the governor of the Transvaal (then Lord Milner). Lord Milner
visited Swaziland in July 1904 and denounced "the abominable
network of concessions" in which the country was entangled.

On the 3rd of October following the governor issued a pro-
clamation providing further for the administration, and for the
expropriation of the concessions other than those relating to
land and minerals. In September 1906 Lord Selborne, who had
succeeded Lord Milner, conferred with the queen regent and her
council on questions specially affecting the natives. A Swazi
sovereign born about 1889 was selected as para-
mount chief, Naba Taiben, his grandmother, being confirmed
as regent during his minority. In December 1906 the control of
Swaziland was severed from the government of the Transvaal
and transferred to the High Commissioner for South Africa,
and in March 1907 a resident commissioner was appointed.

When the Union of South Africa was established in 1910,
Swaziland, with other native territories, remained under direct
Imperial control.

SWERING (O. Eng. sweiring, to swear, originally to speak aloud,
ciaud, and sweiring, to answer, Ger. schwören, Dan. svørga,
dc., all from root svør- , to make a sound, cf. "swarm," pro-
perly buzzing of bees, Lat. suspurrus), the affirmation or utter-
ing of a solemn declaration with an appeal to the Deity, some
holy personage or sacred object as confirmation, hence the act
of declaring the truth of a statement upon oath (see OATH
and EVIDENCE). The common use of the word is for the uttering
of profane oaths or curses. In English law, when blasphemy
(g. b.) was at common law an indictable offence, cursing or
swearing was left to the ecclesiastical courts. The Profane
Oaths Act 1745 inflicted a sliding scale of fines for the use of
profane oaths according to the rank of the offender, 1s. for
a common labourer, 5s. for a soldier or seaman, 2s. for everyone below
the rank of gentleman and 5s. for those of or above that rank; the
procedure under this act is regulated by the Summary Juris-
diction Acts. By s. 8 of the Town Police Clauses Act 1847
the use of profane or obscene language is an offence punishable
on summary conviction by a fine not exceeding 40s. or
imprisonment not exceeding 14 days. The offence must be
committed in a street and the act is confined to urban sanitary
districts or to such rural districts to which s. 276 of the Public
Health Act 1875 has extended it. By s. 12 of the Metropolitan
Police Court Acts 1839 a similar offence is punishable in the
metropolitan police area, and various districts have put in force
by-laws for punishing swearing, cursing, or causing annoyance
in public places. The restriction as to the place where the
offence must be committed to be liable to punishment has led to
the enforcement on occasions of the Profane Oaths Act,
which applies to the whole of England and Wales and is not
limited to cursing in the streets. It should not, however,
apply to obscene language.

SWEATING-SICKNESS. A remarkable form of disease, not
known in England before, attracted attention at the very
outbreak of the reign of Henry VIII. It was known, indeed, a few days after the landing of Henry at Milford Haven on the
7th of August 1485, as there is clear evidence of its being
spoken of before the battle of Bosworth on the 22nd of
August. Soon after the arrival of Henry in London on the
28th of August it broke out in the capital, and caused
great mortality. This alarming malady soon became known
as the sweating-sickness. It was regarded as being quite
distinct from the plague, the pestilential fever or other
edemics previously known, not only by the special symptom
which gave it its name, but also by its extremely rapid and fatal

From 1485 nothing more was heard of it till 1507, when the
second outbreak occurred, which was much less fatal than the
first. In 1517 was a third and much more severe epidemic.
In Oxford and Cambridge it was very fatal, as well as in other
towns, where in some cases half the population are said to have
perished. There is evidence of the disease having spread to
Calais and Antwerp, but with these exceptions it was confined
to England.

In 1528 the disease recurred for the fourth time, and with
great ferocity. It first showed itself in London at the end of
May, and speedily spread over the whole of England, though
not into Scotland or Ireland. In London the mortality was
very great; the court was broken up, and Henry VIII. left
London, frequently changing his residence. The most remark-
able fact about this epidemic is that it spread over the
Continent, suddenly appearing at Hamburg, and spreading
so rapidly that in a few weeks more than a thousand persons
died. Thus was the terrible sweating-sickness started on a
destructive course, during which it caused fearful mortality
throughout eastern Europe. France, Italy and the southern
countries were spared. It spread much in the same way as
cholera, passing, in one direction, from north to south, arriving
at Switzerland in December, in another northwards to Denmark,
Sweden and Norway, also eastwards to Lithuania, Poland and
Russia, and westwards to Flanders and Holland, unless indeed
the epidemic, which declared itself simultaneously at Antwerp
and Amsterdam on the morning of the 27th of September,
came from England direct. In each place which it affected it
prevailed for a short time only—generally not more than a
fortnight. By the end of the year it had entirely disappeared,
except in eastern Switzerland, where it lingered into the next
year; and the terrible "English sweat" has never appeared
again, at least in the same form, on the Continent.

England was, however, destined to suffer from one more out-
break of the disease, which occurred in 1551, and with regard
to this we have the great advantage of an account by an eye-
itness, John Kaye or Caius, the eminent physician.

Symptoms. The symptoms as described by Caius and others
were as follows. The disease began very suddenly with a sense of
apprehension, followed by cold shivers (sometimes very violent);
giddiness, headache and severe pains in the neck, shoulders and
limbs, with great prostration. After the cold stage, which might
last from ten to half an hour and sometimes up to three hours, followed the stage of heat
and sweating. The characteristic sweat broke out suddenly, and,
as it seemed to those accustomed to the disease, without any
obvious cause. With the sweat, or after that was poured out,
came great distress of heart and lungs, with palpitation, throb,
pulse and intense thirst. Palpitation and pain in the heart were
frequent symptoms. No eruption of any kind on the skin
was generally observed; Caius makes no allusion to such a symptom. In the throat there may have been cough, hoarseness
or an irresistible tendency to sleep, which was thought to be fatal
if the patient were permitted to give way to it. The malady was
1 GugenbühI, Der englische Schweiz in der Schweiz (Lichtensteig,
1858).
SWEATING SYSTEM

187

 remarked rapid in its course, being sometimes fatal even in two or three days, and in these cases, not more than one case than that time. Moreover, it was protracted to a period of twelve to twenty-four hours, beyond which it rarely lasted. Those who survived for twenty-four hours were considered safe.

As with the plague, the sweating-sickness was not especially fatal to the poor, but rather, as Caius affirms, attacked the richer sort and those who were free livers according to the custom of England in those days, and was most prevalent with people who were men of wealth, ease or welfare, or of the poorer sort, such as idle persons, good ale drinkers and taverners.  

Causes.—Some attributed the disease to the English climate, its moderate habits, the temperate climate, and the habits of the people, and to the frightful want of cleanliness in their houses and surroundings which is noticed by Erasmus in a well-known passage, and about which Caius is equally explicit. But we must conclude with Hecker that the sweating-sickness is not, either separately or collectively, to produce the disease, though each may have acted sometimes as a predisposing cause. The sweating-sickness was, in fact, to use modern language, a specific infective disease, in the same sense as plague, typhus, scarlatina or malaria.

The only disease of modern times which bears any resemblance to the sweating-sickness that is known as military fever ("Schwitz-friesel" "sweat miliaria" or the "Picardy sweat"), a malady which has been repeatedly observed in France, Italy and southern Germany, but not in the United Kingdom. It is characterized by severe sweating, and occurs in limited epidemics, not lasting in each case more than two or three days, in an individual or an Institute. On the other hand, the attack lasts longer than the sweating-sickness did, is usually accompanied by eruptions of vesicles, and is not usually fatal. The first clearly described epidemic (though not as a sweat-sickness) occurred before the last in 1861. Between these dates some one hundred and seventy-five epidemics have been counted in France alone.

For a short history see Bacon's Life of Henry VII, and the chronicles of Grafton, Holinshed, Baker, Fabyan, &c. The only English medical account is that of John Caius, who wrote in English A Boke or Counsell Against the Disease commonly called the Sweate, or Sweating Sickness (London, 1552); and in Latin De ephemeria britannica (Louvain, 1556; reprinted London, 1721). The English tract is reprinted in Babington's translation of Hecker's Epidemics of the Middle Ages (Syd. Soc., 1844). This also contains Hecker's valuable treatise on the English sweating sickness of the 16th century (1834), and also printed in his Volkskunde der Mittelalter, edited by Hirsch (Berlin, 1865). Grüner's Scriptores de sudore anglico (Frankfort, 1847), contains nearly all the original documents, including the writings of Caius. See also Hirsch, Handbook of Geographical and Historical Pathology, trans. by Creighton (New Syd. Soc., 1885).

SWEATING SYSTEM, a term loosely used in connection with oppressive industrial conditions in certain trades. This "system" originated early in the 19th century, when it was known as "the contract system." Contractors supplying the government with clothing for the army and navy got the work done by giving it out to sub-contractors, who in some cases made the garments and sold them at a profit; in others the sweaters, with the workman, are called the sub-contractor or subcontractor, and in others sublet their sub-contracts to men who carried them out with similar help. Afterwards this plan was adopted in the manufacture of ready-made clothing for civilian use, and of "bespoke" garments (made to the order of the customer). Previously the practice had been for coats, &c., to be made up by workmen employed on the premises of the master tailor or working together in common workshops, but in either case directly employed by the master tailor. The new plan brought a large number of workpeople possessing little skill and belonging to a very needy class into competition with the regular tailors and showed that the sweaters, with the workman, are called the sub-contractor or subcontractor, and in others sublet their sub-contracts to men who carried them out with similar help. Afterwards this plan was adopted in the manufacture of ready-made clothing for civilian use, and of "bespoke" garments (made to the order of the customer). Previously the practice had been for coats, &c., to be made up by workmen employed on the premises of the master tailor or working together in common workshops, but in either case directly employed by the master tailor. The new plan brought a large number of workpeople possessing little skill and belonging to a very needy class into competition with the regular tailors and showed that the sweaters, with the workman, are called the sub-contractor or subcontractor, and in others sublet their sub-contracts to men who carried them out with similar help. Afterwards this plan was adopted in the manufacture of ready-made clothing for civilian use, and of "bespoke" garments; garments made up in insanitary surroundings, the matter attracted little public notice until 1834, when the system again came into prominence in connexion with the immigration of poor foreigners into East London, where large numbers of these people were employed in various trades, especially in the tailoring, boot-making, and cabinet-making industries, under conditions generally similar to those complained of in the earlier agitations. In 1888 a select committee of the House of Lords was appointed to inquire into the subject; and after a lengthy investigation—in the course of which evidence was given by 291 witnesses in relation to tailoring, boot-making, furrery, shirt-making, mantle-making, cabinet-making and upholstery, cutlery and hardware manufacture, chain and nail-making, military accoutrements, saddlery and harness-making, and other handicrafts. The committee presented its final report in April 1890. The committee found themselves unable to assign an exact meaning to the term "sweating," but enumerated the following conditions as those to which that name was applied: "(1) A rate of wages inadequate to the necessities of the workers or disproportionate to the work done; (2) excessive hours of labour; (3) the insanitary state of the houses in which the work is carried on. They stated that, "as a rule, the observations made with respect to sweating apply, in the main, to unskilled or only partially skilled workers, as the thoroughly skilled workers can almost always obtain adequate wages."

With regard to the sweating system, the committee declared that this cannot be regarded as responsible for the industrial conditions described; for "the middleman is the consequence, not the cause of the evil; the instrument, not the hand which gives motion to the instrument, which does the mischief. Moreover, the middleman is found to be absent in many cases in which the evils complained of abound." While, on the one hand, we find, as pointed out by this committee, that "sweating" exists without the presence of the "middleman," (the fact being that many grossly underpaid workpeople are in the direct employment of large firms), it is, on the other hand, the "sub-contractor or subcontractor" who is common in numerous trades in which there is no trace of any such oppression of the workpeople employed by the sub-contractors as is denoted by the term "sweating." Thus, for example, in shipbuilding in many cases men work in squads, the leading workmen employing their own helpers; in the cotton trade the mule-minders engage and pay their own pieces, and the weavers their own tenets; in the manufactured-iron trade, in mining, &c., a good deal of work is done under sub-employers employing their own assistants, none of these sub-contractors being alleged to "sweat" their helpers. There is, in short, no system of employment which can properly be called "the sweating system." At the same time, whatever workers possessing a small degree of skill and deficient in organization are employed under a number of small masters, there "sweating" is likely to occur.

The common idea that the "sweater" is an unscrupulous tyrant, who fulfils no useful function, and who makes enormous profits, has no counterpart in fact. Whatever may have been the case in earlier days, before the interminable competition of the "middlemen" had time to produce its inevitable effects upon the position of these sub-employers, it may now be considered to be of no consequence in the context. The "too great," "too little," and "too large" employment which is injurious to the individuals." The committee also found that "sweating" is likely to occur in the case of those who do not work. He is also free from restrictions as to the subdivision of labour and the employment of a certain class of workpeople which the detriment of the regular factory workers would impose upon him. The regular tailor, for example, thinks that no one who has not, by a lengthy period of tuition,
acquired the capacity to make a coat "right out" ought to be allowed to enter the tailoring trade. But in the workshop of the sub-contractor the work is split up into fractions, each of which is soon learned, so that it becomes possible to introduce into the trade persons possessing no previous training, and generally willing to work for wages far lower than those to which the regular tailors consider themselves entitled, and which, so long as they are not exposed to the competition of these outsiders, they are usually able to secure. On the other hand, while it may suit the manufacturer, anxious and keen to increase his own share of production, to give his work out to middlemen, it is beyond question that any form of the "small master" system is necessarily liable to abuse in many directions. Among these small masters the eagerness to secure employment is usually so keen that the work is often taken at a price too low for it to be possible for these sub-employers to pay to their workpeople wages adequate to provide the reasonable requirements of working-class life. The workshops of the middlemen are scattered over large districts, and these little masters frequently move their business from one to another. Both of these are instinctances which tend strongly to make efficient regulation by the factory and the sanitary inspectors very difficult. Not seldom, especially when trade is brisk, these work-places are overcrowded in a manner injurious to health, and in not a few cases their sanitary condition is defective. It will readily be understood that combination among the people employed in these numerous small isolated work-places is much less easy than among the compact bodies of workers employed in large factories, so that any attempt to resist oppressive conditions of employment by combination organization meets with serious obstacles. But perhaps the worst of all the features which this method of manufacture presents is the absence of motor power and machinery. The fact that a manufacturer has laid out a large sum in plant, thus entailing a heavy expenditure in "standing charges," necessarily induces him to do his best to make employment regular. In the little outside workshop, on the other hand, lengthy spells of enforced idleness are followed by short periods of most severe toil, during which the hours of daily labour are prolonged to an inhuman extent. At the same time, the workpeople employed in the ill-equipped workshop of the little master are competing with the much more efficient production of the factory provided with labour-saving machinery driven by steam or other mechanical power; and in many cases their only chance of retaining the work under these circumstances is to take it at starvation prices. But the progress of invention moves fast, and antiquated methods of production are gradually being abandoned. Already, in many of the trades in which the sweating system has hitherto largely prevailed, especially in the tailoring, the boot-making, the cabinet-making and the nail-making industries, the factory system is coming so far to the front in the race for cheapness of production that, although in certain industrial centres, in which the rents of factories are high and a specially abundant supply of needy and unskilled workpeople is available, a good deal of work is still given out to small outside masters, the proportion of the total output manufactured in this manner is day by day diminishing. (D.Sch.)

An endeavour has been made in the United Kingdom to combat legislatively the evils of sweating. The Trade Boards Act 1909 established trade boards for trades to which the act applied. The trades specified were ready-made and wholesale tailoring, the making of paper or chip boxes, machine-lace making and chain-making, but the board of trade was given power to apply the Act to any other trade if it so desired. The Act requires traders to fix, subject to certain restrictions, minimum rates of wages with a view to the standardization of wages paid in the same trade for their trades, while they may also fix general minimum rates of wages for work, and these rates may not be applied either universally to the trade, or to any special process in the work of the trade or to any special class of workers, or to any special period of the year. There must become obligatory by order of the board of trade upon the expiration of six months from the date when made by a trade board, but they may, in the meantime, have a limited operation (1) in the absence of a written agreement; (2) where an employer has given written notice to the board of trade that he is willing to pay them; and (3) in the case of contracts with government departments and local authorities. If the minimum rate of wages has been made obligatory and an employer has already paid a lower rate of wages, he is liable to a penalty of not exceeding £20 in respect of each offence and to a penalty of not exceeding £5 for each day on which the offence is continued. The Act provides for the imposition of an additional tax, in addition, a sum equal to the wages due. The trade boards consist of an equal number of representative members of employers and workers, together with appointed members whose number must be specified by Act. The board of trade may also establish district trade committees with a constitution similar to their own and may delegate to them their powers and duties under the act. Women are eligible for membership of trade boards or district trade committees. The Act does not apply for a trade in which women are largely employed, at least one of the appointed members must be a woman.

SWEDEN [Sverige], a kingdom of northern Europe, occupying an island and a large part of the Scandinavian peninsula. It is bounded N. by Finland (Russian Empire), E. by the Gulf of Bothnia and the Baltic Sea, S.W. by the Cattegat and Skagerrack, and W. by Norway. It extends from 60° 3' 21" to 55° 20' 18" N., and from 11° 6' 15" E. on the south-west coast to 24° 9' 11" E. on the Finnish frontier, the extreme length being about 990 m., the extreme breadth (mainland) about 250 m., and the total area estimated at 173,547 sq. m. Out of a detailed total estimate of the boundary line at 6100 m., 4737 m. are coastal, the Norwegian frontier is 1030 m., and the Finnish 333 m.

Topography. The backbone of the Scandinavian peninsula is a range, or series of masses, of mountains (in Swedish Kölén, the keel) extending through nearly the whole length of the peninsula towards the western side. The eastern or Swedish flank has, therefore, the more incised character slopes of the country. The western (Finnish) side is mainly an upland of hills, an upland which is more or less a continuation of the Swedish coast and stretches out to the Baltic. The border of Finland being of low level, the line of junction between Sweden and Norway from the extreme north to the north of Svealand, the central of the three main territorial divisions of Sweden and Svalbard, and the Baltic is, therefore, a convenient line of demarcation. Although this boundary is not so well marked that the political frontier may follow it throughout, Sweden itself may be considered in four main physical divisions—the mountains and highland district, covering all Norrland; the forested districts of central Sweden; the so-called Småland highlands, in the south and south-east; and the plains of Skåne, occupying the extreme southward projection of the peninsula.

The first district, thus defined, is the largest, and includes the greatest elevations in the country and the finest scenery. The highest mountains are found in the north, the bold peak of Kebnekaise reaching 7065 ft., Sarjekstjakta, 6792 ft., being the highest point in a mountain range including the Sarjeksfall, Alaksjafell and Partefjell, which range, from 6500 ft. upwards; and, farther south, Sulitjelma, 6158 ft. of these mountains are in the border district of Norway, and are composed of pre-Cambrian rocks. There is an abrupt fall from Storgull to the Svalbard range, which, from 2500 ft. at the south of which the railway from Trondhjem in Norway into Sweden crosses the fine pass at Storlien. South of this lies the ridge, from which descend the glaciers and from which issue the waterfalls of the great river, the Storfjell in Norway, the Falunbo in Sweden.

Within the region of the mountains, the general aspect is high and rugged, with steep and rocky sides, often rounded, and abounding in masses, of masses, of mountains (in Swedish Kölén, the keel) extending through nearly the whole length of the peninsula towards the western side. The eastern or Swedish flank has, therefore, the more incised character slopes of the country. The western (Finnish) side is mainly an upland of hills, an upland which is more or less a continuation of the Swedish coast and stretches out to the Baltic. The border of Finland being of low level, the line of junction between Sweden and Norway from the extreme north to the north of Svealand, the central of the three main territorial divisions of Sweden and Svalbard, and the Baltic is, therefore, a convenient line of demarcation. Although this boundary is not so well marked that the political frontier may follow it throughout, Sweden itself may be considered in four main physical divisions—the mountains and highland district, covering all Norrland; the forested districts of central Sweden; the so-called Småland highlands, in the south and south-east; and the plains of Skåne, occupying the extreme southward projection of the peninsula.

The first district, thus defined, is the largest, and includes the greatest elevations in the country and the finest scenery. The highest mountains are found in the north, the bold peak of Kebnekaise reaching 7065 ft., Sarjekstjakta, 6792 ft., being the highest point in a mountain range including the Sarjeksfall, Alaksjafell and Partefjell, which range, from 6500 ft. upwards; and, farther south, Sulitjelma, 6158 ft. of these mountains are in the border district of Norway, and are composed of pre-Cambrian rocks. There is an abrupt fall from Storgull to the Svalbard range, which, from 2500 ft. at the south of which the railway from Trondhjem in Norway into Sweden crosses the fine pass at Storlien. South of this lies the ridge, from which descend the glaciers and from which issue the waterfalls of the great river, the Storfjell in Norway, the Falunbo in Sweden.

Of these districts, the two most remarkable are: Northern Highlands, including the Sarjeksfall, Alaksjafell and Partefjell, which range, from 6500 ft. upwards; and, farther south, Sulitjelma, 6158 ft. In the north this is the highest point in a mountain range which decreases, throughSIDE578 ft. and Åreskutan (566 ft.), to the southern of which the railway from Trondhjem in Norway into Sweden crosses the fine pass at Storlien. South of this lies the ridge, from which descend the glaciers and from which issue the waterfalls of the great river, the Storfjell in Norway, the Falunbo in Sweden.
From the spinal mountain range a series of large rivers run in a south-easterly direction to the Gulf of Bothnia. In their upper parts they drain great lakes which have resulted from the formation of morainic dams, and in some cases the streams are at present very deep and have a great elevation above sea-level. All lie at elevations between 900 and 1300 ft. All are narrow in comparison with their length, which is not infrequently magnified, to view when two lakes are connected by a very short stretch of running water. An example of this is the divide between Hornafvan, Uddejaur and Storafvan on the Skellefte river. The following are the principal rivers from north to south: The Torne, which flows from Lake Torne to Lake Karesuando, drains with Finland, has a length of 227 m, and drains lake Torne (Torne-träsk), the area of which is 126 sq. m. The Kalix is 208 m. in length. The Lule is formed of two branches, Storn and Lilla (Great Lule). The total length, however, is 503 m. The Stora Lule branches drain the Langas and Stora Lule lakes (Langsajaur, Luleträsk), which have a length together exceeding 50 m., a fall between them of some 16 ft. and a total area of only 87 sq. m. as they are very narrow. Below Stora Lule the lake forms the Harspräng (hare's leap); Njömmelsuska of the Lapps, the largest and one of the finest cataracts in Europe. The sheer fall is about 100 ft., and there is a further fall of 150 ft. in a series of tremendous rapids extending for 1.5 m. Farther up, at the head of Langsajaur, is the Stora Sjöfallet (great lake fall; Lapp, Attu Muorki Karjje), a fall of 1.50 m. only less grand than the Harspräng. Below, and at a distance somewhat more than half the length of the SkellefteÄngen, an interruption of the Skellefte river, are the two falls which are visited. Following the Pite river (191 m.), The Skellefte (205 m.) drains Hornafvan and Storafvan, with a fall of 20 ft., and an area together of 275 sq. m. Hornafvan is a stream undefined by trough, flat-bottomed valleys, and lower falls of Skellefte, Storafvan and then the evening Uddejaur are broad, throwing off deep irregular inlets, and picturesquely studded with numerous islets. The Ume (237 m.) runs through a fine plain, the2nd largest basin in the country, and north bank some 20 m. from its mouth, and among several lakes drains Stor Uman (64 sq. m.). The further principal rivers of this region are the Angerman (243 m.), Indal (196 m.), draining the lakes Angerman and Indalsjaur, which in its lowest course forms these the two last rise in the southernmost part of the mountain region described, but do not as a whole belong to the region under consideration. The Angerman drains 3300 sq. m. of northern Sweden; the Indalsjaur drains the lakes north of it, and has thus a drainage area of 12,591 sq. m., which is exceeded only by that of the Torne (16,690 sq. m.), the average of the remaining rivers being 50 sq. m. Beyond the Harspräng and the Stora Sjöfallet the northern rivers do not generally form great falls, though many of the rapids are grand. The Indal, by changing its course in 1796 near Dyspsgården on the northern, has left bare the remarkable bed of a fall called Döda (dead) Fall, in which many "giants' caldrons" are exposed. In the uplands above the chain of lakes called Strömsvalltud, which are within the drainage area of the Angerman, there are almost lake chain without another fall. Fall are rare, but southern mountain valleys of the region there are several beautiful falls, such as the Tännfors, not far from Åre and the Storbo, Hällefors (250 m.).

Eastward from the main mountain range the highland region is divided into two belts: a middle belt of morainic deposits and marshes, and a coastal belt. The middle belt is gently undulating; view from the coast one sees little evidence of the morainic forests resembles a dark green sea, through which the great rivers flow straight between steep, flat-topped banks, with long quiet reaches broken by occasional rapids. The few lakes they form in this belt are rather mere widening in their courses; but the tributary streams drain numerous small lakes and peat-mosses. In the extreme north this belt is almost flat, a few low hills standing isolated and conspicuous; and the rivers have serpentines system, while steep banks are absent. The middle belt melts into the coastal belt, covered by geologically recent marine deposits, reaching an extreme height of 700 to 800 ft., and extending inland some 60 to 80 m. The chief tributary of the great rivers are characteristic, and the rivers have cut deep into the soft deposits of sand and clay, leaving lofty and picturesque bluffs (mipor).

The orographical division of the central lowlands bears comparison with the coast in the northern part of the country. Here are flat fertile plains of clay, well wooded, with innumerable lakes, including the four main basins, Valavan, Vetter, Mälar and Hjelmare. These, except the last, far exceed in area any lakes in the country except that of Vetter. Hjelmare (183 sq. m.) is only exceeded by Hornafvan-Storafvan. The areas of the other three lakes are respectively 2419, 733 and 442 sq. m. The four basins are divided by an innumerable system of very irregular and in form, and of great length. Mälar, Vener and Hjelmare contain many islands; in Vetter there are comparatively few. None of the lakes is of very great depth, the deepest sounding occurring in the middle of Mälar, which, however, is not more than 60 ft. from east to west, and is 12 m. in extreme width, the greatest depth is only 50 ft., but as its flat shores were formerly subject to inundation its level was sunk 6 ft. by deepening the navigable channel through it and clearing out various waterways (the

**Eskeläntuna river, Hjelmar canal, &c.) in 1878–1887.** The scenery of these lakes, though never grand, is always quietly beautiful, especially in the case of Mälar, the wooded shores and islands of which form a notable feature in the pleasant environs of the city of Stockholm, formed by elevations above sea-level as high as 240 ft., but a few isolated heights of Silurian rock appear, such as Kinnekulle, rising 988 ft. above sea-level on the south-eastern shore of Vener, and Källungen (978 ft.) between Lake Mälaren and Lake Vener (865 ft.) on the eastern shore of Vetter. Noteworthy local features in the landscape of the central lowlands are the eskers or gravel-ridges (kärr), traversing the land in a direction from east to west, and the sides of the eskers are often of a rounded surface. Typical instances occur in the cities of Stockholm (Brunkebergstaken and Upsala (Upsala-åsen). South of the central lowlands the so-called Småland highlands extend. These highlands are composed of the loess deposits (Great Drift) which cover large parts of the old province of Skane (Scania). Level plains, with rich open meadows and cultivated lands, the monotonous of which is in some parts relieved by bighills which are separated by slight ridges with small lakes. Småland is situated in the north-west, with an extreme elevation of 741 ft.

The hydrographical survey may now be completed. The Dal river at its southern entrance to the Baltic is joined by the union of eastern and western branches (Oster Dal, Vester Dal) not far from the town of Falun. The eastern branch drains various small lakes on the Norwegian coast and has a length of 227 m. The western branch drains the so-called Lake Vener, which is drained to the Cattegat by the short Gota river, on which, not far below the lake, are the celebrated falls of Trollhättan. Lake Vetter is drained by two branches (Söder Dal, norther branch) in the same direction by a short channel at Stockholm, the normal fall of which is so slight that the stream is sometimes reversed. The Småland highlands are drained to the Baltic and Cattegat by numerous rivers of less importance. Excepting Finland no country is so full of lakes as Sweden. About 14,000 sq. m., nearly one-twelfth of the total area, are under water.

The coast of Sweden is not indented by so many or so deep inlets as those of the Gulf of Bothnia, the Baltic and the Cattegat share in the peculiar grandeur of the North Sea coast. All, however, have the same feature in that they are bounded by a steep coast, almost entirely impassable, and they have been cut through the beautiful Lake Siljan.

The length of the whole river including the eastern as main branch is 283 m. The Klar river (228 m.) rises as the Eemund river in Pienomursia, or large lakes, and empties into the Baltic through the Beautiful Lake Siljan.

Farther north, a narrow sound (Alands Hal) intervening on the Swedish side, the vast Aaland archipelago, belonging to Russia, extends across the Gulf of Bothnia. The coast of Sweden is here also developed than that of either the Baltic or the Cattegat. The islands of the skärgård as a whole are rugged and picturesque, though never lofty like many of those of the Baltic coast. In some parts of this archipelago, especially the skargard near to which from the sea is famous for its beauty. Farther north, a narrow sound (Alands Hal) intervening on the Swedish side, the vast Aaland archipelago, belonging to Russia, extends across the Gulf of Bothnia. The coast of Sweden is here also developed than that of either the Baltic or the Cattegat. The islands of the skärgård as a whole are rugged and picturesque, though never lofty like many of those of the Baltic coast. In some parts of this archipelago, especially
of Vemland, Skaraborg, Elsbo, and down to the province of Kronoberg, where it becomes a sandstone. In every respect it is very similar to the Grauwacke of the same type with a red and yellowish tinge, and the diluvial clay. In most parts of Sweden these deposits were swept away when the ice advanced, but in Skåne they often occur as long, thin, highly compacted, and ordinary krossgrus (terminal and side moraine). The former generally consists of a hard and compact mass of rounded, scratched pebbles, with rounded edges and broken surfaces, and is often covered by a layer of crushed rock. The latter is less compact and contains angular boulders, often of a considerable size, but no powder. Of later origin than the krossgrus is the rollstensgrus (gravel of rolled stones), which is a mixture of huge stones, pebbles, and small pebbles, called åsar. During the disappearance of the great inland ice large masses of mud and sand were carried by the rivers and deposited on the sea floor. These deposits, known as argillaceous and glacial clay, cover most parts of Sweden south of the line of Kopparberg and Vemland, the more elevated portions of the provinces of Elsbo and Kronoberg excepted. In the glacial clay also called Yttel arctica have been met with in many places to the north (or Stockholm). At this epoch the North Sea and the Baltic were connected along the line of Vener, Vetter, Hjelmor and Måler. On the other side the White Sea was connected by Lakes Onega and Läng, and the Gulf of Finland, and the Baltic and of Lakes Vener and Vetter there actually exist animals which belong to the arctic fauna and are remnants of the mammals that used to be more widespread in the Baltic and into the Baltic Sea. The glacial clay of the Silurian regions is generally rich in lime and is calcareous. The glacial clay is often found developed into the island of Oland in the country, called the Tjörn. In Sweden, the glacial clay is found in the southern part of Sweden at a height ranging from 70 to 150 ft. above the level of the sea, but in the interior of the country at a height of 400 ft. above the sea.

On the coasts of the ancient ice-sea, in which the glacial clay was deposited, there were heaped-up masses of shells which belonged to species still extant around Spitzbergen and Greenland. Most remarkable are the bivalves, among which the Silurian genus, called the Truncklaiden, is often found. These shells are rich in lime and seldom less than 2 ft. thick. They are generally of insignificant thickness. In the shallow lakes and enclosed bays of the sea there began to form the new deposits of the thick, heavy, clay waters, known by the name gyttja, characterized by the diatomaceous shells it contains. Sometimes the gyttja consists mainly of diatoms, and is then called terrymil. The gyttja of the lakes is generally preserved by the preservation of the gyttja in places near the sea, there is still in progress the formation of an iron ore, called sjuslim, with which the sea becomes covered by peat later than the sea has become surrounded by the first glaciation. The climate is very mild and the summers are long, of an enormous thickness, which have been brought into their present positions. The climate inclines to the character, others to the other. As a result of the wide latitudinal extent of the country there are also marked local variations to be contrasted. About one-seventh of the coasts of Norway are mountainous, and the climate of the Swedish part of the Baltic and the Baltic Sea. The climate of the Baltic is so far tempered by the warm Atlantic drift from the south-west that it is very unique in comparison with other countries of the same high latitude. The mountains of the Keel are not so high as the Iceland to destroy this effect over Sweden, and the maritime influence of the Baltic system has also to be considered. Sweden thus occupies a climatic position between the purely coastal conditions of Norway and the purely continental conditions of Russia; and in some years the climate inclines to the character, others to the other. As a result of the wide latitudinal extent of the country there are also marked local variations to be contrasted. About one-seventh of the coasts of Norway are mountainous, and the climate of the Swedish part of the Baltic and the Baltic Sea. The climate of the Baltic is so far tempered by the warm Atlantic drift from the south-west that it is very unique in comparison with other countries of the same high latitude. The mountains of the Keel are not so high as the Iceland to destroy this effect over Sweden, and the maritime influence of the Baltic system has also to be considered. Sweden thus occupies a climatic position between the purely coastal conditions of Norway and the purely continental conditions of Russia; and in some years the climate inclines to the character, others to the other.
at the south of lake Vetter—42°44'; and Vestervik (43 ft.) on the Baltic—43°2'.

But the local variations thus indicated are brought out more fully by the monthly isotherms, or lines of equal temperature, contained in the inland parts. The one is in the mountainous region of the south of Jemtland and the north of Dalarne, extending into Norway and Sweden, and appears as a thick line on the map in February. The average temperature in January is 8-9°, whereas at Östersund it is over 12°. The other and more strongly marked centre is in the far north, extending into Norway and Finland, where the average temperature in January is 2-3°, and isotherms run west of Lake Siljan and bends north-east to the Bothnian coast near Skellefteå. In July, on the other hand, the isotherms show an almost constant temperature all over the country, and the uniform curve is characteristic.

The relative length of the seasons shows contrasts similar to those of temperature. In the north spring begins in May, summer in the middle of June and autumn in the middle of August. In the south and west spring begins in March; summer in May and autumn in October. At Karesuando the last frost of spring occurs on an average on the 15th of June, and the first of autumn on or about the 6th of September; whereas at Stockholm the first of spring is on or about the 15th of April, and the first of autumn on or about the 1st of October; whereas at Stockholm 4½ months are free of frost. Ice forms about October in the north, in November or December in the midlands and south, and breaks up in May or June and in April respectively. In the great lakes the ice is formed in the north, 150 in the midlands and 200 to 220 in the north. A local increase of the ice period naturally takes place in the upper parts of the Småland highlands; and in the case of the great lakes of Norrland, the western parts have a shorter ice period than the eastern. As to the seas, the formation of ice on the west and south coasts is rare, but it is common and throughout the Baltic drift-ice and a frazil ice, ice in the form of needle-like crystals, takes place on the north coast from the 15th of December to the beginning of April. Navigation in the northern part of the Gulf of Bothnia is impeded from the end of November to the beginning of May, and in the north the gulf is covered with ice from November to the last half of May. Snow lies 47 days on an average on the plains of Skåne, while in the north it lies from 140 to 190 days.

The northern summers find compensation for brevity in duration of sunshine and light. At Karesuando in 68°26' N. and 1093 ft. above sea-level the sun is seen continuously above the horizon from the 26th of May to the 18th of July; at Haparanda for 23 hours, at Tornio for 15 and at Lofsdalen for 14. In the south at Stockholm the summer solstice brings not an inch of sunshine. Atmospheric refraction causes the sun to be visible for periods varying from south to north for a quarter to half an hour after it has actually sunk below the horizon. With the long twilight, perhaps 8 or 9 hours during the period of the summer solstice, a succession of atmospheric effects, day-light last without interruption from the 16th to the 27th of June as far south as Hernösand (60°36' N.).

The average annual rainfall for Sweden is 1972 in., locally increasing on the whole from north to south, and reaching a maximum towards the south-west, precipitation on this coast greatly exceeding that on the coast of the North Sea. Thus the average in the north of Norrland is 165 in., in the south of Norrland 226 in. At Borås, midway between the south end of Lake Vetter and the Cattgat, the average is 35-08 in., and 45-82 in. were registered in 1898. At Kalmar, however, on the Baltic opposite Öland, the average is 14-6 in. This is an extreme instance for the locality, but the minimum for all Sweden is found at Karesuando, with 12-32 in. of precipitation. The period of maximum is generally the latter half of summer, and the minimum in February; though at Stockholm the minimum occurs in January. The coast stations in Skåne and in the island of Gotland. The proportion of total precipitation which falls as snow exceeds 36% in the north, to 9% in the south.

Flora and Fauna.
The accompanying physical description is given of the vast extent of forest in Sweden. The alpine treeless region occupies only the upper flanks of the spinal mountain-range above 5000 ft. above sea-level, and extends from the Arctic circle to the 6000 ft. coast of the Greenland Sea, and from the mouth of the Baltic to the mouth of the Norwegian Sea. It is a belt of birch wood, with occasional mountain-ash and aspen, varying in width from about 20 m. in the north to a fraction of a mile in the south. Below this extends a great sub-alpine or mountain tract, with spruce, larch, fir, and pine. Pine bands below at the coast of the Baltic, Lake Vener and north of the Dal River. The fir (Pinus sylvestris) and pine (Pinus abies) are the predominating trees. Spruce is common, and even predominates in the higher parts (between the great valleys and immediately below the birch-belt) in the north of Norrland. Southern of the southern limit indicated, in the midland district of the great lakes, the oak (Quercus pedunculata) appears as well as pine and fir; and, as much of this area is under cultivation, many other trees have been introduced, as the ash, maple, elm and beech. The pines are numerous along the Swedish shore of the Baltic, Kalmar on the Baltic coast the beech begins to appear, and in Skåne and the southern part of the Cattgat seaboard becomes predominant in the woods which break the wide cultivated places. The oak, elm and alder are also found in the sheltered bays and inlets, where the maritime conditions are more endemic varieties); the bulk are immigrants after the last glacial epoch. Of these most are common to arctic lands, or occur in the mountainous regions of Europe, and which can therefore be regarded as belonging to the same faunal region as Sweden, as we advance from the south according to geographical distribution from south to north; thus while upwards of 1000 are found in Skåne, there are only about 700 in the midlands, 500 in the lower parts of southern Norrland and lower, and 100 in the far north.

Fauna.—The effects of the great latitudinal range of Sweden on its climate and flora has its parallel to a modified extent in the case of fauna. Only a few animals are common to the entire peninsula, and as the great majority of the species which occur are of the more southerly races, it is probable that certain others may be added if the high mountain region be left out of consideration, such as the squirrel, fox and various shrews. Among large animals, the common bear and the wolf have been greatly reduced in numbers even within later historic times. These and the lynx are now restricted to the solitary depths of the northern forests. Characteristic of the high mountain region are the arctic hare and the reindeer, which are almost the only animals that have remained imprinted in the forests of the high mountain massifs. In the north the partial retreats of the lowlands have a considerable temporary influence on the distribution of beasts and birds of prey. There may also be mentioned the wild reindeer, which is rare, though large domesticated herds are kept in the north, and the white-tailed deer which enter the lonely forests from the Arctic Circle even to the Småland highlands. The roe-deer and red-deer are confined to the southern parts; and the hare is found throughout the country. Among birds, which these plains the fox is most abundant, and the badger and hedgehog are found. Martens and otters are to some extent hunted for their fur. A white winter fur is characteristic of several of the smaller birds, which are confined to the forests. A few red deer and many ibex, and on the coasts the bears. On the coasts the seals are met with in the neighbouring seas, and Phoca vitulina is confined to the Baltic. Among birds by far the greater proportion is migratory. Characteristic types common to the whole country are the black grouse, sump, daub, and green plover and grey plover. In the northern mountains the ptarmigan is common, and like other creatures assumes a white winter dress; ducks and other water-fowl frequent the lakes; the ruff and the black-necked grebe, cormorant, black-throated loon, shelduck and sandy loon. Small birds the Lapland bunting (Emberiza lapponica) may be mentioned. In the coniferous forests the black grouse, hazel grouse and willow grouse, capercaillie and woodcock are the principal game birds; the crane is found in muddy clearings, birds of prey are numerous, and the Siberian jay in the north and the common jay in the south are often heard. But in the northern forests small birds are few, and even in summer these wildfowl give a strong general impression of wildness. In the middle part the ptarmigan is fairly common, though not readily enduring the harder winters; and ring-doves and stock-doves occur. The lakes are the habitat of the white-specialty; especially the middle and eastern lakes, while in the north the arctic murre, eider, auk, and gulls and terns are found, also the eider-duck and the sea-eagle, which, however, is also distributed far over the land. The species of reptiles and amphibians are few and chiefly confined to the south. Fresh-water fishes which are found are the common carp, the eel, the perch; three of lizard; and eleven of batrachians. The rivers and lakes are generally well stocked with fish, such as salmon, trout of various species, gwyniad and vendace (especially in the north), pike, eels, perch of various species, turbot, bream and roach. Few sportsmen who have visited the higher parts of the great northern rivers have found excellent trout-fishing, with pike, perch, char and grayling, the char occurring in the uppermost parts of the rivers, and the grayling below them. The fisheries, both fresh-water and sea, are important, and fall for consideration as an industry. The herring, cod, flatfish, mackerel and sprat are taken in the seas, and the latter seems to be the home of many species. The brackish waters of the east coast sea fish are found, together with pike, perch and other fresh-water forms. The crayfish is common in many places in central and southern Sweden. Pearls are some-
The population in 1908 was about 5,429,600. In 1721 it was 1,802,373, and in 1865, 4,114,141. The average annual increase was 7.86 per thousand in the 19th century, reaching a maximum of 19.39 in 1841-1860, before the period of rapid emigration set in. Emigrants numbered 38,259 men and 424,560 women between 1851 and 1900, these figures helping to account for the considerable excess of women over men in the resident population, which in 1900 was as 104:100. The periods of greatest emigration were 1868-1873 and 1879-1883; the decline in later years is regarded as a favourable sign. The United States of America receive a large majority of the emigrants, and only a very small percentage returns. The Swedish people belong to the Scandinavian branch, but the population includes in the north about 20,000 Finns and 7000 Lapps. Other foreigners, however, are few, and the population is a whole homogeneous.

Immigrants in the period 1851-1900 numbered only 165,357.

The highest mortality is found in the districts about Lken and Vetter; the highest in Norrotten, the east midland districts, Skde, and Gtebo och Bohus Län. The percentage of illegitimacy is rather high (though it decreased during the second half of the nineteenth century); one cause of this may be found in the fact that the percentage of married persons is lower than in most European countries. As regards social evils generally, however, the low, though undoubtedly improving, position of Sweden has had one of its chief reasons in the national intemperance. In 1775 Gustavus III. made the sale of spirits (brannvin) a government monopoly, and the drinking habit was actually fostered. After 1868 it is estimated that nine gallons of spirits were then consumed annually per head of the population. Mainly through the efforts of Peter Wiesegren, dean of Gothenburg (1800-1877), a strong temperance movement set in, and in 1885 important liquor laws were passed to restrict both production and sale of intoxicating liquors. The so-called Gothenburg System, providing for municipal control of the sale of intoxicants (see Liquor Laws), remained in full operation in Gothenburg until 1885. The temperance movement has had its reward; the average of consumption of beer and spirits in Sweden is considerably lower than in Europe as a whole, though the effect of prohibition on intoxication is somewhat limited and difference of temperatne is noticeable between the Swedes and Norwegians, the Swedes being the more light-hearted and vivacious. In some of the more remote parts of the country old customs are maintained and picturesque local costumes still worn, as in Dalecarlia (q.v.). The Lapps moreover retain their distinctive dress. In other cases early customs are preserved only as a historical reminiscence at festivities. Although the characteristic celebrations at weddings or periodical festivals are, as elsewhere, decreasing in favour, there are certain occasions which are observed as local customs. Christmas is a typical example. The carol-singing is a long established custom among the people. This alcoholic beverage, with its mixture of spirits and a glass of spirits. The more characteristic Swedish sports are naturally those of the winter. These include ski-running (skidlpping), skating and skate-sailing, tobogganing and sledding. The numerous inland waters and sheltered channels within the stergård have caused the high development of sailing as a summer sport, the Royal Swedish Yacht Club having its headquarters in Stockholm. Athletic sports are in high favour, especially such winter sports as snow-shoeing (skib), and, among ball games, lawn-tennis, and to some extent football, together with the game of park, peculiar to Gotland, are played.

1 Island included in Kalmar Län.
2 Including the four great lakes, Vener, Vetter, Målar Hjelmar, 3516 sq. m.
rich in historic sites and remains. In ecclesiastical architecture Sweden possesses the noble cathedrals of Lund, Upsala and Linköping; while that of Skara, near the southern shore of Lake Vener, dates originally from 1150, and that of Stenstägn on Lake Milar was constructed in 1262. All are Gothic in style, with aisles, transepts and towers, and constitute admirable examples of the national architecture of the 14th and 15th centuries. But the richest locality as regards ancient ecclesiastical architecture is the island of Gotland (q.v.).

Travel and Communication. - As a resort for foreign travelers and tourists Sweden is in the first rank in the northern territory of the continent, and possesses one of the most extensive railway systems in Europe. The Göta canal route, however, is used by many; the uplands of Dalecarlia (Dalarna) are frequented; and the railway through the Jämtland and Värmland parcellings into the western region, where numerous sanatoria are in favour with the Swedes themselves. The northern railway offers a land route to the Arctic coast of Norway. Along the southern coasts there are many watering-places. Malmö and near Gothenburg is one of the most fashionable. Örnsköldsvik, Lysekil and Varberg are on the same coast, Ronneby on the Baltic, with its chalybeate springs. Västra kaptenen, and several villages in the neighbourhood of Stockholm may also be noted. The government has made grants towards the construction of its trunk lines, and has in a few cases taken over such lines. The railways form a network over the country as far north as Gelle and across the northern parcellings of the country, and lines from Stockholm to Malmö, to Gothenburg and to Christiania as far as the Norwegian frontier, and other important through lines in the south. The great northern line is also worked by the government. The length of the construction and the main lines is nearly 6500 miles, or about one-third of all the government lines and about 60% of the private lines is 1435 metres (4 ft. 8½ in.). Nearly all the lines are single. Passenger travelling is slow, but extremely comfortable. The principal communication is through the chain of cathedrals from Malmö to Copenhagen, and from Trelleborg to Sassnitz in Germany.

The extensive system of natural waterways, especially in central Sweden, has been utilized to the full in the development of internal traffic. Where there is a river, a lake, or an estuary, water affords opportunity for safe and economical coastwise traffic. The earliest construction of canals dates from the 15th century, the patriot Engelbrekt and King Gustavus Vasa both foreseeing its importance. The theories of construction remained rudimentary until early in the 19th century, when the Göta (q.v.) canal was opened. The total length of the canaled water-system of Sweden is a battle over 700 m., though wholly artificial waterways amount only to 115 m. out of this total. A large local traffic is carried on by steam launches on the lakes during the season of open navigation; and vessels have been even introduced on the construction of canals in the province of Värmland. A connection with the timber trade. Posting, which is of importance only in the highland districts and the valley roads of Norland, is carried on by posting-stations (skjutstation) under government control. There are also ferries over the many navigable parts of the great northern rivers, rowing boats on the lakes form the only means of travel. The condition of the high roads is fair as a whole, and the inland waterways are in a very good state. Public ferries are in extensive use. They are not numerous in proportion to their upkeep; but in Norrland they are naturally not of the best. The postal and telegraph system is efficacious, and the telephone service, maintained partly by the state and partly by companies, is more and more extensively introduced. Telephone is in use per thousand of population, and a system of trunk-lines between the important towns has been established since 1889.

Agriculture. - Of the total area land of Sweden only about 13% is actually arable. The export of raw materials and foodstuffs forms a large part of the total export from the country, and will be considered in detail below. In the midlands about 50%, in the north from 4½% in southern Norrland to 3% in northern Norrland. Almost exactly half the total area is under forest, its proportion ranging from 25% in Skåne to upwards of 70% in the inland parts of Svealand and in the south of Norrland. Land which is neither cultivable nor under forest (mainly marshy, peaty districts, land above the upper limit of the forests) amounts to 61% in the far north and 36% in the Småland highlands, but only to 15% in the central plains and in Skåne. In the more highly cultivated districts the forest is mainly maintained by small independent farmers (only about 15% of the farms are worked by tenants), but until late in the 18th century a curious method of forest management prevailed. Each forest, consisting of a number of detached plots or strips, the divisions often becoming so minute that deforestation was inevitable. Early in the 19th century various enactments made it possible for each property to become a coherent whole. A legal parceling (förråde) was introduced in 1827 and slowly carried out in the face of considerable local opposition; instead, in the island of Gotland the system could not be enforced until 1870-1880. Roughly about 48½% of the total cultivated area is under cereals, 33½% under fodder-plants, 5½ under root-crops, and 11½ fallow, this last showing a steady decrease. Oats, rye, barley, mixed grain and wheat are the principal grains. But oats increased more in the earlier decades than any other, becoming the staple crop in Norrland, becoming the only grain-crop in the extreme north; in the richer agricultural lands of the midlands and south rye is predominant in the east, oats in the west. The distribution of agricultural cultivation is very irregular, perhaps the fact that although that province occupies only one-forth of the total area of Sweden, it produces 30% of the entire wheat crop, 33% of the barley, 18% of the rye and 13% of the oats. A system of rotation (cereal, roots, grass) is commonly followed, each division of land lying fallow one year as a rule; not more than two ripe grain-crops are commonly taken consecutively. Potatoes occupy about 2% of the land. These include the sugar-beet, the profitable growing of which is confined to Skåne and the islands of Åland and Gotland. The sugar industry, however, is very important. Orchards and gardens occupy about 1% of the land. Fruit trees are grown in the south and midlands; northward (as far as Härnösand) they flourish only in sheltered spots on the coast. Between 1850 and 1900 the total head of livestock increased from 4,500,000 to 5,360,000, and the great advance of cattle-farming is under the following proportions. Whereas in 1850-1875 imported cattle and cattle-farming produce exceeded exports as 12 to 7, in 1900 the value of the exports was to the imports as 3 to 1. As in the southern provinces as well as less as 1870-1885 the exports of agricultural produce exceeded imports in value, in 1896-1900 they were less than one-tenth. The principal breeds of cattle are the alpine in Norrland, and Swedish trotters, hard-shouldered, and heavy as a race, in the south. The Gotland, an old native light yellow breed, survives in the island of Gotland. Oxen, formerly the principal draught animals, have been replaced by horses. Cattle, especially cows, have greatly decreased in numbers. The Lapps own upwards of 230,000 head of reindeer. Dairy-farming is profitable. England and Denmark being the principal foreign consumers of produce, and the industry is carefully fostered by the government. A board of agriculture had been in operation for many years when in 1900 a separate department of agriculture was formed. There are one or more educational establishments in agriculture, such as the agricultural high schools at Ultuna nearUpsala, and at Alnarp near Lund in Skåne, an important agricultural centre, with dairy schools and other departments. There are in the province at large agricultural societies, large nurseries and gardening schools at Stockholm, Alnarp and elsewhere, and botanical gardens attached to the universities of Lund and Upsala.
dates from 1828. There are very numerous sawmills, using water-power, steam and electricity; they are situated chiefly in the coast districts of the Gulf of Bothnia, from Gelle northwards, especially in the vicinity of Sundsvall. There is also a large amount of fishing, and in the neighbourhood of all the ports as far north as Luleå and Haparanda. There are also upland mills in Dalarna and Värmland, and there are also some of them in the western provinces. The wood-pulp industry centres in the districts west and north of Lake Vener and south of Lake Vetter. In the latter vast quantities of timber are floated down the great rivers, and the lesser streams are used for ordinary purposes. There are many iron-ore districts, of which the limestone for the blast furnaces is often worked in the same quarry. Textile industry is Skåne, at the south end of the Sound, the cement works of Lomma in this vicinity, and the pottery works of Körstand in, and close to, Sweden, where beautiful manufactured china is produced. Stone is worked chiefly in Göteborg och Bohus and Blekinge Län.

**COMMERCE**—Exports include £20,000,000 and imports £40,000,000, of a aggregate tonnage of 17,500,000, enter and clear the ports. The principal ports of register are Gothenburg, Stockholm, Helsingborg and Gelle, in order; though the principal commercial ports are Stockholm, Gothenburg, and Helsingborg. The coast trade is considerable, and the skärgård excellent natural harbours are almost without number. Artificial harbours are consequently few. But, those at Helsingborg, Malmö, Halmstad, Ystad and Kalmar are exceptionally fine, and may be considered indicative of the high standard of construction. They are of stone, and their most westerly, at the mouth of the Kattegat, are reared on the rock. They are not more than 4-5 ft. above the sea at low water, and are on the coast 66% in the north of Sweden; and less than that of Göteborg; this far exceeds other European ports, though it is equalled by those in America. The vessels used in the pig-iron is produced with charcoal only; its quality is excellent, but Sweden’s proportion to the world’s produce is hardly more than 1%, whereas in the 17th and 18th centuries, before the use of coal, the production was high. The ironworks and blast-furnaces are almost wholly in the midland districts. Copper has been mined at Falun since the 14th century; it is also produced at Arvidshög in Österbotten, often of considerable quality, and in the neighbourhood of the lakes. Coal is produced in small beds in Skåne, east and north of Helsingborg, at Billingeby, Bjurf and in other parts; important rafts of iron-ore are found in the vicinity, some 300,000 tons annually. Mining administration is in the charge of a special bureau of the board of trade. The Iron Institute (Järnkontoret) was established in 1748 as a financial institution, in which the iron-mining companies have share in management of advantageous loans and promotion of the industry generally. It maintains a special education and investigation fund. The iron-mining at Stockholm (the higher school), Falun and Filipstad in Värmland.

Manufactures.—In the total value of the output of the manufacturing industries in Sweden be taken as 106, the following are the main branches: 1st. textile industry in the provinces of Skåne and Östergötland, especially for its cotton goods. 2nd. iron and steel, largely used in the shipbuilding industry, and in the neighbourhood of the ports. 3rd. machinery, especially for its cutting. A few other establishments, including both mechanical workshops and ore-extraction works may be mentioned: Domnarvet, on the Dal River, near Falun; Sundviken,等情况。
other banks are joint-stock banks and savings-banks, of which the total number in Sweden in 1890. The post office savings-bank was opened in 1884.

Coinsage.—The counting unit in the Swedish coinage is the krona, equal to £1 shilling. The monetary unit is 10 kronor gold, and gold pieces, not wide in the revenue (bodisagor), which was seven-eighths of the whole, customs, the taxes on spirits and beet-sugar, and income from the post office.

The departments to which the revenue expenditure is devoted are those of the army, the interior, the navy and education. A large proportion of the army expenditure was formerly defrayed by a system of military tenure on certain lands. Land-taxes, however, were finally abolished in 1804, and their place was taken by an increased taxation on real estate, the triennially, and by an income tax arranged on a sliding scale, up to 4% of the income (6-9 pence in the £), settled according to individual declaration. The national debt was practically nil until c. 1835, and the debt contracted thereafter owes its existence almost wholly to railway construction. It increased from about £5,300,000 in 1860 to £6,400,000 in 1870 and £18,600,000 in 1900. In 1901, it exceeded £20,000,000.

The greater proportion of communal revenue comes from income and capital from property under the Gothenburg System, and contributions from the treasury. Primary education, poor relief, and Church purposes form the principal items of this revenue.

Constitution and Government.—Sweden is a limited monarchy, the constitution resting primarily on a law (regerings-forren) of the 6th of June 1809. The king is irresponsible, and executive power is vested in him alone. All his resolutions, however, must be taken in the presence of the cabinet (statsråd). The cabinet councillors are appointed by the king and are responsible to the parliament (Riksdag). They are eleven in number, one being prime minister, two others consultative ministers, and the remaining eight heads of the departments of administration, which are justice, foreign affairs, land defence, naval defence, home affairs, finance, public works, agriculture. The councillors must be of Swedish birth, and must have been in the possession of the Lutheran confession. The appointment of the majority of public officials is vested in the king, who can himself dismiss cabinet ministers and certain others, whereas in most cases a judicial inquiry is necessary before dismissal. The king shares legislative powers with the Riksdag, (parliament or diet), possessing the rights of initiation and absolute veto. He has also, in certain administrative and economic matters, a special legislative right.

The Riksdag consists of two chambers. The members of the first chamber are elected by the landsdöningar, or representative bodies of the län, and by the municipal councils of some of the län, or the representatives of the inhabitants of the towns. The members of the second chamber number 230, of whom 150 are elected from rural constituencies and 80 from towns. The members receive a salary of 1,200 kronor (£60), and are elected for a period of three years by electors, or directly, according to the method of the electoral districts. If a member retires during that period, or if the chamber is dissolved, succeeding members are elected for the remainder of the three years, and thus the house is wholly renewed at regular intervals, which is not the case with the first house. The franchise was for long extremely limited in comparison with other countries, but in 1897 universal manhood suffrage was introduced, after protracted dissension and negotiation between the two houses. Eligibility to the lower house necessitates possession of the elective franchise, an age of at least 25 years, and residence within the electoral constituency. Both chambers have in theory equal power. Before a bill becomes law, but when they differ on budget questions the matter is settled by a common vote of both, which arrangement gives the second chamber a certain advantage from the greater number of its members. By revisers elected annually the Riksdag controls the finances of the kingdom, and by an official (justitieombudsmannen) the administration of justice is controlled; he can indict any king's servant of the state who has abused his power. The bank of the kingdom is supervised by trustees elected by the Riksdag, and in the same way the public debt is administered through an office (rissgällskontoret), whose head is appointed by the Riksdag.

Local Government.—For the purposes of local government Sweden is divided into the 25 administrative counties (län) each of which is governed by a council and an executive council (majors). A large proportion of the revenue is given in the paragraph dealing with population. The elected representative body in each is the landsdöningar, which deliberates on the affairs of the län and has a right to levy taxes. The chief official of the län is the länshöfder, under whom are secretaries and fiscal departments. Privilegion towns, receiving their privileges from the government (not necessarily on the basis of population), are governed by a mayor (borgmästare) and aldermen (rådmän), the aldermen being elected by the citizens, while the mayor is appointed by the government from the first three aldermen on the poll, is paid, and holds office for life. Gothenburg has two mayors, and the city of Stockholm has three.

The major rural divisions are the fägderier, under bailiffs, a subdivision of which is the länsmansdistrikt under a länsmann. The fägderier are subdivided into judicial divisions (tingslag). Each tingslag has a court (härads-tingslag), consisting of a judge and twelve unpaid assessors (häradsränta), of whom at least three are by law to vote them. The town-courts in the privileged towns are called rättstingsförvaltare, and consist of the mayor and at least two aldermen.

The navy.—General military service is enforced. Every Swedish man below 50 years of age (85 years for officers) between the age of 21 and 40, during which time he serves eight years in the first levy, four in the second, and eight in the reserves. The conscripts were formerly trained for 90 days, but according to the law of 1901, the conscript is bound to serve in time of peace in the infantry, position artillery, fortress artillery, fortress engineers, and the army service corps a total of 240 days; and in the cavalry, field artillery, (Kavalleriet, Fältartilleriet, and the Tingslag) a total of 120 days. The permanent cadres number about 22,000, and about 85,000 men are annually trained as recruits or recalled for further training. The organization of the army in time of peace is as follows: 82 battalions of line infantry, 799 regiments of line cavalry, 351 field batteries, 24 field and 7 position artillery batteries, 10 fortress artillery, 16 engineer, and 18 army service corps companies. There are six divisions, (I. to VI.), of which the 1st and 2nd are divided into the Gotland troops and the 3rd, 4th, 5th, and 6th into the Gotland troops at Visby. A division in time of war would probably consist of 2 battalions of infantry (4 regiments, 12 battalions), with 4 squadrons of cavalry, 1 artillery regiment, 1 company of engineers, &c. A cavalry division would consist of 2 brigades of 8 squadrons each, and 1 brigade of horse artillery. It is estimated that 500,000 men are available for service in the various capacities in case of war. There are fortresses at Stockholm (Vaxholm and Oscar-Fredriksborg), Boden on the northern railway near the Russian frontier, Karlsborg on Lake Vetter, and Karlskrona; and there are forts at Flora, Ystad, and on 60 islands.

The reforms of 1801 abolished the sällskapsrätter, a body including both infantry and cavalry, which was divided in various parts of the country, in some cases having their houses provided for them. This peculiar system of military tenure (indel) of the samhällsrätt, was originated in the reign of Charles XI, and certain landowners were exempt from other military obligations if they provided and maintained armed men. The navy is small, including 11 ironclads of 3100 to 3650 tons. The personnel consists of a cadre, reserve and fleet conscripts, including all the trained seamen and 1000 officers, with headquarters at Vaxholm and Karlskrona. The principal naval station is Karlskrona, and there is another at Stockholm.

Religion.—More than 99% of the total population belong to the Swedish Lutheran Church, which the state supports. The country is divided into 12 dioceses and 186 deaneries, the head of the church of Upsala being archbishop. The parish is an independent unit in Swedish ecclesiastical connexions. The rector presides over the local school board, which is appointed by the church assembly (kyrkostämman), and thus an intimate relation between the church and education has long been maintained. A peculiar duty of the clergy is found in the husförhör or meetings.
designed to enable the priest to test and develop the religious knowledge of his parishioners by methods of catechism. It was formerly enjoined upon the clergy to visit parishioners for this purpose, and the system is still maintained in the form of meetings, which have been held in Lutheran parishes since 1618. The clergy have a choice between a devotional or a pastoral form. The parishes number 2556, but one living may include more or less only one parish. In the sparsely inhabited districts of the north, parishes sometimes extend over many square miles. Gullivara, an area of about 6500 sq. m. In such cases the priest often makes protracted journeys from farm to farm through his parish, and on certain occasions the congregation at his church will include men and women from many different farms for several days in order to be present. Dissenters are bound to contribute to the maintenance of the Swedish Church, in consideration of the secular duties of the priests.

The connection between the church and education is so close that the control of both is vested in a single department of the government. Primary education is carried on in common schools of different grades, under both local and state inspection, the parish being the school district. Seminaries are maintained for common school teachers, with a four-years' course. At Haparanda and Mattissudden in Norbotten there are special institutions for teachers for the Finnish and Lapp populations respectively. Wide attention was awarded to Swedish educational methods principally by the introduction of the system of Sloyd (stöfd), initiated at the Näs seminary near Gothenburg, and consisting of the manual training of boys and girls, both for boys and girls. The higher education of the people is provided by people's high schools in the rural districts, especially for the peasantry, maintained by the county councils, agricultural societies and the state, Tove. These schools are provided in geographically extensive areas and in special practical subjects according to local needs. The men's course is held in winter; and a women's course, in some instances, has been worked out which includes in their studies a similar object. A system of university extension has been developed on the English pattern, summer courses being held at Upsala and Lund. In connexion with the army reform of 1901 a system of military instruction has been introduced into the public schools. Technical education is provided in higher schools at Stockholm, Gothenburg and certain other large industrial centres; and in lower schools distributed throughout the country, in which special attention is paid to the teaching of local languages and the more practical subjects. Technical training for boys and forestry schools have been mentioned in the paragraphs on these subjects. Public schools for boys are provided by the state, each bishopric having a separate system. In his system there are three lower classes (out of a total of nine) a single system of instruction is practised; thereafter there are classical and scientific sides. Greek is taught only in a section of the upper classical classes. Of modern languages, German is taught throughout; English in all classes of the scientific side, and the upper classical classes. Much attention is paid to singing, drill and gymnastics. The school terms together occupy 341 weeks in the year. At the schools exceedingly few entrants are allowed into the universities or higher special schools. Owing to the high development of state public schools, private schools for boys are few; but higher schools for girls are numerous. The state normal schools for girls and the state normal school at Stockholm. The state universities are at Upsala and Lund, and with these ranks the Caroline Medical Institution at Stockholm. There are universities (founded by princely establishments), the Catholic university at Upsala, and the State university at Gothenburg. The faculties at Upsala and Lund are theology, law, medicine and philosophy (including both art and science). The courses are long, ranging from six to nine years; and the degrees are those of candidate, licentiate and doctor. The students, who are distinguished by their white caps, are divided for social purposes into "nations" (landshuf) of ancient origin, based upon the distinctions between natives of different parts.

Scientific Institutions.—Among the scientific and literary societies are to be noted the Swedish Academy, consisting of 18 members, which was instituted in 1786 by Gustavus III., after the pattern of the French Academy. It is the culmination of the Swedish language and literature; and the Academy of Sciences was founded in 1739 by Linnaeus and others for the promotion of the natural sciences. The first distributes one and the second two prizes annually. The upland and People's University is a fourth institution under the Caroline Institution at Stockholm. There may be mentioned further the Royal Academies of History, Literature and Antiquities (1786), of Agriculture (1811), of Arts (1725) and of Music (1748). There are also Academies of Sciences in Stockholm, Upsala and Lund, and Gothenburg. The Royal Library in the Humlegård Park at Stockholm, and the university library at Lund, contain the largest collection of historical and scientific works published in the kingdom. Certain of the large towns have excellent public libraries, and parish libraries are widely distributed.

See Sweden, its People and its Industry, a government publication (eng. ver., Stockholm, 1894); Dagens Elvhans officiell Statistik (Stockholm, 1857 seq.); Statistisk Tidskrift, periodically from 1862; Publications (year-book, guides, &c.) of the Svenska Turistsällskapet (Swedish Touring Club) Stockholm; periodical Bulletin of the Geological Institute of Upsala University, in which may be noted K. Ahlénius, Beiträge zur Kenntniss der Seenkettenregion in Schwedisch- Lappland, No. V, (1900); Also, Dahlman, Introd. till Sveriges geografi (Stockholm, 1857); Statistisk Lexicon over Sveriges geografi (Stockholm, 1859-1870); M. Höjer, Konungariket Sverige (Stockholm, 1875-1885); C. Almqvist, La Suède, ses progrès sociaux (Stockholm, 1879); P. B. Di Chaillo, The Land of the Midnight Sun (London, 1881); C. M. Rosenberg, Geografisk-statistiskt handlexicon over Sveriges geografi, (Stockholm, 1882-1883); W. W. Thomas, Sweden and the Swedes (Chicago and New York, 1891); Healey, Educational Systems of Sweden, Norway and Denmark (London, 1883); Nyström, Handbok i Sveriges geografi (Stockholm, 1895), and Sveriges rike (Stockholm, 1902); G. Andersson, Geschichte der Vegetation Schwedens (Leipzig, 1873); K. Ahlénius, Sverige, geografiskt-statistiskt betræffende (Stockholm); and for geology, A. G. Nathorst, Sveriges geologi (Stockholm). For more detailed accounts of the various districts see the publications of the Sveriges Geologiska Undersöknin, and also the volumes of the Geografiska Föreningen i Stockholm Förhandlingar.

Remains dating from the Stone Age are found scattered over the southern half of Sweden, but it is only along the south coast and in the districts bordering on the Cattegat that they occur in any considerable quantity. The antiquities of the Bronze Age are much more widely distributed and reach as far as the north of Helsingland. It is evident that the country must at that period have been inhabited by a people who knew the art of metal which they have acquired from the human remains found the population in general, and both the Stone and Bronze Ages seems to have been similar in type to that of the present day, and there is no clear evidence for the advent of a new race. The Iron Age probably began in the south of Sweden at any rate some three or four centuries before the beginning of the Christian era. (See further Scandinavian Civilization.)

The first historical notice relating to Sweden is contained in Tacitus, Germania, cap. 44. This book was probably published in a.d. 98 or 99 and in the passage mentioned we find the earliest mention of the people of the peninsula, the Swedes proper, Suiones (O. N. Svar, Swe., Swed. and Swar A. S. Sveon), who eventually gave their name to the whole country. According to Tacitus they were governed by a king whose power was absolute and comprehensive, and possessed a strong fleet which secured them from the fear of hostile incursions. Hence arms were not borne in times of peace but stored away under charge of a slave, and Tacitus suggests in explanation that the royal policy did not commit this trust to noble, Freeman or freedman. Their original territories were the Baltic coast and the peninsula later governed by Upland, Södermanland and Westergötland. Tacitus mentions another tribe, the Sittones, which he places next to the Suiones, but they have not been identified, and it is not clear from his description whether they lived within the peninsula or not. The only information he gives about them is that they were ruled over by a woman. Other early Roman writers, Mela and Pliny, mention the country under the name Scandinavia (Skåne), a name which in native records seems always to have been confined to the southernmost district in the peninsula. Little information, however, is given by these authorities with regard to the people.

The people next in importance to the Suiones in the peninsula (Swed. Gütar, O. N. Gautar, A. S. Geotar) are first mentioned by Ptolemy (under the form Goutai for Gautoi), together with a number of other tribal names, most of which unfortunately cannot be identified, owing to the corrupt state of the text. Ptolemy puts the Gütar in the southern part of the country, and from the earliest historical times their name has been given to the whole region between the Cattegat and the Baltic, exclusive of the provinces of Halland and Skåne which down to the 17th century always belonged to Denmark. The coast of the Cattegat north of the Göta Elv was reckoned in Norway. Götalnd consisted of the provinces of Västergötland and Östergötland divided from one another by Lake Vetter, together with Småland. In early times Västergötland seems to have been by far the most important. Vermland, the district to the north of Lake Vener and the
whole of the country to the north of Svealand seem to have been of small importance. Jämtland was always considered a part of Norway. After the time of Orðgenteow we hear no more of Sweden until the 6th century, when a surprisingly full account of its peoples is given by the Gothic historian Jordanes. He mentions both the Svear (Swethans) and the Götar together with other peoples, the names of several of which can be recognized in the district—names of later times, in spite of the numerous corruptions of the text. He praises the horses of the Svear and speaks of their great trade in furs of arctic animals which were transferred, from merchant to merchant until they reached Rome. About the other peoples of Sweden he gives a few details, chiefly of physical or moral characteristics, commenting upon the wild nature of the Visigauti, the mildness of the Finns, the lofty stature of the Vinovii and the meat and egg diet of the Rerfenae. Jordanes's statement regarding the prevalence of trade with Sweden is corroborated by the fact that many coins and bracteates of the period have been found in the country. Of these the coins are chiefly Roman and Byzantine gold pieces of the 5th century, the bracteates copies of Roman coins of the same period.

Procopius, the contemporary of Jordanes (Gothica, ii. 15) likewise gives an account of Sweden, which he calls Thule, but the only tribes which he names are the Skridephennio (A. S. Scríðenmas), a wild people of Finnish stock, and the Götar (Gautoi) whom he describes as "a nation abounding in men." For the same period we derive a considerable amount of information with regard to Swedish affairs from the Anglo-Saxon poem Beowulf. The hero himself belonged to the Greatas (i.e. in all probability Götar, though the identification is disputed by some scholars), his mother being the daughter of their king Hrethel. Haethcyn, the son and successor of this Hrethel, is said to have perished in a disastrous battle against the Svear, but his fall was avenged by his brother Hygelac in a subsequent engagement in which the Swedish king Olfur, son and successor of Hygelac. According to the poem Beowulf himself now became king of the Götar and assisted Eadgils in a campaign which resulted in the death of Onela and the acquisition of the throne by his nephew. What is said in the poem with regard to the end of Beowulf belongs to the realm of myth, and for three centuries after this time we have no reference to Swedish affairs in English or other foreign authorities. Moreover after the time of Beowulf and Jordanes there are very few references to the kingdom of the Götar and in Olaf Skattkonungr's time it was much reduced. The kingdom must have come to an end between the 6th and 10th centuries A.D., and probably quite early in that period.

The Ynglingatal, a poem said to have been composed by Thjóðólfr of Hvín, court-poet of Harold Fairhair, king of Norway, gives a genealogy of Harold's family, which it carries back to the early kings of the Svear. Snorri Sturluson (1178–1241) the Icelandic author using this poem as a basis and amplifying it from other sources, wrote the Ynglinga Saga, which traces back the history of the family, generation by generation, to its beginning. In this saga Æblis (the Eadgils of Beowulf), son of Öttar is one of the most prominent figures. The account given of him is in general in keeping with the statements in Beowulf, though the nature of his relations with Ali (Onela) has been misunderstood. The decisive battle between the two kings is said to have taken place on the frozen surface of Lake Wener. Öngenteow appears to have been entirely forgotten in Norse tradition and his place is taken by a certain Egil. The saga further states that Æblis was an enthusiastic horse-bredner and that he met with his death through a fall from his horse. This point is of interest in connexion with the notice of Jordanes, mentioned above, with regard to the horses of the Svear. Other northern authorities such as Saxo and the Hroths Saga Kraka represent Æblis in a very unfavourable light as niggardly and addicted to sorcery.

The Ynglingatal and Ynglinga Saga enumerate Æblis's ancestors to no less than seventeen generations, with short accounts of each. We have no means of checking the genealogy from other sources, and the majority of the characters are probably to be regarded as mythical. The origin of the family is traced to the god Frey, son of Níðr, who is said to have founded Upsala, the ancient capital of Sweden. His reign is represented as a golden age of peace and prosperity and the great wealth of the sanctuary is said to have taken its beginning from the offerings at his tomb. His full name appears to have been Ævnigfrír or Ingunar Freyr and his descendants are collectively termed Ynglingar, though we also occasionally meet with the name Skillingar, which corresponds with the name Skillingar borne by the Swedish royal family in Beowulf.

After the time of Æblis the Ynglingar remained in possession of Upsala for four generations according to the saga. Ultimater, the treachery and the murderous disposition of the king named Ingiald led to his overthrow by a prince from Skåne, called Ívarr Vífaðaði. His son Olafr Trételega withdrew to Vermland, which he brought into a state of cultivation, though he was subsequently sacrificed by his subjects in a time of famine. It is stated in the saga that the Swedish kings were believed to have control over the seasons like their ancestor, the god Frey, and traces of this belief seem to have lingered in the country down to the times of Gustavus Vasa. The sons of Olafr Trételega moved westward into Norway, and if we may trust the saga, the Swedish kingdom never again came into the possession of their family.

The subsequent kings of Sweden are said to have been descended from Ívarr Vífaðaði. The most prominent figures in this family are Harald Hilditönn Ívarr's grandson and his introduc
tion at Christianity. The story of the battle between these two at Bråvik, in which Harald lost his life, is one of the most famous in northern literature. But the position of these kings with regard to Sweden is far from clear. Their home is probably to be placed on the Cattegat rather than on the Baltic. The same is true also of Ragnar Leifbrók, who is said to have been the son of Ívarr Hringr. About the year 830 the missionary bishop Ansgar made his first expedition to Sweden. He made his way to Birca on the Mälar. The king whom he found reigning there is called Björn (Bern) and is generally identified with the king Björn for whom Bragi the Old composed the poem called Ragnaradrýpa. On his subsequent journeys to Sweden Ansgar encountered kings called Olafr and Önundr. He appears to have met with considerable immediate success in his missionary enterprises, although there is no evidence to show that the churches he founded long survived his death, and no serious mission seems to have been attempted for more than a century afterwards.

During the 9th century extensive Scandinavian settlements were made on the east side of the Baltic, and even as early as the reign of Louis I. we hear of piratical expeditions on the Black Sea and on the Caspian. The famous expeditions of Rurik and Askold which resulted in the origin of the Russian monarchy appear to have taken place towards the middle of the 9th century, but it has not been found possible to connect these names with any families known to us from Swedish tradition. Proofs of extensive Scandinavian settlement in Russia are to be found partly in the Russian names assumed by the Dnieper rapids by Constantine Porphyrogenitus, partly in references to this people made by foreign representatives at the court of Byzantium. The fact that many of the names which occur
in Russian chronicles seem to be peculiarly Swedish suggests
that Sweden was the home of the settlers, and the best authorities
consider that the original Scandinavian conquerors were Swedes
who had settled on the east coast of the Baltic.

In the time of Harold Fairhair, probably about the beginning
of the 10th century, we hear of a king named Eric the son of
Emund at Upsala, whose authority seems to have
reached as far as Norway. Later in the century
there is record of a king named Bjorn a Haugi
who is said to have been the son of Eric and to have reigned
fifty years. Bjorn's sons and successors were Olaf and Eric the Victorious.
Systorbjorn Starkf, of Olaf the Victorious, and
Flodd, who came to England with Eric after his father's death,
made himself a stronghold at Jomsborg in Pomerania and
spent some years in piratical expeditions. Eventually he betook him-
self to Harold Bluetooth, then king of Denmark, and endeav-
oured to secure his assistance in gaining the Swedish throne
by force of arms. Although he failed in this attempt he was
not deterred from attacking Eric, and a battle took place between
the two at the Fyrise (close to Upsala) in which Systborm was
defeated and killed. Eric himself died ten years after this battle,
apparently about 993. According to the story he had obtained
victory over Bolin in return for a promise made him by Eric the Victorious,
but had in the meantime himself
established himself as the
overlord of the north, in spite of the king's own inactivity. She lost her lands east of the Baltic, but received as
compensation in Norway part of Trondheim and the district
of Hadeland. The latter king of Norway, probably
Olaf Tryggvason, had married his sister Ingibiorg to Ragnvald,
earl of Vestergotland, on condition that he should receive
baptism, and the Swedish king's wife was also a Christian, though
he himself was not baptized until 1008 by Sigfrid at Husaby.
A quarrel arose in the last years of the 10th century between
Olaf Skottkonung and Olaf Tryggvason. The latter had applied
for the hand of Sigrid, the widow of Eric the Victorious, but had
then himself received her refusal to become a Christian. In the year
1000, when the Norwegian king was in Pomerania, a coalition
was formed between the king of Sweden, Sweyn Forkbeard,
king of Denmark, and Earl Eric of Lade, and the allies waylaid
their enemy off the coast near Rigen and overthrew him in
the great sea-battle of Svolder. Under Olaf Skott-
konung, Christianity was fully established in
Sweden. Olaf Tryggvason, the king of Norway,
married his sister Ingibiorg to Ragnvald, earl of
Vestergotland, on condition that he should receive
baptism, and the Swedish king's wife was also a Christian, though
he himself was not baptized until 1008 by Sigfrid at Husaby.

konung, Christianity was fully established in
Sweden. Olaf Tryggvason, the king of Norway,
Under Blotsweyn's grandson, King Sverker (1134–1155), who permanently amalgamated the Swedes and Goths (each of the two nations supplying the common king with sufficient troops for the duration, and alternately for the next hundred years), Sweden began to feel the advantage of a centralized monarchical government. Eric IX. (1190–1162) organized the Swedish Church on the model prevalent elsewhere, and undertook a crusade against the heathen Finlanders, which marks the beginning of Sweden's overseas dominion. Under Charles VII., the archbishopric of Upsala was founded (1154). But the greatest medieval statesman of Sweden was Earl Birger, who practically ruled the land from 1248 to 1266. To him is attributed the foundation of Stockholm; but he is best known as a legislator, and his wise reforms prepared the way for the abolition of serfdom. The increased dignity which the royal power owed to Birger was still further enlarged by the election of King Magnus Ladulás (1275–1290). Both these rulers, by the institution of separate and almost independent dukedoms, attempted to introduce into Sweden a feudal system similar to that already established elsewhere in Europe; but the danger of thus weakening the realm by partition was averted, though not without violent and tragic complications. Finally, in 1319, the severed portions of Sweden were once more reunited. Mean-}

## SWEDEN

Bremen in his *History* (iv. 26) apparently dates from the period immediately preceding these events. He describes the temple as one of great splendour and covered with gilding. In it stood the statues of the three chief deities, Thor, Odin and Frico (by whom he probably means Frey). Every nine years a great festival was held there to which embassies were sent by all the peoples of Sweden. A large number of cakes and even meats were sacrificed. Many such temples, the neighbourhood of the temple was a grove of peculiar sanctity in which the bodies of the victims were hung up. After the introduction of Christianity the importance of Upsala began to decline, and owing to its intimate associations with the old religion the kings no longer made it their residence.

### Authorities for Early History.—Tacitus, *Germania*, cap. 44; Claudius Ptolemaeus, *Geographica* ii. 11 ad fin.; Jordanes, *De origine actibusque gentis Goticae* iii. 5; *Hildebrandus, De bello gotico*, ii. 15; Bouchot, *Kerbeits, Vita S. Angarii in monumento Germaniae historicae*, i. 683–725 (Hanover, 1829); King Alfred's translation of *Orosius* iii. 11; Adam of Bremen, *Gesta Hammaburgensium ecclesiae pontificum* iii. and iv.; *Vulgata Sacra*, with the poem *Ynglingatal* contained in the *Heimskringla*; *Olaf's Saga Tryggvasonar* and *Olaf's Saga Hrani Helgi*, both contained in *Heimskringla* and in *Fornminnir*; *Sagor gramaticarum scissae Danum*; a collection of later Swedish Chronicles contained in *Rerum scandinavum scriptores*, vol. iii. (ed. Annerstedt, Upsala, 1871 and 1876); *Sveriges historia*, vol. i. (Monteius & Hildebrand, Stockholm, 1875–1877); Thomsen, *The Relations between Ancient Russia and Scandinavia and the Origin of the Russian State* (Oxford and London, 1877).

**Under Blotsweyn's grandson, King Sverker (1134–1155), who permanently amalgamated the Swedes and Goths (each of the two nations supplying the common king with sufficient troops for the duration, and alternately for the next hundred years), Sweden began to feel the advantage of a centralized monarchical government. Eric IX. (1190–1162) organized the Swedish Church on the model prevalent elsewhere, and undertook a crusade against the heathen Finlanders, which marks the beginning of Sweden's overseas dominion. Under Charles VII., the archbishopric of Upsala was founded (1154). But the greatest medieval statesman of Sweden was Earl Birger, who practically ruled the land from 1248 to 1266. To him is attributed the foundation of Stockholm; but he is best known as a legislator, and his wise reforms prepared the way for the abolition of serfdom. The increased dignity which the royal power owed to Birger was still further enlarged by the election of King Magnus Ladulás (1275–1290). Both these rulers, by the institution of separate and almost independent dukedoms, attempted to introduce into Sweden a feudal system similar to that already established elsewhere in Europe; but the danger of thus weakening the realm by partition was averted, though not without violent and tragic complications. Finally, in 1319, the severed portions of Sweden were once more reunited. Mean-**

### Separation of the Estates.

Between 1319 and 1344 the Riksdag was held twice a year. The union was broken in 1380, and the Estates met separately in Sweden in 1381, and in Norway in 1382. This was the beginning of the so-called *First Union with Norway*. Eric and of the Norwegian princess Ingeborg, who had inherited the throne of Norway from his grandfather Haakon V., was in the same year elected king of Sweden (Convent of Oslo). A long minority weakened the royal influence in both countries, and Magnus lost both his kingdoms before his death. The Swedes, irritated by his misrule, superseded him by his nephew, Albert of Mecklenburg (1363). In Sweden, Magnus's partialities, and necessities led directly to the rise of a powerful landed aristocracy, and, indirectly, to the growth of popular liberties. Forced by the unrelenting of the magnates to lean upon the middle classes, the king summoned (1359) the first Swedish Riksdag, on which occasion representatives from the towns were invited to appear along with the nobles and bishops. Gustav made it a condition that the king was forced to go a step farther and, in 1371, to take the first constitutional oath. In 1388, at the request of the Swedes themselves, Albert was driven out by Margaret, regent of Denmark and Norway; and, at a convention of the representatives of the three Scandinavian kingdoms held at Kalmar (1397), Margaret's great-nephew, Eric of Pomerania, was elected the common king, but the liberties of each of the three realms were expressly reserved and confirmed. The union was to be a personal, not a political union.

### First Union of the Unions.

Neither Margaret herself nor her successors observed the stipulation that in each of the three kingdoms only natives should hold land and high office, and the efforts of Denmark (at that time by far the strongest of the three member of the union) to impose her will on the successor were only a series of semi-ruptures. The Swedes first broke away from it in 1444 under the popular leader Engelbrecht, and after his murder they elected Karl Knutsson Bonde their king under the title of Charles VIII. (1436). In 1441 Charles VIII had to retire in favour of Christopher of Holstein, who was already king of Denmark and Norway; but, on the death of Christopher (1448), a state of confusion ensued in the course of which Charles VIII was twice expelled and twice reinstated. Finally, on his death in 1470, the three kingdoms were reunited under Christian I. of Denmark, the pretates and higher nobility of Sweden being favourable to the union, though the great majority of the Swedish people always detested it as a foreign usurpation. The national party was represented by the three great *Riks- föreständare*, or presidents of the realm, of the Sture family (see *Sturup*), who, with brief intervals, from 1470 to 1520 successively defended the independence of Sweden against the Danish kings and kept the national spirit alive. But this combination was too casual and anomalous an institution to rally the nations round it permanently, and when the tyranny of Christian II. (p.r.) became intolerable the Swedish people elected Gustavus Vasa, 1523, as president who had already driven out the Danes (see *Denmark: History*), king of Sweden at Strengnas (June 6, 1523).

The extraordinary difficulties of Gustavus (see *Gustavus I*) were directly responsible for the eccentric development, both political and religious, of the new kingdom which his genius created. So precarious was the position of the young king, that he was glad to make allies wherever he could find them. Hence his desire to stand well with the Holy See. Only three months after his accession, he addressed letters to the pope begging him to appoint new bishops "who would defend the rights of the Church without detriment to the Crown." He was especially urgent for the confirmation of his nominee Johannes Magni as primate, in the place of the rebellious archbishop Gustavus Trolle, who as a convicted traitor had been formally deposed by the Riksdag and actually an outlawed exile. If the pope would confirm the election of his bishop and remove from the Church. Scarcely had these letters been despatched when the king received a papal bull ordering the immediate reinstatement of Gustavus Trolle. The action of the Curia on this occasion was due to its conviction of the imminent triumph of Christian II. and the instability of Gustavus's position. It was a conviction shared by the rest of Europe; but, none the less, it was another of the many blunders of the Curia at this difficult period. Its immediate effect was the loss of the Swedish Church. Gustavus could not accept as primate an open and
determined traitor like Trolle. He publicly protested, in the
sharpest language, that unless Johannes Magni were recognized
at Rome as archbishop of Upsala, he was determined,
of his own royal authority, henceforth to order the
Church in his realm to the glory of God and the satisfaction of all Christian men. But the Holy
See was immovable, and Gustavus broke definitely with Rome. He
began by protecting and promoting the Swedish reformers
Olavus and Laurentius Petri, and Laurentius Andreae. The
new teaching was allowed to spread, though at first unostenta-
tiously and gradually. A fresh step in the direction of Lutheran-
ism was the translation of the New Testament into
Swedish, which was published in 1526. Simul-
taneously, a systematic attack was made upon the religious
abuses, beginning with the sequestration of the
monastery of Gripsholm in January 1526. But the affair
caused such general indignation that Gustavus felt obliged,
in May, to offer some justification of his conduct. A few months
later there was an open rupture between the king and his own
primate, who ultimately was frightened into exile by a sudden
accusation of treason. But the other bishops were also against
Gustavus, and, irritated by their conscientious opposition, the
king abandoned the no longer tenable position of a mode-
rator and came openly forward as an antagonist. In 1526 the
Catholic printing-presses were suppressed, and two-thirds of
the Church lands were appropriated to the payment of the
national debt. On the 18th of February 1527 two bishops,
the first martyrs of Catholicism in Sweden, were gibbeted at
Stockholm after a trial which was a parody of justice. This
act of violence, evidently designed to terrorize the Church into
submission, was effectual enough, for at the subsequent Riksdag
of Vesterås (June, 1527), the bishops durst not even present
a protest which they had privately prepared, and the assembly
itself was bullied into an absolute submission to the
royal will. The Riksdag of Vesterås, which transferred all ecclesiastical property to the
Crown. By the subsequent Vesterås Ordinance the
Swedish Church was absolutely severed from Rome. Never-
theless, the changes so made were mainly administrative.
There was no modification of doctrine, for the general resolution
that God's Word should be preached plainly and purely was not contrary to the teaching of the ante-Tridentine Church. Even
at the synod of Örebro, summoned in February 1529, "for the
better regulation of church ceremonies and discipline according
to God's Word," there was no formal protest against Rome; and the old ritual was retained for two years longer, though it
would be explained as symbolical. Henceforth the work of the
Reformation continued uninterrupted. In 1531 Laurentius
Petri was elected the first Protestant primate of Sweden. Subse-
quently matters were much complicated by the absolutist
tendencies of Gustavus. From 1539 onwards there was a breach
between him and his own prelates in consequence of his arbitrary
appropriation of the Church's share of the tithes, in direct
violation of the Vesterås Recess. Then Gustavus so curtailed
the power of the bishops (ordinances of 1539 and 1540) that they
had little of the dignity left them, and even that he was
displeased with. After 1543 the prelates appointed by
him, without any pretense of previous election by the cathedral
chapters, were called ordinaries, or superintendents. Finally,
at the Riksdag of Vesterås, in 1544, though no definite
cession of faith was formulated, a final breach was made
with the traditions of the old religion.
Thus the Reformation in Sweden was practically the work
of one strong man, acting (first from purely political and latterly
from purely economical reasons) for the good of the state as
he understood it. In this Gustavus acted contrary to the
religious instincts of the vast majority of the Swedish nation;
for there can be no doubt at all that the Swedes at the beginning
of the 17th century were not only still devoted to the old Church,
but violently anti-Protestant. This popular Romanism was
the greatest of all Gustavus's difficulties, because it tended to
alienate the Swedish peasants.

For the last hundred years the peasants had been a leading
factor in the political life of the land; and perhaps in no other
contemporary European state could so self-reliant
a class of yeomen have been found. Again and
again they had defended their own and the national liberties
against foreign foes. In the national assemblies, too, their voice
had always been powerful, and not infrequently predominant.
In a word, they were the sound kernel of the still but partially
developed Swedish constitution, the democratic safeguard
against the monarchical tendency which was enveloping the
rest of Europe. Gustavus's necessities had compelled him to
break with the ecclesiastical traditions of Sweden; and they
also compelled him, contrary to his masterful disposition,
that he would not be the first to tremble. Moreover, his
military undoubtedly was his natural allies, but, from the nature of the case,
they tended to become his most formidable rivals. They prided
themselves on having "set King Gus in the high seat," but they
were quite ready to unseat him if his rule was not to their liking,
and there were many things with which they were by no means
contented. This anomalous state of things was responsible
for the half-dozen peasant risings which with Gustavus had
to contend from 1525 to 1543. In all these rebellions the religious
difficulty figured largely, though the increasing fiscal burdens
with which Gustavus taxed the Swedes and the peasants, and their private
dependence on the national liberties or to crush altogether
Catholic aspirations. At the time of his death the Riksdag
was already a power in the state, and a Catholic reaction in
Sweden was by no means an impossibility, if only the Catholics
had been able to find capable leaders.

Gustavus's foreign policy at first aimed at little more than
self-preservation. Only with the pecuniary assistance of the
wealthy merchants of Lübeck had he been able to
establish himself originally; and Lübeck, in return,
was admitted to Sweden at a later date, as was Spain, as a 
means to exploit her American colonies. When, with the aid
of Denmark, Gustavus at last freed himself from this greedy
incubus (see Denmark; GUSTAVUS I; CHRISTIAN III) by
the truce of the 28th of August 1537, Sweden for the first time
in her history became the mistress of her own waters. But
even so she was but of subordinate importance in Scandinav-
ian politics. The hegemony of Denmark was indisputable,
and Gustavus regarded that power with an ever-increasing
suspicion which augured ill for peace in the future. The
chief cause of dispute was the quartering by the Danish king of
the troops of Swedes and Danes, the Dano-Norwegian shield, which
was supposed to indicate a claim of sovereignty. Still more
offensive was the attitude of Sweden's eastern neighbour Muscovy,
with whom the Swedish king was nervously anxious to stand
on good terms. Gustavus attributed to Ivan IV., whose resources
he unduly magnified, the design of establishing a universal
monarchy round the Baltic.

Nevertheless events were already occurring which ultimately
 compelled Sweden to depart from her neutrality and lay
the foundations of an overseas empire. In the last
year of Gustavus's life (1560), the ancient military
order of the Sword, amalgamated, since 1537, with the
more powerful order of the Teutonic Knights, had by the seculari-
ization of the latter order into the dukedom of Prussia (1525)
become suddenly isolated in the midst of hostile Slavonians.
It needed but a jolt to bring down the crazy anachronism, and
the jolt came when, in 1558–60, floods of Moscovites poured over the land, threatening the whole province with destruction. In his despair the last master of the order, Gotthard von Ketteler, appealed to all his mild, civilized neighbours to save him, and his dominions were quickly partitioned between Poland, Denmark and Sweden. Sweden's original share of the spoil was Reval, which, driven to extremities, placed itself beneath the protection of the Swedish crown in March 1561. From the moment that Sweden got a firm footing in Estonia by the acquisition of Reval she was committed to a policy of combat and aggrandisement. To have retreated would have meant the ruin of her Baltic trade, upon which the national prosperity so much depended. Her next-door neighbours, Poland and Russia, were necessarily her competitors; fortunately they were also each other's rivals; obviously her best policy was to counterpoise them. To accomplish this effectually she required to have her hands free, and the composition of her long-outstanding differences with Denmark by the Treaty of Stettin on the 13th of December 1570 (see DENMARK: History), which put an end to the Dano-Swedish war of 1563–70, the chief political event of the reign of Eric XIV. (1560–1568), the eldest son and successor of Gustavus Vasa, was therefore a judicious act on the part of the new king of Sweden, John III. (1568–1592). Equally judicious was the anti-Russian league with Stephen Bathory, king of Poland, concluded in 1578. The war between Russia and Sweden for the possession of Estonia and Livonia (1571–77) had been uninterruptedly disastrous to the latter. and, in the beginning of 1577, a countless Russian host sat down before Reval, Sweden's last stronghold in those parts. The energetic intervention of Bathory, however, speedily turned the scales in the opposite direction. Six months after his humiliating peace with the Polish monarch, Ivan IV, was glad to conclude a truce with Sweden also on a uni possidentis basis at Pilsna (Aug. 5, 1582).

The amicable relations between Sweden and Poland promised, at first, to be permanent. Sixteen years before his accession to the throne, John III, then duke of Finland, had wedded Catherine Jagiellonica, the sister of Sigismund II, king of Poland (Oct. 4, 1562). Duke Sigismund, the fruit of this union, was brought up by his mother in the Catholic religion, and, on the 19th of August 1587, he was elected king of Poland. Sixteen days later the Articles of Kalmar, signed by John and Sigismund, regulated the future relations between the two countries when, in process of time, Sigismund should succeed his father as king of Sweden. The two kingdoms were to be in perpetual alliance, but each of them was to retain its own laws and customs. Sweden was also to enjoy her religion, subject to such changes as a general council might make; but neither pope nor council was to claim or exercise the right of releasing Sigismund from his obligations to his Swedish subjects. During Sigismund's absence from Sweden that realm was to be ruled by seven Swedes, six elected by the king and one by his uncle Duke Charles of Sudermania, the leader of the Swedish Protestants. No new tax was to be levied in Sweden during the king's absence, but Sweden was never to be administered from Poland. Any necessary alterations in these articles were only to be made with the common consent of the king, Duke Charles, the senate and the gentry of Sweden.

The endeavours of Swedish statesmen to bind the hands of their future king were due to their fear of the rising flood of the Catholic reaction in Europe. Under Eric XIV. the Reformation in Sweden had proceeded on much the same lines as during the reign of his father, retaining all the old Catholic customs not considered contrary to Scripture. Naturally, after 1544, when the Council of Trent had formally declared the Bible and tradition to be equal and authoritative sources of all Christian doctrine, the contrast between the old and the new teaching became more obvious; and in many countries a middle party arose which aimed at a compromise by going back to the Church of the Fathers. King John III., the most learned of the Vasa, and somewhat of a theological expert, was largely influenced by these "middle" views. As soon as he had mounted the throne he took measures to bring the Swedish Church back to "the primitive Apostolic Church and the Swedish Catholic faith"; and, in 1574, persuaded a synod assembled at Stockholm to adopt certain articles framed by himself on what we should call a High Church basis. In February 1575 a new Church ordinance, approximating still more closely to the patristic Church, was presented to another synod, and accepted thereat, but very unwillingly. In 1576 a new liturgy was issued on the model of the Roman missal, but with considerable modifications. To a modern High Anglican these innovations seem innocent enough, and, despite the opposition of Duke Charles and the ultra-Protestants, they were adopted by the Riksdag of 1577. These measures ireally encouraged the Catholic party in Europe, and John III. was ultimately persuaded to send an embassy to Rome to open negotiations for the reunion of the Swedish Church with the Holy See. But though the Jesuit Antonio Possevino was sent to Stockholm to complete John's "conversion," John would only consent to embrace Catholicism under certain conditions which were never kept, and the only result of all these subterfuge negotiations was to incense the Protestants still more against the new liturgy, the use of which by every congregation in the realm without exception was, nevertheless, decreed by the Riksdag of 1582. At this period Duke Charles and his Protestant friends were clearly outnumbered by the promoters of the via media. Nevertheless, immediately after King John's death, a synod summoned to Upsala by Duke Charles rejected the new liturgy and drew up an anti-Catholic confession of faith (March 5, 1593). Holy Scripture and the three primitive creeds were declared to be the true foundations of Christian faith, and the Augsburg Confession was adopted. That Sigismund, now the lawful king of Sweden, should regard the summoning of a Civil War. the synod of Upsala without his previous knowledge as Expulsion of a direct infringement of the Riksdag, which he had Proclamation of previously refused him that office) made a civil war inevitable. The battle of Stångåbro (Sept. 25, 1595) decides the struggle in favour of Charles—and Protestantism. Sigismund fled from Sweden, never to return, and on the 19th of March 1600 the Riksdag of Linköping proclaimed the duke king, but not till the 6th of March 1604, however, after Duke John, son of John III., had formally renounced his hereditary right to the throne, did Charles IX. begin to style himself king. At the Riksdag of the same year, the estates committed themselves irrevocably to Protestantism by excluding Catholics from the succession to the throne, and prohibiting them from holding any office or dignity in Sweden. Henceforth, too, every recusant was to be deprived of his estates and reduced to beggary.

It was in the reign of Charles IX. that Sweden became not only a predominantly Protestant, but also a predominantly military monarchy. This momentous change, which was to give a martial colouring to the whole policy of Sweden for the next hundred and twenty years, dates from a decree of the Riksdag of Linköping establishing, at the urgent suggestion of Charles, a regular army; each district in the country being henceforward liable to provide and maintain a fixed number of infantry and cavalry for the service of the state. The immediate enemy was then Poland, now dynastically as well as territorially opposed to Sweden. The struggle took the character of a contest for the possession of the northern Baltic provinces. Estonia was recovered by the Swedes in 1600, but their
determined efforts (1601–9) to gain a foothold in Livonia were frustrated by the military ability of the grand hetman of Lithuania, Jon Karol Chodkiewicz. In 1608 hostilities were transferred to Russian territory. At the beginning of that year Charles had concluded an alliance with Tsar Basil IV. (g.v.) against their common foe, the Polish king; but when, in 1611, Basil was deposed by his own subjects and the whole tsardom seemed to be on the verge of dissolution, Sweden's policy towards Russia changed its character. Hitherto Charles had aimed at supporting the weaker Slavonic power against the stronger; but now that Muscovy seemed about to disappear from among the nations of Europe, Swedish statesmen naturally sought some compensation for the expenses of the war before Poland had had time to absorb everything. A beginning was made by the siege and capture of Kexholm in Russian Finland (March 2, 1611), and, on the 9th of July, Great Novgorod was occupied and a convention concluded with the magistrates of that wealthy city whereby Charles IX.'s second son Philip was to be recognized as tsar, unless, in the meantime, relief came to Great Novgorod from Moscow. But now, when everything depended on a continuation of minority Charles's impudent statement amounted to the title of "King of the Lapps of Nordland," which people properly belonged to the Danish Crown, involved him in another war with Denmark, a war known in Scandinavian history as the war of Kalmar because the Swedish fortress of Kalmar was the chief theatre of hostilities. Thus the Swedish forces were diverted from their real objective and transferred to another field where even victory would have been comparatively unprofitable. But it was disaster, not victory, which Charles IX. reaped from this foolishly entreprise. Still worse, the war of Sweden, which was concluded by Charles's son, Gustavus Adolphus, in the second year of his reign, by the peace of Kongsholm, (Jan. 20, 1613) imposed such onerous pecuniary obligations and such intense suffering upon Sweden as to kindle into a fire of hatred, which was to burn fiercely for the next two centuries, the long smouldering antagonism between the two sister nations of Scandinavia which dated back to the bloody days of Christian II.

The Russian difficulty was more easily and more honourably adjusted. When Great Novgorod submitted provisionally to the suzerainty of Sweden, Swedish statesmen had believed, for a moment, in the creation of a Trans-baltic dominion extending from Lake Ilmen northwards to Archangel and eastwards to Vologda. The rallying of the Russian nation round the throne of the new tsar, Michael Romanov, dissipated, once for all, this ambitious dream. By the beginning of 1616, Gustavus had become convinced of the impossibility of partitioning reunited Muscovy, while Muscovy recognized the necessity of buying off the invincible Swedes by some cession of territory. By the Peace of Stolbova (Feb. 27, 1617), the tsar surrendered to the Swedish king the provinces of Kexholm and Ingria, including the fortress of Nöteborg (the modern Schlüsselburg), the key of Finland, Russia, furthermore, renounced all claims upon Ethonia and Livonia, and paid a war indemnity of 20,000 roubles. In return for these concessions, Gustavus restored Great Novgorod and acknowledged Michael Romanov as tsar of Muscovy.

The same period which saw the extension of the Swedish Empire abroad, saw also the peaceful development of the Swedish constitution at home. In this, as in every other matter, Gustavus himself took the initiative. Nominally the Senate still remained the dominant power in the state; but gradually all real authority had been transferred to the crown. The Riksråd speedily lost its ancient character of a grand council representing the semi-feudal landed aristocracy, and became a bureaucracy holding the chief offices of state at the good pleasure of the king. The Riksdag also changed its character at the same time. Whilst in every other European country except England, the ancient popular representation by estates was about to disappear altogether, in Sweden under Gustavus Adolphus it grew into an integral portion of the constitution. The Riksdag ordinance of 1617 first converted a turbulent and haphazard mob of "riksgämen," huddling together like a flock of sheep "or drunken boors," into a dignified national assembly, meeting and deliberating according to rule and order. One of the nobility (first called the Landmärschall, or marshal of the Diet, in the Riksdag ordinance of 1526) was now regularly appointed by the king as the spokesman of the Riddarhus, or House of Nobles, while the primate generally acted as the talman or president of the chamber of estates. The Diet was to meet two times a year, and at a later day each of the three lower estates elected its own talman. At the opening of every session, the king submitted to the estates "royal propositions," or bills, upon which each estate proceeded to deliberate in its own separate chamber. The replies of the estates were delivered to the king at a subsequent session in congress. Whenever the estates differed amongst themselves, the king chose whatever opinion seemed best to him. The rights of the Riksdag were secured by the Konungsforbörjan, or assurance given by every Swedish king on his accession, guaranteeing the collaboration of the estates in the work of legislation, and they were also to be consulted on all questions of foreign policy. The king possessed the initiative; but the estates had the right of objecting to the measures of the government at the close of each session. It is in Gustavus's reign, too, that we first hear of the Hemliga Utskott, or "secret committee" for the transaction of extraordinary affairs, which was elected by the estates themselves.

The eleven Riksdags held by Gustavus Adolphus were almost exclusively occupied in finding ways and means for supporting the ever-increasing burdens of the Polish and German wars. And to the honour of the Swedish people it is said that from first to last, they showed a religious and patriotic zeal which shrunk from no sacrifice. It was to this national devotion quite as much as to his own qualities that Gustavus owed his success as an empire-builder.

The wars with Denmark and Russia had been almost exclusively Scandinavian wars; the Polish war was of worldwide significance. It was, in the first place, a struggle for the Baltic littoral, and the struggle was intensified by the knowledge that the Polish Vasas denied the right of succession, guaranteeing the collaboration of the estates in the work of legislation, and they were also to be consulted on all questions of foreign policy. The king possessed the initiative; but the estates had the right of objecting to the measures of the government at the close of each session. It is in Gustavus's reign, too, that we first hear of the Hemliga Utskott, or "secret committee" for the transaction of extraordinary affairs, which was elected by the estates themselves.

The twelve Riksdags held by Gustavus Adolphus were almost exclusively occupied in finding ways and means for supporting the ever-increasing burdens of the Polish and German wars. And to the honour of the Swedish people it is said that from first to last, they showed a religious and patriotic zeal which shrunk from no sacrifice. It was to this national devotion quite as much as to his own qualities that Gustavus owed his success as an empire-builder.

and, in June 1629, the king gladly accepted the lucrative truce of Altmark. By this truce Sweden was, for six years, to retain possession of her Livonian conquests, besides holding Elbing, the Vistula delta, Braunsberg in West, and Pillau and Memel in East Prussia, with the right to levy tolls at Pillau, Memel, Danzig, Liebiau and Windau. From these tolls Gustavus derived, in 1629 alone, 500,000 rix-dollars, a sum equivalent to the whole of the extraordinary subsidies granted to him by the Riksdag. Thus Sweden held, for a time, the control of the principal trade routes of the Baltic up to the very confines of the empire; and the increment of revenue resulting from this commanding position was of material assistance to her during the earlier stages of the war in Germany, whither Gustavus transferred his forces in June 1630.

The motives of Gustavus in plunging into the Thirty Years' War and the details of the struggle as regards Sweden are elsewhere

**Sweden and where set forth (see Gustavus II.; Oxenstjerna the Thirty [Axel]; Banér [Johan]; Torstensson [Len]; Sart).** Here the only point to be insisted upon is the extreme precariousness of the Swedish position from first to last—a precariousness due entirely to inadequacy of material resources. In 1632 all Germany lay at the feet of Sweden; two years later a single disaster (Nördlingen) brought her empire to the verge of ruin. For the next seven years the German War as regards Sweden was a struggle for existence. She triumphed in the end, it is true, but it was a triumph due entirely to a lucky accident—the possession, during the crisis, of the greatest statesman and the greatest captain of the age. It was the exploits of Oxenstjerna and Banér which alone enabled Sweden to obtain even what she did obtain at the great Westphalian peace congress in 1648. Her original demands were Silesia (she held most of the fortresses there), Pomerania (which had been in her possession for nearly twenty years), and a war indemnity of 20,000,000 rix-dollars. What she actually got was (1) Upper Pomerania, with the islands of Rügen and Usedom, and a strip of Lower Pomerania on the right bank of the Vistula, including the towns of Stettin, Garz, Damm and Golnow, and the island of Wollin, with the right of succession to the rest of Lower Pomerania in the case of the extinction of the Brandenburg Hohenzollerns; (2) the town of Wismar with the districts of Poel and Neukolster; (3) the secularized bishoprics of Bremen and Verden; and (4) 5,000,000 rix-dollars. These German possessions were to be held as fiefs of the empire; and in respect thereof Sweden was to have a vote in the imperial Diet and to "direct" the Lower Saxon Circle alternately with Brandenburg. France and Sweden, moreover, became joint guarantors of the treaty with the emperor, and Sweden suffered with the carrying out of its provisions, which was practically effected by the executive congress of NitreMbarg in 1650.

Sweden's reward for the exertions and sacrifices of eighteen years was meagre, almost paltry. Her newly won possessions were both small and scattered, though, on the other hand, she had secured the practical control of the three principal rivers of north Germany—the Oder, the Elbe and the Weser—and reaped the full advantage of the tolls levied on those great commercial arteries. The jealousy of France and the impatience of Queen Christina were the chief causes of the inadequacy of her final recompense. Yet, though the immediate gain was small, she had not dissipated her blood and treasure altogether in vain. Her vigorous intervention had saved the cause of religious liberty in Europe; and this remains, for all time, her greatest political achievement. Henceforth till her collapse, seventy years later, she was the recognized leader of Continental Protestantism. A more questionable benefit was her rapid elevation to the rank of an imperial power, an elevation which imposed the duty of remaining a military monarchy, armed cap-a-pie for every possible emergency. Every one recognizes now that the poverty and weakness of Sweden united her for such a tremendous destiny. But in the middle of the 17th century the incompatibility between her powers and her pretensions was not so obvious. All her neighbours were either decadent or exhausted states; and France, the most powerful of the Western powers, was her firm ally.

For the moment, however, Sweden held the field. Everything depended upon the policy of the next few years. Very careful statesmanship might mean permanent domination. Queen Christina, 1644-1654. The motives of Gustavus Adolphus's two immediate successors, Christina and Charles X., shook the flimsy fabric of his empire to its very base. Christina's extravagance was financial. At the time of her abdication the state was on the verge of bankruptcy, and the financial difficulty had superintended a serious political agitation. The mass of the Swedish people was penetrated by a justifiable fear that the external, artificial greatness of their country might, in the long run, be purchased with the loss of their civil and political liberties. In a word, the natural equilibrium of Swedish society was seriously threatened by the preponderance of the nobility; and the people at large looked to the new king to redress the balance. A better arbiter between the various estates than Charles X., 1654-1660, it would have been difficult to find. It is true that, primarily a soldier, his whole ambition was directed towards military glory; but he was also an unusually sharp-sighted politician. He attempted to believe that only by force of arms could Sweden retain the dominion which by force of arms she had won; but he also grasped the necessity that there must be no disunion at home if she were to continue powerful abroad. The most pressing question of the day, the so-called Reduktion, or restitution of the alienated crown lands, was adjusted provisionally at the Riksdag of 1655. The king proposed that the actual noble holders of crown property should either pay an annual sum of 200,000 rix-dollars, to be allowed for out of any further crown lands subsequently falling in to them, or should surrender a fourth of the expectant property itself to the estimated amount of 600,000 rix-dollars. The sundry attempted to escape the necessity as far as possible by stipulating that the 6th of November 1612, the day of Gustavus Adolphus's death, should be the extreme limit of any retroactive action on the part of the crown in regard to alienated crown property, and that the present subsidy should be regarded as "a perpetual ordinance" unalterably to be observed by all future sovereigns—in other words, that there should be no further restitution of alienated crown property. Against this interpretation of the subsidy bill the already over-taxed lower estates protested so energetically that the Diet had to be suspended. Then the king intervened personally; not to quell the commotions, as the senate insisted, but to compel the nobility to give way. He proposed that the whole matter should be thoroughly investigated by a special committee before the meeting of the next Riksdag, and that in the meantime a contribution should be levied on all classes proportionately. This equitable arrangement was accepted by the estates forthwith.

Charles X. had done his best to obviate the effects of the financial extravagance of Christina. It may well be doubted, however, whether his own extravagant desire for military glory was not equally injurious to his country. In three days he had succeeded in persuading the Swedish estates of the lucrative expediency of his unnecessary and immoral attack on Poland (see Poland: History); but when he quitted Stockholm for Warsaw, on the 10th of July 1654, he little imagined that he had embarked on an adventure which was to contribute far more to his glory than to the advantage of his country. How the Polish War expanded into a general European war; how Charles's miraculous audacity again and again ravished favours from Fortune and Nature (e.g. the passage of the Belts) when both those great powers combined against him; how, finally, he emerged from all his difficulties triumphant, indeed, but only to die of sheer exhaustion not six months afterwards.

Christina's reign dates, properly, from 1644 when she attained her majority. From 1652 to 1654 Axel Oxenstjerna was virtually the ruler of Sweden.
in his thirty-eighth year—all this has elsewhere been described (see Charles X., king of Sweden; CZARNIECKI [STEPHEN]; Frederick III., king of Denmark). Suffice it to say that, immediately after his death, the regency appointed to govern Sweden during the minority of his only son and successor, Charles XI., a child four years old, hastened to come to terms with Sweden's numerous enemies, which now included Russia, Poland, Brandenburg and Denmark. The Peace of Oliva (May 3, 1660), made under French mediation, put an end to the long feud with Poland and, at the same time, ended the quarrel between Sweden and the German empire, and the emperor and the elector of Brandenburg on the other. By this peace, Sweden's possession of Livonia, and the elector of Brandenburg's sovereignty over east Prussia, were alike confirmed; and the king of Poland renounced all claim to the Swedish crown. As regards Denmark, the Peace of Oliva signified the desertion of her three principal allies, Poland, Brandenburg and the emperor, and thus compelled her to reopen negotiations with Sweden direct. The differences between the two states were finally adjusted by the peace of Copenhagen (May 15, 1660), ceding the three Baltic provinces to Sweden but receiving back the Norwegian province of Trondhjem and the isle of Bornholm which she had surrendered by the peace of Roskilde two years previously. Denmark was also compelled to recognize, practically, the independence of the dukes of Holstein-Gottorp. The Russian War was terminated by the Peace of Kardis (July 2, 1661), confirmatory of the Peace of Stolbova, whereby the tsar surrendered to Sweden all his Baltic provinces—Ingria, Esthonia and Kealholm.

Thus Sweden emerged from the war not only a military power of the first magnitude, but also one of the largest states of Europe, possessing about twice as much territory as modern Sweden. Her area embraced 16,800 geographical square miles, a mass of land 7,000 sq. m. larger than the modern German Empire. Yet the Swedish Empire was rather a geographical expression than a state with natural and national boundaries. Modern Sweden is bounded by the Baltic; during the 17th century the Baltic was merely the bond between her various widely dispersed dominions. All the islands in the Baltic, except the Danish group lying between the southern and eastern estuaries of the German rivers (for the Niemen and Vistula are properly Polish rivers) debouched in Swedish territory, within which also lay two-thirds of Lake Ladoga and one-half of Lake Peipus. Stockholm, the capital, lay in the very centre of the empire, whose second greatest city was Riga, on the other side of the sea. Yet this vast empire contained but half the population of modern Sweden—being only 2,500,000, or about 140 souls to the square mile. Further, Sweden's new boundaries were of the most insecure description, inasmuch as they were anti-ethnographical, parting asunder races which naturally went together, and behind which stood powerful neighbours of the same stock ready, at the first opportunity, to reunite them.

Moreover, the commanding political influence which Sweden had now won was considerably neutralized by her loss of moral prestige. On Charles X.'s accession in 1655, Sweden's neighbours, though suspicious and uneasy, were at least not adversaries, and might have been converted into allies of the new great power who, if she had mulcted them of territory, had, anyhow, compensated them for the loss with the by no means contemptible deus ex machina of religious liberty. At Charles X.'s death, five years later, we find Sweden, herself bred to exhaustion point, surrounded by a broad belt of desolated territory and regarded with ineradicable hatred by every adjacent state. To sink in five years from the position of the champion of Protestantism to that of the common enemy of every Protestant power was a degradation not to be compensated by any amount of military glory. Charles's subsequent endeavour, in stress of circumstances, to gain a friend by dividing his Polish conquests with the aspiring elector of Brandenburg was a reversal of his original policy and only resulted in the establishment on the southern confines of Sweden of a new rival almost as dangerous as Denmark, her ancient rival in the west.

In 1660, after five years of incessant warfare, Sweden had at length obtained peace and with it the opportunity of organizing and developing her newly won empire. Unfortunately, the regency which was to govern her during the next fifteen years was unequal to the difficulties of a situation which might have taxed the resources of the wisest statesmen. Unity and vigour were scarcely to be expected from a many-headed democracy, and the conflicting and contrary opinions speedily gave rise to contending factions. There was the high-aristocratic party with a leaning towards martial adventure headed by Magnus de la Gardie (q.v.), and the party of peace and economy whose ablest representative was the liberal and energetic Johan Gyllenstjerna (q.v.). After a severe struggle, de la Gardie's party prevailed; and its triumph was marked by that general decline of personal and political morality which has given to this regency its unenviable notoriety. Sloth and carelessness speedily invaded every branch of the administration, destroying discipline and leading to a general neglect of business. Another characteristic of the de la Gardie government was its gross corruption, which made Sweden the obsequious hireling of that foreign power which had the longest purse. This shameful "subsidy policy" dates from the Treaty of Fontainebleau, 1661, by a secret paragraph of which Sweden, in exchange for a considerable sum of money, undertook to support the French candidate on the first vacancy of the Polish throne. The complications ensuing from Louis XIV.'s designs on the Spanish Netherlands led to a bid for the Swedish alliance, both from the French king and his adversaries. After much hesitation on the part of Sweden, the French government, the anti-French faction prevailed; and in April 1668 Sweden acceded to the Triple Alliance, which finally checkmated the French king by bringing about the Peace of Aix-la-Chapelle. For the next four years Sweden remained true to the principles of the Triple Alliance; but, in 1672, Louis XIV. succeeded in isolating the Dutch republic and regaining his ancient ally, Sweden. By the Treaty of Stockholm (April 14, 1672), Sweden became, for the next ten years, a "mercenarius Galliae," pledging herself, in return for 400,000 crowns per annum in perpetuity and to discipline and leaving to a greater extent to the personal expeditions of the German princes. Under the alliance, the Swedish army only remained in the field, was charged with 5,000 men, any German princes who might be disposed to assist Holland. In 1674 Louis XIV. peremptorily called upon Sweden to fulfil her obligations by invading Brandenburg. In the course of May 1675 a Swedish army advanced into the Mark, but on the 18th of June was defeated at Fehrbellin, and hastily retreated to Demmin. The Fehrbellin affair was a mere skirmish, the actual casualties amounting to less than 800 men, but it rudely divested Sweden of her nimbus of invincibility and was the signal for a general attack upon her, known as the Scanian War. In the course of the next three years her empire seemed to be crumbling away everywhere. In 1675 Pomerania and the bishopric of Bremen were overrun by the Brandenburgers, Austrians and Danes. In December 1677 the elector of Brandenburg captured Stettin. Stralsund fell on the 15th of October 1678. Greifswald, Sweden's last possession on the Continent, was lost on the 5th of November. A defensive alliance with Sobieski (August 4, 1677) was rendered ineffectual by the annihilation of Sweden's sea-power (battle of Oland, June 17, 1676; battle of Fehmarn, June 1677) and the difficulties of the Polish king. Two accidents at this crisis alone saved Sweden from ruin—the splendid courage of the young king who, resolutely and successfully, kept the Danish invaders at bay (see CHARLES XI., king of Sweden), and the diplomatic activity of Louis XIV. In March 1677 a peace congress began its sessions at Nijmegen; and in the beginning of April 1678 the French king dictated the terms of a general pacification. One of his chief conditions was the complete restitution of Sweden. A strong Sweden was necessary to the accomplishment of his plans. He suggested, however, that Sweden should rid herself of her enemies by
making some “small cession” to them. This Charles XI. refused to do, whereupon Louis took it upon himself to conclude peace on Sweden’s account without consulting the wishes of the Swedish king. By this Treaty of Nijmegen, (Feb. 7) and of St Germain (June 29, 1679) Sweden virtually received full restitution of her German territory. On the 2nd of September by the Peace of Fontainebleau (confirmed by the subsequent Peace of Lund, Oct. 4, 1679), Denmark was also forced to retrocede her conquests. It is certain that Sweden herself could never have extorted such favourable terms, yet “the insufferable tutelage” of France on this occasion inspired Charles XI. with so much distaste that it resulted in a strong anti-French bias (see CHARLES XI.; OXENSTJERNA, BENEDICT).

The remainder of the reign of Charles XI. is remarkable for a revolution which converted the government of Sweden into a semi-absolute monarchy. The king emerged from the war convinced that if Sweden were to retain her position as a great power she must radically reform her whole economical system, and, above all, circumvent the predominant and mischievous influence of an aristocracy which thought far more of its privileges than of its public duties. He felt that he could now draw upon the confidence and liberality of the lower orders to an unlimited extent, and he proceeded to do so. The Riksdag which assembled in Stockholm in October 1680 begins a new era of Swedish history. On the motion of the Estate of Peasants, which had a long memory for aristocratic abuses, the question of the recovery of the alienated crown lands was brought before the Riksdag, and, despite the stubborn opposition of the magnates, a resolution of the Diet directed that all crownships, baronies, domains, and other estates producing an annual rent of more than £50 per annum should revert to the Crown. The same Riksdag decided that the king was not bound by any particular constitution, but only by law and the statutes. Nay, they added that he was not even obliged to consult the council of state, but was to be regarded as a sovereign lord, responsible to God alone for his actions, and requiring no intermediary between himself and his people. The council thereupon acquiesced in its own humiliation by meekly accepting a royal brief changing its official title from Rimskad (council of state) to Kungigard (royal council)—a visible sign that the senators were no longer the king’s colleagues but his servants.

Thus Sweden, as well as Denmark, had become an absolute monarchy, but with this important difference, that the right of the Swedish people, in parliament assembled, to be consulted on all important matters was recognized and acted upon. The Riksdag, completely overshadowed by the throne, was during the reign of Charles XI. to do little more than register the royal decrees; but nevertheless it continued to exist as an essential part of the machinery of government. Moreover, this transfer of authority was voluntary on the people, knowing the king to be their best friend, trusted him, and happily co-operated with him cheerfully. The Riksdag of 1682 proposed a fresh Reduktion, and declared that the whole question of how far the king was empowered by the law of the land to bestow fefts, or, in case of urgent national distress, take them back again, was exclusively his majesty’s affair. In other words, it made the king the disposer of his subjects’ temporal property. Presently this new principle of autocracy was extended to the king’s legislative authority also, for, on the 9th of December 1682, all four estates, by virtue of a common declaration, not only confirmed him in the possession of the legislative powers enjoyed by his predecessors, but even conceded to him the right of interpreting and amending the common law.

The recovery of the alienated crown lands occupied Charles XI. for the rest of his life. It was conducted by a commission which was ultimately converted into a permanent department of state. It acted on the principle that the titles of all private landed estate might be called in question, inasmuch as at some time or other it must have belonged to the Crown; and the burden of proof of ownership was held not to lie with the Crown which made the claim, but with the actual owner of the property. The amount of revenue accruing to the Crown from the whole Reduktion it is impossible to estimate even approximately; but by these means, combined with the most careful management and the most rigid economy, Charles XI. contrived to reduce the national debt from £2,587,000 to £500,000.

These operations represent only a part of Charles XI.’s gigantic activity. Here we have only space sufficient to glance at the reorganization of the national armaments. The king, on regaining his personal independence in 1679, re-established the indeelingsverk introduced by Charles IX.—a system of military tenure whereby the national forces were bound to the soil. Thus there was the rusthäll tenure, under which the tenants, instead of paying rent, were obliged to equip and maintain a cavalry soldier and horse, while the knektbläser supplied duly equipped foot soldiers. These indeelings soldiery were provided with holdings on which they lived in times of peace. Formerly, ordinary conscription had existed alongside this indeeling, or distribution system; but it had proved inadequate as well as highly unpopular; and, in 1682, Charles XI. came to an agreement with the peasantry whereby an extended indeeling system was to be substituted for general conscription. The navy, of even more importance to Sweden if she were to maintain the dominion of the Baltic, was entirely remodelled; and, the recent war having demonstrated the unsuitability of Stockholm as a naval station, the construction of a new arsenal on a gigantic scale was simultaneously begun at Karlskrona. After a seventeen years’ struggle against all manner of financial difficulties, the twofold enterprise was completed. At the death of Charles XI. Sweden could boast of a fleet of forty-three three-deckers (maned by 11,000 men and armed with 2648 guns) and one of the finest arsenals in the world.

Charles XI. had carefully provided against the contingency of his successor’s minority; and the five regents appointed by him, if not great statesmen, were at least practical politicians who had not been trained in his austere school in vain. At home the Reduktion was cautiously pursued, while abroad the successful conclusion of the great peace congress at Ryswick was justly regarded as a signal triumph of Sweden’s pacific diplomacy (see OXENSTJERNA FAMILY). The young king was full of promise, and had not been permitted gradually to gain experience and develop his naturally great talents beneath the guidance of his guardians, as his father had intended, all might have well for Sweden. Unfortunately, the sudden, noiseless revolution of the 6th of November 1697, which made Charles XII. absolute master of his country’s fate in his fifteenth year (see CHARLES XII.), and the league of Denmark, Saxony and Russia, formed two years later to partition Sweden (see PATkul, JOHANN KNEIBOLD; PETER THE GREAT; CHARLES XII.), precipitated Sweden into a sea of troubles in which she was finally submerged.

From the very beginning of the Great Northern War Sweden suffered from the inability of Charles XII. to view the situation from anything but a purely personal point of view. His determination to avenge himself on enemies overwhelmed every other consideration. Again and again during these eighteen years of warfare it was in his power to dictate an advantageous peace. After the dissipation of the first coalition against him by the peace of Trondvall (Aug. 18, 1700) and the victory of Narva (Nov. 20, 1700), the Swedish chancellor, Benedict Oxenstjerna, rightly regarded the universal bidding for the favour of Sweden by France and the maritime powers, then on the eve of the War of the Spanish Succession, as a golden opportunity of “ending this present lean war and making his majesty the arbiter of Europe.” But Charles, intent on dethroning Augustus of Poland, held haughtily aloof. Subsequently in 1701 he rejected a personal appeal from William III. to conclude peace on his
own terms. Five years later (Sept. 24, 1706) he did, indeed, conclude the Polish War by the peace of Altranstädt, but as this treaty brought no advantage to Sweden, not even compensation for the expenses of six years of warfare, it was politically condemnable. Moreover, two of Sweden's Baltic provinces, Esthonia and Ingria, had been seized by the tsar, and a third, Livonia, had been well-nigh ruined. Yet even now Charles, by a stroke of the pen, could have compensated everything he had lost. In 1707 Peter was ready to retrocede everything except St Petersburg and the line of the Neva, and again Charles preferred risking the whole to saving the greater part of his Baltic possessions (for details see CHARLES XII.; PETER THE GREATEST). When at last, after the catastrophe of Poltava (June 1709) and the flight into Turkey, he condescended to use diplomatic methods, it was solely to prolong, not to terminate, the war. Even now he could have made honourable terms with his numerous enemies. The resources of Sweden were still very far from being exhausted, and, during 1710 and 1711, the gallant Magnus Stenbock (q.v.) upheld her military supremacy in the north. But all the efforts of the Swedish government were wrecked on the determination of Charles XII. to surrender nothing. Thus be rejected advantageous offers of mediation and alliance made to him, during 1712, by the maritime powers and by Prussia; and, in 1714, he scouted the friendly overtures of Louis XIV. and the emperor, so that when peace was finally concluded between France and the Empire, at the congress of Baden, Swedish affairs were, by common consent, left out of consideration. When, on the 14th of September 1714, he suddenly returned to his dominions, Stralsund and Wismar were all that remained to his continental possessions; while by the end of 1715 Sweden, now fast approaching the last stage of exhaustion, was at open war with England, Hanover, Russia, Prussia, Saxony and Denmark, who had formed a coalition to partition her continental territory between them. Nevertheless, at this the eleventh hour of her opportunities, Sweden might still have saved something from the wreck of her empire if Charles had behaved like a reasonable being (see CHARLES XII.; PETER THE GREATEST; GÖRTZ, GEORG HEINRICH VON; OSTERBÖCK, ANDREAS); but he would have shown no disposition to play off Russia against England, and his sudden death before Fredrikshald (Dec. 11, 1718) left Sweden practically at the end of her resources and at the mercy of her enemies. At the beginning of 1719 pacific overtures were made to England, Hanover, Prussia and Denmark. By the treaties of Stockholm (Feb. 20, 1719, and Feb. 1, 1720) Hanover obtained the bishoprics of Bremen and Verden for herself and Stettin for her confederate Prussia. By the treaty of Frederiksborg or Copenhagen (March 5, 1720) his dominions were increased by the cession of Esthonia and Livonia, the Finnish province of Kexholm and the fortress of Viborg. Finland west of Viborg and north of Kexholm was restored to Sweden. She also received an indemnity of two millions of thalers and a solemn undertaking of non-interference in her domestic affairs. It was not the least of Sweden's misfortunes after the Great Northern War that the constitution, which was to compensate her for all her past sacrifices, should contain within it the elements of many of her future calamities. Early in 1720 Charles XII.'s sister, Ulrica Leonora, who had been elected queen of Sweden immediately after his death, was permitted to abdicate in favour of her husband, Frederick I., the prince of Hesse, who was elected king under the title of Frederick I.; and Sweden was thus at the same time, converted into the most limited monarchy of monarchies. All that was vested in the people as represented by the Riksdag, consisting, as before, of four distinct estates, nobles, priests, burgesses and peasants, sitting and deliberating apart. The conflicting interests and mutual jealousies of these four independent assemblies made the work of legislation exceptionally difficult. No measure could now become law till it had obtained the assent of three at least of the four estates; but this provision, which seems to have been designed to protect the lower orders against the nobility, produced evils far greater than those which it professed to cure. Thus, measures might be passed by a bare majority in three estates, when a real and substantial majority of all four estates in congress might be actually against it. Or, again, a dominant action in any three of the estates might enact laws highly detrimental to the interests of the remaining estate—a danger the more to be apprehended as in no other country in Europe were class distinctions so sharply defined as in Sweden.

Each estate was ruled by its talman, or speaker, who was now elected at the beginning of each Diet, but the archbishop was, ex officio, the talman of the clergy. The landmästare, or speaker of the House of Nobles, presided when the estates met; but, in the castle of Stockholm, the owner of the Riksdag, was also present, in virtue of his office, as the hemliga skott, or secret committee. This famous body, which consisted of 50 nobles, 25 priests, 25 burgesses, and, very exceptionally, 25 peasants, possessed during the session of the Riksdag not only the supreme executive but also the supreme judicial and legislative functions. It prepared all bills for the Riksdag, created and disposed all ministries, controlled the foreign policy of the nation, and claimed and often exercised the right of superseding the ordinary courts of justice. During the parliamentary recess, however, the executive remained in the hands of the rad, or senate, which was responsible to the Riksdag alone.

It will be obvious that there was no room in this republican constitution for a constitutional monarch in the modern sense of the word. The crowned puppet who possessed a casting vote in the riksdag, of which he was the nominal president, and who was allowed to create peers once in his life (at his coronation), was rather a state decoration than a sovereignty.

At first this cumbersome and complicated instrument of government worked tolerably well under the firm but cautious control of the chancellor, Count Arvid Beernhard Horn (1674-1729). In his discharge of this trust between 1719 and 1720, Horn reversed the traditional policy of Sweden by keeping France at a distance and drawing near to Great Britain, for whose liberal institutions he professed the highest admiration. Thus a twenty years' war was succeeded by a twenty years' peace, during which the nation recovered so rapidly from its wounds that it began to forget them. A new race of politicians was springing up. Since 1719, when the influence of the few great territorial families had been merged in a multitude of needy gentlemen, the first estate had become the nursery and afterwards the stronghold of an opposition at once noble and democratic, which found its natural leaders in such men as Count Carl Gyllenborg and Count Carl Gustaf Tassin (q.v.). These men and their followers were never weary of ridiculing the timid caution of the aged statesman who sacrificed everything to perpetuate an inglorious peace and derisively nicknamed his adherents "Night-caps" (a term subsequently softened into "Caps"), themselves adopting the sobriquet "Hats," from the three-cornered hat worn by officers and gentlemen, which was considered happily to hit off the manly self-assertion of the opposition. These epithets instantly caught the public fancy and had already become party badges when the estates met in 1728. This Riksdag was to mark another turning-point in Swedish
history. The Hats carried everything before them; and the aged Horn was finally compelled to retire from a scene where, for three and thirty years, he had played a leading part.

The policy of the Hats was a return to the traditional alliance between France and Sweden. When Sweden descended to her natural position as a second-rate power the French alliance became too costly a luxury. Horn had clearly perceived this; and his cautious neutrality was therefore the soundest statesmanship. But the politicians who had ousted Horn thought differently. To them Sweden's glory was a thing of the past. They aimed at restoring Sweden to her former position as a great power. France, naturally, hailed with satisfaction the rise of a faction which was content to be her armament-bearer in the north; and the golden streams which flowed from Versailles to Stockholm during the next two generations were the political life-blood of the Hat party.

The first blunder of the Hats was the hasty and ill-advised war with Russia. The European complications consequent upon the almost simultaneous deaths of the emperor Charles VI. and Anne, empress of Russia, seemed to favour their ambitious schemes, and despite the frantic protests of the Caps, a project for the invasion of Russian Finland was rushed through the premature Riksdag of 1740. On the 20th of July 1741 war was formally declared against Russia; a month later the Diet was dissolved and the Hat landstingskåk set off to Finland to take command of the army. The first blow was not struck till six months after the declaration of war; and it was struck by the enemy, who routed the Swedes at Villmanstrand and captured that frontier fortress. Nothing else was done on either side for six months more; and then the Swedish generals made a "tact truce" with the Russians through the mediation of the French ambassador at St Petersburg. By the time that the "tact truce" had come to an end the Swedish forces were so demoralized that the mere rumour of a hostile attack made them retire panic-stricken to Helsingfors; and before the end of the year all Finland was in the hands of the Russians. The fleet, disabled by an epidemic, was, throughout the war, little more than a floating hospital.

To face the Riksdag with such a war as this upon their consciences was a trial from which the Hats naturally shrank; but, to do them justice, they showed themselves better parliaments than their predecessors, and when the conduct of the war was skillfully evaded by obtaining precedence for the succession question (Queen Ulrica Leonora had lately died childless and King Frederick was old); and negotiations were thus opened with the new Russian empress, Elizabeth, who agreed to restore the greater part of Finland if her cousin, Adolphus Frederick of Holstein, were elected successor to the Swedish crown. The Hats eagerly caught at the opportunity of recovering the grand duchy and their own prestige along with it. By the peace of Åbo (May 7, 1743) the terms of the treaty were accepted; and only that small part of Finland which lay beyond the Kymmene was retained by Russia.

In March 1751 old King Frederick died. His slender prerogatives had gradually dwindled down to vanishing point. Adolphus Frederick (g.v.) would have given even less trouble than his predecessor but for the ambitious promptings of his masterful consort Louisa Ulrica, Frederick the Great's sister, and the tyranny of the estates, who seemed bent upon driving the meekest of princes into rebellion. An attempted monarchal revolution, planned by the queen and a few devoted young nobles in 1756, was easily and remorselessly crushed; and, though the unhappy king did not, as he anticipated, share the fate of Charles Stuart, he was humiliated as never monarch was humiliated before.

The same years which beheld this great domestic triumph of the Hats saw also the utter collapse of their foreign "system." At the instigation of France they plunged recklessly into the Seven Years' War; and the result was ruinous. The French subsidies, which might have sufficed for a six weeks' demonstration (it was generally assumed that the king of Prussia would give little trouble to a European coalition), proved quite inadequate; and, after five unsuccessful campaigns, the unhappy Hats were glad to make peace and ignominiously withdraw from a little war which had cost the country 40,000 men and £2,500,000. When the Riksdag met in 1760, the indignation against the Hat leaders was so violent that an impeachment seemed inevitable; but once more the superiority of their parliamentary tactics prevailed, and when, after a session of twenty months, the Riksdag was brought to a deadlock by the mutual consent of both the exhausted factions, the Hat government fell once more without a blow. But the day of reckoning could not be postponed for ever; and when the estates met in 1765 it brought the Caps into power at last. Their leader, Ture Rudbeck, was elected marshal of the Diet over Frederick Axel von Fersen (q.v.), the Hat candidate, by a large majority; and, out of the hundred seats in the secret committee, the Hats succeeded in getting only ten.

The Caps struck at once at the weak point of their opponents by ordering a budget report to be made; and it was speedily found that the whole financial system of the Hats was based upon stockless imprudence and wilful misrepresentation, and that the only fruit of their long rule was an enormous addition to the national debt and a depreciation of the note circulation to one-third of its face value. This revelation led to an all-round retrenchment, carried into effect with a drastic thoroughness which has earned for this parliament the name of the "Reduktion Riksdag." The Caps succeeded in transferring £250,000 from the pockets of the rich to the empty exchequer, reducing the national debt by £575,179, and establishing some sort of equilibrium between revenue and expenditure. They also introduced a few useful reforms, the most remarkable of which was the liberty of the press. But their most important political act was to throw their lot definitely in with Russia, so as to counterpoise the influence of France. Sweden was not then as now quite outside the European Concert. Although no longer a great power, she still had many of the responsibilities of a great power; and if the Swedish alliance had considerably depreciated in value, it was still a marketable commodity. Sweden's peculiar geographical position made her virtually invulnerable for six months out of the twelve, her Norwegian bases upon stickless imprudence and were reinforced by the very heart of the moribund empire, while her Finish frontier was not many leagues from the Russian capital.

A watchful neutrality, not venturing much beyond defensive alliances and commercial treaties with the maritime powers, was therefore Sweden's safest policy, and this the older Caps had always followed out. But when the Hats became the armament-bearers of France in the north, a protector strong enough to counteract French influence became the cardinal exigency of their opponents, the younger Caps, who now flung themselves into the arms of Russia, overlooking the fact that even a pacific union with Russia was more to be feared than a martial alliance with France. For France was too distant to be dangerous. She sought an ally in Sweden and it was her endeavour to make that ally as strong as possible. But it was as a future prey, not as a possible ally, that Russia regarded her ancient rival in the north. In the treaty which partitioned Poland there was a secret clause which engaged the contracting powers to uphold the existing Swedish constitution as the swiftest means of subverting Swedish independence; and an alliance with the credulous Caps, "the Patriots" as they were called at St Petersburg, guaranteeing their constitution, was the corollary to this secret understanding. Thus while the French alliance of the warlike Hats had destroyed the prestige of Sweden, the Russian alliance of the peaceable Caps threatened to destroy her very existence.

Fortunately, the domination of the Caps was not for long. The general distress occasioned by their drastic reforms had found expression in swarms of pamphlets which bit and stung the Cap government, under the protection of the new press laws. The senate retaliated by an order in council (which the
SWEDEN

HISTORY

king refused to sign) declaring that all complaints against the measures of the last Riksdag should be punished with fine and imprisonment. The king, at the suggestion of the crown prince (see Gustavus III.), therupon urged the senate to summon an extraordinary Riksdag as the speediest method of relieving the national distress, and, on their refusing to comply with his wishes, abdicated his throne to secure the 21st of December 1768 Sweden was without a regular government. Then the Cap senate gave way and the estates were convoked for the 19th of April 1769.

On the eve of the contest there was a general assembly of the Hats at the French embassy, where the Comte de Modène furnished them with 6,000,000 livres, but not till they had signed in his presence an undertaking to reform the constitution in a monarchal sense. Still more energetic on the other side, the Russian minister, Ivan Osternia, became the treasurer as well as the chairman of the Caps, and scattered the largesse of the Russian empress with a lavish hand; and so lost to all feeling of patriotism were the Caps that they openly threatened all who ventured to vote against them with the Muscovite vengeance, and fixed Norrköping, instead of Stockholm, as the place of meeting for the Riksdag as being more accessible to the Russian fleet. But it soon became evident that the Caps were playing a losing game; and, when the Riksdag met at Norrköping on the 19th of April, they found themselves in a minority in all four estates. In the contest for the marshalate of the Diet the leaders of the two parties were again pitted against each other, when the verdict of the last Riksdag was exactly reversed, Fersen defeating Rudbeck by 2,34, though Russia spent no less a sum than £1,15,000 to secure the election of the latter.

The Caps had short shrift, and the joint note which the Russian, Prussian and Danish ministers presented to the estates protesting, in menacing terms, against any “reprisals” on the part of the triumphant faction, only hastened the fall of the government. The Cap senate resigned en masse to escape impeachment, and an exclusively Hat ministry took its place.

On April 1, the 1st of June the Riksdag Riksdagen was dissolved as it was generally called, removed to the capital; and it was now that the French ambassador and the crown prince Gustavus called upon the new senators to redeem their promise as to a reform of the constitution which they had made before the elections. But when, at the 1st of June, they half-heartedly brought the matter forward, the Riksdag suddenly seemed to be stricken with paralysis.

Impediments multiplied at every step; the cry was raised: “The constitution is in danger”; and on the 30th of January 1770 the Reaction ministry, formed and reconstituted to an abortive, it is not more than a temporary, a few days, was dissolved. The constitutional, attempt of the new government to actualize its pact with France, and had received solemn assurances of assistance from Louis XV. In case he succeeded in re-establishing monarchical rule in Sweden. France undertook, moreover, to pay the outstanding subsidies to Sweden, amounting to one and a half millions of livres annually, beginning from January 1772; and Vergennes, one of the great names of French diplomacy, was to be sent to circumvent the designs of Russia at Stockholm as he had previously circumvented them at Constantinople. Immediately after his return to Stockholm, Gustavus endeavored to reconstitute the jarring factions by inducing the leaders to form a composition committee to adjust their differences. In thus mediating he was sincere enough, but all his pacific efforts were frustrated by their jealousy of him and of each other. Still worse, the factions now intrenched still further on the prerogative. The new crown oath contained three revolutionary clauses. The first aimed at making abdications in the future impossible by binding the king to reign uninterruptedly. The second obliged him to abide, not by the tension of all the estates together, as hitherto, but by that of the majority only, with the view of enabling the actually dominant lower estates (in which was a large Cap majority) to rule without, and even in spite of, the nobility. The third clause required him, in all cases of preference, to be guided not “principally,” as hitherto, but “solely” by merit, thus striking at the very root of aristocratic privilege. It was clear that the ancient strife of Hats and Caps had become merged in a conflict of classes; the situation was still further complicated by the ominous fact that the non-noble majority was also the Russian faction.

All through 1771 the estates were wrangling over the clauses of the crown oath. A second attempt of the king to mediate between them foundered on the suspicions of the estate of burgesses; and, on the 24th of February 1772, the nobility yielded from sheer weariness. The non-noble Cap majority now proceeded to attack the senate, the last stronghold of the Hats, and, on the 25th of April, succeeded in ousting their opponents. It was now, for the first time, that Gustavus, reduced to the condition of a roi fainéant, began seriously to consider the possibility of a revolution; of its necessity there could be no doubt. Under the sway of the new dominant faction, Sweden, already the vassal, could not fail speedily to become the victim of Russia. She was on the point of being absorbed in that Northern System, the invention of the Russian minister of foreign affairs, Nikita Panin (q.v.), which that patient statesman had made it the ambition of his life to realize. Only a swift and sudden coup d’état could save the independence of a country isolated from the rest of Europe by a hostile league. The details of the famous revolution of the 19th of August 1772 are elsewhere set forth (see Gustavus III.; Toll, Johan Kristoffer; Srenstporten, Jakob Magnus). Here we can only dwell upon its political importance and consequences.

The new constitution of the 20th of August 1772, which Gustavus imposed upon the terrified estates at the bayonet’s point, converted a weak and disunited republic into a strong but limited monarchy, in which the balance of power inclined, on the whole, to the side of the monarch. The estates could only assemble when summoned by him; he could dismiss them whenever he thought fit; and their deliberations were to be confined exclusively to the propositions which he might think fit to lay before them. But these very extensive powers were subjected to many important checks. Thus, without the previous consent of the estates, no new law could be imposed, no old law abolished, no offensive war undertaken, no extraordinary war subsidy levied. The estates alone could tax themselves; they had the absolute control of the Bank of Sweden, and the inalienable right of controlling the national expenditure. Thus the parliament held the purse; and this seemed a sufficient guarantee both of its independence and its frequent convention. The senate, not the Riksdag, was the chief loser of the exchange; and, inasmuch as hereafter the senators were appointed by the king, and were to be responsible to him alone, a senate in opposition to the Crown was barely conceivable.

Abroad the Swedish revolution made a great sensation. Catherine II. of Russia saw in it the triumph of her arch-enemy France, with the prolongation of the costly Turkish War as its immediate result. But the absence of troops on the Finnish border, and the bad condition of the frontier fortresses, constrained the empress to listen to Gustavus’s pacific assurances, and stay her hand. She took the precaution, however, of concluding a fresh secret alliance with Denmark, in which the Swedish revolution was significantly described as an act of violence constituting a casus foederis, and justifying both powers in seizing the first favourable opportunity for intervention to restore the Swedish constitution of 1720.
In Sweden itself the change was, at first, most popular. But Gustavus’s first Riksdag, that of 1778, opened the eyes of the deputies to the fact that their political supremacy had departed. The king was now their sovereign lord; and, for all his courtesy and gentleness, the jealousy with which he guarded and the vigour with which he enforced the prerogative plainly showed that he meant to remain so. But it was not till after eight years more had elapsed that actual trouble began. The Riksdag of 1778 had been obsequious; the Riksdag of 1786 was mutinous. It rejected nearly all the royal measures outright, or so modified them that Gustavus himself withdrew them. When he declared the estates adjourned from the throne held out no prospect of their speedy revocation.

Nevertheless, within three years, the king was obliged to summon another Riksdag, which met at Stockholm on the 26th of January 1789. His attempt in the interval to rule without a parliament had been disastrous. It was only by a breach of his own constitution that he had been able to declare war against Russia (April 1788); the conspiracy of Anjula (July) had paralysed all military operations at the very opening of the campaign; and the sudden invasion of his western provinces by the Danes, almost simultaneously (Sept. 1788), seemed to crush the hopes of the Diet. In the contrast, at this crisis, between his self-sacrificing patriotism and the treachery of the Russophil aristocracy was so striking that, when the Riksdag assembled, Gustavus found that the three lower estates were ultra-royalist, and with their aid he succeeded, not without running great risks (see Gustavus III; Nordin, Gustaf; Wallqvist, Olaf), in crushing the opposition of the nobility by a second coup d’etat (Feb. 16, 1789), and passing the famous Act of Union and Security which gave the king an absolutely free hand as regards foreign affairs and the command of the army, and made further treason impossible. For this the nobility never forgave him. It was impossible, indeed, to resist openly so highly gifted and so popular a sovereign; it was only by the despicable expedient of assassination that the last great monarch of Sweden was finally removed, to the infinite detriment of his country.

The ensuing period was a melancholy one. The aristocratic classes loudly complained that the young king, Gustavus IV., still a minor, was being brought up among crypto-Jacobins; while the middle classes, deprived of the stimulating leadership of the anti-aristocratic “Prince Charming,” and becoming more and more inoculated with French political ideas, drifted into an antagonism not merely to hereditary nobility, but to hereditary monarchy likewise. Everything was vacillating and uncertain; and the general instability was reflected even in foreign affairs, now that the master-hand of Gustavus III. was withdrawn.

The renewed efforts of Catherine II. to interfere in Sweden’s domestic affairs were, indeed, vigorously repulsed, but without tact or discretion, so that the good understanding between the two countries was seriously impaired, especially when the prodigities of Gustaf Reuterholm (q.v.), who then virtually ruled Sweden, induced him to adopt what was generally considered an indelicately friendly attitude towards the government at Paris. Despite the execution of Louis XVI. (Jan. 21, 1793), Sweden, in the hope of obtaining considerable subsidies, recognized the new French republic; and secret negotiations for contracting an alliance were actually begun in May of the same year, till the menacing protests of Catherine, supported as they were by all the other European powers, finally induced Sweden to suspend them.

The negotiations with the French Jacobins exacerbated the hatred which the Gustavians already felt for the Jacobin councillors of the duke-regent (see Charles XIII., king of Sweden). Snarling beneath their grievances and seriously believing that not only the young king’s crown but his very life was in danger, they formed a conspiracy, the soul of which was Gustaf Mauritz Armfelt (q.v.), to overthrow the government, with the aid of a Russian fleet, supported by a rising of the Dalecarlians. The conspiracy was discovered and vigorously suppressed.

The one bright side of this gloomy and sordid period was the rapprochement between the Scandinavian kingdoms during the revolutionary wars. Thus, on the 27th of March 1794, a neutrality compact was formed between Denmark and Sweden; and their united squadrons patrolled the North Sea to protect their merchantmen from the British cruisers. This approximation between the two governments was happily followed by friendly feelings between the twofold Sofia and the Swedish chamber of the duc de Mogor. Presently Reuterholm renewed his coquetry with the French court, which was officially recognized by the Swedish government on the 23rd of April 1795. In return, Sweden received a subsidy of £5,600; and a treaty between the two powers was signed on the 14th of September 1795. On the other hand, an attempt to regain the friendship of Russia, which had broken off diplomatic relations with Sweden, was frustrated by the refusal of the king to accept the bride, the grand duchess Alexandra, Catherine II.’s granddaughter, whom Reuterholm had provided with the promise that it was Reuterholm’s last official act. On the 1st of November 1796, in accordance with the will of his father, Gustavus IV., now in his eighteenth year, took the government into his own hands.

The government of Gustavus IV. (q.v.) was almost a pure autocracy. At his very first Riksdag, held at Norrköping in March 1800, the nobility were compelled, at last, to ratify Gustavus III.’s detested Act of Union and Security, which hitherto they had steadily refused to do. Shortly after this Riksdag rose, a notable change took place in Sweden’s foreign policy. In December 1800 Denmark Sweden and Russia acceded to a second Armed Neutrality of the North, directed against Great Britain; and the arsenal of Karlskrona, in all probability, was only saved from the fate of Copenhagen by the assassination of the emperor Paul, which was followed by another change of system in the north. Hitherto Sweden had kept aloof from continental complications; but the arrest and execution of the duc d’Enghien in 1804 inspired Gustavus IV. with such a hatred of Napoleon that when a general coalition was formed against the French emperor he was one of the first to join it (Dec. 3, 1804), pledging himself to send an army corps to cooperate with the English and Russians in driving the entire fleet of Holland and Hanover. But his senseless quarrel with Frederick William III. of Prussia detained him in Pomerania; and, when at last (December 1805) he led his 6000 men towards the Elbe district the third coalition had already been dissipated by the victories of Ulm and Austerlitz. In 1806 a rupture between Sweden and Prussia was only prevented by Napoleon’s assault upon the latter power. After Jena Napoleon attempted to win over Sweden, but Gustavus rejected every overture. The result was the total loss of Pomerania, and the Swedish army itself was only saved from destruction by the ingenuity of J. K. Toll (q.v.).

At Tilsit the emperor Alexander I. had undertaken to convert all “Russia’s geographical enemy,” as Napoleon designated Sweden, to accede to the newly established Continental System. Gustavus IV. naturally rejected all the proposals of Alexander to close the Baltic against the English; but took no measures to defend Finland against Russia, though, during the autumn of 1807, it was notorious that the tsar was preparing to attack the grand duchy. On the 21st of February 1808 a Russian army crossed the Finnish border without any previous declaration of war. On the 2nd of April the king ordered a general levy of 30,000 men; but while two army corps, under Armfelt and Toll, together with a British contingent of 10,000 men under Moore, were stationed in Scania and on the Norwegian border in anticipation of an attack from Denmark, which, at the instigation of Napoleon, had simultaneously declared war against Sweden, the little Finnish army was left altogether unsupported. The conquest of Finland, after
an heroic struggle against overwhelming odds, is elsewhere recorded (see Finland: History). Its immediate consequence in Sweden proper was the deposition of Gustavus of Sweden IV. (March 13, 1809), who was clearly incapable of governing. The nobility took advantage of this opportunity to pay off old scores against Gustavus III, by excluding not only his unhappy son but also that son's whole family from the succession—an act of injustice which has never been adequately deplored. But indeed the whole of this intermedie period is full of dark subterranean plots and counterplots, still inexplicable, as, for instance, the hideous Fersen murder (June 20, 1810) (see Fersen, Hans Axel von) evidently intended to terrorize the Gustavians, whose loyalty to the ancient dynasty was notorious. As early as the 3rd of June 1809 the duke regent was proclaimed king, Charles XIII, 1809–1818. Under the title of Charles XIII. (q.v.), after accepting the new liberal constitution, which was ratified by the Riksdag the same day.

The new king and his first cabinet, in no way likely to interfere with the liberal revolution which had placed him on the throne. Peace was what the exhausted nation now required; and negotiations had already been opened at Fredrikshavn. But the Russian demands were too humiliating, and the war was resumed. But the defeats of Sävarskr e and Ratan (Aug. 19, 1809) broke the spirit of the Swedish army; and peace was obtained by the sacrifice of Finland, the Åland islands, "the fore-posts of Stockholm," as Napoleon rightly described them, and Vesterbotten as far as the rivers Torned and Muonio (treaty of Fredrikshavn, Sept. 17, 1809).

The throne, for Charles XIII. was both in firm and childless, was settled, after the mysterious death of Bernadotte (May 28, 1810) of the first elected candidate, Prince Charles Augustus of Augustenburg, by the selection of the French marshal, Bernadotte (see Charles XIV., king of Sweden), who was adopted by Charles XIII. and received the homage of the estates on the 5th of November 1810.

The new crown prince was very soon the most popular and the most powerful man in Sweden. The infirmity of the old king, and the discontents in the council of state placed the government and especially the control of foreign affairs almost entirely in his hands; and he boldly adopted a policy which was antagonistic indeed to the wishes and hopes of the old school of Swedish statesmen, but, perhaps, the best adapted to the circumstances. Finland he at once gave up for lost. He knew that Russia would never voluntarily relinquish the grand duchy, while Sweden could not hope to retain it permanently, even if she reconquered it. But the acquisition of Norway might make up for the loss of Finland; and Bernadotte, now known as the crown prince Charles John, argued that it might be an easy matter to persuade the anti-Napoleonic powers to punish Denmark for her loyalty to France by wresting Norway from her. Napoleon he rightly distrusted, though at first he was obliged to submit to the emperor's dictation. Thus on the 13th of November 1810, the Swedish government was forced to declare war against Great Britain, though the British government was privately informed at the same time that Sweden was not a free agent and that the war would be a mere demonstration. But the pressure of Napoleon became more and more intolerable, culminating in the occupation of Pomerania by French troops in 1812. The Swedish government therefore concluded a secret convention with Russia (treaty of Petersburg, April 5, 1812), undertaking to send 30,000 men to operate against Napoleon in Germany in return for a promise from Alexander guaranteeing to Sweden the possession of Norway. Too late Napoleon endeavoured to outbid Alexander by offering to Sweden Finland, all Pomerania and Mecklenburg, in return for Sweden's active co-operation against Russia.

The Orebro Riksdag (April–August 1812), remarkable besides for its partial repudiation of Sweden's national debt and its reactionary press laws, introduced general conscription into Sweden, and thereby enabled the crown prince to carry out his ambitious policy. In May 1812 he mediated a peace between Russia and Turkey, so as to enable Russia to use all her forces against France (peace of Bucharest); and on the 18th of July, at Ørebro, peace was also concluded between Great Britain on one side and Russia and Sweden on the other. These two treaties were, in effect, the corner-stones of a fresh coalition against Napoleon, and were confirmed on the outbreak of the Franco-Russian War by a conference between Alexander and Charles John at Stockholm, on the 21st of August 1812, where he undertook to place an army corps of 33,000 men at the disposal of the Swedish crown prince for the conquest of Norway.

The treaty of Åbo, and indeed the whole of Charles John's foreign policy in 1812, provoked violent and justifiable criticism among the better class of politicians in Sweden. The immorality of indemnifying Sweden at the expense of a weaker friendly power was obvious; and, while Finland was now definitively sacrificed, Norway had still to be won. Moreover, Great Britain and Russia very properly insisted that Charles John's first duty was to the anti-Napoleonic coalition, the former-power ignoring the objection to the expenditure of her subsidies on the nefarious Norwegian adventure before the common enemy had been crushed. Only on his very ungracious compliance did Great Britain also promise to countenance the union of Norway and Sweden (treaty of Stockholm, March 3, 1813); and, on the 23rd of April, Russia gave her guarantee to the same effect. The Swedish crown prince rendered several important services to the allies during the campaign of 1813 (see Charles XIV., king of Sweden); but, after Leipzig, he went his own way, determined at all hazards to cripple Denmark and secure Norway. Moreover, "robbed of his "job" (as Helvig put it) of the nearest wishes of the Norwegians themselves, and how, finally (Nov. 14, 1814), Norway as a free and independent kingdom was united to Sweden under a common king, is a subject elsewhere described (see Denmark; Norway; Charles XIV., king of Sweden; Christian VIII., king of Denmark).

Charles XIII. died on the 5th of February 1818, and was succeeded by Bernadotte under the title of Charles XIV. John.

The new king devoted himself to the promotion of several ambitious projects, notably the construction of a canal absorbing the greater portion of the twenty-four millions of dalers voted for the purpose. The external debt of Sweden was gradually extinguished, the internal debt considerably reduced, and the budget showed an average annual surplus of 700,000 dalers. With returning prosperity the necessity for internal reform became urgent in Sweden. The antiquated Riksdag, where the privileged estates predominated, while the cultivated middle class was practically unrepresented, had become an insuperable obstacle to all free development; but, though the Riksdag of 1840 itself raised the question, the king and the aristocracy refused to entertain it. Yet the reign of Charles XIV. was, on the whole, most beneficial to Sweden; and, if there was much just cause for complaint, his great services to his adopted country were generally acknowledged. Abroad he maintained a policy of peace based mainly on a good understanding with Russia. Charles XIV.'s son and successor King Oscar I. was much more liberally inclined. Shortly after his accession (March 4, 1844) he laid several projects of reform before the Riksdag; but the estates would do little more than abolish the obsolete marriage and inheritance laws and a few commercial monopolies. As the financial situation necessitated a large increase of taxation, there was much popular discontent, which culminated in riots in the streets of Stockholm (March 1848). Yet, when fresh proposals for parliamentary reform were laid before the Riksdag in 1849, they were again rejected by three out of the four estates. As regards foreign politics, Oscar I. was strongly anti-German. As on the outbreak of the Dano-Prussian War of 1848–49, Sweden sympathized warmly with Denmark. Hundreds of Swedish volunteers hastened to Schleswig-Holstein. The Riksdag voted 2,000,000 dalers for additional armaments. It was Sweden, too, who mediated the truce of Malmö (Aug. 26, 1845), which
helped Denmark out of her difficulties. During the Crimean War Sweden remained neutral, although public opinion was decidedly anti-Russian, and sundry politicians regarded the conjunction as favourable for regaining Finland.

Oscar I. was succeeded (July 27, 1859) by his son, Charles XV. (q.v.), who was already aced as regent during his father's illness. He succeeded, with the invaluable assistance of the minister of justice, Baron Louis Gerhard de Geer (q.v.), in at last accomplishing the much-needed reform of the constitution. The way had been prepared in 1860 by a sweeping measure of municipal reform; and, in January 1863, the government brought in a reform bill by the terms of which the Riksdag was henceforth to consist of two chambers, the Upper House being a sort of aristocratic senate, while the membership of the Lower House was to be elected triennially by popular suffrage. The new constitution was accepted by all four estates in 1865 and promulgated on the 22nd of January 1866. On the 1st of September 1866, the first elections under the new system were held; and on the 10th of January 1867, the new Riksdag met for the first time. With this one great reform Charles XV. had to be content; in all other directions he was hampered, more or less, by his own creation. The Riksdag refused to sanction his favourite project of a reform of the Swedish army on the Prussian model, for which he had ample time, partly from motives of economy, partly from an apprehension of the king's martial tendencies. In 1864 Charles XV. had endeavoured to form an anti-Prussian league with Denmark; and after the defeat of Denmark he projected a Scandinavian union, in order, with the help of France, to oppose Prussian predominance in the north—a policy which naturally collapsed with the overthrow of the French Empire in 1870. He died on the 18th of September 1872, and was succeeded by his brother, the duke of Gottland, who reigned as Oscar II. (R. N. B.)

The economic condition of Sweden, owing to the progress in material prosperity, was much better in 1871 than in any former year. The results of the Franco-German War, which had ended in 1871, were not satisfactory. Politically, however, the outlook was not so favourable. In their results, the reforms inaugurated during the preceding reign did not answer expectations. Within three years of the introduction of the new electoral laws De Geer's ministry had forfeited much of its former popularity, and had been forced to resign. In the vital matter of national defence no common understanding had been arrived at, and during the conflicts which had raged round this question, the two warring parties, the Peasants, who had set up the system of taxation, for a reorganization of the army based on a stammtrupp system (regular army), by the enlistment of hired soldiers, and for naval reforms. In this last connexion the most suitable types of vessels for coast defence as for offence were determined upon. But Count Posse, deserted by his own party over the army bill, resigned, and was succeeded on the 16th of May 1884 by Oscar Themtouder, who had been minister of finance in the previous cabinet. The new premier succeeded in persuading the Riksdag to pass a bill increasing the period of service with the colours in the army to six years and that in the militia to forty-two days, and as a set-off a remission of half the corn tax.

Influenced by the economic reaction which took place in 1879 in consequence of the state of affairs in Germany, where Prince Bismarck had introduced the protectionist system, a Protective protectionist party had been formed, which tried to gain adherents in the Riksdag. It is true that in the Riksdag of 1882 the commercial treaty with France was renewed, but since 1885 the protectionist party was prepared to begin the combat, and a duty on corn, which had been proposed in the Riksdag of the same year, was rejected by only a slight majority. During the period of the unusually low price of corn of 1886, which greatly affected the Swedish farm, the Riksdag, by a gain ground to such an extent that its final triumph was considered as certain within a short time. During the Riksdag of the same year, however, the premier, Themtouder, emphatically declared himself against the protectionist party, and while the parties in the Second Chamber were equal in number, the proposed tax on corn was rejected in the First Chamber. In the Riksdag of 1887 there was a majority for protection in the Second Chamber, and in the first the majority against the tax was so small that the tax on corn would have triumphed in a combined meeting of the two chambers. The government, availing itself of its formal right not to dissolve the chamber in which it had the support of a majority, therefore dissolved only the Second Chamber (March 1887).

The new Riksdag assembled in May with a free trade majority
in the Second Chamber, but nothing in connexion with the great question of customs was settled. In the meantime, the powerful majority in the Second Chamber split into two groups—the new “Landtmanna” party, which approved protection in the interests of agricultural classes; and a somewhat smaller group, the old “Landtmanna” party, which favoured free trade.

The victory of the free traders was not, however, destined to be of long duration, as the protectionists obtained a majority in both chambers in the next Riksdag (1888). To the First Chamber protectionists were almost exclusively elected, and in the Second all the twenty-two free traders representing Stockholm were overruled by one of their number not having paid his taxes a few years previously, which prevented his being eligible. Instead, then, of twenty-two free traders representing the majority of the Stockholm electors, twenty-two protectionists, representing the minority, were elected, and Stockholm was thus represented in the Riksdag by the choice of a minority in the capital. This singular way of electing members for the principal city in the kingdom could not fail further to irritate the parties. One result of the Stockholm election came at a convenient time for the Themptauer workshops. The financial affairs of the kingdom were found to be in a most unsatisfactory state. In spite of reduced expenses, a highly estimated revenue, and the contemplated raising of taxes, there was a deficit, for the payment or discharge of which the government would be obliged to demand supplementary supplies. The Themptauer ministry resigned.

The king retained, however, for a time several members of the ministry, but it was difficult to find a premier who would be able, during the transition from one system to another, to command sufficient authority to control the parties. At last Baron Gillis Bildt, who, while Swedish ambassador in Berlin, had witnessed the introduction by Prince Bismarck of the agrarian protectionist system in Germany, accepted the premiership, and it was under his auspices that the two chambers imposed a series of duties on necessaries of life. The new taxes, together with an increase of the excise duty on spirits, soon brought a surplus into the state coffers. At a council of state (Oct. 12, 1888) the king declared his wishes as to the way in which this surplus should be used. He desired that it should be applied to a fund for insurance and old age pensions for workmen and old people, to the lightening of the municipal taxes by state contributions to the schools and workhouses, to the abolition of the land taxes, and of the obligation of keeping a horse and man for military service, and, lastly, to the improvement of the shipping trade; but the Riksdag decided to devote it to other objects, such as the payment of the deficit in the budget, the building of railways and augmentation of their material, as well as to improvements in the defences of the country.

Baron Bildt resigned as soon as the new system seemed settled, making room for Baron Gustav Akerbjelm. The latter, however, also soon resigned, and was succeeded on the 10th of July 1891 by Erik Gustav Bostrom, a landed proprietor. The protectionist system gained in favour on the expiry of the commercial treaty with France in 1892, as it could now be extended to articles of industry. The elections of 1890, when the metropolis returned free traders and Liberals to the Second Chamber, certainly effected a change in the latter, as the representatives of the towns and the old “Landtmanna” party joined issue and established a free-trade majority in the chamber, but in the combined meetings of the two chambers the compact protectionist majority in the First Chamber turned the scale. The customs duties were, however, altered several times in accordance with market prices and ruling circumstances. Thus in 1892, when the import duty on unground corn was reduced from 25. 10d. to 15. 10d., and that on ground corn from 45. 9d. to 25. 10d. for 100 kilogrammes, the same duties were also retained for the following year. They were also retained for 1893 at the request of the government, which desired to keep faith with their promise that while the new organization of the army was going on no increase of duties on the necessaries of life should take place. This measure caused much dissatisfaction, and gave rise to a strong agrarian movement, in consequence of which the government, in the beginning of 1895, before the assembling of the Riksdag, made use of its right of raising the two duties on corn just referred to, 35. 7d. and 7s. 2d., which were afterwards somewhat reduced as far as seed corn for sowing purposes was concerned.

The question of customs duties now settled, that of national defence was taken up afresh, and in the following year the government produced a complete scheme for the abolition of the land tax in the course of ten years, in exchange for a compensation of ninety days’ drill for those liable to military service, “measures to retain the old military system of the country and to strengthen the defences of Norland, and the government bill for a reorganization of the army was accepted by the Riksdag in an extraordinary session. But it was soon perceived that the new plan was unsatisfactory and required recasting, upon which the minister of war, Baron Rappe, resigned, and was succeeded by Colonel von Crustebjorn, who immediately set to work to prepare a complete reorganization of the army, with an increase of the time of active service on the lines of general compulsory service. The Riksdag of 1900, in addition to grants for the fortifications at Boden, in the province of Norrbotten, and the fortresses, provided for the expenditure of objects, voted a considerable grant for an experimental mobilization, which fully exposed the defects and faults of the old system. In the Riksdag of 1901 E. G. Bostrom resigned, and was succeeded by Admiral F. W. von Otter, who introduced a new bill for the army reorganization, the most important item of which was the increase of the period of training to 365 days. The cost in connexion with the new scheme was expected to amount to 22 millions of kronor. The Riksdag, however, did not accept the new plan in its full extent. The time of drilling was reduced to 240 days for the infantry, to 300 days for the navy, while for the cavalry and artillery the time fixed was 365 days. The plan, thus modified, was then accepted by the government.

After the elections in 1890, the alliance already mentioned between the old “Landtmanna” party and the representatives of the towns had the result that the Liberals in the Second Chamber, to whom the representatives of the towns mostly belonged, were now in a position to decide the policy which the two united parties should follow. In order to prevent this, it was proposed to readjust the number of the members of the Riksdag. The question was only settled in 1893, when a bill was on the Russian model, and the members of the Riksdag in the First Chamber at 150, and in the Second at 230, of which 150 should represent the country districts and 80 the towns. The question of protection being now considered settled, there was no longer any reason for the continued separation of the two “Landtmanna” parties, who at the beginning of the Riksdag of 1895 joined issue and became once more a compact majority in the Second Chamber, as they had been up to the Riksdag of May 1887. The influence of the country representatives was thus re-established in the Second Chamber, but now the demands for the extension of the franchise came more and more to the front, and the premier, Bostrom, at last felt bound to do something to meet these demands. He accordingly introduced in the Riksdag of 1896 a very moderate bill for the extension of the franchise, which was, nevertheless, rejected by both chambers, all similar proposals by private members meeting the same fate. When at last the bill for the reorganization of the army, together with a considerably increased taxation, was accepted by the Riksdag of 1901, it was generally acknowledged that, in return for the increased taxation, it would only be just to extend the right of taking part in the political life and the legislative work of the country to those of the population who hitherto had been excluded from it. The government eventually laid a proposal for the extension of the franchise before the Riksdag of 1902, the chief feature of which was that the elector should be twenty-five years of age, and that married men over forty years should be entitled to two votes. The Riksdag, however, finally agreed to a proposal by Bishop Billing, a member of the First Chamber, that an address should be presented to the king asking for a full inquiry into the question of extending the franchise for the election of members to the Second Chamber.
In 1897 the Riksdag had received among its members the first socialist representative in the person of R. H. Brautigam, the leader of the Swedish Social Democrats. The Socialists, who had formerly confined their activity to questions affecting the working classes and their wages, took, however, in 1902 an active part in the agitation for the extension of the franchise. Processions of many thousands of workmen were organized, in Stockholm and in other towns of the kingdom, just before the Riksdag began the discussion on the above-mentioned bill of the government, and when the bill was introduced in the chambers a general and well-organized strike took place and continued during the three days the debate on the bill lasted. As this strike was of an exclusively political kind, and was intended to put pressure on the chambers, it was generally disapproved, and failed in its object.

The prime minister, Admiral von Otter, resigned shortly after the end of the session, and was succeeded by Boström, the ex-premier, who at the request of the king again assumed office.

The relations with Norway during King Oscar's reign had great influence on political life in Sweden, and more than once it seemed as if the union between the two countries was on the point of being wrecked. The dissensions chiefly had their origin in the demand by Norway for separate consuls and foreign ministers, to which reference is made under Norway. At last, after vain negotiations and discussions, the Swedish government in 1895 gave notice to Norway that the commercial treaty which till then had existed between the two countries and had lapsed in July 1897 would, according to a decision in the Riksdag, cease, and as Norway at the time had raised the customs duties, a considerable diminution in the exports of Sweden to Norway took place. The Swedish minister of foreign affairs, Count Lewenhaupt, who was considered as too friendly disposed towards the Norwegians, resigned, and was replaced by Count Ludvig Douglas, who represented the opinion of the majority in the First Chamber.

When, however, the Norwegian Storting, for the third time, passed a bill for a national or "pure" flag, which Richard Oscar I. considered as an insult to the Swedish consular service, Douglas resigned in his turn and was succeeded by the Swedish minister at Berlin, Lagerheim, who managed to pilot the questions of the union into more quiet waters. He succeeded all the better as the new elections to the Riksdag of 1900 showed clearly that the Swedish people was not inclined to follow the ultrconservative or so-called "patriotic" party, which resulted in the resignation of the two leaders of that party, Professor Oscar Alin and Count Marshal Patrick Reuterdal as members of the First Chamber. On the other hand, ex-Professor E. Carlsson, of the High School of Gothenburg, succeeded in forming a minority cabinet, Count Marschall Patrick Reuterdal as President of the Council, which had, besides being in favour of the extension of the franchise, advocated the full equality of Norway with Sweden in the management of foreign affairs.

The state of quietude which for some time prevailed with regard to the relations with Norway now was not, however, to be of long duration. The question of separate consuls for Norway soon came up again. In 1902 the Swedish government proposed that negotiations in this matter should be opened with the Norwegian government end that a joint commission of representatives from both countries, should be appointed to consider the question of a separate consular service without in any way interfering with the existing administration of the diplomatic affairs of the two countries. The result of the negotiations was published in a so-called "communiqué," dated the 24th of March 1903, in which, among other things, it was proposed that the relations of the separate consuls to the joint ministry of foreign affairs and the embassies should be arranged by identical laws, which could not be altered or repealed without the consent of the governments of the two countries. The proposal for these identical laws was accepted by the Norwegian government. As the proposal was submitted, did not meet with the approval of the Swedish government. The latter in their reply proposed that the Swedish foreign minister should have such control over the Norwegian consuls as to prevent the latter from exceeding their authority. This proposal, however, the Norwegian government found unacceptable, and explained that, if such control were insisted upon, all further negotiations would be purposeless. They maintained that the Swedish demands were incompatible with the sovereignty of Norway, as the foreign minister was Swede and the proposed Norwegian consular service, as a Norwegian institution, could not be placed under a foreign authority. A new proposal by the Swedish government was likewise rejected, and in February 1905 the Norwegians broke off the negotiations.

Notwithstanding this an agreement did not appear to be out of the question. All efforts to solve the consular question by itself had failed, but it was considered that an attempt might be made to establish separate consuls in combination with a joint administration of diplomatic affairs on a full unionistic basis. Crown Prince Gustaf, who during the illness of King Oscar was anointed regent, took the initiative of renewing the negotiations between the two countries, and on the 4th of April in a combined Swedish and Norwegian council of state made a proposal for a reform both of the administration of diplomatic affairs and of the consular service on the basis of full equality between the two kingdoms, with the express reservation, however, of a joint foreign minister—Swedish or Norwegian—as a condition for the existence of the union. This proposal was approved of by the Swedish Riksdag on the 3rd of May 1905. In order that no obstacles should be placed in the way for renewed negotiations, Mr Boström, the prime minister, resigned, and was succeeded by Ramstedt. The proposed negotiations were not, however, renewed.

On the 23rd of May the Norwegian Storting passed the government's proposal for the establishment of separate Norwegian consuls, and as King Oscar, who again had resumed the reins of government, made use of his constitutional right to veto the bill, the Norwegian ministry tendered their resignation. The king, however, declared he could not now accept their resignation, whereupon the ministry at a sitting of the Norwegian Storting on the 7th of June placed their resignation in its hands. The Storting thereupon unanimously adopted a resolution stating that, as the king had declared himself unable to form a government, the constitutional royal power "ceased to be operative," whereupon the ministers were requested, until further instructions, to exercise the power vested in the king, and as King Oscar thus had ceased to act as "the king of Norway," the union with Sweden was in consequence dissolved.

In Sweden, where they were least of all prepared for the turn things had taken, the action of the Storting created the greatest surprise and resentment. The king solemnly protested against what had taken place and summoned an extraordinary session of the Riksdag of June to consider what measures should be taken with regard to the question of the union, which had arisen suddenly through the revolt of the Norwegians on the 7th of June. The Riksdag declared that it was not opposed to negotiations being entered upon regarding the conditions for the dissolution of the union if the Norwegian Storting, after a new election, made a proposal for the repeal of the Act of Union between the two countries, or, if a proposal to this effect was made by Norway after the Norwegian people, through a plebiscite, had declared in favour of the dissolution of the union. The Riksdag further resolved that 100 million kroner (about £550,000) should be held in readiness and be available as the Riksdag might decide. On the resignation of the Ramstedt ministry Mr Lundeberg formed a coalition ministry consisting of members of the various parties in the Riksdag, after which the Riksdag was prorogued on the 3rd of August.

After the plebiscite in Norway on the 13th of August had decided in favour of the dissolution of the union and after the Storting had requested the Swedish government to co-operate with it for the repeal of the Act of Union, the Riksdag, in its annual convention, convened at Karlstad on the 31st of August. On the 23rd

1 For further details see NORWAY: History.
of September the delegates came to an agreement, the principal points of which were: that such disputes between the two countries which could not be settled by direct diplomatic negotiations, and which did not affect the vital interests of either country, should be referred to the permanent court of arbitration at the Hague, that on either side of the southern frontier a neutral zone of about fifteen kilometres width should be established, and that within eight months the fortifications within the Norwegian part of the zone should be destroyed. Other clauses dealt with the rights of the Laplanders to graze their reindeer alternatively in either country, and with the question of transport of goods across the frontier by rail or other means of communication, so that the traffic should not be hampered by any import or export prohibitions or otherwise.

From the 2nd to the 19th of October the extraordinary Riksdag was again assembled, and eventually approved of the arrangement come to by the delegates at Karlstad with regard to the dissolution of the union as well as the government proposal for the repeal of the Act of Union and the recognition of Norway as an independent state. An alteration in the Swedish flag was also decided upon, by which the mark of union was to be replaced by an azure-blue square. An offer from the Norwegian Stortingh to elect a prince of the Swedish royal house as king in Norway was declined by King Oscar, who now on behalf of himself and his successors renounced the right to the Norwegian crown. Mr Lundeborg, who had accepted office only to settle the question of the dissolution of the union, now resigned and was succeeded by a Liberal government, with Mr Karl Staaff as prime minister.

The question of the extension of the franchise, which was a burning one, was to be the principal measure of the Staaff government. It brought in a bill for manhood suffrage at elections for the Second Chamber, together with single member constituencies and election on the absolute majority principle. The bill was passed by the Second Chamber on the 15th of May 1906, by 134 to 94 votes, but it was rejected by the First Chamber by 126 to 18. The latter chamber instead passed a bill for manhood suffrage at elections for the Second Chamber, on the condition that the elections for both chambers should take place on the basis of proportional representation. Both chambers thereupon decided to ask the opinion of the king with regard to the simultaneous extension of the franchise to women at elections for the Second Chamber. The government bill having, however, been passed by the Second Chamber, the prime minister proposed to the king that the Riksdag should be dissolved and new elections for the Second Chamber take place in order to hear the opinion of the country, but as the king did not approve of this Mr Staaff and his government resigned.

A Conservative government was then formed on the 29th of May by Mr Lindman, whose principal task was to find a solution of the suffrage question which both chambers could accept. A government bill was introduced, proposing the settlement of the question on the basis of the bill carried by the First Chamber in the Riksdag of the preceding year. A compromise, approved of by the government, was adopted by the First Chamber on the 14th of May 1907 by 110 votes against 29 and in the Second Chamber by 128 against 98. By this act proportional representation was established for both chambers, together with universal manhood suffrage at elections for the Second Chamber, on the condition of the qualifications for eligibility for the First Chamber and a reduction of the electoral term of this chamber from nine to six years, and finally payment of members of the First Chamber, who hitherto had not received any such emolument. King Oscar II. died on the 9th of December 1907, sincerely regretted by his people, and was succeeded as king of Sweden by his eldest son, Prince Gustaf. During King Oscar's reign many important social reforms were carried out by the legislature, and the country developed in all directions. In the Riksdag of 1894 a new patent law was adopted, the age at which women should be held to attain their majority was fixed at twenty-one years and the barbarous prison punishment of "bread and water" abolished. In order to meet the cost of the new army organization the Riksdag of 1902 increased the revenue by progressive taxation, but only for one year. Bills for the improvement of the social conditions of the people and in the interests of the working classes were also passed. During the five years 1884—1889 a committee was appointed with the question of workmen's insurance, and thus the government made proposals for its settlement, on the last occasion adopting the principle of invalidity. The basis for insurance against accidents, illness or old age. The Riksdag, however, delayed coming to a decision, and contented itself by earmarking money for an insurance fund. At last the Riksdag of 1901 accepted a Bill for insurance against accidents which also extended to agricultural labourers, in connexion with the establishment of a state institution for insurance. The bill for protection against accidents, as well as for the limitation of working hours for women and children, was passed, together with one for the appointment of special factory inspectors. When in 1897 King Oscar celebrated his jubilee against the plan of the Narbutowsky, which had been organized in Stockholm offered a convincing proof of the progress the country had made in every direction.

**SWEDISH LITERATURE.**

Swedish literature, as distinguished from compositions in the common norrerna tunga of old Scandinavia, cannot be said to exist earlier than the 13th century. Not until the period of the Reformation was its development in any degree rapid or copious. The form in which Swedish exists as a written language (see SCANDINAVIAN LANGUAGE) is the series of manuscripts known as Landshöadsagernar, or "The Common Laws." These are supposed to be the relics of a still earlier age, and it is hardly believed that we even possess the first that was put down in writing. The most important and the most ancient of these codes is the "Elder West Göta Law," reduced to its present form by the law-man Eschk about 1250. Another of great interest is Magnus Eriksson's "General Common Law," which was written in 1347. These ancient codes have been collected and edited by the learned jurist, K. J. Schneyer (1775—1888) as Consys turis Svea-Gotorom antiqii (4 vols., 1827—1849). The chief ornament of medieval Swedish literature is Um styrelse kununga ok höfthoga ("On the Conduct of Kings and Princes"), first printed by command of Gustavus II. Adolphus, in 1634. The writer is not known; it has been conjecturally dated 1325. It is a handbook of moral and political teaching, expressed in terse and vigorous language. St Bridge, or Birgitta (1303—1373), an historical figure of extraordinary interest, has left her name attached to several important religious works, in particular to a collection of Uppenbarelse ("Revelations"), in which her visions and ecstatic
meditations are recorded, and a version, the first into Swedish, of the five books of Moses. This latter was undertaken, at her desire, by her father-confessor Matthias (d. 1350), a priest at Linköping. The translation of the Bible was continued a century later by a monk named Johannes Budde (d. 1482).

In verse the earliest Swedish productions were probably the folk-song. The age of these, however, has been commonly exaggerated. It is doubtful whether any still exist which are as old, in their present form, as the 13th century. The bulk are now attributed to the 15th, and many are doubtless much later still. The last, such as "Axel och Valborg," "Liten Karin," "Kämpen Grimborg," and "Habor och Signild," deal with the adventures of romantic medieval romance. Almost the only positive clue we hold to the date of these poems is the fact that on one occasion one of them, written in Old Swedish, was "credited" to the 12th century, written by Thomas, bishop of Strängnäs, who died in 1443. Thomas, who left other poetical pieces, is usually called the first Swedish poet. There are three rhyming chronicles in medieval Swedish, all anonymous. The earliest, Erickskronikan, is attributed to 1320; the romance of Karl Magnus, Nyta Karlskrönikan, describing the period between 1387 and 1452, which is sometimes added to the earlier work, dates from the middle of the 15th century; and the third, Sturekrönikorna, was probably written about 1500. The collection of rhymed romances which bears the name of Queen Ephiphanius' Song must have been written before the death of the Norwegian queen in 1312. They are versions of three medieval stories taken from French and German sources, and dealt with the Chevalier au lion, of Chrestien de Troyes, with Duke Frederick of Normandy, and with Flores and Blanchefer. They possess very slight poetic merit in their Swedish form. A little later the romance of King Alexander was translated by, or at the command of, Bo Jonsson Grip; this is more meritorious. Bishop Thomas, who died in 1443, wrote many political songs; and a number of narrative poems date from the close of the century. A brilliant and pathetic relic of the 15th century is the "Lied" of Sigurd von Floda, addressed in 1498 by Ingrid Persdotter, a nun of Vadstena, to the young knight Axel Nilsson. The first book printed in the Swedish language appeared in 1495.

The 16th century added but little to Swedish literature, and that little is mostly connected with the newly-founded university of Upsala. The Renaissance scarcely made itself felt in Scandinavia, and even the Reformation failed to waken the genius of the country. Psalms and didactic spiritual poems were the main products of Swedish letters in the 16th century. Two writers, the brothers Petri, sons of a smith at Orebro, take an easy prominence in so barren a period. Olaus Petri (1493-1552) and his history of Sweden, a mystery-play, Tobiae covenant, which is the first Swedish drama, and three psalm-books, the best known being published in 1530 under the title of Några gudhelige visor ("Certain Divine Songs"). His Chronicle was based on a number of sources, in the treatment of which he showed a discrimination which makes the work still useful. Laurentius Petri, who was a man of calmer temperament, was archbishop of all Sweden, and edited or superintended the translation of the Bible published at Upsala in 1540. He also wrote many psalms. Laurentius Andreae, 1532, had previously prepared a translation of the New Testament, which appeared in 1526. He was a polemical writer of prominence on the side of the Reformers. Finally, Petrus Niger (Peder Svervit), bishop of Vesterås (d. 1562), wrote a chronicle of the life of Gustavus I. up to 1553, in excellent prose. The same writer left unpublished a history of the bishops of Vesterås, his predecessors. The latter half of the 16th century is a blank in Swedish literature.

With the accession of Charles IX., and the consequent development of Swedish greatness, literature began to assert itself in more vigorous forms. The long life of the royal librarian, Johannes Bure or Bureaus (1568-1632), formed a link between the age of the Petri and that of Stjernhjelm. He was a learned man of the school of modern sciences, but his interest was mainly philosophical and jurisprudence; he was a wanderer in the world, and embalmed in his work the spirit of the Reformation, which was his noblest work, a universal philosophy in a multitude of unreadable volumes. But he was a patient antiquary, and advanced the knowledge of ancient Scandinavian mythology and language very considerably. He awakened curiosity and roused a public sympathy with letters; nor was it without significance that two of the greatest Swedes of the century, Gustavus Adolphus and the poet Stjernhjelm, were his pupils. The reign of Charles IX. saw the rise of secular drama in Sweden. The first comedy was The Tale of Magus Olai and Aetheropus (d. 1607), a coarse but witty piece on the story of Pyramus and Thisbe, acted by the schoolboys of the college of Arboga in 1610. This play is the Ralph Roister Doister of Swedish literature. A greater dramatist was Johannes Messenius (1570-1636), who was the son of a miller near Vadstena and had been carefully educated abroad by the Jesuits. Being discovered plotting against the government during the absence of Gustavus in Russia, he was condemned to imprisonment for life—that is, for twenty years. Before this disaster he had been professor of jurisprudence in Upsala, where his first historical comedy Dina was performed in 1611 and the Roman War, 1614. He published two novels, one on the history of his country in fifty plays; he completed and produced six. These dramas are not particularly well arranged, but they form a little body of theatrical literature of singular interest and value. Messenius was a genuine poet; the lyrics he introduces have something of the charm of the old ballads. He wrote abundantly in prison; his magnum opus was a history of Sweden in Latin, but he has also left, in Swedish, two important rhyme-chronicles. Messenius was imitated by a little crowd of playwrights. Nikolaus Holger Catonius (d. 1652) wrote a fine tragedy on the Trojan War, Trojenborgh, in which he excelled Messenius as a dramatist. Andreas Prytz, who died in 1659, a bishop of Linköping, produced several religious chronicle plays from Swedish history. Jacobus Rondeliius (d. 1662) wrote a curious "Christian tragi-comedy" of Judas redivivus, which contains some amusing scenes from daily Swedish life. Another good play was an anonymous Holofernes and Judith (edited at Upsala, 1895, by O. Sylvan). These plays were all acted by schoolboys and university youths, and when they went out of fashion among these classes the drama in Sweden almost entirely ceased to exist. Two historians of the reign of Charles IX., Erik Gorranson, Tezel (d. 1611), the Aspödahl Skrifter, wrote monographs. The chamberllor Magnus Gabriel de la Gardie (1622-1686) did much to promote the study of Swedish antiquities. He founded the College of Antiquities at Upsala in 1667, and bought back the Gothic Codex argenteus which he presented to the university library.

The reign of Gustavus Adolphus was adorned by one great writer, the most considerable in all the early history of Sweden. The title of "the Father of Swedish poetry" has been universally, awarded to Göran Lilja, better known by his adopted name of Georg Stjernhjelm (q.v.; 1586-1672). Stjernhjelm was a man of almost universal attainment, but it is mainly in verse that he has left his stamp upon Swedish literature. His greatest work is the Sveriges föritters riksgudom ("The King of the Swedes"") and his Sveriges herrestammar ("The House of Sweden")

1Skanska folkvisor, edited by E. G. Geijer and A. A. Afzelius (3 vols., Stockholm, 1879).
2See Cederhielm, Om Erikskrönikan (1890).
3Editions of these chronicles and romances have been issued by the "Svenska Fornskrift Sällskapet" (Stockholm): Jean Lejonridaren (ed. Stephens), Hertig Fredrik of Normandie (ed. Ahlstrand) Flores och Blanchefer (ed. G. E. Klemming), Alexander (ed. Klemming), Carl Magnus (ed. Klemming, in Föreorbiten från medeltiden).

4Selections from his writings were edited by G. E. Klemming, (Upsala, 1883-1888).

SWEDEN [LITERATURE]

The country of his language. He found the language Swedish and halting, and he moulded it into perfect smoothness and elasticity. His master, Buraeus, had written a few Swedish hexameters by way of experiment. Stjernhjem took the form and made it national.

The claim of Stjernhjem to be the first Swedish poet may be contested by a younger man, but a slightly earlier writer, Peter von Rosenhane (1632-1678) was a reformer on quite other lines. If Stjernhjem studied Opitz, Rosenhane took the French poets of the Renaissance for his models, and in 1650 wrote a cycle of one hundred sonnets, the earliest in the language; these were published under the title Venerid in 1668. Rosenhane printed in 1668 a "Complaint of the Swedish Language" in thirteen hundred rattling rhyming lines, and in 1682 a collection of eighty songs. He was a metrist of the artistic order, skilful, learned and unimpassioned. His zeal for the improvement of the literature of his country was beyond question. Most of the young poets, however, followed Stjernhjem rather than Rosenhane. As personal friends and pupils of the former, the brothers Columbus deserves special attention. They were sons of a musician and poet, Jonas Columbus (1586-1663). Each wrote copiously in verse, but Johan (1640-1684), who was professor of poetry at Upsala, almost entirely in Latin, while Samuel (1642-1679), especially in his Odas poeticae, showed himself an apt and fervid imitator of the Swedish hexameters of Stjernhjem, to whom he was at one time secretary, and whose Hercules he dramatized. His works were included by P. Hansell in vol. ii. of Semlae vitterhets-arsken, &c.

Of a rhyming family of Hjarne, it is enough to mention one member, Urban Hjarne (1641-1724), who introduced the new form of classical tragedy from France, in a species of transition from the masques of Stjernhjem to the later regular rhymed dramas. His best play was a Rosimunda. Lars Johansson (1542-1674), who called himself "Lucidor the Unfortunate," has been the subject of a whole tissue of romance, most of which is fabulous. It is true, however, that he was stabbed, like Marlowe, in a midnight brawl at a tavern. His poems were posthumously collected as Flowers of Helicon, Plucked and Distributed on various occasions by Lucidor the Unfortunate. Stripped of the myth which had attracted so much attention to his name, Lucidor proves to be an occasional rhymer of a very low order. Haquin Spigel (1654-1714), the famous archbishop of Upsala, wrote a long didactic epic in alexandrines, God's Labour and Rest, with an introductory ode to the Deity in rhymed hexameters. He was also a good writer of hymns. Another ecclesiastic, the bishop of Skara, Jesper Svobgod (1605-1735), wrote sacred verses, but is better remembered as the father of Stjernhjem's brother Petter. His lively and lighthearted character and his pastoral vein in his ingenious lyrics Elenandra and Lycylius, he was professor of poetry, that is to say, of the art of writing Latin verses, at Upsala. Olof Wexionius (1665-1692) published his Sinne-Afsl, a collection of graceful miscellaneous pieces, in 1684, in an edition of only 100 copies. Its existence was presently forgotten, and the name of Wexionius had dropped out of the history of literature, when Hansell recovered a copy and reprinted its contents in 1863.

We have hitherto considered only the followers of Stjernhjem; we have not noticed an important writer who followed in the footsteps of Rosenhane. Gunno Eurelius, Dahlstjerna, Afterwards ennobled with the name of Dahlstjerna (q.v.; 1661-1709), early showed an interest in the poetry of Italy. In 1690 he translated Guarini's Pastor Fido, and in or just after 1697 published, in afolio volume without a date, his Kungo-Sald, the first original poem in ottava rima produced in Swedish. This is a bombastic and vainglorious epic in honour of Charles XI, whom Eurelius adored; it is not, however, without great merits, richness of language, flow of metre, and the breadth of a genuine poetic enthusiasm. He published his little collection of sonnets when his great master died. Johan Paulinus Liljestedt (1655-1732), a Finn, was a graceful imitator of Ronsard and Guarini. Johan Runius (1679-1713), called the "Prince of Poets," published a collection entitled Dduaim, in which there is nothing to praise, and with him the generation of the 17th century closes. Talent had been shown by certain individuals, but no healthy school of Swedish poetry had been founded, and the latest imitators of Stjernhjem had lost every vestige of taste and independence. In protest the 17th century produced but little of importance in Sweden. Gustavus Adolphus (1594-1632) was the most polished writer of its earlier half, and his speeches take an important place in the development of the language. The most original mind of the next age was Olof Rudbeck (1630-1702), the famous author of Atlant eller Manhem. He spent nearly all his life in Upsala, building anatomical laboratories, conducting musical concerts, laying out botanical gardens, arranging medical lecture rooms—in a word, expending ceaseless energy on the practical improvement of the university. He was a genius in all the known branches of learning; at twenty-three his physiological discoveries had made him famous throughout Europe. His Atlant (or Atlantika) appeared in fourfolio volumes, in Latin and Swedish, in 1675-1698; it was an attempt to summon all the authority of the past, all the sages of Greece and the bards of Iceland, to prove the inherent and indisputable greatness of the Swedish nation, in which the fabulous Atlantis had been at last discovered. It was the literary expression of the majesty of Charles XI., and of his autocratical dreams for the destiny of Sweden. From another point of view it is a monstrous hoard of rough-hewn antiquarian learning, which, however, sometimes quoted from, and never read. Olof Verulius (1618-1682) had led the way for Rudbeck, by his translations of Icelandic sagas, a work which was carried on with greater intelligence by Johan Peringskold (1634-1700), the editor of the Heimskringla (1667), and J. Hadorph (1630-1693). The French philosopher Descartes, who died at Christina's court at Stockholm in 1650, found his chief, though posthumous, disciple in Andreas Rydelius (1671-1738), bishop of Lund, who was the master of Dalin, and thus connects us with the next epoch. His chief work, Nidico framsatsfningar ... (5 vols.) appeared in 1718. Charles XII., under whose special patronage Rydelius wrote, was himself a metaphysician and physiologist of merit.

A much more brilliant period followed the death of Charles XII. The literature of France and England took the place of that of Germany and Italy. The taste of Louis XIV., tempered by the study of Addison and Pope, gave its tone to the academical court of Queen Louise Ulrica, who founded in 1758 the academy of literature, which developed later into the academy of literature, history and antiquities.

Most of the early and brilliant contemporaries of Dalin became completely a slave to the perquisites of literature, to the unities and graces of classical France. Nevertheless this was a period of great intellectual stimulus and activity, and Swedish literature took a solid shape for the first time. This Augustan period in Sweden closed somewhat abruptly about 1765. Two writers in verse connect it with the school of the preceding century. Jacob Frese (1692-1728), a Finn, whose poems were published in 1726, was an elegiac writer of much grace, who foreshadowed the idyllic manner of Creutz. Atterbom pronounces Frese the best Swedish poet between Stjernhjem and Dalin. Samuel von Triewald (1688-1743) played a very imperfect Dryden to Dalin's Pope. He was the first Swedish satirist, and introduced Boileau to his countrymen. His Satire upon our Stupid Poets may still be read with entertainment.1 Both in verse and prose Olof von Dalin (q.v.; 1708-1763) takes a higher place than any writer since Stjernhjem. He was inspired by the study of his great English contemporaries. His Swedish Argus (1733-1734) was modelled on Addison's Spectator, his Thoughts about Critics (1736) on Pope's Essay on Criticism, his Tale of a Horse on Swift's Tale of a Tub. Dalin's style, 1The works of the three writers between Stjernhjem and Dalin were edited by P. Hansell (Upsala, 1856, &c.) as Samlaede vitterhetsoverfor af svenska forfarare.
whether in prose or verse, was of a finished elegance. As a prose writer Dalin is chiefly memorable for his History of the Swedish Kingdoms (4 vols., 1746–1762). His great epic, Swedish Freedom (1742) was written in alexandrines of far greater smoothness and vigour than had previously been attempted. When in 1737 the new Royal Swedish Theatre was opened, Dalin led the way to a new school of dramatists with his Brynhilda, a regular tragedy in the style of Crébillon père. In his comedy Of the Eunuch Man he introduced the manner of Molière, or more properly that of Holberg. His songs, his satires, his occasional pieces, without displaying any real originality, show Dalin’s tact and skill as a workman with the pen. He stole from England and France, but with the plagiarism of a man of genius; and his multifarious labours raised Sweden to a level with the other literary countries of Europe. They formed a basis upon which more national and more scrupulous writers could build their various structures. A foreign critic, especially an English one, will never be able to give Dalin so much credit as the Swedes do; but he was certainly an unsurpassable master of pastiche.

Fru Nordenflycht. Fru Nordenflycht (1718–1763) was the centre of a society which took the name of Tankbyggare Orden and ventured to rival Voltaire’s Société des Écrivains. In December 1746 it was left by Pelle Rosén von Rosenstein (1706–1773), in navigation by Admiral Fredrik Henrik af Chapman (d. 1808), in philology by Carl Aurivillus (d. 1786). But these and other distinguished savants whose names might be enumerated scarcely belong to the history of Swedish literature. The same may be said about that marvellous and many-sided genius, Emanuel Swedenborg (1688–1772), who, though the son of a Swedish poet, preferred to prophesy to the world in Latin.

What is called the Gustavian period is supposed to commence with the reign of Gustavus III. in 1771 and to close with his death (1792), the period of less than forty years was particularly rich in literary talent, and the taste of the people in literary matters widened to a remarkable extent. Journalism began to develop; the Swedish Academy was founded; the drama first learned to flourish in Stockholm; and literature began to take a characteristically national shape. This fruitful period naturally divides itself into two divisions, equivalent to the reigns of the two kings. The royal personages of Sweden have commonly been protectors of literature; they have strangely often been able men of letters themselves. Gustavus III. (1746–1792), the founder of the Swedish Academy and of the Swedish theatre, was himself a playwright of considerable ability. One of his prose dramas, Siri Bräde och Johan Gyllenborg, held the stage for many years. But his best work was his national drama of Gustaf Vasa (1783), written by the king in prose, and afterwards versified by Kellgren. In 1773 the king opened the national theatre in Stockholm, and on that occasion an opera of Thetis och Pelle was performed, written by himself. In 1786 Gustavus created the Swedish Academy, on the lines of the French Academy, but with eighteen members instead of forty. The first list of immortals, which included the survivors of a previous age and such young celebrities as Kellgren and Leopold, embraced all that was most brilliant in the best society of Stockholm; the king himself presided, and won the first prize for an oration. The works of Gustavus III. in six volumes were printed at Stockholm in 1802–1806.

The principal writers of the reign of Gustavus III. bear the name of the academical school. But Karl Mikael Bellman (q.v.; 1740–1795), the most original and one of the most able of all Swedish writers, an improvisatore of the first order, had nothing academical in his composition. The poet of his dithyrambic hymns sounded a strange note of nature amid the conventional music of the Gustavians. Of the academical poets Johan Gabriel Oxenstjerna (1750–1818), the nephew of Gyllenborg, was a descriptive idyllist of grace.

Glossarium suogothicum (1760), a historical dictionary with many valuable examples from the ancient monuments of the language. In doing this he was assisted by the labours of two other grammarians, Sven Hol (d. 1786) and Abraham Sahstedt (d. 1776). The chief historians were Sven Lagerberg (d. 1707–1787), author of a still valuable history of Sweden down to 1437 (Svea Rikes historia, 4 vols., 1769–1793); Olof Celsius (1716–1794), bishop of Lund, who wrote histories of Gustavus I. (1746–1753) and of Eric XIV. (1774); and Carl Gustaf Tessin (1605–1779) who wrote on politics and on aesthetics. Tessin’s Old Man’s Letters to a Young Prince were addressed to his pupil, afterwards Gustavus III. Count Anders Johan von Höpken (1712–1788), the friend of Louise Ulrica, was a master of rhetorical compliment in addresses and funeral orations.

In spirit all of the earlier poets of whom we have spoken did not flourish in Sweden. Among the tragic writers of the age we may mention Dalin, Gyllenborg, and Erik Wrangel (1686–1705). In comedy Reinhold Gustaf Modèe (d. 1752) wrote three good plays in rivalry of Holberg.

In science Linnaeus, or Karl von Linné (1707–1778), was the name of greatest genius in the whole century; but he wrote almost entirely in Latin. The two great Swedish chemists, Torbern Olof Bergman (1735–1784) and Karl Vilhelm Scheele (1742–1786), flourished at this time. In pathology a great voice was heard from Elias Rothen von Rosenstein (1706–1773), in navigation by Admiral Fredrik Henrik af Chapman (d. 1808), in philology by Carl Aurivillus (d. 1786). But these and other distinguished savants whose names might be enumerated scarcely belong to the history of Swedish literature. The same may be said about that marvellous and many-sided genius, Emanuel Swedenborg (1688–1772), who, though the son of a Swedish poet, preferred to prophesy to the world in Latin.
He translated *Paradise Lost*. A writer of far more power and versatility was Johan Henrik Kellgren (q.v.; 1751–1790), the leader of taste in his time. He was the first writer of the end of the century in Sweden, and the second undoubtedly was Karl Gustaf af Leopold (1756–1829), "the blind see Tiresias-Leopold," who lived on to represent the old school in the midst of romantic times. Leopold attracted the notice of Gustavus III. by a volume of *Erotic Odes* (1783). The king gave him a pension and rooms in the palace, admitting him on intimate terms. He was not equal to Kellgren in general poetical ability, but he is great in didactic and satiric writing. He wrote a satire, the *Enebomad*, against a certain luckless Per Enebom, and a classic tragedy of *Virginia*. Gudmund Göran Adlerbeth (1751–1818) made translations from the classics and from the Norse, and was the author of a successful tragic opera, *Cora och Alonso* (1782). Anna Maria Lenngren (1754–1817) was a very popular sentimental writer of graceful domestic verse, chiefly between 1792 and 1798. She was less French and more national than most of her contemporaries; she was a Swedish Mrs Hemans. Much of her work appeared anonymously, and was generally attributed to her contemporaries Kellgren and Leopold.

Two writers of the academic period, besides Bellman, and a generation later than he, kept apart, and served to lead up to the romantic revival. Bengt Lidner (1759–1793), a melancholy and profoundly elegiac writer, had analogies with Novalis. He interrupted his studies at the university by a voyage to the East Indies, and returned to Stockholm after many adventures. In spite of the patronage of Gustavus III. he continued to lead a disordered, wandering life, and died in poverty. A short narrative poem, *The Death of the Countess Spastora* (1783), has retained its popularity. Lidner was a genuine poet, and his lack of durable success must be set down to faults of character, not to lack of inspiration. His poems appeared in 1788. Thomas Thorild (1759–1808) was a much stronger nature, and led the revolt against prevailing taste with far more vigour. But he is an irregular and inartistic versifier, and it is mainly as a prose writer, and especially as a very original and courageous critic, that he is now mainly remembered. He settled in Germany and died as a professor in Greifswald. Karl August Ehrensvard (1745–1800) may be mentioned here as a critic whose aims somewhat resembled those of Thorild. The creation of the Academy led to a great production of aesthetic and philosophical writing. Among critics of taste may be mentioned Nils Rosén von Rosenstein (1752–1824); the rhetorical bishop of Linköping, Magnus Lönberg (1758–1808); and Count Georg Adlersparre (1760–1809). Rosén von Rosenstein embraced the principles of the encyclopaedists while he was attached to the Swedish embassy in Paris. On his return to Sweden he became tutor to the crown prince, and held in succession a number of important offices. As the first secretary of the Swedish Academy he exercised great influence over Swedish literature and thought. His prose writings, which include prefaces to the works of Kellgren and Lidner, and an eloquent argument against Rousseau's theory of the injurious influence of art and letters, rank with the best of the period. Kellgren and Leopold were both of these writers.

The excellent lyrical poet Frans Mikael Franzén (q.v.; 1772–1847) and a belated academian Johan David Valerius (1776–1822), fill up the space between the Gustavian period and the domination of romantic ideas from Germany. It was Lorenzo Hammersköld (1785–1827) who in 1803 introduced the views of Tieck and Schelling by founding the society in Upsala called "Vitterhetens Vänner," and by numerous critical essays. His chief work was *Svenska bilderlitteratur* (1818, &c.) a history of Swedish literature. Hammersköld's society was succeeded in 1807 by the famous "Aurora förbundet," founded by two youths of genius, Per Atterbom. Daniel Amadeus Atterbom (1790–1855) and Vilhelm Fredrik Palmblad (1788–1852). These young men had at first to endure bitter opposition and ridicule from the academic writers then in power, but they supported this with cheerfulness, and answered back in their magazines *Polyphem* and *Forsoras* (1810–1813). They were named "Forsoristerna" ("Phosphorists") from the latter. Another principal member of the school was Karl Frederik Dahlgren (q.v.; 1791–1844), a humorist who owed much to the example of Bellman. Fru Julia Nyberg (1792–1859) under the title of Ephrasyne, was their tenth Muse, and wrote agreeable lyrics. Among the Phosphorists Atterbom was the man of most genius. On the side of the Academy they were vigorously attacked by Per Adam Wallmark (1777–1838), to whom they replied in a satire which was the joint work of several of the romanticists, *Markall's Sleepless Nights*. One of the innovators, Atterbom, eventually forced the doors of the Academy itself.

In 1811 certain young men in Stockholm founded a society for the elevation of society by means of the study of Scandinavian antiquity. This was the Gothic Society, which began to issue the magazine called *Iduna* as its organ. Of its patriotic editors the most prominent was Erik Gustaf Geijer (q.v.; 1783–1847), but he was presently joined by a young man slightly older than himself, Esaias Tegnér (q.v.; 1782–1846), afterwards bishop of Växjö, the greatest of Swedish writers. Even more enthusiastic than either in pushing to its last extreme the worship of ancient myths and manners was Per Henrik Ling (1776–1859), now better remembered as the father of gymnastic science than as a poet. The Gothic Society eventually included certain younger men than these—Arvid August Afselius (1785–1871), the first editor of the Swedish folk-songs; Gustaf Vilhelm Gamaelius (1789–1877), who has been somewhat pretentiously styled "The Swedish Walter Scott," author of the historical novel of *Tord Bonde*; Baron Bernhard von Beskow (q.v.; 1796–1868), lyric and dramatist; and Karl August Nicander (1799–1839), a lyric poet who approached the Phosphorists in manner. The two great lights of the Gothic school are Geijer, mainly in prose, and Tegnér, in his splendid and copious verse. Johan Olaf Wallin (1779–1839) may be mentioned in the same category, although he is really distinct from all the others.

He was archbishop of Upsala, and in 1819 he published the national hymn-book of Sweden; of the hymns in this collection, 126 are written by Wallin himself.

From 1810 to 1840 was the blossoming-time in Swedish poetry, and there were several writers of distinguished merit who could not be included in either of the groups enumerated above. Second only to Tegnér in genius, the brief life and mysterious death of Erik Johan Stagelius (1793–1820) have given him a place among all that is connected with his name. His first publication was the epic of *Vladimir the Great* (1817); to this succeeded the romantic poem *Blonda*. His singular dramas, *The Bacchantes* (1822), *Sigurd Ring*, which was posthumous, and *The Martyrs* (1823), are esteemed by many critics to be his most original productions. His mystical lyrics, entitled *Ljifer i Saron* ("Lilies in Sharon"); (1820), and his sonnets, which are the best in Swedish, may be recommended as among the most delicate products of the Scandinavian mind. Stagelius has been compared, and not improperly, to Shelley. His work, which he called himself "Vitalis" (1794–1828), was another gifted poet, whose career was short and wretched. A volume of his poems appeared in 1820; they are few in number and all brief. His work divides itself into two classes—the one profoundly melancholy, the other witty or boisterous. Two humorous poets of the same period who deserve mention are Johan Anders Wadam (1777–1837), an improvisatore of the same class as Bellman, and Christian Erik Fahlcrantz (q.v.; 1790–1866).

Among the poets who have been mentioned above, the
majority distinguished themselves also in prose. But the period was not one in which Swedish prose shone with any special lustre. The first proasist of the time was, without question, the novelist, Karl Jonas Ludvig Almqvist, (q.v.; 1793–1866), around whose extraordinary personal character and career a mythical romance has already collected (see Almqvist). He was encyclopaedic in his range, although his stories preserve most charm; on whatever subject he wrote his style was always exquisite. Fredrik Cederberg (1784–1854), Jeff the vartor novel, in his Utan i Vassesby and Omskrättling. The historical novels of Gumaaloe have already been alluded to Sweden history supplied themes for the romances of Count Per Georg Sparre (1790–1871) and of Gustaf Henrik Mellin (1803–1876). But all these writers sink before the sustained popularity of the Finnish poet Fredrika Bremer (q.v.; 1801–1869), whose stories reached farther into the distant provinces of the world of letters than the writings of any other Sweden except Tegnér. She was preceded by Sofia Margareta Zelow, afterwards Baroness von Knorringer (1797–1848), who wrote a long series of popular didactic poems, the most popular of which was his "The One and the Other." As an historian of Swedish literature Per Wieselgren (1800–1877) composed a valuable work, and made other valuable contributions to history and bibliography. In history we meet again with the great name of Geijer, with that of Jonas Hallenberg (1748–1834), and with that of Anders Magnus Strinnholm (1786–1862), whose labours in the field of Swedish history were extremely valuable. Geijer and Strinnholm prepared the way for the most popular of all Swedish historians, Anders Fryxell (1795–1881), whose famous Berättelser ur svenska historien appeared in parts during a space of nearly sixty years, and awakened a great interest in Swedish history and legend.

In 1850 the first poet of Sweden, without a rival, was Johan Ludvig Runeberg (q.v.; 1804–1877), whose reputation rivals that of Tegnér. Bernhard Elias Malmström (1816–1863), who was a professor of aesthetics at the university of Upsala, was the author of many important books on art, poetry and taste, notably a monograph on Fransén. His poetry, although small in volume, gives him a place beside Runeberg. A volume of elegies, Angeliska (1840), established his fame, and two volumes of poems published in 1845 and 1847 contain a number of ballads, romances and songs which keep their hold on Swedish literature. He was an exact and discriminating critic, and inclined to severity in his strictures on the romanticists. The other leading verse-writers were Karl Vilhelm Böttiger (1807–1878), the son-in-law and biographer of Tegnér, who, in addition to his lyrical poetry, chiefly of the sentimental kind, wrote an admirable series of monographs on Swedish men of letters; Johan Börjeson (1790–1860), the head of the Phosphorists, author of various romantic dramas; Vilhelm August Deltof von Braun (1813–1860), a humorous lyricist; "Talis Qualis," whose real name was Karl Vilhelm August Strandberg (1818–1877); Oscar Patrick Sturzen-Becker (1812–1866), better known as "Orvar Odd," a lyrical poet who was also the author of a series of amusing sketches of everyday life; and August Teodor Blanche (1811–1868), the popular dramatist. Blanche produced a number of farces and comedies which were announced as pictures from real life. His pieces abound in comic situations, and some of them, Magister Black-stad, "Vem är det i huvudet?" i "Vem är det?" (1845), the famous vremvminhet (1848) and others, maintain their reputation. Fredrik August Dahlgen (1816–1895) gained a great reputation as a dramatist by his national opera, Verlovningarne (1846). He is also the author of translations from Shakespeare and Calderon, and of considerable historical works. Other notable plays of the period were the En Komedii of J. C. Jolin (1818–1884) and the Brölopet på Ulfså (1865) of Frans Hedberg (1828–1908). But Runeberg is the only great poetical name of this period.

In prose there was not even a Runeberg. The best novelist of the time was Emile Flygare-Carlén (1807–1892). The art was sustained by Karl Anton Wetterberg (1804–1859), who called himself "Onkel Adam," by August Blanche the dramatist, and by Marie Sofie Schwartz (1816–1892). Fru Schwartz (née Birat) wrote novels demonstrating the rights of the poor against the rich, of which The Man of Birth and the Woman of the People (Eng. trans., 1868) is a good example. Lars Johan Hierta (1806–1872) was the leading journalist, Johan Henrik Thomander, bishop of Lund (1798–1865), the greatest orator, Matthias Alexander Cæstrén (1813–1852) a prominent man of science, and Karl Gustaf af Forsell (1782–1848), the principal statistician of this not very brilliant period. Elias Lönnrot (q.v.; 1802–1884) is distinguished as the Finnish professor who discovered and edited the Kalevaka.

The most popular poet at the close of the 19th century was the patriotic Finn, Zakris Topelius (q.v.; 1818–1885). Of less importance were Karl Herman Sätherberg (1811–1877), a romantic poet who was also a practising physician of distinction; the elegiac poet Johan Nyblom (1815–1886); and the poet, novelist, and dramatist Fredrik Hedberg (d. 1908), who in his old age made many concessions to the modern taste. He found a vehement polemical defence of the poems of the bishop of Strängnäs, Adam Teodor Strömberg (1820–1888), were collected by Wirsén, and created some sensation. A typical academian was the poet, antiquary and connoisseur, Nils Fredrik Sander (1828–1900). The improvisator of Gluntarne, Gunnar Wennerberg (q.v.; 1817–1901) survived as a romantic figure of the past. Still older was the poetess Wilhelmina Nordström (1815–1902), long a schoolmistress in Finland. The aesthetic critic and poet, Carl Rupert Nyblom (1832–1907), continued the studies, translations and original pieces which had created him a reputation as one of the most accomplished general writers of Sweden. His wife, Helen Nyblom, was well known as a novelist. A. T. Gellerstedt (b. 1836), an archbishop of position, was known as a poet of small range but of very fine quality. Among writers of the earlier generation were Achatius Johan Kahl (1794–1888), the biographer of Tegnér; Per Erik Bergfalk (1798–1890), the critic and supporter of Geijer; the distinguished historian and academian, Karl Johan Schlyter (1795–1888) and the historical writers, Fredrik Ferdinand Carlsson (1811–1887), Vilhelm Erik Svedså (1816–1886), and Martin Weibull (1835–1902). The range of their sympathies also extended beyond the modern to the intellectual life of the country. But the interest of such veteran reputations is eclipsed by the more modern school.

The serenity of Swedish literature was rudely shaken about 1884 by an incursion of realism and by a stream of novel and violent imaginative impulse. The controversy between the old and the new schools raged so fiercely, and the victory has remained so obviously in the hands of the latter, that it is difficult, especially for a foreigner, to hold the balance perfectly even. It will therefore be best in this brief sketch to say that the leader of the older school was Viktor Rydberg (q.v.; 1828–1895) and that he was ably supported by Carl Snolisky (q.v.; 1841–1904) who at the beginning of the 20th century was the principal living poet of the bygone generation in Sweden. Snolisky was prominent for the richness of his lyrical style, his cosmopolitan interests and his great width of culture. Carl David af Wirsén (b. 1842) distinguished himself, and made himself very unhappy, by his dogged resistance to every species of nesdance in Swedish thought, or art, or literature. A man of great talent, he was a violent reactionary, and suffered from the consequences of an attitude so unpopular. He found a vehicle for his criticism in the Post och Inrikes Tidskrifter, of which he was editor. He published his Lyrical Poems in 1876; New Lyrical Poems in 1880; Songs and Sketches in 1885.

Four influences may be mentioned as having acted upon young Sweden, and as having combined to release its literature from the old hard-bound conventions. These are English philosophy in the writings of Herbert Spencer, French realism
in the practice and the preaching of Zola, Norwegian drama mainly through Ibsen, and Danish criticism in the essays and monographs of Georg Brandes. Unquestionably the greatest name in recent Swedish literature is that of Johan August Strindberg (q.v.; b. 1849). His drama of Master Olaf (1885) began the revolutionary movement. In 1879 the success of his realistic novel, The Red Room, fixed universal attention upon his talent. It was the sensation caused in 1884 by the lawsuit brought against Strindberg's Married (a collection of short stories dealing realistically with some of the seamy sides of marriage) which brought to a head the rebellion against the elegant and superficial conventions which were strangling Swedish literature. He affronts every canon of taste, more by a radical absence, it would seem, of the sense of proportion than by any desire to shock. His distributes against woman suggest a touch of madness, and he was in fact at one time seized with an attack of insanity. He writes like a man whose view is distorted by physical or mental pain. His phraseology and his turns of invention are too empirically pseudoscientific for the simplicity of nature. With all these faults, and in spite of a terrible vulgarity of mind, an absence of humour, and a boundless confidence in the philosophy of Nietzsche, Strindberg is a writer of very remarkable power and unquestionable originality. His mind underwent singular transformations. After devoting himself wholly to realistic, and occasionally to the sort of mystico-pathological novels about life in the archipelago of Stockholm. This led him to a culte du moi, of which the strangest result was an autobiography of crude invective, A Fool's Confession (1893), the printing of which in Swedish was forbidden. He rapidly passed on, through books like Inferno (1897), the diary of a semi-lunatic, up into the sheer mysticism of To Damascus (1898), where he reconciles himself at last to Christianity. His best work is classic in its breadth of style, exquisite in local colour and fidelity to the national characteristic of Sweden.

A curious antidote to the harsh pessimism of Strindberg was offered by the delicate and fantastic temperament of Ola Hansson (b. 1860), whose poems came prominently before the public in 1884, and who, in Sensitiva amorosa (1887), preached a gospel of austere self-restraint. Hansson has been as ardent in the idolatry of woman as Strindberg has been in his hostility to the sex. Of those who have worked side by side with Strindberg, the most prominent and active was Gustaf af Geijerstam (b. 1859), in his curious and severely realistic studies of country life, Anna Pern-People (1885) and other volumes. In 1885 he produced a gloomy sketch of student life at Upsala, and the following year published a novel which made a great sensation. Since then Geijerstam has published more than forty volumes, and has become one of the most popular writers of the north of Europe. A melancholy interest surrounds the name of Victoria Benedictson (Ernst Ahlgren, 1850-1889), who committed suicide in Copenhagen after achieving marked success with her sketches of humble life in Från Slahe, and with the more ambitious works Money and Marianne. She was perhaps the most original of the many women writers of modern Sweden, and Money was hailed by Swedish critics as the most important work of fiction since Strindberg's Red Room. Her biography, a most affecting narrative, was published by Ellen Key, and her autobiography by Axel Lundegård (b. 1861), who, after some miscellaneous writing, produced in 1889 a curious novel of analysis called The Red Prince, and who, becoming a devoted clergyman, published a number of popular stories in a neo-romantic manner. In 1896-1900 he produced a historical trilogy, Struensea, tracing the career of the minister from his early years as a doctor in Altona to his final downfall. In 1904 appeared the first volume of a second historical trilogy, The Story of Queen Wetzipa. Fru Athild Aghrell (née Martin), who was born in 1849, produced a series of plays dealing with the woman question, Rescued (1883) and others. She also showed great ability as a novelist, among the best of her books being a series of sketches of country life (1884-1887). An historical novelist of unequal powers, but great occasional merit, is Mattilda Malling, née Kruse (b. 1864), whose romance about Napoleon (1894) enjoyed a huge success. Tor Hedberg (b. 1861) also began as a decided realist, and turned to a more psychological and idealist treatment of life. His most striking work was Judas (1886); he has written some execrable dramas. His essays in the novel has been those of Hilma Angerled-Strandberg (On the Prairie, 1895) and Gustaf Janson (Paradise, 1900). The most remarkable of the novelists of the latest group is Selma Lagerlöf (b. 1858), who achieved a great success with Gosta Berlings Saga in 1891-1892. She employs the Swedish language with an extraordinary richness and variety, and stands in the front rank of Swedish novelists. But perhaps the most cosmopolitan recent novelist of Sweden is Per Hallström (b. 1866), who spent much of his youth in America, and appeared as an imaginative writer first in 1891. He has published volumes of ballads, short stories, monologues, and sketches, fantastic and humorous, all admirable in style. His play, A Venetian Comedy, enjoyed a substantial success in 1904.

Among the recent lyrical poets of Sweden, the first to adopt the naturalistic manner was Albert Ulrik Båthå (b. 1853), whose earliest poems appeared in 1879. In his rebellion against the sweetness of Swedish convention he proved himself somewhat indifferent to beauty of form, returned to "early national" types of versification, and concentrated his attention on dismal and distressing conditions of life. He is a resolute, but, in his early volumes, harsh and rocky writer. In 1884-1885 his Båth was steadily productive. Karl Alfred Melin (b. 1849) has described in verse the life in the islands of the Stockholm archipelago. Among lyricists who have attracted attention in their various fields are Oskar Levertin (1862-1906) and Emil Kléen (1868-1898). Of these Levertin is the more highly coloured and perfumed, with an almost Oriental richness; Kléen has not been surpassed in the velvety softness of his language. But by far the most original and enjoyable lyrical genius of the later period is that of Gustaf Fröding (b. 1860), whom several contemporaries have called the "godfather of the new generation." He is a writer of some violent, humorous, amatory, and pathetic, produced a great sensation in 1891. Three other volumes followed in 1894, 1895 and 1897, each displaying to further advantage the versatility and sensuous splendour of Fröding's talent, as well as its somewhat scandalous recklessness. In 1897 he was struck down with insanity, and after three months' confinement in the asylum at Upsala, although he recovered his senses, all his joyousness and wildness had left him. He became gloomily religious, and in a new volume of poems he denounced all that he valued and esteemed before his conversion. A younger poet is K. G. Ossian-Nilsen (b. 1875), the author of several volumes of vigorous dramatic and satiric verse.

The writer who was exercising most influence in Sweden at the opening of the 20th century was Verner von Heidenstam (b. 1859). He started authorship with a book of verse in 1888, after which time he led a reaction against realism and pessimism, and has turned back to a rich romantic idealism in his novels of Endymion (1886) and Hans Atenus (1892), and in his stories (1897) of the time of Charles XII. Heidenstam also published interesting volumes of literary criticism, and he is a member of the very important literary circle around Ellen Key (b. 1849), a secularist lecturer of great fervour, became an author in biographical and critical studies of remarkable originality. She is distinguished from Selma Lagerlöf, who is simply an artist, by her exercise of pure intellect; she is a moral leader; she has been called "the Pallas of Sweden." She published in 1897 a biography of the Swedish author, Almqvist; in 1899 she collected her finest essays in the volume called Thought Pictures; in 1900 appeared, under the title Human Beings, studies of the Brownings and of Goethe; but the finest of Ellen Key's books is The Costers of Childhood (1901), a philosophical survey of the progress of elementary education in the last hundred years. She exercises a very remarkable power over the minds of the latest generation in Sweden. A polemical essayist of elaborate decorice of style is Hjalmar Söderberg (b. 1869), who has been influenced by Strindberg and by Anatole.
France. His ironic romance, *Martin Birck’s Youth*, created a sensation in 1901. Karl Johan Warburg (1852) has done good work both as an essayist and as an historian of literature. But in this latter field by far the most eminent recent name in Swedish literature is that of Professor Johan Henrik Schück (1859), who has made great discoveries in the 16th and 17th centuries, and who has published, besides a good book about Shakespeare, studies in which a profound learning is relieved by elegance of delivery. Warburg and Schück have written an essay, *Anne Charlotta Edgren-Leffler*, 1849—1893), possessed considerable dramatic talent, working under a direct impulse from Ibsen; but her greatest gift was as a novelist. The plays of Harald Johan Målander (1835—1900) have been popular in the theatres of Sweden and Finland since his first success with *Rosaco* in 1880. Another remarkable revival of belles-lettres has taken place in Sweden after a long period of inertness and conventionality. It is regrettable, for its own sake, that the Swedish Academy, which in earlier generations had identified itself with the manifestations of original literary genius, has closed its doors to new writers with such virulently pedantic indifference.

**Swedish Philosophy.**—Swedish philosophy proper began in the 17th century, with the distinguishedGeorg Bureau (1633-1712). The centre of the movement was J. Bilberg (1464-1717), who, in various theses and discussions, defended the new ideas against the scholastic Aristotelianism of the orthodox churchmen. A. Rydelsius (1671-1738), an intimate friend of Charles XII, endeavoured to find a common ground for the opposing schools, and the Leibniz-Wolffian philosophy was maintained by N. Wallerius (1706-1764). Together with the Church, and especially of the German rationalists, they strove to expand the philosophy of the Enlightenment under the influence of English and French ideas—J. H. Kellgren (1751-1795), K. G. af Leopold (1756-1829), T. Thorild (1759-1808), A. K. Ehrensvärd (1760-1830)—and the Swedes, being by birth and occupation a nation of a peculiarly warlike character, contributed to the art of war. D. B. Böthius (1751-1810), whose work paved the way for a great idealistic speculative movement headed by B. Höijer (1767-1812), the poet F. D. A. Atterbom (1790-1855), a follower of Schelling, and J. J. Berdén (1825), the great Swedish exponent of Hegelianism. All the above thinkers reflected the general development of European thought. There exists, however, a body of thought which is the product of the peculiar genius of the Swedish people, namely, the development of the individual soul in accordance with a coherent social order and a strong religious spirit. This *Personal Philosophy* owes its development to K. J. Boström (p. xii) and, throughout the development of the so-called *idealist* or *idealistic* philosophy, a distinctive character from the investigations of N. F. Bilberg (1767-1837), S. Grubbe (1786-1853) and E. G. Geijer (p. xix) (1783-1847), all professors at Upsala. Boström’s philosophy is logically expressed and, like most great conceptions, eternal, eternal and unchangeable. Being, whose existence is absolute, absolute and external to the finite world of time and space. It has for a long time exercised almost unquestioned authority over Swedish thought, religious and philosophical. It is strong in its unequivocal insistence on the personal purity and responsibility, and in the uncompromising simplicity of its fundamental principle. Boström wrote little, but his views are to be found in the works of the two great philosophers who followed him. The older group includes S. Ribbing (1816-1899), C. Y. Sahlin (1824), K. Chasson (1827-1899), H. E. Edelfeld (1830), the eldest father of the New Sweden philosophy, and his works, C. A. Nybract (1821-1899) and P. J. H. Leander (1831), and in the younger group, another, but adhering in the main to the same tradition, are E. O. Burman (1845), K. R. Geijer (1849), L. H. Åberg (1851-1900) and H. A. Nordin (1856-1930), of Gothenburg, and P. E. Liljeström (1856), of Lund. Of these Nybract compiled a lucid account of Swedish philosophy from the beginning of the 16th century up to and including Boström; Ribbing (Philosophi 1864) and Leander (Subjectiviteten) treated the principle of subjectivism as a whole; the former is allied to Greek. P. Vikner (1837-1888) broke away from the Boströmian tradition and followed out a path of his own in a more pronounced religious spirit. V. Rydberg (p. xii) (1828-1895) closely followed Boström and was one of the most influential spirits that did much to crystallize and extend the principles of idealism. Among prominent modern writers may also be mentioned H. Larsson and P. Runesson (1863-1938) and A. V. Malmström (1859-1934) of Stockholm.

**Authorities.**—*Swenska litteraturhistoria* (1660) by O. Schefferus (1621-1679) is the first serious attempt at a bibliography of Swedish literature. The *Svenska tidskr och skildr* (Upsala, 1841-1855) contains an admirable series of portraits of Swedish writers up to the end of the reign of Gustavus III.; many of Atterbom’s judgments are reversed in the *Grundrissen der Svenska litteraturhistoria* (1866-1868) of B. E. Malmström; and a body of excellent criticism of the subsequent period was supplied by W. M. Bostrom’s *Svenska litteraturhistoria* (1853, new ed. by Sondern, 1853), which remains a classic exposition of the views of the school. The letters as it reflects the life of the nation is dealt with by C. R. Nyholm (1891) of Stockholm. The *Svenska litteraturhistoria* (1865-1868) has been published by the Swedish Central Bureau of Statistics for the Parish Exhibition (English ed., Stockholm, 1904); P. Swedenberg, *Geschichte der skandinavischen Litteratur*, vol. vii. of *Die Welt Litteratur in Einzeldarstellungen* (Leipzig, 3 pts., 1886-1886); Oscar Levitin, *Svenska Gesalter* (1904).
his time. His work on palaeontology shows him the predecessor of all the Scandinavian geologists, and his contributions in this field alone would have been sufficient to perpetuate his fame. He was also a great physicist and had arrived at the nebular hypothesis of the formation of the planets and the sun long before Kant and Laplace. His theory of light and those of the atomic cosmology were equally astonishing. He wrote a lucid account of the phenomena of phosphorescence, and added a molecular magnetic theory which anticipated some of the chief features of the hypothesis of to-day. The great French chemist, Dumas, gives him the credit for the first attempt to establish a system of crystallography. He was the first to employ mercury for the air-pump, and devised a method of determining longitude at sea by observations of the moon among the stars. He suggested the use of experimental tanks for testing the powers of ship models, invented an electric lamp free of visible flame, improved the common house-stove of his native land, cured smoky chimneys, took a lively interest in machine-guns and even sketched a flying machine.

This flying machine consisted of a light frame covered with strong canvas and provided with two large oars or wings moving on a horizontal axis, and so arranged that the upstroke met with no resistance. He spoke proudly of the flying power with which he knew the machine would not fly, but suggested it as a start and was confident that the problem would be solved. He also suggested that the canvas by being made thicker than to the actuality, for it requires greater force and less weight than exists in a human body. The science of mechanics might perhaps suggest a means, namely, a strong spiral spring. If these advantages and requisite atoms were real, perhaps in time some one might know how better to utilize our sketch and cause some addition to be made so as to accomplish that which we can only suggest. Yet there are sufficient proofs and examples from nature that such flights can take place without danger, although when the first trials are made you may have to pay for the experience, and not mind an arm or leg.

In 1734 he also published Prodromus philosophiae rationalis, in which he treated of the relation of the finite to the infinite, and of the soul to the body, seeking to establish a nexus in each case as a means of overcoming the difficulty of their relation. From this time he applied himself to the problem of discovering the nature of soul and spirit by means of anatomical studies. In all his researches he acknowledged and contended for the existence and the supremacy of the spiritual and the divine. He travelled in Germany, France and Italy, in quest of the most eminent teachers and the best books dealing with the human frame, and published, as the results of his inquiries among other works, his Oeconomia regni animalis (London, 1740-1741) and Regnum Animalium (the Hague, 1744-1745; London, 1745). In no field were Swedenborg's researches more noteworthy than in those of physiological science. In 1901, Professor Max Neuber of Vienna called attention to the modern views made by Swedenborg in relation to the functions of the brain. The university of Vienna appealed to the Royal Swedish Academy for a complete issue of the scientific treatises, and this resulted in the formation of a committee of experts who have been entrusted with the task. It is clear that Swedenborg showed (150 years before any other scientist) that the motion of the brain was synonymous with the respiration and not with the action of the heart and the circulation of the blood, a discovery the full bearings of which are still far from being realized. He had arrived at the modern conception of the activity of the brain as the combined activity of its individual cells. The cerebral cortex, and, more definitely, the cortical elements (nerve cells), formed the seat of the activity of the soul, and were ordered into departments according to various functions. His views as to the physiological functions of the spinal cord are also in agreement with recent research, and he anticipated many of the pre-eminent offices of the denticulate glands which students of the present time are only beginning to discover.

Up to middle age Swedenborg's position was that of a scholar, a scientist, a practical administrator, a legislator, and a preacher of unending change was coming over him, which led him to leave the domain of physical research for that of psychical and spiritual inquiry. Neither by geometrical, nor physical, nor metaphysical principles had he succeeded in reaching and grasping the infinitely great and the spiritual, or in elucidating their relation to man and man's organism, though he had caught glimpses of facts and methods which he thought only required confirmation and development. Late in life he wrote to Dr. George Bering, "I was introduced to the Lord first into the natural sciences, and thus prepared, and, indeed, from the year 1710 to 1745, when heaven was opened to him." This latter great event is described by him in a letter to Thomas Hartley, rector of Winwick, as "the opening of his spiritual sight," "the manifestation of the Lord to him in person," "his introduction into the spiritual world." Before his illumination he had been instructed by dreams, and enjoyed extraordinary visions, and heard mysterious conversations. According to his own account, the Lord filled him with His spirit to teach the doctrines of the church by the mouth of angels, and to draw him to do this work, opened the sight of his spirit, and so let him into the spiritual world, permitting him to see the heavens and the hells, and to converse with angels and spirits for years, but he never received anything relating to the doctrines of the church from any angel but from the Lord alone while he was reading the word (True Christian Religion, No. 779). He elsewhere speaks of his office as principally an opening of the spiritual sense of the word. His friend Rolsahm reports, from Swedenborg's own account to him, the circumstances of the first extraordinary talk with the Lord, when He appeared to him and said, "I am God the Lord, the Creator of all things, of the whole of the world. I have chosen thee to unfold the spiritual sense of the Holy Scripture. I will Myself dictate to thee what thou shalt write." From that time he gave up all worldly learning and laboured solely to expound spiritual things. In the year 1747, to the great regret of his colleagues, he resigned his post of assessor of the board of mines that he might devote himself to his higher vocation, requesting only to be allowed to receive as a pension the half of his salary. He took up after his study of Hebrew, and began his voluminous works on the interpretation of the Bible and the organization of the True Christian religion, which were published in Sweden, Holland and London, in the composition of his works and their publication, till his death, which took place in London on the 29th of March 1772. He was buried in the Swedish church in Princes Square, in the parish of St George's-in-the-East, and on the 7th of April 1768 his remains were removed at the request of the Swedish government to Stockholm.

Swedishborg was a man who won the respect, confidence and love of those who came into contact with him. Though he might disbelieve in his visions, they feared to ridicule them in his presence. Those who talked with him felt that he was truth itself. He never disputed on matters of religion, and if obliged to defend himself, did so with perfect gentleness and in a way that was so simple in the extreme; his diet consisted chiefly of bread and milk and large quantities of coffee. He paid no attention to the distinction of church high and low. He had his own house, while his servants were often disturbed at night by hearing what he called his conflicts with evil spirits. But his intercourse with spirits was often perfectly calm, in broad daylight, and with all his faculties awake. Three extraordinary instances are produced by his friends and followers in proof of his seership and admission into the unseen world. But there exists no account at first hand of the exact facts, and Swedenborg's own reference to one of these respects limits of time and place in this manner of the world. Thus, for example, in 1763, Emanuel Kant was struck by them in 1765, but in 1785, after further inquiries, concluded that two of them had no other foundation than common reports (genius Sagen). See Keilbach's edition of Kant's Traume eines Geistesreisenden (Leipzig, 1889).

As a theologian Swedenborg never attempted to preach or to found a sect. He believed that members of all the churches could now live happily together. His theological writings roughly fall into four groups: (1) books of spiritual philosophy, including The Divine Love and Wisdom, The Divine Providence, the Aristotelian and the Body, Conjugial Love, (2) Esoteric, including Arcana Celestia (giving the spiritual sense of Genesis and Exodus), The Apocalypse Revealed, The Apocalypse Explained; (3) Doctrinal, including The True Jerusalem, The True Christian Religion, The Doctrine of the Church, The Holy Scriptural Doctrines, The Doctrine of Charity, The True Christian Religion, Canons of the New Church; (4) Eschatological, including Heaven and Hell, and The Last Judgment. About forty volumes are available in English, and many have been translated into most
of the European languages as well as into Arabic, Hindi and Japanese.

Swedenborg's theosophic system is most briefly and comprehensively described in the book The Divine Love and Wisdom. The point of view from which God must be regarded is that of His being the Divine Man. His esse is infinite love; His manifestation, form or body is infinite wisdom. Divine love is the self-subsisting life in the Divine Man, and the nature of God. It is the active principle, for it gives life to all things and makes them alive. The two worlds of nature and spirit are perfectly distinct, but they are intimately related by analogous substances, laws, and causes. In its continuity with the universe, the being of God is the same, but in the one they are natural and in the other spiritual. In God there are three infinite and created "degrees" of being, and in man and all things corresponding three degrees, finite and created. The highest degree in God is uncreated; or, as Swedenborg expresses it, the ends of all things are in the Divine Mind, the causes of all things in the spiritual world, and their effects in the natural world. By a love of each degree man comes into conjunction with them and the worlds of nature, spirit and God. The end of creation is that man may have this conjunction and become the image of his Creator and creation. In man are two receptacles for God—the will for "correspondences" in which to unfold the divine treasure of love and wisdom flowing into both so that they become human. Before the fall this influx was free and unhindered, and the conjunction of man with God and the creation complete, but from that time forth these correspondences are interrupted and God hid himself from man and the effects of the fall ensued. Swedenborg believes the purpose of revelation is to restore the connexion between Himself and man. He could not come in His unveiled divinity, for the "hells" would have the greatest desire to see it, but only to subjugate. Another purpose of Jehovah's incarnation was the manifestation of His divine love more fully than ever before. Swedenborg wholly rejects the orthodox doctrine of atonement; and the unity of God, as opposed to the division of the Trinity, is a feature of his teaching. Another distinctive feature is that Jehovah did not go back to heaven without leaving behind him a visible representative of Himself in the world of the Scripture. This word is an external representation of the spiritual—natural world of the celestial. And Swedenborg is the divinely commissioned expounder of this threecold sense of the word, and so the founder of the New Church, the par excellence of the last dispensation. That he might perceive and understand the spiritual and the celestial senses of the word he enjoyed immediate revelation from the Lord, was admitted into the angelic world, and had committed to him the key of correspondences with which to unfold the divine treasurers of love and wisdom. Swedenborg claimed also to have learnt by his admission into the spiritual world the true states of men in the next life, their rewards and punishments, and occupations of heaven and hell, the true doctrine of Providence, the origin of evil, the sanctity and sanctity of property, the power of God, and to have been a witness of the "last judgment," or the second coming of the Lord, which is a contemporary event. "All religion," he says, "is founded on the present and the future, and to do good is the kingdom of Heaven is a kingdom of uses." He exercised a great influence over S. T. Coleridge, Robert and Elizabeth Browning, Coventry Patmore, Henry Ward Beecher and Thomas Carlyle. And thus Swedenborg is now drawn to his doctrine of the relation of the elements of the universe to the membranes of the body.

Swedenborgianism, as professed by Swedenborg's followers, is based on the belief of Swedenborg's claims to have witnessed the last judgment, or the second advent of the Lord, with the inauguration of the New Church, through the new system of doctrine promulgated by him and derived from the Scriptures, into the true sense of which he was the first to be introduced. The "doctrine of the New Church as given in the Liturgy (which also contains the "Credences" and "Articles of Faith") are as follows:

1. There is a Divine Trinity; and that He is the Lord Jesus Christ.
2. That a saving faith is to believe on Him.
3. That evil is to be shunned, because they are of the devil and from evil.
4. That good actions are to be done, because they are of God and from God.

If these are to be done by a man as from himself, but that it ought to be believed that they are done from the Lord with him and by him.

Swedenborgians now constitute a widely spread and considerable society, the organization of which is a reformation and a zealous missionary activity (see New Jerusalem Church). See R. L. Tafel, Documents concerning the Life and Character of Emanuel Swedenborg, collected, translated and annotated (3 vols., Swedenborg Society, 1878-1879); J. Hyde, A Bridge is to be Drawn to Emanuel Swedenborg (743 pp., Swedenborg Society, London, 1883). Some of his writings, e.g., The Divine Providence and the Divine Love and Wisdom. The projects of the Church, the Society, and Heaven and Hell have been published in popular editions. A useful handbook of Swedenborg's theology is the Compendium of the Theological Writings of Emanuel Swedenborg (4 vols., London, 1885). Summaries of his system and writings are given in all the above biographies, also in Edmund Swift, Manual of the Doctrines of the New Church (London, 1882); and T. Parsons, Outlines of Swedenborg's Religions and Philosophical Doctrine (London, 1885). Swedenborgians believe that from independent points of view are "The Mystic," in R. W. Emerson's Representative Men (1830); Kant's Traume eines Geistersehers (1876); the best edition by Rehrbush, Leipzig, 1880; and Herder's "Emanuel Swedenborg," in his Adrastes (Werke zur Phil. und Gesch., xii. 110-125); J. J. V. Goerres's Emanuel Swedenborg, seine Visionen und sein Verkldnztzt zur Kirche (1877); A. Dorner's "Das Emanuel Swedenborg," in the German ed. of this and two translations of the International Swedenborg Congress (London, 1910), summarized in The New Church Magazine (August, 1910). See also Transactions of the International Swedenborg Congress (London, 1910), summarized in The New Church Magazine (August, 1910).

SWEETBREAD. A popular term for certain glands of animals, particularly when used as articles of food; these are usually the pancreas, the "stomach-sweetbread" of butchers, and the thymus, or "breast sweetbread." The term is also sometimes used to include the salivary and lymphatic glands (see Duckless Glands, Pancreas and Lymphatic System).

SWEET POTATO. This plant, known botanically as Ipomoea batatas, is a favorite in the New World. It is valued as a potato, or root potato, in many countries, especially the tropics, where the climate is as mild as at higher latitudes. The plant is not known in a truly wild state, nor has its origin been ascertained. A. de Candolle concludes that it is in all probability of American origin, where it has been cultivated from prehistoric times by the aborigines. It is mentioned by Gerard as the "potato," or "potatos," or "potatoes," in contradistinction to the "potatoes" of Virginia (Solanum tuberosum). He grew it in his garden, but the climate was not warm enough to allow it to flower, and in winter it perished and rotted. But as the appellation "common" is applied to them the roots must have been introduced commonly. Gerard tells us that he bought them from the planters, who were sold at higher prices, or at a higher discount, because he had an interesting account of the uses to which they were put, and in manner in which they were prepared as "sweetmeats," and the invigorating properties assigned to them. The allusions in the Merry Wives of Windsor and other Shakespeare's plays in all probability refer to this plant, and not to what we now call the "potato." The plants require a warm, sunny climate, long season, and a liberal supply of water during the growing season. For an account of the cultivation in North America, where large quantities are grown in the Southern states, see H. B. Watson, "The Crop of American Hospitality" (1909). Sir George Watt, Dictionary of the Economic Products of India (1890), gives an account of its cultivation in India, where some confusion has arisen by the use of the name batatas for the yam (g.e.); the author suggests that the introduction of the sweet potato into India is comparatively recent.

SWEET-SOP, or Sugar Apple, botanical name Anona squamosa, a small tree or shrub with thin oblong-ovate leaves, solitary gynoecium flowers and a yellowish-green fruit, like a shortened pine cone in shape with a tubercle corresponding to each of the carpels from the aggregation of which it has been formed. The fruit is 3 to 4 in. in diameter and contains a sweet, creamy yellow custard-like pulp. It is native to the New Indies and tropical America; it is much prized as a fruit, and has been widely introduced into the eastern hemisphere.
Another species, *A. maricola*, is the sour-sop, a small evergreen tree bearing a larger dark-green fruit, 6 to 8 in. long and 1 to 5 lb in weight, oblong or bluntly conical in shape, with a rough spiny skin and containing a soft white juicy sub-acid pulp with a flavour of turpentine. It is a popular fruit in the West Indies, where it is native, and is grown with special cultivation in Porto Rico. A drink is made from the juice. *A. reticulata* is the custard apple (*q.v.*) and *A. polystachus* the alligator apple.

SWELLENDAM, a town of South Africa, Cape province, in the valley of the Breede River, 192 m. by rail E. by S. of Cape Town. Pop. (1904), 2406, of whom 1139 were white. Swellendam is one of the older Dutch settlements in the Cape, dating from 1745, and was named after Hendrik Swellengrebel (then governor of the Cape) and his wife, whose maiden name was Damme. Early in 1795 the burghers of the town and district rose in revolt against the Dutch East India Company and proclaimed a “free republic,” and elected a sostyled national assembly. At the same time the burghers of Graaff Reinet also rebelled against the Cape authorities, who were powerless to suppress the insurrectionary movement. One of the claims of the “free republic” was “the absolute and unconditional slavery of all Hottentots and Bushmen.” In September of that year Cape Town surrendered to the British and the “National” party at Swellendam quietly accepted British rule.

The town is a trading centre of some importance, and in the surrounding district is much cattle raising and outstrip farming. The neighbourhood is noted for its abundance of evergreen f folklore.

SWETCHINE, MADAME (1782-1857), Russian mystic, whose maiden name was Soymanof, was born in Moscow, and under the influence of Joseph de Maistre became a member of the Roman Catholic Church in 1815. In the following year she settled in Paris where, until her death, she maintained a famous salon remarkable no less for its high courtesy and intellectual brillance than for its religious atmosphere. Though not physically beautiful she had a personality of rare spiritual charm, nurtured in the private chapel of her house. Her husband, General Swetchine, was a convert to Catholicism. Her *Life and Works* (of which the best known are *Old Age* and “Resignation”) were published by M. de Falloux (2 vols., 1860) and her *Letters* by the same editor (2 vols., 1861).

SWENY, J., KING OF DENMARK (1210-1214), son of Harold Blutho, the christianizer of Denmark, by his peasant mistress Aesa, according to the Joms Vikingsaga, though much more probably his mother was Queen Gundl, Harold’s consort. The lad was a miscreant and became a noted villainy and misfortune in alliance with the Jomsborg Viking, Palmboke, against his own father, who perished during the struggle (c. 986). Six years later he conducted a large fleet of warships to England, which did infinite damage, but failed to capture London. During his absence, Denmark was temporarily occupied by the Swedish king, Eric Sersd, on whose death (c. 994) Sweny recovered his patrimony. About the same time he repudiated his first wife Gundl, daughter of duke Miesko of Poland, and married King Eric’s widow, Sigrid. This lady who had been a nun, was noted for a disquieting strength of character. Two viceroy, earlier viceroy, wasSweny’s second to death by orders for their impertinence, and she refused the hand of Olaf Tryggvesson, king of Norway, rather than submit to baptism, whereupon the indignant monarch struck her on the mouth with his gauntlet and told her she was a worse pagan than any dog. Shortly afterwards she married Sweny, and easily persuaded her warlike husband to unite with Olaf, king of Sweden, against Olaf Tryggvesson, who fell in the famous sea-fight off Svolde (1000) on the west coast of Rügen, after a heroic resistance immortalized by the sagas, whereupon the confederates divided his kingdom between them. After his first English expedition Sweny was content to blackmail England instead of ravaging it, till the ruthless massacre of the Danes on St Brice’s day, the 3rd of November 1002, by Ethelred the Unready (Sweny’s sister was among the victims) brought the Danish king to Exeter (1003). During each of the following eleven years, the Danes, materially assisted by the universal and shameless disloyalty of the Saxons ealdormen, systematically ravaged England, and from 991 to 1014 the wretched land is said to have paid its invaders in ransom alone £158,000. Sweny died suddenly at Gainsborough on the 17th of February 1014. The data relating to his whole history are scanty and obscure, and his memory has suffered materially from the fact that the chief chroniclers of his deeds and misdeeds were ecclesiastics. It was certainly unfortunate that he began life by attacking his own father. It is undeniable that his favourite wife was the most stift-necked pagan of her day. His most remarkable exploit, Svolde, was certainly won at the expense of Christianity, resulting, as it did, in the death of the saintly Olaf. Small wonder, then, if Adam of Bremen, and the monkish annalists who follow him, describe Sweny as a grim and bloody semi-pagan, perpetually warring against Christian states. But there is another side to the picture. Viking though he was, Sweny was certainly a Christian viking. We know that he built churches; that he invited English bishops to settle in Denmark (notably Godibald, who did good work in Scania); that on his death-bed he earnestly commended the Christian cause to his son Canute. He was cruel to his enemies no doubt, but he never forgot a benefit. Thus he rewarded the patriotic of the Danish ladies who sacrificed all their jewels to pay the heavy ransom exacted from him by his cupbearers, the Jomsborg pirates, by enacting a law that their women should be of the same blood as their male relatives. Of his valour as a captain and his capacity as an administrator there can be no question. His comrades adored him for his liberality, and the frequent visits of Icelandic skalds to his court testify to a love of poetry on his part, indeed one of his own strophes has come down to us. As to his personal appearance we only know that he had a long cleft beard, whence his nickname of *Tingeskaeg or Fork-Beard.*

SWIFT, JONATHAN (1667–1745), dean of St Patrick’s, Dublin, British satirist, was born at No. 7 Hoe’s Court, Dublin, on the 30th of November 1667, a few months after the death of his father, Jonathan Swift (1640–1667), who married after 1664 Abigaille Erick, of an old Leicestershire family. He was taken over to England as an infant and nursed at Whitehaven, whence he returned to Ireland in his fourth year. His grandfather, Thomas Swift, vicar of Goodrich near Ross, appears to have been a thoroughly foul-mouthed member of the church militant, who lost his possessions by taking the losing side in the Civil War and in 1659 afterwards became a pensioner of the Restoration court and went by the new title. He married Elizabeth, niece of Sir Erasmus Dryden, the poet’s grandfather. Hence the familiarity of the poet’s well-known “cooling-card” to the budding genius of his kinsman Jonathan: “Cousin Swift, you will never be a poet.” The young Jonathan was educated mainly at the charges of his uncle Godwin, a Tipperary official, who was thought to dole out his help in a somewhat grudging manner. In fact the apparently prosperous relative was the victim of unfortunate speculations, and chose rather to be reproached with avarice than with impudence. The youth was restless of spirit, who regarded as a mere misguided treatment, a bitterness became ingrained and began to corrode his whole nature; and although he came in time to grasp the real state of the case he never mentioned his uncle with kindness or regard. At six he went to Kilkenny School, where Congreve was a schoolfellow; at fourteen he entered pensioner at Trinity College, Dublin, where he seems to have neglected his opportunities. He was referred in natural philosophy, including mathematics, and obtained his degree only by a special but by no means infrequent act of indulgence. The patronage of his uncle galled him: he was dull and unhappy. We find in Swift few signs of precocious genius. As S. Gough mitiD. Young was one of the men who have become artists of the pen, college proved a stepmother to him. In 1688 the rich uncle, whose supposed riches had dwindled
so much that at his death he was almost insomnolent, died, having decayed, it would seem, not less in mind than in body and estate, and Swift sought counsel of his mother at Leicester. After a brief residence with his mother, who was needlessly alarmed at the idea of her son falling to some casual coquett, Swift towards the close of 1689 entered upon an engagement as secretary to Sir William Temple, whose wife (Dorothy Osborne) was distantly related to Mrs Swift. It was at Moor Park, near Farnham, the residence to which Temple had retired to cultivate apricots after the rapid decline of his influence during the critical period of Charles II's reign (1679-1681), that Swift's acquaintance with Esther Johnson, the "Stella" of the famous Journal, was begun. Stella's mother was living at Moor Park, as servant of dame de compagnie of Temple's strong-minded sister, Lady Gifford. In turn was twenty-six and a half years old, and the time, and a curious friendship sprang up between them. He taught the little girl how to write and gave her advice in reading. On his arrival at Moor Park, Swift was, in his own words, a raw, inexperienced youth, and his duties were merely those of accountant and amanuensis: his ability gradually won him the confidence of his employer, and he was entrusted with some important missions. He was introduced to William III. during that monarch's visit to Sir William's, and on one occasion accompanied the king in his walks round the grounds. In 1693 Temple sent him to try and convince the king of the inevitable necessity of treating those of his subjects who were so unfortunate as to be lunatics. The king was sceptical. Swift's vanity received a useful lesson. The king had previously taught him "how to cut asparagus after the Dutch fashion." Next year, however, Swift (who had in the meantime obtained the degree of M.A. ad eundem at Oxford)quit Temple, who had, he considered, delayed too long in obtaining him preferment. A certificate of conduct while under Temple's roof was required by all the Irish bishops he consulted before they would proceed in the matter of his ordination, and after five months' delay, caused by wounded pride, Swift had to kiss the rod and solicit in obtuse terms the privilege of being admitted to the degree of M.A. at the age of thirty a year. Forgiveness was easy to a man of Temple's elevation and temperament, and he not only despactched the necessary recommendation but added a personal request which obtained for Swift the small prebend of Kilroot near Belfast (January 1695), where the new incumbent carried on a premature flirtation with a Miss Jane Waring, whom he called "Varina." In the spring of 1696 he asked the reluctant Varina to wait until he was in a position to marry. Just four years later he wrote to her in terms of such calculated harshness and imposed such conditions as to make further intercourse virtually impossible. But in the meantime he had gained the esteem of Irish life and was glad to accept Temple's proposal for his return to Moor Park, where he continued until Temple's death in January 1699. During this period he wrote much and burned most of what he had written. He read and learned even more than he wrote. Moor Park took him away from brooding and glooming in Ireland and brought him into the corridor of contemporary history, an intimate acquaintance with which became the chief passion of Swift's life. His Pindaric Odes, written at this period or earlier, in the manner of Cowley, indicate the rudiments of a real satirist, but a satirist struggling with a sort of unengaging form and expression. Of more importance was his first essay in satiric prose which arose directly from the position which he occupied as domestic author in the Temple household. Sir William had in 1692 published his Essay upon Ancient and Modern Learning, transplanting to England a controversy begun in France by Fontenelle. Incidentally Temple had cited the letters of Phalaris as evidence of the superiority of the Ancients over the Moderns. Temple's praise of Phalaris led to an Oxford edition of the Epistles nominally edited by Charles Boyle. While this was preparing, William Wotton, in 1694, wrote his Reflections upon Ancient and Modern Learning, traversing Temple's general conclusions. Swift's Battle of the Books was written in 1697 expressly to refute this. Boyle's Vindication and Bentley's refutation of the authenticity of Phalaris came later. Swift's aim was limited to cooperation in what was then deemed the well-deserved putting down of Bentley by Boyle, with a view to which he represented Bentley and Wotton as the representatives of modern pedantry, transfixed by Boyle in a suit of armour given him by the gods as the representative of the "two noblest of things, sweetness and light." The satire remained unpublished until 1704, which was issued along with The Tale of a Tub. Next year Wotton declared that Swift had borrowed his Combat des livres from the Histoire poétique de la guerre nouvellement déclarée entre les anciens et les modernes (Paris, 1688). He might have derived the idea of a battle from the French title, but the resemblances and parallels between the two books are slight. Swift was manifestly extremely imperfectly acquainted with the facts of the case at issue. Such data as he displays may well have been derived from no authority more recondite than Temple's own correspondence.

In addition to £1000, Temple left to Swift the trust and profit of publishing his posthumous writings. Five volumes appeared in 1700, 1703 and 1709. The resulting profit was small, and Swift's editorial duties brought him into acrimonious relation with Lady Gifford. The dedication to King William was to have procured Swift an English prebend, but this miscarried owing to the negligence or indifference of Henry Sidney, earl of Romney. Swift then accepted an offer from Lord Berkeley, who in the summer of 1699 was appointed one of the lords justices of Ireland. Swift was to be his chaplain and secretary, but upon reaching Dublin Berkeley gave him one thousand guineas and persuaded him that it was an unfit post for a clergyman. The rich deanship of Derry then became vacant and Swift applied for it. The secretary had already accepted a bribe, but Swift was informed that he might still have the place for £1000. With bitter indignation Swift denounced the simony and threw up his chaplaincy, but he was ultimately reconciled to Berkeley by the presentation to the rectory of Agher in Meath with the united vicarages of Laracor and Rathbeggan, to which was added the prebend of Dunlavin in St Patrick's—the total value being about £200 a year. He was now often in Dublin at twenty miles distant, and through Lady Berkeley and her daughters he became the familiar and chartered satirist of the fashionable society there. At Laracor, near Trim, Swift rebuilt the parsonage, made a fish-pond, and planted a garden with poplars and willows, bordering a canal. His congregation consisted of about fifteen persons, "most of them gentle and all of them simple." He read prayers on Wednesdays and Fridays to himself and his clerk, beginning the exhortation "Dearly beloved Roger, the Scripture moveth you and me in sundry places. But he soon began to grow tired of Ireland again and moved about in Leinster in company with a gentleman in a small house to rebuild The Tale of a Tub, which he had had by him since 1696 or 1698. He must have felt conscious of powers capable of far more effective exercise than reading-desk or pulpit at Laracor could supply; and his resolution to exchange divinity for politics must appear fully justified by the result. The Discourse on the Dissensions in Athens and Rome (September 1701), written to repel the tactics of the Tory commons in their attack on the Partition Treaties "without humour and without satire," and intended as a dissuasive from the pending impeachment of Somers, Oxford, Halifax and Walpole, received the highest, extraordinary honours; for the sudden publication of a young politician, of being generally attributed to Somers himself or to Burnet, the latter of whom found a public disavowal necessary. In April or May 1704 appeared a more remarkable work. Clearness, cogency, masculine simplicity of diction, are conspicuous in the pamphlet, but true creative power told the Tale of a Tub. "Good God! what a genius I had when I wrote that book!" was his own exclamation in his latter years. It is, indeed, if not the most amusing of Swift's satirical works, the most strikingly original, and the one in which the compass of his powers is most fully displayed. In his kindred productions he relies mainly upon a single element of the humorous—logical sequence and unrruffled gravity bridging in an otherwise frantic absurdity, and investing it with an air of sense. In the Tale of a Tub he lashes out in all directions. The humour, if less cogent and cumulative, is richer and more varied; the invention, too,
is more daringly original and more completely out of the reach of ordinary faculties. The supernatural coat and the Quintes-

sential loaf may be paralleled but cannot be surpassed; and the

book is throughout a mine of suggestiveness, as, for example, in the anticipation of Carlyle's clothes philosophy within the

compass of a few lines. At the same time it wants unity and coherence, it attains no conclusion, and the author abuses his
digressive method of composition and his convenient fiction of

hiatuses in the original manuscript. The charges it occasioned of

profanity and irreverence were natural, but groundless. There is

nothing in the book inconsistent with Swift's professed and

real character as a sturdy Church of England parson, who accepted

the doctrines of his Church as an essential constituent of his

character, and bound himself, from the beginning, to the

attachment of a soldier defending his colours, and held it no part of his duty

to understand, interpret, or assimilate them.

In February 1701 Swift took his D.D. degree at Dublin, and

before the close of the year he had taken a step destined to

exercise a most important influence on his life, by inviting two

ladies to Laracor. Esther, daughter of a merchant named Edward

Johnson, a dependant, and legatee to a small amount, of Sir

William Temple's (born in March 1660), whose acquaintance he

had made at Moor Park in 1689, and whom he has immortalized

as "Stella," came over with her companion Rebecca Dinsley, as a

poor relative of the Temple family, and was soon permanently

domiciled in his neighbourhood. The melancholy tale of Swift's

attachment will be more conveniently narrated in another place,

and is only alluded to here for the sake of chronology. Mean-

while the sphere of his intimacies was rapidly widening. He had

been in England for three years together, 1701 to 1704, and

counted Pope, Steele and Addison among his friends. The

success of his pamphlet gained him ready access to all Whig

circles; but already his confidence in that party was shaken, and he

was beginning to meditate that change of sides which has

drawn him all through his life, but which has not been unjustifiable.

The true state of the case may easily be collected from his next

publications—The Sentiments of a Church of England Man, and

On the Reasonableness of a Test (1708). The vital differences

among the friends of the Hanover succession were not political,

but ecclesiastical. From this point of view Swift's sympathies

were entirely with the Tories. As a minister of the Church he felt

his duty and his interest equally concerned in the support of her

cause; nor could he fail to discover the inevitable tendency of Whig

methods to change the character of the clergy by transferring them

to the bestow on individual clergymen, to abuse the Establishment as a

corporation. He sincerely believed that the ultimate purpose of

freethinkers was to escape from moral restraints, and that he

had an unreasoning antipathy to Scotch Presbyterians and English

Dissenters. If Whiggism could be proved to entail Dissent, he

was prepared to abandon it. One of his pamphlets, written

about this time, contains his recipe for the promotion of religion,

and is of itself a sufficient testimony to the extreme materialism

of his views. Censorships and penalties are among the means

he recommends. His pen was exerted to better purpose in the

most consummate example of his irony, the Argument to prove

that the abolishing of Christianity in England may, as things now

stand, be attended with some inconveniences (1708). About

this time, too (November 1707), he produced his best narrative poem,

Bacis and Philomen, while the next few months witnessed one

of the most amusing hoaxes ever perpetrated against the gullibility

of astrologers. In his Almanac for 1707 a Protestant aristocrat

and plot vaticinator styled John Partridge warned customers

against rivals and impostors. This notice attracted Swift's and

Steele's attention. In January 1707 they both published, under the

ensuing year by Isaac Bickerstaff, written to prevent the people

of England being imposed upon by vulgar almanac makers.

In this brochure he predicts solemnly that on the 29th of March

1 The name "Stella" is simply a translation of Esther. Swift

may have learned that Esther means "star" from the Elementa

linguae per sacrae of John Gravae or from some Persian scholar;

but he is more likely to have seen the etymology in the form given

by Jewish sources in Buxtorf's Lexicon, where the interpretation

takes more suggestive form "Stella Veneris."
Swift, Jonathan

which it began, after Malplaquet, to think might be purchased at too heavy a cost, the nation wanted a convenient excuse for relinquishing a burdensome war, which the great military genius of the age was suspected of prolonging to fill his pockets. The Whigs had been long in office. That High Church party had derived great strength from the Sacheverell trial. Swift did not bring about the revolution with which, notwithstanding, he associated his name. There seems no reason to suppose that he was consulted respecting the great Tory strokes of the creation of the twelve new peers and the dismissal of Marlborough (December 1711), but they would hardly have been ventured upon if The Conduct of the Allies and the Examiners had not prepared the way. A scarcely less important service was rendered to the ministry by his Letter to the October Club, artfully composed to soothe the impatience of Harley's extreme followers. He had every of him to the highest preferment that ministers could give him, but his own pride and prejudice in high places stood in his way.

Generous men like Oxford and Bolingbroke cannot have been unwilling to reward so serviceable a friend, especially when their own interest lay in keeping him in England. Harley by this time was losing influence and was becoming chronically incapable of any sustained effort. Swift was naturally a little sore at seeing the see of Hereford slipping through his fingers. He had already lost Waterford owing to the prejudice against making the author of the Tale of a Tub a bishop, and still had formed designs on the archbishop of York, whom he had scandalized, and the duchess of Somerset, whom he had satirized. Anne was particularly amenable to the influence of priestly and female favourites, and it must be considered a proof of the strong interest made for Swift that she was eventually persuaded to appoint him to the deanship of St Patrick's, Dublin, vacant by the removal of Bishop Sterne to Dromore. It is to his honour that he never speaks of the queen with resentment or bitterness. In June 1713 he set out to take possession of his dignity, and encountered a very cold reception from the bishops of the provincials. His decision however, caused his party speedily recalled him to England. He found affairs in a desperate condition. The queen's demise was evidently at hand, and the same instinctive sense which had ranged the nation on the side of the Tories, when Tories alone could terminate a fatiguing war, rendered it Whig when Tories manifestly could not be trusted to maintain the Protestant succession. In any event the occupants of office could merely have had the choice of risking their heads in an attempt to exclude the elector of Hanover, or of waiting patiently till he should come and eject them from their posts; yet they might have remained formidable could they have remained united. Swift had formed designs on which he regarded Oxford's refusal to advance him in the peerage the active St John added an old disgust at the treasurer's pedantic and dilatory formalism, as well as his evident propensities, while leaving his colleague the fatigues, to engross for himself the chief credit of the administration. Their schemes of policy diverged as widely as their characters: Bolingbroke's brain teemed with the wildest plans, which Oxford might have more effectually discountenanced had he been prepared with anything in their place. Swift's endeavours after an accommodation were as fruitless as unremitting. His meditation was little compared the habitual virulence of his pen, which rarely produced anything more acrimonious than the attacks he at this period directed against Burnet and his former friend Steele. One of his pamphlets against the latter (The Public Spirit of the Whigs set forth in their Generous Encouragement of the Author of the Crisis, 1714) was near involving him in a prosecution, some invectives against the Scottish peers having proved so exasperating to Argyll and others that they repaired to the queen to demand the punishment of the author, of whose identity there could be no doubt, although, like all Swift's writings, except the Proposal for the Extension of Religion, the pamphlet had been published anonymously. The immediate withdrawal of the offensive passage, and a sham prosecution instituted against the printer, extricated Swift from his danger.

Meanwhile the crisis had arrived, and the discord of Oxford and Bolingbroke had become patent to all the nation. Foreseeing, as is probable, the impending fall of the former, Swift retired to Upper Letcombe, in Berkshire, and there spent some weeks in the strictest seclusion. This leisure was occupied in the composition of his remarkable pamphlet, Some Free Thoughts on the Present State of Affairs, which indicates his complete conversion to the bold policy of Bolingbroke. The utter exclusion of Whigs as well as Dissenters from office, the remodelling of the army, the imposition of the most rigid restraints on the heir to the throne—such were the measures which, by recommending, Swift tacitly admitted to be necessary to the triumph of his party. If he was serious, it can only be said that the desperation of his circumstances had momentarily troubled the lucidity of his understanding; if the pamphlet were merely intended as a feint after public opinion, it is surprising that he did not perceive how irretrievably he was ruining his friends in the eyes of all moderate men. Bolingbroke's daring spirit, however, recoiled from no extreme, and, fortunately for Swift, he added so much of his own to the latter's MS. that the production was first delayed and then, upon the news of Anne's death, immediately suppressed. This incident but just anticipated the revolution which, after Bolingbroke had enjoyed a three days' triumph over Oxford, drove him into exile and prostrated his party, but enabled Swift to perform the noblest action of his life. Almost the first acts of Bolingbroke's ephemeral premiership were to order with Pope and Arbuthnot to establish the exchequer and despam the most flattering invitations. The same post brought a letter from Oxford, soliciting Swift's company in his retirement; and, to the latter's immortal honour, he hesitated not an instant in preferring the solace of his friend to the offers of St John. When, a few days afterwards, Oxford was in prison and in danger of his life, Swift begged to share his captivity; and it was only on the offer being declined that he finally directed his steps towards Ireland, where he was very ill received. The draft on the exchequer was intercepted by the queen's death.

These four busy years of Swift's London life had not been entirely engrossed by politics. First as the associate of Steele, with whom he quarrelled, and of Addison, whose esteem for him survived all differences, afterwards as the intimate comrade of Pope and Arbuthnot, the friend of Congreve and Atterbury, Parnell and Gay, he entered deeply into the literary life of the period. He was treasurer and a leading member of the Brothers, a society of wits and statesmen which recalls the days of Horace and Maecenas. He promoted the subscription for Pope's Homer, contributed some numbers to the Tatler, Spectator, and Intelligencer, joined with Pope and Arbuthnot in establishing the Scriblerus Club, writing Martinus Scriblerus, his share in which can have been but small, as well as John Bull, where the chapter recommending the education of all blue-eyed children in depravity for the public good must surely be his. His miscellanies, in some of which his satire made the nearest approach perhaps ever made to the methods of physical force, such as A Meditation upon a Broomstick, and the poems Sid Hamet's Rod, The City Shower, The Windsor Prophecy, The Prediction of Merlin, and The History of Vanbrugh's House, belong to this period. A more laboured work, his Proposal for Correcting, Improving and Ascertaining the English Tongue (1712), in a letter to Harley, suggesting the regulation of the English language by an academy, is chiefly remarkable as a proof of the deference paid to French taste by the most original English writer of his day. His History of the Four Last Years of the Reign of Queen Anne is not on a level with his other political writings. To sum up the incidents of this eventful period of his life, it was during it that he lost his mother, always loved and dutifully honoured, by death; his sister had been estranged from him some years before by an improper marriage, which, though making her a liberal allowance, had never forgiven. The change from London to Dublin can seldom be an agreeable one. To Swift it meant for the time the fall from unique authority to absolute insignificance. All share in the administration of even Irish affairs was denied him; every politician
shunned him; and his society hardly included a single author or wit. He "continued in the greatest privacy" and "began to think of death." At a later period he talked of "dying of rage, like a poisoned rat in a hole"; for some time, however, he was buoyed up by feeble hopes of a restoration to England. So late as 1726 he was in England making overtures to Walpole, but he had no claim on ministerial goodwill, and as an opponent he had by that time done his worst. By an especial cruelty of fate, what should have been the comfort became the bane of his existence. We have already mentioned his invitation of Esther Johnson and Mrs Dingley to Ireland. Both before and after his elevation to the dignity of St Patrick's, the possibility that the latter might, by residing near him, and supervened his household during his absence in London. He had offered no obstacle in 1704 to a match proposed for Stella to Dr William Tisdall of Dublin, and, with his evident delight in the society of the dark-haired, bright-eyed, witty beauty—a model, if we may take his word, of all that woman should be—it seemed unaccountable that he did not secure it to himself by the expedient of matrimony. A constitutional infirmity has been suggested as the reason, and the conjecture derives support from several peculiarities in his writings. But, whatever the cause of his censure of matrimony, we may believe that his course was foredoomed. But his life and Stella's and yet another's. He had always been unlucky in his relations with the fair sex. In 1695 he had idealized "Varina." Varina was avenged by Vanessa, who pursued Swift to far other purpose. Esther Vanhomrigh (b. February 14, 1690), the daughter of a Dublin merchant of Dutch origin, who died in 1703 leaving £16,000, had become known to Swift at the height of his political influence. He lodged close to her mother, was introduced to the family by Sir A. Fountaine in 1708 and became an intimate of the house. Vanessa insensibly became his pupil, and he insensibly became the object of her insatiable admiration. Her letters reveal a spirit full of ardour and enthusiasm, and was harped by that perverse bent which leads so many women to prefer a tyrant to a companion. Swift, on the other hand, was devoid of passion. Of friendship, even of tender regard, he was fully capable, but it was not of love. The spiritual realm, whether in divine or earthy things, was a region closed to him, where he had never set foot. As a friend he must have greatly preferred Stella to Vanessa. Marriage was out of the question with him, and, judged in the light of Stella's dignity and womanliness, this ardent and unrelenting display of passion was preposterous. But whenever Vanessa assaulted him on a very weak side. The strongest of all his instincts was the thirst for imperious domination. Vanessa hugged the leters to which Stella merely submitted. Flattered to excess by her surrender, yet conscious of his binding obligations and his real preference, he could neither discard the one beauty nor desert the other. It is humiliating to human strength and consoling to human weakness to find the Titan behaving like the least resolute of mortals, seeking refuge in temporizing, in evasion, in fortuitous circumstance. He no doubt trusted that his removal to Dublin would bring relief, but here again his evil star interposed. Vanessa's mother died (1714), and she followed him to Ireland, taking up her abode at Celbridge within ten miles of Dublin. Unable to marry Stella without destroying Vanessa, or to openly welcome Vanessa without destroying Stella, he was thus involved in the most miserable embarrassment; he continued to temporize. Had the solution of marriage been open Stella would undoubtedly have been Swift's choice. Some mysterious obstacle intervened. It was rumoured at the time that Stella was the natural daughter of Temple, and Swift himself at times seems to have been doubtful as to his own paternity. There is naturally no evidence for such reports, which may have been fabrications of the anti-deanery faction in Dublin. From the same source sprang the report of Swift's marriage to Stella by Bishop Ashe in the deanery garden at Clogher in the summer of 1716. The ceremony, it is suggested, may have been extorted by the jealousy of Stella and have been accompanied by the express condition on Swift's side that the marriage was never to be avowed. The evidence is by no means complete and has never been exhaustively reviewed. John Lyon, Swift's constant attendant from 1735 onwards, disbelieved the story. It was accepted by the early biographers, Deane Swift, Orrery, Delany and Sheridan; also by Johnson, Scott, Dr Garnett, Craik, Dr Bernard and others. The arguments against the marriage were first marshalled by Monck Mason in his History of St Patrick's, and the conjecture, though plausible, has failed to convince Forster, Stephen, Aitken, Hill, Lane Poole and Churton Collins. Never more than a nominal wife at most, the unfortunate Stella commonly passed for his mistress till the day of her death (in her will she writes herself spinster), bearing her doom with uncomplaining resignation, and consoled in some degree by unquestioning preference, without ever succeeding in his immediate aim or in thereby opening her eyes to the hopelessness of her passion. In 1720, on what occasion is uncertain, he began to pay her regular visits. Sir Walter Scott found the Abbey garden at Celbridge still full of laurels, several of which she was accustomed to send in a packet with her letter to Stella; the packet at which they had been used to sit was still shown. But the catastrophe of her tragedy was at hand. Worn out with his evasions, she at last (1732) took the desperate step of writing to Stella or, according to another account, to Swift himself, demanding to know the nature of the connexion with him, and this terminated the melancholy history as with a clap of thunder. Stella sent her rival's letter to Swift, and retired to a friend's house. Swift rode down to Marley Abbey with a terrible countenance, petrified Vanessa by his frown, and departed without a word, flinging down a packet which only contained her own letter to Stella. Vanessa died within a few weeks. She left the modern her correspondence for publication. The former appeared immediately, the latter was suppressed until it was published by Sir Walter Scott.

Five years afterwards Stella followed Vanessa to the grave. The grief which the gradual decay of her health evidently occasioned Swift is sufficient proof of the sincerity of his attachment, as he understood it. It is a just remark of Thackeray's that he everywhere half-consciously recognizes her as his better angel, and dwells on her wit and her tenderness with a fondness he never exhibits for any other topic. On the 28th of January 1718, he died upon themselves and for many generations his name was the most universally popular in the country. With his fierce hatred of what he recognized as injustice, it was impossible that he should not feel exasperated at the gross misgovernment of Ireland for the supposed benefit of England, the systematic exclusion of Irishmen from places of honour and profit, the spoliation of the country by absentee landlords, the deliberate discouragement of Irish trade and manufactures. An Irish patriot in the strict sense of the term he was not; he was proud
of being an Englishman, who had been accidentally "dropped in Ireland"; he looked upon the indigenous population as conquered savages; but his pride and sense of equity alike revolted against the stay-at-home Englishmen's contemptuous treatment of their own garrison, and he delighted in finding a point in which the triumphant faction was still vulnerable. His Proposal for the Universal Use of Irish Manufactures, published anonymously in 1720, urging the Irish to disuse English goods, became the subject of a prosecution, which at length had to be dropped; Swift was raised to a height of popularity which, with the chief wants of Ireland in that day, and for many a day afterwards, was that of small currency adapted to the daily transactions of life. Questions of coinage occupy a large part of the correspondence of the prime, Archbishop Boulter, whose anxiety to deal rightly with the matter is evidently very real and conscientious. There is no reason to think that the English ministry wished otherwise; but secret influences were at work, and a patent for supplying Ireland with a coinage of copper halfpence was accorded to William Wood on such terms that the profit accruing from the difference between the intrinsic and the nominal value of the coin, about 20%, was divided between him and George I.'s favourite duke of Kendal by whose influence Wood had obtained the privilege. Swift now had his opportunity, and the famous six letters signed M. B. Drapier (April to Dec. 1724) soon set Ireland in a flame. Every effort was used to discover, or rather to obtain legal evidence against, the author, whom, Walpole was assured, it would then have taken ten thousand men to apprehend. None could be procured; the public passion swept everything before it; the patent was cancelled; Wood was compensated by a pension; Swift was raised to a height of popularity which he retained for the rest of his life; and the only real sufferers were the Irish people, who lost a convenience so badly needed that they might well have afforded to connive at Wood's illicit profits. Perhaps, however, it was worth while to teach the English ministry that not everything could be done in Ireland. Swift's pamphlets, written in a style more level with the popular intelligence than even his own ordinary manner, are models alike to the controversialist who aids a good cause and to him who is burdened with a bad one. The former may profit by the study of his marvellous lucidity and vehemence, the latter by his sublime and witty exegesis of the human mind, with which he involves the innocent halfpence in the obloquy of the nefarious patentee.

The noise of the Drapier Letters had hardly died away when Swift acquired a more durable glory by the publication of Travels Into Several Remote Nations of the World, in four parts. By Lemuel Gulliver, first a surgeon and then a captain of several ships (Benjamin Motto, October 1726). The first hint came to him at the meetings of the Scriblerus Club in 1714, and the work was well advanced, it would seem, by 1720. Allusions show that it was circulated privately for a considerable period before its actual (anonymous) publication, on the 28th of October 1726. Pope arranged that Erasmus Lewis should act as literary agent in negotiating the manuscript. Swift was afraid of the reception the book would meet with, especially in political circles. The keenness of the satire on courts, parties and statesmen certainly suggests that it was planned while Swift's disappointments as a public man were still ranking and recent. It is Swift's peculiar good fortune that his book can dispense with the interpretation of which it is nevertheless susceptible, and may be equally enjoyed whether its inner meaning is apprehended or not. It is so true, so entirely based upon the facts of human nature, that the question what particular class of persons supplied the author with his examples of folly or misdoings, however interesting to the commentator, may be neglected by the reader. It is also fortunate for him that in three parts out of the four he should have entirely missed "the chief end I propose to myself, to vex the world rather than divert it." The world, which perhaps ought to have been vexed, chose rather to be diverted; and the great satirist literally strains his power at puéris placet. Few books have added so much to the innocent mirth of mankind of the first two parts of Gulliver; the misanthropy is quite overpowered by the fun. The third part, equally masterly in composition, is less felicitous in invention; and in the fourth Swift has indeed carried out his design of vexing the world at his own cost. Human nature indignantly rejects her portrait in the Yahoo as a gross libel, and the protest is fully warranted. An intelligence from a superior sphere, bound on a voyage to the earth, might actually have obtained a fair idea of average humanity by a preliminary call at Lilliput or Brobdingnag, but not from a visit to the Yahoos. While Gulliver is infinitely the most famous and popular of Swift's works, it exhibits no greater powers of mind than many others. The secret of success, here as elsewhere, is the writer's marvelous imperturbability in paradox, his teeming imagination and his rigid logic. Grant his premises, and all the rest follows; his world may be turned topsy-turvy, but the relative situation of its contents is unchanged. The laborious attempts that have been made, particularly in Germany, to affilate the Travels only serve to bring Swift's essential originality into stronger relief. He had naturally read Lucian and Rabelais—possibly Crusoe and the Arabian Nights. He had read as a young man in the lunary adventure of Bishop Wilkins, Bishop Godwin and Cyrano de Bergerac. He had read contemporary accounts of Peter the Wild Boy, the History of Secarambes by D'Alais (1677) and Foligny's Journey of Jacques Sades to Australia (1603). He may have read Joshua Barnes's description of a race of "Pygmies" in his Gerania of 1675. He copied the account of the storm in the second voyage almost literally from Sturmy's Compleat Mariner. Travellers' tales were deliberately embalmed by Swift in the amber of his irony. Something similar was attempted by Raspe in his Munchausen sixty years later.

Swift's grave humour and power of enforcing momentous truth by ludicrous exaggeration were next displayed in his Modest Proposal for Preventing the Children of Poor People from being a Burden to their Parents or the Country, by fattening and eating them (1729), a parallel to the Argument against Abolishing Christianity, and as great a masterpiece of tragic as the latter is of comic irony. The Directions to Servants (first published in 1745) in like manner derive their overpowering comic force from the imperturbable solemnity with which all the actions and thoughts of his hero are described, and which are made the more effective by the irony with which they are put upon them as duties. The power of minute observation displayed is most remarkable, as also in Politic Conversation (written in 1731, published in 1738), a surprising assemblage of the vulgarities and trivialities current in ordinary talk. As in the Directions, the satire, though cutting, is good-natured, and the piece shows more animal spirits than usual in Swift's latter years. It was a last flash of gaiety. The attacks of giddiness and deafness to which he had always been liable increased upon him. Already in 1721 he complains that the buzzing in his ears disinconcerts and confounds him. After the Directions he writes little beyond occasional verses, not seldom indecent and comcomon trivial. He sought refuge from inferior society often in nonsense, occasionally in obscurity. An exception must be made in the case of the delightful Hamilton's Bayn, and still more of the verses on his own death (1731), one of the most powerful and also one of the saddest of his poems. In The Legion Club of 1736 he composed the finest of all his verse satires. He hated the Irish parliament for its lyncharty and the Irish bishops for their interference. He fiercely opposed Archbishop Boulter's plans for the reform of the Irish currency, but admitted that his real objection was sentimental: the coin should be struck as well as circulated in Ireland. His exertions in repressing robbery and mendicancy were strenuous and successful. His popularity remained as great as ever (he received the freedom of Dublin in 1720), and, when he was menaced by the busy Bettesworth, Dublin rose as one man to defend him. He governed his cathedral with great strictness and conscientiousness, and for years after Stella's death continued to hold a miniature court at the deanery. But his failings of mind were exacerbated by his bodily infirmities; he
grew more and more whimsical and capricious, morbidly suspicious and morbidly parsimonious; old friends were estranged or removed by death, and new friends did not come forward in their place. For many years, nevertheless, he maintained a constant and sincere friendship and correspondence with Addison, not and Gay until their deaths, with such warmth as to prove that an ill opinion of mankind had not made him a misanthrope, and that human affection and sympathy were still very necessary to him. The letters become scarcer and scarcer with the decay of his faculties; at last, in 1740, comes one to his kind niece, Mrs Whiteway, of heartrending pathos:—

"I have been very miserable all night, and to-day extremely deaf and full of pain. I am so stupid and confounded that I cannot express the mortification I am under both of body and mind. All I can say is that I am not in torture; but I daily and hourly expect it. Pray let me know how your health is and your family: I hardly understand one word I write. I am sure my days will be very few; few and miserable they must be. I am, for those few days, yours entirely—Jonathan Swift.

"If I do not blunder, it is Saturday, July 26, 1740.

"If I live till Monday I shall hope to see you, perhaps for the last time."

Account book entries continue until 1742.

In March 1742 it was necessary to appoint guardians of Swift's person and estate. In September of the same year his physical malady reached a crisis, from which he emerged a helpless wreck, with faculties paralysed rather than destroyed. He never talked with a sound voice, and by the end of the year had ceased to talk at all. The partial paralyses of his case have been investigated by Dr Bucknill and Sir William Wilde, who have proved that he suffered from something that could be called mental derangement until the "labyrinthine vertigo" from which he had suffered all his life, and which he erroneously attributed to a surfeit of fruit, produced paralysis, "a symptom of which was the not uncommon one of aphasia, or the automatic utterance of words unguarded by intention. As a consequence of that paralysis, but not before, the brain, already weakened by senile decay, at length gave way, and Swift sank into the dementia which preceded his death." In other words he retained his reason until in his 74th year he was struck down by a new disease in the form of a localized left-sided apoplexy or cerebral softening. Aphasia due to the local trouble and general decay then progressed rapidly together, and even then at 76, two more years were still to elapse before he "exchanged the sleep of idiocy for the sleep of death." The scene closed on the 19th of October 1745. With what he himself described as a satiric touch, his fortune was bequeathed to find a hospital for idiots and lunatics, now an important institution, as it was in many respects a pioneer work. He was interred in his cathedral and the first Sunday in October, in the cathedral of St. Stella, with the epitaph, written by himself, "Hic depositus est corpus Jonathan Swift, S.T.P., hujus ecclesiae cathedralis decani; ubi seaeva indignatio cor ulterius lacerare nequit. Abi, viator, et imitate, si poteris, strenuum pro virili libertatis vindicem."

The stress which Swift thus laid upon his character as an asserter of liberty has hardly been ratified by posterity, which has apparently neglected the patriot for the genius and the wit. Not unreasonably; for if half his patriotism sprang from an instinct of loathing and revulsion of all that was aristocratic and egotism. He utterly lacked the ideal aspiration which the patriot should possess: his hatred of villany was far more intense than his love of virtue. The same cramping realism clings to him everywhere beyond the domain of politics—in his religion, in his fancies, in his affections. At the same time, it is the secret of his wonderful concentration of power: he realizes everything with such intensity that he cannot fail to be impressive. Except in his unsuccessful essay in history, he never, after the mistake of his first Pindaric attempts, strays beyond his sphere, never asked what he said and a foolish thing to do, and never fails to do it. His writings have not one literary fault except their occasional looseness of grammar and their frequent indecency. Within certain limits, his imagination and invention are as active as those of the most creative poets. As a master of humour, irony and invective he has no superior; his reasoning powers are no less remarkable within their range, but he never gets beyond the range of an advocate. Few men of so much mental force have had so little genius for speculation, and he is constantly dominated by fierce instincts which he mistakes for reason. As a man the leading note of his character is the same—strength without elevation. His master passion is imperious pride—the lust of despotic dominion. He would have his superiority acknowledged, and cared little for the rest. Place and profit were comparatively indifferent to him; he declares that he never received a farthing for any of his works except Gulliver's Travels, and that only by Pope's management; and he had so little regard for literary fame that he put his name to only one of his writings. Contemptuous of the opinion of his fellows, he hid his virtues, paraded his faults, affected some failings which were the real cause of, and since his munificence and charity could not be concealed from the public, laboured to spoil it by gratuitous surliness. Judged by some passages of his life he would appear a heartless egotist, and yet he was capable of the sincerest friendship and could never dispense with human sympathy. Thus an object of pity as well as awe, he is the most tragic figure in our literature—the only man of his age who could be conceived as affording a groundwork for one of the creations of Shakespeare. "To think of him," says Thackeray, "is like thinking of the ruin of a great empire."

Nothing finer or truer has been said of Swift than the description of the Scriblerus Club with his own hatred of pedantry, cant and circumspection. His own prose is the acme of incisive force and directness. He uses the vernacular with an economy which no other English writer has rivalled. There is a masculinity about his phrases which makes him as clear to the humblest capacity as they are of being made to anyone. Ironist as he is, there is no writer that ever wrote whose meaning is more absolutely unmistakable. He is the grand master of the order of plain speech. His influence, which grew during the 18th century in spite of the depreciation of Dr Johnson, who was an enemy of Swift, and whom he regarded as the author of Gulliver he is still read all over the world, while in England discipleship to Swift is recognized as one of the surest passports to a prose style. Among those upon whom Swift's influence has been most discernible may be mentioned Chesterfield, Smollett, Cobbett, Hazlitt, Scott, Borrow, Newman, Bello.

Authorities.—Among the authorities for Swift's life the first place is still of course occupied by his own writings, especially the fragment of autobiography in the University of Dublin and the Correspondence, which still awaits an authoritative annotated edition. The most important portion is contained in the Journal to Stella, which was the result of twenty-three letters, and was written between the 1st and 28th of May 1711, and which began about the time of Jeffrey. Yet as the author of Gulliver he is still read all over the world, while in England discipleship to Swift is recognized as one of the surest passports to a prose style. Among those upon whom Swift's influence has been most discernible may be mentioned Chesterfield, Smollett, Cobbett, Hazlitt, Scott, Borrow, Newman, Bello.
SWIFT—SWIMMING

SWIFT, a bird so called from the extraordinary speed of its flight, which actually exceeds that of any other British bird except the Hirundo apus of Linnaeus and Cypselus apus or maniruri of modern ornithologists. Swifts were formerly associated with swallows (q.v.) in classification, but whilst the latter are true Passeres, it is now established that swifts are Coraciiform birds (see BIRDS) and the sub-order Cypseli has been formed to include them and their nearest allies, the humming-birds. The four toes are all directed forwards, whereas in the Passeres the hallux is directed backwards and by opposing the other three makes the foot a grasping organ. In the swifts, moreover, the middle and outer digits have only three joints and the metatarsi, and even the toes may be feathered. Swifts are divided into three sub-families: Macropteriginiæ, the true swifts, of tropical Asia, which form a nest gunned by saliva to branches of trees; Chæturiæ, building in rocks or houses, and with an almost world-wide range: it includes Chætura palagica, the "chinny-swallow" of the United States, Collocaia fusciphaga which obtained its specific name from the erroneous idea that its edible nests were formed by partly digested seaweed; Cypselinae, also world-wide and containing Cypselus apus, the common European swift. All the swifts are migratory. Well known as a summer visitor throughout the greater part of Europe, the swift is one of the latest to return from Africa, and its stay in the country of its birth is of the shortest, for it generally disappears from England very early in August, though occasionally to be seen for even two months later.

The swift commonly chooses its nesting-place in holes under the eaves of buildings, but a crevice in the face of a quarry, or even a hollow tree, will serve it with the accommodation it requires. This, indeed, is not much, since every natural function except sleep, oviposition and incubation, is performed on the wing, and the entire length of this bird in the air, where it remains for hours together, are the admiration of all who witness them. Though considerably larger than a swallow, it can be recognized at a distance by its size than by its peculiar shape. The head scarcely projects from the anterior outline of the pointed wings, which form an almost continuous curve, at right angles to which extend the body and tail, resembling the handle of the crescentic cutting-knife used in several trades, while the wings represent the blade. The mode of flight of the two birds is also unlike, that of the swift being much more steady, and, rapid as it is, ordinarily free from jerks. The whole plumage, except a greyish white patch under the chin, is a sooty black, but glossy above. Though its actual breeding-places are by no means numerous, its extraordinary speed and discursive habits make the swift widely distributed; and throughout England scarcely a summer's day passes without its being seen in most places. A larger species, C. melba or C. alpinus, with the lower parts dusky white, which has its home in many of the mountainous parts of Europe, and has twice been observed in Britain, and two examples of a species of a very distinct genus Chætura, which has its home in northern Asia, but regularly emigrates thence to Australia, have been obtained in England (Proc. Zool. Soc., 1880, p. 1).

Among other peculiarities the swifts, as long ago described (probably from John Hunter's notes) by Sir E. Home (Phil. Trans. 1817, pp. 332 et seq., pl. xvi.), are remarkable for the development of their salivary glands, the secretions of which serve in most species to glue together the materials of which the nests are composed, and in the species of the genus Collocaia form almost the whole substance of the structure. These are the "edible" nests so eagerly sought by Chinese epicures as an ingredient for soup. These remarkable nests consist essentially of mucus, secreted by the salivary glands above mentioned, which dries and looks like isinglass. They are extremely valuable for other purposes, and by the natives of Japan are often intermixed with feathers and other foreign substances. The swifts that construct these "edible" nests form a genus Collocaia, with many species; but they inhabit chiefly the islands of the Indian Archipelago and from that period to the Malay Peninsula, as well as many of the tropical islands of the Pacific so far as the Marquesas— one species occurring in the hill-country of India. They breed in caves, to which they resort in great numbers, and occupy them jointly in the form of alternate roosts—the mammals being guests at the door by the birds by night.

(A.N.)

SWIMMING (from "swim," A.S. swimman, the root being common in Teutonic languages), the action of self-support and self-propulsion on or in water; though used by analogy of inanimate objects, the term is generally connected with animal progression and specially with the art of self-propulsion on water as practised by man. Natation (the synonym derived from Lat. nātare) is one of the most useful of the physical acquirements of man. There have been cases in which beginners have demonstrated some ability in the art upon their first immersion in deep water, but generally speaking it is an art which has to be acquired. For many years Great Britain held the supremacy in this particular form of athletics, but continental, Australian and American swimmers have so much improved and have developed such speedy strokes, that the claim can no longer be maintained. English swimmers have, however, the satisfaction of knowing that in a great measure through them has come about the very great interest which is now taken in the teaching of swimming throughout the world, and more particularly on the continent of Europe, where they have made frequent tours and given instructive displays of swimming, life-saving (see DROWNING), and water polo (q.v.); the latter a water game entirely British in its origin.

The teaching of swimming has been taken up in schools, and where the work is well done it is customary to use a form of land drill so as to impress upon the pupils some idea of the motions which have to be made in order to progress through the water. This drill is the preliminary practice to the teaching of the breast stroke. This stroke is about the most useful of all the known forms of swimming, more particularly when any one is thrown overboard in clothes; and though speed swimmers look upon it as obsolete, it is undoubtedly the best for a long-distance swim, such as across the English Channel, or other similar feats. A knowledge of it, as well as of the back stroke, is essential to the effective teaching of swimming.

When learning the breast stroke, the first thing to avoid is undue haste and rapidity in the movements. It is this fault, probably born of nervousness, which causes many to aver that though eager to do so, they have never been able to learn to swim. Rapid action of the arms only exhausts the learner, whose breathing then becomes hurried and irregular, and as a consequence he fails to preserve the buoyancy necessary for carrying him along the surface. When starting for the first stroke the beginner should draw the elbows nearly to the side, at the same
time bringing up the forearm and hands to the front of the chest, with the palms of the hands downwards near to the surface of the water, the fingers being extended and closed and the forefingers and thumbs nearly touching. The hands are then pushed forward in front of the body to the full extent of the arms, the palms of the hands are turned slightly outwards, and the arms swept round until in a right angle with the shoulders, when the elbows are dropped and the hands come up in front of the chest for the next stroke. The arms should not be kept rigid, but allowed to work gracefully. As the arms are swept backwards the legs are drawn up, the knees being turned outwards to the right and left and the heels nearly touching. The legs are then kicked outward and swept round as the arms are being pushed forward to their fullest extent, a "sweep" being given with each of the feet, which must be kept loose at the ankles and in the same position as when standing. All beginners have the great fault of trying to make the limbs too rigid, thereby causing stiffness and possibly cramp. Another difficulty with them is the question of breathing, but if the learner will remember to inhale when making each backward sweep of the arms, much of the difficulty usually experienced at the start will be overcome.

Expiration should be carried out during the other portion of each stroke. The important thing is to keep the body as level along the water as possible, and at the same time maintain a natural and easy breathing. The holding of the breath for two or three strokes will exhaust the beginner more than anything else.

A knowledge of the back stroke can easily be acquired by those who are able to swim on the breast, for the leg action is very similar and the principles relating to the use of the arms are almost the same. The arms, instead of being moved through the water, are lifted in the air and carried out to beyond the head with the palms upwards. The palms are then slightly turned and the arms swept round. Just as this action is being made the legs are drawn up as in the breast stroke, the body being allowed to travel on with the force of the kick as the arms are extended beyond the head. The great difficulty that a back swimmer has to contend with in open water is that of steering, and the best way to overcome it is to take an object for a guide before starting and hold the head slightly to the side so as to steer by it.

At one time the side stroke was the great racing stroke; the body being placed on the side, the upper arm worked from the head to the upper side of the body, the lower arm taken downward through the water to the underside of the body and a scissors-like kick made with the legs; but this has now been generally given up in favour of the over-arm, trudgen and crawl strokes.

In the over-arm stroke the body is usually turned on the right side. At the start the lower arm is pulled downwards towards the hips, the fingers being kept closed and the hand flat, so as to present a large surface to the water. When the stroke is finished the hand is turned quickly palm upwards, so that together with the lower part of the arm it cuts the water sideways, the arm being almost bent double. Then, as it is shot forward, the hand is gradually turned from palm upwards to palm downwards, until, when it arrives at its position beyond the head, it is ready for the next stroke. The recovery and the pull ought to be effected as quickly as possible. The upper arm stroke is started when the downward stroke of the under or right arm is finished. It is started in front of the forehead, the arm being slightly bent and the fingers pointing downwards. The hand is pulled past the face and chest with the arm bent at right angles and swept back in front of the body, the arm gradually straightening as it leaves the water opposite the hip. When the hand is opposite the shoulder in its pull through the water the legs are kicked wide apart and closed again at the moment when the hand leaves the water. The kick is completed and the legs straightened before the left hand is replaced ready for the next stroke. As the legs are opened the upper leg is kicked forward with the knee slightly bent, and the foot kept in its ordinary position. The lower leg is bent double until the heel approaches the thigh, which is brought backwards slightly. In the actual kick the upper leg is sent forward, and as it is straightened the knee in water is swept downward and, as the lower leg comes forward to meet it with a vicious kick, the swirl of the feet and closing of the legs drives the body forward. This is what has come to be known in Great Britain as the "Northern Kick," by reason of its first being introduced by Lancashire swimmers.

The trudgen stroke, more commonly known as the trudgen stroke, and on the continent of Europe as Spanish swimming, was first made prominent in England in 1873 by a swimmer named J. Trudgen, who stated that he had acquired a knowledge of it while in South America. It was, however, a writer on swimming, who described it in 1825 as "The Thrust." Trudgen's speed was so great for his time that swimmers quickly copied his style, and it is from this stroke that the crawl stroke has been developed. When swimming Trudgen kept on the chest and lifted the upper part of his body at each stroke out of the water, and at each swing of the arms pulled himself forward, a considerable swirl of the water occurring as each movement was finished. The arms were brought forward sideways, each completing a circle on each side of the body, and the head kept constantly above the water. Trudgen's stroke was found to be less laborious and equally as fast to use a double-over-arm stroke with the head and chest well down, and thus have the body supported by the water, using the ordinary over-arm kick. At first it was considered a stroke only useful for short distances and for water polo where speed is essential, but the idea was quickly dispelled, and several men, as well as women, have swum as far as fifteen miles with this stroke.

The crawl stroke is, like the trudgen, an adaptation from native swimmers. It was not generally known in Great Britain until 1902, when Mr. Richard Cavill came from Australia to compete in the English championships, and it is believed to have been taught to natives of the South Sea Islands, and from there introduced into Australia about the year 1900. From thence it came to Europe, and there Mr. C. M. Daniels, the American amateur champion, made so excellent a study of it that he not only so greatly increased his own pace as to be able to win the English championship, and beat the world's record for a hundred yards, but also introduced various improvements upon it. This stroke is different from any other form of swimming: the legs from the knee upwards are kept in line with the body and almost completely straight when opening the legs or drawing the knee downward, as for the breast, back and side strokes. The swimmer lies flat upon his breast on the surface, the lower part of the legs from the knee downward are alternately lifted above the surface up to the middle of the calf and then they are struck down upon the water with the instep with all force possible. This striking is done from an upward to a downward direction, one leg at a time. The arms are used somewhat similarly, as in the trudgen stroke, they are bent at the elbows, dipped in just beyond the head and drawn smartly backwards till they come out of the water at the hips. The right arm is dipped in when the left foot strikes downward and vice versa. The result of this movement is that when one or the other of the limbs is pulling or propelling the body through the water at the same moment another limb is being recovered for the next stroke, most of the limbs are recovered through the air, fewer dead or retarding points are produced than in any other stroke, and less resistance is caused in the line of progress. In performing any other stroke most of the limbs are recovered through the water.

One of the most useful accomplishments for a swimmer is that of floating, but curiously enough many of them cannot acquire a knowledge of it. It is purely a matter of buoyancy, and requires constant practice before one can become perfect in it. In learning to float the beginner experiences great difficulty in overcoming the tendency of the legs to sink, and if after frequent trials they are still found to sink he should get some one to hold them up or else place them on the steps or behind the rail of the bath, and thus assisted learn to balance the body on
SWIMMING

the surface. Before doing so he should completely fill his lungs, spread his legs wide, and then lie backwards with the arms extended in a line with the body and beyond the head, with the palms upwards, care being taken to throw as much weight beyond the head as possible. Furthermore he must lie perfectly still and take care not to holler the back or raise the shoulder above water. One may sink for an instant, but, if the breath be held the lips will come above the surface, when easy breathing may be indulged in. Only the face, chest and toes should appear above the surface of the water. If the feet still have a tendency to sink after they have been gently released from the step or rail, more weight should be thrown beyond the head by turning it well back and lifting the hands out of the water, which will raise the feet. A knowledge of floating is of good service to those attempting to save life and is also essential to those desirous of making a study of the many tricks and scientific feats which are performed by swimmers.

The usual method of entering the water is by what is known as diving; some think that it should be termed "springing." The best method of learning to dive is to stand on the side of the bath or on the bank of the river, and then stoop down until the body is nearly double, stretch out the arms in front of the head, sink the head between them and gradually fall over into the water. The ability to enter the water head first will then soon be acquired. To begin, the legs should be placed together and the body kept erect, then a few short inspirations should be made and the lungs cleared and the head lowered to the water. The face should be turned forward and the head should be lowered for a moment to the bottom of the stroke, then brought up before the nose is wholly lost from sight. The body faces the water, the head bends down and the body remains in the same position. A little practice and the body is made to enter the water in a graceful manner. A useful accomplishment is that known as surface diving, because it enables you to find and bring an object to the surface. The correct method of performing it is to first swim a few yards on the surface with the breast stroke, take a breath, then suddenly depress the head, look downwards, elevate the body at the hips, and at the same time make a powerful stroke with the legs and an upward stroke with the hands. The impetus thus obtained will suffice to take the swimmer to the bottom in 10 ft. of water. The surface it is necessary to keep the body straightened and the breath by means of the breast stroke in order to find the object of search. When about to rise to the surface, the head should be turned backwards with the eyes upwards, and a vigorous stroke made with arms and legs. Plunging is not very generally practised, though there is a championship for it. A plunge is a standing dive made head first from a firm take off, free from spring. The body must be kept motionless face downwards, no progressive movement must be imparted other than the action of the dive. The plunge terminates when the plunger raises his face above the surface of the water. With the idea of preventing long tests without breathing, it was deemed in 1893 advisable by the swimming association to impose a time limit of one minute in all competitions. Yet even with this time limit, over 80 ft. has been plunged. In Sweden and Germany skilled forms of acrobatic and gymnastic diving have been more largely practised than in England, and as a consequence diving in those countries is in a much higher state of perfection than in England, though even in England great improvement has been made owing to a large influx of Swedish teachers.

In the matter of the principal races as decided in baths, but there has been a tendency of late years to revert to open water in the summer and also to encourage long-distance swimming. The first public baths in Great Britain were opened by the corporation of Liverpool in 1828 and the Baths and Washhouses Act was passed in 1846, the first of the London parishes to adopt the act being St Martin's in the Fields, who opened baths in Green Street, Leicester Square in 1846. Since then public baths have been erected all over Great Britain and Ireland, and open water swimming has become, by reason of the lack of reasonable open water accommodation, the principal means of the teaching of the young. But open water swimming, and more particularly swimming in the sea, is the best training and practice for those who really love the art, because they are able to swim under normal climatic conditions, instead of in tepid water. Many persons in England bathe in the open all the year round, notably in the Serpentine in London, on the sea-coast and in various inland waters.

In the matter of bathing there has been and is continued to be taken to avoid weeds or undercurrents. In the event of accidentally getting hold of a bed of weeds, the swimmer should cease kicking and work with the arms, and the current will then take him through. If he tries to swim the weeds will entangle his legs and put him in an awkward plight. If he be carried away by a current in a river, he should select a spot on either bank and swim diagonally towards it, never minding where he has left his clothes. When in the sea, the conditions are not always the same, though the general rule of swimming diagonally for shore also applies. For sea bathing, however, it is far better, no matter how good a swimmer one may be, to have a boat in attendance. The hundred yards record has been for some years by a diver who has been bathing in any strange place, the swimmer should make himself acquainted with the currents and the direction of the tide. When the tide is going out the course should be made along the coast, close in shore. In a rough sea the swimmer should not attempt to breast the waves, but as each wave rises he should swim through, thereby saving himself from buffeting, which, if long continued would cause insensibility or else great waste of physical power. When using a boat for bathing the best way is to dive from the stem, to which some steps or a rope ladder should be fixed, in order to aid the swimmer when getting in again. Failing these being at hand, the best way is to lay hold of the stern with both hands and then, making a hard rising kick, raise the body till it rests on the edge of the hips. Then softly slip the hands a little forward, turn to a sitting position and enter the boat.

Speed swimming records are so frequently altered, that students had best obtain the Amateur Swimming Association's Annual Handbook, in which are detailed the accepted records up to date. The improvement in speed has been most remarkable. In 1871 the mile amateur record was 29 m. 245 secs.; and that stood until 1892. The record in 1907 was 24 m. 425 secs. made by Mr. D. Billington. In 1897 Webb's 662 yards record was similarly reduced. In 1878 it was 1 m. 161 secs.; in 1888 it had been lowered by Mr J. Nuttall to 1 m. 61 secs.; and in 1907 Mr C. M. Daniels, of America, created a world's record of 55! 1/2 secs. The records over intermediate distances have also been considerably lowered and many long-distance swimming records have from time to time been created. One of the most remarkable of these long-distance swims is the race which is known as the "Swim through London," from Richmond lock and weir to Blackfriars, which was instituted in 1907 and won by Mr J. A. Jarvis of Leicester, in 3 hours 24 minutes 68 secs. In this event 34 started, and 21 finished the distance, which goes to show that much attention is being devoted to long-distance trials; in this event Miss Lilian M. Smith finished fourteenth. Much interest has centred in attempts to swim across the English Channel; Captain Webb, D. Dalton and F. Cavill, all claim to have done it, but only the swim of Captain Webb has been accepted as genuine. The first recorded attempt was made on the 24th of August 1872 by J. B. Johnson, who started from Dover, but remained in the water only 65 minutes. It was on the 12th of August 1875 that Captain Matthew Webb made his first attempt. He started from Dover and remained in the water 6 hours 49 m., when the weather became too rough for him to continue. It is estimated he was about 134 m.
across when he had to give up. On the 24th-25th of August 1875, he swam across the English Channel, diving from the Admiralty Pier, Dover, and touching Calais sands, France, after swimming for 21 hours 45 m. It is the greatest swim ever recorded, and at the time of the accomplishment created a great sensation in England. Since this great achievement, numerous unsuccessful attempts have been made, the best being those of Montague Holbein, Jabez Wolff and T. W. Burgess, and their efforts created an interest in long-distance swimming in all parts of the world, which has resulted in the accomplishment of trials and tests once thought impossible.

BIBLIOGRAPHY.—The literature of the subject of swimming is considerable, and modern works of general reference is Swimming, by Ralph Thomas (London, 1904), with bibliography. Other chief works on the technique of swimming that may be mentioned are: Thevenot, The Art of Swimming (London, 1789); Steedman, Manual of Swimming (Melbourne, 1867); W. Wilson, The Swimming Instructor (London, 1883); A. Sinclair and W. Henry, Swimming (Badminton Library, London, 1883); C. M. Daniels, How to Swim and Save Life (Spalding's Library, London, 1897). (W. H.)

SWINBURNE, ALGERNON CHARLES (1837-1909), English poet and critic, was born on 14th March 1837. He was the son of Admiral Charles Henry Swinburne (of an old Northumbrian family) and of Lady Jane Henrietta, a daughter of George, 3rd earl of Ashburnham. It may almost be said to have been by accident that Swinburne owned London for his birthplace, since he was removed from it immediately, and always felt a cordial dislike for the surroundings and influences of life in the heart of a great city. His own childhood was spent in a very different environment. His grandfather, Sir John Edward Swinburne, bart., owned an estate in Northumberland, and his father, the admiral, bought a beautiful spot near Norden, and Niton, on the Isle of Wight, called East Dene, together with a strip of undercliff known as the Landslip. The two homes were in a sense amalgamated. Sir Edward used to spend half the year in the Isle of Wight, and the admiral's family shared his northern home for the other half; so that the poet's earliest recollections took the form of strangely contrasted emotions, inspired on the one hand by the bleak north, and on the other by the luxuriant and tepid south. Of the two, the influences of the island are, perhaps naturally, the stronger in his poetry; and many of his most beautiful pieces were actually written at the Orchard, an exquisite spot between Norden and Niton, and are imbued with the spirit of the Dene, or the spirit of the sea, and the spirit of the Elysian south.

After some years of private tuition, Swinburne was sent to Eton, where he remained for five years, proceeding to Balliol College, Oxford, in 1857. He was three years at the University, but left without taking a degree. Clearly he must have cultivated while there his passionate and altogether unacademic love for the literature of Greece; but his undergraduate career was unattended by university successes, beyond the Taylorian prize for French and Italian, which he gained in 1858. He contributed to the "Undergraduate Papers," published during his first year, under the editorship of John Nichol, and he wrote a good deal of poetry from time to time, but his name was probably regarded without much favour by the college authorities. He took a second class in classical moderations in 1858, but his name does not occur in any of the "Final" honour schools. He left Oxford in 1860, and in the same year published those remarkable dramas, The Queen Mother and Rosamond, which, despite a certain rigidity of style, must be considered a wonderful performance for so young a poet, being fuller of dramatic energy than most of his later plays, and rich in really magnificent blank verse. The volume was scarcely noticed at the time, but it attracted the attention of one or two literary judges, and was by them regarded as a first appearance of uncommon promise.

It is a mistake to say, as most biographers do, that Swinburne, after leaving Oxford, spent some time in Italy with Walter Savage Landor. The facts are quite otherwise. The Swinburne family went for a few weeks to Italy, where the poet's mother, Lady Jane, had been educated, and among other places they visited Fiesole, where Landor was then living in the house that had been arranged for him by the kindness of the Brownings. Swinburne was a great admirer of Landor, and, knowing that he was likely to be in the same town with him, had provided himself with an introduction from his friend, Richard Monckton Milnes. Landor and Swinburne met and conversed, with great interest and mutual esteem; but the meetings were not for more than an hour at a time, nor did they exceed four or five in number. Swinburne never lived in Italy for any length of time. In 1865 appeared the lyrical tragedy of Atalanta in Calydon, followed in the next year by the famous Poems and Ballads, and with them the poet took his seat, within sound of the London literary world, that may almost be likened to the vogue of Byron. His sudden and imperative attraction did not, it is true, extend, like Byron's, to the unliturgical; but among lovers of poetry it was sweeping, permeating and sincere. The Poems and Ballads were vehemently attacked, but Dolores and Fousine were on everyone's lips: as a poet of the time has said, "We all went about chanting to one another these new, astonishing melodies." Chastelard, which appeared between Atalanta and Poems and Ballads, enjoyed perhaps less unstinted attention; but it is not too much to say that by the close of his thirtieth year, in spite of detraction, Swinburne had placed himself in the highest rank of contemporary poets, but had even established himself as leader of a choir of singers to whom he was at once master and prophet.

Meanwhile, his private life was disturbed by troublesome influences. A favourite sister died at East Dene, and was buried in the little shady churchyard of Bonchurch. Her loss overwhelmed the poet's father with grief, and he could no longer tolerate the house that was so full of tender memories. So the family moved to Holmwood, in the Thames Valley, near Reading, and the poet, who had been placed in the highest rank of contemporary poets, but had even established himself as leader of a choir of singers to whom he was at once master and prophet.

The Pre-Raphaelite movement was in full swing, and for the next few years he was involved in a rush of fresh emotions and rapidly changing loyalties. It is indeed necessary to any appreciation of Swinburne's genius that one should understand that his inspiration was almost invariably derivative. His first book is deliberately Shake-spearian in design and expression; the Atalanta, of course, is Virgilian, and the Faustine and the Hellenic spirit. With a wider swing of the pendulum, he recedes, in Poems and Ballads, to the example of Baudelaire and of the Pre-Raphaelites themselves; with the Song of Italy (1867) he is drawing towards the revolt of Mazzini; by the time Songs before Sunrise are completed (in 1871) he is altogether under the influence of Victor Hugo, while Rome has become to him "first name of the world's names." But, if Swinburne's inspiration was derivative, his manner was in no sense imitative; he brought to poetry a spirit entirely his own, and a method even more individual than his spirit. In summing up his work we shall seek to indicate wherein his originality and his service to poetry has lain; meanwhile, it is well to distinguish clearly between the influences which touched him and the original, personal fashion in which he assumed those influences, and made them his own. The spirit of Swinburne's muse was always a spirit of revolution. In Poems and Ballads the revolt is against moral conventions and restraints; in Songs before Sunrise the arena of the contest is no longer the sensual sphere, but the political and the ecclesiastical. The detestation of kings and priests, which marked so much of the work of his maturity, is now in full swing, and Swinburne's language is tinged with extravagance and an almost virulent animosity. With Backwell (1874) he returned to drama and the story of Mary Stuart. The play has fine scenes and is burning with poetry, but its length not only precludes patient enjoyment, but transcends all possibilities of harmonious unity. Erechtheus (1876) was a return to the Greek inspiration of Atalanta; and then in the second series of Poems and Ballads (1878) the French influence is seen to be at work, and Victor Hugo begins to hold alone the place possessed, at different times, by Baudelaire and Mazzini. At
this time Swinburne's energy was at fever height; in 1879 he published his eloquent Study of Shakespeare, and in 1880 no fewer than three volumes, The Modern Heptalogy, a brilliant anonymous essay in parody, Songs of the Springtides, and Studies in Song. It was shortly after this date that Swinburne's friendship for Theodore Watts-Dunton (then Theodore Watts) grew into one of almost more than brotherly intimacy. After 1880 Swinburne's life remained without disturbing event, devoted entirely to the pursuit of literature in peace and leisure. The conclusion of the Elizabethan trilogy, Mary Stuart, was published in 1881, and in the following year Tristram of Lyonesse, a wonderfully individual contribution to the art of poetic fiction; in which the heroic couplet is made to assume opulent, romantic cadences of which it had hitherto seemed incapable. Among the publications of the next few years must be mentioned A Century of Roundels, 1883; A Midsummer Holiday, 1884; and Miscellanies, 1886. The current of his poetry, indeed, continued unchecked; and though it would be vain to pretend that he added greatly either to the range of his subjects or to the fecundity of his versification, it is at least true that his melody was unbroken, and his magnificently tormented prose inexhaustible. His Marino (1881) and Locrine (1887) have passages of power and intensity unsurpassed in any of his earlier work, and the rich metrical effects of Astrophel (1894) and The Tale of Balin (1896) are inferior in music and range to none but his own masterpieces. In 1899 appeared his Rosamund, Queen of the Lombards; in 1908 his Duke of G Gäste; and in 1904 was begun the publication of a collected edition of his Poems and Dramas in eleven volumes.

Besides this wealth of poetry, Swinburne was active as a critic, and several volumes of fine impassioned prose testify to the variety and fluctuation of his literary allegiances. His Note on Charlotte Brenton (1897) must be read by every student of her subject; the Study of Shakespeare (1880)—followed in 1900 by The Age of Shakespeare—is full of vigorous and arresting thought, and many of his scattered essays are rich in suggestion and appreciation. His studies of Elizabethan literature are, indeed, full of "the noble tribute of praise," and no contemporary critic did so much to revivify an interest in that wonderful period of dramatic recrudescence, the side-issues of which have been generally somewhat obscured by the pervading and dominating genius of Shakespeare. Where his enthusiasm was heart-whole, Swinburne's appreciation was stimulating and infectious, but the very qualities which give his poetry its unique charm and character were antithetic to his success as a critic. He had very little capacity for cool and reasoned judgment, and his criticism is often a tangled thicket of prejudices and predilections. He was, of course, a master of the phrase; and it never happened that he touched a subject without illuminating it with some lightning-flash of genius, some vivid penetrating suggestion that outflames its shadowy and confused environment. But no one of his studies is satisfactory as a whole; the faculty for sustained exercise of the judgment was denied him, and even his best appreciations are disfigured by error in taste and proportion. On the other hand, when he is aroused to literary indignation the avalanche of his invective sweeps before it judgment, taste and dignity. His dislikes have all the superlative violence of his affections, and while both alike present points of great interest to the analyst, revealing as they do a rich, varied and fearless individuality, the criticism which his hatreds evoke is seldom a safe guide. His prose work also includes an early novel of some interest, Love's Cross-currents, disinterred from a defunct weekly, the Taller, and revised for publication in 1905.

Whatever may be said in criticism of Swinburne's prose, there is at least no question of the quality of his poetry, or of its important position in the evolution of English literary form. To treat first of its technique, it may safely be said to have revolutionized the whole system of metrical expression. It found English poetry bound in the bondage of the iambic; it left it revelling in the freedom of the choriambus, the dactyl and the anapaest. Entirely new effects; a richness of orchestration resembling the harmony of a band of many instruments; the thunder of the waves, and the lip of leaves in the wind; these, and a score other astonishing poetic developments were allied in his poetry to a mastery of language and an overwhelming impulse towards beauty of form and exquisiteness of imagination. In Tristram of Lyonesse the heroic couplet underwent a complete metamorphosis. No longer wedded to antithesis and a sharp caesura, it grew into a rich melodious measure, capable of an infinite variety of notes and harmonies, palpitating, intense. The service which Swinburne rendered to the English language is as a whole for lyrical effect is simply incalculable. He revolutionized the entire scheme of English prosody. Nor was his singular vogue due only to this extraordinary metrical ingenuity. The effect of his artistic personality was in itself intoxicating, even delicious. He was the poet of youth insurgent against all the restraints of conventionalism and custom. The young lover of poetry, when first he encounters Swinburne's influence, is almost bound to be swept away by it; the wild, extravagant licence, the apparent sincerity, the vigour and the verve, cry directly to the aspirations of youth like a clarion in the wilderness. But, while this is inevitable, it is also lamentable to see that the young poet is often led into resting allegiance to the Swinburnian mood more quickly than any other of the diverse emotions aroused by the study of the great poets. It is not that what has been called his "pananthropism"—his universal worship of the holy spirit of man—is in itself an unsound philosophy; there have been many creeds founded on such a basis which have impartially withstood the attacks of criticism. But the unsoundness of Swinburne's philosophy lies in the fact that it celebrates the spirit of man engaged in a defiant rebellion that leads nowhere; and that as a "criticism of life" it has neither finality nor a sufficiently high seriousness of purpose. Walt Whitman preaches very much the same gospel of the "body electric" and the glory of human nature; but Whitman's attitude is far saner, far more satisfying than Swinburne's, for it is concerned with the human spirit realizing itself in accordance with the unchangeable laws of nature; while Swinburne's enthusiasm is, more often than not, directed to a spiritual revolution which sets the laws of nature at defiance. It is impossible to acquit his poetry entirely of the charge of an animalism which wars against the higher issues of the spirit—an animalism sometimes of love, sometimes of hatred, but, in both extremes, out of centre and harmony.

Yet, when everything has been said that can be said against the unesthetic violence of the poet's excesses, his service to contemporary poetry outweighed all disadvantages. No one did more to free English literature from the shackles of formalism; no one, among his contemporaries, pursued the poetic calling with so sincere and resplendent an allegiance to the claims of absolute and unadulterated poetry. Some English poets have turned preachers; others have been seduced by the attractions of philosophy; but Swinburne always remained an artist absorbed in a lyrical ecstasy, a singer and not a seer. When the history of Victorian poetry comes to be written, it will be found that his personality was, in its due perspective, among the most potent of his time; and as an artistic influence it will be pronounced both inspiring and beneficent. The topics that he touched were often ephemeral; the causes that he celebrated will, many of them, wither and desiccate; but the magnificent freedom and lyrical resource which he introduced into the language will enlarge its borders and extend its sway so long as English poetry survives.

On the 10th of April 1909, after a short attack of influenza followed by pneumonia, the great poet died at the house on Putney Hill, "The Pines," where with Mr Watts-Dunton he had lived for many years. He was buried at Bonchurch, Isle of Wight. (E. G.)

SWINDON, a market town and municipal borough in the Cricklade parliamentary division of Wiltshire, England, 77½ m. W. of London by the Great Western railway. Pop. (1891), 33,001; (1901), 45,006. It has two parts, New and Old. The
SWINE

new town grew up around the vast locomotive and wagon works of the Great Western railway, and is an important junction on that system with a separate station on the Midland and South-Western Junction railway. It arose rapidly on a strip of waste land, and churches and chapels were built for the workmen, whose numbers soon exceeded 10,000. Each man contributes to a medical fund which maintains the fever, accident and general hospitals, providing also laundries and baths. There are a mechanics' institute, containing a large library, theatre, reading-rooms and lecture-hall. The company owns a park with football and cricket grounds. An aisle of St Saviour's Church, dedicated in 1905, was built by the priest and congregation with their own hands. The picturesque old town stands on a hill overlooking the Gloucestershire borders, the White Horse Vale and Lambourn Down in Berkshire, and the great chalk uplands of Marlborough; while the camps of Blunsdon, Kingsbury, Barbury and Badbury are all visible. Here the chief buildings are the church, town-hall, market-hall and corn exchange. Old Swindon received the right of holding a fair from Charles I. Coate Reservoir, less than 2 m. south-east, is a broad lake which supplies a branch of the Berks and Wilts Canal. Its shores are beautifully wooded, and it abound with fish. Swindon is governed by a mayor, 12 aldermen and 36 councillors. Area, 4,265 acres.

SWINE, a name properly applicable to the domesticated pig (Sus scrofa), but also including its wild relatives. As stated in the article ARTIODACTyla, these animals typify the family Suidae, which, with the Hipposopomatidae, constitute the section Suina, a group of equal rank with the Pecora. The Suine animals are divisible into the true Old World swine (Suinae) and the American peccaries (Dicotylinae). Of the former the leading characteristics are as follows: an elongated mobile snout, with an expanded, truncated, nearly naked, flat, oval terminal surface in which the nostrils are placed. Feet narrow, with four completely developed toes on each. Hoofs of the two middle toes with their contiguous surfaces flattened. The outer toes not reaching to the ground in the ordinary walking position. Teeth variable in number, owing to the suppression in some forms of an upper incisor and one or more premolars.

In the typical genus Sus, as exemplified by domesticated pigs (see Pig) and the wild boar (see Boar), the dentition is i, j, c, p, i; m, j; total 44; the upper incisors diminishing rapidly in size from the first to the third, and the lower incisors long, narrow, closely approximated, and almost horizontal in position, their tips inclining towards the middle line, the second slightly larger than the first, the third much smaller. The tusks or canines are strongly developed, with persistent roots and a partial enamel covering, those of the upper jaw not having the usual downward direction, but curving outwards, upwards and finally inwards, while those of the lower jaw are directed upwards and outwards with a gentle backward curve, their hinder edges working and wearing against the front edges of the upper pair. The tusks appear externally to the mouth, the form of the upper lip being modified to allow of their protrusion, but are much less developed in females than in males. The teeth of the molar series gradually increase in size and complexity from first to last, and are arranged in contiguous series, except that the first lower premolar is separated by an interval from the second. First and second upper premolars with compressed crowns and two roots; and the third and fourth with an inner lobe of the crown, and an additional pair of roots. The first and second molars have quadrate crowns, with four principal obtuse conical cusps, around which numerous accessory cusps are clustered. The crown of the third molar is nearly as long as those of the first and second together, having, in addition to the four principal lobes, a large posterior heel, composed of clustered conical cusps, and supported by additional roots. The lower molars resemble generally those of the upper jaw, but are narrower. Milk dentition: i, j, c, p, m, j; total 28—the first permanent premolar having no predecessor. The third incisor in both upper and lower jaws is large, developed before the others, with much the size, form and direction of the canine. Vertebrae: C, 7, D, 13-14, L, 6, S, 4, Ca, 20-24. The hairy covering of the body varies under different conditions of climate, but when best developed, as in the European wild boar, consists of long stiff bristles, abundant on the back and sides, and of a close softer curling undercoat.

All the typical swine are further characterized by the fact that the young are longitudinally striped with bands of dark brown and some paler tint; this striped coat disappearing in the course of a few months. On the other hand, this peculiar marking is rarely seen in domestic pigs in any part of the world, although it has been occasionally observed. It is stated by Darwin that the pigs which have run wild in Jamaica and New Granada have assumed this aboriginal character, and produce longitudinally striped young; these being the descendants of domestic animals introduced from Europe since the Spanish conquest, as before that time there were no true pigs in the New World. Another character by which the European domesticated pig differs from any of the wild species is the concave outline of the frontal region of the skull.

In the wild boar (Sus scrofa) the upper or hinder surface of the lower tusk, which has no enamel, inclines obliquely outwards and is broader than the outer surface. The distributional area of this species includes northern Africa, Europe and central and northern Asia as far as Amurland. Whether the Nubian S. senaresi is really distinct, seems doubtful. To the same group belongs the Indian S. cristatus, distinguished by the more pronounced development of the crest of long hairs on the nape of the neck, and closely related to the next species. The third species is the banded pig S. vitatus, of Sumatra, characterized by having a broad reddish or whitish band running from the middle of the snout along the upper lip to disappear on the side of the neck; the skull being short and high, with the facial portion of the lachrymal bone small. Races of this type are also met with in Java, Cochinchina and Formosa; the pig from the latter island having been named S. tibonius. Near akin is the Japanese S. leucomystax and the small Andamanese S. andamanensis. Whether the New Guinea S. populensis and S. niger are really indigenous members of this group or modified descendants of European tame pigs is doubtful; although the general character of the Papuan fauna supports the idea that they are introduced.
A second group is typified by the wary pig, S. verrucosus, of Java, in which the hinder or upper unenamelled surface of the lower tusk is narrower than the outer, concave, and set nearly in the long axis of the skull. The skull itself is elongated, with comparatively simple and primitive molars, the latter being relatively short. There are also three small warts on each side of the face, the largest of which is just below the eye and carries long bristles. The small S. celebensis of Celebes and S. philippinus are probably only varieties of this species. The bearded pig (Sus barbatus, L.) is distinguished from the preceding by the great elongation of the skull, and the presence of a tuft of long hair near the muzzle. In Sumatra it is represented by the subspecies S. b. di, and in south-west Borneo by S. b. gorgonius. Some doubt exists whether the pygmy hog of the Nepal Terai, which is not much larger than a hare, is best regarded as a member of the typical genus, under the name of Sus salaminus or as representing a genus by itself, with the title Porcula salaminia.

Similar doubts have also been entertained with regard to the African bush-pigs or river-hogs, but from geographical considerations alone these are but regarded as representing a separate genus, Potamochoerus, although they are nearly allied to the verrucosus group of Sus. They are specially distinguished by the great development of the anterior half of the zygomatic arch of the skull, and by the presence in the boars of a horny protuberance of the skin in front of each eye, which overlies a tuberosity on the nasal bone; the molars are also small and simple, and the anterior premolars are generally shed at an early stage of life. The group is represented in Madagascar, as well as in Africa south of the Sahara.

The recently discovered Hylochoerus of the equatorial forest districts of Africa comes nearest to the under-mentioned wart-hogs, but the skull is of a much less specialized type, while the upper tusks are much smaller although they have the same general curvature and direction, and the cheek-teeth lack the peculiar characteristics of those of Potamochoerus, although they present a certain approximation thereto. On the other hand, resemblance to that genus is shown by the reduction of the upper incisors to a single pair. The skin is clothed with a thick coat of coarse black hair of a bristly nature, but there are a few whitish hairs on the face and in the groin.

In the African wart-hogs (Potamochoerus), which take their name from the large wart-labs projecting from each side of the face, the teeth are remarkably modified. The molar-dentine, and even the early condition of the permanent dentition, is formed on the same general type as that of Sus, except that the cheek teeth are much smaller. The formula being 3, 3, 3, 3, 3, 3, total 34; but as age advances all the teeth have a tendency to disappear, except the canines and the posterior premolars, which are the teeth that are retained. In the lower jaw, there are only two incisors on each side, which, owing to the position of the upper incisors, are always in contact with the lower ones, and there is a continuous superficial leaf-like enamel, which is very thick, and is preserved throughout the body.

Extinct Swine.—Species of Sus are met with in Pliocene strata of Europe and Asia, the Lower Pliocene S. ermyanthus of Greece and S. giganteus and S. titan of India being enormous animals; the last with comparatively simple molars. The European S. palaeocherus and the Indian S. khyudrucus are smaller forms; the first exhibiting signs of relationship with Potamochoerus. In India also occurs Hylochoerus, a distinct species, that bears none of the characters of its molars. In the European Miocene we have Hypotherium and Palaeocherus, and in the Upper Oligocene Propalaeocherus, which have square molars without any tendency to a solenodont structure in their cusps. Curiously enough a solenodont type is, however, apparent in those of the imperfectly known Egyptian Genyictis of the Upper Eocene, the earliest species which can be included in the family. Even in the same stratum and section of some of the lower incisors is noticeable. Choeroderma is a European Oligocene genus which bears bunodont molars which show a conspicuous basal cingulum in the lower dentition; the first premolar is absent. In the European Miocene Lophodon not infrequently occurs in the Indian Tertiaries, the molars have a pair of transverse ridges, like those of the proboscidean Dinootherium (q.v.); but the genus is believed to be related to the Oligocene Dolichorhino and Choerotherium, in which these teeth show a more normal type of structure.

For the genus Eotherium, of the Lower Miocene and Upper Oligocene of both hemispheres, which is often placed next the Susidae, see Arvactyta. The American Dicotyline are noticed under Peccary.

SWINEMÜNDE—SWING, D.

SWINEMÜNDE, a port and seaside resort of Germany, is situated at the east extremity of the island of Usedom, and on the left bank of the river Swine which connects the Stettiner Haff with the Baltic. Pop. (1905), 13,272. It serves as a port of Stettin (q.v.), 42 m. distant by water, with which, as with Heringsdorf, it has direct railway connection. Its broad unpaved streets and one-storey houses built in the Dutch style give it an almost rustic appearance. although its industries, beyond some fishing, are entirely connected with its shipping. The entrance to the harbour, the best on the Prussian Baltic coast, is protected by two long breakwaters, and is strongly fortified. The grand lighthouse, 216 ft. high, rises beside the new dock on the island which, on the other side of the narrow Swine, in 1897 the river continued of the Kaiserfahrt was opened to navigation, and, further, the waterway between the Haff and the Baltic was deepened to 24 ft. in 1900-1901 and in other ways improved. The connexion between Swinemünde and Stettin is kept open in winter by ice breakers. Formerly ships of heavy burden bound for Stettin discharged or lightened their cargo at Swinemünde, but since the recent deepening of the river Oder they can proceed direct to the larger port.

The Swine, the central and shortest passage between the Stettiner Haff and the Baltic Sea, was formerly flanked by the fishing villages of West and East Swine. Towards the beginning of last century it was made navigable for large ships, and Swinemünde, which was founded on the site of West Swine in 1748, was fortiﬁed and raised to the dignity of a town by Frederick the Great in 1755.

See Wittenberg, Swinemünde, Ahlbech and Heringsdorf (Linz, 1893).

SWING, DAVID (1830-1894), American clergyman, was born of Alsatian stock in Cincinnati, Ohio, on the 23rd of August 1830. He spent most of his boyhood on a farm and earned his schooling; graduated at Miami University in 1852; studied theology at Lane Seminary; and was principal of the preparatory school at Miami in 1853-1866. He became pastor in 1866 of the Westminster Presbyterian Church (after 1868 the Fourth Church) in Chicago, which was destroyed in the fire of 1871; he then preached in McVicker's theatre until 1874, when a new building was completed. In April 1874 he was tried before the presbytery of Chicago on charges of heresy preferred by Dr Francis Landey Patton, who argued that Professor Swing preached that men were saved by works, that he held a "mod ald" Trinity, that he did not believe in the necessity of any saving religion or order of worship (see Unitarianism, &c.), and that he countenanced Unitarianism, &c. The presbytery acquitted Dr Swing, who resigned from the presbytery when he learned that the case was to be appealed to the synod. As an action was taken against the church, of which he had remained pastor, he resigned the pastorate, again leased McVicker's theatre (and after 1880 leased Central Music Hall, which was built for the purpose), and in 1875 founded the Central Church, to which many of his former parishioners followed him, in which he

SWINTON—SWITZERLAND

built up a large Sunday school, and established a kindergarten, industrial schools, and other important charities. He died in Chicago on the 3rd of October 1894. He was an excellent preacher, but no theologian. He published Sermons (1874), including most of his “heretical” utterances, Truths for To-day (2 vols., 1874-1876), Motives of Life (1875), and Club Essays (1881).

SWINTON, Joseph F. Newton, David Swing, Poet-Preacher (Chicago, 1909).

SWINTON AND PENDLEBURY, an urban district in the Eccles parliamentary division of Lancashire, England, 5 m. N.W. of Manchester, with stations on the Lancashire & Yorkshire railway. Pop. (1901), 27,695. The church of St Peter, a fine building of stone with a lofty western tower, was erected from the designs of Sir Gilbert Scott in 1865. The Swinton industrial schools, opened in February 1846, are a fine range of tidings of the West, the kitchen ranges), and earthenware manufactures. The town was formerly renowned for its Rockingham ware. A free warren was granted to Swinton by Henry II.

SWITCHBACK, a form of pleasure railway, built over alternate descents and ascents, the train or car first gathering momentum by running down a incline, and surmounting by means of this a lesser ascent. Switchbacks were originally merely an imitation, using cars upon wheels, of the sledge-coasting courses of Russia, and were indeed named by the French montagnes russes. They were introduced in Paris in 1816, but soon disappeared in consequence of several serious accidents. About 1880 they again became popular both in Europe and America. A variation of the switchback, though lacking its essential principle of climbing by means of momentum, is the water-chute, an imitation of the Canadian toboggan-slide, in which cars built in the shape of boats glide down steep inclines into artificial lakes at their bases. This is popularly called “shooting the chutes.” A further variation is “looping the loop,” in which a heavy car on wheels, or a bicycle, starting at a considerable altitude, descends an incline so steep that sufficient momentum is accumulated to carry it completely round a track in the form of a perpendicular loop, in the course of which journey the occupants or rider, while crossing the top of the loop, are actually head downwards. Later it was made even more dangerous by taking out part of the top of the loop, so that the car or bicycle actually passes through the air across the gap.

SWITCH PLANTS, a botanical term for plants, such as broom, with leaves very small or absent, and slender green shoots.

SWITHIN (or Swithin), ST (d. 862), bishop of Winchester and also the saint of Winchester Cathedral from the 10th to the 16th century. He is scarcely mentioned in any document of his own time. His death is entered in the Anglo-Saxon Chronicle under the year 862; and his signature is appended to several charters in Elmore’s Codex diplomaticus. Of these charters three belong to 833, 838, 860-862. In the first the saint signs as “Swithinus presbyter regis Egberti,” in the second as “Swithinus diaconus,” and in the third as “Swithinus episcopus.” Hence if the second charter be genuine the first must be spurious, and is so marked in Elmore. More than a hundred years later, when Dunstan and Ethelwold of Winchester were inaugurating their church reform, St Swithun was adopted as patron of the restored church at Winchester, formerly dedicated to St Peter and St Paul. His body was transferred from its almost forgotten grave to Ethelwold’s new basilica on the 15th of July 971, and according to contemporary writers, numerous miracles preceded and followed the translation.

The revival of St Swithun’s fame gave rise to a mass of legendary literature. The so-called Vita Swithuni of Lanfranc and Wulstan, written A.D. 1080, contains a fragment of the Life; and all that has in later years passed for authentic detail of St Swithun’s life is extracted from a biography ascribed to Gotzelin, a monk whose name occurs amongst the disciples of the bishop of Swithun from 1058 to 1078. From this writer, who has perhaps preserved some fragments of genuine tradition, we learn that St Swithun was born in the reign of Egbert, and was ordained priest by Ethelbert, bishop of Winchester, and became a hermit in the king’s woods, which he afterwards enclosed in a garden, and finally became the abbot and founder of the monastic houses which subsequently took its name. He seems to have been a learned and holy man, and was one of the first monks to be consecrated by Archbishop Ceolnoth. In his new office he was remarkable for his piety and zeal in building new churches or restoring old ones. At his request Ethelwulf gave the tenth of his royal lands to the Church. His humility was such that he made his diocesan journeys on foot; and when he gave a banquet he invited the poor and not the rich. He built near the eastern gateway of his cathedral city a bridge whose stone arches were so strongly connected together that, according to Ethelwulf, bishop of Swithun, they are a fine range of cataracts; and he marked the stone facing of the bridge with his name. He was buried in his cathedral, and his tomb was visited by multitudes 287; and Ethelwulf commemorated him as the patron of Winchester, appointing a bishop of that see. He retired to the hermitage in the grounds of his cathedral, and was the first Englishman who built himself a monastery.

SWITZERLAND, a republic of central Europe, comprising the Swiss Confederation, and bounded N. by the
German Empire, E. by Austria (except where the principality of Liechtenstein intervenes), S. by Italy, and W. by France.

Physical Description.—Switzerland extends between the parallels 43° 49' 2" and 47° 48' 32" lat. (Greenwich) and the meridians 5° 57' 26" and 10° 29' 40" long. (Greenwich). It forms an irregular quadrilateral, of which the greatest length from east to west is 226 m., and the greatest breadth from north to south is nearly 137 m. (136°). It has, however, no proper physical unity, as it consists of a number of small districts, differing from each other widely in language, religion, ethnology, customs, &c., but bound together in a political alliance, made originally for common defence against a common foe. It is therefore an artificial land, just as its inhabitants form an artificial nation, though nowadays it is becoming more homogeneous in both respects. Its political boundaries thus do not coincide with those of nature. The entire canton of Ticino is south of the Alps, as are the valleys of Simplon (Valais), Mesocco, Bregaglia, Poschiavo and Münster (all in the Grisons); the whole canton of Schaffhausen and part of that of Basel are north of the Rhine, while a large part of the Grisons lies to the east of the Rhine basin, and Porrentruy is far down on the western slope of the Jura. But it is to be noted that all these exceptional cases were outside the limits of the Swiss Confederation up to 1798. Putting them aside, the physical geography of Switzerland may thus be described—

1. On the south runs the main chain of the Alps (q.v.), which is joined, at the Mont Dolent (12,553 ft.) in the chain of Mont Blanc, by the lower ranges that rise south of the Lake of Geneva, and which continues partly Swiss till close to the Stelvio Pass on the east.
2. To the north of this main chain there is another great range of mountains (wholly Swiss) only slightly inferior in extent and height, which starts from the hills known as the Jorat range above Lausanne, and culminates in the great snowy summits of the Bernese Oberland and of the Tödi group, before trending to the north near Coire, and, after rising once more in the Säntis group, dies away on the southern shore of the Lake of Constance.

3. The Swiss portion of the main chain of the Alps and this great northern outlier run parallel to each other from the Mont Dolent to near Coire, while for a short distance they actually unite near the Pizzo Rotondo (west of the St Gotthard Pass), parting again near the Oberalp Pass (east of the St Gotthard). Between these two great snowclad ranges flow two of the mightiest European rivers, the Rhine towards the west and the Rhone towards the east, their headwaters being only separated by the tangled mountain mass between the Pizzo Rotondo and the Oberalp Pass, which sends the Reuss towards the north and the Ticino towards the south.
4. To the north of this great northern outlier rises the Jura range (q.v.), really a huge spur of the Alps (with which it is connected by the Jorat range), while between the northern outlier and the Jura extends what may be called the plains or "plateaux" of Switzerland, consisting all but wholly of the undulating valley of the Aar (below Thun) with its numerous affluents. To that river valley we must add the valley of the Thur (a direct affluent of the Rhine), that lies between the Aar basin and the Rhine basin (the Lake of Constance).

We may thus roughly describe Switzerland (as it exists at the present time) as consisting of three great river valleys (Rhône, Rhine and Aar) with the smaller one of the Thur, which all lie to the north of the main chain of the Alps and include the region between the Alps and the Jura. If we examine matters more carefully we note that the Rhône and Rhine valleys are shut off from that of the Aar (and, of course, of the Thur) by the great northern outlier of the Alps, which consists of the Bernese Oberland and Tödi Alps. Two wide and undulating valleys (Aar and Thur) and two deep cut trenches (Rhône and Rhine) thus lie on the northern slope of the Alps, to the north and south respectively of the great northern outlier of the Alps. The main chain of the Alps rises in Swiss territory to the height of 15,217 ft. in the loftiest summit or DuFourspitze (wholly Swiss) of Monte Rosa, though the Dom (14,942 ft.), in the Mischabel range, between Zermatt and Saas, is the highest mountain mass which is entirely Swiss. The great northern outlier attains a height of 14,026 ft. in the Finsteraarhorn (Bernese Oberland), while the lowest level (58 ft.) within the Confederation is on the Lago Maggiore. The highest
permanently inhabited village in Switzerland is Jul (699 ft.), at the head of the Avers valley (a tributary of the Hinter Rhine, Grisons), while the lowest is Ascona (666 ft.), on the Lago Maggiore and just southwest of Locarno.

According to the most recent calculations, the total area of Switzerland is 55,551 sq. m. (some 2,500 sq. m. less than that of Sweden). Of this 11,027-5 sq. m. (20.4%) are reckoned as "productive," forests occupying 3,990-9 sq. m. and vineyards 108.7 sq. m., the remainder, or 8,427.7 sq. m., consisting of arable and pasture land. Of the "unproductive" area of 4023.5 sq. m. (25.2%) much consists of lakes and rivers, while glaciers cover 709.7 sq. m. Approximately the Alps occupy one-sixth of this area, the Jura about one-tenth, and the "platen" the rest. Of the entire area the great cantons of the Grisons, Bern and the Valais take up 7411.8 sq. m., or nearly one-half, while if to them be added Vaud, Ticino and St Gall the extent of these six out of twenty-two cantons is 10,537.6 sq. m., or almost two-thirds of the area of the Confederation.

Not included in the total area of Switzerland are three small "enclaves" (4 sq. m. in all), Büsingen and Verenahof (both in Schaffhausen) belonging to Baden, while Campione (opposite Lugano) is Italian. Switzerland borders on many countries—France west and south-west, Italy south, Austria east (Tirol and Vorarlberg), and Germany north (Bavaria, Württemberg, Baden and Alsace). Switzerland sends its waters to four great river basins (which drain to three different seas). In the following proportions: Rhine basin, 11,159 sq. m.; Rhone basin, 2768.8 sq.; Po basin, 1561.5 sq.; and Inn basin, 663 sq. m.

The thirteen cantons which till 1798 formed the Confederation are all comprised in the Rhine basin, the ten oldest (i.e. before 1490) having still that character, while the three youngest (the Treviso, the Milanese and the Ticino) include each other, as it were, at the southwest and north-east corners of the land. But neither of these is wholly Swiss, this distinction being claimed by the next in size, that of Neuchâtel (924 sq. m.). In the Swiss Cantons of the west, the mountains are being followed by the wholly Swiss lakes of Lucerne and of Zürich. Then come Lugano, Thou, Bienne, Zug, Brienz, Morat, the Walensee, and Glarus (316 sq. m.). The Cheran basin (218 sq. m.) is in extent. Eleven of them are in the Rhine basin (also in that of the Aar), two (Maggiore and Lugano) in that of the Po, and one (Geneva) in that of the Rhone. There are no large lakes in the Swiss portion of the Inn basin, the most extensive being that of Siles (41 sq. m.). Of the smaller lakes those best known to travellers are the Daubensee (near the summit of the Gümmer), the Oeschinensee (at the foot of the Bünland Alp range) and the Mänerlence, formed by the damming up of the waters of the Great Aletsch glacier by a huge lateral moraine. Alpine tarns are innumerable.

Of the countless waterfalls in Switzerland those of the Rhine (most northern outlier) are the only really remarkable, where the case is in varying degrees with those of the Aar at the Handegg, of the Reichenbach, of Pisseevache, and particularly of the Staubbach, a mere thread of water falling clear of a cliff of great height.

The snow-clad Alps of Switzerland are really impossible to estimate the number accurately, as practically all are now in retreat, and it is not easy to say whether an isolated fragment of ice is or is not entitled to rank as an independent glacier. "Proper" glaciers are considered as such when they have a lateral extent of eighty yards, or more, and a height of fifty feet, or more, above the bed of the valley. Yet their distribution is very unequal, for eleven cantons (just one-half of the Confederation) have none. The Valais heads the list with 77-3, while the Grisons has 25, and the Uri (44.3), Glarus (15.9) and Ticino (13.1). The five others (Unterwalden, Vaud, St Gall, Schwyz and Appenzell) boast of 13-3 all together. The three longest glaciers in the Alps are all in the greatest canton (Bern): the Glarus (164 m.), the Fiescher and the Unteraar (each 10 m.). In the main chain the Gorner (91 m.) is the longest. Of glaciers covering an area of over 6 sq. m. no fewer than 17 are in Switzerland, as against two each in the French portion of the chain of Mont Blanc and in the Eastern Alps.

Covering 21.2% (3390-99 sq. m.) of the total area of Switzerland. Of the six most extensive cantons five are also at the head in the matter of forests: Bern (594 sq. m.), the Grisons (503), Vaud (320), the Valais (297.4) and Ticino (267.2). St Gall (157) cut a like respectable figure. The only other cantons with over 100 sq. m. are Lucerne (120.4), Fribourg (119) and Soleure (111.3), the lowest place being taken by Basle (4.9). The timber growing area belongs to the communities or private corporations, while 28.3% is in the hands of private individuals (much of this having become private property in the time of Napoleon I.), but only 4.5% is included in the property of the forest corporations of many monasteries. The cantons own 94.3% of the forest area in the Valais, private individuals 78.8% in Lucerne, and the state 9.7% in the Schaffhausen. The great cantons and the Jura cantons are the most wooded in proportion to their area, while at the other end of the scale are the towns of Geneva and Basel, and the barren canton of Uri. The great floods of 1832, 1852 and 1868 drew attention to the negligent administration of the forests, considered specially as a protection against damage due to the forces of nature. A forestry department was created in the polytechnic school in Zürich when it was opened in 1855. The Federal Constitution of 1841 (art. 24) handed over to the Confederation the oversight of the forests "in the high mountains," this being interpreted to mean the Alps with their spurs, but not to include the Jura, and a law of 1874 has regulated the action of the cantons in respect of the woods. During this period the efforts of the cantons, to reforest districts where the trees had been recklessly cut down, and to ensure the proper administration of forests generally.

The greater part of Switzerland is occupied by the belts of folded rock which constitute the Alps and the Jura (q.v.). The central plain, however, is covered by nearly undisturbed deposits (pleistocene and glossose), which have been laid down, so to speak, by the glaciers and have been the subject of further deposition by glacial, alluvial and other accumulations of later date. Both the Oligocene and the Miocene beds are, for the most part, of fresh-water or brackish-water origin, but the middle of the Miocene series (between marls and sandstones) is believed to have included, when the Alps were covered by the sea. When these formations were worn down the glaciers of the Mediterranean spread up the valley of the Rhone. It reached its maximum extension during the middle portion of theertiary period, when it appears to have stretched continuously along the outer Alps from the Adriatic to the Swiss territory, while in Italian Switzerland winter lasts only three months, at Glarus (1578 ft.) it lasts four, in the Engadine (9945 to 4360 ft.) six, on the St Gotthard (6956 ft.) eight, on the Great St Bernard (8111 ft.) nine, while on the St Beatus (6966 ft.) it lasts eleven months. The highest mean annual temperature (53°F.) in Switzerland is naturally that at Lugano (900 ft.), while at Bevers (6510 ft.), Upper Engadine 55°F., or 13°F. and at Zermatt 50°F. While the highest in summer is 77°F., an immense difference. At Montreux the annual mean is 50°F., at Sion, Basel, Geneva and Coire about 49°F., at Zürich 48°F., at Bern and Lucerne 47.5°F., at St Gall 45°F., at Davos 37-5°F., at Sils Maria 34.5°F. and on the Great St Bernard 29°F. Of course many factors, such as the shape of the ground, the sheltered position of the place, the degree of exposure to sunshine, counterbalance the mere height at which the town is situated.

The snow-clad Alps of course have the heaviest rain or snow-fall in Switzerland, this being estimated at 89-7 in. per annum. The greatest fall is at Davos Pass (6765 ft.), while the lowest (21-7 in.) was at Sierre (1767 ft.). At Lugano the average annual rainfall is 65-4 in., on the Great St Bernard 48-7 in., at Lucerne 45-6 in., at Montreux 42-6 in., at St Gall 37 in., at Davos 37-5 in., at Sils Maria 34-5 in., and on the Great St Bernard 29-7 in. Of course many factors, such as the shape of the ground, the sheltered position of the place, the degree of exposure to sunshine, counterbalance the mere height at which the town is situated.
Aar valleys are very fertile, the two great trenches between the main chain and its north outlier, though warm, are less productive, as the water comes from the rivers and not from the skies.

People.—The first estimate of the population of Switzerland with any pretence to accuracy was that of 1817, which put the number at 1,687,900. The first regular census took place in 1836 to 1838, but was therefore not synchronous, while it was also not very systematic—the number was put at 2,190,926. That of 1850 was better organized, while in 1860 the census was really conducted and had the result that of 1888 for practical reasons. The following was the number of the population usually resident (the number of those actually present was also taken, but all detailed subdivisions refer only to the residents): in 1850, 2,302,740; in 1860, 2,510,404; in 1870, 2,655,001; in 1880, 2,831,787; in 1888, 2,917,754; and in 1900, 3,315,443. The density per square mile was as follows: 150 in 1850; 157 in 1860; 150 in 1870; 177 in 1850; 152 in 1888; and 207 in 1900. The increase in the whole of the country from 1850 to 1900 was 39%. Thirteen cantons showed an increase greater than this average, the rest being moderate. In Bern the increase of the towns did not counterbalance the diminution in the country districts. The nine counties which increased above the average rate did so either owing to special circumstances (e.g. the construction of the Simplon railway in the Valais), or because their industries were very flourishing (e.g. St Gall), or because they contain great towns (e.g. Zürich). The highest rates of increase were shown by Geneva (107% increase) and the half canton of Urban Basel (278% increase). As to the actual distribution of the population, the Alpine regions are the sparest generally (with the exception of the Outer Rhone valley, that of the Jura is a vast region in which a high ratio, while the densest region of all is the Swiss plateau. The strong attraction of the towns is shown by the facts that between 1850 and 1900 the population of the nineteenth nearly tripled, while in 1900, of the 187 "political districts" in Switzerland 41 showed a decrease, and they were all exclusively rural.

The shifting of the population within the country is also proved when we note that in 1850 but 36.5% of the Swiss citizens inhabited their commune of birth, though the proportion was 64% in 1850. If we consider the different cantons, we find that in 1850, 59.7% in 1850 but 26.4% lived in another commune within their canton of birth, while 18.4% (as against 6.6% in 1850) dwelt in a canton other than their canton of birth. To sum up, in 1850, out of the 25 cantons, 12 remained republican and 18 had a majority of citizens living in their commune of birth, while in 1900 the number was but 11, and those all rural cantons. Of the 3164 communes (or civil parish) in the Basel, 1827 had a majority of citizens, while 3862,000, while 20 had under 50 inhabitants. If we look at the height of the communes above the sea-level, we find that there were but 3 (with a population of 465 souls) above 1900 metres (2986 ft) and 132 below 200 metres (656 ft). The communes enclosed by a perimeter of 1000 metres (3280 ft) and 300 metres (984 ft). The number of inhabited houses rose from 347,327 in 1850 (the number was not taken in 1850) to 434,084 in 1900, while that of separate households mounted from 485,087 in 1850 (328,105 in 1860) to 572,920 in 1900. The non-Swiss element of the population increased from 3% in 1850 to 11% in 1900, and its number from 71,570 in 1850 to 383,424 in 1900. The first two are the most numerous, next in order are Italians, French, and Austrians. In 1900 there were 3,535 British resident in Switzerland, and 1,595 citizens of the United States. Of course most of the non-Swiss are found in the cantons or in rural districts where any great railway line is being constructed.

The emigration of Swiss beyond seas was but 1691 in 1877, though it rose in 1883 to 15,802 (the maximum as yet attained). Then the number retired still to 1,303, and 1,305 respectively, but the Jews increased from 3% in 1850 to 4% in 1900—the remainder (other religions or none) being 2% in 1860 (not reckoned separately in 1850) and in 1900. Ten and a half cantons had a majority of Protestants, whereas the "Catholics" have the upper hand. The same proportion prevailed in 1850, save that then Geneva had a Protestant majority, whereas in 1870 already the balance had shifted, owing to the number of immigrants from France and Italy.

As to languages habitually spoken, Switzerland presents a very varied picture. The Federal Constitution of 1848 (art. 106) and 1874 (art. 116), German, French and Italian are recognized as "national languages," so that debates in the Federal parliament are held almost equally in all three. The use of French is, of course, limited to the departments founded for the "French" population, and are not even in the majority (which is German) in the Grisons. Of the other 21 cantons, all have a German-speaking majority except Fribourg, Vaud, the Valais, Neuchâtel and Geneva, and Italian in Ticino. Since the census of 1860, when detailed inquiries as to language were made for the first time, there has been a certain amount of shifting, as is shown by the following figures (as in 1875 and 1893, while 55.7 for 1906): 71.4 in 1888 and by 69 8-9 in 1900; the figures for French are respectively 21.4, 21.8 and 22, and for Italian 5.7, 5.3 and 6.7; while Romonch fell from 1.4 to 1.2 and 1.2%. Other languages were 2, 2 and 3%. Thus in 1900 there were nearly 70% of German-speaking persons, as against nearly 30% who spoke one or other of the Romance tongues. The most interesting cases are the cantons of Fribourg (g.) and the Valais (g.), in which French is advancing at the expense of German.

Chief Political Divisions and Towns.—When considering Switzerland it must never be forgotten that, strictly speaking, the only political "divisions" are the 187 "districts" into which the cantons are divided (Bern has 30, Vaud 19 and St Gall 15, no others having over 15) These are administrative districts, created for political purposes. The cantons themselves are not "divisions" but sovereign states, which have formed an alliance for certain purposes, while they are built up out of the 3164 "communes," which are really the political units. Of these, the 310 canton-wise divided—130 from Bern into Obwalden and Nidwalden, and Appenzell (since 1597) into the Outer Rhones and the Inner Rhones, while Basel (since 1853) forms urban Basel (the city) and rural Basel (the country districts). The Swiss political capital is Bern (by virtue of a Federal law of 1848), while the Federal Supreme Tribunal is (since its foundation in 1874) at Lausanne, and the Federal Polytechnic School (since it was opened in 1855) at Zürich.

In 1900 there were 19 towns in Switzerland which had a population exceeding 10,000 souls, all having increased very much within the 50 previous years. The following are the six largest, the figures for 1850 being enclosed within brackets: Zürich, 150,703 (35,483); Basel, 109,161 (27,844); Geneva, 104,795 (23,127); Bern, 64,227 and 18,902; Lausanne, 49,903 (17,103), and La Chaux de Fonds, 35,965 (15,650). Thus Geneva was first in 1850, but only third in 1900. Thirteen of these nineteen towns are cantonal capitals, though La Chaux de Fonds, Winterthur, Biennar, Tubus (practically a city within the canton of Zurich), Derno-Gall, and the two states of Vaud, have the same status. Twelve cantonal capitals (Sion, Bellinzona, Aarau, Altford, Schwyz, Frauenfeld, Glarus, Lertal, Sarnen, Stans, Appenzell and Zug) are also towns of 10,000 souls. Some of these, though over 10,000 inhabitants had in 1850 a population of 355,722, that number had swollen in 1900 to 747,205.

Communications.—The carriage roads of Switzerland were much improved and increased in number after a strong Federal government was set up in 1848, for it largely subsidized cantonal undertakings. In the course of the 19th century many splendid roads were carried over the Alpine passes, whether within or leading from Swiss territory; in the latter case within the canton of Glarus and from the Austrian State ( chiefly the Milanese). The earliest in date was that over the Simplon (1800-1857), while others were opened respectively over the Furka (7992 ft.) in 1867, to the top of the Great St Bernard (8111 ft.) in 1853, over the Grimsel (7100 ft.) in 1853, and over the Klausen Pass (6404 ft.) in 1900. The highest carriage road entirely within Switzerland is that over the Umbrail Pass (8242 ft.), opened in 1901, and leading from the Swiss upper Münter valley to close to the Stelvio.

The first Swiss lake over which a steamer plied regularly was that of Geneva (1823), followed by Constance (1824), Lago Maggiore (1826), Neuchâtel (1827), Thun (1835), Lucerne (1835), and

The cantons are—Aargau, Appenzell, Basel, Bern, Fribourg, Geneva, Glarus, Graubunden, Lucerne, Obwalden, Payerne, Schaffhausen, Schwyz, Solucore, Thurgau, Ticino, Unterwalden, Uri, Vaud, Zürich (see separate articles).
SWITZERLAND

Industries.—a. Of the Land. If we look at the annual turnover through the near-by railway, the pleasant and seductive entertainment of foreign visitors, for its gross receipts are larger than those of any other branch. It appears from the official statistics that in 1905 its gross receipts amounted to rather over £7,500,000 (as against about £5,000,000 in 1890 and rather over £2,000,000 in 1880), the net profit being nearly £1,500,000 (as against £659,000 and nearly £300,000 respectively), while in 1905 the capital invested in railways was nearly £12,000,000 (as against £7,000,000, £12,750,000 respectively). In 1905 there were in Switzerland 1924 hotels (of which 402 were in Bern and 358 in the Grisons) specially built for the accommodation of foreign visitors, containing 12,000 bedrooms and 35,000 beds. In 1894 and 1890 are 1905 and 1906 occupied in the tourist houses for 68,534 and 58,137, and 23,997 and 16,022 respectively). Part of this increase is due to the fashion of going to a better location for their holidays, tourism, skiing and camping. Of the actual productive soil about two-thirds is devoted to arable or pasture purposes, but the latter branch is by far the more important, occupying about 83% of this two-thirds, for Switzerland is much more a pastoral than an agricultural country. In 1906 the number of cattle was officially put at 1,497,904 (as against 1,349,375 in 1901 and 993,291 in 1866). In summer they are supported on the numerous mountain pastures or pastures, which are mostly level and capable of being estimated capital value of rather over £3,000,000, while in winter they are fed on the hay mow on the lower meadows or purchased from the lord of the manor. Meat and dairy foods are sold in Switzerland, the dun race (best represented by the cattle of Schwyz) and the dappled race (of which the Simme valley beasts are the red and white kind, and those of the Gruyère the black and white varietal), but to this breed is added the East Frisian of the Gruyère, while the two principal condensed milk factories (Nestlé at Vevey and that at Cham) are now united. It should be noted that the proportion of the land devoted to pastoral purposes increases, like the rainfall, from the west and north-west to the east and north-east, so that it is highest (near 90%) in Appenzell and St Gall. As regards other domestic animals, the number of swine increased from 304,428 in 1886 to 556,474 in 1896 (the maximum recorded), but in 1906 fell to 548,355. The number of goats has remained pretty steady (350,913 in 1906 to 375,482 in 1886, the maximum, 416,323, being attained in 1886), but that of sheep has decreased, falling from 2,001,443 in 1886 to 1,965,787 in 1906. It is stated that but 14% of the productive area of Switzerland is corn-growing, this proportion being rather doubled in Vaud. Hence for its food the country is largely dependent on its imports, the home supply sufficing for 153,761,231 of which 20%, mainly sugar from Brazil, are procured from abroad. Corn is grown to a certain extent, especially near Payenre in the Broye valley (Vaud) and in Ticino, while more recently beetroot has been cultivated, for the manufacture of molasses and sugar. The district of the vineyards and vineyard wines, vegetables are made into jams and concentrated foods at Lenzburg and Kemptthal, while hirschenstücker (cherry brandy) is made in Zug. Vineyards cover about 28% of the productive area of Switzerland. There are more than 2,063 vineyards and 110,000,000 bottles manufactured. Vineyards in Switzerland now cover 108,741 m. sq., though the area is steadily decreasing owing to the competition of foreign cheap wines. The total production, which has been rather constant for a long time, was valued at £21,370,000 in 1906, 9,750,000 in 1905. Among the best Swiss wines are those of La Côte, Lavaux and Yvorne (all in Vaud), and Muscat, Fenand and Vin du Glacier (all in the Valais). Those grown near Neuchâtel, at the northern end of the lake of Zürich, near Baden (Aargau), and along the Swiss bank of the Rhine, are much esteemed. The value of raw mineral products of Switzerland the most important is asphalt, which is worked by an English company in the Val de Travers (Neuchâtel). Various minerals (even including gold and copper) are worked in Switzerland, the best known are Lenzburg (Delémont), copper (Val d'Anniviers) and argentiferous lead (Lötschberg). True coal is wholly absent, but lignites occur here and there, and are sometimes worked (e.g. at Käppach, Zürich). An early industry on the limestone deposits in the Neuchâtel Salt in first found at Bex (Vaud) in 1544, and the mines are still worked. But far more important are the saline deposits along the shores of Lake Geneva and near Bischofszell, the one being the famous Aar, which were discovered at Schweizerhalle in the year 1836, at Kaiseraugut in 1844, at Rheinfelden in 1845 and at Ryburg in 1848. Marble, sandstone and granite are worked in various spots and are mainly used for the ornamentation of churches and public buildings, and are much used for the manufacture of various kinds of cement. There are said to be 620 mineral springs in Switzerland, the best known being those at Baden (Aargau) and at Schinzach (both sulphur), Schutz-Tann and St Moritz. Laugh-bath, Reussberg, Pfäfers, Leukerbad and Weissenburg. The most important slate quarries are those in the canton of Glarus. The relative importance of the different industries concerned with the land, is derived from the census taken in 1900 as to the occupations of the inhabitants. No fewer than 1,035,010 (about one-third of the total population) were engaged in pastoral or agricultural pursuits, as against 19,334 engaged in the carving of stone. The most important markets are those of the forests, 12,735 in the vineyards and 12,323 in extracting minerals (of these 8004 were employed in stone or marble quarries). b. Manufactures.—The same census also shows the relative importance of the various manufactures. This is calculated from the number of registered persons employed in each line of business. In the textile industries 270,114 (of which 88,457 were in the silk branch and 63,853 in that of cotton), watchmaking 115,617, embroidery 89,558, besides 74,148 engaged in the manufacture of machinery. The most important industries are the spinning, weaving and spinning of cotton, watchmaking and some minor industries are carried on in the textile industries. The textile industries are by far the most important in Switzerland, almost 20% of the population being engaged in them. This branch (this branch was revived by the Protestants exiles from Italy in the 16th century) and cotton, while St Gall, Appenzell and Thurgau are mainly devoted to embroidery, and the silk branch and the embroidery industry were extensively engaged and cutaneous and machine tools. The industry was first established in Geneva since the end of the 16th century, and spread in the early 18th century to the Neuchâtel portion of the Jura (centre La Chaux-de-Fonds and Le Locle), which were chiefly made at St Croix in the Vaud section of the Jura, while Geneva was, for its jewelry and goldsmiths' work. The growth of the manufacture of machines is much more recent, having originally been a mere adjunct of the textile industry, and the development is due to the increasing demand of England. Its centres are in and around Zürich, Winterthur, St Gall and Basel. Among other products and industries are chocolate (Suchard, Cailler, Sprüngli, etc.), soap, rubber goods, milk products, harness and saddles, machine tools, watches and other watchmaker's industry, and chemical industry. There are some 132,000 persons engaged in commerce. The general increase of the trade is from 1848, customs duties within the land were abolished, while moderate duties only were levied on imports, the sum increasing as the articles came more or less within the category of luxuries, but being lowest on necessaries of life. Down to 1870 Switzerland was all but entirely on the side of free trade. Since that time it has been becoming more and more protectionist. This change was due in part to the increased tariffs levied in Germany and France, and in part to the strong pressure exerted by certain branches of the Swiss manufacturing industries, while treaties of commercial preference have been made with divers countries. Hence in 1903 the number of people engaged in commerce fell to 57,850,000—other words, the unfavourable balance of trade had increased from 10,000,000 in 1895 to 16,250,000 in 1905. The increase during the same period in the case of the four great articles of export (cotton, wool, silk and iron) was from £2,530,000 to £8,500,000 to rather over £10,000,000, embrodiery from nearly £3,000,000 to £5,000,000, watches from £1,500,000 to £5,250,000, and machinery from rather £1,000,000 to £2,500,000.

Government.—The Swiss Confederation must be carefully distinguished from the 22 cantons of which it is composed, and which are sovereign states, save in so far as they have given up their rights to the Federal government. These cantons themselves are built up of many political communes, or Gemeinden, or civil parishes, which are the real political units of the country (and not merely local subdivisions); for any one desiring to become naturalized a Swiss must first become (by purchase or grant) a member of a commune, and then, if his burgershript of the commune is confirmed by the cantonal authorities, he obtains also, simultaneously, both cantonal and Federal citizenship.

a. Now in Switzerland there are 3164 political communes (municipalités ou Einwohnergemeinden). These are composed of the areas situated over which the canton recognizes a peculiar character and resident in the commune for at least three months. The meeting of these persons is called the assemblée générale or Gemeindeversammlung, while the executive council chosen by it is the conseil municipal or Gemeinderat, the chief person in the commune (elected by the larger meeting) being termed the syndic or maire, the Gemeindepräsident or the Gemeindeammann. This kind of commune includes all Swiss residents (hence the German name) within its territorial limits, and has practically all powers of management of local affairs, including the carrying out of cantonal and Federal laws or decrees, save and except matters concerning the jurisdiction devolved on the Federal government.

This class of commune dates only from the time of the Helvetic republic (1798–1802), and its duties were largely increased after the liberal movement of 1830; the care of the highways, the police, the schools, the administration of the poor law being successively handed over to it, so that it became a political body. As regards Swiss citizens belonging to cantons other than that in which they reside, the Federal Constitution of 1848 (art. 41) gave them rights of voting there in cantonal and Federal matters, but not in those relating exclusively to the commune itself. This provision was revoked by the people in 1874, and cantons have to choose one of three solutions to enforce this principle; as those named above (établis ou Niedergelasenen—that is, permanent settlers) all voting rights, cantonal and communal (save as below), the two last named after a stay of three months. Temporary residents being Swiss citizens (e.g. labourers, servants, students, officials not being communal officials) are called résidents or Aufenthalter, and are in most cantons considered to be as such incapable of voting in communal matters until after a residence of three months, though some cantons require a longer sojourn. Foreign residents are included under this class of Aufenthalter.

Communes bourgeoises or Bürgergemeinden, now principally of historical interest, having for the most part gradually merged with the other class of communes, were originally simply the communities that dealt with the management of the "fiefs" or the "manor," perhaps usus agrorum (the old Burgergemeinden (the burghers of which only have rights of user over the common lands) was very delicate, and has been settled (if settled at all) in various fashions. In some cases the older communes simply merged with the newer, the ownership of the common lands thus passing from one to the other class. In other cases the Bürgergemeinden still exist as distinct from the "political communes," but solely for purposes (enjoyment, management, &c.) relating to the common lands, and thus form a sort of privileged community inside the larger and now more generally important community. In some cases the common lands have been divided in varying proportions between the two classes of communes, the Bürgergemeinden thus continuing to exist solely as regards that part of the common lands which they have retained. In other cases the common lands, whether before or after the reforms of 1802, passed to the possession of the burghers, who form a close corporation, the revenues of which are enjoyed by the members as such, and not as citizens—in short are subject to no public obligations or burdens save rates and taxes.

b. The twenty-two cantons (three are subdivided—Unterwalden, Appenzell and Basel—into two halves) are divided into "administrative districts" (18 in number), which are ruled by prefects, in the French fashion, appointed by the cantonal authorities. These are the true local divisions in the country. Each canton has its own legislature, executive and judiciary. The older cantons have in some cases (Uri, Unterwalden, Appenzell and Glarus) preserved their ancient democratic assemblies (or Landesgemeinden), in which each burgher appears in person, and which usually meet once a year, on the last Sunday in April or the first Sunday in May, always (weather permitting) in the open air. These annual assemblies elect annually a sort of standing committee, and also the chief magistrate or Landammann, as well as the judiciary. In the other eighteen cantons the legislative body (Grande or general council) is composed of representatives chosen by the canton, voting by population, varying in each canton, to the population. They are thus local parliaments rather than mere county councils. The executive (Regierungsrat or conseil d'état) is elected everywhere (save Fribourg, the Valais and Vaud) by a popular vote, this plan having gradually superseded election by the cantonal legislature. All the cantons (save Fribourg) have the referendum and initiative, by which the electors can exercise control over their elected representatives. The cantonal judiciary is chosen by the people.

In 1848 the Federal government was reorganized according to the plan adopted in the United States, at any rate so far as regards the legislature (Bundesversammlung or assemblee fédérale). This is composed of two houses: (1) the Ständerat or conseil des états, to which each canton, great or small, sends two representatives (generally chosen for varying terms by the people, but, in 1907, still by the cantonal legislature in Bern, Fribourg, Neuchâtel, St Gall, the Valais and Vaud), this house being like the American Senate; (2) the Nationalrat or conseil national, composed of representatives (at present 167 in number) elected within the cantons in the proportion of 1 to every 20,000 (or 10,000 persons) of the population, and holding office for three years, before the expiration of which it cannot be dissolved. The two houses are on an absolutely equal footing, and bills are introduced into one or the other simply because of reasons of practical convenience. The Federal parliament meets, at least, once a year, in Bern, the Federal capital. The Federal executive (Bundesrat or conseil fédéral) was set up in 1848 and is composed of seven members, who are elected for three years by the two houses of the Federal legislature, sitting together as a congress, but no two members may belong to the same canton. The Federal president (the chairman of the Federal council), and the vice-president, are not elected for more than one term, and in the case where the president dies or is removed from office, the vice-president succeeds to the presidency. But, in 1907, the Swiss people adopted the "circle system," by which, if the Federal president should die or be removed from office, his place is filled by a member of the Federal council, not elected for the purpose. To avoid some of these inconveniences "political communes" were set up, consisting practically of all Swiss permanent residents. By the constitution of 1848, those between these and the old Bürgergemeinden (the burghers of which only have rights of user over the common lands) were very delicate, and has been settled (if settled at all) in various fashions. In some cases the older communes simply merged with the newer, the ownership of the common lands thus passing from one to the other class. In other cases the Bürgergemeinden still
and vice-president of the Federal tribunal. Its seat is at Lausanne. Its jurisdiction extends to disputes between the Confederation, the cantons, and private individuals, so far as these differences refer to Federal matters. An appeal lies in some cases (not too clearly distinguished) to the Federal council, and in some to the two houses of the Federal legislature sitting together. As to the referendum and initiative (whether as to the revision of the constitution or as to bills) see REFERENDUM.

It was natural that, as the interests of the Christian cantons and those of the French-speaking district grew closer together, there should arise the idea of a Federal code as distinguished from the manifold cantonal legal systems. The Federal Constitution of 1874 conferred on the Federal authorities the power to legislate on certain defined legal subjects, and advantage was taken of this to revise and codify the Law of Obligations (1881) and the Law of Bankruptcy (1886). The success of these attempts led to the adoption by the Swiss people (1898) of new constitutional articles, extending the powers of the Federal authorities to the other departments of civil law and also to criminal law. Drafts prepared by commissions of specialists were slowly considered during nearly two years by the two houses of the Federal parliament, which finally adopted the civil code on the 10th of December 1907, and it was expected that by 1912 both a complete Federal civil code and a complete Federal criminal code would come into operation.

Before 1848 there was scarcely such a thing as Federal finances for there was no strong central Federal authority. As the power of those authorities increased, so naturally did their expenditure and receipts. In 1849 the receipts were nearly £130,000, as against an expenditure of £260,000, and each canton had raised rather over £1,250,000, while in 1883 they just overtopped £2,000,000 sterling each, and in 1900 the receipts were just over £8,000,000, with an expenditure of nearly £4,000,000. For the two years 1906 and 1907 the receipts were £5,750,000 as against just over £5,500,000, and are the highest yet recorded. The funded Federal debt rose from a modest £150,000 in 1849 to over £2,000,000 in 1864, and rather over £4,000,000 in 1905.

By the Federal Constitution of 1848 the post office was made a Federal authority, and the first Federal law on the subject was passed in 1849 (postage stamps were introduced in the country in 1845 for an expenditure of £1,500,000 in 1877), and in 1892 the prices were taken up by public subscription in June 1906. The remaining fifth was reserved to the existing thirty-six banks in Switzerland (all founded between 1834 and 1900), which have hitherto enjoyed the right of issuing notes. It was stipulated that within three years of the opening of the National Bank all notes issued by these thirty-six banks must be withdrawn, and many had by 1907 taken this course in anticipation of it.

There is no "established Swiss Church" recognized by the Federal Constitution, but there may be one or more "established churches" in any canton. The Federal Constitution of 1874 guarantees full religious freedom, but contrary to morals and the public peace, as well as exemption from any compulsory church rates (arts. 49 and 50). But it repeats, with fresh pricks (art. 51), the provision of the Constitution of 1851, that the public authorities are forbidden to settle in Switzerland, extending this prohibition to any other orders that may endanger the safety of the state or the public peace. It also introduces a new article (art. 188) providing that if any new dioceses are formed or new monasteries or the re-establishment of old ones, and also a new clause (last part of art. 50) by which the erection of new bishoprics on Swiss soil is subject to the approval of the Federal authorities. This last article is inconsistent with the principles of the Constitution of 1874 and the rest of the exceptional legislation to the "Kulturrampf" which raged in Switzerland in 1872-1874. The Protostats form rather over three-fifths of the population, but have the majority in only 22 cantons only. In the German-speaking districts they are Zwinglians, and in the French-speaking cantons Calvinists, though in neither case of the original and orthodox shade. The Protostats alone are "established" in the Outer Rhones of Appenzell; while the Romanists alone are "established" in 71 cantons (Lucerne, St Gall, Unterwald, and the Inner Rhones of Appenzell), but only jointly in the 3 other cantons (Fribourg, St Gall and Solouere) in which they are in a majority. In June 1907 Geneva decided on the complete separation of church and State, and now 27 cantons, including the Old Romanists, are "established church" at all (previously it had two—Protestants and Catholic Churches). In the other 21 cantons, the Protostats and Romanists are jointly "established" in 113, as are the Prot-
religious instruction in the school, this being compulsory on the children professing the religion that is in the majority in that particular commune—consequently a Protestant teacher would never be appointed to a Catholic school. The teacher occupies an hour (always at the beginning of the school hours) three a week, while special dogmatic instruction is imparted by the pastor, outside the school-house as a rule, or in a room especially set apart for this purpose. The teacher is elected by the cantonal school commission, while the religious teaching in school is based on a special "school Bible," containing short versions of the chief events in Bible history. The exact curriculum (which is the same for all schools) is fixed by the respective canton, and during which the school must be open annually, but the precise reparation of these is left to the local Schulkommission. The attendance registers kept by the teachers are subjected to audit by the Schulkommission, and the measures against truant children or negligent parents by means of a written warning, followed (if need be) by a summons before a court. The treasurer of the Schulkommission receives and distributes the money provided by the canton, including the idea of making the primary schools wholly dependent financially on the Confederation and also of the communes, or of benevolent private individuals. The school hours are as a rule four hours (from 7 a.m. in summer and 8 a.m. winter) in the morning (in the winter) three hours in the afternoon, but on two afternoons in the week there is a sewing school for the girls, the boys being free. There are no regular half-holidays. Private schools are permitted, where the teacher must hold a certificate of efficiency as in the state schools, must adopt the same curriculum, and is subject to the by-laws made by the Schulkommission. On the other hand he is not bound by any rules, may open and close his school at will, and examines each school (of either class) annually and reports to the cantonal educational authorities, who point out any deficiencies to the local Schulkommission, and cause the school to be examined by paid inspectors, but do not the money contributions (from any source) depend on the number of attendances made, though of course they are more or less in proportion to the number of scholars attending. The idea of making the primary schools wholly dependent financially on the Confederation has obvious consequences, but a first attempt was defeated in 1882, and the scheme is still opposed, mainly on the ground that it would seriously impair the principle of cantonal sovereignty, and immensely strengthen the power of the Federal educational authorities. By the law of 1903 the quota of the Federal subvention was limited at the expense of the canton of the poorer ones—an extra twopence was added.

b. The secondary schools are meant on the one side to help those scholarcs of the primary schools who desire to increase their knowledge though without any idea of going on to higher studies, and on the other to prepare certain students for entrance into the middle schools. The attendance everywhere is optional, save in the city of Basel, where it is compulsory. These schools vary very much from canton to canton. The course of studies extends over two to four years, and students are admitted at ages from ten upwards. The curriculum includes the elements of the classical and modern languages, of mathematics, and of the natural sciences. They receive no Federal subvention, but are supported by the cantons and the communes. In 1905 the cantons contributed £20,000 less than the expenditure of the total amount of £84,000.

c. Under the general name of middle schools (Mittelschulen or écoles moyennes) the Swiss include a variety of educational establishments, which fall roughly under two heads.

1. Technical schools (like those at Bienna and Winterthur) and schools for instruction in various professions (commerce, agriculture, forestry, and the training colleges for teachers).

2. Grammar schools, colleges and cantonal schools, which in some cases prepare for the universities and in some do not.

The expenses of both classes fall mainly on the cantons (in 1905 about £524,000), school fees from the parents (who pay an income tax (including certain departments of the second) receive a grant in aid from the Confederation—in 1905 about £84,000.

d. As regards the higher education the Federal Constitution of 1848 provides that the cantons are to erect schools of science, besides the existing Federal Polytechnic School (opened at Zürich in 1855, having been founded by virtue of art. 22 of the Federal Constitution of 1848), a Federal university (this has not been done) and other establishments for the higher education (see above). This clause would seem to authorize the Confederation to make grants in aid of the cantonal universities, but as yet this has not been done. The University at Berne (1835), which is supported by the cantons and Neuchâtel (established 1840–1848, re-founded in 1866, and raised from the rank of an académie to that of a university in 1909), is being called a university, and others are being established. In general they each (save Sion, of course) have four faculties—theology, medicine, law and philosophy. Fribourg and Neuchâtel both lack a medical faculty, while Zürich and Bern have distinct faculties for veterinary medicine, and Zürich a special one for dentistry (in Geneva there is a school of dentistry), while Geneva and Lausanne have schools of pharmacy. 

Army.—The Swiss army is a purely military force, receiving only periodical training (so far as regards men between 20 and 48 years of age), based upon the principle of universal compulsory personal military service. Till 1848 the cantons alone raised, armed, equipped and trained all military units and nominated the officers. By the Federal Constitution of 1848 (art. 20) the Confederation was entrusted with the training of the engineers, artillery and the cavalry, with the education of instructors for all other arms, and with the higher training of all army and navy officers; it was also empowered to found military schools, to organize general military manoeuvres, and to supply a part of the war matériel. The Confederation, too, was given the supervision of the training of the infantry, as well as the furnishing, the construction and the maintenance of all war matériel, which the cantons were bound to supply to the Confederation. The Federal Constitution of 1874 marked an advance on that of 1848 as to the following points. The principle of universal military service and the organization of the Federal army were developed according to the proportion of the population capable of bearing arms (in contradistinction to the 1848 system, art. 19, of fixed contingents in the proportion of 3 to every 100 men of the population of each canton); the entire military training and arming of these men and the cost of their uniform and equipment were taken over by the Confederation, which, too, supervised the military administration of the cantons. The uniform, equipment and weapons of the men were to be free of cost to them, while compensation was due from the Confederation to the families of those killed or permanently injured in the course of their military service, as well as to the invalids themselves. Thus remained to the cantons the raising of all the infantry units and of most of the cavalry and artillery units as well as the nomination of the officers of all arms; all these acts were subject to the supervision of the Confederation and had to be in accordance with Federal laws and regulations. An attempt made in 1895 to extend still further the sphere of action of the Confederation in military matters was rejected by a vote of the Swiss people. Thus the present system rests partly on the 1874 Constitution, and partly on the new military law, passed by the Federal parliament on the 12th of April 1907.
SWITZERLAND

[HISTORY]

The Confederation has control of the Federal army and of the war matériel, the cantons being only allowed certain defined rights within their respective territories. By art. 20 the limits of the Federal army are defined. After the treaty of 1877 the cantons are exempted from the provisions of art. 21. The Confederation has the sole right of legislation in military matters, but the execution of these laws is in the hands of the cantons, though under Federal supervision, while all branches of the public service, both civil and military, are in the hands of the cantons. On the other hand, the cantons supply and keep up the equipment and the uniforms of the soldiers, though these expenses are reimbursed by the Confederation and are reckoned as part of the general nomination and the promotion of the officers, belong to the cantons, subject to certain general principles to be laid down by the Confederation. Finally, the Confederation has (art. 22) the right of using or confiscating property which is needed for the protection of a canton, by which more uniformity was introduced into administrative matters and the whole system remodelled, of course according to the general principles formulated in the Federal Constitution of 1874.

The following is a bird's-eye view of the actual organization of the Swiss army. Every Swiss male citizen is bound to render personal military service between the ages of twenty and forty-eight. Certain classes are exempt, such as high Federal officials, clergy (not being military chaplains), officials of hospitals and prisons, as well as custom-house and police officials and officers of public means of communication, but in the last case only those whose services would be indispensable in time of war, e.g., post office, telegraph, telephone, railway and steamer employés (all exempted before 1897)—custom-house men, policemen and the like, as well as rural postmen, before they are exempted. Those who are totally disqualified for any reason must, till the age of forty, pay an extra tax of 6 francs a head, plus 1½ francs on every 1000 francs of their net property, and 1 franc on every 100 francs of their net income, the maximum tax that can be levied in any particular case being 3000 francs a year (property under 1000 francs and the first 600 francs of income are free from this tax, which is only levied as to its half in case of the men in the Landwehr); this tax is equally divided between the Confederation and the cantons, its total yield in 1905 being about £171,000. The cantonal authorities must in certain fixed centres their officers (chief, gunners, surgeons, etc.), who are bound, in order to submit themselves at the hands of the Federal officials to a medical examination, a literary examination (reading, arithmetic, elementary Swiss geography and history, and the composition of a short essay), and, if required, to undergo gymnastic tests (a long jump of at least 8 ft., lifting at least four times a weight of about 37 lb in both hands at once, and running about 25 yds in 26 seconds) in order to be accepted for military service, whether by stimulating bodily training or the practice of rifle shooting, in which case rifles, ammunition and equipment are supplied free—in all these cases the attendance of the lad is partially or wholly remunerated. In the next age (ages of eighteen and twenty), are required to attend a night school (in order to rub up their school knowledge) for sixty hours a winter for three years, and the last age of twenty and twenty-two, for their soldier service, but in all cases the service is paid for. The Swiss army is divided into the Landwehr (men between thirty-three and forty) and the Landsturm (men between forty-one and forty-eight). The recruits serve for different periods, the engagements varying from one to twenty years. In the Landwehr they are incorporated—infantry and engineers sixty-five days, artillery and garrison troops seventy-five days and cavalry ninety days (forty-five days in the case of Switzerland. The Swiss army is made up (according to the new law of 1907) of a staff, composed of all the commanding officers on active service from the rank of major upwards (in this as in all the following laws), the general staff, the army service corps (post office, telegraph, railways, motor cars, chaplains, police, courts of justice, secretaries, &c., and the auxiliary services), while the soldiers proper are divided into a number of classes—infantry (including sharpshooters and cyclists), cavalry, artillery (including the mountain batteries), engineers (including sappers and railway labourers), garrison troops, the medical, veterinary, (veterinary surgeons and surgeons), the commissariat and transport services (drivers and leaders of laden horses and mules). On the first of January 1907 (still under the old system) the numbers of the Swiss army were as follows: the Landwehr, 18,544 artillery and 556 engineers, and the Landsturm 93,163 (including 67,955 infantry, 4378 cavalry, 13,332 artillery and 4313 engineers)—making thus a total of 282,577 men between the ages of twenty and forty-eight years of age (17,221 infantry, 981 cavalry, 31,866 artillery and 9880 engineers). To this total must be added 44,294 men in the armed Landsturm (forty-five to fifty years of age) and 26,2038 auxiliary troops (pioneers, workmen in military camps, medical, commissariat and transport departments, police, firemen, clerks, and men at a military dépôt). The total of the Landsturm and the auxiliary services is 306,432, so that a maximum of 489,000 men is available, of which 226,648 (in the Landwehr forty-eight, and in the Landsturm fifty-five). The total expenses of the Swiss army rose from £28,000 in 1896 to £4,900,001 in 1906. Rifles are manufactured in Berne, ammunition at Lucerne, and the depot is at Schaffhausen. The remount dépôt is at Thun, which is also the chief artillerie centre of Switzerland. There is a department for military education at the Federal Polytechnic School at Zürich, and there is a special training of mechanics in general, and the other specially for officers. (W. A. B. C.)

HISTORY

The Swiss Confederation is made up of twenty-two small states, differing from each other in nearly every point—religious, political, social, industrial, physical and linguistic; yet it forms a nation the patriotism of whose members is universally acknowledged. History alone can supply us with the key to this puzzle; but Swiss history, while thus essential if we could thoroughly grasp the nature of the Confederation, is very intricate and very local. A firm hold on a few guiding principles is therefore most desirable, and of these there are three which we must always bear in mind. (1) The first is the growth of a confederation of small provinces or cantons. Swiss history is largely the history of the drawing together of bits of each of the imperial kingdoms (Germany, Italy and Burgundy) for common defence against a common foe—the Habsburgs; and, when this family have secured to themselves the permanent possession of the Empire, the Swiss League little by little wins its independence of the Empire, practically in 1499, formally in 1648. Originally a member of the Empire, the Confederation becomes first an ally, then merely a friend. (2) The second is the German origin and nature of the Confederation. Round
a German nucleus (the three Forest districts) there gradually gather other German districts; the Confederation is exclusively German (save partially in the case of Fribourg, in which after its admission in 1481 Teutonic influences gradually supplanted the Romance speech); and it is not till 1803 and 1815 that its French- and Italian-speaking "subjects" are raised to political equality with their former masters, and that the Romonosh-speaking Leagues of Raetia (Graubünden) pass from the status of an ally to that of a member of the Confederation. (3) Swiss history is a study in federalism. Based on the defensive alliances of 1291 and 1315 between the three Forest districts, the Confederation is formed by the admission of other districts and towns, all leagues with the original three members, but not necessarily with each other. Hence great difficulties are encountered in looking after common interests, in maintaining any real union; the Diet was merely an assembly of ambassadors with powers very strictly limited by their instructions, and there was no central executive authority. The Confederation is a Staatenbund, or permanent alliance of several small states. After the break-up of the old system in 1798 we see the idea of a Bundesstaat, or an organized state with a central legislative, executive, and judicial work, in Switzerland. (4) Political liberty is gradually realized in the Constitutions of 1848 and 1874. The whole constitutional history of the Confederation is summed up in this transition to a federal state, which, while a single state in its foreign relations, in home matters maintains the more or less absolute independence of its several members.

Swiss history falls naturally into five great divisions: (1) the origins of the Confederation—up to 1291 (for the legendary origin see Tell, William); (2) the shaking off dependence on the Habsburgs—up to 1394 (1474); (3) the shaking off dependence on the Empire—up to 1499 (1648); (4) the period of religious divisions and French influence—up to 1814; (5) the construction of an independent state as embodied in the Constitutions of 1848 and 1874.

1. On the 1st of August 1291 the men of the valley of Uri (homines vallis Uraniæ), the free community of the valley of Schwyz (universitas vallis de Switz), and the association of the men of the lower valley or Nidwalden (communitas hominum intramontanorum vallis inferioris)—Obwalden or the upper valley is not mentioned in the text, though it is named on the seal appended—formed an Everlasting League for the purpose of self-defence against all who should make an attack or trouble them, a league which is expressly stated to be a confirmation of a former one (antiquum confederationes formam juramento vallatam presentibus innovando). This league was the foundation of the Swiss Federation.

What were these districts? and why at this particular moment was it necessary for them to form a defensive league? The legal and political conditions of each were very different. (a) In 853 Louis the German granted (inter alia) all his lands (and the rights annexed to them) situated in the pagiis Uraniæ to the convent of Sts Felix and Regula in Zürich (the present Frauenmünster), of which his daughter Hildegarde was the first abbess, and gave to this district the privilege of exemption from all the jurisdiction save that of the king (Reichsfreiheit), so that though locally within the Zürichgau it was not subject to its county, the king's deputy. The abbey thus became possessed of the greater part of the valley of the Reuss between the present Devil's Bridge and the Lake of Lucerne, for the upper valley (Urseren) belonged at that time to the abbey of Disentis in the Rhine valley, and did not become permanently allied with Uri till 1410. The privileged position of the abbey tenants gradually led the other men of the valley to "commend" themselves to the abbey, whether they were tenants of other lords or free men as in the Schächental. The meeting of all the inhabitants of the valley, for purposes connected with the customary cultivation of the soil according to fixed rules and methods, served to prepare them for the enjoyment of full political liberty in later days. The important post of "protector" (advocatus or Vogt) of the abbey was given to one family after another by the emperor as a sign of trust; but when, on the extinction of the house of Zähringen in 1218, the office was granted to the Habsburgs, the protests of the abbey tenants, who feared the rapidly rising power of that family, and perhaps also the desire of the German king to obtain command of the St Gotthard Pass (of which the first authentic mention occurs about 1326, when of course it could only be traversed on foot), led to the recall of the grant in 1231, the valley being thus restored to its original privileged position, and depending immediately on the king. (b) In Schwyz (first mentioned in 972) we must distinguish between the districts west and east of Steinen. In the former the land was in the hands of many nobles, amongst whom were the Habsburgs; in the latter there was, at the foot of the Mythen, a free community of townsmen, of the latter as soon as it could maintain on their land in common; both, however, were politically subject to the king's delegates, the counts of the Zürichgau, who after 1173 were the ever-advancing Habsburgs. But in 1240 the free community of Schwyz obtained from the emperor Frederick II. a charter which removed them from the jurisdiction of the counts, placing them in immediate dependence on the king, like the abbey men of Uri. In a few years, however, the Habsburgs contrived to dispense with this charter in practice. (c) In Unterwalden things were very different. The upper valley of Schwyz, with its former abbey of Grossmünster, was formed part of the Zürichgau, while in both the soil was owned by many ecclesiastical and lay lords, among them being the Habsburgs and the Alsatian abbey of Murbach. Hence in this district there were privileged tenants, but no free community, and no centre of unity, and this explains why Obwalden and Nidwalden won their way upwards so much more slowly than their neighbours in Uri and Schwyz. Thus the early history and legal position of these three districts was very far from being the same. In Uri the Habsburgs, save for a brief space, had absolutely no rights; while in Schwyz, Obwalden and Nidwalden they were also, as counts of the Zürichgau, the representatives of the king, and thus could enforce their will as they chose.

The Habsburgs had been steadily rising for many years from the position of an unimportant family in the Aargau to that of a powerful clan of large landed proprietors in Swabia and Alsace, and had attained a certain political importance as counts of the Zürichgau and Aargau. In one or both qualities the cadet or Laufenburg line, to which the family estates in the Forest districts round the Lake of Lucerne had fallen on the division of the inheritance in 1232, seem to have exercised their legal rights in a harsh manner. In 1240 the free men of Schwyz obtained protection from the emperor, and in 1244 we hear of the castle of New Habsburg, built by the Habsburgs on a promontory jutting out into the lake not far below Lucerne, with the object of enforcing their real or pretended rights. It is therefore not a matter for surprise that when, after the excommunication and deposition of Frederick II. by Innocent IV. at the Council of Lyons in 1245, the head of the cadet line of Habsburg sided with the pope, some of the men of the Forest districts should rally round the emperor. Schwyz joined Sarnen and Lucerne (though Uri and Obwalden supported the pope); the castle of New Habsburg was reduced to its present ruined state; and in 1247 the men of Schwyz, Sarnen and Lucerne were threatened by the pope with excommunication if they persisted in upholding the emperor and defying their hereditary lords the counts of Habsburg. The rapid decline of Frederick's cause soon enabled the Habsburgs to regain their authority in these districts. Yet these obscure risings have an historical interest, for they are the foundation in fact (so far as they have any) of the legendary stories of Habsburg oppression told of and by a later age. After this temporary check the power of the Habsburgs continued to increase rapidly. In 1273 the head of the cadet line sold all his lands and rights in the Forest districts to the head of the elder or Alsatian line, Rudolph, who a few months later was elected to the imperial throne, in virtue of which he acquired for his family in 1282 the duchy of Austria, which now for the first time became connected with the Habsburgs. Rudolph recognized the privileges of Uri but not those of Schwyz; and, as he now united in his own person the characters of emperor, count of the Zürichgau, and landowner in the Forest districts (a name occurring first in the 14th century), such a union of offices might

[**HISTORY**]
be expected to result in a confusion of rights. On the 16th of April 1291 Rudolph bought from the abbey of Murbach in Alsace (of which he was "advocate") all its rights over the town of Lucerne and the abbey estates in Unterwalden. It thus seemed probable that the other Forest districts would be shut off from their natural means of communication with the outer world by way of the lake. Rudolph's death, on the 15th of July of the same year, cleared the way, and a fortnight later (August 1) the Everlasting League was made between the men of Uri, Schwyz and Nidwalden (the words et vallis superioris, i.e. Obwalden, were inserted, perhaps between the time of the drawing up of the document, the text of which does not mention Obwalden, and the moment of its sealing on the original seal of Nidwalden) for the purpose of self-defence against a common foe. We do not know the names of the delegates of each valley who concluded the treaty, nor the place where it was made, nor have we any account of the deliberations of which it was the result. The common seal—that great outward sign of the right of a corporate body to act in its own name—appears first in Uri in 1243, in Schwyz in 1281, in Unterwalden not till this very document of 1291; yet, despite the great differences in their political status, they all joined in concluding this League, and confirmed it by their separate seals, thereby laying claim, on behalf of their union to an independent existence. Besides promises of aid and assistance in the case of attack, they agreed to punish great criminals by their own authority, but advise that, in minor cases and in all civil cases, each man should make his complaint to a "judex" (i.e. a judge) whom the League had appointed. All this the Confederates will, in case of need, enforce the decision of the "judex." At the same time they unanimously refuse to recognize any "judex" who has bought his charge or is a stranger to the valleys. All disputes between the parties to the treaty are, as far as possible, to be settled by a reference to arbiters, a principle which remained in force for over six hundred years. "Judex" is a general term for any local official, especially the chief of the community, whether named by the lord or by the community; and, as earlier in the same year Rudolph had promised the men of Schwyz not to force upon them a "judex" belonging to the class of serfs, we may conjecture from this very decided protest that the chief source of disagreement was in the matter of the jurisdictions of the lord and the free community, and that some recent event in Schwyz led it to insist on the insertion of this provision. It is stipulated also that every man shall be bound to obey his own lord "convenienter," or so far as is fitting and right. The antiqua confederatio mentioned in this document was probably merely an ordinary agreement to preserve the peace in that particular district, made probably during the interregnum (1254-1273) in the Empire.

Margarten and the League of 1218.

On the 24th of July 1291 the 20,000 men moved forward along the shore of the Lake of Lucerne, and met the Austrians and Hussars of Schwyz by defeating the advance of Margarten above the south-eastern end of the lake. There they were awaited by the valiant band of the Confederates from 1300 to 1500 strong. The march up the rugged and slippery slope threw the Austrian army into disarray, which became a rout and mad flight when huge boulders and trunks of trees were hurled from above by their foes, who charged down and drove them into the lake. Leopold fled in hot haste to Winterthur, and the attack by the Brünig was driven back by the men of Unterwalden. On the 9th of December 1315 representatives of the victorious highlanders met at Brunnen, on the Lake of Lucerne, not far from Schwyz, and renewed the Everlasting League of 1291. In their main lines the two documents are very similar, the later being chiefly an expansion of the earlier. That of 1315 is in German (in contrast to the 1291 League, which is in Latin), and has one or two striking clauses largely indebted to a decree issued by Zürich on the 24th of July 1291.

None of the three districts or their dependents is to recognize a new lord without the consent and counsel of the rest. (This is probably meant to provide for an interregnum in disputed election to the Empire, possibly for the chance of the election of a Habsburg or, if the law of the lawfulness of the 1291 League is to be rendered to the rightful lord in each case, unless he attacks or wrongs any of the Confederates, in which case they are to be
free from all obligations. No negotiations, so long as the "Länder" have no lord, are to be entered on with outside powers, save by common agreement of all. Louis solemnly recognized and confirmed the new league in 1316, and in 1318 a truce was concluded between the Confederates and the Habsburgs, who treat with them on equal terms. The lands and rights annexed belonging to the Habsburgs in the Forest districts are fully recognized as they existed in the days of Henry of Luxemburg, and freedom of commerce is granted. But there is not one word about the political rights of the Habsburgs as count of the Zürichgau and Aarau. This distinction gives the key to the whole history of the relations between the Confederates and Habsburgs; the rights of the latter as landowners are fully allowed, and till 1801 they possessed estates within the Confederacy; it is their political rights which were always contested by the Swiss, who desired to rule themselves.

As early as 1320 we find the name "Switzerland" (Sweitz) (derived from Schwyz, which had always been the leader in the struggle) applied to the three Forest cantons, and in 1352 extended to the Confederation as a whole. But it was not till after Sempach (1386) that it came into popular use, the historian J. von Müller (1783) fixing the distinction between "Schweiz" (for the country) and "Schweiz" (for the canton), and it did not form the official name of the Confederation till 1803. (Officially in the middle ages and later the Confederation was named "les Liques de la Haute Allemagne," or, as Commynes, late in the 15th century, puts it, "les vieilles Liques d'Allemagne qu'on appelle Suisses," while from c. 1450 onwards the people were called "Swiss"). This is in itself a proof of the great renown which the League won by its victory at Morgarten. Another is that as years go by we find other members admitted to the privileges of the original alliance of the three Forest districts. First to join the League (1332) was the neighbouring town of Lucerne, which had grown up round the monastery of St Leodegar or Leger (whence the place took its name), perhaps a colony, certainly a cell of the great house of Murbach in Alsace, under the rule of which the town remained till its sale in 1291 to the Habsburgs. This act of Lucerne was opposed by the house of Austria, but, despite the decision of certain chosen arbiters in favour of the Habsburg claims, the town clung to the League with which it was connected by its natural position, and thus brought a new element into the pastoral associations of the Forest districts. For a long time later the entire Lake of Lucerne, and in 1351, the ancient town of Zürich, which in 1218, on the extinction of the house of Züiringen, had become a free imperial city in which the abbess of the Fraumünster (the lady of Uri) had great influence, while in 1336 there had been a great civic revolution, headed by Rudolph Brun, who had raised the members of the craft guilds to a position in the municipal government of equal power with that of the patricians, who, however, did not cease intriguing to regain their lost privileges, so that Brun, after long hesitation, decided to throw in the lot of the town with the League rather than with Austria. In this way the League now advanced from the hilly country to the plains, though the terms of the treaty with Zürich did not bind it so closely to the Confederates as in the other cases (the right of making alliances apart from the League being reserved though the League was to rank before these), and hence rendered it possible for Zürich now and again to incline towards Austria in a fashion which did great hurt to its allies. In 1352 the League was enlarged by the admission of Glarus and Zug. Glarus belonged to the monastery of Säckingen on the Rhine (founded by the Irish monk Fridolin), of which the Habsburgs were "allsaints," claiming therefore many rights over the valley, which refused to admit them, and joyfully received the Confederates who came to its aid; but it was placed on a lower footing than the other members of the League, being bound to obey their orders. Three weeks later the town and district of Zug, attacked by the League and abandoned by their Habsburg masters, joined the Confederation, forming a transition link between the civic and rural members of the League. The immediate occasion of the union of these two districts was the war begun by the Austrian duke against Zürich, which was ended by the Brandenburg peace of 1352, by which Glarus and Zug were to be restored to the Habsburgs, who also regained their rights over Lucerne. Zug was won for good by a bold stroke of the men of Schwyz in 1364, but it was not till the day of Náefels (1388) that Glarus recovered its lost freedom. These temporary losses and the treaty made by Brun of Zürich with Austria in 1356 were, however, far outweighed by the entrance into the League in 1353 of the famous town of Bern, which, founded in 1191 by Berthold V. of Züiringen, and endowed with great privileges, had become a free imperial city in 1358 on the extinction of the Züiringen dynasty. Founded for the purpose of bridling the turbulent feudal nobles around, many of whom had become citizens, Bern beat them back at Dornbühl (1298), and made a treaty with the Forest districts as early as 1373. In 1339, at the bloody fight of Laupen, she had broken the power of the nobles for ever, and in 1352 had been forced by a treaty with Austria to take part in the war against Zürich, but soon after the conclusion of peace entered the League as the ally of the three Forest districts, being thus only indirectly joined to Lucerne and Zürich. The special importance of the accession of Bern was that the League now began to spread to the west, and was thus brought into connexion for the first time with the French-speaking land of Savoy. The League thus numbered eight members, the fruits of Morgarten, and no further members were admitted till 1481, after the Burgundian War. But, in order thoroughly to understand the nature of the League, it must be remembered that, while each of the five new members was allied with the original nucleus—the three Forest districts—these five were not directly allied to one another: Lucerne was allied with Zürich and Zug; Zürich with Lucerne, Zug and Glarus; Glarus with Zürich; Zug with Lucerne and Zürich; Bern with no one except the three original members. The circumstances under which each entered the League can alone explain these very intricate relations. After a short interval of peace the quarrels with Austria broke out afresh; all the members of the League, save the three Forest districts and Glarus, joined (1385) the great union of the south German cities; but their attention was soon called to events nearer home. Lucerne fretted much under the Austrian rule, received many Austrian subjects among her citizens, and refused to pay custom duties to the Austrian bailiff at Rothenburg, on the ground that she had the right of free commerce with her neighbours in the west. The king of Germany threatened her with the loss of the privileges of burghership to the discontented inhabitants of the little town of Sempach a short way off, so irritated Leopold III. (who then held all the possessions of his house outside Austria) that he collected an army, with the intention of crushing his rebellious town. Lucerne meanwhile had summoned the other members of the League to her aid, and, though Leopold's feat of attacking Zürich caused the troops of the League to march at first in that direction, they discovered their mistake in time to turn back and check his advance on Lucerne. From 1500 to 1560 men of Uri, Schwyz, Unterwalden, and Lucerne opposed the 6000 which made up the Austrian army. The decisive fight took place on the 4th of July 1386, near Sempach, on a bit of sloping meadow-land, cut up by streams and hedges, which forced the Austrian knights to dismount. The great heat of the day, which rendered it impossible to fight in armour, and the furious attacks of the Confederates, finally broke the Austrian line after more than one repulse and turned the day (see Winkelried). Leopold, with a large number of his followers, was slain, and the Habsburg power within the borders of the Confederation finally broken. Glarus at once rose in arms against Austria, but it was not till the expiration of the truce made after Sempach that Leopold's brother, Albert of Austria, brought an army against Glarus, and was defeated at Náefels (not far from Glarus) on the 9th of April 1388, by a handful of Glarus and Schwyz men.

In 1389 a peace for seven years was made, the Confederates being secured in all their conquests; an attempt made in 1393 by Austria by means of Schöno, the chief magistrate of Zürich and leader of the patrician party, to stir up a fresh attack
failed owing to a rising of the burghers, who sympathized with the Confederates, and on the 16th of July 1394 the peace was prolonged for twenty years (and again in 1412 for fifty years), various stipulations being made by which the long struggle of the League against the Habsburgs was finally crowned with success.

By the peace of 1394 Olarz was freed on payment of £200 annually; (in 1395 it bought up all the rights of Stübingen). Zug too was released from Austrian rule. Schwyz was given the advocatia of the great abbey of Einsiedeln; Lucerne got the Entlebuch (finally in 1405), Sempach and Rothenburg, Bern and Soleure were confirmed in their conquests. Above all, the Confederation as a whole was released from the overlordship of the Habsburgs, to whom, however, all their rights and dues as landed proprietors were expressly reserved; Bern, Zürich and Soleure guaranteeing the maintenance of these rights and dues, with power in case of need to call on the other Confederates to support them by arms. Though the house of Habsburg entertained hopes of recovering its former rights, so that technically the treaties of 1380, 1394 and 1412 were but truces, it finally and for ever renounced all its feudal rights and privileges within the Confederation by the "Everlasting Compact" of 1474.

It is probable that Bern did not take any active shire in the Sempach War because she was bound by the treaty of peace made with the Austrians in 1368; and Soleure, allied with Bern, was doubtless a party to the treaty of 1394 (though not yet in the League), because of its sufferings in 1382 at the hands of the Kyburg line of the Habsburgs, whose possessions (Thun, Briegdorf, etc.) were ceded to the League by the Aargau. The treaty of 1394 also gave the Confederacy considerable lands (known as the Freie Aemter) were joined together and governed as bailiwicks held in common by all the members of the League (save Uri, busied in the south, and Bern, who had already secured the lion's share of the spoil for herself). This is the first case in which the League as a whole took up the position of rulers over districts which, though guaranteed in the enjoyment of their old rights, were nevertheless politically unfree. As an encouragement and a reward, Sigismund had granted in advance to the League the right of criminal jurisdiction (haute justice or Bläbans), which points to the fact that they were soon to appear as the representative of the great districts.

As the natural policy of Bern was to seek to enlarge its borders at the expense of Austria, and later of Savoy, so we find that Uri, shut off by physical causes from extension in other directions, as steadily turned its eyes towards the south. In 1410 the valley of Urseren was finally joined to Uri; though communications were difficult, and carried on only by means of the "Steilende Brücke," a wooden bridge suspended by chains over the Reuss, along the side of a great rocky buttress (pierced in 1797 by the tunnel known as the Urnerloch). By this to recover the Val d'Ossola caused the Confederates to send a force to rescue these adventurers; but

permanently the Val d'Ossola on the south side of the Simplon Pass. Bern, however, supported its burgler, the lord of Raron, and peace was made in 1420. Such were the first links which bound these lands with the League; but they did not become full members for a long time—Appenzell in 1513, St Gall in 1803, the Valais in 1515.

Space will not allow us to enumerate all the small conquests made by the League in the first half of the 15th century by every member of the League; suffice it to say that each increased and defended off its territory, but did not give the conquered lands any political rights, governing them as "subject lands," often very harshly. The same phenomenon of lands which had won their own freedom playing the part of tyrant over other lands which joined them more or less by their voluntary action is seen on a larger scale in the case of the conquest of the Aargau, and in the first attempts to secure a footing south of the Alps.

In 1412 the treaty of 1394 between the League and the Habsburgs had been renewed for fifty years; but when in 1415 Duke Leopold of Austria helped Pope John XXII. to war against Constance, where the great ecclesiastical council was then sitting, and the emperor Sigismund placed the duke under the ban of the Empire, summoning all members of the Empire to arm against him, the League hesitated, because of their treaty of 1412, till the emperor declared that all the rights and lands of Austria in the League were forfeited, and that their compact did not release them from their obligations to the Empire. In the name, therefore, of the emperor, and by his special command, the different members of the League overran the extensive Habsburg possessions in the Aargau. The terrible case of the Aargau, and the other districts (known as the Freie Aemter) were joined together and governed as bailiwicks held in common by all the members of the League (save Uri, busied in the south, and Bern, who had already secured the lion's share of the spoil for herself). This is the first case in which the League as a whole took up the position of rulers over districts which, though guaranteed in the enjoyment of their old rights, were nevertheless politically unfree. As an encouragement and a reward, Sigismund had granted in advance to the League the right of criminal jurisdiction (haute justice or Bläbans), which points to the fact that they were soon to appear as the representative of the great districts.

As the natural policy of Bern was to seek to enlarge its borders at the expense of Austria, and later of Savoy, so we find that Uri, shut off by physical causes from extension in other directions, as steadily turned its eyes towards the south. In 1410 the valley of Urseren was finally joined to Uri; though communications were difficult, and carried on only by means of the "Steilende Brücke," a wooden bridge suspended by chains over the Reuss, along the side of a great rocky buttress (pierced in 1797 by the tunnel known as the Urnerloch) and the road of the Confederacy.

The titles of the heroic defence of Uri Rotach of Appenzell, and of the appearance of a company of Appenzell women disguised as warriors which turned the battle, are told in connexion with this fight, but do not appear till the 17th and 18th centuries, being thus quite unhistorical, so far as our genuine evidence goes. Schwyz had given them, some help, and in 1415 Appenzell was placed under the protection of the League (save Bern), with which in the next year the city of St Gall made a similar treaty to last ten years. So too in 1416-1417 several of the "tithings" of the Upper Valais (i.e. the upper stretch of the Rhone valley), which in 1388 had beaten the bishop and the nobles in a great fight at Visp, became closely associated with Lucerne, Uri and Unterwalden. It required aid in its final struggle (1418-19) against the great house of Raron, the count-bishop of Sitten (or Sion), and the house of Savoy, which held the Lower Valais—the Forest districts on the other hand, wishing to secure themselves against Raron and Savoy in their attempt to conquer

SWITZERLAND [HISTORY]

\[250\]
the duke of Milan ingratiated with the divided Confederates, and finally in 1446, by a payment of a large sum of money and the grant of certain commercial privileges, the Val Leventina, the Val d’Ossola and Bellinzona were formally restored to him. Thus the first attempt of Uri to acquire a footing south of the Alps failed; but a later attempt was successful, leading to the inclusion in the Confederation of what has been called “Italian Switzerland”.

The original contrasts between the social condition of the different members of the League became more marked when the period of conquest began, and led to quarrels and ill-feeling in the matter of the Aargau and the Italian conquests which a few years later ripened into a civil war, brought about by the dispute as to the succession to the lands of Frederick, count of Toggenburg, the last male representative of his house. Count Frederick’s predecessors had greatly extended their domains, so that they took in not only the Toggenburg or upper valley of the Thur, but Uznach, Sargans, the Rhine valley of Feldkirch and Sargans, the Prättigau or Davos valley. He himself, the last great feudal lord on the left bank of the Rhine, had managed to secure his vast possessions by making treaties with several members of the League, particularly Zürich (1400) and Schwyz (1417)—from 1428 inclining more and more to Schwyz (then ruled by Ital Riding), as he was disgusted with the arrogant behaviour of Stüssi, the burgomaster of Zürich. His death (April 30, 1436) was the signal for the breaking out of strife. The Prättigau and Davos valley formed the League of the Ten Jurisdictions in Raetia (see below), while Frederick’s wishes concurred with Zürich against Schwyz for different portions of the great Italian possessions held in common in the valley of the Rhine. After being twice defeated, Zürich was forced in 1440 to buy peace by certain cessions (the “Höfe”) to Schwyz, the general feeling of the Confederates being opposed to Zürich, so that several of them went so far as to send men and arms to Schwyz. Zürich, however, was bitterly disappointed at these defeats, and had recourse to the policy which she had adopted in 1356 and 1393—an alliance with Austria (concluded in 1442), which now held the imperial throne in the person of Frederick III. Though technically within her rights according to the terms on which she had joined the League in 1435, this act of Zürich caused the greatest irritation in the Confederation, and civil war at once broke out, especially when the Habsburg emperor had been solemnly received and acknowledged in Zürich. In 1443 the Zürich troops were completely defeated at St Jakob on the Sihl, close under the walls of the city, Stüssi himself being slain. Next year the city itself was long besieged. Frederick, unable to get help elsewhere, procured from Charles VII of France the despatch of a body of Armagnac free lances (the Écorcheurs), who came, 30,000 strong, under the dauphin Louis, plundering and harrying the land, till at the very gates of the free imperial city of Basel (which had made a twenty years’ alliance with Bern), by the leper house of St Jakob on the Birs (Aug. 26, 1444), the desperate resistance of a small body of Confederates (1200 to 1500), till cut to pieces, checked the advance of the freebooters, who sustained such tremendous losses that, though the victors, they hastily made peace, and returned whence they had come. Several small engagements ensued, Zürich long declining to make peace because the Confederates required, as the result of a solemn arbitration, the abandonment of the Austrian alliance. At length it was concluded in 1450, the Confederates restoring almost all the lands they had won from Zürich. Thus ended the third attempt of Austria to conquer the League by means of Zürich, which used its position as an imperial free city to the harm of the League, and caused the first civil war by which it was distracted.

These fresh proofs of the valour of the Confederates, and of the growing importance of the League, did not fail to produce important results. In 1452 the “Confederates of the Old League of Upper Germany” (as they styled themselves) made their first treaty of alliance with France, a connexion which was destined to exercise so much influence on their history. Round the League there began to gather a new class of allies (known as “Zugswandte Orte,” or associated districts), more closely joined to it, or to certain members of it, than by a mere treaty of friendship, yet not being admitted to the rank of a full member of the League. Of these associates three, the abbot (1451) and town of St Gall (1454), and the town of Bienna (Biel), through its alliance (1352) with Bern, were given seats and votes in the Diet, being called socii; while others, known as confessorati, were not so closely bound to the League, such as the Valais (1416–1417), Schaffhausen (1450–1473), and the cities of the class of confessorati belonged in later times Neuchâtel 1406–1501, the Three Leagues of Raetia (1497–1498), Geneva (1510–1536), and the bishop of Basel (1570). Appenzell, too, in 1452, rose from the rank of a “protected district” into the class of associates, outside which were certain places “protected” by several members of the League, such as Gersau (1359), the abbey of Engelberg (c. 1421), and the town of Rapperswil (1464). The relation of the “associates” to the League may be compared with the ancient practice of “commendation”: they were bound to certain orders in declaring war, making alliances, &c.

In 1439 Sigismund succeeded his father Frédéric Arichon as the Habsburg lands in Alsace, the Thurgau, and Tirol and, being much irritated by the constant encroachments of the Confederates, in particular by the loss of Rapperswil (1458), declared war against them, but fared very badly. In 1460 the Confederates overran the Thurgau and occupied Sargans. Winterthur was only saved by an heroic defence. Hence in 1461 Sigismund had to give up his claim on those lands and renew the peace for fifteen years, while in 1467 he sold Winterthur to Zürich. Thus the whole line of the Rhine was lost to the Habsburgs, who claimed (1454) the territories of the Confederates in the Frickthal only. The Thurgovian bailiwicks were governed in common as “subject” lands by all the Confederates except Bern. The touchiness of the now rapidly advancing League was shown by the eagerness with which in 1468 its members took up arms against certain small feudal nobles who were carrying on a harassing guerrilla warfare with their allies Schaffhausen and Mühlhausen. They laid siege to Waldshut, and to buy them off Sigismund in August 1468 engaged to pay 10,000 guilden as damages by the 24th of June 1469; in default of payment the Confederates were to keep for twelve years the Black Forest, and Waldshut, one of the Black Forest towns on the Rhine. A short time before (1467) the League had made treaties of friendship with Philip the Good, duke of Burgundy, and with the duke of Milan. All was now prepared for the intricate series of intrigues which led up to the Burgundian War—a great epoch in the history of the League, as it created a common national feeling, enormously raised its military reputation, and brought about the close connexion with certain parts of Savoy, which finally (1803–1815) were admitted into the League.

Sigismund did not know where to obtain the sum he had promised to pay. In this strait he turned to Charles the Bold (properly the Rash), Duke of Burgundy, who was then beginning his wonderful career, and aiming at Burgundian restoration of the kingdom of Burgundy. For this purpose Charles wished to marry his daughter and heiress to Maximilian, son of the emperor, and first cousin of Sigismund, in order that the emperor might be induced to give him the Burgundian crown. Hence he was ready to meet Sigismund’s advances. On the 9th of May 1469 Charles promised to give Sigismund 50,000 florins, receiving as security for repayment Upper Alsace, the Breisgau, the Sundgau, the Black Forest, and the four Black Forest towns on the Rhine (Rheinfelden, Stäckingen, Lauternburg, and Waldshut), and agreed to give Sigismund aid against the Swiss, if he was attacked by them. It was not unnatural for Sigismund to think of attacking the League, but Charles’s engagement to him is quite inconsistent with the friendly agreement made between Burgundy and the League as late as 1467. The emperor then on his side annulled Sigismund’s treaty of 1468 with the Swiss, and placed them under the ban of the Empire. Charles committed the mortgaged lands to Peter von Hagenbach, who proceeded to try to establish his master’s power there by such harsh measures as to cause the people to rise against him.
The Swiss in these circumstances began to look towards Louis XI. of France, who had confirmed the treaty of friendship made with them by his father in 1452. Sigismund had applied to him early in 1469 to help him in his many troubles, and to give him aid against the Swiss, but Louis had point-blank refused. Anxious to secure their neutrality in case of his war with Charles, he made a treaty with them on the 13th of August 1470 to this effect. All the evidence goes to show that Sigismund was not a tool in the hands of Louis, and that Louis, at least at that time, had no definite intention of involving Charles and the Swiss in a war, but wished only to secure his own flank.

Sigismund in the next few years tried hard to get from Charles the promised aid against the Swiss (the money was paid punctually enough by Charles on his behalf), who put him off with various excuses. Charles on his side, in 1471–1472, tried to make an alliance with the Swiss, his efforts being supported by a party in Bern headed by Adrian von Bubenberg. Probably Charles wished to use both Sigismund and the Swiss to further his own interests, but his shifty policy had the effect of alienating both from him. Sigismund, disgusted with Charles, now inclined towards Louis, whose ally he formally became in the summer of 1475—a change which was the real cause of the emperor’s flight from Treves in November 1473, when he had come there expressly to crown Charles. The Confederates on their side were greatly moved by the oppression of their friends and allies in Alsace by Hagenbach, and tried in vain (January 1474) to obtain some redress from his master. Charles’s too astute policy had thus lost him both Sigismund and the Swiss. They now looked upon Louis, who, throughout, promised Charles support, as the latter to be the least disappointing at Treves would soon lead to open war, aimed at a master stroke—no less than the reconciliation of Sigismund and the Swiss. This on the face of it seemed impracticable, but common need and Louis’s dexterous management brought it to pass, so that on the 9th of March 1474 the Everlasting Compact was signed at Constance, by which Sigismund finally renounced all Austrian claims on the lands of the Confederates, and guaranteed them in quiet enjoyment to them; they, on the other hand, agreed to support him if Charles did not give up the mortgaged lands within a week. The next day the Swiss joined the league of the Alsatian and Rhine cities, as also did Sigismund. Charles was called on to receive the money contributed by the Alsatian cities, and to restore his lands to Sigismund. He, however, took no steps. Within a week the oppressive bailiff Hagenbach was captured, and a month later (May 9, 1474) he was put to death, Bern alone of the Confederates being represented. On the 9th of October the emperor, acting of course at the instance of Sigismund, ordered them to declare war against Charles, which took place on the 25th of October. Next day Louis formally ratified his alliance with the Confederates, promising money and troops to them if Sigismund’s defeat produced the result of which he did not send men. Throughout these negotiations and later Bern directs Swiss policy, though all the Confederates are not quite agreed. She was specially exposed to attack from Charles and Charles’s ally (since 1468) Savoy, and her best chance of extending her territory lay towards the west and south. A forward policy was thus distinctly the best for Bern, and this was the line supported by the French party under Nicholas von Diesbach, Adrian von Bubenberg opposing it, though not with any idea of handing over Bern to Charles. The Forest districts, however, were very suspicious of this movement to the west, by which Bern alone could profit, though the League as a whole might lose; then, too, Uri had in 1440 finally won the Val Leventina, and she and her neighbours favoured a southerly policy—a policy which was crowned with success after the gallant victory won at Giornico in 1478 by a handful of men from Zürich, Lucerne, Uri and Schwyz over 12,000 Milanese troops. Thus Uri first gained a permanent footing south of the Alps, not long before Bern won its first conquests from Savoy.

The war in the west was begun by Bern and her allies (Fribourg, Solothurn, etc.) by marauding expeditions across the Jura, in which Héricourt (November 1474) and Blamont (August 1475) were taken, both towns being held of Charles by the “sires” de Neuchâtel, a cadet line of the counts of Montbéliard. It is said that in the former expedition the white cross was borne (for the first time) as the ensign of the Confederates, but not in the other. Meanwhile Yolande, the duchess of Savoy, had, through fear of her brother Louis XI. and hatred of Bern, finally joined Charles and Milan (January 1475), the immediate result of which was the capture, by the Bernese and friends (on the way back from a foray on Pontzailier in the free county of Burgundy or Franche-Comté), of several places in Vaud, notably Grandson and Échallens, both held of Savoy by a member of the house of Chalon, princes of Orange (April 1475), as well as of Orbe and Jougne, held by the same, but under the count of Burgundy. In the summer Bern seized on the Savoyard district of Aigle. Soon after (October–November 1475) the same energetic policy won for her the Savoyard towns of Morat, Avenches, Estavayer and Yverdon; while (September) the Upper Valais, which had conquered all Lower or Savoyard Valais, entered into alliance with Bern for the purpose of opposing Savoy by preventing the arrival of Milanese troops. Alarmed at their success, the emperor and Louis deserted (June–September) the Confederates, who thus, by the influence of Louis and Bernese ambition, saw themselves led on and then abandoned to the wrath of Charles, and very likely to lose their new conquests. They had entered on the war as “helpers” of the emperor, and now became principals in the war against Charles, who raised the siege of Neuss, made an alliance with Edward IV. of England, received the surrender of Lorrach and Kempten (June 1476), and Jura (February 1476) in the north of his ally Yolande. On the 21st July he laid siege to the castle of Grandson, and after a week’s siege the garrison of Bernese and Fribourgers had to surrender (Oct. 28), while, by way of retaliation for the massacre of the garrison of Estavayer in 1475, of the 412 men two only were spared in order to act as executioners of their comrades. This hideous news met a large body of the Confederates gathered together in great haste to relieve the garrison, and going to their rendezvous at Neuchâtel, where both the count and town had become allies of Bern in 1466. An advance body of Bernese, Fribourgers and Schwyzers, in order to avoid the castle of Vauxmarx (seized by Charles), on the shore of the Lake of Neuchâtel, and on the direct road from Neuchâtel to Grandson, climbed over a wooded spur to the north, and attacked (March 2) the Burgundian outposts. Charles drew back his force in order to bring down the Swiss to the more level ground where his cavalry could act, but his rear misinterpreted the order, and when the main Swiss force appeared over the spur the Burgundian army was seized with a panic and fled in disorder. The Swiss had gained a glorious victory, and regained their conquest of Grandson, besides capturing very rich spoil in Charles’s camp, parts of which are preserved to the present day in various Swiss armouries. Such was the famous battle of Grandson. Charles at once retired to Lausanne, and set about reorganizing his army. He resolved to advance on Bern by way of Morat (or Murten), which was occupied by a Bernese garrison under Adrian von Bubenberg, and laid siege to it on the 9th of June. The Confederates had now put away all jealousy of Bern, and collected a large army. The decisive battle took place on the afternoon of the 22nd of June, after the arrival of the Zürich contingent under Hans Waldmann. English archers were in Charles’s army, while with the Swiss was René, the despoissèd duke of Lorraine. After facing each other many hours in the driving rain, a body of Swiss, by outflanking Charles’s van, stormed his palisaded camp, and the Burgundians were soon hopelessly beaten, the losses on both sides (a contrast to Grandson) being exceedingly heavy. Vaud was recaptured by the Swiss (Savoy having overrun it on Charles’s advance); but Louis now stepped in and procured the restoration of that region to Savoy, save Grandson, Morat, Orbe and Échallens, which were to be held by the Bernese jointly with the Fribourgers, Aigle by Bern alone—Savoy the same time renouncing all its claims over Fribourg. Thus French-speaking districts first became permanently...
connected with the Confederation, hitherto purely German, and the war had been one for the maintenance of recent conquests, rather than purely in defence of Swiss freedom. Charles tried in vain to raise a third army; René recovered Lorraine, and on the 5th of January 1477, under the walls of Nancy, Charles's wide-reaching plans were ended by his defeat and death, many Swiss being with René's troops. The wish of the Bernese to overturned French claims on territory, and the conflict of the members of the Confederation, and finally, in 1479, Louis, by very large payments, secured the abandonment of all claims on that province, which was annexed to the French crown.
