One often confounds that in the beginning of the 20th century there is more life or health in doctrine, in philosophy, and much more in either than in dogmatic theology.

Sub-divisions of Dogmatic, whether well chosen or ill, throw light upon theology as developed in the past. The six usual Protestant headings are as follows: Theology proper, Anthropology, Christology (C. Hodge here inserts Hamartiology), Soteriology, Ecclesiology (omitted by C. Hodge), Eschatology. The Lombard's Sentences deal in bk. I. with God; bk. II. the creatures; bk. III. Incarnation, Redemption, Virtues; bk. IV. the threefold estate.

Two Things. Aquinas's Summa has no such clear lines of division.

The Church carried forward from the middle ages a tradition of "Moral Theology" answering to Christian Ethics, alongside of Dogmaties or of all-inclusive Summae. Casuistry (with parallels in early Protestantism like Jeremy Taylor's Ductor Dubitantum), growing out of the Confessional, is characteristic of this Roman Catholic Ethics; yet the study is not restricted to the technical equipment of confessors. The Roman Catholic contributors to the volume on Christianity in Die Kultur der Gegenwart write on:—I. Dogmatic: A. Apologetic or General Dogmatic; B. Special Dogmatic or Dogmatic proper. II. Moral Theology. III. Practical Theology. The Protestant contributors, representing somewhat varied standpoints in German religion, follow much the same plan. Apologetic has no separate place with them; but the system of theology (in a sense midway between the dogmatists and the encyclopedists), is allotted between Dogmatic, Christian Ethics and Practical Theology.

Literature.—A bibliography of theology cannot name every important book. The effort is made here (1) to mention works covering the threefold division, (2) to the chief works to some one Christian confession, (3) without needless repetition of what has already been said, (4) dogmatic treatises being preferred but not to the exclusion of everything else.

One of the great interests in theology is the system. Athanasius's On the Incarnation of the Eternal Word represents his central thoughts not less interestingly because it is earlier than the Arian controversy of the 3rd century. The chief object of doctrine for popular use, but arranged as a complete system. Gregory of Nyssa's Great Catechesis is an instruction to catechists how they should proceed—though of course stating the writer's theology and apologetic, with his belief in universal salvation. Theodoret has an outline of theology in the last book (v.) of his treatise Against Heresies. Theodore of Mopsuestia is a more respected representative of the same scholarship—that of Antioch. John Chrysostom is the orator of the school of Alexandria. Theology represents the later Alexandrian theology. With John of Damascus the progress of Greek divinity ends. A good modern statement is in Gregory of Sinai's Summa Christiana. The West's contribution is chief again in breaking new ground for theology. The Enchiridion ad Laurentium is a slight but interesting sketch of a system, while the De Doctrina Christiana is another lesson in the imparting of Christian instruction, as is also, naturally, the De Christianis Ritus. The City of God and the Confessions are of unmatched importance in their several ways; and nothing of Augustine's was without influence. Gregory the Great's Magna Moralia should also be named.

In the middle ages Isidore (at its gateway, then Peter Lombard), then Aquinas (and his rivals), are pre-eminent for system, Anselm and Abelard for originality, Bernard of Clairvaux as the theologian who pre-eminent by its practical medieval and popular character, its most literary, its most characteristic forms, while Thomas à Kempis' devotional masterpiece, The Imitation of Christ, with Tauler's Sermons and the Theologia Germanica belongs to the world's classics. All the Protestant reformers are of theological importance—Luther, Melanchthon and

1 "Mystical Theology" is described in Addis and Arnold's "A Branch" of Moral Theology.
Theo-Phaneses, surnamed "the Confessor" (c. A.D. 758-817). Greek ascetic, chronicler and saint, belonged to a noble and wealthy family, and held several offices under Constantine V. C. Copronymus (741-775). He subsequently retired from the world and founded a monastery (rōu Μεγάλον Ἀγρόν) near Sighiara. He was a strong supporter of the worship of images, and in 815 was summoned to Constantinople by Leo the Armenian, who formally ordered him to renounce his principles. He, however, refused, and, after two years of imprisonment, was banished to the island of Samothrace, where he died. He subsequently received the honours of canonization. At the request of his dying friend, George the Synellus (q.v.), Theophanes undertook to continue his Chronicle, which he carried on from the accession of Dicriotian to the downfall of Michael I. Rhangabes (824-873). The work, although wanting in critical insight and chronological accuracy, is of great value as supplying the accounts of lost authorities. The language occupies a place midway between the stiff ecclesiastical and the vulgar Greek. In chronology, in addition to reckoning by the years of the world and the Christian era, Theophanes introduces in tabular form the regnal years of the Roman emperors, of the Persian kings and Arab caliphs, and of the five oecumenical patriarchs, a system which leads to considerable confusion. The Chronicle was much used by succeeding chroniclers, and in 873-875 a compilation in barbarian Latin (in vol. ii. of De Boor's edition) was made by the papal librarian Anastasius from Niecephorus, George the Synellus, and Theophanes for the use of a deacon named Johannes. The translation (or rather paraphrase) of Theophanes really begins with the work of Fredegar in II. and there is a good deal of genuine material; but the latter part, especially the section in the latter part,
THEOPHANO—THEOPHILUS

THEOPHANO (c. 950–991), wife of the Roman emperor Otto II, was a daughter of the Eastern emperor Romanus II, and passed her early years amid the tragic and changing fortunes which beset the court of Constantinople. Otto the Great having prevailed over his rival to his son Otto II, she was married to him and crowned empress at Rome by Pope John XIII, on the 14th of April 972. In return for costly gifts brought by her to his wife, she was granted extensive estates in all parts of the empire. She appears to have been a woman of great beauty and considerable intelligence, and after the death of Otto the Great in 973 gradually superseded her widow Adelaide as the chief adviser of the new emperor, whom she accompanied on several military expeditions. She introduced many Byzantine customs into the German court. After the death of Otto in December 983 she returned to Germany, which she governed with conspicuous success in the name of her son, Otto III. In 989 she visited Rome, where she exercised as imperatrix the imperial prerogatives, and probably compelled the Romans to swear to acknowledge her son. Theophano died at Nimwegen on the 15th of June 991, and was buried in the church of St Pantaleon at Cologne.

See J. Moltmann, Theophano, die Gemahlin Otto II. in ihrer Bedeutung für die Politik Otos I. und Otos II. (Göttingen, 1878).

THÉOPHILE, the name by which Théophile de Viau (or Viav), French poet (1591–1626), is more commonly called. He was born in 1591, at Clairac, near Agen, and died some forty years at Boussetres de Mazères, his father's property. He was educated at the Protestant college of Saumur, and he went to Paris in his twentieth year. In 1612 he met Balzac, with whom he made an expedition to the Netherlands, which ended in a serious quarrel. On his return he seems to have been for two years a regular playwright to the actors at the Hôtel de Bourgogne. In 1615 he attached himself to the ill-fated Henry, duke of Montmorency (1595–1632), under whose protection he produced with success the tragedy of Pyrame et Thisbé, acted probably about 1617 and printed in 1623, although placed later by some critics. This piece, written in the extravagant Spanish-Italian manner, which was fashionable in the interval between the Pléiade model and the innovations of Corneille, was ridiculed by Boileau (Preface to his Œuvres, 1701). Théophile was the acknowledged leader of a set of Parisian libertines, whose excesses seem to have been chiefly dictated by a general hatred of restraint. He himself was not only a Huguenot, but a freethinker, and had made unsparing use of his sharp wit in epigrams on the Church and on the government. In 1615 he was accused of blasphemous and indecent writings, and was banished from Paris. He took refuge in the south of France, where he found protection with many friends. He was allowed to return in the next year, and effected a partial reconciliation with one of his most powerful enemies, the duc de Luynes. He served in that year in the campaign against the Huguenots, but in the autumn was again in exile, this time in England. He was recalled in 1621, and began to be instructed in the Roman Catholic religion, though his abjuration of Protestantism was deferred until the end of 1622. There is nothing to show that this conversion was purely political; in any case it did little to mollify his enemies. In 1622 he had contributed four pieces to the Nouveau Parnasse Soltièrge, a collection which had caused him much trouble. In the next year a new edition appeared, with the addition of some licentious verse, and the inscription par le sieur Théophile on the title-page. Contemporary opinion justified Théophile's denial of this ascription, but the Jesuit father, François Garasse, published a tract against him entitled La Doctrine curieuse (1623). Théophile was again prosecuted. This time he fled from Paris, to the court of Montmorency, and was condemned in his absence (19th of August 1623) to death. On his flight to the border he was arrested, and imprisoned in the Conciergerie in Paris. He defended himself in an Apologie au roi (1625), and was liberated in September, his sentence being commuted to banishment for life. Under Montmorency's protection he was able to hide in Paris for some time, and subsequently accompanied his friend and patron to the south. He died in Paris on the 25th of September 1626.

The great interest aroused by the prosecution and defence of Théophile is shown by the number of pamphlets on the subject, for many years after his death Georges de Scudéry edited his work with a Tombeau (copy of obituary verses), and a challenge in the preface to anyone who might be offended by the editor's eulogy of the poet. A copy of a printed, but not entitled to be called a Theophile's, and is not included in his works, the standard modern edition of which is that of Alleaume in the Bibliothèque Illustrée (4 vols. 1856). Besides Pyrame et Thisbé, his works include a para-phrase of the Roman de Thèbes in Latin, a translation of the Greek and Latin letters, his Apologie, a promising fragment of comic prose narrative, and a large collection of occasional verses, odes, elegies, stanzas, &c.

THEOPHILUS, East Roman emperor (829–842), the second of the "Phrygian" dynasty. Unlike his father Michael II, he was a Greek as well as a Cypriot, and spent most of his years at Boussetres de Mazères, his father's property. He was educated at the Protestant college of Saumur, and he went to Paris in his twentieth year. In 1612 he met Balzac, with whom he made an expedition to the Netherlands, which ended in a serious quarrel. On his return he seems to have been for two years a regular playwright to the actors at the Hôtel de Bourgogne. In 1615 he attached himself to the ill-fated Henry, duke of Montmorency (1595–1632), under whose protection he produced with success the tragedy of Pyrame et Thisbé, acted probably about 1617 and printed in 1623, although placed later by some critics. This piece, written in the extravagant Spanish-Italian manner, which was fashionable in the interval between the Pléiade model and the innovations of Corneille, was ridiculed by Boileau (Preface to his Œuvres, 1701). Théophile was the acknowledged leader of a set of Parisian libertines, whose excesses seem to have been chiefly dictated by a general hatred of restraint. He himself was not only a Huguenot, but a freethinker, and had made unsparing use of his sharp wit in epigrams on the Church and on the government. In 1615 he was accused of blasphemous and indecent writings, and was banished from Paris. He took refuge in the south of France, where he found protection with many friends. He was allowed to return in the next year, and effected a partial reconciliation with one of his most powerful enemies, the duc de Luynes. He served in that year in the campaign against the Huguenots, but in the autumn was again in exile, this time in England. He was recalled in 1621, and began to be instructed in the Roman Catholic religion, though his abjuration of Protestantism was deferred until the end of 1622. There is nothing to show that this conversion was purely political; in any case it did little to mollify his enemies. In 1622 he had contributed four pieces to the Nouveau Parnasse Soltièrge, a collection which had caused him much trouble. In the next year a new edition appeared, with the addition of some licentious verse, and the inscription par le sieur Théophile on the title-page. Contemporary opinion justified Théophile's denial of this ascription, but the Jesuit father, François Garasse, published a tract against him entitled La Doctrine curieuse (1623). Théophile was again prosecuted. This time he fled from Paris, to the court of Montmorency, and was condemned in his absence (19th of August 1623) to death. THEOPHRASTUS—THEOPOMPUSS

1897); and authorities under ROMAN EMPIRE, LATER. On the early campaigns against the Arabs see J. B. Bury, in Journ. Hell. Stud. vol. xxvi., p. 550. 1900.

THEOPHRASTUS, the successor of Aristotle in the Peripatetic school, a native of Eresus in Lesbos, was born about 372 B.C. His original name was Tyrtamus, but he later became known by the nickname "Theophrastus," given to him, it is said, by Aristotle to indicate the grace of his conversation. After receiving his first introduction to philosophy in Lesbos from one Leucippus or Alcippus, he proceeded to Athens, and became a member of the Platonic circle. After Plato's death he attached himself to Aristotle, and in all probability accompanied him to Stagira. The intimate friendship of Theophrastus with Callisthenes, the royal-pupil of Alexander the Great, the mention made in his will of Aristotle being bequeathed to him at Stagira, and the repeated notices of the town and its museum in the "Plants," are facts which point to this conclusion. Aristotle in his will made him guardian of his children, bequeathed to him his library and the originals of his works, and designated him as his successor at the Lyceum on his own removal to Chalce. Eudemus of Rhodes also had some claims to this position, and Aëtornaxus is said to have resented Aristotle's choice. Theophrastus presided over the Peripatetic school for thirty-five years, and died in 287 B.C. Under his guidance the school flourished greatly during the period more than 2000 students—and at his death he bequeathed to it his house and colonnades as a permanent seat of instruction. Menander was among his pupils. His popularity was shown in the regard paid to him by Philip, Cassander and Ptolemy, and by the complete failure of a charge of impiety brought against him. He was honoured with a public funeral, and "the whole population of Athens, honouring him greatly, followed him to the grave" (Diog. Laërt.).

From the lists of the ancients it appears that the activity of Theophrastus was directed to the cultivation of contemporary knowledge. His writing probably differed little from the treatment of the same themes, though supplementary in detail (see PERIPATETICS). He served his age mainly as a great popularizer of science. The most important of his books are two large botanical treatises, *On the History of Plants*, in nine books (originally ten), and *On the Causes of Plants*, in six books (originally eight), which constitute the most important contribution to botanical science during antiquity and the middle ages. We also possess in fragments a *History of Physics*, a treatise *On Sense*, and a work *On Sensation*, and certain metaphysical *Apologia*, which probably once formed part of it. Various smaller scientific fragments have been collected in the editions of Stahl (1759), Renard (1817), Beecles (1837), and F. Wimmer (1842-62) and in Usener's *Analecta Theophrastae*. The Ethical Characters (Προσωπικές) *deserves a separate monograph* in the work consists of brief, vigorous and trenchant notices of moral types, which contain a most valuable picture of the life of his time. They form the first recorded attempt at systematic character writing. The book has been regarded by some as an independent work; others incline to the theory that the sketches were written from time to time by Theophrastus, and collected and edited after his death; others, again, regard the Characters as part of a larger systematic work, but the style of the book is against this. Theophrastus has found many imitators in this kind of writing, notably Hall (1668), Sir Thomas Overbury (1613-16), Bishop Earle (1628) and La Bruyere (1688), who also translated the Characters.

BIBLIOGRAPHY.—A good account of Theophrastus is found in Zeller, Aristotle and the Earlier Peripatetics (Eng. trans. by B. F. C. Costelloe and J. H. Muirhead, vol. ii., chap. 18, 1897). For his astronomical work a monograph on the "Antikythera" astronomic and botanical works, see Dr J. Berendes, *Die Pharmacie bei den alten Culturolken* (vol. i., 1891). The Ethical Characters was edited by Cambridge in 1892 and translated by La Bruyere (1688-89); the best modern translation (with introduction) is that by R. C. Jebb (1870; new ed. J. E. Sands, 1909); recent editions are that of J. M. Edmonds and G. E. V. Austen (1904), containing text, transliteration, critical notes (literary and scientific schools), and that of C. E. Bennett and W. A. Hammond (1902), containing a transliteration and introduction. The work has been translated into nearly all European languages (see Baldwin's *Dict. of Philos. and Psych.*, vol. iii., pp. 99-103 (E. Wh.).

THEOPHYLACT (d. c. 1130), biblical commentator, was born most probably at Epirus, in Euoboea, about the middle of the 11th century. He became a deacon at Constantinople, attained a high reputation as a scholar, and became the tutor of Constantine Porphyrogenitus, son of the Emperor Michael VII., for whom he wrote *The Education of Princes* (Μαθησια του Βασιλείου). About 1078 he went into Bulgaria as archbishop of Achepia. In his letters he complains much of the rude manners of the Bulgarians, and he sought to be relieved of his office, but apparently without success. His death took place after 1107.

His commentaries on the Gospels, Acts, the Pauline epistles and the Minor Prophets are founded on those of Chrysostom, but preserve the considerable place they hold in exegetical literature for their appositeness, sobriety, accuracy and judiciousness. His other extant works include 130 letters and various homilies and discourses, on various other topics. A careful edition of nearly all his writings, in Greek and Latin, was published from 1862 with a full critical apparatus, was published in 1754-63 by J. F. B. m. de Rossi (4 vols., fol., Venice).

THEOPOMPUSS (b. c. 380), Greek historian and rhetorician, was born at Chios about 380 B.C. In early youth he seems to have spent some time at Athens, along with his father, who had been exiled on account of his Laconian sympathies. Here he became a pupil of Isocrates, and rapidly made great progress in rhetoric; we are told that Isocrates used to say that Euphorus required the spur but Theopompos the bit (Cicero, *Ad Att.*, xii. 3). At first he appears to have composed epidemic speeches, in which he displayed such proficiency that in 352-351 he gained the prize of oratory given to him in honour of his husband, although Isocrates was himself among the competitors. It is said to have been the advice of his teacher that finally determined his career as an historian—a career for which he was peculiarly qualified owing to his abundant promiscuity and his wide knowledge of men and places. Through the influence of Alexander, he was restored to Chios about 333, and figured for some time as one of the leaders of the democratic party in his native town. After Alexander's death he was once again exiled, and took refuge with Ptolemy in Egypt, where he appears to have remained with a somewhat cold reception. The date of his death is unknown.

The works of Theopompos were chiefly historical, and are much quoted by later writers. They included an *Epitome of Herodotus* *History* (the genuineness of which is doubted), the *Hellenics* (Πολεμικά, *Ἐλληνικά ἀριστοτέλεια*), the *History of Philip* (Πολεμικά, * PHI*., *Φιλίππη*), of several epicycles and horatious addresses, the chief of which was the *Letter to Alexander*. The *Hellenics* treated of the history of Greece, the *Philippic* (Πολεμικά, *Φιλίππη*), of 411 (where Thucydides breaks off) to 394—the date of the battle of Leuctra (B.C. 371) to 338. Of this work only a few fragments were known up to 1907. The papyrus fragment of a Greek historian of the 4th century B.C., discovered by H. P. R. Strassburger, and published by them in *Oxyrhynchus Papiri*, vol. v. (1908), by J. Hales and E. Meyer, *Untersuchungen* (1892). Of this we possess only a few fragments is of considerable extent, to Cratinus (4th to 5th century, B.C.), a far more elaborate work was the *Μεταμορφωμένα* in 58 books. In this *Theopompos* narrated the history of Philip's reign (350-336), with digressions on the names and customs of the various races and countries of which he had occasion to speak, which were so numerous that Philip V. of Macedon reduced the bulk of the history from 58 to 16 books by cutting out those parts which had no connexion with Macedonia. It was from this history that Trogus Pompeius (of whose *Historiae Philippicæ* we possess the epitome by Justin) derived the material of his *Historiae Philippicae* and *Alexandrines*. In the 3rd century B.C. a similar oration of the *Letter to Alexander* we possess one or two fragments cited by Athenaeus, animadverting severely upon the immorality and dissensions of Harpalus. The *Attack upon Plato*, and the treatise *On Poetry*, (φιλοσοφία), which are from a different hand and have been ascribed to Athenaeus, are perhaps only two of the many digressions in the history of Philip; some writers have doubted their authenticity. The libellous attack (τραχύσας.executeUpdate) on the three cities—Athens, Sparta and Thebes—was published under the names of Theopompos by his enemy Anaximenes of Lampscus. The nature of the extant fragments fully bears out the divergent criticisms of antiquity on the works of Theopompos. The style of Theopompos was much the same as that of his master and pointed expressions, but lacking in weight and dignity. The artistic unity of his work suffered severely from the frequent and lengthy digressions already referred to. The most important was
that *On the Athenian Demagogues* in the 10th book of the *Philippicas*, containing a bitter attack on many of the chief Athenian statesmen, and generally recognized as having been freely used by Plutarch in several of the *Lives*. Another fault of Theopompus was his excessive fondness for romantic and incredible stories; a collection of some of these (ομανδα) was afterwards made and published under his name. He was also severely blamed in antiquity for his audacity, and throughout his fragmentary nature is more striking than this. On the whole, however, he appears to have been fairly impartial. Philip himself censures severely for drunkenness and immorality, while Demosthenes receives his warm praise.

**THEORBO** [Fr. théorbe, Ger. Theorbe, Ital. theorbo, Barbitonel, the large double-necked bass lute much used during the 16th and 17th centuries as general bass in the orchestra. The body of the theorbo was constructed on the same principles as that of the lute but larger, and of greater capacity. The construction was followed. The theorbo, instead of being bent back at an angle to form the head, was straight, having sufficient pegs set in the sides of the body for from 12 to 16 strings tuned in pairs of unisons; on the fingerboards were marked 8 or more frets for semitones. Above this neck was another without frets, curving forwards and slightly to one side to enable the long bass strings, stretched not over but at the side of the neck, to escape the pegs of the shorter strings. These free strings, known as diapason strings (Ger. *Begleitseilen*) were plucked à side like those of the lyre, each giving but one note; the number of these strings varied from 8 to 11.

The theorbo was made in two sizes, the ordinary instrument measuring about 3 ft. 6 in., and the Paduan, also known as archlute, about 5 ft. The chitarrone, or Roman theorbo, was the largest of all, a contrabass lute in fact, and frequently stood over 6 ft. high. It differed slightly from the theorbo; the body was a little smaller, about 2 ft. 4 in., and the bridge of the extra length not being in the second neck. The strings over the fingerboard were of steel or brass, and the diapason strings of spun wire. For the history of the theorbo, see *Barbiton and Lute*.

**THEOSOPHY** (from Gr. θεός, god, and εὐφως, wisdom), a term used to denote those forms of philosophic and religious thought which claim a special insight into the Divine nature and its constitutive moments or processes. Sometimes this insight is claimed as the result of the operation of some higher faculty or some supernatural revelation to the individual; in other instances the theosophical theory is not based upon any special illumination, but is simply put forward as the deepest speculative wisdom of its author. But in any case it is characteristic of theosophy that it starts with an explication of the Divine essence, and endeavours to deduce the phenomenal universe from the play of forces within the Divine nature itself.

**General Theory.**—Theosophy is thus differentiated at once from all philosophic systems which attempt to rise from an analysis of phenomena to a knowledge, more or less adequate, of the existence and nature of God. In all such systems, God is the unknown, and throughout his fragmentary nature is more striking than this. The theosophist, on the other hand, is most at ease when moving within the circle of the Divine essence, into which he seems to claim absolute insight. This, however, would be insufficient to distinguish theosophy from those systems of philosophy which are sometimes called "speculative" and "absolute," and which also in many cases proceed deductively from the idea of God.

In a wide sense, the system of Hegel or the system of Spinoza may be cited as examples of what is meant. Both thinkers claim to exhibit the universe as the evolution of the Divine nature. They must believe, therefore, that they have grasped the inmost principles of that nature; so much is involved, indeed, in the construction of an absolute system. But it is to be noted that, though there is much talk of God in such systems, the known universe—the world that now is—nowhere truly matters, and so it is the principle of unity is omitted in the whole. Hence, while the accusation of pantheism is frequently brought against these thinkers, the term theosophical is never used in their regard. A theosophical system may also be pantheistic, in tendency if not in intention; but the transcendent character of its Godhead definitely distinguishes it from the speculative philosophies which might otherwise seem to fall under the same definition. God is regarded as the transcendent source of being and purity, from which the individual in his natural state is alienated and afar off. An historical survey shows, indeed, that theosophy generally in contact with religious needs, and is the expression of religious convictions or aspirations. Accepting the testimony of religion that the present world lies in wickedness and imperfection, theosophy faces the problem of speculatively accounting for this state of things from the nature of the Godhead itself. It is thus in some sort a mystical philosophy of the existence of evil; or at least it assumes this form in some of its most typical representatives.

The term Mysticism (q.v.) has properly a practical rather than a speculative reference; but it is currently applied as to include the systems of thought on which practical mysticism was based. Thus, to take only one prominent example, the profound speculations of Meister Eckhart (q.v.) are always treated under the head of Mysticism, but they might with equal right appear under the rubric Theosophy. In other words, while an emotional and practical mysticism may exist without attempting philosophically to explain itself, speculative mysticism is almost another name for theosophy. There is still a certain difference observable, however, in so far as the speculative mystic remains primarily concerned with the theory of the soul's relation to God, while the theosophist gives his thoughts a wider range, and loudly devotes himself to the elaboration of a fantastic philosophy of nature.

In the above acceptation of the term, the Neoplatonic doctrine of emanations from the super-essential One, the fanciful emanation-doctrine of some of the Gnostics (the aeons of the Valentinian system might be mentioned), and the elaborate esoteric system of the Kabbalah, to which the two former in all probability largely contributed, are generally included under the head of theosophy. In the two latter instances there may be noted the allegorical interpretation of traditional doctrines and sacred writings which is a common characteristic of theosophical writers. Still more typical examples of theosophy are furnished by the mystical system of Meister Eckhart and the doctrine of Jacob Boehme (q.v.), who is known as "the theosophist" par excellence. Eckhart's doctrine asserts behind God a predicateless Godhead, which, though unknowable not only to man but also to itself, is, as it were, the essence or potentiality of all things. From it proceed, and in it, as their nature, exist, the three persons of the Trinity, conceived as stadia of an eternal self-revealing process. The eternal generation of the Son is equivalent to the eternal creation of the world. But the sensuous and phenomenal, as such, as far as they are, are to imply independence of God. This thingness; things exist only through the presence of God in them, and the goal of creation, like its outset, is the repose of the Godhead. The soul of man, which as a microcosmos resumes the nature of things, strives by self-abnegation or self-annihilation to attain this unspeakable reunion (which Eckhart calls being buried in God). Regarding evil simply as privation, Eckhart does not make it the pivot of his thought, as was afterwards done by Boehme; but his notion of the Godhead as a dark and formless essence is a favourite thesis of theosophy.
Besides mystical theology, Boehme was indebted to the writings of Paracelsus. This circumstance is not accidental, but points to an affinity in thought. The nature-philosophers of the Renaissance, such as Nicolaus Cusanus, Paracelsus, Cardan and others, curiously blend scientific ideas with speculative notions derived from scholastic theology, from Neoplatonism and even from the Kabbalah. Hence it is customary to speak of their theories as a mixture of theosophy and physics, or theosophy and chemistry, as the case may be. Boehme offers us a natural philosophy of the same sort. As Boehme is the typical theosophist, so the theosophist is almost in every case upon the study of his works, his dominating conceptions supply us with the best illustration of the general trend of this mode of thought. His speculation turns, as has been said, upon the necessity of reconciling the existence and the might of evil with the existence of an all-embracing and all-powerful God, without falling into Manichaeanism on the one hand, or, on the other, into a naturalistic pantheism that denies the reality of the distinction between good and evil. He faces the difficulty boldly, and the eternal conflict between the two may be said to furnish him with the principal of his philosophy. It is in this connexion that he insists on the necessity of the Nay to the Yea, of the negative to the positive. Eckhart's Godhead appears in Boehme as the abyss, the eternal nothing, the essenceless quiet ("Ungrund" and "Stille ohne Wesen") are two of Boehme's phrases. But, if this were all, the Divine Being would remain an abyss dark even to itself. In God, however, as the condition of His manifestation, lies, according to Boehme, the "eternal nature" or the mysterium magnum, which is as anger to love, as darkness to light, and, in general, as the negative to the positive. This principle (which Boehme often calls the evil in God) illuminates both sides of the antithesis, and thus contains the possibility of their real existence. By the "Qual" or torture, as it were, of this diereption, the universe has qualitative existence, and is knowable. Even the three persons of the Trinity, though existing ideäler beforehand, attain reality only through this principle of nature in God, which is hence spoken of as their matrix. It forms also the matter, as it were, out of which the world is created; without the dark and fiery principle, we are told, there would be no creature. Hence God is sometimes spoken of as the father, and the eternal nature as the mother, of the world. (Of his philosophy, conceived of as an eternal process) begins with the creation of the angels. The subsequent fall of Lucifer is explained as his surrender of himself to the principle of nature, instead of dwelling in the heart of God. He sought to make anger predominate over love; and he had his will, becoming prince of hell, the kingdom of God's anger, which still remains, however, an integral part of the Divine universe. It is useless to follow Boehme further, for his cosmogony is disfigured by a wild Paracelsian symbolism, and his constructive efforts in general are full of the uncouth straining of an untrained writer. In spite of these defects, his speculations have exercised a remarkable influence.

Schelling's Philosophical Inquiries into the Nature of Human Freedom (1800) is almost entirely a reproduction of Boehme's ideas, and forms, along with Baader's writings, the best modern example of theosophical speculation. In his philosophy of identity Schelling (q.v.) had already defined the Absolute as pure indifference, or the identity of subject and object, but without advancing further into theogony. He now proceeded to distinguish three moments in God, the first of which is the pure indifference which, in a sense, precedes all existence—the primal basis or abyss, as he calls it, in agreement with Boehme. But, as there is nothing before or besides God, God must have the ground or cause of His existence in Himself. This is the second moment, called nature in God, distinguishable from God, but inseparable from Him. It is that in which is not God Himself, it is the yearning of the eternal One to give birth to itself. This yearning is a dumb unintelligent longing, which moves like a heaving sea in obedience to some dark and indefinite law, and is powerless to fashion anything in permanence. But in correspondence to the first stirring of the Divine existence there awakes in God Himself an inner reflective perception, by means of which—since no object is possible for it but God—God beholds Himself in His own image. In this, God is for the first time as it were realized, although as yet only within Himself. This perception combines, as understanding, with the primal yearning, which becomes thereby a free creative will, and works formatively in the originally lawless nature or ground. In this wise is created the world as we know it. In every natural existence there are, therefore, two principles to be distinguished—first, the dark principle, through which the world is separated from God, and exists, as it were, in the middle ground; and, secondly, the Divine principle of understanding. The first is the particular will of the creature, the second is the universal will. In irrational creations the particular will or greed of the individual is controlled by external forces, and thus used as an instrument of the universal. But in man the two principles are consciously present together, not, however, in inseparable union, as they are in God, but with the possibility of separation. This possibility of separation is the possibility of good and evil. In Boehme's spirit, Schelling defended his idea of God as the Trinitarian hypothesis, in which there is consciousness which naturalism denies, and which ordinary theology emptily asserts. This theosophical transformation of Schelling's doctrine was largely due to the influence of his contemporary Baader (q.v.). Baader distinguishes, in a manner which may be paralleled from Boehme, between an immanent or esoteric process of self-production in God, through which He issues from His unrevealed state, and the emanant, exoteric or real process, in which God overcomes and takes up into Himself the external "nature" or the principle of selfhood, and appears as a Trinity of persons. The Creation of the world is still further to be distinguished from these two processes as an act of freedom or will; it cannot, therefore, be speculatively constructed, but must be historically accepted. Baader, who combined his theosophy with the doctrines of Roman Catholicism, has had many followers. Among thinkers on the same lines, but more or less independent, Molitor is perhaps the most important. Swedenborg (q.v.) is usually reckoned among the theosophists, and some parts of his theory justify this inclusion; but his system as a whole has little in common with those speculative constructions of the Divine nature, within which form the essence of theosophy, as strictly understood.

Besides the books mentioned under Mysticism, and those referred to under individual authors, Baur's Die christliche Gnosi in ihrer geschichtlichen Entwicklung (1835) and Hamberger, Stimmen aus dem Heiligtum der christlichen Mystik und Theosophie (1867), may be mentioned. (A. S. P.-P.)

**ORIENTAL THEOSOPHY**

The term "theosophy" has in recent years obtained a somewhat wide currency in a restricted signification as denoting the beliefs and teachings of the Theosophical Society. This society was founded in the United States of America in the year 1875 by Madame H. P. Blavatsky (q.v.), in connexion with Colonel H. S. Olcott (d. 1906) and others. The main objects of the society were thus set out: (1) To establish a nucleus of the universal brotherhood of humanity; (2) to promote the study of comparative religion and philosophy; (3) to make a systematic investigation into the mystic potencies of life and matter, or what is usually termed "occultism." As regards the first object the mere fact of joining the society and becoming an "initiated fellow" was supposed to involve a certain kind of intellectual and social brotherhood, though not implying anything in the nature of an economic union. This latter aspect of the fraternity was to be satisfied by the contribution from each fellow of five dollars by way of initiation fee. The society's theory of universal brotherhood was, however, of far wider scope, being based upon a mystical conception of the "One Life"—an idea derived from and common to various forms of Eastern thought, Vedie and Buddhist. It implies the necessary interdependence of all that is—that ultimate Oneness which underlies and sustains all phenomenal diversity, whether
inwardly or outwardly, whether individual or universal. The theosophical conception of brotherhood is thus rather transcendental than materialistic, and is not therefore to be regarded as the exact equivalent of the socialistic doctrine of the solidarity of the human race.

The second object of the society, the study of comparative religion and philosophy, soon crystallized into an exposition of a more or less definite system of dogmatic teaching. The leading tenets of the system had its origin in the great religions of the world, as well as from various other sources; but all were to be regarded as so many divergent expressions of one and the same fundamental truth, or "Wisdom Religion," in such form and dress as was best adapted to suit the times and the people for whose spiritual growth and development religious instruction was required. Now, in order to discern this underlying truth in the various and apparently conflicting world creeds, appeal was made to a "Secret Doctrine," and "Esoteric Teaching," which Madame Blavatsky proclaimed had been held for ages as a sacred possession and trust by certain mystic adepts in occultism, or "Mahâtmâs," with whom she said she was in psychological as well as in direct physical communication. It is here that the theosophical movement showed its most serious shortcomings. From time to time Madame Blavatsky's numerous friends and associates were allowed to witness the manifestations of "occult phenomena," which she averred were the outcome of her connexion with these "Mahâtmâs." The fraudulent character of the "phenomena" was on several occasions exposed by numerous painstaking investigators (see Proceedings of the Society for Psychical Research, vol. iii. and iv.; A Modern Priestess of Isis, by Solovyoff). There are, moreover, numerous passages in the sacred books of the East, especially those of the Buddhists, which warn the student against the assumption that "magical" performances of any kind are to be regarded as proving the truth of the performer's teaching; and indeed it must be owned in justice to the theosophists that similar warnings are to be found scattered throughout their writings; while even Madame Blavatsky herself was wont to expatiate on the folly of accepting her "phenomena" as the mark of spiritual truth. Yet at the same time it cannot well be denied that she was in the highest degree sensitive to the said marvels as evidence of her Mahâtmâ's existence.

If theosophy were to be judged solely by the published revelations of this "Secret Doctrine" it would hardly be deserving of serious consideration; for, as suggested in the separate article on Madame Blavatsky, the revelations themselves appear to have been no more than a crude compilation of vague, contradictory and garbled extracts from various periodicals, books and translations. It was an article of faith with her disciples that the outward and visible Helena Petrovna Blavatsky was on certain occasions the vehicle of psychic powers of transcendent spiritual import. Although there is not much to justify such a proposition, it may perhaps be conceded that she was in many respects abnormal and that some of her work is characteristic of a process known to modern psychologists as "automatism," or in other words that it is the result of a spasmodic uprush to the surface of sub-conscious mental activities. Apart, however, from these pseudo-revelations the Theosophical Society has given rise to an extensive literature, some of which displays a high degree of argumentative and expository ability; and moreover the movement has from time to time attracted the attention and secured the co-operation of many earnest seekers, of some few of whom it can be truly said that they possessed undoubted spiritual power, insight and knowledge.

Soon after the death of Madame Blavatsky a split in the society was brought about by Mr Wm. Q. Judge (d. 1896) of New York, who claimed the leadership; and there came into existence two if not three separate theosophical societies (following Judge and later Mrs Katherine Tingley in America, Olcott and Mrs Annie Besant in America and India, with a more or less independent organization in England), each one contending that the original affair of the founder had descended upon it exclusively. The fortunes of the societies are, however, of less importance than their leading doctrine.

It will be surmised from what has been said that any concise statement of orthodox theosophy is hardly to be expected; though from the materials available a fairly definite outline of its leading tenets can be deciphered. We will try to give a cursory view of three of the most important of these, viz.: the constitution and development of the personality or ego; the doctrine of "Karma"; and the Way or Path towards enlightenment and emancipation. Human personality, we learn, is the temporary manifestation of a complex organization consisting of "seven principles," which are united and interdependent, yet divided into certain groups, each capable of maintaining temporarily a spurious kind of personality of its own and sometimes capable of acting, so to speak, as a distinct vehicle of our conscious individual life. Each "principle" is composed of its own form of matter, determined and conditioned by its own laws of time, space and motion, and as, in it waxes and wanes alternately, more especially those of Professor T. W. Rhys Davids, and also from the many translations in all the European languages of the Bhagavad Gitâ and Upanishads. Theosophic teachings on this subject are not, however, exclusively Oriental, for following their contention that they are the exponents of the universal and unchangeable "Wisdom Religion" of all the ages, theosophists have selected from various sources—Vedic, Buddhist, Greek and Cabalistic—certain passages for the purpose of exposition and illustration. To the uninitiated it would appear that this selection has been made, generally speaking, at random; it is at any rate lacking in the wise discrimination one would expect from the supposed source of its inspiration. Nevertheless theosophists by their investigations and expositions have undoubtedly been brought in touch with some of the most profound thought in both ancient and modern worlds; and this fact in itself has assuredly had an inspiring and ennobling influence upon their lives and work. The histories of all the great religious and philosophic movements show them as developments of an evolutionary process, arriving at their accepted dogmas through long periods of contention between numerous tendencies and cross-currents, resulting in some compromises and not a little confusion of thought. So it is in the main with theosophy. It has followed Buddhism in deprecating any reliance upon ritual. Ceremonial and sacrificial observances of all kinds are held to be useless in themselves, but operative for good or ill indirectly by their effect upon the mental attitude of those who practise them. Theosophists insist, however, that all religious observances had their origin in some mystical process, the true meaning of which has in most instances been lost. The Path is represented as the great work whereby the inner nature of the individual is consciously transformed and developed. The views of life held by the ordinary mortal as well as his aims and motives
must be radically altered; and simultaneously a change must take place in his modes of speech, conduct and thought. The Path is said to be long and difficult, and with most individuals must extend over many lives. It is divided into four stages, each one representing the degree of spiritual growth and karmic development at which the "chela" or disciple has arrived. But even the entrance upon the very first stage implies something more than, and something fundamentally different from, the life of common morality; otherwise, how hopefully, indeed this life may be. Morality, important though it be as preparatory to the "higher life," does not alone lend itself to that awakening of the spiritual faculties without which progress along the Path is not possible. In good citizenship morality is practised out of regard to certain preconceived notions of the needs, the health and happiness of ourselves, our fellows and the community at large. According to theosophy, it would appear that these notions are for the most part mistaken, or at any rate they are quite insignificant in comparison with the interests with which the traveller along the Path soon finds himself absorbed. It is not that human needs are to be disregarded, but that the pabulum which he now sees that humanity really requires is of an incomparably higher order than that which is generally so considered. The physical methods and spiritual exercises recommended by theosophists are those inculcated in the systems known in Hindu philosophy as Rāja Yoga in contradistinction to the Hath Yoga system, which is most commonly to be met with in India, and in which the material aspects are given greater prominence. The Path has an active and a passive side. Fitness of both faculties and faculties, has to be acquired by positive and strenuous effort. On the one hand, delusions and superstitions are to be abandoned by an attitude of conscious neglect; or to use the phraseology of the Hindus, Avidyā, nescience—the mental state of the unenlightened—through which the individual energies are scattered and dissipated in futile effort, is gradually replaced by Vidyā, the higher wisdom which dispels the darkness of the mind, awakens our latent faculties and concentrates our efforts in the direction of that harmonious union, which ultimately results in Nirvāna. Although the way of the disciple or "chela" is always represented as long and difficult, it is said that he proceeds, the transcendental faculties which arise to help him enable him to pursue the right course with ever increasing confidence and security. These powers of the mind, or "śiddhi," should never be sought for their own sake, or be used for selfish purposes. The attempt to develop and use them without regard to the higher purpose is spoken of as practising the arts of "black magic," the exercise of which invariably leads to disaster. It is proclaimed that were the "chela" to attempt to make an improper use of his powers—that is to say, were he to yield to the promptings of selfishness, lust or antagonism—such a lapse would at once set in action countering forces, which not only retard his upward growth, but which would, were such evil courses persisted in, lead ultimately to the obliteration of all his newly acquired psychic possessions.

The Path may also be described in terms of the "seven principles." It may be said to be a process of unification, whereby the centres of volition, consciousness and active memory are systematically shifted upwards from the lower to the higher "principles" until they have become firmly established in the "Buddhi," or "sixth principle." As this last stage is approached the "chela" becomes less and less dependent on the guidance of traditions and scriptures. The truth becomes revealed to him by the opening of his inner vision, and he learns to see Dharma, the Eternal Law, as it were, face to face. Thus theosophists may be said to accept in their own sense the saying: "He who does the Will shall know the doctrine."

Along the Path are ranged ten great obstacles, or fetters, the Buddhist Sanyojanas, which have to be successively overcome before the final goal is reached. As these sanyojanas give a very good idea of what has been termed the negative aspect of the Path, we may enumerate them as follows:

1. The delusion of personality—the belief in a permanent and unchangeable egoentity.
2. Doubt as to the use of the higher efforts, or as to the possibility of solving the great mysteries of life.
3. The reliance upon ritual—seeking salvation through outward acts.
4. Lust.
5. Illicit, or antagonism.
6. Love of this life and its possessions—"The care of the world and the deceitfulness of riches."
7. The egoistic longing for a future life.
8. Pride.

A few words should be added as to the theosophic hell, or "Avīchā." This is described as a long drawn-out dream of bitter memories—a vivid consciousness of failure without volition, or the power of initiative—a dream of lost opportunities and futile regrets, of ambitions thwarted and hopes denied, of neglected duties, abused powers and impotent hate; a dream ending ultimately in the oblivion of utter annihilation.

There is no doubt much of valuable suggestion to be found in the philosophic system, or rather the conglomerate of systems, which pass to-day under the name of theosophy; and probably much has been done by means of its propaganda to popularize Eastern thought in the West, and in the East to reawaken a truer appreciation of its own philosophic treasures; but however that may be, the serious student would be well advised to seek his inspiration and his inspiration from the fountain-heads of the theosophists' doctrines, which are all easily accessible in translations; and to avoid the confusions and errors of writers who in most cases have but a superficial if any knowledge of the original languages and systems from which their doctrines have been arbitrarily culled.

(Sr G. L. F.-P.)

THÉOT, CATHERINE (d. 1794). French visionary, was born at Barenton (Manche). From her youth a victim of hallucinations, a long course of religious asceticism in the convent of the Miramiones in Paris unhinged her mind, and she was placed under restraint. Liberated in 1782, her early delusions concerning a Messiah became accentuated; that she was destined to be the mother of the new Messiah, she was now assured; she pictured to her followers the fantastic features of the coming Paradise on earth; and was hailed as the "Mother of God." From the idea of the advent of a Messiah to its realization was but a step; in Robespierre the Théotists saw the redeemer of mankind; and preparations for his initiation were put in train. The enemies of Robespierre, resenting his theocratic aims, seized upon his relations with the Théotists as an engine of revenge; Catherine, with Gerle (q.v.) and others, was arrested and imprisoned, and a letter to Robespierre discovered in her house. In the Convention M. G. A. Vadier trumped up the conspiracy of Théot, asserting that Catherine was a tool of Pitt, that the mummeries of the Théotists were but a cloak for clerical and reactionary intrigue, and hinting that Robespierre had this longchered their designs. The case was adjourned to the Revolutionary Tribunal, and figured in the proceedings of the 9th Thermidor. The accused were ultimately acquitted, Catherine herself having died in prison on the 1st of September 1794.

THERA, the southernmost island of the Sporades, now called Santorin (q.v.). It was known as Thera until after the Fourth Crusade, when it became part of the duchy of the Archipelago.

THERALITE (Gk. ἁγνᾶς, to pursue), in petrology, a group of plutonic holocrystalline rocks consisting of nepheline, basic plagioclase, augite and olivine, and so called because it is of rare occurrence, and its discovery was looked forward to with interest as completing the series of basic rocks containing nepheline as an essential constituent. The felspars are mostly of basic character and are often zonal; the nepheline is of later crystallization, rarely idiomorphic and often decomposed. Pyroxene in these rocks may be of green colour or purplish-brown and rich in titanium; olivine is usually abundant. Among the accessories may be mentioned apatite and iron oxides, biotite and dark brown hornblende, the latter often surrounding the purple augite. The rocks have rarely ophitic structure, but their minerals tend to have good crystalline form, except in the case of nepheline and orthoclase (if that be...
present). By decomposition the nepheline yields zeolites such as natrolite and analcine. The theraites are rarely crystalline and have much resemblance to dolerites in hand specimens. Among these rocks are Doupau in central Bohemia, Friddazo (W. Alps), Umpire (on the White Sea), Madagascar and the Crazy Mountains in Montana. A variety of them are known in British Columbia, Canada, and rocks from Crawford John in Lanarkshire and from Carsley in Renfrewshire have recently been ascribed to this group.

Very close to the theraites is a series of rock types known as the teschenites (from Teschen in Moravia). Instead of nepheline they usually contain analcine from their microscopic characters it is by no means likely that the analcine, which is very rare after nepheline in this case; it appears, in fact, to be either primary or of pneumatolytic origin. Nepheline, however, has been found in saprolites in North and South America, so that the distinction between the two series practically vanished. In central Scotland, around Edinburgh and Glasgow, teschenites are abundant, forming thick sills intrusive into the Carboniferous rocks, and some are also known from Leicestershire (Whitchick) and from Aran.

These teschenites are sometimes ophitic and present transitions to olivine-diabases on the one hand and to picrites on the other. They are the deep-seated representatives of the basaltic lavas which were emitted in great numbers in the early part of the Carboniferous period. Other localities for teschenite are the Caucasus and the coast of California (Cuyuna Valley, &c.).

They contain serpentine containing a large amount of alkali feldspar. Nepheline also occurs by no means uncommonly; the augite is sometimes green, but in other specimens is a rich purple colour with well-marked zonal structure. Olivine is by no means common. They are derived from hornblende biotite in some cases and from biotite in others.

The type rock is from Essex (Massachusetts) and other examples have been described from Rongstock on the Elbe, from Mount Royal (Montreal), from S. Norway, north of Christiania, and from St. Vincent in the Cape Verde Islands. A few specimens have been found in Britain, accompanying the Carboniferous teschenites near Edinburgh and in the Campsie Hills of Stirlingshire. As they contain both orthoclase and plagioclase feldspar they have a certain affinity to the olivine-monzonites and kentallenites.

The shonkinites are dark grey rocks consisting of olivine, green augite, dark brown biotite, nepheline and orthoclase, which are frequently present in the Hessisch Lichtenberg Mountains. They are basic varieties of sodalite-syenite and have some resemblance to theraites, especially in the association of nepheline with large amounts of augite and olivine. They are of exceedingly rare occurrence.

**THERAMENES**

(d. 403 B.C.), Athenian statesman, was the adopted son of Hagnon, a prominent conservative who in 430 impeached Pericles, and after the Sicilian expedition became one of the ten **probuli** (προβολοί, commissioners) appointed to devise economies in the administration. As a pupil of the sophist Prodicus he acquired facility in public speaking. Under his father's patronage he joined in the conservative reaction which came to a head in 411, when hopes of a Persian alliance or peace with Sparta strengthened the existing dissatisfaction with the democratic rule. Theramenes specially studied the constitution of the **boule** (πολίτης) and formulated a new party-cry, "the constitution of our fathers." It was no doubt largely due to his advocacy that the **probuli**, strengthened by further members, were commissioned to draft new measures on behalf of the public safety and to examine Cleisthenes' "ancestral code." In their report the following measures were recommended: (i.) annulment of the act promulgating illegal measures; (ii.) abolition of pay, save for the troops in the field and the archons; (iii.) restriction of the franchise to 5000 able to serve "with person and purse." (iv.) the appointment of 400 to hold office of the **boule**. When these proposals were passed (apparently in a packed assembly outside the walls), a Constituent Assembly of 100 was elected, nominally by the 5000, who as yet were a mere phantom body, in point of fact by the leading conspirators. The new constitution provided for a boule whose members were to be recruited by lot from all citizens above thirty; the functions of this body to be exercised by four sections succeeding one another by yearly rotation and serving without pay; all high officials to be chosen by it out of its own members. This scheme embodied the chief reforms desired by Theramenes, and marks the triumph of his policy. But before it could be carried into effect it was superseded by "provisional constitution," which gave unlimited power to a boule of 400 (chosen by a roundabout system which favoured intrigue) and its nominees, the ten "absolute" generals. This extreme reaction displeased Theramenes, who in return began to agitate for the calling of the 5000 into real existence. Furthermore he warned Athens against the treason of the extreme oligarchs, and induced the troops to raise a mole erected to facilitate a Spartan descent on Piraeus.

After the disaster at Eretia (see PELOPONNESIAN WAR), which caused the fall of the extremists and the institution of a government of "5000" (i.e. all citizens who could afford a suit of armour), Theramenes stood in high esteem. After assisting in the prosecution of his former colleagues he received the command of a squadron with which he helped to win the great victory at Cyaicus (410) and to recover the Bosporus. After the triumph of the radical democrats which followed upon these successes he lost his high command. At Arginusae (406) he fought as a simple ship's captain, but after the battle was commissioned by the generals to rescue some drowning men, for which, with his ill-trained and exhausted troops, in a heavy storm, he was unable to carry out. For this failure the generals were severely criticized at Athens; an inquiry by the boule led to their arrest, and before the ecclesia they aggravated their case by pleading (i.) that the storm made a rescue impossible, (ii.) that Theramenes was to blame. Theramenes in reply brought out the implied contradiction in these statements, and in consequence the assembly condemned the accused to death and subsequently returned Theramenes general.

In 405 Theramenes went as plenipotentiary to Lyons (q.v.) to obtain peace terms; after long negotiations he proceeded to Sparta and arranged a settlement which the Athenians ratified (April 404). In spite of this peace the disorder in Athens did not abate. The restored fugitives selected five "ephors," including Critias, to organize a revolution, while the radicals opposed that return to the "ancestral constitution," for which Theramenes had stipulated. Hereupon Lysander returned to Athens and had a Constituent Committee elected, of whom ten members were nominees of each section. In this body Theramenes at first assumed the chief part, and the new measures, regarding the laws against the Areopagus and suppressing sycophancy were well received. But, exactly as in 411, a more violent party under Critias, forgetting its real duties, appointed an autocratic boule of its own creatures, and proceeded by judicial murders and confiscations to earn for the new government the name of "the Thirty Tyrants." Theramenes protested, and managed to get a citizen-body of 3000 admitted to a share of the government. Critias, however, fearing a renewal of the collapse of 411, disarmed the people and decided to remove Theramenes before he could create a new democratic party. The latter successfully repelled Critias' denunciation of treason, but was led away by violence and forced to take poison. His well-known gibe, "Here's to the noble Critias," attests his strength of mind at the hour of death.1

Theramenes demonstrably had a definite policy throughout his career. His ideal was a return to a 6th century constitution, which his contemporaries could equally regard as a moderate oligarchy or a restricted democracy. The main features of his programme were: (i) property qualification for franchise; (ii) abolition of pay; (iii) transference of some judicial powers from the popular courts to a restored Areopagus. At times he seemed likely to succeed, but amid the violent oscillations of party he could not definitely join any one faction, and so earned the nickname Κάποιος (a stage-boot fitting either foot). Aristotle, however, discerned Theramenes' real policy, and, like Cicero and Caesar, in later years ranked him among the greatest Athenian statesmen.

**Sources.**—**The Constitution of Athens** with its numerous documents affords much valuable knowledge, but does not give the inner history of 411. Thucydides viii. supplies this, but his

1 The attempted rescue by Isocrates (Pseudo-Plutarch, *Vitae X. Orationum*) is improbable; but Theramenes may have taught Isocrates in oratory.
knowledge of the constitutional side of the revolution and of Therapeutae—Therapeuthics

793

of the Law to the spiritual truth that lay hidden within. When the president's address had been duly applauded, there followed the singing of hymns ancient and modern. Then came the meal of the simple kind already described. And after this a per-vigilium, celebrated with antiphonal and joint singing on the part of men and women and with choral dancing in imitation of Moses and Miriam at the Red Sea. At sunrise, turning to the east, they decreed that the lights of ancient might illumine their minds, and then returned to their studies.

Such is the account of the Therapeutae given by Philo. It seems to have formed part of the Apology for the Jews (Eus. Pr. Ev. viii. 10, § 12)—hence its highly rhetorical character—from which Eusebius gives the extract about the Essenes; while this in its turn may have constituted the fourth book of a large work entitled "sarcastically," says Eusebius, H. E. ii. 18 ηεϊ Απέρων, of which the Legatio ad Gaium formed the first. The De Vita Contemplativa thus owes its place next to the Quod Omnium Probus Liber, a place which it already occupied in the copy of Philo's works possessed by Eusebius (H. E. ii. 18), merely to the mention of the Essenes at the beginning of it.

To the modern reader the importance of the Therapeutae, as of the Essenes, lies in the evidence they afford of the existence of the monastic system long before the Christian era. We have no clue to the origin of the Therapeutae, but it is plain that they were already ancient when Philo described them. Eusebius was so much struck by the likeness of the Therapeutae to the Christian monks of his own day as to claim that they were Christian converts from the preaching of St Mark. He goes so far as to say that "the men of the sect," referred to by Philo, may very well have been the Gospels and Epistles (which were not yet written). This is a strong instance of how the wish may be father to the thought even in a fairly critical mind. Eusebius having gone wrong on this point, others of the Fathers followed suit, so that Philo is reckoned by Jerome among the ecclesiastical writers of the Christians.

Nothing is more likely than that Christianity gained adherents among the Therapeutae, and that their institutions were adapted to the new religion, just as they seem to have been borrowed by the Jews from the Egyptians. Strabo (xi. 29, p. 866) tells us how he saw at Heliopolis large buildings belonging to the priests, which had once been tenanted by men skilled in philosophy and astronomy, who had been consulted by Plato and Eudoxus, but that the σωτηρία and δοξασις (the very words used by Philo in speaking of the Therapeutae) had then fallen into decay. The system, however, was not even then extinct, for it was described by Chaeeron the Stoic, a contemporary of Strabo's. Chaeeron's account has been preserved by Porphyry (Life of Apollonius, vi. 9), and has curious resemblances to Philo's description of the Therapeutae, even down to such details as their posture and gait and the eating of hyssop with their bread.

After 1879 a theory became current in Germany (first stated in P. E. Lucius, Die Therapeutae und ihre Stellung), and accepted in England, to the effect that the De Vita Contemplativa is not a work of Philo's at all, but a forgery put forward about the end of the 3rd century and intended to procure the authority of Philo's name for the then rising monasticism of the Church. But this theory was signaly refuted by F. C. Conybeare in his Philo about the Contemplative Life (Oxford, 1893).

See also works quoted by Conybeare (pp. 591-599); Bousset, Religion des Judenmoden im nieutestamentlichen Zeitalter (1903); A. Harnack, s.v. "Therapeutae" in Herzog-Hauck, Realencykl., xi. 677 (1907).

ThERAPEUTHICS (Gr. θεραπευτης, sc. της, from θεραπευω, to serve), the name given to that branch of medicine which deals specifically with the means employed to cure disease if possible, or to control and lessen its evil results when a cure is impossible.

The cure which is sought for may either be symptomatic or radical. Various morbid conditions of the body generally may give rise to different symptoms. Thus a gouty condition may
manifest itself in one man as eczema of the skin, giving rise to redness and intense itching; in another as neuralgia, causing most severe pain; in a third as bronchitis, producing a distressing cough; in a fourth as dyspepsia, giving rise to flatulence and intestinal disturbance; and in a fifth as inflammation of the great toe, accompanied by redness, swelling and pain. The therapeutic measures employed in these different cases may be directed towards alleviating the symptoms, such as itching, pain, cough and swelling, in which case the treatment will be merely symptomatic; or they may be directed towards removing the root of the disease, viz. the gouty condition underlying them all, and thus effecting a radical cure. It very frequently happens that we do not know what the underlying condition is, and consequently rely to a great extent on empirical methods, the most prominent and most distressing symptoms. In symptomatic treatment we are frequently obliged to use remedies simply because we know they have done good before in similar cases, and we expect them to do so again without having the least idea of how they act. Thus in acute gout the most common and most trusted remedy for removing the pain is colchicum, but at present we do not know what action it has upon the system, or why it gives so much ease in the pain of gout while it has comparatively little effect upon pain due to other causes. This plan of treatment is termed empirical. It is a useful method of attack, and if the treatment is attended with success, the patient is satisfied, but it has the disadvantage that it admits of but little progress, and when a trusted empirical remedy fails we do not know precisely in what direction to look for a substitute. In contradistinction to empirical we have rational therapeutics, by which we mean the application of a remedy, whose mode of action we know more or less perfectly, in diseased conditions, the nature of which we also understand more or less fully. As an example may be taken the use of nitrite of amyl in angina pectoris. It has been found that in many cases of this disease the pressure of blood within the arteries becomes increased, probably from spasmodic contraction of the arteries themselves. Nitrite of amyl has the power of dilating the arteries; it has consequently been employed with much success in lowering the blood pressure and removing the pain in angina pectoris. But such rational knowledge as this not only enables us to remove pain at the time, but helps us to prevent its recurrence. For on the one hand knowledge of the fact that nitrite of amyl lessens blood pressure has led to the successful employment of other nitrites and bodies having a similar action, and on the other the knowledge that increased blood pressure tends to cause anginal pain leads to the prohibition of any strain, any food, any exposure to cold, and avoidance of any medicines which would unduly raise the blood pressure. Here we notice one of the greatest advantages of rational over empirical therapeutics. In cases of angina, while the resistance opposed to the action of the heart by spasm in the vessels may be great, the heart itself may be feeble, and it may therefore be necessary to give some remedy which will increase the power of the heart. But if such a remedy were given alone it might, and probably would, act on the arteries as well as the heart, and by causing the contraction of the vessels do more harm than good. But if we know what remedies will increase the power of the heart and yet not affect the arteries we may combine them and thus obtain the objects we desired, viz. removal of the pain, better action of the heart, and more perfect circulation.

The testing of ideas by observation and experiment which was begun in anatomy by Vesalius, and by Harvey in physiology, was applied by Morgagni to alterations in the organs produced by disease, by Bichat to the tissues, and by Virchow to the cell. The study of disease in the living body may be said to have been begun by John Hunter, developed by Magendie, Claude Bernard, Brown-Séquard and others. Of late years enormous impulse has been given to our knowledge of the causation of disease by microbes, through the works of Gaspard, who injected putrid matter into the veins of a living animal; by Villemain, who discovered that tuberculosis is infective; by Davaine; and especially by Pasteur, Koch and others too numerous to mention, who have worked, and are still working, at the microbe causation of disease with marvellous success.

The natural end of life is that all the organs should become old and gradually decay at the same time, so that at the last the individual should become less and less active, weaker and weaker, and finally die without any definite disease, without pain and without struggle. But this is exceptional, and generally one part gives way before another, either on account of one part being naturally weaker or of one part having been overtaxed or more severely attacked by some injurious external influence, or by some undue preponderance of another part of the body itself. For health consists in a due proportion between the actions of all the different parts of the body, and if one part be abnormally strong it will lead the system to destruction. Thus a very strong heart, although it may be useful to its possessor for many years, driving the blood rapidly through the vessels, and supplying all his tissues with such abundant nutriment as to enable him to endure great exertion, mental or bodily, may in the end cause death by bursting a vessel in the brain, which might have resisted the pressure of a feeble circulation for years longer. On the other hand, a heart that is too feeble may cause its owner's death by its inability to carry on the circulation against increased resistance, or by acting as a valve, and being obstructed. If the resistance is increased in the arterial system by a sudden exertion or strain, and more slowly when the resistance is increased in the pulmonary circulation by inflammation of the respiratory passages. The thyroid gland, which is situated in front of the neck, yields a secretion which passes into the blood and there tends to maintain a state of moderate dilatation in the blood-vessels and of oxidation in the tissues, so that the circulation remains good and the body-heat and muscular activity remain well maintained. When this gland becomes enlarged, and its secretion consequently increases, the vessels dilate, the heart beats more rapidly, the skin becomes too hot, the nervous system becomes irritable, and tremors occur in the limbs. On the other hand, when it becomes atrophied the circulation becomes feeble, the face heavy and dull, the patient suffers from cold, the features grow lumpy, mental processes become sluggish, and bodily vigour diminishes.

Disease of the whole body may thus be produced by over-action or under-action of some part of it, but such causes of disease are slight as compared with the effect of external noxious influences, and more especially the effect of microbes. These enter the body through various channels, and once they have effected a lodgment they grow, multiply and give rise to various poisons which attack and injure or destroy different tissues or organs in the body. Various safeguards are provided by nature to prevent their entrance. On the skin we have a thick epidermis through which microbes cannot pass, although if an entrance is obtained for them by a prick or cut they may readily grow in the tissues below and spread from them throughout the whole body. They pass more readily through mucous membranes, but almost every one of these is provided not only with a coating of mucus, which obstructs their passage, but also with abundantly supplied with leucocytes - white blood-cells. Thus irritation of the eye causes winking and secretion of tears, by which the irritant is removed; irritation of the nose causes sneezing; of the air-passages, coughing; of the stomach, vomiting; and of the intestines, diarrhoea. Even when they have passed through an abrasion in the skin or through the mucous membranes and enter the blood they are met, in some instances, by a toxic action of the blood itself upon them; and in others they are attacked by the white corpuscles, which destroy them, eat them up, and digest them, the process being known as phagocytosis. The greater the number of leucocytes that can reach the spot where the invading microbes enter the more quickly can the microbes be destroyed and general infection prevented. The microbes appear in many cases to attract the leucocytes (positive chemiotaxis), but when very virulent they usually repel the leucocytes (negative chemiotaxis).
and excrete toxins which kill the leucocytes. The irritation caused by the microbes generally is followed by dilatation of the vessels of that part and thus more leucocytes are brought up to the fight. This dilatation may be increased by local warmth, and poultices or fomentations are commonly applied to inflamed parts; recently suction apparatus has been used for the same purpose or ligature so as to cause venous stasis (Bier’s treatment). Blisters also cause local dilatation of vessels, but are usually applied to the skin for inflammation in deep-seated parts, such as the lungs, though they also relieve pain in the joints in acute rheumatism. Bier increases the blood in a part by compressing the veins and thus producing passive instead of active congestion. The toxins produced by microbes, however, are weak in their destructive power, but are able to secrete anti-toxins, which not only act as antidotes to the toxins and are injurious to the microbes, but also increase the phagocytic power of the leucocytes (opsonius of Wright). By inoculation with increasing doses of these the resistance of the organism is greatly increased and the invading microbes destroyed. The vaccine is usually made by sterilizing a virulent culture and the proper dose is ascertainment by noting the extent to which the power of the leucocytes to envelop and digest the microbes is increased.

Moreover, the products of microbial secretion tend to produce fever. The high temperature characteristic of this condition is no doubt injurious to the body itself, but it is frequently more so to the microbes which have invaded the organism; and thus fever, instead of now being regarded as a morbid condition to be suppressed by every means in our power, is considered to be a reaction of the organism tending to protect it by destroying the infection. But it must be kept within limits, lest it should of itself cause death, and here again we see the difference between empirical and rational medicine. Fever is not to be looked upon as an unmitigated evil to be removed if possible, but rather as a defensive mechanism by which the organism may prevent invasion from noxious microbes. Nevertheless, as in a campaign the general’s plan may be spoiled by too hasty or too eager action on the part of some of his troops, so the defensive arrangement carried to excess may prove injurious or fatal to the organism. Thus too great a rise of temperature in fever may kill the patient; and the aim of therapeutics is to restrain the temperature within proper limits, neither allowing it to rise too high nor to fall too low. The old plan of lowering it by means of cold baths was known to Musa, the physician of Augustus, and it is said he saved the emperor’s life; but the same treatment killed the emperor’s nephew. The introduction of the clinical thermometer, which allows us to ascertain exactly the amount to which the temperature rises in fever or to which it is reduced by antipyretic measures, is to the physician like the compass to the sailor, and allows him to steer safely between two extremes.

After the struggle between the organism and the microbes is over, even when it has ended victoriously for the former, injuries are left behind which require repair. Every one has noticed after prolonged fever how thin and weak the patient is, and both the muscular and nervous power throughout the whole body are sadly in want of repair. Where there has been local mischief due to inflammation the dead leucocytes must be removed, and this is done either by their being converted into pus in one mass, and making their way through the tissues to the nearest surface, whether of skin or mucous membrane, from which it can be discharged, or they may undergo a process of fatty degeneration and absorption, leaving behind in some cases cheesy matter, in others hard connective tissue.

Poisons formed by microbes are partly eliminated by the kidneys, partly by the mucous membrane of the stomach and intestines, and possibly also by the skin. In old days free elimination by these channels was looked upon as a sign of returning health, and was termed a “critical” diuresis, diarrhoea or sweating, according to the channel through which the eliminative act had occurred.

By therapeutic measures we strive to limit as far as possible the entry of injurious microbes into the organism, to expel or destroy them and their harmful products, and to maintain the strength of the organism itself. One of the influences which is most injurious to the body, and favours most the invasion of microbes, is chill. So much is this the case that some diseases which are now known to be due to infection were formerly attributed entirely to the effect of cold. Thus pneumonia is now known to be due to the diplococcus pneumoniae, and yet its invasion occurs so frequently after a chill that it is almost impossible not to look upon chill and pneumonia as cause and effect. The reason of this appears to be that the diplococcus is frequently present in the mouth or air-passages without giving rise to any symptoms; but when the patient is exposed to a chill, and the tissue resistance weakened, the diplococcus grows, multiplies and gives rise to inflammation of the lungs. Even what are known as common colds are probably due chiefly to microbial infection aided by a chill, just as in the case of pneumonia. Therapeutic measures which are commonly adopted in the treatment of a cold have for their object to destroy the microbes before they penetrate fairly into the organism, and to restore the balance of the circulation and increase the strength of the invaded parts.

By the use of hot spirits or carbolized ammonia are sniffed into the nose to destroy the microbes, which are destroyed by an antiseptic solution as a nasal douche; bismuth or morphine are insufflated, or zinc ointment is applied, to cover the mucous membrane, and protect it from further irritation; and various antiseptic gargles, paints and powders applied to the pharynx in order to prevent the microbial inflammation from extending to the pharynx and down the trachea and bronchi, for many a severe bronchitis begins first by sneezing and nasal irritation. Sometimes the patient is put to bed and the circulation is encouraged, especially on the surface of the body, by the use of hot spirits and water, or opium and pepsicum, while the outside of the nose is protected to a certain extent from loss of heat, and consequent irritation, by smearing it with a tallow candle or rubbing some ointment over the skin. At the same time, if the throat has begun to show signs of being involved, a hot poultice or wet pack is applied to the neck.

Both inflammation and fever are protective processes calculated to defend the organism against the attacks of microbes. But protective processes misdirected or carried to excess may become injurious or even dangerous to the organism. As an example of this take the irritation which may come about in the eye after a particle of dust has been removed from it or the itching of the skin which occurs in eczema. The irritation of the conjunctiva caused by dust leads to winking of the eye-lids, lachrymation and rubbing, which tend to remove it; but after the dust has been removed violent rubbing tends rather to keep up the irritation; and sometimes, if the particle of dust remains under the eyelid and is sharp and angular, the process of rubbing may cause it to injure the conjunctiva much more than if it were left alone. In the same way itching is often caused by the presence of insects or other irritants upon the skin, and it tends reflexly to cause rubbing, which is useful by removing the irritant. But when the irritation is situated in the skin itself, as in eczema, the scratching tends to increase inflammation, and makes the irritation worse. In the same way, the reflex act of coughing is useful in removing either foreign bodies or excessive secretion from the air passages; but when the mucous membrane of the respiratory tract is irritated and inflamed, it produces a feeling of tickling and a desire to cough sometimes very violently; yet the coughing simply tends to exhaust the patient, because there is really little or nothing to bring up. The same microbes in the organ to which the lung substance itself. As an example of excessive action we may take sneezing, which is calculated to remove irritants from the nose, but when too powerful may cause the patient to burst a blood-vessel. In phthisis also, although there may be some expectation to bring up, yet a good deal of the irritation is in the lung substance, and the efforts of coughing are far greater and more continuous than are required for the removal of
THERAPEUTICS

expectoration, and they simply exhaust the patient. In inflammation of the stomach also such continuous vomiting occasionally occurs that the patient’s life is in danger by his inability to retain food; and similar danger also occurs from inflammation of the intestines and consequent diarrhoea.

We will next take the various parts of the body, and consider more in detail the therapeutic measures most commonly employed in the treatment of their diseases. The defensive measures. protective powers of the body against microbes, when actually on or in it, may be classed as means (1) of passive defence, (2) of active defence, and (3) of repair. Besides these, however, we may regard as passive defence the inhibition of the whole body from injury caused by (a) inaction, or (b) overaction, or (c) weakness of any one of its parts. The means of passive and active defence are sometimes so closely associated that it is difficult to distinguish between them. Thus if a little diphtheritic sputum were coughed into a person’s eye, or some blood containing anthrax bacilli were to touch a raw spot upon the hand, the removal of microbes in either case by washing with simple water might be regarded as a means of passive defence, whilst washing them away with an antiseptic lotion might be regarded as active defence, because the antiseptic would tend not only to take the microbes off, but to destroy the microbes. In the same way, washing the skin with spirit would tend to harden the epidermis and thus prevent the entrance of microbes; and the application of an ointment to an abrasion would have a similar action. But by the addition of some antiseptic to the ointment its defensive action would be converted from passive to active, and its power to prevent infection would become greater; and if inflammation had already set up in the skin, the addition of opium, belladonna, or cocaine would lessen local pain; and an astringent, either metallic or organic, would restrain inflammation and accelerate repair. The thickening of the epidermis in the hands and feet, which occurs from constant use, is nature’s provision for meeting the extra wear to which these parts are subjected by much use; but pressure is apt to cause the defensive process to be carried too far, and to lead to corns, which give rise to much pain and annoyance. To remove these salicylic acid dissolved in flexible collodion is now generally employed. When this is painted upon the part the corn usually peels off in a day or two, and the patient is cured.

But the object of therapeutics is not merely to cure. It is, in the words of the old formula, Curare, cito, iuto, et jucunde, to cure quickly, safely, and pleasantly. There are principles to cure, therefore in most prescriptions (1) a basis or chief ingredient intended to cure (curare), (2) an adjuvant to assist its action and make it cure quickly (cito), (3) a corrective to prevent or lessen any undesirable effect (iuto), and (4) a vehicle or excipient to make it suitable for administration and pleasant to the patient (jucunde). In the remedy just mentioned the salicylic acid forms the basis; but sometimes chloride of zinc or lactic acid is added to it to make it act more quickly, and these are the adjuvants. Extract of belladonna is added to lessen the pain which might occur during the removal of the corn, and this acts as a corrective; while the flexible collodion forms a means of applying it conveniently, and constitutes the vehicle.

The surface of the skin may be invaded by parasitic organisms and may exhibit spots, which are removed by something which will destroy the parasite, such as ointments containing mercurial salts. In psoriasis the epidermis separates in flakes at various spots which have not been subjected to pressure, and to cure it ointment containing tar or other products of the dry distillation of wood is employed. When the true skin is inflamed various appearances may arise, according to the intensity and extent of the inflammation, and the eruption may be papular, vesicular, pustular, tubercular, bullous or ulcerative. To lessen irritation the skin is protected by dusting powders, such as oxide of zinc, starch, fuller’s earth, &c., or by ointments. Irritation is lessened by lotions containing substances that will diminish irritability of the nerve-endings and skin, such as carbolic acid, hydrocyanic acid, morphine or opium, cocaine, belladonna or atropine. Where the surface is ulcerated it may be protected from external violence and placed under favourable conditions for healing by covering it with lint moistened with water and with oil-silk over it to prevent evaporation. If the granulations tend to become too abundant, some astringent, such as sulphate of copper or sulphate of zinc, is added to the water. On the other hand, when the ulceration is old and the circulation through it poor, the aim of the therapeutist is to reawaken the normal reparative process, to bring about increased circulation and increased tissue change, and thereby induce healing. For this reason a substance is placed upon the callous ulcer, which heals with the fresh inflammation thus excited.

The treatment of inflammation of mucous membrane is based upon the same principles as inflammation of the skin, and there too we usually associate means (1) for removing microbes, (2) for destroying them, (3) for lessening the irritation they produce, and (4) for repairing any mischief they have done. Thus in the eye and ear, lotions containing an antiseptic, a sedative and an astringent are very generally used. For inflammation of the mouth a similar combination is used as a gargle, or in the form of a salve, in the latter case, and sometimes as an ointment or spray, the ointment possessing the advantage of protecting the delicate nasal mucous membrane from irritation by stopping the entrance of irritant dust into the nasal cavities. In the stomach we aid the vomiting by which microbes or the products of decomposition of food are usually eliminated by giving to the patient repeated draughts of hot water so as to wash the stomach clean. Frequently this is sufficient; but if the stomach refuses to eject its objectionable contents, we may either give an emetic or wash it out by means of a stomach-pump or siphon. Similar procedures are used for the intestine, and one of the best methods of treating the diarrhoea consequent upon the presence of irritating substances in the intestinal canal is to give a dose of castor-oil together with a few drops of laudanum. For bowel movements the irritating substances are removed, and the laudanum which is mixed with the purgative soothes the intestine. Even in cases of very acute intestinal diseases similar treatment is now pursued, and instead of treating dysentery simply by sedatives or astringents, an eliminative treatment by means of sulphate of magnesia is largely employed. After the irritant has been removed either from the stomach or intestine, a feeling of irritation of the mucous membrane may remain, and sickness and diarrhoea or pain may continue in the stomach and intestine although the irritant is no longer present within them, just as the flow of tears and desire to rub may remain in the eye after the piece of grit which has occasioned it may have been removed. The condition which remains after the irritant has been removed is one of inflammation more or less intense. The process of inflammation is a defensive one, but if carried too far may prove injurious.

For the purpose of checking the inflammatory processes and lessening discharge from mucous membranes astringents are employed. Some of these are of mineral and some of vegetable origin, but they almost all possess one chemical property in common, namely, they precipitate albumin. This power is possessed alike by a glass of brandy, by solution of lime, soluble salts of zinc, copper, or silver, by tannic and gallic acids, as well as vegetable juices and extracts which contain them. The strength of the astringent application and the mode of its administration are varied according to the delicacy and position of the mucous membrane affected. Thus to the eye we may use a solution of sulphate of zinc of half a grain to the ounce, while to the ear, urethra or vagina a solution of four to eight grains or even more may be applied. For the stomach and intestines we employ the same drug in the form of a pill; and when it is desired to act especially upon the intestines, the pills are made of a harder consistence or less soluble preparation, or are covered with keratin, so that they may not act much, if at all, upon the stomach while passing through it before reaching the intestines. The heat which occurs in inflamed parts is chiefly due to the
larger amount of blood circulating in the part on account of the dilatation of the vessels. The pain is due to stretching of the nerve fibrils or compression of them by the turgid vessels in the swollen tissues. This latter cause is chiefly observed when the tissues are of a very unyielding character; for example, when the inflammation occurs in a bone or under a thick fibrous and unyielding membrane. The swelling, heat and pain may sometimes be relieved by mere change of position altering the flow of blood to the inflamed part. Thus when inflammation occurs in the finger, as in a whitlow, the pain is not only constantly severe, but it is increased by every pulsation of the heart. A rapid rise and fall of the heart, as occasioned by rapid dilating the vessels around forms a side channel through which the blood passes, the tension in the seat of inflammation being thus lessened in both cases. When the inflammation occurs in soft parts where the surrounding vessels can be readily dilated, heat often affords more relief to the pain than cold, but when the inflammation is in a bone or in unyielding fibrous tissues, cold generally gives more relief. For example, the pain of a gum-boil is generally relieved more by warmth, because the yielding tissues of the gum, mouth and cheek can be readily relaxed by heat and their vessels dilated; but when the pain is dependent upon inflammation in the hard unyielding socket of a tooth, cold generally gives greater relief. The removal of blood, either by incision or by the application of leeches, sometimes gives considerable relief to the pain and tension of inflamed parts. Blisters applied at some distance from inflamed parts are also sometimes useful; and probably they produce this good effect by causing a reflex contraction of the arteries in the inflamed part, and thus acting like a cold application. Certain drugs have the power of relieving inflammation by slowing the heart and rendering its impulse more feeble. Amongst those are volatile oils, which when applied to the forehead generally by means of a fan especially tends to lessen the process of inflammation generally, when it is not too severe. There can be little doubt that the intensity of inflammation frequently depends very much on the condition of the blood, and that by altering the blood inflammation may be lessened. Thus free purification, and especially purification by chologogues and salines, has long been recognized as a useful means of reducing the inflammatory process. For example, a mercurial pill at night, followed by salts and scena in the morning, will often relieve the pain in toothache or gum-boil, and lessen inflammation not only in the mouth, but other parts of the body as well. Such remedies are termed antiphlogistic. Venesection (blood-letting) at one time was highly esteemed as an antiphlogistic measure, and while it is possible that it has now fallen too much into disuse, there can be no doubt that at one time it was very greatly abused, and was carried to such an excess as to kill many patients who would have recovered perfectly had they been let alone. Although the high temperature in an inflamed part is chiefly due to the increased circulation of blood in it, yet the presence of inflammation appears to cause increased formation of heat either in the inflamed part itself or in the body generally, because we rarely find inflammation exist to any extent without the temperature of the body being raised and a febrile condition produced.

Two very old remedies for fever are acetate of ammonia and nitrous ether. These were formerly given empirically, simply because they had been found to do good. Now we can see the reason for their administration, because the nitrous ether, consisting chiefly of ethyl nitrite, dilates the superficial vessels and thus allows greater escape of heat from the surface; while acetate of ammonia, by acting as a diaphoretic and stimulating the secretion of sweat, increases the loss of heat by evaporation. When a patient is covered with several blankets, loss of heat from the surface both by radiation and evaporation is to a great extent prevented, but if a cradle be placed over him, so as to raise the bedclothes and allow of free circulation of air around his body, both radiation and evaporation will be increased and the temperature consequently lowered. If his body be left uncovered except by the sheet or blanket thrown over the cradle, the loss of heat is still greater, and may be much increased by sponging the surface with either hot or cold water so as to leave it slightly moist and increase evaporation. The temperature may be still further reduced by placing vessels filled with ice inside the cradle. When the patient is very restless, so that cradling is impossible, a wet pack may be employed, a sheet wrung out of cold water being wrapped round him, and over this a blanket. The pack has the double effect of restraining his movements and thus lessening the production of heat, while at the same time it dilates the vessels of the skin and produces loss of heat. The restraint on the body and the moisture on the surface frequently cause sleep quickly in patients who have previously been wildly delirious and entirely sleepless. When the temperature continues to rise in spite of wet sponging and cradling, recourse must be had to the cold bath. The bath should be brought to the bedside and the patient, wrapped in a sheet, should be lifted into it by two attendants. The water should be at the temperature of 90° and gradually reduced by the removal of hot water and displacement by cold, until the temperature of the patient as taken in the mouth is reduced to about 95° or 96°. After this the patient should be taken out and again put into bed. It is inadvisable to lower the temperature quite to the normal while the patient is in the bath, as frequently it falls after his removal, and may fall so far as to induce collapse. In cases where no bath is available a large mackintosh sheet may be spread upon the bed under the patient, the sides and top may be raised by pillows, and cold water may be applied to the surface of the body with large sponges. The mackintosh sheet forms a shallow bath, and the water may afterwards be run off from it at the lower end of the bed. Another way of applying cold is to dip an ordinary sheet into cold water, ring it out, and apply it to the body, then remove it and replace it by another sheet while the first one is being dipped in water. By the alternate use of the two sheets, or by the use of one quickly wrung out of cold water as soon as it becomes warm, the patient's temperature may be rapidly reduced.

There are a number of drugs which have a very powerful action in lowering temperature. Most of these belong to the aromatic group of bodies, although one of them, antipyrin, belongs rather to the furfurol group. Carbohelic acid has an antipyretic action, but on account of its poisonous properties it cannot be employed as an antipyrin. Salicylic acid has a strong antipyretic action, and is most commonly used in the form of its sodium salt, which is much more soluble than the acid itself. Amongst other antipyretics, the most important are quinine, phenacetin and antifebrin. These probably lessen fever by their action upon the nerve centres which regulate the temperature of the body, and partly by their peripheral action in causing the secretion of sweat. Very high fever in itself will cause death, the fatal temperature in rabbits being 114.5°. Before death occurs the pulse and respiration become extremely rapid and weak, and complete unconsciousness sets in. That these symptoms are simply due to heat is shown by the fact that if the temperature be quickly reduced by the application of cold the symptoms at once subside. But the delirium which is common in fever, although it may be partly due to rise of temperature, is very often due to poisons in the blood, for in some cases it occurs with quite a low temperature, 101° or 102°, whereas in others the temperature rises to 104° and 105° with no delirium whatever. The presence of toxins in the blood not only
affects the brain, causing delirium, but also other organs, the heart and lung, and may cause fatal syncope or respiratory failure.

Many years ago Dr S. L. Mitchell (1764-1831) pointed out in America the resemblance which exists between symptoms of poisoning by snake venom and infective fevers. S. Weir Mitchell and others have shown that serpent venom consists chiefly of albumoses, and the toxins formed by infective bacilli have a somewhat similar chemical nature. Calmette and Fraser found that when small doses of some snake venom are injected into an animal, temporary disturbance is produced; but after a few days the animal recovers, and a larger dose is then required to produce any symptoms. By gradually increasing the dose the animal becomes more and more resistant, until at last a dose fifty times as great as that which would at first have produced immediate death can be injected without doing the animal any harm. If a horse be chosen for the experiment, a considerable quantity of blood may be withdrawn without injuring the animal. When this is clotted the serum is found to act as an anti-aemic in that way it hardens the plasma and makes the snake venom harmless. Although this result is best obtained when the venom and serum are mixed in a glass before injection, yet if they be injected at the same time in different parts of the body the animal will still be protected and the poison will not produce its usual deadly results. What occurs with snake venom takes place also when the toxins are formed by microbes, and a new method of treatment by anti-toxic serums has been introduced of late years with great success. This is most commonly and successfully used in the treatment of diphtheria. This disease depends upon the presence of a bacillus which grows rapidly at the back of the throat and in the air passages specially of children, causing the formation of a membrane which, by plugging the windpipe, causes suffocation and death. At the same time it produces a poison which causes inflammation of the nerves, leading to paralysis, which sometimes proves fatal. By growing this bacillus in broth a toxin is formed which remains in solution and can be separated from the bacilli themselves by filtration. This toxin-containing broth is injected into a horse in increasing doses, just as in the case of the serpent venom, and after the resistance of the horse has been increased to that into which it has been infected the filtrate blood is allowed to coagulate. The serum is then removed and its anti-toxie power tested by ascertaining the amount necessary to counteract a given amount of active toxin in a guinea-pig of a certain size, the standard weight being three hundred grammes. The serum, the strength of which has thus been ascertained, is distributed in bottles and injected in the proper quantity under the skin of children suffering from diphtheria. If used at an early stage of the disease, and in sufficient quantity, the results are wonderful. The same method of serum therapeutic has been used in other infective diseases, but not with the same success.

Another therapeutic method which is historically much older than that of serum therapeutic is that of inoculation.

Inoculation. The virulence of infective diseases varies in different epidemics, and at different times in the same epidemic. It had been noted that many infective diseases did not attack an individual a second time, the first attack appearing to protect from subsequent ones. The idea of inoculation, therefore, was to infect an individual with a mild form of the disease, so that he should escape infection by a more virulent one. This was tried largely in the case of smallpox, and since at least in Dr Erasmus Darwin's case of scarlet fever. The worst of this method was that the disease thus inoculated did not always prove of a mild character, and in the case of Dr Erasmus Darwin's son the scarlet fever was exceedingly severe and very nearly proved fatal. To Edward Jenner we owe the discovery that vaccination protects against smallpox, and it is now generally acknowledged that smallpox and vaccine are probably the same disease, the virus of which is modified and its virulence lessened by passing through the body of the cow. Pasteur found that the germs of anthrax could be cultivated outside the body and their virulence weakened either by growing them at too high a temperature or in an unsuitable medium. By inoculating first with a weak virus and then with others which were stronger and stronger, he was able completely to protect oxen either from the effects of inoculation with the strongest virus or from infection through contact with other animals suffering from the disorder. On the other hand, he found that homogenized virus could be again strengthened by inoculating a feeble animal such as a guinea-pig a day or two old with it, and then inoculating stronger and stronger animals; an increase in strength was gained with each inoculation, until at last the virus could attack the strongest. A similar increase in virulence appears to occur in plague, where animals, especially rats and mice, seem to be affected before human beings, and not only increase the virulence of the microbes, but convey the infection. Two methods of protective inoculation have been used. In one, Halfkine employs the toxins obtained by growing plumps in broth for six weeks, and then heating the whole to 65° or 70° C. so as to destroy the bacilli. This preparation is prophylactic, but does not seem to be curative. Yersin has prepared a serum from horses in the same way as diphtheria anti-toxin, and this is said to have a curative action during the attack. In the same way sterilized cultures of typhoid bacilli have been used to protect against attacks of typhoid fever, and an anti-typhoid serum has been employed with intent to cure. Protection does seem to be afforded, but the curative action of the serum is still somewhat doubtful. Although the anti-toxins which are used in the cure of infective diseases are not dangerous to life, yet they sometimes cause unpleasant consequences, more especially an urticarial eruption almost exactly like that which follows eating mussels or other shell-fish. Sometimes the swelling of the skin is much more general, so that the whole body may be so swollen and puffy as exactly to resemble that of a person suffering from advanced kidney disease. These disagreeable results, however, are not to be compared with the benefits obtained by the injection of anti-toxic serum, and this method of treatment is likely to maintain its place in therapeutics.

For many years peptone has been used as a remedy in dyspepsia to supplement the deficiency of digestive juice in the stomach, and it has been used popularly in dyspepsia for a still longer period. From time immemorial savages have been accustomed to eat the hearts of lions and other wild animals, under the belief that they will thereby obtain courage and strength like that of the animal from which the heart had been taken, but in 1889 Brown-Séquard proposed to use testicular juice as a general tonic and stimulant. Observations were made on the connexion between thyroid gland and myxoedema, which appeared to show that this disease was dependent upon atrophy of the gland. Accordingly the liquid extracts of the gland, or the gland substance itself compressed into tablets, have become largely used in the treatment of the disorder. The success which has been achieved has led to the use of many other organs in a raw or compressed form, or as extracts, in other diseases; e.g. of suprarenal capsule in Addison's disease, of bone marrow in pernicious anaemia, of thymus and suprarenal capsule in exophthalmic goitre, of kidney in renal disease, and of pituitary body in acromegaly. To this method of treatment the name of organo-therapeutics or opo-therapy has been given. The first scientific attempt to employ organs raw or in the testicular juice was made by Lauder Brunton in diabetes in 1873, sixteen years before Brown-Séquard's paper on the effect of testicular juice. From considering the nature of diabetes, he had come to the conclusion that many cases were due to imperfect oxidation of sugar in the body; that this oxidation was normally carried out by a ferment in the muscles, and that probably the disease was in some cases dependent upon absence of the ferment. He tried to supply this by giving raw
meat and glycerine extract of meat, but although he seemed
to get some benefit from the treatment, it was not sufficiently
marked to attract general attention. His attempts to isolate
a glycolytic ferment from flesh were also only partially success-
ful. One of the great difficulties in the way of applying this
treatment is that in all probability many of the ferments or
enzymes are altered during the process of absorption in the same
way as the normal ferments of digestion, and unless the tissue
enzymes can be isolated and injected subcutaneously the desired
results will not be obtained. The most striking of all the results
of the treatment obtained in myxoeema. In this disease
the face is heavy, puffy and expressionless; the skin is thick,
the speech slow, the hands shapeless and spade-like, the
patient apathetic, the circulation slow and the extremities
cold. Under the influence of thyroid gland these symptoms all
disappear, and the patient is frequently restored to a normal
condition. When the thyroid gland is absent in children, not
only is the expression of the face dull and heavy as in the adult,
but the growth both of body and mind is arrested, and the child
remains a stunted idiot. The effect of thyroid gland in such
cases is now notorious; the child growing in body and becoming
healthy and intelligent in those children in which this adenoma
of the gland appears to be a preparation which is poured
out into the blood and alters tissue-change. When the thyroid
tables or extract of thyroid are given in too large quantities
to patients suffering from myxoeema, the symptoms of
myxoeema disappear, but in their place appear others indi-
cative of increased metabolism and accelerated circulation.
The pulse-rate becomes very rapid, the extremities become
warm, so that the patient is obliged to wear few clothes, the
temper becomes irritable, the patient nervous, and a fine tremor
is observed in the hands. On stopping the administration of
thyroid these symptoms again disappear. When the thyroid
is hypertonished, as in Graves’s disease, the same symptoms
are observed, and these are probably due to increased secretion
from the thyroid. At the same time other symptoms, such as
exophthalmos, may appear, which have an independent origin
and are not due to the secretion of the gland. The whole of
the secretion here is poured into the blood and not at all on to
a mucous surface, and herein the thyroid gland differs largely
from such glands as the pancreas or peptic and intestinal glands.
But it seems probable that all glands which have what
may be termed an external secretion like the pancreas, stomach,
intestine, skin and kidneys have also an internal secretion,
so that while they are pouring one secretion from the ducts
into the intestine or external air, they are also pouring into the
lymphatics, and thus into the blood, an internal secretion.
In fact, a splitting appears to take place in the process of
secretion somewhat resembling that which takes place in the
formation of a toxin and anti-toxin. The secretion of some
digestive glands would prove poisonous if absorbed unchanged.
For example, the trypsin of the pancreas (see NUTRITION)
digests albuminous bodies in neutral or alkaline situation, and
if the whole of that which is secreted in the pancreas for the
digestion of meat in the intestine were absorbed unchanged into
the circulation, it would digest the body itself and quickly
cause death. The secretion of trypsin by the pancreas may
therefore be looked upon as the formation of a toxin. We do
not know at present if any corresponding anti-toxin or anti-
trypsin, as we may term it, is returned into the lymphatics or
blood from the gland, but the pancreas, which in addition to
secreting trypsin secretes a diastatic ferment forming sugar
from starches, moves this into the intestine and secretion at the
same time a glycolytic ferment which breaks up sugar, and this
latter passes into the blood by way of the lymphatics. Thus
the gland not only breaks up starch into sugar in the intestine,
but breaks up the sugar thus formed after it has been absorbed
into the blood. It is known that several, perhaps very many,
if not all glands have also the power of secreting substances
to which Starling has given the name of “hormones.” These
pass into the blood and cause other glands to secrete. Thus
an acid in the duodenum causes it to secrete a hormone to which
the name of “secretin” has been given. This passes to the
pancreas and causes increased secretion from that gland. It
is probable that the pancreas in its turn also secretes something
which activates a ferment in the muscles. It is evident there-
fore that the connexion between the different glands of the
body is a very complicated one and that the effects of a drug
which acts upon any one of them may be of a very far-reaching
character. It is by no means improbable that all glands have
a double or even triple function, and that sometimes the external
may be even less important than the internal secretion. On
this point, however, we have but little definite knowledge, and
it is probable that the subject is open for future research. At the same time,
there are many indications of the importance of an internal
secretion in popular treatment. For example, there are many
people who feel very much better after prose perspiration,
and as sweat appears to contain little but water and a few salts,
it is not improbable that the improvement in their condition
is due rather to the internal secretion from the skin than to
the elimination effected by the sweat. It is probable that the
kidneys also have an internal secretion, and that the great
oeedema sometimes found in kidney disease is rather due to the
lack of this secretion than to the development of a streptococcus anti-toxin, than to accumulation of water due to
imperfect action of the kidney. Similarly the beneficial effects
of purgation may be due not only to the elimination which
takes place through the bowel, but also to the internal secretion
from the intestinal glands.

The health of the body depends upon the proper kind and
and supply of food, upon its proper digestion and absorption, on
the proper metabolism or tissue-change in the body, and the
proper excretion of waste. We have considered how these may
also be disturbed by microbes from without and from within. We
have also considered in a general way the treatment of local
diseases by passive protection, active protection and repair of
waste; but both maintenance of health and repair of waste
depend very largely upon the condition of the blood. When
this is healthy the attacks of microbes are resisted, wounds heal
readily, and patients recover from serious diseases which in
persons of debilitated constitution would prove fatal. In order
to keep the blood in a satisfactory condition it must be well
supplied with fresh nutriment, and the products of waste freely eliminated. The food required for
nutrition and elimi-
nation.
THERAPEUTICS

being more complete, because persons cannot wash the unnastipated food down by drinking, and it prevents the gastric juice from being greatly diluted, and so allows it to digest more rapidly. Should these rules be insufficient, then (4) protein and farinaceous food should be taken in separate meals—farinaceous food at breakfast, proteid alone at lunch; farinaceous in the afternoon, and proteid again in the evening. The reason for this is that farinaceous foods are digested in the intestine and not in the stomach, where they may undergo fermentation, whereas proteid foods are to a great extent digested in the stomach. When the secretion of gastric juice is deficient it may be excited by farinaceous tonics, such as ten grains of bicarbonate of soda and a drachm of compound tincture of gentian in water shortly before meals, and may be supplemented by the administration of pepsin and hydrochloric acid after meals. When the nervous system is below par, and both secretion and movements are deficient in the stomach, nervous tonics, such as nux vomica or strychnine, are most useful.

High tension in the arteries is often associated with sleeplessness, the pressure of blood being such that the circulation in the brain is constantly maintained at a high rate of speed and the brain is unable to obtain rest. The means of removing the excess may be divided into those (1) which lessen the circulation, and which (2) diminish the excitability of the brain cells. The circulation in the brain may be lessened by warmth to the feet, cold to the head, warm food in the stomach, warm polioites or compresses to the abdomen, antipyretics, which reduce the temperature and consequently slow the beats of the heart in fever, and cardiac or vascular tonics, which slow the heart and tend to restore tone to the blood-vessels, so that the circulation in the brain may be more efficiently regulated. Amongst those which lessen excitability of the brain-cells are opium, morphine, hyoscyamus, chloral, sulphonal, trional, paraldehyde, chloralamide, chlorose, hop and many others. A combination of the two kinds of remedy is sometimes useful, and chloral sometimes succeeds where other things fail, because it depresses the circulation as well as lessens the activity of the brain-cells.

Irritation of sensory nerves tends to cause contraction of the vessels and to raise the blood pressure, and where pain is present opium or morphine is the most efficient sedative. The sensation of pain is felt in the brain, and the cause of it may be in the sensory centres of the brain alone, as it may be by a general pain, with no lesion to cause it. Ordinarily, however, it is due to some peripheral irritation which is conducted by sensory nerves to the spinal cord and thence up to the sensory centre in the brain. Pain may be stopped by removing the cause of irritation, as, for example, by the extraction of a carious tooth or by rendering the nerve-endings insensitive to irritation, as by the application of cocaine; by preventing its transmission along the spinal cord by antipyrin, phenaacetin, acetanilide, cocaine, &c.; or by dulling the perceptive centre in the brain by means of opium or its alkaloids, by anaesthetics, and probably also, to a certain extent, by antipyrin and its congeners.

Both sleeplessness and pain are sometimes due to the action of toxins absorbed from the intestine, and both of them may sometimes be relieved more efficiently by thorough purgation than by narcotics. Another condition which is probably due to toxins is high pressure within the arteries. When this continues for a length of time it tends by itself to cause deterioration of the blood-vessels and leads to death either by cerebral apoplexy or by cardiac failure. It is therefore very important to discover high tension at an early period. It may be diminished or its increases prevented by a diet from which red meat and meat extracts are excluded, by the use of the lactic acid bacillus, by the administration of laxatives and cholagogues to regulate the bowels, and by the use of iodides and nitrates. By such régime and medicines life may sometimes be prolonged for many years.

Deficient nervous action also leads to defective secretion and movement in the intestine, sometimes with flatulent accumula-

Platulence.

In such cases nux vomica or strychnine is useful. Flatulent distension in the stomach or bowels is partly due to air which has been swallowed and partly to gas which has been formed by the decomposition of food. The stomach may become distended with gas on account of acid fermentation leading to the frequent swallowing of saliva, and both this form of flatulence and that caused by the actual formation of gas are much diminished by such drugs as tend to prevent fermentation. Amongst the best of these are carbolic acid in doses of one or two grains, creosote in one or two drops, and sulpho-carbulate of soda in doses of ten grains. Others which may be mentioned are carbonate of bismuth, salol, 8-naphthol and naphthalene. By preventing fermentation in the intestine these also tend to prevent or check diarrhoea, and they may do good after the irritant has been removed by castor oil. After the irritant has been removed and fermentation stopped, the irritation still remaining in the intestinal wall may be soothed by chalk mixture and bismuth, to which if necessary small quantities of opium may be added. In cases where diarrhoea is very obstinate and lasts for weeks, sulphuric acid is sometimes more efficacious than alkalis; and in chronic colic it is the practice sometimes to introduce a few grains of charcoal or a local application of astringent solutions. For this purpose solutions of sulphate of copper or of nitrate of silver may be gently introduced into the bowel in quantities of a quart at a time. It is essential that a large quantity should be used, as otherwise the seat of irritation may not be reached by the astringent. Flatulence and diarrhoea as well as many general disorders are often due to intestinal depression caused by microbes. To these injurious microbes Metchnikoff has given the name of "wild," and he proposes to restore health by giving tame "microbes, such as lactic acid bacilli. This treatment on the principle of "setting a thief to catch a thief" is frequently very useful. The lactic acid bacilli are given either in the form of tablets or milk soured by them, or cheese made from the sour milk. The most efficient form is soured milk, which acts as a food as well as medicine.

Constipation is so common that it may be almost looked upon as the normal condition in civilized countries. Two of its chief causes probably are (1) improvement in cookery, whereby the harder and more irritating parts of the food are softened or removed; and (2) improvement in grinding machinery; whereby the harder and more stimulant parts of the grain are separated from the finer flour which is usually used for bread. In consequence of the absence of mechanical stimulant the bowels act more slowly, and constipation is the result. It may be considerably diminished by a return to a more natural system of feeding, as by using brown bread instead of white, by taking oatmeal porridge, and by eating raw or cooked fruits, such as apples, oranges, prunes and figs, or preserves made of fruit, such as raspberry and strawberry jam, marmalade, &c., by vegetables or by dried and powdered seaweed. Should these means fail, aperients may be used. The commonest are senna in the form of compound liquorice powder, sulphur in the form of lozenges, cascara sagrada, either in tablets or in the form of liquid or dry extract, rhubarb, colocynthis and especially aloes. The last acts chiefly upon the lower bowel, and forms a constituent of nearly every purgative pill. The medicines above mentioned may be taken either in a moderate dose at bedtime or in the form of a dinner pill, or they may be taken in small doses three times a day just before or after meals. Some sufferers from constipation find that they get greater relief from salts dissolved in water, or from natural aperient water taken on rising in the morning; and others again find that the best way of opening the bowels is to inject one or two dracones of glycerine into the rectum, or use it as a suppository. If these means fail, exercise, massage and electricity may help a cure.

The most common diseases of malassimilation (or "metabolic" diseases) are gout, rheumatism and diabetes. In health most of the nitrogenous waste in the body is eliminated as urea, but in gout uric acid is either formed in too great quantity or
Diseases of mal-absorption.

It is generally admitted that the urine of the kidneys, the life of the patient is rendered more or less uncertain and the health frequently seriously impaired. In some cases of chronic inflammation of the kidneys, where the disease is not extensive, the patient may continue in fair health for a number of years, provided attention be paid to the following rules:—(1) The body must be kept warm, and chills must be scrupulously avoided; (2) the diet and provisions must be carefully attended to, so that there shall be no excess of poisonous bodies and meat, or the intestine or absorbed from it; (3) eliminating channels such as the skin and bowel must be kept active. It is usual to reduce the quantity of proteid food to a minimum, in order to lessen the amount of nitrogenous waste to be excreted by the kidneys. Sometimes an entirely milk diet is useful, but in others it does not agree, and a more liberal diet is essential. Alcohol should be avoided as much as possible. The small contracted kidneys, which is common in elderly gouty people, is usually associated with a very large secretion of urine containing only a minute trace of albumin. The tension within the blood-vessels is generally high, and the patients run a risk of anginal attacks or of apoplexy. A nearly vegetarian diet and a complete abstention from alcoholic stimulants is the ideal in such cases, but it must be modified to suit individuals, as sometimes very strict limitations prove injurious. The daily use of potash, and especially nitrates of potash, tends to reduce the tension and increase the patient's safety, but if pushed too far may some- times become very dangerous and fatal.

It has already been mentioned that water is absolutely necessary for the body: by taking it hot it does not lie like a Diets and "cure." before meals it washes out the remnants of the previous meal; and being absorbed into the blood, it probably renders the secretion of gastric juice freer and accelerates digestion, instead of diluting it and interfering with the digestive processes. Where the stomach and bowels are irritable, all food likely to cause mechanical irritation should be avoided, such as skins, bones, fibres and seeds. In some cases of diarrhoea an entirely milk diet has to be prescribed, and in the diarrhoea of children it is sometimes necessary to alternate a diet of barley water with one of beef juice or white of egg and water, or to give whey instead of milk. The drinking of large quantities of whey is used as a means of cure for dyspepsia in adults, and also in cases of chronic bronchitis. The whey is drunk warm, and for this cure it is usual to go to some Alpine resort where pasturage is abundant and fresh milk can be had at all times of the day. The cure is greatly helped by the fresh air and sun. The body being reduced, the salicylate is then supplied as a medicine. The chief remedy for inflammatory stomach and bowels is water, which, being absorbed through the skin, renders the patient cool and comfortable. The cure is often called "Salisbury," and consists of living entire upon minced beef and hot water. Sometimes answers very well in persons troubled with flatulence, since meat does not give rise to the same amount of gas in the intestines as carbohydrates. During its continuance, fat is absorbed from the subcutaneous tissue, since the rapidity of its absorption is much greater than the rate of its deposition. The patient becomes very much thinner, and suffers less from flatulence, but reduces obesity. It is, in fact, very much the same system as that proposed a number of years ago by Banting (see Corpulence). It is very important for those who are trying this diet to bear in mind the necessity of abundance of water, because sometimes they may be tempted to lessen the water on account of the inconvenience produced either by frequent micturition or too profuse sweats. If the meat diet be continued with too small a proportion of water, a gouty condition may be brought on. This diet has been recommended in gout, and no doubt the essential part of it is the hot water, but there can be little doubt that in fat gouty people it is often useful. An entirely opposite dietary is that in which butcher's meat is completely excluded and proteins reduced to a minimum, as advocated by Dr Haig. This dietary also is very useful in gout, but it answers better in thin gouty people than in fat ones.

The diets already mentioned, the whey cure, the grape cure, the meat cure and the vegetarian cure, are all more or less systems of starvation, one or other article of ordinary diet being either reduced to a minimum or omitted altogether. In three of them at least—the whey cure, the grape cure and the meat cure—a diminution in one or other of the solid constituents of food is associated with the ingestion of an unusually large quantity of water. In visiting the most famous watering-places, it is curious to note how one finds, in the various waters, here some chloride, there some sulphate, here some potash, there some magnesium, but in all of them we find water. In watching the troops of patients who go to the wells we notice that most of them do more early rising, take more regular exercise, and drink more water in the course of a month at the commencement of their cure, and no doubt the essential part of it is the water. The watering-places divide themselves, according to the temperature of the waters, into cold and thermal, and according to the composition of the waters, into purgative saline, indifferent saline, sulphur and iron. Amongst the most celebrated saline waters are those of Carlsbad, which contain sulphate of soda and bicarbonate of soda. These salts crystallize out when the water is partially evaporated and may be used with hot water at home, the best imitation of the Carlsbad water being obtained by mixing with hot water the powdered Carlsbad salts (pusver-"formig"), which contain all the constituents of the natural water. Where it is impossible for the patient to visit Carlsbad, half a teaspoonful or a teaspoonful of salt may be taken in a large tumbler of hot water on rising every morning; but when taken at home the treatment is not so effective as at Carlsbad, because

XXVI. 26
at the wells sipping water is associated with early rising, considerable exercise and a very carefully regulated diet. It is, indeed, the care with which the diet of patients is regulated and the difficulty that patients find in obtaining forbidden foods at hotels and restaurants, that make Carlsbad better for the liver than any other watering-place. Amongst other places having a similar action are Marienbad, Franzensbad and Tarasp. The waters just mentioned contain free alkali as well as sulphates, and are employed more especially in cases of hepatic disorder, such as congestion of the liver, jaundice, gall-stone and diabetes. A number of other waters containing sulphides and chlorides are powerful purgative, and are more often drunk at home than at the springs. Amongst these are the Hungarian waters, Aesculap, Apenta, Franz Josef and Hunyadi Janos; and the Rubinat and Condal waters of Spain. Waters which have a similar composition are drunk at the springs of Leamington and Cheltenham in England, Bridges Salins and St Gervais in France, for chronic constipation, dyspepsia, gout and hepatic disorders of a milder character than those usually treated at Carlsbad. The waters in which chlorides form the purgative principle are those of Homburg, Kissingen, Wiesbaden and Baden Baden in Germany, and Bridge of Allan in Scotland. Similar waters, but much weaker, are found at Innerleithen and Pitkeithly. Sulphur waters are chiefly used for painful and stiff joints, chronic skin disease, and chronic catarrhal affections. The most important are Aix-les-Bains, and a number of springs in France, such as Vichy, St Gervais, Contrexeville, Royat and Plombieres; also in England, Strathpeffer and Moffat in Scotland. Iron waters are used in anaemia and the affections which are frequently associated with it. The most important are Spa in Belgium, Schwalbach in Germany, St Moritz and Tarasp in Switzerland. Iron waters are, however, common, and are generally found at all those places which have sulphur waters. Simple alkali waters containing carbonates, chiefly of sodium along with some magnesiuim and calcium, are drunk for their utility in gastric and intestinal disorders as well as in rheumatism and gout. They are also employed locally in sprays and douches to the nose, throat, vagina and rectum, for catarrhal conditions of the mucous membranes. The most important are Vichy and Vals in France and Neuenahr in Germany. Alkaline waters containing a little common salt are perhaps even more important than the pure alkaline, as the salt lessens the depressing effect of the alkali. They are therefore used largely in chronic gout, rheumatism and in calculus affections of the kidney. Amongst the most important are Ems and Wildungen in Germany, Contrexéville and Royat in France.

Simple thermal waters are those which contain only a very small quantity of solids, and owe their efficacy chiefly to their temperature. They are used partly for drinking, but even more so for baths. Bath, Buxton and Matlock in England; Mallow in Ireland; Wildbad, Schlangenbad and Badenweiler in Germany; Gastein and Teplitz in Austria; Ragatz in Switzerland; Plombières and Dax in France; and Bormio in Italy are amongst the best known. When water is dashed against the body with more or less violence, its effects are more powerful than when the body is simply immersed in it. Thus the stimulating effect of sea-bathing is more marked than simple bathing for the body. The feeling of exhilaration produced by the skin produced by the salt and by the temperature of the water, we have the quicker removal of heat by the continual renewal of the water as the waves dash over the body, and mechanical stimulus from its weight and impetus. Somewhat similar effects are produced by so-called wave-baths, and at Nauheim, although the fresh movement of the water against the surface of the body is much less than in the sea, yet its stimulating effect is greatly increased by the presence of carbonic acid in it. Douches have a still more powerful action than waves. They are generally given in the air, but at Plombières very simple douches are given under water. These form a more powerful wave-bath, and in combination with intestinal irrigation, are used very successfully for the treatment of abdominal disorders. Douches to the spine are much employed for nervous debility, and good effects are also obtained in such cases from the so-called needle-bath, where small streams of water at high pressure are driven against the whole surface of the body. In the treatment of stiffened joints, massage under water is very serviceable, and in the so-called Aix douche a stream of water continuously streams is fastened to the wrist of the massuer, so that a current of water is constantly playing upon the joint which he is rubbing. While water containing much saline matter, and more especially water containing free carbonic acid, has a very stimulating action upon the skin, mud has a sedative effect, so that in a mud-bath one feels a pleasant soothing sensation as if bathing in cream. These mud-baths are chiefly employed at Marienbad, Franzensbad and Homburg. Sulphur-baths and sulphur waters are chiefly used in combination for rheumatism and gout, and massage, especially under water, is frequently combined most advantageously with baths and drinking water to effect a cure.

Exercises, passive and active, are also used in diseases of the joints, as well as massage and baths, but exercises and training are even more important in cases of cardiac disease.

Exercise.

In very bad cases of heart disease, where the patient is unable to go about, the best plan of treatment usually is to make him stay absolutely quiet in bed and have massage, which aids the circulation, tends to remove waste, and increases the appetite. To this is added gentle exercise, beginning with the fingers at first. At Meran walks have been arranged according to Oertel’s system, and the sea-level. For those who suffer from nervous depression, exercise in the Swiss mountains is useful, and even living at a height of about 6000 ft. above the sea-level seems to have an exhilarating influence. The nature of this is not very easy to analyse, but as mental depression is closely associated with irritation of the vague nerve and weakening of the circulation, it seems not at all unlikely that mountain air acts by accelerating the pulse and quickening the circulation, and thus creating a sense of well-being. Indeed, many patients liken its effect to that of drinking champagne. In some persons rarefied air is too stimulating, so that they find difficulty in sleeping, and for those who suffer from insomnia a warm moist air near the sea-level is preferable.

It sometimes happens, however, that people cannot sleep at the seaside itself, although they do so perfectly well a mile or two inland. Where the nervous system is exhausted, such warm and moist climates as Malaga, Madeira, Tenerife and Grand Canary are suitable. In these places not only is the air moist, but the temperature is particularly equable, and they are therefore suitable places also for persons suffering from kidney disease. Many such persons also do well in dry warm places, such as the higher reaches of the Nile, Egypt, and desert stations in the United States, and the places on the Rivieria. The places mentioned are all suitable for persons suffering from chronic bronchitis, who should avoid any irritation
of the larynx, trachea or bronchi by air which is too dry or which is liable to great changes of temperature. Some cases of phthisis, therefore, do better in warmer and moist climates, and especially those where the larynx has become affected by the disease. Such patients are apt to suffer much from cough and laryngeal irritation in the cold, dry air of the Alps, whereas they live in comparative comfort on the Riviera, Isla de la Madeira, Madeira or at Capri. But warm, moist climates rather favour sedentary habits and tend to lessen appetite, so that the nutrition of the patient is apt to suffer; and although phthisical patients may live in comparative comfort in such climates, their tendency to recovery in them is small. At the Swiss health resorts, on the contrary, during the winter the air is very pure, and has just sufficient coldness to make exercise agreeable to patients. They are thus induced to be out the whole day, and to take food with an appetite which greatly improves their nutrition and aids their restoration to health. The best-known Alpine health resorts are St Moritz and Davos, to which lately Grindelwald has been added. St Moritz is, upon the whole, better for less advanced cases, while Davos is more sheltered and better for cases which are severe. It is a mistake, however, to send those in whom the disease is very far advanced away from home and friends, because when there is no hope of cure it is better for them to die in comfort at home. At the health resorts just mentioned the amount of food taken is regulated by the appetite of the patient himself, but a system of the appetite has been inaugurated by Dr Breher at Götberdorf, by Dr Dettweiler at Falkenstein, and by Dr Walther at Nordrach, in the Black Forest. The most important point in this treatment consists in forced feeding, the want of appetite which is so prominent in many cases of phthisis being regarded as an abnormal sensation not to be regarded; and under the forced feeding, combined with open-air life, many marvellous recoveries are recorded. Numerous other institutions have been started in Great Britain in imitation of Dr Walther's with a considerable amount of success. Even when patients are unable to stay long at a sanatorium they learn there the advantages of open-air and can continue the treatment at home to their great advantage.

In the well-known "rest" cure, which we owe to Weir Mitchell, forced feeding takes a prominent part. The essence of this cure is to give to the patient rest, bodily and mental, by confinement to bed and isolation from the outside world. While this treatment by itself would aid recovery from nervous exhaustion, it would lessen appetite and thus interfere with nervous repair; but the want of exertion is supplied by means of massage, which stimulates the circulation and increases the appetite has been inaugurated by Dr Breher at Götberdorf, by Dr Dettweiler at Falkenstein, and by Dr Walther at Nordrach, in the Black Forest. The most important point in this treatment consists in forced feeding, the want of appetite which is so prominent in many cases of phthisis being regarded as an abnormal sensation not to be regarded; and under the forced feeding, combined with open-air life, many marvellous recoveries are recorded. Numerous other institutions have been started in Great Britain in imitation of Dr Walther's with a considerable amount of success. Even when patients are unable to stay long at a sanatorium they learn there the advantages of open-air and can continue the treatment at home to their great advantage.

In the well-known "rest" cure, which we owe to Weir Mitchell, forced feeding takes a prominent part. The essence of this cure is to give to the patient rest, bodily and mental, by confinement to bed and isolation from the outside world. While this treatment by itself would aid recovery from nervous exhaustion, it would lessen appetite and thus interfere with nervous repair; but the want of exertion is supplied by means of massage, which stimulates the circulation and increases the appetite which is so prominent in many cases of phthisis being regarded as an abnormal sensation not to be regarded; and under the forced feeding, combined with open-air life, many marvellous recoveries are recorded. Numerous other institutions have been started in Great Britain in imitation of Dr Walther's with a considerable amount of success. Even when patients are unable to stay long at a sanatorium they learn there the advantages of open-air and can continue the treatment at home to their great advantage.

THEREZINA—THERMOCHEMISTRY

though she was far from basing any claim to holiness upon them. The general of the order visited her at Avila, and gave her permission to found other houses of Descalzas, for both men and women. The last fifteen years of her life were spent mainly in hard journeys with this end and in the continually growing labour of organization. Convents were founded at Medina, Malaga, Valladolid, Toledo, Segovia and Salamanca, and two at Alva under the patronage of the famous duke. Then she had three years of rest, as pruissor of her old convent of the Incarnation. She next went to Seville to found a house, thus overstepping for the first time the boundaries of the Castiles, to which her authorization limited her. The latent hostility of the old order was aroused; the general ordered the immediate suppression of the new foundation, and the family of the duke from Gregory XIII. prohibiting the further extension of the reformed houses (1575).

But the movement against her came from Italy, and was repented by Philip and the Spanish authorities as undue interference; and after a fierce struggle, during which Teresa was two years under arrest at Toledo, the Carmelites were divided into two bodies in 1586, and the Descalzos obtained the right to elect all the provincial-general (see CARMELITES). The few remaining years of Teresa's life were spent in the old way, organizing the order she had founded, and travelling about to open new convents for her followers, which were founded by her efforts; she wrote a history of her foundations, which forms a supplement to her autobiography. Her last journey of inspection was cut short at Alva, where she died on the 20th of September 1582. A violet odour and a fragrant oil were said to distil from her tomb; and when it was opened nine months afterwards the flesh was found uncorrupted. A hand cut off by a fervent brother was found to work miracles, and the order became convinced that her founder had been a saint. It was resolved in 1585 to remove her remains to Avila, where she was born, the sisters at Alva being consigned by permission of the king to the care of the Duke of Alva procured an order from the pope enjoining that the body should be restored to Alva, and she was accordingly laid there once more in a splendid tomb. But even then she was not allowed to rest: she was again desecrated, to be laid in a more magnificient coffin, and the greed of reverential relic-seekers made unseemly havoc of her bones.

Teresa was canonized by Gregory XV. in 1622. The honour was doubtless largely due to her asceticism and mystic visions. She called herself Teresa de Jesus, to signify the closeness of her relation to the heavenly Bridegroom, whom she directly and unreservedly loved. Through her devotion to perfection of ascetic severity in others, she scourged herself habitually, and wore a peculiarly painful hair-cloth. But her life shows her to have been, besides, a woman of strong practicality and good sense, full of natural shrewdness, and with unusual powers of organization. “You deceived me in saying she was a woman,” writes one of her confessors; “she is a bearded man.” She was brave in the face of difficulties and dangers, pure in her motives, and her utterances, some of which have been quoted, have the true ethical ring about them. Her MSS. were collected by Philip II. and placed in a rich case in the Escorial; the key of which the king himself charged her with. Besides her autobiography and the history of her foundations, her works (all written in Spanish) contain a great number of letters and various treatises of mystical religions, the chief of which are the Way of Perfection and The Castle of the Soul. Both describe the progress of the soul towards perfect union with God.

Her works, edited by two Dominicans were first published in 1587, and have since appeared in various editions. They were soon afterwards translated into Italian, French (3 vols., Paris, 1840-45) and Latin; an English translation of the Life and works (except the letters) by A. Woodhead appeared in 1669. Other translations of the Life are those by John Dalton (1851), who also translated The Way of Perfection and the Leiters (1902), and by David Lewis (1879), who in 1871 also translated the Foundations. A. R. Waller reprinted Woodhead’s translation of The Way of Perfection in “The Cloister Library” (1901). Biographies appeared soon after her death by the Jesuit Ribera, who had been her confessor (1602), and by Diego de Vépez, confessor to Philip II. (1599).

Details are also given in Ribadeneyra’s Flora Sanctorum and in Alban Butler’s Lives of the Saints. A separate biography, with preface by Cardinal Manning, appeared in 1865; a full and critical edition of the Life is that by Mrs. C. G. Graham, 2 vols. (1894). See also H. Prinz v. Oettingen-Spielberg, Geschichte d. heil. Teresa (Regensburg, 1899); A. Whyte, Santa Teresa, an appreciation, with some of the best passages of the writings (1897); E. Hello, Studies in Sainthood (1903).

THEREZINA, a city of Brazil, capital of the state of Piauhy, on the left bank of the Parahyba river, about 220 m. from its mouth. Pop. (1890) 21,620; for the commune or municipio, 31,523; (1906, estimated), 25,000. It is prettily situated on an open plain and is laid out regularly with broad straight streets. Among its public buildings are the government palace, the legislative and administrative hall, the “Quatro de Setembro” theatre, Misericordia hospital, public market, sanitation and public works, building, courts, police headquarters, barracks, &c. The town is characteristically Portuguese in appearance, its buildings being one or two stories in height, plastered and frequently coloured outside, with large rooms, thick walls, and tile roofs to ensure coolness. There is one lyceum, or high school, with about 400 students, in addition to its primary schools. Its manufacturing industries include a cotton mill, foundry, and soap-works. A steamboat service with three small boats, maintains regular communication with Paranhába, near the mouth of the river, besides which there are a number of independent freight-carrying boats. Therезina was founded in 1582, its site being originally called Chapada de Corisco, and was named in honour of the empress, Doña Thereza Christiana. It was made the capital of Piauhy in succession to Oeiras.

THERMIDOR (from Gr. θερμός, heat, and δόρυ, gift), the name given during the French Revolution to the eleventh month of the year in the Republican Calendar. The month fell in the hottest season of the year, beginning on the 15th or 20th of July and ending on the 15th or 10th of August, according to the year. As in all the other months of the Republican Calendar, each of the days of Thermidor was, in accordance with the suggestion of Fabre d’Églantine, consecrated to some useful object. Thus 1 Thermidor was consecrated to spelt, 10 Thermidor to the watering-pot, 15 Thermidor to sheep, and 27 Thermidor to lentils. The most important event that took place in this month was the revolution of 9 Thermidor year II. (27th of July 1794), which resulted in the fall of Robespierre and the collapse of the Terror. The name Thermidorian (Thermidoriens) was given to the authors of this revolution and to the supporters of the reactionary movement of which it was the signal.

See C. d’Héricault, La Révolution de thermidor (2nd ed., Paris, 1878); E. B. Courtois, Rapport fait au nom de la commission chargée de l’examen des papiers trouvés chez Robespierre et ses complices (1795); D. A. Martin, Papiers inédits ... subparrés ou omis par Courtois (3 vols., 1828); also bibliography in M. Tourneux, Bibliogr. de la ville de Paris ... (1860), vol. I., nos. 4265-4309.

THERMOCHEMISTRY, a branch of Energetics, treating of the thermal phenomena which are associated with chemical change.

That vigorous chemical action is accompanied by a brisk evolution of heat is evident from such familiar examples as the combustion of fuel or the explosion of gunpowder. The heat attendant on these actions, and on the vital processes of the animal organism, naturally first attracted attention. Robert Boyle, A. Crawford, A. L. Lavoisier and P. S. Laplace, P. L. Dulong, H. Davy, Count Rumford, all concerned themselves with thermochemical investigations of such processes. Their quantitative experiments were, however, too rough to permit of accurate generalization; and although Lavoisier and Laplace stated the principle that the same amount of heat must be supplied to decompose a compound as would be produced on its formation, the statement was not based on exact experiment, and only received experimental confirmation much later.

The beginnings of modern thermochemistry, though made independently of the doctrine of the conservation of energy,
are practically contemporaneous with the recognition of that law, and without it the science could scarcely have reached the degree of development which it rapidly attained. Thomas Andrews and, especially, G. H. Hess (1840) were the first who systematically investigated thermochemical effects in solution, and arrived at conclusions from their experimental data which still hold as valid today. Andrews, for example, found that when a series of acids were under similar conditions used to neutralize a given amount of a base, the quantity of heat evolved on the neutralization was the same in all cases. Hess, from his work, arrived at the converse conclusion, that when a series of bases were used to neutralize a given amount of an acid, the heat of neutralization was always the same. Both of these statements are correct when the powerful mineral acid and bases are considered, exceptions only arising when weak acids and bases are employed. Again, Andrews discovered that when one metal displaces another from solution of its salts (e.g., zinc with solutions of copper salts), the thermal effect is practically independent of the nature of the acid radical in the salt employed. Andrews likewise found that when the heat evolved on the displacement from its salts of a metal M' by a metal M is added to the heat of displacement of another metal M'' by M', the sum is equal to the heat which is evolved on the direct displacement of M'' from its salts by M. This affords an example of a principle which had been stated by Hess in a very general form under the name of the Law of Constant Heat Sums—namely, that the thermal effect of a given chemical action is the same, independent of the order in which the stages in which it takes place. Thus, in the above example, it is immaterial whether M displaces M'' from its salt directly, or whether M first displaces M', which is then used to displace M''. This important principle is a direct consequence of the law of the conservation of energy, but was discovered independently by Hess from accurate experiment.

Hess employed this principle to determine indirectly the heat of formation of compounds from their elements, when this magnitude, as is generally the case, was inaccessible to direct measurement. Thus the heat of formation of anhydrous zinc sulphate, ZnSO₄, which cannot be determined directly, may be arrived at by summation (in Hess's units) as follows:

<table>
<thead>

</tbody>
</table>

Heats of formation are still determined for the most part in a precisely similar manner.

Hess also stated another principle on empirical grounds, which, although admitting of many exceptions, is of considerable utility and significance. It had been known long before his time that when solutions of neutral salts were mixed, and no precipitate resulted, the mixed solution was also neutral. Hess now observed that in the process of mixing such neutral solutions no thermal effect was produced—that is, neutral salts in aqueous solution could apparently interchange their radicals without evolution or absorption of heat. These experimental results were generalized by him under the title of the Law of Thermoneutrality.

After the investigations of Hess and Andrews, a great deal of excellent experimental work was performed by P. A. Favre and J. T. Silbermann, whose chief theoretical achievement was the recognition that the heat of neutralization of acids and bases was additively composed of two constants, one determined by the acid and the other by the base. This deduction harmonized the observations of Andrews and of Hess previously alluded to, and also accounted satisfactorily for the Law of Thermoneutrality.

Julius Thomsen was the first investigator who deliberately adopted the principle of the conservation of energy as the basis of a thermochemical system. His thermochemical work was begun in 1853, but most of his experiments were performed in the years 1869-82, the whole being published collectively, under the title Thermochemische Untersuchungen, in four volumes. Somewhat later than Thomsen, Marcellin P. E. Berthelot began (in 1873) a long series of thermochemical determinations. It is to these two investigators and their pupils that most of our exact thermochemical data are due.

Thomsen and Berthelot independently enunciated a generalization (commonly known as Berthelot's Third Principle, or Principle of Maximum Work), which may be stated in brief as follows:—Every pure chemical reaction is accompanied by evolution of heat. Whilst this principle is undoubtedly applicable to the great majority of chemical actions under ordinary conditions, it is subject to numerous exceptions, and cannot therefore be taken (as its authors originally intended) as a secure basis for theoretical reasoning on the connexion between thermal effect and chemical affinity. The existence of reactions which are reversible on slight alteration of conditions at once invalidates the principle, for if the action proceeding in one direction evolves heat, it must absorb heat when proceeding in the reverse direction. As the principle was abandoned even by its authors, it is now only of historical importance, although for many years it exerted considerable influence on thermochemical research.

§2. From the standpoint of the law of conservation of energy, the relation between chemical and thermochemical changes may be considered in the following manner. A given amount of any substance under given conditions possesses a perfectly definite amount of intrinsic energy, and, no matter what chemical and physical transformations the substance may undergo, it will, when it returns to its original state, possess the original amount of intrinsic energy. If we consider now the transformation of one system of chemical substances into another system under specified conditions, we shall find that in general the intrinsic energy of the second system is different from the intrinsic energy of the first. Let us assume, as is commonly the case, that the intrinsic energy of the initial system is greater than that of the final system. When the first system then is transformed into the second, the excess of energy which the former possess must appear in the shape of heat, light, electrical energy, &c. It is for the most part a simple matter to obtain the excess of energy entirely in the form of heat, the amount of which is easily susceptible of measurement, and thus the existence of thermochemistry as a practical science is rendered possible. Since the intrinsic energies of the two systems under given conditions are invariably the difference between them is constant, so that the heat evolved when the first system is converted into the second is equal to that absorbed when the second system is re-transformed into the first (cf. Lavoisier and Laplace, ante, § 1). The total thermal effect, too, which is associated with the transformation, must be the same, whether the transformation is conducted directly or indirectly (Hess's Law of Constant Heat Sums), since the thermal effect depends only on the intrinsic energies of the initial and final systems.

Since the intrinsic energy of a substance varies with the conditions under which the substance exists, it is necessary, before proceeding to the practical application of any of the laws mentioned above, accurately to specify the conditions of the initial and final systems, or at least to secure that they shall not vary in the operations considered. It is also a necessary condition for the application of the preceding laws that no form of energy except heat and the intrinsic energy of the substances should be ultimately involved. For example, when metallic zinc is dissolved in dilute sulphuric acid with production of zinc sulphate (in solution) and hydrogen gas, a definite quantity of heat is produced for a given amount of zinc dissolved, provided that the excess of energy in the initial system appears entirely as heat. This provision may not always be fulfilled, since by placing the zinc in electrical contact with a piece of platinum, likewise immersed in the sulphuric acid, we can
generate a current of electricity through the solution and the metallic part of the circuit. The reaction as before is completely expressed by the chemical equation Zn + H₂SO₄ = ZnSO₄ + H₂. The initial and final systems being exactly the same as in the first case; yet the amount of heat generated by the reaction is much smaller, a quantity of the intrinsic energy having been converted into electrical energy. This electrical energy, however, is equivalent to the heat which has disappeared, for it has been shown experimentally that if it is converted into heat and added to the heat already evolved, the total quantity of heat obtained is exactly equal to that produced by the direct dissolution of the zinc in the absence of platinum.

§ 3. The following conditions have to be considered as affecting in a greater or less degree the intrinsic energy of the initial and final systems:

1. Dilution of solutions.
2. Physical state.
3. Change of volume.
4. Allotrophic modifications.
5. Temperature.

1. Generally speaking, there is a considerable thermal effect when substances are used in solution, and this effect varies with the magnitude according to the amount of water employed. It is only, however, when we deal with comparatively concentrated solutions that the heat-effect of diluting the solutions is at all great, the heat change on diluting an already dilute solution being for most practical purposes negligible. In dealing, therefore, with dilute solutions, it is only necessary to state that the solutions are dilute, the exact degree of dilution being comparatively unimportant. It is to be noted that a change in dilution affects the chemical action that occurs. Thus if concentrated instead of dilute sulphuric acid acts upon zinc, the reaction takes place to a greater extent not according to the equation given above, but according to the equation:

\[
Zn + 2H₂SO₄ = ZnSO₄ + SO₂ + 2H₂O
\]

sulphur dioxide and water being produced instead of hydrogen. Here we have a different final system with a different amount of intrinsic energy, so that the thermal effect of the action is altogether different.

2. The physical state of the reacting substances must be considered, since comparatively large amounts of heat are absorbed on fusion and on vaporization. Thus the heat of fusion of ice (for 1 g. = 18 cal.) is 840 cal., and the heat of vaporization of water at 100°, for the same quantity, 9670 cal.

3. The change of effect of volume against external pressure (due to production or consumption of mechanical energy) may be neglected in the case of solids, liquids, or solutions, but must usually be taken into account when gases are dealt with. Each gramme-molecule of a gas which appears under constant pressure during a chemical action (e.g., dilute hydrogen during the action of zinc on dilute sulphuric acid) performs work equivalent to 880 cal. at the ordinary temperature, which must be allowed for in the thermochemical calculation. A similar correction, of opposite sign, must be made with gramme-molecules of gas disappearing during the chemical action.

4. When a substance—e.g., carbon, phosphorus, sulphur—exists in allotropic forms, the particular variety employed should always be stated, as the conversion of one modification into another is frequently attended by a considerable thermal effect. Thus the conversion of yellow into red phosphorus shows about one-sixth of the heat of combustion of the latter in oxygen, and the knowledge of which variety of phosphorus has been employed is of essential importance in the thermochemistry of that element.

5. The influence of temperature on the thermal effect of a chemical reaction is very small, compared with the magnitude of the reaction; but since the initial and final temperatures, which alone determine the variation in the thermal effect, are in almost all cases within the ordinary laboratory range of a few degrees, this influence may in general be neglected without serious error.

§ 4. Methods.—In order to estimate the thermal effect of any chemical process, use is made of the ordinary methods of calorimetry, the particular method being selected according to the nature of the chemical action involved. In almost every case the method of mixture (see CALORIMETRY) is employed, the method of fusion with Bunsen's ice-calorimeter being only used in special and rarely occurring circumstances.

As a very great number of important chemical actions take place on mixing solutions, the method for such cases has been thoroughly discussed. When the solutions employed are dilute, no water is placed in the calorimeter, the temperature-change of the solutions themselves being used to estimate the thermal effect brought about by mixing them. Known quantities of the solutions are taken, and the temperature of each is accurately measured before mixing, the solutions having been allowed as far as possible to adjust themselves to the same temperature. The change of temperature of the solutions after the mixing has taken place is then observed with the usual precautions. It is of course in such a case necessary to know the specific heat of the liquid in the calorimeter. Thomsen by direct experiment found that the heat-capacity of a dilute aqueous solution diverged in general less than 1 per cent. from the heat-capacity of the water contained in it, the divergence being sometimes in one sense, sometimes in the other. He therefore abstained from determining for each case the specific heats of the solutions he employed, and contented himself with the above approximation. Berthelot, on the other hand, assumed that the heat-capacity of an aqueous solution is equal to that of an equal volume of water, and calculated his results on this assumption, which involves much the same uncertainty as that of Thomsen. Since thermochemical measurements of this type may be frequently performed with an error due to other causes of much less than 1 per cent., the error introduced by either of these assumptions is the chief cause of uncertainty in the method.

The calorimeter used for solutions is usually cylindrical, and made of glass or a metal which is not attacked by the reacting substances. The total quantity of liquid employed need not in general exceed half a litre if a sufficiently delicate thermometer is available. The same type of calorimeter is useful in determining the heat of solution of a solid or liquid in water.

Combustion calorimeters are employed for observing the heat generated by the brisk interaction of substances, one of which at least is gaseous. They are of two kinds. In the older type the combustion chamber (of metal or glass) is sunk in the calorimeter proper, tubes being provided for the entrance and exit of the gaseous substances involved in the action. These tubes are generally in the form of worms immersed in the water of the calorimeter. In the newer type (which was first proposed by Andrews for the combustion of gases) the chemical action takes place in a completely closed combustion chamber of sufficient strength to resist the pressure generated by the sudden action, which is often of explosive violence. The steel combustion chamber is of about 250 c.c. capacity, and is wholly immersed in the calorimeter. To withstand the chemical action of the gases, the "calorimetric bomb" is lined either with platinum, as in Berthelot's apparatus, or with porcelain, as in Mahler's. For ordinary combustions compressed oxygen is used, so that the combustible substance burns almost instantaneously, the action being induced by means of some device which is without the calorimeter. The accuracy of heats of combustion determined in the closed calorimeter is in favourable cases about one-half per cent. of the quantity estimated.

§ 5. Units and Notation.—The heat-units employed in thermochemistry have varied from time to time. The following are those which have been in most general use:

- Small calorie or gramme calorie
- Large or kilogramme calorie
- Horsepower or kilogramme calorie
- Calorie
- Kilocalorie
- Joule
- Kilojoule
- Watt
- Horsepower
- Calorie
- Kilocalorie
- Joule
- Kilogramme-molecule

The centipede calorie is the amount of heat required to raise 1 kg. of water from 10° C. to 100° C., and is approximately equal to 100 cal. The large calorie is equal to 1000 cal. In view of the not very great accuracy of thermochemical measurements, the precise definition of the heat-unit employed is not a matter of special importance. It has been proposed to adopt the joule, with the symbol j, as thermochemical unit for small quantities of heat, large amounts being expressed in terms of the kilojoule, Kj = 1000 j. (For the exact relation between these heat-units, see CALORIMETRY.) For ordinary thermochemical work we may adopt the relation 1 cal. = 4.18 j, or 1 Cal. = 4.18 Kj.

Except for technological purposes, thermochemical data are not referred to unit quantity of matter, but to chemical quantities of the grammiequivalents or gramme-molecules of the
reacting substances, or to some multiples of them. The notation which Julius Thomsen employed to express his thermochemical measurements is still extensively used, and is as follows:—The chemical symbols of the reacting substances are written in juxtaposition and separated by commas; the whole is then enclosed in brackets and connected by the sign of equality to the number expressing the thermal effect of the action. The chemical symbols stand for quantities measured in gram atoms, and heat-evolution is reckoned as positive, heat-absorption as negative. Thus

\[ [S, 2O] = 71100 \text{ cal.} \]

indicates that 71100 calories are evolved when 32 grammes of sulphur react with 2\times16 grammes of free oxygen to form sulphur dioxide. It is of course necessary in accurate work to state the conditions of the reaction, and when by the above instance, the sulphur is supposed to be in the solid rhombic modification, the oxygen and sulphur dioxide being in the gaseous state, and the initial and final systems being at the ordinary temperature. Again, the equation

\[ [2N, O] = 18500 \text{ cal.} \]

indicates that it 28 grammes of nitrogen could be made to unite directly with 16 grammes of oxygen to form nitrous oxide, the union would cause the absorption of 18500 calories. When substances in solution are dealt with, Thomsen indicates their state by affixing Aq to their symbols. Thus

\[ \text{NaOH Aq, HNO}_3 \text{ Aq} = 13680 \text{ cal.} \]

represents the heat of neutralization of one gramme-equivalent of caustic soda with nitric acid, each in dilute aqueous solution before being brought into contact. One drawback of Thomsen's notation is that the nature of the final system is not indicated, although this defect in general causes no ambiguity.

The Berthelot notation defines both initial and final systems by giving the chemical equation for the reaction considered, the thermal effect being appended, and the state of the various substances being affixed to their formulae after brackets. W. Ostwald has proposed a modification of Berthelot's method which has many advantages, and is now commonly in use. Like Berthelot, he writes the chemical equation of the reaction, but in addition he considers the chemical formula of each substance to express not only its material composition, but also the (unknown) value of its intrinsic energy. To the right-hand member of the equation he then adds the number expressing the thermal effect of the reaction, heat-evolution being as before counted positive, and heat-absorption negative. The mass-equation then becomes an energy-equation. He thus writes

\[ \text{S} + \text{O}_2 = \text{SO}_2 + 71100 \text{ cal.}, \]

which expresses the fact that the intrinsic energy of the quantities of sulphur and oxygen considered exceeds that of the sulphur dioxide derived from them by 71100 cal. when thermal units are employed. The equation

\[ \text{H}_2 + \text{I}_2 = 2\text{HI} + 12200 \text{ cal.} \]

expresses that under certain conditions the intrinsic energy of hydriodic acid is greater than the intrinsic energy of its component elements by 12200 cal., i.e. that hydriodic acid is formed from its elements by an amount of heat. Energy equations, such as the above, may be operated with precisely as if they were algebraic equations, a property which is of great advantage in calculation. Thus by transposition we may write the last equation as follows:—

\[ 2\text{HI} = \text{H}_2 + \text{I}_2 + 12200 \text{ cal.} \]

and thus express that hydriodic acid when decomposed into its elements evolves 12200 cal. for the quantity indicated by the equation.

Ostwald has made the further proposal that the formulae of solids should be printed in heavy type (or within square brackets), of liquids (solutions, &c.) in ordinary type, and of gases in italics (or within curved brackets), so that the physical state of the substances might be indicated by the equation itself. Thus the equation

\[ \text{Cl}_2 + 2\text{KI}, \text{Aq} = 2\text{KCl}, \text{Aq} + \text{I}_2 + 52400 \text{ cal.}, \]

or

\[ (\text{Cl}_2) + 2\text{KI}, \text{Aq} = 2\text{KCl}, \text{Aq} + [\text{I}_2] + 52400 \text{ cal.}, \]

would express that when gaseous chlorine acts on a solution of potassium iodide, with separation of solid iodine, 52400 calories are evolved.

§ 6. Heat of Formation.—For thermochemical calculations it is of great importance to know the heat of formation of compounds from their elements, even when the combination cannot be brought about directly. As an example of the use of Ostwald's energy-equations for the indirect determination we may take the case of carbon monoxide.

The following equations give the result of direct experiment:—

\[ \text{C} + \text{O}_2 = \text{CO}_2 + 94300 \text{ cal.}, \]

\[ \text{CO} + \text{O} = \text{CO}_2 + 68000 \text{ cal.} \]

If now it is required to find the heat of formation of the compound CO, which cannot be directly ascertained, we have merely to subtract the second equation from the first, each symbol representing constant intrinsic energy, and thus we obtain

\[ \text{C} + \text{O}_2 = 26000 \text{ cal.}, \]

or that is, the heat of formation of a gramme-molecule of carbon monoxide is 26300 cal.

As has already been stated, the heat of formation of a compound is the amount (expressed in thermal units) by which its intrinsic energy exceeds or falls short of that of the elements which enter into its composition. Now of the absolute values of intrinsic energy we know nothing; we can only estimate differences of intrinsic energy of one system is compared with another into which it may be directly or indirectly converted. But since the elements cannot be converted one into the other, we are absolutely without knowledge of the relative values of their intrinsic energy. This being the case, we are at liberty to make the assumption that the intrinsic energy of each element (under specified conditions) is zero, without thereby introducing any risk of self-contradiction in thermochemical calculations. This assumption has the great advantage, that the intrinsic energy of a compound relatively to its elements now appears as the heat of formation of the compound with its sign reversed. Thus if we consider the energy-equation

\[ \text{C} + \text{O}_2 = \text{CO}_2 + 94300 \text{ cal.}, \]

and replace the symbols by the values of the intrinsic energy, viz., zero for carbon and oxygen, and for carbon dioxide, we obtain the equation

\[ 0 + 0 = x + 94300 \text{ cal.} \]

or

\[ x = -94300 \text{ cal.} \]

With knowledge of the heats of formation of the substances involved in any chemical compounds we can from once calculate the thermal effect of the action, by placing for each compound in the energy-equation its heat of formation with the sign reversed, i.e. its heat of decomposition into its elements. Thus if we wish to ascertain the thermal effect of the action

\[ \text{Mg} + \text{CaO} = \text{MgO} + \text{Ca}, \]

we may write, knowing the heats of formation of CaO and MgO to be 131000 and 146000 respectively,

\[ 0 = -131000 + x \]

and therefore

\[ x = 15000 \text{ cal.} \]

Since heats of formation afford such convenient data for calculation on the above method, they have been ascertained for as many compounds as possible.

Substances with positive heats of formation are termed exothermic; those with negative heats of formation are termed endothermic. The latter, which are not very numerous, give out heat on decomposition into their elements, and are more or less unstable. Amongst endothermic compounds none may be more interesting than hydriodic acid, HI, acetylene, C_2H_2, nitrous oxide, N_2O, nitric oxide, NO, azomide, N_2H_4, nitrogen trichloride, NCl. Some of these pass into their elements with explosive violence, owing to the heat generated by their decomposition and the gaseous nature of the products.

§ 7. Heat of Combustion.—The thermochemical magnitude which is universally determined for organic compounds is the heat of combustion, usually by means of the calorimetric bomb. The relation between the heat of combustion of a hydrocarbon and its heat of formation may be readily seen from the following example. The hydrocarbon methane, CH_4, when completely burned to carbon dioxide and water, generates 213800 cal. We may therefore write

\[ \text{CH}_4 + 4\text{O} = \text{CO}_2 + 2\text{H}_2\text{O} + 213800 \text{ cal.} \]

Now we know the heats of formation of carbon dioxide (from diamond) and of liquid water to be 94300 cal. and 683000 cal. respectively. The above equation may consequently be written, if x is the heat of formation of methane,

\[ -x = -94300 + 2(68300) + 213800 \]

or

\[ x = 17000 \text{ cal.} \]

This heat of formation, like that of most hydrocarbons, is comparatively small: the heat of formation of saturated hydrocarbons is always positive, but the heat of formation of unsaturated hydrocarbons is frequently negative. For example, ethylene, C_2H_4, is formed with absorption of 16200 cal., acetylene, C_2H_2, with absorption of 59100 cal., and liquid benzene, C_6H_6, with absorption of 9100 cal. Since the heat of combustion of a hydrocarbon is equal to the heat of combustion of the carbon and hydrogen it contains minus its heat of formation,
those hydrocarbons with positive heat of formation generate less heat on burning than the elements from which they were formed, whilst those with a negative heat of formation generate more. Thus the heat generated by the combustion of acetylene, $C_2H_2$, is 316000 cal., whereas the heat of combustion of the carbon and hydrogen composing it is only 256000 cal., the difference being equal to the negative heat of formation of the acetylene.

For substances consisting of carbon, hydrogen and oxygen, a rule was early devised for the purpose of roughly calculating their heat of combustion (J. J. Welter’s rule). The oxygen contained in the compound was deducted, together with the equivalent amount of hydrogen, and the heat of combustion of the compound was then taken to be equal to the heats of combustion of the elements in it. That the rule is not very accurate may be seen from the following example. Cane-sugar has the formula $C_{12}H_{22}O_{11}$. According to Welter’s rule, we deduct 11 O with the equivalent amount of hydrogen, namely, 22 H, and are left with the residue 12 C, the heat of combustion of which is 1135000 cal. The observed heat of combustion of sugar is, however, 1354000, so that the error of the rule is here 20 per cent. A much better approximation to the heat of combustion of such substances is obtained by deducting the oxygen together with the amount of carbon necessary to form CO, and then ascertaining the amount of heat produced by the residual carbon and hydrogen. In the above case we should deduct with 11 O the equivalent amount of carbon 5.5 C, thus obtaining the residue 6.5 C and 22 H. These when burnt would yield ($6.5 \times 94300$) + ($11 \times 68300$) = 1364250 cal., an amount which is less than 1 per cent. different from the observed heat of combustion of sugar. Neither of the above rules can be applied to carbon compounds containing nitrogen.

§ 8. Heat of Neutralisation.—It has already been stated that the heats of neutralisation of acids and bases in aqueous solution are additively composed of two terms, one being constant for a given base, the other constant for a given acid. In addition to this, the further regularity has been observed that when the powerful monobasic acids are neutralized by the powerful monacid bases, the heat of neutralisation is in all cases the same. The following table gives the heats of neutralisation of the commoner strong monobasic acids with soda:

<table>
<thead>
<tr>
<th>Acid</th>
<th>Heat of Neutralisation (cal.)</th>
</tr>
</thead>
<tbody>
<tr>
<td>Hydrochloric</td>
<td>137400</td>
</tr>
<tr>
<td>Hydrobromic</td>
<td>137500</td>
</tr>
<tr>
<td>Hydrobromic</td>
<td>136800</td>
</tr>
<tr>
<td>Nitric</td>
<td>136800</td>
</tr>
<tr>
<td>Chloric</td>
<td>137600</td>
</tr>
<tr>
<td>Bromeic</td>
<td>137800</td>
</tr>
</tbody>
</table>

Within the error of experiment these numbers are identical.

It was at one time thought that the greater the heat of neutralization of an acid with a given base, the greater was the strength of the acid. It is now known, however, that when weak acids or bases are used, the heat of neutralization may be either greater or less than the numerical value for powerful acids and bases, so that there is no proportionality, or even parallelism, between the strengths of acids and their heats of neutralization (see SOLUTIONS).

§ 9. Heat of Solution.—When substances readily combine with water to form hydrates, the heat of solution in water is usually positive; when, on the other hand, they do not readily form hydrates, or when they are already hydrated, the heat of solution is usually negative. The following examples show the effect of hydration on heat of solution in a large quantity of water:

<table>

§ 10. Application of the Second Law of Thermodynamics to Thermochemistry.—What is commonly understood by thermochemistry is based entirely on the first law of thermodynamics, but of recent years great progress has been made in the study of chemical equilibrium by the application of the second law. For an account of work in this direction see CHEMICAL ACTION.

**THERMODYNAMICS** (from Gr. θερμή, hot, δύναμις, force):

1. The name thermodynamics is given to that branch of the general science of Energetics which deals with the relations between thermal and mechanical energy, and the transformations of heat into work, and vice versa. Other transformations of heat are often included under the same title (see ENERGETICS). An historical account of the development of thermodynamics is given in the article HEAT. The object of the present article is to illustrate the practical application of the two general principles—(1) Joule’s law of the equivalence of heat and work, and (2) Carnot’s principle, that the efficiency of a reversible engine is limited by the ratio of the temperature between its working fluids; these principles are commonly known as the first and second laws of thermodynamics. The application will necessarily be confined to simple cases such as are commonly met with in practice, or are required for reference in cognate subjects.

2. Application of the First Law.—The complete transformation of mechanical energy into heat by friction, or some analogous process of degradation, is always possible, and is made the basis of experiments for the determination of the mechanical equivalent of the heat unit (see CALORIMETRY). The converse process, of the transformation of heat into mechanical work or other forms of energy is subject to limitations.

When a quantity of heat, $E$, is supplied to a body, part is expended in raising the temperature of the body, or in expanding the volume against molecular forces, and is represented by an increase in the total quantity of energy contained in the body, which is generally called Its Intrinsic Energy, and will be denoted by the symbol $E$. The remainder is equivalent to the external work, $W$, done by the body in expanding or otherwise, which can be utilized for mechanical purposes, and ceases to exist as heat in the body. The application of the first law leads immediately to the equation,

$$H=E-E_0+W,$$

in which $E_0$ represents the quantity of energy originally present in the body, and all the quantities are supposed, as usual, to be expressed in mechanical units. This equation is generally true for any series of transformations, provided that we regard $H$ and $W$ as representing the algebraic sums of all the quantities of heat supplied to, and of work done by, the body, heat taken from the body or work done on the body being reckoned negative in the summation. $E-E_0$, then, represents the total increase of the intrinsic energy of the body in its final state, which may be determined by measuring $H$ and $W$. If after any series or cycle of transformations the body is restored to its initial state, we must have $E=E_0$ whence it follows that $H=W$. But this simple relation is only true of the net balances of heat and work in a complete cyclical process, which must be adopted for theoretical purposes if we wish to eliminate the unknown changes of intrinsic energy. The method of work in obtaining $H$ and $W$ is usually subject to the limits of temperature in a manner which forms the subject of the second law.

3. Indicator or p.s. Diagram.—The significance of relation (1) is best appreciated by considering the graphic representation of quantities of heat and energy on a work-diagram.

On the familiar indicator diagram the state of the working substance is represented by the position of a point called the state-point, determined by the values of the pressure and temperature or unit mass, as ordinate and abscissa respectively (fig. 1). Any line ("path" or "graph") on the diagram, such as BCD, represents an "operation" or "process" i.e. a continuous series of states through which the substance may move without change of temperature or pressure. Otherwise the transformation could not be fully represented on the diagram, and would not be reversible. The area $B$CDD is

Under the path represents the external work done by the substance in...
expanding from B to D, which is analytically represented by the integral of pdv taken along the given path. Any closed path or figure in the temperature-pressure diagram represents work done on the substance and is equal to the area under the curve in the temperature-pressure plane, which represents work done on the body and is equal to the area under the curve in the temperature-pressure plane. The area ABCD represents a particular cycle, which is one way the energy is used. The area of the cycle, viz., that enclosed by the path BCDA, represents the balance of external work done by the substance in one cycle, and is positive if the cycle is positive. The curve ADEBC represents a heating and cooling process on the temperature-pressure plane, and is arranged in the normal manner as indicated by the arrows. The simplest types of process are those in which the substance is heated or cooled at constant temperature, represented by vertical lines such as AB, called isothermals. The pressure varies, but no external work is done. (2) Heating or cooling at constant pressure, represented by horizontal lines such as NA, called isobars, in which the energy absorbed or released is the product of the pressure p and the expansion or compression. (3) Expansion or compression under the condition of heat-insulation, represented by curves called adiabatics, such as BAZ or CDZ', which are necessarily steeper than the isothermals.

A cycle such as ABCD enclosed by parts of two isothermals, BC, AD, and two adiabatics, AB, CD, is the simplest form of cycle for theoretical purposes, since all the heat is transferred in during the process represented by one isothermal at the temperature T, and all the heat rejected, H', is given out during the process represented by the other at the temperature T'. This is the cycle employed by Carnot for the establishment of his fundamental principle of reversibility as the criterion of perfect efficiency in a heat engine. The area ABCD, representing the work done, represented on the diagram by the whole area BAZcd under the adiabatics through the state-point B, bounded by the isobars AB and CD, is the work done. The change of the intrinsic energy in passing from one state to another is BC cd, and the subtraction of the work-area W = BAZcd. It follows from the first law that the intrinsic energy of a substance in a given state must always be the same, that is, independent of the path followed. The transformation must depend only on the initial and final states, and not on the path or process. It will be observed that the areas representing H and W both depend on the form of the path BC, but the area representing the specific internal energy dE is independent of BC, which is a boundary common to both H and W. This is mathematically expressed by the statement that dE is an exact differential of a function of the co-ordinates defining the state of the body, and since it is more convenient to keep the relation between limits without reference to the representation relating the path along which the variations are taken.

4. Application of Carnot's Principle.—Carnot adopted as the analytical expression of his principle the statement that the efficiency W/H', or the work obtainable per unit of heat by means of a perfect engine taking in heat at a temperature T' and rejecting heat at a temperature T, must be some function F(T') of the temperature T', the lower limit T being supposed constant. He was unable to apply the principle directly in this form, as it would require an exact knowledge of the properties of substances through a wide range of temperatures. The principle in this form is really applicable to all cases, and is independent of any view with regard to the nature of the heat. It simply asserts that the efficiency function F(T') is the same as the efficiency function F(T) of Carnot's cycle, and that the efficiency of any other cycle is less, since its asymptotes coincide with those of the ideal Carnot cycle. The formula for this efficiency function is expressed by the equation

\[ dW = H' dT / dF(T') \]

where F(T) is the derived function of F(T), or dF(T)/dT, and represents the work obtainable per unit of heat per degree fall of temperature in a cycle. The principle in this form is really applicable to all cases, and is independent of any view with regard to the nature of the heat. It simply asserts that the efficiency function F(T') is the same as the efficiency function F(T) of Carnot's cycle, and that the efficiency of any other cycle is less, since its asymptotes coincide with those of the ideal Carnot cycle. Carnot verified this by calculating the values of F(T) at various temperatures from the known properties of vapours and gases, and showed that the efficiency function F(T) is the same in all cases as measured by the heating of an alcohol thermometer, or of a mercury or gas thermometer, from about 1.40 kilogrammetres per kilo-calorie per degree C. at 0° C. to about 1.14 at 100° C., according to the imperfect data available in his time. Applying the above equation to a gas obeying the law p = RT, for which the work done in isothermal expansion from a volume V to a volume v is

\[ W = RT \log v / R \log v \]

whence \( dW = R \log v \, dF(T') \), he deduced the expression for the heat absorbed by a gas in isothermal expansion

\[ H = R \log v / F(T') \]

He also showed that the difference of the specific heats at constant pressure and constant volume, or the ratio of these specific heats, is represented by the expression \( F(T') / F(T) \), and that the specific heats of all gases at the same temperature and pressure, being represented by the expression \( F(T') / F(T) \), he remarks that the law according to which the motive power of heat varies at different points of the thermometer was shown to be the same for all gases, and that the temperature of the various specific heats of gases at different temperatures—a law which experiment has not yet made known to us—will be given by the relation \( F(T') / F(T) \). Mayer (1842) made this assumption in calculating the mechanical equivalent of heat. Joule (1845) was the first to prove it approximately by direct experiment, but did not see his way to verify it, as regards its bearing on the fundamental theory. Holtzmann (1845) by the same assumption deduced the value \( W^2 / F(T') \) for the function F(T), but obtained erroneous results by combining this assumption with the caloric theory. Clausius (1850) applied the same assumption, and deduced the value of F(T), that the law ascribed to the mechanical theory and Joule's experiments, but required that a vapour like steam should deviate more considerably from the gaseous laws than was at that time generally admitted. The values of F(T) calculated previously by Sir W. Thomson (Lord Kelvin) from Regnault's tables of the properties of steam, assuming the gaseous form of water, were not consistent with the fundamental assumption W = RT in isothermal expansion, which is very nearly true for permanent gases, and that F(T) must therefore vary very slowly with the temperature. He deduced the scale of temperature independent of the properties of any particular substance in terms of Carnot's function by making F(T) constant. He now proposed to define absolute temperature as proportional to the reciprocal of Carnot's function, so as to agree as closely as possible with the scale of the gas thermometer. With this definition of temperature T, if the heat H is measured in work units, the expression of Carnot's principle for an infinitesimal cycle of range dT reduces to the result H = dF(T)/dT. Combining this with the first law, for a Carnot cycle of finite range, if \( T' \) is the heat taken in at \( \theta' \), and \( T' \) is the heat rejected at \( \theta' \), the work done in the cycle is equal to the difference \( T' - T \), and we have the simple relations

\[ W(\theta' - \theta) = H' \theta' - H' \theta \]  

5. Thermodynamical Relations.—The most important and most useful of the relations between the thermodynamical properties of a substance may be very simply deduced from a consideration of the indicator diagram by a geometrical method, which is in principle the same as that employed by Regnault. Referring to fig. 2, let BC be a small portion of any isothermal corresponding to the temperature \( \theta' \), and AD the isothermal of the same temperature, and cut off the area ABCD by meeting at E, and EC an isocpetic through E meeting BC in C. Let BA, CD be adiabatics through B and C meeting the isothermal \( \theta' \) in A and D. Then by relations (2) the heat, \( H' \), work done in the isothermal change BC, is to the work, \( W' = H' \theta' - H' \theta \), done in the cycle ABCD in the ratio of \( \theta' \) to \( \theta' - \theta \). If the difference
of temperature \(\theta - \theta^0\) is small, the figure ABCD may be regarded as a parallelogram, and its area \(W\) as equal to the rectangle \(BE \times EC\). This is accurately true in the limit when \(\theta - \theta^0\) is infinitesimal, but in practice it is necessary to measure specific heats, &c., over finite ranges of temperature, and the error involved is generally negligible if the range does not exceed a few degrees. \(BE\) is the increase of \(\phi\) produced by the rise of temperature \(\theta - \theta^0\) if the volume is kept constant. \(EC\) is the expansion \((v^0 - v')\) produced by the same rise of temperature if the pressure is kept constant. Subtracting these symbols in the expression for the area, the relation becomes

\[
H = \theta^0(v^0 - v') + \frac{\partial V}{\partial \theta}(v^0 - v').
\]

This relation may be interpreted in two ways, according as we require the heat absorbed in terms of the change of pressure or volume. The heat \(H\) absorbed at constant pressure (latent heat of expansion) from \(p'\) to \(p^0\) is equal to the diminution of pressure \((p^0 - p')\) multiplied by the absolute temperature and by the increase of temperature \((\theta - \theta^0)\), and by the increase of volume \((v^0 - v')\). The heat \(H\) absorbed at constant volume, and by the increase of pressure per degree \((p^0 - p')(\theta - \theta^0)\), at constant volume. In the notation of the calculus the relations become

\[
dH/dp (\theta \text{ const}) = \partial V/\partial \theta (v \text{ const})
\]

The negative sign is prefixed to \(dH/dp\) because absorption of heat \(+dH\) corresponds to diminution of pressure \(-dp\). The utility of these relations results from the circumstance that the specific heat and expansion coefficients are familiar and easily measured, whereas the latent heat of expansion is difficult to determine.

The most instructive example of the application of these relations (1) and (2) is afforded by the change of state of a substance at constant temperature or pressure. Starting with unit mass of the substance in the first state (e.g. liquid), Possessed of a known volume \(v^0\) at the temperature \(\theta^0\), the heat absorbed in this change is called the latent heat of change of state, and may be represented by the symbol \(L'\). The substance is then cooled to the lower temperature \(\theta'\) along the path CD, keeping it in the saturated state. The heat \(H\) absorbed in this change may be represented by \(s'(\theta')\), where \(s'\) is the specific heat of the substance in the second state at saturation pressure. Finally, the substance is reconverted into the first state at the temperature \(\theta^0\), completing the cycle by the abstraction of a quantity of heat \(L^0\). By the application of the first law, the difference of the quantities of heat absorbed and evolved in this cycle must be equal to the work performed by the area of the cycle, which is equal to \((p^0 - p')(\theta^0 - \theta^0)\) in the limit when the difference of pressure is small. By the application of the second law, relations (2), the same work area is equal to \((\theta - \theta^0)\times L'\). Dividing by \((\theta - \theta^0)\) and writing \(dp/d\theta\) and \(dL/d\theta\) for the derivatives of the relations \((p^0 - p')(\theta^0 - \theta^0)\) and \((L - L^0)(\theta^0 - \theta^0)\), we obtain the identities

\[
is' - s + \frac{dL}{d\theta} = (v^0 - v') dp/d\theta = sL/\theta,
n\]

in which \(dp/d\theta\) is the rate of change of pressure with temperature when the two states are in equilibrium. It is not necessary in this example that \(AB\), \(CD\) should be adiabatic, because the area of volume \(BC\) is finite. The same equations apply to the case of fusion of a solid, if \(L\) is the latest heat of fusion, and \(v', s', v''\) the specific volumes and specific heats of the solid and liquid respectively.

6. Ratio and Difference of Specific Heats.—If we take unit mass of the substance at B, fig. 2, and cool it at constant volume to E, through an interval of temperature \(\theta\), the specific heat \(s\) at constant volume may be written \(h = s(\theta^0 - \theta^0)\), where \(s\) is the specific heat at constant volume. If, starting from E, the same amount of heat \(h\) is restored at constant pressure, we should arrive at the point F on the adiabatic through B, since the substance has been transformed from B to F by a reversible path without loss or gain of heat on the whole. In order to restore the substance to its original temperature \(\theta'\) at constant pressure, it would be necessary to supply a further quantity of heat \(H\), represented by the area between the two adiabatics from FC down to the absolute zero. This quantity of heat \(H\) is the difference between the total heat found in equation (3), but for the small area BFC, or for the small change of state considered in this limit compared with \(H\). The whole quantity of heat required to raise the temperature from \(\theta^0\) to \(\theta'\) at constant pressure along the path EC is \(H + h\), which is equal to \(s(\theta - \theta^0)\), where \(s\) is the specific heat at constant pressure. Since \(h = s(\theta - \theta^0)\), the difference \(\theta - \theta^0\) of constant pressure heats at constant pressure and volume is evidently \(H(\theta - \theta^0)\). Substituting for \(H\) its value from (3), and employing the notation of the calculus, the relation

\[
S = s \text{ or } S = \theta dp/d\theta (v \text{ const})
\]

in which the partial differential coefficients have the same meaning as in (4).

Since the amounts of heat supplied at constant pressure from E to F and from F to C are in the limit proportional to the expansional heats \(s\), these are proportional to the ratio \(EC/EF\). \(EF\) is the change of volume corresponding to a change of pressure \(BE\) when no heat is allowed to escape and the path is the adiabatic \(BC\). \(EC\) is the change of volume for the same change of pressure \(BE\) when the path is the isothermal \(BC\). These changes of volume are directly as the compressibilities, or inversely as the elasticities. If we write \(K\) for the adiabatic elasticity, and \(k\) for the isothermal elasticity, we obtain

\[
S = EC/EF = K/k
\]

The value of the specific heat \(S\) at constant pressure can always be determined by experiments and in practice is one of the most important thermodynamical properties of a substance. The value of the specific heat \(s\) at constant volume can also be measured in a few cases, but it is generally necessary to deduce it from that at constant pressure by means of equation (6). It is often impossible to observe the pressure-coefficient \(dp/d\theta\) directly, but it may be deduced from the isothermal compressibility by means of the geometrically obvious relation, \(BE = (BE/EC)\times EC\). The ratio \(BE/EC\) is independent of the path, and is equal to the reciprocal of the elasticities of the substance. If \(dp/d\theta\) is known, \(S\) may be calculated by equation (4). If \(dp/d\theta\) is not known, \(S\) may be found by substituting in equation (6) the relation \(dp/d\theta = \partial V/\partial \theta\) for the derivative of the expression for the volume. The change of specific heat \(S\) at constant pressure is the change at constant temperature \(dp/d\theta\), or \(dp/d\theta\) at constant temperature, or \(-dp/d\theta\), is readily observed.

The amount of heat absorbed in any small change of state, as from \(E\) to \(G\) in fig. 2, may be found by adding the heat required for the change of temperature at constant volume, \(s\), or at constant pressure, \(s\), the heat absorbed in isothermal expansion as given by relations (4). We thus obtain the expression

\[
H = s + s' + s'' + \left(\frac{dp}{d\theta}\right)\left(\frac{dv}{d\theta}\right)
\]

The first is equivalent to the area \(BFC\), while the second is the area \(BEC\). The two differ by the area \(BEC\), which can be neglected if the change is small. For a finite change it is necessary to represent the path by a series of small steps, and the change of specific heat, which may be calculated by the addition of integration along the path represented by the given relation between \(s\) and \(\theta\) or \(p\) and \(\theta\). If we put \(dH = 0\) in equations (8), we obtain the relations between \(dv\) and \(dp\), or \(dp\) and \(\theta\), under the condition of no heat-supply, i.e. along the adiabatic, which can be integrated, and the heat absorbed in isothermal or isopiestic, and to integrate along each separately. The change of energy at constant volume is small, while the change at constant temperature is \(dp/d\theta\), which may be written

\[
dE/d\theta (v \text{ const}) = s, dE/dv (p \text{ const}) = dp/d\theta.
\]

These must be expressed as functions of \(v\) and \(p\), which is theoretically possible if the values of \(s\), \(p\), and \(dp/d\theta\) are known. Since the expression \(dp/d\theta\) is the partial differential-coefficient of a single function \(E\) of the independent variables \(v\) and \(p\), we shall obtain the same result, namely \(dE/dPdv\), if we differentiate the first with respect to \(v\) and the second with respect to \(\theta\). We thus obtain the relation

\[
\frac{dE}{dv} (p \text{ const}) = \frac{dp}{d\theta} (p \text{ const}).
\]
Deviations measure (8), we the gas. ideally may which (p by is a The issues (16) diminution. the density function where from. energy the we (14) must 8. form pv p. (n) into dv, we (11) change that constant is defined. exponential density function of the is the state defined. both integrating the specific heat cV. In the case the expression achieved. Since dE = dH - p dv, we have evidently for the variation of the total heat from the second expression (12).

\[ \frac{dE}{dp} = \frac{dH}{dp} - p \frac{dv}{dp} \]

This expression shows that the rate of variation of the total heat with temperature at constant pressure is equal to the specific heat at constant pressure. To find the total heat of a substance in any given state defined by the values of p and \( \theta \), starting from any constant pressure and heat content, we must find the total heat required to raise the substance to the final temperature under a constant pressure equal to \( \theta \). For instance, in the boiler of a steam engine the feed water is pumped into the boiler against the final pressure of the steam, and is heated under this constant pressure up to the temperature of the steam. The total heat with which we are actually concerned in the working of a steam engine is as follows. The state equation takes the simple form (8) \( \frac{(p \theta - s)\theta}{p} \) constant, which is obtained by Regnault, which, however, differs from (E+pV) only by a quantity which is inapplicable in ordinary practice. We are assuming that \( F \) is a function of the co-ordinates expressing the state of the system. We obtain the equation of the lines in terms of \( \varphi \) and \( \theta \) is obtained by integrating:

\[ dE = sdp + (\theta dp - \varphi dv) \]  

If, on the other hand, the heat supplied is equal to \( \theta dp \), we see from (11) that \( F \) remains constant. The equation to the lines of constant total heat is found in terms of \( \theta \) and \( \varphi \) by putting \( dp = 0 \) and \( dv = 0 \) (13).

8. Ideal Gases.—An ideal gas is a substance possessing very simple thermodynamic properties to which actual gases and vapours appear to approximate indefinitely at low pressures and high temperatures. It has the characteristic equation \( \rho = \frac{R}{\theta} \), and obeys Boyle's law at all temperatures. The coefficient of expansion at constant pressure is equal to the coefficient of increase of pressure at constant volume. The difference of the specific heats by equation (6) is constant and equal to \( R \). The isothermal elasticity \( -\frac{d\rho}{d\rho} \) is equal to the pressure \( \rho \). The adiabatic elasticity is equal to \( \gamma \rho \), where \( \gamma \) is the ratio \( s/R \) of the specific heats. The heat absorbed in raising the temperature of the specific heat \( \theta \) by \( \varphi \) may be written \( E - \frac{E_0}{\theta} = \frac{E_0}{\theta} \), \( F = \frac{F_0}{\theta} \). In this case the ratio of the specific heats is constant as well as the difference, and the adiabatic elasticity is a constant specific heat, which is at once obtained by integrating the equation for the adiabatic elasticity, \( -\frac{d\rho}{d\rho} = c^2 \).

The specific heats may be any function of the temperature contained in a series for each value of the temperature and that their difference is constant. If we assume that \( s \) is a linear function of \( \theta \), \( s = s_0 + a \theta \), the adiabatic equation takes the form:

\[ \sum \log(\theta / \theta_0) + s_0 \log(\theta / \theta_0) + R \log(\theta / \theta_0) = 0 \]

where \( \theta_0 \), \( \theta_0, \theta_0, \theta_0 \) are any two points on the adiabatic. The corresponding expression for the change of energy or total heat is obtained by adding the term \( s_0 \log(\theta / \theta_0) \) to those already given, thus:

\[ E = E_0 - \sum \log(\theta / \theta_0) + s_0 \log(\theta / \theta_0) + \frac{R}{\theta} \log(\theta / \theta_0) \]

where \( s_0 = s_0 + R \).  

9. Deviations of Actual Gases from the Ideal State.—Since no gas is ideally perfect, it is most important for practical purposes to discuss the deviations of actual gases from the ideal state, and to consider how their properties may be thermodynamically explained and defined. The most natural method of procedure is to observe
devised by Clausius (Phil. Mag., 1880) to represent the behaviour of CO₂ up to the critical point. Experiments by Natanson on CO₂ by similar methods, carried out in 1903, showed a slight increase of the ratio \( \frac{d\theta}{dp} \) at higher pressures, which is otherwise rendered probable by the form of the isothermals as determined by Andrews and Amagat. More recent experiments by J. H. Guinness and J. A. Groddeck (Proc. Roy. Soc., 1900) on steam confirm this type of equation, but give much larger values of the cooling effect than for CO₂, and a more rapid rate of variation with temperature.

The assumption usually made is that the total kinetic energy of the molecules, including possible energy of rotation or vibration if the molecules consist of more than one atom, is proportional to the energy of translation in the case of an ideal gas. In the case of imperfect gases, all the available experimental evidence shows that the specific volume tends towards its ideal value, \( V = \frac{R}{p} \), in the limit, when the pressure is indefinitely reduced, and the molecules are widely separated so as to eliminate the effects of their mutual actions. We may therefore reasonably assume that the limiting values of the specific heats at zero pressure do not vary with the temperature, provided that the molecules are not stable, and there is no dissociation. Denoting by \( s_0 \) these constant limiting values at \( p = 0 \), we may obtain the values at any pressure by integrating the expression (20) and (21) from 0 to \( p \) respectively. We thus obtain

\[
E = E_0 + s_0 \theta - p s_0 \frac{\rho}{\rho_0}.
\]

We have similarly for the total heat \( F = E + p s \),

\[
F = F_0 = s_0 \theta - (s_1 + p e_{c_1} - c_2 p) + p e_{c_1}.
\]

The energy is less than that of an ideal gas by the term \( n p c \). If we imagine that the defect of volume \( c \) is due to the formation of molecular aggregates consisting of two or more single molecules, and if the kinetic energy of translation of any one of these aggregates is equal to that of one of the single molecules, it is clear that some energy must be lost in co-aggregating, but that the proportion lost will be different for different types of molecules and also for different parallel lines. If we consider the effect of having energy of translation only, equivalent to 3 degrees of freedom, combined to form a datomic molecule with 5 degrees of freedom, the co- and cross-aggregates will be much more complicated, and the number of degrees of freedom of the aggregates were limited to 6, or were the same as for single molecules, we should have \( n s_0 R \). The loss of energy could not be greater than this on the simple kinetic theory, unless there were some evolution of latent heat of co-aggregation, due to the work done by the mutual attractions of the co-aggregating molecules.
The expression for the change of entropy between any two states is given by one of the equations of the form of the differential

dS = \frac{dW}{T}

interacting between two states, \(\delta S = dS\), is a function of the

In the case of a solid or a liquid, the latent heat of

isothermal expansion may often be neglected, and if the specific heat has a constant value, we have simply

\(\delta S = \frac{dW}{T}\). If the substance at the temperature \(\theta\) is a change

absorbing latent heat, \(L\), we have merely to add the term \(L/\theta\) to the

above expression. In the case of an ideal gas, \(dp/d\theta\) at constant

volume is \(-R\theta\), or

\(\delta S = -R\theta dp\); thus we obtain the expression for the change of

entropy \(\delta S\) from the state \(\theta_0, p_0\) to the state \(\theta, p\),

\[\delta S = S(\theta, p) - S(\theta_0, p_0) = \int_{\theta_0}^{\theta} \frac{dW}{T}.
\]

In the case of an imperfect gas or a vapour, the above expressions

are frequently employed. \(\delta S\) may be obtained by employing

expression (17) with the value of the specific heat \(S\), from (29), which gives the expression

\[\delta S = \frac{1}{\rho} \frac{dH}{T},\]

the state of a substance may be defined by means of the temperature

and entropy as co-ordinates, instead of employing the pressure

and volume as in the indicator diagram. This method of represen-
tation is applicable to certain kinds of problems, and has been

developed by Macfarlane Gray and other writers in its application to

the gas engine. (See STEAM ENGINE.) Areas on the tempera-
ture-entropy diagram represent processes of the same kind in

the same way as areas on the indicator diagram represent quantities of

work. The \(\theta, S\) diagram is useful in the study of heat waste and

the transfer cannot be reversed without an expenditure of work.

If mechanical work or kinetic energy is directly converted into

heat by friction, reversal of the motion does not restore the energy

so converted. In all such cases there is necessarily, by Carnot's

principle, a loss of efficiency or available energy, accompanied by

an increase of entropy. In cases where it is convenient to

measure the quantity of parts of the gas. If this could be co-ordinated and utilized

without dissipation, the gas might conceivably be restored to its

initial state; but in practice violent local differences of pressure and

temperature are always present, and the energy is converted into heat by viscous eddy friction, and residual differences of

temperature are equalized by diffusion throughout the mass. Even if the expansion is adiabatic, in the sense that it takes place

inside a non-conducting enclosure and no heat is supplied from

external sources, it will not be isentropic, since the heat supplied

by internal friction must be included in reckoning the change

of entropy. Assuming that no heat is supplied from external sources

and no external work is done, the intrinsic energy remains constant

by the first law. The final state of the substance, when equilibrium has

been reached, may be deduced from this condition, if the energy can be expressed in terms of its components. An other

line of constant energy on the diagram does not represent the path of

the transformation, unless it be supposed to be effected in a

series of infinitesimal steps. This condition may be expressed by

\(dE = dW\). An irreversible process permits a more complete experimental investigation is the steady flow of a fluid in a tube already referred to in section to. If the tube is a long fine tube, the flow of fluid is reversible, and the state of the fluid is the same at points where the section of the tube is the same. In practice, however, a small amount of frictional dissipation is accompanied by an increase of entropy and by a fall of pressure. In the limiting case of a long fine tube, the bore of which varies in such a manner that \(U\) is constant, the state of the substance along a line of flow may be represented by the line of constant

total heat, \(d(E+p_v) = 0\); but in the case of a porous plug or small

throttling aperture, the steps of the process cannot be followed, though the final state is the same.

It will be seen later in which the substance absorbs

heat, \(dH\), from external sources, the increase of entropy of the final state is equal to \(dH/\theta\). If the change is not reversible, but the final

state is the same, the change of entropy, \(\delta S\), is the same; but it is

not longer equal to \(dH/\theta\). In all irreversible processes, \(\delta S/\theta\) must be at least as much as it would be

in the case of a reversible cycle. It is found that a cycle more efficient than a

reversible cycle, although it is not always possible to devise a cycle more efficient than a

reversible cycle, is always more difficult. The change of entropy is zero in a

reversible process, but in an irreversible process it is positive, even if the process is not

reversible. The entropy cannot diminish indefinitely, because the increase of entropy is impossible. The entropy tends to a maximum, and the state is one of stable equilibrium when the value of the entropy is the maximum value consistent with the conditions of the problem.

15. Heterogeneous Equilibrium.—In a system, as distinguished from a homogeneous substance, consisting of two or more states or phases, a similar condition of equilibrium applies. In spontaneous irreversible change, if the system is heat-isolated, there must be an increase of entropy. The total entropy of the system is equal to the entropy per unit mass of the substance in each state by the mere fact of adding the products so obtained. The simplest case to consider is that of equilibrium between solid and liquid, or liquid and vapour. This case is treated in general in the works of Boltzmann, and in the original memoirs of Willard Gibbs and others. Since the condition of heat-isolation is impracticable, the condition of maxi-
mum entropy is not, as a rule, directly applicable, and it is neces-
sary to find a more convenient criterion which may be used, even in the external work done, \(dH\) the heat absorbed from external sources, and \(dE\) the increase of intrinsic energy, we have in all cases by the first law of thermodynamics, \(dE = dH + dW\), and hence, by the second law (\(\delta S > 0\), cannot be less than \(dH\), consequently

the difference \(dE-\delta S\) cannot be less than \(dW\). This inequality

holds in all cases, but cannot in general be applied to an irrever-
sible change, because \(\delta S\) is not a perfect differential, and cannot be considered as the work done in the transformation. In the special case, however, in which the transforma-
tion is conducted in an isothermal enclosure, a common condition

considered, by an area on the indicator diagram similar to that repre-
sentating the intrinsic energy, \(E\). The product \(\delta\theta\) may be represented by an area such as \(\theta D\), and the change in the

isothermal \(\delta D\) and the adiabatic \(D'\), bounded by the axes of

pressure and volume. The intrinsic energy, \(E\), is similarly repre-
sented by the area \(D'\) or the area \(D'\) adiabatic to the right of the

isothermal \(\delta D\). The difference \(E - \theta D = \delta \theta D\) to the left of the isomorphic \(\delta D\) under the isothermal \(\theta D\). The increment of this area (or the decrement of the negative area

\(E-\theta D\) at constant temperature represents the external work

obtained from the substance in isothermal expansion, in the same way

that the decrement of the intrinsic energy represents the work done in adiabatic expansion. The function \(J = 1 - \theta D\), has been called the 'free energy' of the substance by Helmholtz, and \(\theta D\) the 'bound energy'. These functions do not, however, represent energy existing in the substance, like the intrinsic energy; but, on the contrary, \(\theta D\) represents heat supplied to, and the decre-
moment of \((E-\theta D)\) represents heat obtainable from, the substance

when the temperature is kept constant. The condition of stable
equilibrium of a system at constant temperature and volume is

represented by the line \(J = 1\). The condition of stable

equilibrium to the case of the state of a mixture. If \(J, J'\) represent the values of the function for unit mass of the substance of specific volumes \(v\) and \(v'\) in the two states at temperature \(\theta\) and pressure \(p\), and if a mass \(m\) is in

the two states \(1-m\) and \(m\) respectively, the volume of the mixture is \(m^p + (1-m)J\). This must be a minimum in the state of equilibrium at constant temperature. Since the volume is constant, we have the condition \(m^p + (1-m)J = 0\). The relations

\[dJ/dv = p - dJ/dv',\]

at constant temperature. Putting \(dJ/dm = 0\) at constant volume, we obtain as the condition of equilibrium of the two states J = \(v' + v = J' + J'\). This may be interpreted as
the equation of the border line giving the relation between \( p \) and \( \sigma \), but is more easily obtained by considering the equilibrium at constant temperature in the case of the constant volume.

(b) The second case, which is of greater practical utility, is that in which the external pressure, \( p \), is kept constant. In this case \( dW = pdv + \sigma d\sigma \), so that, if an external work is done, is known from the initial and final states. In any possible transformation \( d(\theta E - T) \) cannot be less than \( d(p \sigma) \), or the function \( (E-\theta \sigma + p) \) cannot increase. The condition of stable equilibrium, for a number of these cases, which has been called the "thermodynamic potential at constant pressure."

The product \( p\sigma \) for any state such as \( D \) in fig. 1 is represented by the rectangle \( MDEO \), bounded by the isoplastic and the isometric through \( D \). The function \( G \) is represented by the negative of \( \theta DM \) under the isothermal, bounded by the isoplastic DM and the axis of pressure. The increment of \( 2p \) is always greater than that of \( E+\theta \sigma + p \), and this is the reason why it cannot be found without that of \( \phi \), and although the consideration of the properties of the thermodynamic potential cannot in any case lead to results which are not directly deducible from the two fundamental laws, it affords a much more convenient method in abstract thermodynamics for the condition of equilibrium between different phases, or the criterion of the possibility of a transformation. For such purposes, the possibility of a number of numerical evaluation of the functions is of secondary importance, and it is often possible to make qualitative deductions with regard to the general nature of a transformation without any knowledge of the actual form of the function. A more common method of procedure, however, is to infer the general relations of the thermodynamic potential from a consideration of the phenomena of equilibrium.

As it would be impossible within the limits of this article to illustrate or explain adequately the applications which have been made of the principles of thermodynamics, it has been necessary to select such illustrations only as are required for other reasons, or for the purpose of filling the blank spaces between the more important facts of the subject in a way that will be clear to the general reader. The treatment of the second law of thermodynamics, whether from the point of view of the number of possible states, or from the practical point of view, is a matter of great importance, and a discussion of it will be found in the next article. In the present article, the relations between the various thermodynamic processes are considered, and the treatment of the second law of thermodynamics is not included.

### THERMOELECTRICITY.

1. **Fundamental Phenomena.**

Alessandro Volta (1801) showed that although a separation of the two electricity was produced by the contact of two different metals (Volta Effect), which could be detected by a sensitive electrometer, a continuous current of corresponding magnitude could not be produced in a purely metallic circuit without the interposition of a liquid, because the electromotive force at one junction was exactly balanced by an equal and opposite force at the other. T. J. Seebeck (1822), employing a galvanometer then recently invented, which was more suited for the detection of small electromotive forces, found that a current was produced if the junctions of the two metals were at different temperatures. He explained this effect by supposing that the Volta contact electromotive force varied with the temperature, so that the exact balance was destroyed by unequal heating. The intensity

\[
R \log p = A - B \theta - \left( C - S_0 \right) \theta^2 + \left( D + \theta \right) \theta^3 + \ldots
\]

where \( A, B, C, D, \ldots \) are constants characteristic of the metal and of the temperature. The term \( (\theta \theta - \theta \theta) \) depends on the variation of the specific heat of the liquid may be made very small in the case of water by a proper choice of the constant \( \theta \). It is of the same order as the
Thermoelectricity 815

of the current, \( C \), for any given pair of metals, was found to vary directly as the difference of temperature, \( t' - t \), between the hot and cold junctions, and inversely as the resistance, \( R \), of the circuit. We conclude by applying Ohm's law that the electromotive force, \( E \), of the thermocouple may be approximately represented for small differences of temperature by the formula

\[
E = CR \log \left( \frac{t}{t'} \right).
\]

1. Principles. - Thermoelectric current is due to the difference of temperature at two points of a conductor, or junction of two conductors, \( E \), which is always in the direction of the heat flow from the hotter to the colder point.

2. Thermoelectric Power, Series, Inversion.-The limiting value, \( dE/dt \), of the coefficient, \( p \), for an infinitesimal difference, \( dt \), between the junctions is called the Thermoelectric Power of the couple. One metal \( A \) is said to be thermoelectrically positive to another \( B \), if positive electricity flows from \( A \) to \( B \) across the cold junction when the circuit is completed. The opposite convention is sometimes adopted, but the above is the most convenient in practice, as the circuit is generally broken at or near the cold junction for the insertion of the galvanometer. Seebec found that the metals could be arranged in a Thermoelectric Series, in the order of their power when combined with any one metal, such that the power of any thermocouple \( p \), composed of the metals \( A \) and \( B \), was equal to the algebraic difference \( (p' - p') \) of their powers when combined with the standard metal \( C \). The order of the metals in this series was found to be different from that in the corresponding Volta series, and to be considerably altered by variations in purity, hardness, and other physical conditions. J. Cuming shortly afterwards discovered the phenomenon of Thermoelectric Inversion, or the change of the order of the metals in the thermoelectric series at different temperatures. Copper, for instance, is negative to iron at ordinary temperatures, but is positive to it at 300°C or above. The E.M.F. of a copper-iron thermocouple reaches a maximum when the temperature of the hot junction is raised to 170°C, at which temperature the thermoelectric power vanishes and the metals are said to be neutral to one another. Beyond this point the E.M.F. diminishes, vanishes, and changing sign when the temperature of the hot junction is nearly as much above the neutral point as the temperature of the cold junction is below it. Similar phenomena occur in the case of many other couples, and it is found that the thermoelectric power \( p \) is not in general a constant, and that the simple linear formula (1) is applicable only for small differences of temperature. More accurately it may be stated that the thermoelectric force in any given circuit containing a series of different metals is a function of the temperatures of the junctions only, and is independent of the distribution of the temperature at any intermediate points, provided that each of the metals in the series is of uniform quality. This statement admits of the simple mathematical expression

\[
E = \int \frac{dp}{dt} dt + \int \frac{dp}{dt} dt + \cdots.
\]

where \( p', p, \&c. \), are the thermoelectric powers of the metals, and \( t_0, t, t', \&c. \), the temperatures of the junctions. There are some special cases of sufficient practical importance to be separately stated.

3. Homogeneous Circuit. Strain Hysteresis.—In a circuit consisting of a single metal, no current can be produced by variations of temperature, provided that the metal is not thereby strained or altered. This was particularly demonstrated by the experiments of H. G. Magnus. The effects produced by abrupt changes of temperature or section, or by pressing together pieces of the same metal at different temperatures, are probably to be explained as effects of strain. A number of interesting effects of this nature have been investigated by Thomson, F. P. Le Roux, P. G. Tait and others, but the theory has not as yet been fully developed. An interesting example is furnished by an experiment due to F. T. Trouton (Proc. R. S. Dub., 1888). A piece of iron or steel wire in the circuit of a galvanometer is heated in a flame to bright redness at any point. No effect is noticed so long as the flame is stationary, but if the flame be moved slowly in one direction a current is observed, which changes its direction with the direction of motion of the flame. The explanation of this phenomenon is that the metal is transformed at a red heat into another modification, as is proved by simultaneous changes in its magnetic and electrical properties. The change from one state to the other takes place at a higher temperature on heating than on cooling. The junctions of the magnetic and the non-magnetic steel are therefore at different temperatures if the flame is moved, and a current is produced when a piece of different metal was used. If different temperatures had been introduced into the circuit. Other effects of "hysteresis" occur in alloys of iron, which have been studied by W. F. Barrett (Trans. R. S. Dub., January 1900).

4. Law of Successive Temperatures.—The E.M.F. of a given couple between any temperatures \( t \) and \( t' \) is the algebraic sum of the E.M.F. between \( t \) and any other temperature \( t'' \) and the E.M.F. between \( t'' \) and \( t' \). A useful result of this law is that it is sufficient to keep one junction always at some convenient standard temperature, such as 0°C, and to tabulate only the values of the E.M.F. in the circuit corresponding to different temperatures of the other junction.

5. Law of Intermediate Metals.—A thermoelectric circuit may be cut at any point and a wire of some other metal introduced without altering the E.M.F. in the circuit, provided that the two junctions with the metal introduced are kept at the same temperature. This law is commonly applied in connecting a thermocouple to a galvanometer with coils of copper wire, the junctions of the copper wires with the other metals being placed side by side in a vessel of water or otherwise kept at the same temperature. Another way of stating this law is that apparently quite different, is really equivalent in effect, is the following: The E.M.F. of any couple, \( AB \), for any given limits of temperature is the algebraic sum of the E.M.F.'s between the same limits of temperature of the couples BC and CA formed with any other metal \( C \). It is for this reason unnecessary to tabulate the E.M.F.'s of all possible combinations of metals, since the E.M.F. of any couple can be at once deduced by addition from the values given by its components with a single standard metal.

Different observers have chosen different metals as the standard of reference. Tait and J. A. Fleming select lead in accordance with the smallness of the Thomson effect in it, as observed by Le Roux. Noll adopts mercury because it is easily purified, and its physical condition in the liquid state is determinate; there is, however, a discontinuity involved in passing from the liquid to the solid state at a temperature of -40°C, and it cannot be used with all metals, such as lead, on account of the rapidity with which it dissolves them. Both lead and mercury have the disadvantage that they cannot be employed for temperatures much above 300°C. Of all metals, copper is the most generally convenient, as it is electrically connected with all others, and is easily obtained in the annealed state of uniform purity. For high temperature work it is necessary to employ platinum, which would be an ideal standard for all purposes on account of its constancy and insusceptibility, did not the thermoelectric properties of different specimens differ considerably.

6. Thermoelectric Formulas.—On the basis of the principles stated above, the most obvious method of tabulating the observations would be to give the values \( E \) of the E.M.F. between 0°C. and \( t \) for each metal against the standard. This involves no assumptions as to the law of variation of E.M.F. with temperature, but is somewhat cumbersome. In the majority of cases, the observations can be represented within the limits of experimental error by a fairly simple empirical formula, at least for moderate ranges of temperatures. The following formulae are some of those employed for this purpose by different observers:

\[
E = E_0 - E_1 T + \frac{E_2}{T} + \frac{E_3}{T^2} + \frac{E_4}{T^3} + \frac{E_5}{T^4} + \cdots
\]

(Where \( E_0 \) and \( E_1 \) are constants, \( T \) is the temperature, and \( E_2, E_3, E_4, \cdots \) are small.)

(See sect. 15.)

**Thermoelectricity**

For moderate ranges of temperature the binomial formula of M. P. Avenarius is generally sufficient, and has been employed by many observers. It is figured by Avenarius (Pogg. Ann., 119, p. 406) as a semicircle, but it is really a parabola with its axis parallel to the axis of E, and its vertex at the point \( t = b/2c \), which gives the neutral temperature. We have also the relations \( dE/dt = b + 2ct \) and \( dE/dt^2 = 2c \). The first relation gives the thermoelectric power \( b \) at any temperature, and is probably the most convenient method of stating results in all cases in which this formula is applicable.

A discussion of some of the exponential formulae is given by S. W. Holman (Phil. Mag., 41, p. 465, June 1896).

7. Experimental Results.—In the following comparative table of the results of different observers the values are referred to lead. Before the time of Tait's researches such data were of little interest or value, on account of insufficient care in securing the purity of the materials tested; but increased facilities in this respect, combined with great improvements in electrical measurements, have put the question on a different footing. The comparison of independent results shows in many cases a remarkable concordance, and the data are becoming of great value for the testing of various theories of the relations between heat and electricity.

**Table I.—Thermoelectric power, \( b = dE/dt \), in microvolts at 50° C. of pure metals with respect to lead.** (The mean change, \( 2c = dE/dt^2 \), of the thermoelectric power per degree C. over the range covered by the experiments, is added in each case.)

</table>

Explanation of Table.—The figures marked with an asterisk (*) represent discrepancies which are probably caused by imperfections in the specimens. At the time of Tait's work in 1873 it was difficult, if not impossible, in many cases to procure pure materials. The work of the other three observers dates from 1894-95. The value of the thermoelectric power \( dE/dt \) at 50° C. is taken as the mean value between 0° and 100° C., over which range it can be most accurately determined. The values of \( dE/dt^2 \) are given as well as can be expected, considering the difference of the ranges of temperature and the great variety in the methods of observation adopted; they are calculated assuming the parabolic formula, which is certainly in many cases inadequate. Noll's values apply to the temperature of +100° C., Dewar and Fleming's to that of -100° C., approximately.

In using the above table to find the value of \( E \) or \( dE/dt \) at any temperature or between any limits, denoting by \( b \) the value of \( dE/dt \) at 50° C., and by \( 2c \) the constant value of the second coefficient, we have the following equations:

\[
\frac{dE}{dt} = \frac{b}{2t} - 2c(t - 50), \quad \text{at any temperature } t, \quad \text{Cent.} \quad \ldots \quad (3)
\]

\[
E(\infty) = \left(\frac{b}{2t} + 2c(1 + t - 100)\right) \quad \ldots \quad (4)
\]

for the E.M.F. between any temperature \( t \) and \( t' \).

7. Methods of Observation.—In Tait's observations the E.M.F. was measured by the deflection of a mirror galvanometer, and the temperature by means of a mercury thermometer or an auxiliary thermocouple. He states that the deviations from the formula were "quite within the limits of error introduced by the alternation of the resistance of the circuit with rise of temperature, the deviations of the mercury thermometers from the absolute scale, and the error of estimation of the temperature which gives the long column of mercury not immersed in the hot oil round the junctions." The latter correction may amount to about 10° C. at 350°. Later observers have generally employed a balance method (some modification of the method of Dr. Poggendorff) for measuring the E.M.F. The range of Steele's observations was too small to show any certain deviation from the formula, but he notes capricious changes attributed to change of condition of the wires. Noll employed mercury thermometers, but as he worked over a small range with vapour baths, it is probable that he did not experience any trouble from immersion corrections. He does not record any systematic deviations from the formula. Dewar and Fleming, working at very low temperatures, were compelled to use the platinum thermometer, and expressed their results in terms of the platinum scale. Their observations were probably free from immersion errors, but they record some deviations from the formula which they consider to be beyond the possible limits of error of their work. The writer has reduced their results to the scale of the gas thermometer, assuming the boiling-point of oxygen to be -182.5° C.

**Peltier Effect.**—The discovery by J. C. A. Peltier (1834) that heat is absorbed at the junction of two metals by passing a current through it in the same direction as the current produced by heating it, was recognized by Joule as a clue to the source of the energy of the current by the application of the principles of thermodynamics. Unlike the frictional generation of heat due to the resistance of the conductor, which Joule (1841) proved to be proportional to the square of the current, the Peltier effect is reversible with the current, and being directly proportional to the first power of the current, changes sign when the current is reversed. The effect is most easily shown by connecting a voltaic cell to a thermopile for a short interval, then quickly (by means of a suitable key, such as a Poli commutator with the cross connectors removed) disconnecting the pile from the cell and connecting it to a galvanometer, which will indicate a current in the reverse direction through the pile, and approximately proportional to the original current in intensity, provided that the other conditions of the experiment are constant. It was by an experiment of this kind that Quinquis Lellus (1853) verified the proportionality of the heat absorbed or generated to the first power of the current. It had been observed by Peltier and A. E. Becquerel that the intensity of the effect depended on the thermoelectric power of the junction and was independent of its form or dimensions. The order of the metals in respect of the Peltier effect was found to be the same as the thermoelectric series. But on account of the difficulty of the measurements involved, the verification of the accurate relation between the Peltier effect and thermoelectric power was left to more recent times. If \( C \) is the intensity of the current through a simple thermocouple, the junctions of which are at temperatures \( t \) and \( t' \), a quantity of heat, \( P \times C \), is absorbed by the passage of the current per second at the hot junction, \( t \), and a quantity, \( P \times C \), is evolved at the cold junction, \( t' \). The coefficients, \( P \) and \( P' \), are called coefficients of the Peltier effect, and may be stated in calories or joules per ampere-second. The Peltier coefficient may also be expressed in volts or micro-volts, and may be regarded as the measure of an E.M.F. located...
THERMOELECTRICITY

at the junction, and transforming heat into electrical energy or vice versa. If $R$ is the whole resistance of the circuit, and $E$ the E.M.F. of the couple, and if the flow of the current does not produce any other thermal effects in the circuit besides the Joule and Peltier effects, we should find by applying the principle of the conservation of energy, i.e. by equating the balance of the heat absorbed by the Peltier effects to the heat generated in the circuit by the Joule effect,

$$(P-R)C = Q + R = EC,$$  
whence $E = P - R$ . . . (5)

If we might also regard the couple as a reversible thermodynamic engine for converting heat into work, we might neglect irreversible effects, such as conduction, which are independent of the current, we should expect to find the ratio of the heat absorbed at the hot junction to the heat evolved at the cold junction, namely, $(P - R)/T$, to be the same as the ratio $T'/T$ of the absolute temperatures of the junctions. This would lead to the conclusion given by R. J. E. Clausius (1853) that the Peltier effect varied directly as the absolute temperature, and that the E.M.F. of the couple should be directly proportional to the difference of temperature between the junctions.

10. Thomson Effect.—Thomson (Lord Kelvin) had already pointed out (Proc. R.S. Edin., 1851) that this conclusion was inconsistent with the known facts of thermoelectric inversion.

(1) The E.M.F. was not a linear function of the temperature difference.

(2) If the Peltier effect was proportional to the thermoelectric power and changed sign with it, as all experiments appeared to indicate, there would be no absorption of heat in the circuit due to the Peltier effect, and therefore no thermal source to account for the energy of the current, in the case in which the hot junction was at or above the neutral temperature. He therefore predicted that there must be a reversible absorption of heat in some other part of the circuit due to the flow of the current through the unequally heated conductors. He succeeded a few years afterwards in verifying this remarkable prediction by the experimental demonstration that a current of positive electricity flowing from hot to cold in iron produced an absorption of heat, as though a positive heat was being released from the metal iron. He also succeeded in showing that a current from hot to cold evolved heat in copper, but the effect was smaller and more difficult to observe than in iron.

The Thomson effect may be readily demonstrated as a lecture experiment by the following method (fig. 1). A piece of wire (No. 28) about 4 cm. long is soldered to one end A, and a thick wire (No. 12), and is heated 100° to 150° C. A steady current from a storage cell adjusted by a suitable rheostat. The experimental wire AB is connected in parallel with about 2 metres of thicker wire (No. 22), which is not appreciably heated. A low-resistance galvanometer is connected by a very fine wire (2 to 3 mils) to the centre C of the experimental wire AB, and also to the middle point D of the parallel wire so as to form a Wheatstone bridge. The balance is adjusted by shunting either AD or BD with a box, S, containing 20 to 100 ohms. All the wires in the quadrilateral must be of the same metal as AB, to avoid accidental thermoelectric effects which would obscure the result. When the current flows from A to B there will be heat absorbed in AC and evolved in CB by the Thomson effect, if the specific heat of electricity in AB is positive as in copper. When the current is reversed, the temperature of AC will be raised and that of CB lowered by the reversal of the effect. This will disturb the resistance balance by an amount which can be measured by the deflection of the galvanometer, or by the change of the Wheatstone bridge, to restore the balance. Owing to the small size of the experimental wire, the method is very quick and sensitive, and the apparatus can be set up in a few minutes when once the experimental quadrilaterals have been done.

11. Thomson's Theory.—Taking account of the Thomson effect, the thermodynamical theory of the couple was satisfactorily completed by Thomson (Trans. R. S. Edin., 1854). If the quantity of heat absorbed and converted into electrical energy, when unit quantity of electricity (one ampere-second) flows from cold to hot through a difference of temperature, $dt$, be represented by $sdt$, the coefficient $s$ is called the specific heat of the couple, and $sdt$ the coefficient of the Thomson effect. Like the Peltier coefficient, it may be measured in degrees or calories per ampere-second per degree, or more conveniently and simply in microvolts per degree.

Consider an elementary couple of two metals A and B for which $s$ has the values $s'$ and $s''$ respectively, with junctions at the temperature $T$ and $T + dT$ (absolute), at which the coefficients of the material are $P$ and $P + dP$. Equating the quantity of heat absorbed to the quantity of electrical energy generated, we have by the first law of thermodynamics the relation

$$dE/dT = dP/dT + (s' - s'').$$

If we apply the second law, regarding the couple as a reversible engine, and considering the irreversible, we obtain

$$(s' - s'')/T = -dP/dT dT/dT$$

Eliminating $(s' - s'')$ we find for the Peltier effect

$$P = -T dP/dT.$$  

Whence we obtain for the difference of the specific heats

$$(s' - s'') = -dP/dT = -T dP/dT.$$  

From these relations we observe that the Peltier effect $P$, and the difference of the Thomson effects $(s' - s'')$, for any two metals can be easily deduced from $dE/dT$ and $dP/dT$ respectively. The signs in the above equations are chosen on the assumption that positive electricity flows from cold to hot in the metal $s$. The signs of the Peltier and Thomson effects will be the same as the signs of the coefficients given in Table 1, if we suppose the metal $s''$ to be lead, and assume that the value of $s'$ may be taken as zero at all temperatures.

12. Experimental Verification of Thomson's Theory.—In order to justify the assumption involved in the application of the second law of thermodynamics to the theory of the thermocouple in the manner above specified, it would be necessary and sufficient, as Thomson pointed out (Phil. Mag. Oct. 1853), to make experiments to verify quantitatively the relation $P/T = dE/dT$ between the Peltier effect and the thermoelectric power. A qualitative relation was known at that time to exist, but no tests of sufficient accuracy had been made. The most accurate measurements of the heat absorption due to the Peltier effect at present available are probably those of H. M. Jahn (Wied. Ann., 34, 1858). He measured the specific resistances and coefficients of absorption in a Bunsen ice calorimeter, and observed the evolution of heat per hour with a current of about 1 ampere in either direction. The Peltier effect was only a small fraction of the total effect, but could be separated from the Joule effect owing to the reversal of the current. The values of $dE/dT$ for the same specimen of metal at $0^\circ$ C. were determined by experiments between $+20^\circ$ C. and $-20^\circ$ C. The results of his observations are contained in the following table, heat absorbed being reckoned positive as in Table II.

The agreement between the observed and calculated values in the last two columns is as good as can be expected considering the great difficulty of measuring such small quantities of heat. The analogous reversible heat effects which occur at the junction of a metal and an electrolyte were also investigated by Jahn, but he did not succeed in obtaining so complete an agreement with theory in this case."

Fig. 1.—Diagram of Apparatus for Demonstrating the Thomson Effect.
13. Tait's Hypothesis.—From general considerations concerning minimum dissipation of energy (Proc. R. S. Edin., 1867–68), Tait was led to the conclusion that "the thermal and electric conductivities of metals varied inversely as the absolute temperature, and that the specific heat of electricity was directly proportional to the same." Subsequent experiments led him to doubt this conclusion as regards conductivity, but his thermoelectric experiments (Proc. R. S. Edin., December 1879) appeared to be in good agreement with it. If we adopt this hypothesis, and substitute $s = 2\theta T$, where $c$ is a constant, in the fundamental equation (9), we obtain at once $dE/dT = 2(c'c'' - c'c)$, which is immediately integrable, and gives

$$dE/dT = b(2c(T-\theta) - (c'c' - c''c''))$$

(10)

$$E_{sw} = \frac{1}{2}(c''c' - c'c') (2\log(T-\theta) - (c''c' - c'c'))$$

(11)

where $\theta$ is the temperature of the neutral point at which $dE/dT = 0$. This is the equation to a parabola, and is equivalent to the empirical formula of Avenarius, with this difference, that in Tait's formula the constants have all a simple and direct interpretation in relation to the theory. Tait's theory and formula were subsequently assimilated by Avenarius (Pogg. Ann., 149, p. 372, 1879), and are now generally attributed to Avenarius in foreign periodicals.

In accordance with this hypothesis, the curves representing the variations of thermoelectric power, $dE/dT$, with temperature are straight lines, the slope of which for any couple is equal to the difference of the constants $2(c'c'' - c'c)$.) The diagram constructed by Tait on this principle is fully explained and illustrated in many text-books, and has been generally adopted as embodying in a simple form the fundamental phenomena of thermoelectricity.

14. Experimental Verification.—Tait's verification of this hypothesis consisted in showing that the experimental curves of E.M.F. were parabolas in most cases within the limits of error of his observations. He records, however, certain notable divergencies, particularly in the case of iron and nickel, and many others have since come to light from other observers. It should also be remarked that even if the curves were not parabolas, it would always be possible to draw parabolas to agree closely with the observations over a restricted range of temperature. When the question is tested more carefully, either by taking more accurate measurements of temperature, or by extending the observations over a wider range, it is found that there are systematic deviations from the parabolic form of curves, which cannot but be explained by errors of experiment. A more accurate verification of these relations, both at high and low extremes of temperature, has become possible of late years owing to the development of the thermoelectric phenomena and application of the platinum resistance thermometer. (See Thermometry.) The curves in fig. 2 illustrate the differences from the parabolic formula, measured in degrees of temperature, as observed by H. M. Tory (B.A. Report, 1887). The deviations for the copper-iron couple, and for the copper cast-iron couple over the range $0^\circ$ to $200^\circ$, appear to be of the order of $1^\circ C$, and were carefully verified by repeated and independent series of observations. The deviations of the platinum and platinum-rhodium 10 per cent.

**FIG. 2.—Temperature by Thermocouple. Difference from Tait's Formula.**

The effect was calculated by multiplying this difference of temperature by the thermal capacity of either calorimeter, and dividing by the curve of the number of seconds in twenty minutes, and so by twice the difference of temperature (about $20^\circ$) between the ends of the couple $a$ and $b$. The method appears to be open to the objection that the difference of temperature reached in so long an interval would be more or less independent of the thermal.
capacities of the calorimeters, and would also be difficult to measure accurately with a thermocouple under the conditions described. The general results of the work appeared to support Tait's hypothesis that the effect was proportional to the absolute temperature, but direct thermoelectric tests do not appear to have been made on the specimens employed, which would have afforded a valuable confirmation by the comparison of the values of $dE/dT$, as in Jahn's experiments.

17. King's Experiments.—The method employed by the writer, to which the allusion has already been made, consisted in observing the change of distribution of temperature in terms of the resistance along a wire heated by an electric current, when the heating current was reversed. It has been fully described by King (Proc. Amer. Acad., June 1898), who applied it most successfully to the case of copper. Although the effect in copper is so small, he succeeded in obtaining changes of temperature due to the Thomson effect of the order of 1° C., which could be measured with satisfaction, although not with accuracy. He also determined the effect on change of temperature distribution on the rate of generation of heat by the current; and on the external loss of heat by radiation, convection and conduction. It is necessary to take all these conditions carefully into account in calculating the balance due to the Thomson effect. According to King's experiments, the value of the effect

appears to diminish with rise of temperature to a slight extent in copper, but the diminution is so small that he does not regard it as established with certainty. The value found at a temperature of 150° C. was 2.5 microvolts per ampere-second per degree, or $2.5$ microvolts per degree in the case of copper, which agrees very fairly with the value deduced from thermoelectric tests. The value found by Batelli for iron was $-50$ microvolts per degree at 108° C., which appears too small in comparison. These measurements, though subject to some uncertainty on account of the great experimental difficulties, are a very valuable confirmation of the accuracy of Thomson's theory, because they show that the magnitude of the effect is of the required order, but they cannot be said to throw much light upon its cause. A comparison of the results of different observers would also suggest that the law of variation may be different in different metals, although the differences in the values of $dE/dT$ may be due in part to differences of purity or errors of observation. It would appear, for instance, according to the observations of Dewar and Fleming, that the value of $s$ for iron is positive below 150° C., at which point it vanishes. At ordinary temperatures the value is negative, increasing rapidly in the negative direction as the temperature rises. This might be appropriately represented, as already suggested, by a linear formula $s = b - cT$.

18. Potential Diagrams on the Contact Theory.—It is instructive to consider the distribution of potential in a thermoelectric circuit, and its relation to the resultant E.M.F. and to the seat of the E.M.F. In fig. 4, which is given as an illustration, the cold junctions are supposed to be at 0° C. and the hot junction at 108° C., and the variation in $dE/dT$ is taken for the E.M.F., and it is supposed that the coefficient of the Thomson effect is zero in lead, i.e. that there is no E.M.F. and that the potential is uniform throughout the length of the lead wire. Taking the lead-iron couple as an example, the value of $dE/dT$ at the hot junction 100° C. is 10 microvolts per degree, and the value of the Peltier coefficient $P = TdE/dT$ is $+3844$ microvolts. In other words, we may suppose that there is an E.M.F. of that magnitude situated at the junction which causes positive electricity to flow from the lead to the iron. If the circuit is open, as represented in the diagram, there is a resultant E.M.F. of $4000$ volts as soon as it has raised the potential of the iron 3844 microvolts above that of the lead. In the substance of the iron itself there is an E.M.F. due to the Thomson effect of about 10 microvolts per degree tending to drive positive electricity from the iron to the lead on account of the cold junction, and there is a sudden drop of potential due to the Peltier effect of 3844 microvolts. If the circuit is cut at this point, there remains a difference of potential $E = 1184$ microvolts, the resultant E.M.F. of the circuit, tending to drive positive electricity from the iron to the lead at the cold junction. If the circuit is closed, there will be a current $C = E/R$, where $R = R_1 + R_2$, the sum of the resistances of the lead and iron. The flow of the current will produce a fall of potential $E/R$ in the lead from cold to hot, and $E/R$ in the iron from hot to cold, but the potential difference due to the Peltier effect at either junction will not be affected. For simplicity in the diagram, the temperature gradient has been taken as uniform, and the specific heat $c$ constant, but the total P.D. would be the same whatever the gradient.

Similar diagrams are given in fig. 4 for cadmium in which both the specific heat and the Peltier effect are positive, and also for platinum and nickel in which both coefficients are negative. The metals are supposed to be all joined together at the hot junction, and the circuit cut in the lead near the cold junction. The diagram will serve for any selected couple, such as lead-copper, not restricted to combinations with lead. The following table shows the component parts of the E.M.F. in each case:

<table>
<thead>
<tr>

The components for any other combination of two are found by taking the algebraic difference of the values with respect to lead.

19. Relation to the Volta Effect.—It is now generally conceded that the relatively large differences of potential observable with an electrometer between metals on open circuit, as discovered by Volta, are due to the chemical affinities of the metals, and have no direct relation to thermoelectric phenomena or to the Peltier effect. The order of the metals in respect of the two effects is quite different. The potential difference, due to the Volta effect in air, has been shown by Thomson (Lord Kelvin) and his pupils to be of the same order of magnitude, if not absolutely the same, as that produced in a dilute electrolyte in which two metallically connected plates (e.g. zinc and copper) are immersed. (On this hypothesis, it may be explained by regarding the air as an electrolyte of infinite specific resistance.) It is also profoundly modified by the state of the exposed surfaces, a coating of oxide on the copper greatly increasing the effect, as it would in a voltaic cell. The Peltier effect and the thermo-E.M.F., on the other hand, do not depend on the state of the surfaces, but only on the state of the substance. An attempt has been made to explain the Volta effect as due to the affinity of the metals for each other, but that would not account for the variation of the effect with the state of the surface, except as affecting the actual surface of contact. It is equally evident that chemical affinity between the metals cannot be the explanation of the Peltier E.M.F. This would necessitate chemical action between the metals when current is passed through it, as in an electrolytic cell, whereas the action appears to be purely thermal, and leads to a consistent theory on that hypothesis. The chemical action between metals in the solid state must be infinitesimal, and could only suffice to produce small charges analogous to those of frictional electricity; it could not maintain a permanent difference of potential at a metallic junction through which a current was passing. Although it is possible that differences of potential larger than the Peltier effect might exist between two metals in contact on open circuit, it is certain that only the effective E.M.F. in practice is the
Peltier effect, and that the difference of potential in the substance of the metals when the circuit is complete cannot be greater than the coefficient $P$. The Peltier effect, it may be objected, measures that part only of the potential difference which depends upon temperature, and can therefore give no information about the absolute potential difference. But the reason for concluding that there is no other effective source of potential difference at the junction besides the Peltier effect, is simply that no other appreciable action takes place at the junction when a current passes except the Peltier generation or absorption of heat.

20. Convection Theory.—The idea of convection of heat by an electric current, and the phrase "specific heat of electricity" were introduced by Thomson as a convenient mode of expressing the phenomena of the Thomson effect. He did not intend to imply that electricity really possessed a positive or negative specific heat, but merely that a quantity of heat was absorbed in a metal when unit quantity of electricity flowed from cold to hot through a difference of temperature of $t^\circ$. The absorption of heat was considered as representing an equivalent conversion of heat energy into electrical energy in the element. The element might thus be regarded as the seat of an E.M.F. $dE=sdT$, where $dT$ is the difference of temperature between its ends. The potential diagrams already given have been drawn on this assumption, that the Thomson effect is not really due to convection of heat by the current, but is the measure of an E.M.F. located in the substance of the conductor. This view with regard to the seat of the E.M.F. has been generally taken by the majority of writers on the subject. It is not, however, necessarily implied in the reasoning or in the equations given by Thomson, which are not founded on any assumptions with regard to the seat of the E.M.F., but only on the balance of heat absorbed and evolved in all the different parts of the circuit. In fact, the equations themselves are open to an entirely different interpretation in this respect from that which is generally given.

Returning again to the equations already given in § 11 for an elementary thermocouple, we have the following equivalent expressions for the E.M.F. $dE$, namely,

$$dE=dp'(t'-t)dT=(P/T)dT=dpT=(p'-p)dT,$$

in which the coefficient, $P$, of the Peltier effect, and the thermoelectric power, $p$, of the couple, may be expressed in terms of the difference of the thermoelectric powers, $p'$ and $p''$, of the separate metals with respect to a neutral standard. So far as these equations are concerned, we might evidently regard the seat of the E.M.F. as located entirely in the conductors themselves, and not at all at the junctions, if $p' (or p''-p)$ is the difference of the E.M.F.s per degree in corresponding elements of the two metals. In this case, however, in order to account for the phenomenon of the Peltier effect at the junctions, it is necessary to suppose that there is a real convection of heat by an electric current, and that the coefficient $P$ or $pT$ is the difference of the quantities of heat carried by unit quantity of electricity in the two metals. On this hypothesis, if we confine our attention to one of the two metals, say $p''$, in which the current is supposed to flow from hot to cold, we observe that $p''dT$ expresses the quantity of heat converted into electrical energy per unit of electricity by an E.M.F. $p''$ per $t^\circ$ located in the element $dT$. It happens that the absolute magnitude of $p''$ cannot be experimentally determined, but this is immaterial, as we are only concerned with differences. The quantity of heat liberated by convection as the current flows from hot to cold is represented in the expression by $dP=d(dT)$. Since $dE=dpT+d{T}p''$, it is clear that the balance of heat liberated in the element is only $Tdp''=s'ddT$, namely, the Thomson effect, and is not the equivalent of the E.M.F. $p'ddT$, because on this theory the absorption of heat is masked by the convection. If $p$ is constant there is no Thomson effect, but it does not follow that there is no E.M.F. located in the element. The Peltier effect, on the other hand, may be ascribed entirely to convection. The quantity of heat $p'T$ is brought up to one side of the junction per unit of electricity, and the quantity of heat $p'T$ taken away on the other. The balance $(p'-p')T$ is evolved at the junction. If, therefore, we are prepared to admit that an electric current can carry heat, the existence of the Peltier effect is no proof that a corresponding E.M.F. is located at the junction, or, in other words, that the conversion of heat into electrical energy occurs at this point of the circuit, or is due to the contact of dissimilar metals. On the contact theory, as generally adopted, the E.M.F. is due entirely to change of substance $(dp'-Tdp)$; on the convection theory, it is due entirely to change of temperature $(dT)$. But the two expressions are equivalent, and give the same results.

21. Potential Diagrams on Convection Theory.—The difference between the two theories is most readily appreciated by drawing the potential diagrams corresponding to the supposed locations of the E.M.F. in each case. The contact theory has been already illustrated in fig. 4. Corresponding diagrams for the same metals on the convection theory are given in fig. 5. In this diagram the metals are supposed to be all joined together and to be at the same time potential at the cold junction at $0^\circ \text{C}$. The ordinate of the curve at any temperature is the difference of potential between any point in the metal and a point in lead at the same temperature. Since there is no contact E.M.F. on this theory, the ordinates also represent the E.M.F. of a thermocouple metal-lead, in which one junction is at $0^\circ \text{C}$ and the other at $t^\circ \text{C}$. For this reason the potential diagrams on the convection theory are more simple and useful than those on the contact theories. The curves of E.M.F. are in fact the most natural and most convenient method of recording the numerical data, more particularly in cases where they do not admit of being adequately represented by a formula. The line of lead is taken to be horizontal in the diagram, because the thermoelectric power, $p$, may be reckoned from any convenient zero. It is not intended to imply that there is no E.M.F. in the metal-lead with change of temperature, but that the value of $p$ in this metal is nearly constant as the Thomson effect is very small. It is very probable that the absolute values of $p$ in different metals are of the same sign and of the same order of magnitude, being large compared with the differences observed. It would be theoretically possible to measure the absolute value in some metal by observing with an electrometer the P.D. between parts of the same metal at different temperatures, but the differences would probably be of the order of only one-hundredth of a volt for a difference of $100^\circ \text{C}$. It would be sufficiently difficult to detect so small a difference under the best conditions. The difficulty would be greatly increased, if not rendered practically insuperable, by the large differences of temperature.

22. Conduction Theory.—In Thomson's theory it is expressly assumed that the reversible thermal effects may be considered separately without reference to conduction. In the conduction theory of W. C. Kohlrausch (Pogg. Ann., 1875, vol. 156, p. 601), the fundamental postulate is that the thermo-E.M.F. is due to the conduction of heat in the metal, which is contrary to Thomson's theory. It is assumed that a flow of heat takes place; but it tends to carry with it a proportional electric current $C=0$. This is interpreted to mean that there is an E.M.F. $dE=akr$ $dT$ $=skdT$, in each element, where $k$ is the thermal conductivity and...
The specific resistance. The "thermoelectric constant," \( \theta \), of Kohlrausch, is evidently the same as the thermoelectric power, \( \phi \), in Thomson's theory. In order to explain the Peltier effect, Kohlrausch has shown that an electric current, \( C \), carries a heat-flow, \( Q = \phi C \), with it, where \( A \) is a constant which can be made equal to unity by a proper choice of units. If \( A \) and \( \theta \) are constant, the Peltier effect at the hot and cold junctions are equal and opposite, and the combination of the two postulates leads to a complication. By the second postulate the flow of the current increases the heat-flow, and this by the first postulate the thermoelectric resistance, which therefore depends on the current. It is difficult to see how this complication can be avoided, unless the first postulate is abandoned, and the heat-flow due to conduction is assumed to be independent of the thermoelectric phenomena. By applying the first law of thermodynamics, Kohlrausch deduces that a quantity of heat, \( QdT \), is absorbed in the element \( dT \) second by the current \( C \). He wrongly identifies this with the Thomson effect, by omitting to allow for the heat carried. He does not make any application of the second law to the theory. If we apply Thomson's condition \( T = \frac{QdT}{\Delta T} = T \phi \), we have \( A = T \). If we also assume the ratio of the current to the heat-flow to be the same in both postulates, we have \( \frac{a}{10} = \theta \), whence \( \theta = \frac{1}{2} |T| \). This condition was applied in 1899 by C. H. J. Liebenow (Wied. Ann., 68, p. 316). It simplifies the theory, and gives a possible relation between the constants, but it does not appear to remove the complication above referred to, which seems to be inseparable from any conduction theory.

23. Thermoelectric Relations.—A number of suggestions have been made as to the possible relations between heat and electricity, and one of this by which an electric current might also be a carrier of heat. The simplest is probably that of W. E. Weber (Wied. Ann., 1875), who regarded electricity as consisting of atoms much smaller than those of matter, and supposed that heat was the kinetic energy of these electric atoms. If we suppose that an electric current in a metal is a flow of negative electric atoms in one direction, the positive electricity associated with the far heavier material atoms remaining practically stationary, and if the atomic heat of electricity is of the same order as that of an equivalent quantity of hydrogen or any other element, the heat carried per ampere-second at \( 0^\circ \)C, namely \( \rho \), would give the order of \( 100 \) or \( 1000 \) of the temperature in order to account for all the observed effects on the convection theory. Others have considered conduction in a metal to be analogous to electrolytic conduction, and the observed effects to be due to "migration of the ions." The majority of these theories are too vague to be profitably discussed in an article like the present, but there can be little doubt that the study of thermoelectricity affords one of the most promising roads to the discovery of the true relations between heat and electricity.

Alphabetical Index of Symbols.

- \( a, b, c = \) Numerical constants in formulae.
- \( C = \) Electric Current.
- \( E = \) E.M.F. = Electromotive Force.
- \( F = \) Force.
- \( G = \) Gravitational Acceleration.
- \( P = \) Coefficient of Peltier Effect.
- \( \phi = dE/dT = \) Thermoelectric Power.
- \( Q = \) Heat-flow due to Conduction.
- \( \theta = \) Electrical Resistance; \( r = \) Specific Resistance.
- \( t = \) Temperature, or Heat, or Coefficient of Thomson Effect.
- \( T = \) Temperature on the Centigrade Scale.
- \( f = \) Temperature on the Absolute Scale.

THERMOMETRY

The present article is to discuss the general principles on which the accurate measurement of temperature depends, and to describe the application of these principles to the construction and use of the most important types of thermometer. Special attention will be devoted to more recent advances in scientific methods of testing thermometers and to the application of electrical and optical methods to the difficult problem of measuring high temperatures. In the article PYROMETER an account will be found of some of the thermoscopic methods employed in the arts for determining high temperatures.

2. Zero: Fundamental Interval.—In all systems of measuring temperature it is necessary (1) to choose a zero or starting-point (from which to reckon), (2) to determine the size of the degree by subdividing the interval between two selected fixed points of the scale (called the "fundamental interval") into a given number of equal parts. The fundamental interval selected is that between the temperature of melting ice and the temperature of condensing steam, under standard atmospheric pressure. On the Centigrade system the fundamental interval is divided into 100 parts, and the melting-point of ice is taken as the zero of the scale. We shall denote temperature reckoned on this system by the letter \( T \), and by the letter \( t \) its value on the fundamental absolute scale of temperature; thus \( T = t + T_0 \). It is often convenient to reckon temperature, expressly excluding the melting-point of ice, but from a theoretical or absolute zero representing the lowest conceivable temperature. We shall denote temperature reckoned in this manner by the letter \( T \) or \( t \), or by affixing the letters \( Abs \). In practice, since the absolute zero is unattainable, the absolute temperature is deduced from the Centigrade temperature by adding a constant quantity, \( T_0 \), representing the interval between the absolute zero and the melting-point of ice; thus \( T = t + T_0 \).

3. Arbitrary Scales.—An arbitrary scale can be constructed by selecting any physical property of a substance which varies regularly with the temperature, such as the volume of a liquid, or the pressure or density of a gas, or the electrical resistance of a metal. Thus if \( V \) denote the volume of a given mass at the temperature \( t \), and if \( V_0, V_i \) represent the volumes of the same mass at the temperatures \( 0^\circ \) and \( 100^\circ \)C, the size of a degree \( C \) on the scale of this arbitrary thermometer is one hundredth part of the fundamental interval, namely \( V = V_0 = 100 \), and the temperature \( t \) at volume \( V \) is the number of these degrees contained in the expansion \( V - V_0 \) between \( 0^\circ \) and \( 1^\circ \)C. We thus arrive at the formula

\[
T = 100(V - V_0)/(V_i - V_0)
\]

which is the general expression for the temperature Centigrade on any such arbitrary scale, provided that we substitute for \( V \) the particular physical property selected as the basis of the scale. If we prefer to reckon temperature from an arbitrary zero defined by the vanishing of \( V \), which may conveniently be called the fundamental zero of the scale considered, we have, putting \( V = 0 \) in equation (1), the numerical values of the fundamental zero \( T_0 \), and of the temperature \( T \) reckoned from this zero.

\[
T_0 = 100 V_0 (V_i - V_0) = V_0
\]

(2)

It is frequently convenient to measure temperature in this manner when dealing with gases, or electrical resistance thermometers.

4. Absolute Scale.—It is necessary for theoretical purposes to reduce all experimental results as far as possible to the absolute scale, defined as explained in HEAT, § 21, on the basis of Carnot's principle, which is independent of the properties of any particular substance. Temperature on this scale measured from the absolute zero will be denoted by the letter \( \theta \). This scale can be most nearly realized in practice by observing the temperature \( T \) on the scale of a gas-thermometer, and making special experiments on the gas to determine how far its scale deviates from that of the thermodynamical engine. In the case of the gases hydrogen and helium, which can exist in the liquid state only at very low temperatures, the deviations from the absolute scale at ordinary temperatures are so small that
they cannot be certainly determined. Thermometers containing these gases are generally taken as the ultimate standards of reference in practical thermometry.

**MERCURIAL THERMOMETER**

5. The most familiar type of thermometer depends on the apparent expansion of a liquid hermetically sealed in a glass bulb attached to a graduated stem of fine bore. Of all liquid-in-glass thermometers those containing mercury are almost invariably selected for scientific purposes, although at first sight mercury would appear to be the least suitable liquid on account of its small coefficient of expansion. The smallness of the expansion necessitates an extremely fine bore for the stem, which introduces errors in consequence of the high surface tension of mercury. The considerable density of the liquid also tends to exaggerate the effects of change of position due to variation of the pressure exerted on the interior of the bulb by the liquid column. These errors are small and fairly regular, and can be corrected within certain limits. A much more serious source of trouble, especially at high temperatures, is the imperfect elasticity of the glass, which causes more or less irregular changes in the volume of the bulb. The effect of these changes on the readings of the thermometer is enhanced by the smallness of the expansion of mercury, and might be reduced by employing a more expansible liquid. It is more likely, however, that the defect will be remedied by the construction of thermometers of fused quartz, which is the most perfectly elastic solid hitherto discovered. For work at low temperatures the range of a mercury thermometer is limited by its freezing-point (−38°C).

These are the serious disadvantages attending the use of mercury, but in other respects it possesses so many advantages over alcohol or other substitutes, that it will in all probability continue to be used almost exclusively in thermometers of this type for scientific work. Among its chief advantages may be reckoned its high boiling-point (357°C), and the absence of evaporation from the top of the thread, which is so serious a source of error with the alcohol thermometer. With mercury the evaporation is almost inappreciable at 100°C, and can in all cases be avoided by exposing the upper parts of the emergent thread to the atmosphere. Although an evacuated mercury thermometer cannot be safely used at temperatures above 300°C, owing to the breaking up of the thread of liquid in the stem, it has been found possible, by filling the upper part of the stem with nitrogen or carbon dioxide under high pressure, to extend the range to 550°C. A more important advantage for accurate work is the fact that mercury does not wet glass, and avoids any possible errors due to adherent films of liquid on the walls of the tube. This greatly facilitates observations, and also renders it possible to calibrate the thermometer after construction, which cannot be satisfactorily accomplished with other liquids. The process of construction and calibration is further facilitated by the fact that mercury does not dissolve air to any appreciable extent. In consequence of the regularity of expansion of mercury at ordinary temperatures, the scale of the mercury thermometer agrees very closely with that of the gas thermometer. The liquid is very easily obtained in a high state of purity by distillation, and has practically no chemical action on glass. In this respect it is superior to the liquid alloy of potassium and sodium, which has been employed in some high-temperature thermometers, but which rapidly reduces to the state of a black deposit. The high conductivity and low specific heat of mercury as compared with most other liquids tend to render the thermometer quick and sensitive in action. Its opacity considerably facilitates accurate reading, and even the smallness of its expansion has one great countervailing advantage, in that the correction for stem-exposure is proportionately reduced. This correction, which (even in the case of mercury) may amount to as much as 40°C at 550°C, is far the most uncertain in its application, and is the most serious objection to the use of the liquid-in-glass thermometer at high temperatures.

6. **Construction**.—The construction of the most accurate type of mercury thermometer has undergone some changes of detail in recent years. The range of the most accurate standards is generally restricted to the fundamental interval. The length of a degree on the stem can be increased to any extent by enlarging the bulb or diminishing the bore of the stem, but it is found in practice that there is no advantage in making the scale more open than one centimetre to the degree C. In standard instruments, due to the number of divisions beyond ten or at most twenty to the degree, enlargement of the stem makes the instrument sluggish, and exaggerates the errors due to imperfect elasticity. Diminishing the bore of the tube increases the errors due to capillary friction. Even one centimetre to the degree is an impracticable scale for thermometers graduated continuously from 0°C to 100°C, owing to the excessive length of the stem. In order to secure so open a scale, it is necessary to limit the range to 35°C, or at most 50°C. The fixed points 0°C and 100°C may still be retained, for purposes of testing and re-use, in the device now commonly employed, of blowing auxiliary bulbs or ampoules on to the stem, the volume of which is carefully adjusted to correspond with the number of degrees that it is desired to suppress.

In the best instruments for work of precision the bulb is not blown on the capillary tube itself, but is formed of a separate piece of tube fused on the stem. It is possible in this manner to secure greater uniformity of strength and regularity of dimensions. The thickness of the glass is generally between half a millimetre and one millimetre. The advantage in point of cost is not gained by making the glass thin is more than counterbalanced by increased fragility and liability to distortion. The best form of bulb is cylindrical, of the same external diameter as the stem. The bore of the stem should also be cylindrical, and not oval or flattened, in order to diminish errors due to capillarity, and to secure the greatest possible uniformity of section. The glass should be clear, and not backed with opal, both to admit of reading from either side, and to minimize risk of bending or distortion. In the commoner sorts of thermometers, which are intended for rough purposes and to be read without the application of minute corrections, it is not unusual to divide the tube into divisions of equal volume by a preliminary calibration. In the more accurate instruments it is preferable to divide the tube into divisions of equal length, as this can be more accurately effected. The corrections to be applied to the readings to allow for inequalities of bore can be most satisfactorily determined in the case of mercury thermometers by calibrating the tube after the instrument is completed (see CALIBRATION). This correction is known as the “calibration correction.” Instead of being separately determined it may be included in the scale correction by comparison with a standard instrument, such as a platinum-resistance thermometer.

7. **Corrections**.—The corrections to be applied to the readings of a mercury thermometer, in addition to the calibration correction, may be summarized under the following heads: (i), Zero. (ii) Fundamental Interval. (iii) Internal and External Pressure. (iv) Stem Exposure. (v) Scale Correction, including Poggendorff’s correction.

(i) The changes of zero are of two kinds. (a) **Semical rise of zero** due to gradual recovery from changes or strain acquired by the bulb during the process of manufacture. This process may be hastened and subsequent changes practically eliminated by annealing the bulb after manufacture, and allowing it to cool slowly from a high temperature, after each exposure to a high temperature, followed by a slow recovery which may last for days or weeks. The best thermometers of this kind show a depression of zero amounting to about one-tenth of 1°C. (b) **Temperature displacement** of zero after each exposure to a high temperature, followed by a slow recovery which may last for days or weeks. The best thermometers of this kind show a depression of zero amounting to about one-tenth of 1°C.

FIG. 1.-HYSPOMETER.

steam point. If \( n \) be the interval in degrees of the scale between the zero observation and if \( h \) be the temperature of the steam, the fundamental interval for the thermometer is 100 \( n/h \), provided that \( h \) is nearly 100° C. Since all the readings of a thermometer have to be corrected for the error of the fundamental interval, by multiplying by \( h \) for the fundamental interval thus observed and multiplying by 100, it is a matter of some convenience in practice to have the instrument graduated so that the difference between the readings in ice and at 100° C. is very nearly 100° of the stem. The correction \( b \) then be expressed as a small percentage independently of the other corrections. The method of determining the fundamental interval above described applies to all kinds of thermometers except that it is not generally necessary to observe the zero after the steam temperature of the stem \( t \) should be expressed in the scale of the thermometer tested, if the scale differs appreciably from that of Regnault.

(III) Pressure Correction. The corrections for variations of internal and external pressure on the bulb are of some importance in absolute thermometry, but can be applied with considerable certainty at moderate temperatures. The correction for pressure is assumed to be proportional to the change of pressure, and to be independent of the temperature. It is generally determined by enclosing the thermometer to be tested in a vessel of water, and observing the change of reading on exhausting or readmitting the air. The correction is generally between one and two thousands of a degree per centimetre of mercury change of pressure. It is convenient to reduce the corrections to a pressure of 760 mm. of mercury. The correction for internal pressure is greater than that for external pressure by the difference between the steam pressure and the atmospheric pressure, and may be calculated from it by assuming this relation. If \( b_1 \), \( b_2 \) are the external and internal coefficients, expressed in degrees of temperature per centimetre of mercury, we have the relation

\[ b = b_1 - b_2 \times 0.00105 \text{, degrees per cm. of mercury} \]

(6)

The coefficient of internal pressure can also be determined by taking readings in the horizontal and vertical positions when the thermometer is at some steady temperature such as that of ice or steam. The reading of the thermometer is generally reduced to an external pressure of one standard atmosphere, and to an internal pressure corresponding to the bore of the bulb. It is possible to include the internal pressure correction in the scale correction, if the thermometer is always read in the vertical position. In addition to the variations of internal pressure due to the column of mercury in the stem, there are variations due to capillarity. The internal pressure is greater when the mercury is rising than when it is falling, and the reading is depressed to an extent dependent on the fineness of the bore and the thinness of the walls of the bulb. The capillary pressure does not depend only on the bore of the tube, but also apparently to an even greater extent on the state of the walls of the tube. The least trace of dirt on the bore of the mercury stops the expansion or contraction of the mercury and causes the bubble to have an appreciable size. It is seldom found that the mercury runs equally easily in all parts of the stem. These variations of capillary pressure are somewhat capricious, and set a limit to the degree of accuracy attainable with the mercury thermometer. A good thermometer is expressed as the difference of reading of a good thermometer between a rising and a falling meniscus may amount to five or ten thousandths of a degree. The difference may be reduced by continuous tapping, but it is generally best to take readings always on a rising column, especially as the variations in the angle of contact, and therefore in the capillary pressure, appear to be much smaller for the rising meniscus. In ordinary work the zero reading and the steam reading would both generally correspond to a falling meniscus; the former necessarily, the latter on account of the phenomenon of the temporary depression of zero, which causes the thermometer to read higher during the first moment the pressure in the stem is increased by the rise of the bulb has reached its limit. It is easy to secure a rising meniscus at the steam point by momentarily cooling the thermometer. At the zero point the meniscus generally begins to rise after five or ten minutes. The question, however, is not of much importance, as the error, if any, is regular, and the correction for capillarity is necessarily uncertain.

(IV) Stem-Exposure Correction. When the bulb of a mercury thermometer is immersed in water at a temperature \( t \), and a part of the column of mercury having a length of \( n \) degrees is exposed to a lower temperature \( s \), the reading of the thermometer will be

\[ T = T_s + n \frac{C_s}{C} \]

For the first few degrees, the correction \( T_s \) is given by the tables, and for higher temperatures it is

\[ T_s = T_s + n \frac{C_s}{C} \]

Approximate formula \( dh = 0.0067 \cdot (H - 760) - 0.00020 \cdot (H - 760)^2 \)

(5)

If the barometer has a brass scale correct at \( o \)° C., and \( H \) be the reading in millimetres, the correction for temperature is made approximately by subtracting 0.000163 \( H \) mm.

If \( L \) is the latitude and \( M \) the height of the station in metres above the sea-level, the correction is made by subtracting (0.0026 \( L \) + 0.000002) \( M \) H mm.

The zero of the thermometer is observed immediately after the

TABLE I.-Temperature of Steam at pressures from 790 to 710 mm.
THERMOMETRY

lower by a\(a x_{(L-H)}\) degrees (nearly) than it would have been if the whole of the mercury and stem had been at the temperature \(T\).

The factor \(a\) in this expression is the apparent coefficient of expansion of mercury in glass, and varies from -0.00150 to -0.00165 for different mercury glasses. It is customary to correct for this in order to have an absolute scale of temperature. It is usual to observe \(h\) by means of an auxiliary "stem-thermometer" with its bulb placed near the middle of the emergent column \(h\). Occasionally stem-thermometers with long thin bulbs are employed to avoid the reading of the large emergent column. Owing to conduction along the stem of the thermometer, and to heated vapours near the bath, the mean temperature determined by the thermometer is always less than the true mean temperature. Consequently, an arbitrary reduction is often made in the value taken for \(h\) or \(a\), but this cannot be regarded as satisfactory for work of precision. The only practical method of reducing the correction is to use the number of degrees \(h\) exposed, or, in other words, to work with thermometers of "limited range." Each of these thermometers must then be corrected by comparison with a standard thermometer free from stem-exposure correction, such as a platinum-resistance thermometer. To secure results of any value the correction must be determined at each point under the actual conditions of observation under which the thermometer is to be used. In work of the highest precision it is usual to calibrate the thermometer to cover a range of 300\(^\circ\), as this is the only method of securing an open scale and reasonable accuracy as regards stem-exposure.

To quote the opinion of C. E. Guillaume, one of the leading authorities on mercurial thermometers, "...the corrections are considerable and it cannot generally be determined with sufficient approximation for measurements of precision. The mercury thermometer should then be replaced by other instruments, among which those based on the third law of the electrical resistance of metals hold the first rank."

(V) Scale Correction.—The correction required to reduce the readings of the thermometer to the normal scale may appropriately be called the "scale correction." One of the chief advantages of the mercurial thermometer for scientific purposes is that its scale agrees very closely with the thermodynamical scale. The scale corrections of the standard French thermometers of verre dur have been very carefully determined over the range 0\(^\circ\) to 80\(^\circ\) C. by P. Chappuis using a constant-volume gas thermometer containing hydrogen (at an initial pressure of one metre of mercury at 0\(^\circ\) C) as the representative of the normal scale. His observations between 0\(^\circ\) and 80\(^\circ\) C are represented by the quartic equation

\[ \Delta t = \frac{f(100)}{(61.590 + 47351 \cdot t - 0.001157 \cdot t^2) 	imes 10^{-6}} \]

where \(\Delta t\) and \(t\) represent temperature on the scales of the hydrogen and mercury thermometers respectively. The verre dur mark of thermometers reads 0-1\(^\circ\) C. above the hydrogen thermometer at 40\(^\circ\) C. where the difference of the scales is a maximum. The scale corrections of the Jena-glass thermometers, deduced by comparison with the French verre dur, appear to be practically of the same magnitude, but these thermometers are of much smaller size than the former on either side of the mean. It may be questioned whether it is possible to construct mercury thermometers with scales agreeing more closely that this, owing to inevitable variations in the quality and composition of the glass. According to Guillaume the correction of a French cristal thermometer \(t_*\) differs from that of the standard verre dur thermometer \(t\) by \(0-25\) and 50\(^\circ\) C, according to the cubic formula

\[ \Delta t = \frac{f(100)}{(12.600 - 0.03101) 	imes 10^{-6}} \]

According to scale corrections published elsewhere in the writer in 1893-1894, the scale of an English flat-glass thermometer, compared with a platinum thermometer, does not differ from that of the constant-pressure air thermometer by more than one or two hundredths of a degree between 0\(^\circ\) and 100\(^\circ\) C. But for the comparison of the scales to be of any value, it would be necessary to study a large number of such thermometers. It is possible to obtain much more consistent results if the thermometers are not heated above 50\(^\circ\) C.

The comparisons of the verre dur thermometers with the normal scale at the International Bureau at Paris have not as yet extended beyond 150\(^\circ\) C. The most important observations on the mercury thermometer above these limits appear to be those of Regnault. The later observations of J. M. Crafts were confined to French thermometers of cristal dur (Comptes Rendus, 1882, 95, p. 863). He found the following deviations from the hydrogen scale

\[ L_{0-50} = 150^\circ \left[ 200^\circ - 230^\circ + 250^\circ - 300^\circ ight] + 25^\circ - 27^\circ \]

The correction changes sign at about 230\(^\circ\) C., owing to the rapid increase in the expansion of mercury. Between 0\(^\circ\) and 150\(^\circ\) C. it would appear that the empirical formula of expansion of glass increases more rapidly than that of mercury.

Poggendorff's Correction.—It should be observed that, since in the construction of a mercury thermometer the tube is divided or calibrated so as to read in divisions of equal volume when the whole of the tube is at one temperature, the degrees do not at any rate of matter of fact correspond to equal increments of the apparent expansion of mercury. The scale does not therefore agree in practice with the theoretical formula (1) for the scale of the expansion of mercury, since the expansion is measured in a tube which itself is expanding. A similar argument applies to the method of the weight thermometer, in which the overfill is measured by weight. Even if the expansion of mercury and glass were both uniform, as measured on the thermodynamical scale, the scale of the mercury thermometer, as ordinarily calibrated, would not agree with the thermodynamical scale. The difference can be easily calculated if the actual expansion of mercury and glass is known.

The correction is known as Poggendorff's, but is generally included in the scale correction, and is not applied separately. It has the effect of making the thermometer read higher at temperatures between 0\(^\circ\) and 100\(^\circ\) than it would if the divisions of the stem did not expand as the temperature rose. The amount of the correction for verre dur is given by Guillaume

\[ t = \frac{p - 0}{(43.920 + 0.02400) 	imes 10^{-6}} \]

The value of this correction is between -0.65 and -0.86 at 50\(^\circ\) C.

GAS THERMOMETRY

8. The deviations of the gas thermometer from the absolute scale are so small that this instrument is now universally regarded as the ultimate standard in thermometry. It had, in fact, already been adopted for this purpose by Regnault and others, on a priori considerations, before the absolute scale itself had been invented. Although the indications of a gas thermometer are not absolutely independent of the changes of volume of the envelope or bulb in which the gas is contained, the effect of any uncertainty in this respect is minimized by the relatively large expansibility of the gas. The capricious changes of volume of the bulb, which are so great a difficulty in mercurial thermometry, are twenty times less important in the case of the gas thermometer. As additional reasons for the choice we have the great simplicity of the laws of gases, and the approximate equality of expansion and close agreement of the thermometric scales of all gases, provided that they are above their critical temperatures. Subject to this condition, at moderate pressures and provided that they are not dissociated or decomposed, all gases satisfy approximately the laws of Boyle and Charles. These two laws are combined in the characteristic equation of the gaseous state, viz., \( p = R T \), in which \( p \) is the pressure and \( T \) the volume of unit mass of the gas in question, and \( R \) is a constant which varies inversely as the molecular weight of the gas, and is approximately equal to the difference of the specific heats.

9. Practical Conditions.—In practice it is not convenient to deal with unit mass, but with an arbitrary mass \( M \) occupying a fixed volume \( V \), so that the specific volume \( V/M \) is in fact necessary to measure the pressure \( p \) in terms of mercury columns and not in absolute units. The numerical value of the constant \( R \) is adjusted to suit these conditions, but is of no consequence in thermometry, as we are concerned with ratios and differences only. The equation may be written in the form \( T = pV/RM \), but in order to satisfy the essential condition that \( T \) shall be a definite function of the temperature in the case of a gas which does not satisfy Boyle's law exactly, it is necessary to limit
Thermometry

The application of the equation to special cases which lead to definite, but not necessarily identical, thermometric scales. There are three special cases of practical importance, corresponding to three essentially distinct experimental methods.

(i.) **Volumetric Method** (constant-pressure).—In this method, \( V \) is variable and \( p \) and \( M \) are constant. This method was employed by Gay-Lussac, and is typified in the ideal thermometer with reservoir of variable capacity designed by Lord Kelvin (Encyc. Brit., ed. ix., vol. xi. p. 575, fig. 10). It corresponds to the method ordinarily employed in the common liquid-in-glass thermometer, but is not satisfactory in practice, owing to the difficulty of making a bulb of variable and measurable volume the whole of which can be exposed to the temperature of the surrounding air. The mercury makes contact with another point fixed in the upper end of the barometer tube. The distance between the two contact-points, giving the pressure of the gas in the thermometer, is deduced from the reading of a vernier fixed relatively to the upper contact-point. This method of reading the pressure is probably more accurate than the method of the cathetometer, which is usually employed, but has the disadvantage of requiring a double adjustment.

(ii.) **Manometric Method** (constant-volume or density).—In this method \( p \) is variable and \( V \) and \( M \) are constant. Variations of temperature are observed and measured by observing the corresponding variations of pressure with a mercury manometer, keeping a constant mass, \( M \), of gas enclosed in a volume, \( V \), which is constant except for the unavoidable but small expansion of the material of which the bulb is made.

(iii.) **Gravimetric Method** (constant-pressure).—In this method \( M \) is variable and \( p \) and \( V \) are constant. This method is generally confounded with (i), under the name of the constant-pressure method, but it really corrects to the other method of the weight thermometer, or the "overflow" method, and is quite distinct from an experimental standpoint, although it leads to the same thermometric scale. In applying this method, the weight \( M \) of the vapour itself may be measured, as in Regnault’s mercury-vapour thermometer, or in Deville and Troost’s iodine-vapour thermometer. The best method of measuring the overflow is that of weighing mercury displaced by the gas. The mass of the overflow may also be estimated by observing its volume in a graduated tube, but this method is much less accurate.

In practice, in addition to the above, there are mixed methods in which both \( p \) and \( V \) or \( M \) are variable, such as those employed by Rudberg or Becquerel; but these are unsatisfactory for precision, as not leading to a sufficiently definite thermometric scale. There is also a variation of the constant-volume method (ii.), in which the pressure is measured by the volumetric compression of an equal mass of gas kept at a constant temperature, instead of by a manometer. This method is experimentally similar to (iii.), and gives the same equations, but a different thermometric scale from either (ii.) or (iii.). It will be considered with method (iii.), as the apparatus required is the same, and it is very closely allied to the instrument. We shall consider in detail methods (ii.) and (iii.) only, as they are the most important for accurate work.

10. **Construction of Apparatus.**—The manometric or constant-volume method was selected by Regnault as the standard, and has been most generally adopted since his time. His apparatus has not been modified except in points of detail. A description of his instrument will be found in most text-books on heat.

A simple and convenient form of the instrument for general use is Jolly’s (described in Poggendorff’s Joubelband, p. 82, 1874), and is represented in fig. 3. The two vertical tubes of the manometer are connected by an india-rubber tube properly strengthened by a cotton covering, and they can be made to slide vertically up and down a wooden pillar which supports them; they are provided with clamps for fixing them in any position and a tangent screw for fine adjustment. The connexion between the bulb and the manometer is made by means of a three-way tap. The scale of the instrument is engraved on the back of a strip of plane mirror before silvering, and the divisions are carried sufficiently far across the scale for the reflections of the two surfaces of the mercury to be seen. Each division may be accurately read and an accurate reading obtained without the necessity of using a cathetometer. In order to allow for the expansion of the glass of the reservoir a weight-thermometer bulb is supplied with the instrument, made from another kind of glass, and the relative expansion of the mercury and the glass can thus be determined by the observer himself. The volume of the air-bulb and that of the capillary tube and the small portion of the manometer tube above the small beak of glass, the point of which serves as the fiducial mark, are determined by the instru-

ment-makers. The improvements introduced by Chappuis, of the Bureau des Mètres, in the construction of the constant-volume hydrogen thermometer selected by the committee for the determination of the normal scale, are described in the textbooks (e.g. Watson’s Physics). The most important is the combination of the manometer with a small manometer tube and a single scale, thus reducing the number of readings required. By making the mercury in the branch of the manometer communicating with the bulb of the gas thermometer is adjusted in the usual manner up to a fixed contact-point, so as to reduced the contained gas to a constant volume. Simultaneously the barometer branch of the manometer is adjusted so that the mercury in the manometer makes contact with another point fixed in the upper end of the barometer tube. The distance between the two contact-points, giving the pressure of the gas in the thermometer, is deduced from the reading of a vernier fixed relatively to the upper contact-point. This method of reading the pressure is probably more accurate than the method of the cathetometer which is usually employed, but has the disadvantage of requiring a double adjustment.

11. **Pressure Correction.**—In the practical application of the manometric method there are certain corrections peculiar to the method, of which account must be taken in work of precision. The volume of the bulb is not accurately constant, but varies with change of pressure and temperature. The thermal expansion of the bulb is common to all methods, and will be considered in detail later. The pressure correction is small, and is determined in the same manner as for a mercury thermometer. The value so determined, however, does not apply strictly except at the temperature to which it refers. If the pressure-coefficient were constant at all temperatures and equal to \( e \), the pressure correction, \( dl \), at any point \( t \) of the scale would be obtainable from the simple formula

\[
\Delta t = (\rho_p - 100)/T_0
\]

where \( \rho_p \) is the initial pressure at the temperature \( T_0 \). But as the coefficient probably varies in an unknown manner, the correction is somewhat troublesome, especially at high temperatures. Another very necessary but comparatively small correction is the reduction of the manometer readings to allow for the varying temperatures of the mercury and scale. Since it is generally impracticable to immerse the manometer in a liquid bath to secure certainty and uniformity of temperature, the temperature must be estimated from the readings of mercury thermometers suspended in mercury tubes or in the air near the manometer. It is therefore necessary to work in a room specially designed to secure great constancy of temperature, and to screen the manometer with the utmost care from the source of heat in the instrument. Regnault considered that the limit of accuracy of correction was one-tenth of a millimetre of mercury, but it is probably possible to measure to one-hundredth as a mean of several readings under the best conditions, at ordinary temperatures.

12. **Steam-Exposure.**—In all gas thermometers it is necessary in practice that the part of the gas in contact with the mercury or other liquid in the manometer should not be heated, but kept at nearly constant temperature. The space above the mercury, together with the exposed portion of the capillary tube connecting the manometer with the thermometer bulb, may be called the "dead space." If the volume of the dead space is kept as nearly as possible constant by adjusting the mercury always up to a fixed mark, the quantity of air in this space varies nearly in direct proportion to the pressure, i.e. in proportion to the temperature of the thermometric bulb.
at constant volume. This necessitates the application of a stem-exposure correction, the value of which is approximately given by the formula
\[ dT = \frac{r}{100(T_0)} \]
where \( r \) is the ratio of the volume of the dead space to the volume of the thermometric bulb, and \( T_0 \) is the mean temperature of the dead space, which is supposed to be constant. The magnitude of the correction is proportional to the ratio \( r \), and increases very rapidly at high temperatures. If the dead space is 1 per cent. of the bulb, the correction will amount to only one-tenth of a degree at 50°C, but reaches 5° at 445°C, and 30° at 1000°C. Overflow of the mercury is prevented in the manometer by placing a liquid which wets the tube, as shown in fig. 4, by placing side by side with the tube AB, containing the bulb B to the manometer A, an exact duplicate CD, closed at the end D, and containing liquid in the limb C, which is of the same size as the branch A of the manometer and in direct communication with it. The tube CD, which is called the compensating tube, contains a constant mass of gas under exactly similar conditions of volume and temperature to the tube AB. If therefore the volume of the liquid is always adjusted to be the same in both tubes AB and CD, the mass of gas contained in the tube CD will also be constant, and is automatically eliminated from the equation, as they contain differences only.

14. **Gravimetric Method.**—In the writer's opinion, the gravimetric or overflow method, although it has seldom been adopted, and is not generally regarded as the most accurate, is much to be preferred to the manometric method, especially for work at high temperatures. It is free from the uncertain corrections above enumerated as being peculiar to the manometric method. The apparatus is much simpler to manipulate and less costly to construct. If the pressure is kept constant and equal to the external atmospheric pressure, there is no strain of the bulb, which is particularly important at high temperatures. There is no dead space correction so long as the temperature of the dead space is kept constant. The troublesome operation of reading and adjusting the mercury columns of the manometer is replaced by the simpler and more accurate operation of weighing the mercury displaced, which can be performed at leisure. The uncertain correction for the temperature of the mercury in the manometer is entirely avoided.

The objections which led Regnault to prefer the constant-volume thermometer are frequently quoted, and are generally accepted as entirely conclusive, but it is very easy to construct the constant-pressure or gravimetric instrument in such a manner as to escape the objections which he urges against it. Briefly stated, his objections are as follows: (1) Any error in the observation of the temperature of the gas in the overflow space produces a considerable error in the temperature deduced, when the volume of the overflow is large. This source of error is very simply avoided by keeping the whole of the overflow in melting ice, an expedient which also considerably simplifies the equations. It happened that Regnault's form of thermometer could not be treated in this manner, because he had to observe the level of the mercury in order to measure the pressure and the volume. It is much better, however, to use a separate gauge, containing oil or sulphuric acid, for observing small changes of pressure. The use of ice also eliminates the correction for the variation of density of the mercury by which the overflow is measured. (2) Regnault's second objection was that an error in the reading of the pressure, or in reading the thermometer, was more serious at high temperatures in the case of the constant-pressure thermometer than in the constant-volume method. Owing to the incessant variations in the pressure of the atmosphere, and in the temperature of the mercury columns, he did not feel able to rely on the pressure readings (depending on observations of four mercury surfaces with the cathetometer) to less than a tenth of a millimetre of mercury, which experience showed to be about the limit of accuracy of his observations. This would be equivalent to an error of 0.036° in the constant-volume thermometer at any point on the scale, but with the constant-pressure thermometer the error would be largely greater. (3) The mercury absorbs heat, and the temperature of the mass of mercury in the manometer tube is not the same as that of the free mercury, which experiences a change of temperature. For instance, when the pressure is increased by an amount sufficient to cause the mercury to rise 1 cm in the manometer, the manometer tube walls are raised several centimetres, and the temperature of the mercury in the manometer tube is consequently less than that of the free mercury, since the free mercury is prevented from descending to this lower temperature by the manometer tube walls. This objection is really unsound, because the ideal condition to be aimed at is to keep the **proportional error** of the thermometer. That the proportional error diminishes with rise of temperature, in the case of the constant-volume thermometer, is really of no advantage, because we can never hope to be able to measure high temperatures with greater proportionate accuracy than ordinary temperatures. The great increase of pressure at high temperatures in the manometric method is really a serious objection, because it becomes necessary to work with much lower initial pressures, which implies an inaccuracy of a constant at ordinary temperatures, and in the determination of the initial pressure and the fundamental interval.

15. **Compensated Differential Gas Thermometer.**—The chief advantage of the gravimetric method, which Regnault and others appear to have missed, is that it is possible to make the measurements altogether independent of the atmospheric pressure and of the observation of mercury columns. This is accomplished by using, as a standard of constant pressure, a bulb S, fig. 5, containing a constant mass of gas in melting ice, side by side with the bulb M, in which the volumes of the overflow are measured. The pressure in the thermometric bulb T is adjusted to equality with the standard by means of a delicate oil-gauge G of small bore, in which the difference of pressure is observed by means of a cathetometer microscope. This kind of gauge permits the rapid observation of small changes of pressure, and is far more accurate and delicate than the mercury manometer. The fundamental measurement of the volume of the overflow in terms of the weight of mercury displaced at 0°C involves a single weighing made at leisure, and requires no temperature correction. The accuracy obtainable at ordinary temperatures in this measurement is about ten times as great as that attainable under the best conditions with the mercury manometer. At higher temperatures the relative accuracy diminishes in proportion to the absolute temperature, or the error of determination increases according to the formula
\[ \frac{dT}{T} = \frac{w}{w_T} \]
where \( w \) is the weight of the overflow and \( dw \) the error. This diminution of the sensitiveness of the method at high temperatures is commonly urged as a serious objection to the method, but the objection is really without weight in practice, as the possible accuracy of measurement is limited by other conditions. So far as the weighing alone is concerned, the method is sensitive to one-hundredth of a degree at 100°C, which is far beyond the order of accuracy attainable in the application of the other corrections.

16. **Method of Using the Instrument.**—A form of gas thermometer constructed on the principles above laid down, with the
addition of a duplicate set of connecting tubes C for the elimination of the stem-expansion correction by the method of automatic compensation already explained, is shown in fig. 5 (Proc. R. S. vol. 59, p. 243; Preston’s Heat, p. 133).

In setting up the instrument, after cleaning, and drying and calibrating the bulbs and connecting tubes, the masses of gas on the two sides are adjusted as nearly as possible to equality, in order that any changes of temperature in the two sets of connecting tubes may compensate each other. This is effected with all the bulbs in melting ice, by adjusting the quantities of mercury in the bulbs M and S and equalizing the pressures. The bulb T is then heated in steam to determine the fundamental interval. A weight \( w \) of mercury is removed from the overflow bulb M in order to equalize the pressures again. If \( W \) is the weight of the mercury at \( 0^\circ \) C. which would be required to fill the bulb T at \( 0^\circ \) C., and if \( W-W_i \) is the weight of mercury at \( 0^\circ \) C. which would be required to fill a volume equal to that of the bulb in steam at \( t_i \), we have the following equation for determining the coefficient of expansion \( a \), or the fundamental zero \( T_a \):

\[
d_i = \frac{W}{T_a} = \frac{(w_i + dW_i)(W - w_i)}{T_i}.
\]

Similarly if \( w \) is the overflow when the bulb is at any other temperature \( t \), and the expansion of the bulb is \( dW \), we have a precisely similar equation for determining \( t \) in terms of \( T_a \), but with \( t_i \) and \( w_i \) and \( dW \) substituted for \( t_i \) and \( w_i \) and \( dW_i \). In practice, if the pressures are not adjusted to exact equality, or if the volumes of the connecting tubes do not exactly compensate, it is only necessary to include in \( w \) a small correction \( dw \), equivalent to the observed difference, which need never exceed one part in ten thousand.

It is possible to employ the same apparatus at constant volume as well as at constant pressure, but the manipulation is not quite so simple, in consequence of the change of pressure. Instead of removing mercury from the overflow bulb M in connexion with the thermometric bulb, mercury is introduced from a higher level into the standard bulb S so as to raise its pressure to equality with that of T at constant volume. The equations of the method are precisely the same as those already given, except that \( w \) now signifies the “inflow” weight introduced into the bulb S, instead of the overflow weight from M. It is necessary, however, to take account of the pressure-coefficient of the bulb T, and it is much more important to have the masses of gas on the two sides of the apparatus equal than in the other case. The thermometric scale obtained in this method differs slightly from the scale of the manometric method, on account of the deviation of the gas compressed at \( 0^\circ \) C. from Boyle’s law, but it is easy to take account of this with certainty.

A correction to which the same apparatus may be put is the accurate comparison of the scales of two different gases at constant volume by a differential method. It is usual to effect this comparison indirectly, by comparing the gas thermometers separately with a mercury thermometer, or other secondary standard. It is done by using a pair of bulbs like M and S simultaneously in the same bath, and measuring the small difference of pressure with an oil gauge, a higher order of accuracy may be attained in the measurement of the small differences than by the method of indirect comparison. For instance, in the curves representing the difference between the nitrogen and hydrogen scales (fig. 1), as found by Chappuis by comparison of the nitrogen and hydrogen thermometers with the mercury thermometer, it is probable that the contrary flexure of the curve between 70° and 100° C. is due to a minute error of observation, which is quite as likely to be caused by the increasing aberrations of the mercury thermometer. These temperatures as by the difficulties of the manometric method. It may be taken as an axiom in all such cases that it is better to make use of a very small difference to deduce it from the much more laborious observations of the separate magnitudes concerned.

17. Expansion Correction.—In the use of the mercury thermometer we are content to overlook the modification of the scale due to the expansion of the envelope, which is known as Poggendorff’s correction, or rather to include it in the scale correction. In the case of the gas thermometer it is necessary to determine the expansion correction separately, as our object is to arrive at the closest approximation possible to the absolute scale. It is a common mistake to imagine that if the rate of expansion of the bulb were uniform, the scale of the apparent expansion of the gas would be the same as the scale of the real expansion—in other words, that the correction for the expansion of the bulb would affect the value of the coefficient of expansion \( t/T_a \) only, and would be without effect on the value of the temperature \( t \) deduced. A result of this kind would be produced by a constant error in the initial pressure on the manometric method, or by a constant error in the initial volume on the volumetric method, or by a constant error in the fundamental interval on any method, but not by a constant error in the coefficient of expansion of the bulb, which would produce a modification of the scale exactly analogous to Poggendorff’s correction. The correction to be applied to the value of \( t \) in any case to allow for any systematic error or variation in the data is easily found by differentiating the formula for t with respect to the variable considered. Another method, which is in some respects more instructive, is the following:

Let \( T \) be the function of the temperature which is taken as the basis of the scale considered, then we have the value of \( t \) given by the general formula (1), already quoted in § 3. Let \( dT \) be the correction to be added to the observed value of \( T \) to allow for any systematic change or error in the measurement of any of the data on which the value of \( T \) depends, and let \( dt \) be the corresponding correction produced in the value of \( t \), substituting in formula (1) we have:

\[
dt = 100(T - T_a + dT - dT_a)(T_i - T_a + dT - dT_i)/100.
\]

It is frequently simpler to express the correction in this manner, rather than by differentiating the general formula.

In the special case of the gas thermometer the value of \( T \) is given by the formula

\[
T = \frac{pV}{RM} = \frac{pV}{(M_2 - M_3)},
\]

where \( p \) is the observed pressure at any temperature \( T \), \( V \) the volume of the thermometric bulb, and \( M \) the mass of gas remaining in the bulb. The quantity \( M \) cannot be directly observed, but is deduced by subtracting from the whole mass of gas \( M_3 \) contained in the apparatus the mass \( M_2 \) which is contained in the dead space and overflow bulb. In applying these formulae to deduce the effect of the expansion of the bulb, we observe that if \( dV \) is the expansion from \( 0^\circ \) C. and \( V_0 \) the volume at \( 0^\circ \) C., we may write

\[
V = V_0 + dV, \quad T = \frac{p(V + dV)/R}{M} = \frac{(pV_0/R)(1 + dV/V_0)}{M},
\]

whence we obtain approximately

\[
dT = TdV/V_0.
\]

If the coefficient of expansion of the bulb is constant and equal to the fundamental coefficient \( f \) (the mean coefficient between \( 0^\circ \) and \( 100^\circ \) C.), we may write \( dV/V_0 = f; \) and if we substitute this value in the general expression (14) for \( dt \) we obtain

\[
dt = dT(T - T_0) = f(T - 100).
\]

Provided that the correction can be expressed as a rational integral function of \( t \), it is evident that it must contain the factors \( t \) and \( (t - 100) \), since by hypothesis the scale must be correct at the fixed points \( 0^\circ \) and \( 100^\circ \) C., and the correction must vanish at these points. It is clear from the above that the scale of the gas thermometer is not independent of the expansion of the bulb even in the simple case where the coefficient is constant. The correction is by no means unimportant. In the case of an average glass or
platinum reservoir, for which \( f \) may be taken as 0-000025 nearly, the correction amounts to 0-00625 at 50° C, to 3-833 at 445° C, and to 82-8 at 828° C.

The value of the fundamental coefficient \( f \) can be determined with much greater accuracy than the coefficient over any other range of temperature. The most satisfactory method is to use the bulb of the thermometer as a primary standard and deduce from the expansion of the glass the absolute expansion of mercury as determined by Regnault. Unfortunately the reductions of Regnault have been attacked and the results differ by much as 0-00018153 from 0-000182010 Broch, to 0-00018253 Wüller. The extreme departure represents an uncertainty of 0-00000037, and it is probable that the uncertainties involved in this assumption are greater in the case of glass or porcelain bulbs, on account of the difficulty of perfect annealing, than in the case of metallic bulbs.

Except for small ranges of temperature, the assumption of a constant coefficient of expansion is not sufficiently exact. It is therefore usual to assume that the coefficient is a linear function of the temperature, the equation being expressed in the form \( \frac{dV}{V} = (a + b)T \), where \( a \) is the coefficient of expansion at zero, and \( b \) the correction, which in general will not exceed 0-0015. The uncertainty is of the same order as the uncertainty of the absolute expansion of the bulb, as mentioned above.

It will be observed that the term involving \( b \) becomes of considerable importance at high temperatures. Unfortunately, it cannot be determined with the same accuracy as \( f \), because the conditions of observation at the fixed points are much more perfect than at other temperatures. Provided that the scale of the observations is such that the range of the observations for the determination of the expansi on is co-extensive with the range of the temperature measurements for which the correction is required, the assumption will not greatly exceed 0-00018153 from 0-000182010 Broch, to 0-00018253 Wüller. The extreme departure represents an uncertainty of 0-00000037, and it is probable that the uncertainties involved in this assumption are greater in the case of glass or porcelain bulbs, on account of the difficulty of perfect annealing, than in the case of metallic bulbs.

Values of the Corrections.— If we take for the gas hydrogen the values 2 c = 1.5 c.c. at 0° C., b = 0.5 c.c., with the index n = 1.5, which was determined by Joule and Thomson, and for helium the values \( a = 3.03 \times 10^{-5} \) and \( b = 0.08 \) c.c., with the index \( n = 1 \), which was determined by others, we obtain for the absolute zero the correction \( \theta_0 - T_0 \) in this case amounting to nearly 1°. The agreement is very good considering the difficulty of determining the small deviations \( c = d = e = f = g = h = i = j = k = l = m = n = o = p = q = r = s = t = u = v = w = x = y = z = 0 \) of the perfect gas law. The experimental values agree with the calculated ones to within the limits of experimental error. The value of the index \( n = 1.5 \) has been taken as the best one for diatomic gases, but this does not satisfy either the observations on the cooling effect or those on the compressibility so well as \( n = 1 \), although it makes comparatively little difference to the value of the absolute zero. The value deduced from Travers’s observation of the pressure-coefficient of helium is 273.13, taking \( n = 1.5 \), which is the probable value of the index for a monatomic gas. The application of the method to the condensible gas carbonic acid is interesting as a test of the method (although the gas itself is not suited for thermometry), because its deviations from the ideal state are large and have been carefully studied. The observations of Joule and Thomson on the cooling effect give \( c = 3.76 \) c.c., \( b = 0.08 \) c.c., \( n = 2 \), provided that allowance is made for the variation of the specific heat with temperature as determined by Berthelot. These values of the index \( n \) are very close, and the correction \( \theta_0 - T_0 \) for the absolute zero, the values of the corrections \( \theta_0 - T_0 \) being 4.6° and 5.8° respectively.

The values of the scale correction \( dt \) deduced from these formulae agree with those experimentally determined by Chappuis in the case of carbonic acid within the limits of agreement of the observations themselves. The calculated values for nitrogen and hydrogen give rather smaller differences than those found experimentally, but the differences themselves are of the same order as the experimental errors. The deviations of hydrogen and helium from the absolute scale are large and have been carefully studied. The observations of Joule and Thomson on the cooling effect give \( c = 3.76 \) c.c., \( b = 0.08 \) c.c., \( n = 2 \), provided that allowance is made for the variation of the specific heat with temperature as determined by the specific heat of nitrogen. These values of the index \( n \) are very close, and the correction \( \theta_0 - T_0 \) for the absolute zero, the values of the corrections \( \theta_0 - T_0 \) being 4.6° and 5.8° respectively.

The values of the scale correction \( dt \) deduced from these formulae agree with those experimentally determined by Chappuis in the case of carbonic acid within the limits of agreement of the observations themselves. The calculated values for nitrogen and hydrogen give rather smaller differences than those found experimentally, but the differences themselves are of the same order as the experimental errors. These values of the index \( n \) are very close, and the correction \( \theta_0 - T_0 \) for the absolute zero, the values of the corrections \( \theta_0 - T_0 \) being 4.6° and 5.8° respectively.

19. Limitations.— In the application of the gas thermometer to the measurement of high temperatures certain difficulties are encountered which materially limit the range of measurement and the degree of accuracy attainable. The principal objections are due to the following causes: (a) the changes in the volume of the bulb; (b) leakage, occlusion and porosity; (c) chemical change and dissociation. The difficulties arise partly from defects in the materials available for the bulb, and partly from the small mass of gas enclosed. The troubles due to irregular changes of volume of glass bulbs, which affect the mercury thermometer at ordinary temperatures, become so exaggerated at higher points of the scale as to be a serious source of trouble in gas thermometry in spite of the twentyfold larger expansion. For instance, the volume of a glass bulb will be diminished by one-quarter to one-half of 1 per cent. The first time it is heated to the boiling temperature of boiling sulphur (445° C.). This would not matter so much if the volume then remained constant. Unfortunately, the volume continues to change, especially in the case of hard glass, each time it is heated, by amounts which cannot be predicted, and which are too large to neglect. The most accurate method of taking account of these variations in a series of observations, without recalibrating and refilling and cleaning the bulb, is to assume the known constant value of the coefficient of expansion of the gas, and to calculate the volume of the bulb at any time by taking observations in ice and steam (Phil. Trans. A, 1891, p. 124, p. 125). These changes take place with porcelan at higher temperatures.

Metallic bulbs are far more perfect than glass bulbs in this respect. It is probable that silica bulbs would be the most perfect. The writer suggested the use of this material (in the Journ. Iron and Steel Inst. for 1892), but failed to construct bulbs of sufficient size. W. A. Shenstone, however, subsequently succeeded, and there seems to be a good prospect that this difficulty will soon be minimized. The difficulties of leakage and porosity occur chiefly with porcelain bulbs, especially if they are not perfectly glazed inside. A similar difficulty occurs with metallic bulbs of platinum or platinum-iridium, in the case of hydrogen, which passes freely through the metal by occlusion at high temperatures. The difficulty can be avoided by substituting either nitrogen or preferably argon or helium as the thermometric material at high temperatures. With many kinds of glass and porcelain the chemical action of hydrogen begins to be appreciable at temperatures as low as 200° or 300° C. In any case, if metallic bulbs are used, it is absolutely necessary to protect them from furnace gases which may contain hydrogen. This can be effected either by enclosing the bulb in a tube of porcelain, or by using some method of electrical heating which cannot give rise to the presence of hydrogen. At very high temperatures it is probable that the dissociation of diatomic gases like nitrogen might begin to be appreciable before the limit of resistance of the bulb itself was reached. It would probably be better, for this reason, to use the monatomic and extremely inert gases argon or helium.

20. Other Methods.— Many attempts have been made to overcome the difficulties of gas pyrometry by adopting other methods of measurement. Among the most interesting may be mentioned: (i) The variation in the wave-length of sound. The objection to this method is the difficulty of accurately observing the wave-length, and of correcting for the expansion of the material of the tubes in which it is measured. There is the further objection that the velocity varies as the square root of the absolute temperature. (ii) A similar method, but more promising, is the variation of the refractivity of a gas, which can be measured with great accuracy by an interference method. Here again there is difficulty in determining the exact length of the heated column of gas, and in maintaining the temperature uniform throughout a long column at high temperatures. These difficulties have been ingeniously met by D. Berthelot (Comptes Rendus, 1895, 120, p. 831). But the method is not easy to apply, and the degree of accuracy attainable is probably inferior to the bulb methods. (iii) Methods depending on the diffusion and transpiration of gases through fine orifices and tubes have been put in practice by Barus and by the writer. The method of transpiration, when the resistance of the tube through which the current of gas is passed is measured on the Wilson thermometer (Science, p. 219 of March 1890), is extremely delicate, and the apparatus may be made very small and sensitive, but the method cannot be used for extrapolation at high temperatures until the law of increase of resistance has been determined with certainty. This may be successfully accomplished in the near future, but the law is apparently not so simple as is usually supposed.

On account of these and similar difficulties, the limit of gas thermometry at the present time must be placed at 1500° C., or even lower, and the accuracy with which temperatures near 1000° C. are known does not probably exceed 2° C. Although measurements can be made with greater consistency of this by means of electrical pyrometers, the absolute values corresponding to those temperatures must remain uncertain to this extent, inasmuch as they depend on observations made with the gas thermometer.

Electrical Thermometry

21. The convenience of the mercurial thermometer lies in the fact that it is complete in itself, and can be read without subsidiary appliances beyond a magnifying glass. Its weakness lies in the very limited range of each single instrument, and in the troublesome and often uncertain corrections which must be applied to its readings in all work of precision. Electrical
thermometers have the disadvantage of requiring auxiliary apparatus, such as galvanometers and resistances, the use of which involves some electrical training. But they far surpass the mercurial thermometer in point of range, delicacy and adaptability, and can be applied to many investigations in which ordinary thermometers are quite useless.

There are two kinds of electrical thermometers, which depend on different sensitivities by setting the physical properties of metals: (1) The Thermocouple, or Thermopile, which depends on the production of a thermoelectric force when the junctions of different metals in an electric circuit are at different temperatures; and (2) the Electrical Resistance Thermometer, the action of which depends on the fact that the resistance of a pure metal to the passage of an electric current increases very considerably when the temperature is raised. The theory of the thermocouple is discussed in the article THERMOELECTRICITY, as it possesses many points of interest, and has been studied by many skilful experimentalists. The electrical resistance thermometer is of more recent origin; but although the theory has been less fully developed, the practice of the method bids fair to surpass all others in the variety and accuracy of its applications.

In order to secure the widest possible range and the greatest constancy, in either variety of electrical thermometer, advantage is taken of the great stability and insusceptibility characteristic of the metals of the platinum group. Other metals are occasionally used in work at low temperatures with thermocouples for the sake of obtaining a larger electromotive force, but different sensitivities are attended by considerable uncertainty of reduction, unless the range is greatly restricted.

22. Applications of the Thermocouple.—The principal uses of the thermocouple in thermometry are for measuring high temperatures, and for measuring small differences of temperature, more particularly when the temperature is required to be measured at a point, or in a very small space. The electromotive force of the couple depends only on the temperature at the plane of junction of the two metals, which can be very exactly located. A typical instance of a measurement to which the thermocouple is peculiarly suited, is the determination of the cyclical variations of temperature at accurately measured depths from one-tenth to one-hundredth of an inch in the metal of the cylinder of a heat engine, the interior surface of which is exposed to cyclical variations of temperature in the working of the engine.\textsuperscript{1} The exact depth of the plane of junction can be measured without difficulty to the thousandth of an inch. The insertion of the wire makes the least possible disturbance of the continuity of the metal. There is no lag, as the thermometer itself is part of the metal. The instantaneous value of the temperature at any particular point of the stroke can be measured in the most satisfactory manner by passing a current through the thermocouple at the desired point. A further advantage is gained by measuring only the difference of temperature between two junctions of a thermocouple at different depths, instead of the whole interval from some fixed point. None of these advantages could be secured by the use of any ordinary thermometer; some depend on the fact that the method is electrical, but some are peculiar to the thermocouple, and could not be otherwise attained.

On the other hand, the thermocouple is not well suited for thermometry on account of the smallness of the electromotive force, which is of the order of ten microvolts only per degree for the most constant couples. By the use of very delicate galvanometers it is possible to read to the hundredth or even in special cases to the thousandth of a degree on this small difference, but unfortunately it is not possible to eliminate accidental thermal effects in other parts of the circuit due to small differences of temperature and material. These accidental effects seldom amount to less than one or two microvolts even in the best work, and limit the accuracy attainable in temperature determination to within less than a degree with a single platinum thermocouple. This limit can be surpassed by using couples of greater thermoelectric power and less permanence, or by using a pile or series of couples, but in either case it is doubtful whether the advantage gained in power is not balanced by loss of simplicity and constancy.

A method of avoiding these effects, which the writer has found to be of great use in delicate thermoelectric researches, is to make the whole circuit, including all the terminals and even the slide-wires, of pure copper, and to use in the thermocouples, and other alloys most commonly used for resistances and slide-wires, are particularly to be avoided, on account of their great thermoelectric power when connected to copper. Manganin and platinum-silver are the least objectionable, but the improvement effected by substituting copper is very marked. It is clear that this objection to the use of the couple does not apply so strongly to high temperatures, because the electromotive force of the couple itself is greater, and the accuracy attainable is limited by other considerations.

23. The Resistance Thermometer.—In practice the resistance thermometer is almost invariably made of platinum, since there is very seldom any advantage to be gained by the substitution of baser metals. The instrument is for this reason often referred to simply as the "platinum thermometer." It is important that the platinum should be pure, both for the sake of uniformity and also because the change of electrical resistance with temperature is greatly diminished by impurities. The observation of the fundamental coefficient, which is $-0.0390$ (or rather larger than the coefficient of expansion of a gas) for the purest metal hitherto obtained, is one of the most delicate tests of the purity of the metal. In addition to the constancy and insusceptibility of the metal, a special advantage which is secured by the use of platinum is the close agreement of the thermal scale with the platinum scale of temperature, as defined by the formula

$$pt = 100(R - R_0)/(R_1 - R_0), \quad (24)$$

in which the symbol $pt$ stands for the temperature on the platinum scale centigrade, and $R_0$, $R_1$, and $R_4$ are the observed resistances of the thermometer at the temperatures $pt$, $100^\circ$ and $0^\circ$ C, respectively. A platinum thermometer is generally arranged to read directly in degrees of temperature on the platinum scale, just as a mercury thermometer is graduated in degrees of the mercury scale. The reduction to the scale of the gas thermometer is most conveniently effected by the difference formula

$$t - pt = d(t - 100)/10,000, \quad (25)$$

in which $d$ is a constant, called the difference-coefficient, the value of which for pure platinum is about 1.50, but varies slightly for different specimens. This formula was first given by T. Hall, Trans. Amer. Inst. Elect. Eng. 1893, vol. viii. p. 226; Cullender and Nicolson, Proc. Inst. C. E. vol. cxxxi. p. 1.

\end{footnote}
the comparison of platinum thermometers with the constant-volume nitrogen thermometer by Harker and Chapuis (Phil. Trans. A. 1900), working at the International Bureau at Sèvres, over the range 0° to 650° C. It has also been shown to satisfy very closely the observations on the variation of electrical resistance of other metals over wide ranges of temperature. Although the theoretical explanation of the formula has not yet been given, owing to our ignorance of the true nature of electrical contact and of the calculated constitution of metals, it may be regarded from an empirical point of view as being one of the most accurately established of all thermometric formulae. It will be observed that it also represents the simplest possible type of divergence from the thermodynamical scale.

24. Methods and Apparatus.—The methods of electrical thermometry may be roughly classified under two heads as (1) deflection methods, in which the temperature is deduced from the observed deflection of a galvanometer; and (2) balance methods, in which the resistance or the electromotive force is balanced against a known adjustable resistance or potential difference. The former methods are most suitable for rough work and rapid reading, the latter for accurate measurements. In the practice of the deflection method it is customary to use a movable-coil galvanometer, the sensitiveness of which can be varied by varying the resistance in circuit, or by varying the stiffness of the suspension. The accuracy attainable is of the order of one-half of 1 per cent. on the deflection, and is limited by variations of resistance of the galvanometer, and by the imperfection of the suspension. In any case the scale of the galvanometer should be calibrated for the resistance used.

In this kind of work the thermocouple has the advantage over the resistance thermometer in that the latter requires an auxiliary battery to supply the current; but in many cases this is no disadvantage, because it permits a greater latitude of adjustment, and makes it possible to obtain greater power than with the thermocouple.

In cases where it is desired to obtain greater accuracy without abandoning the quickness of reading which is the principal advantage of the deflection method, it is possible to combine the two, by balancing the part of the potential difference by means of a potentiometer and using the galvanometer for the small changes only. In cases where the greatest accuracy is required, a very sensitive galvanometer should be used, and the whole of the potential difference should be balanced as nearly as possible, leaving very little to depend on the deflection of the galvanometer. The degree of sensitiveness and accuracy obtainable depends primarily on the delicacy of the galvanometer, on the power available, and on the steadiness of the conditions of experiment. For thermometry of precision the resistance thermometer possesses three very great advantages over the thermocouple: (1) The power available, owing to the use of a battery, is much greater; (2) it is possible completely to eliminate the errors due to accidental thermal effects by reversing the battery; (3) the Wheatstone bridge method can be employed in place of the potentiometer, so that the constancy of the battery is immaterial, and it is not necessary to use a standard cell. The conditions to be satisfied in the attainment of the greatest possible accuracy in the measurement of temperature by this method differ somewhat from those which obtain in ordinary measurements of resistance, so that a special type of apparatus has been evolved for the purpose, a brief description of which will be given.

25. Compensated Bridge Apparatus.—It is necessary that the thermometer should be connected to the measuring apparatus by wires or "leads" of considerable length, generally at least two or three metres, in order to avoid exposing the galvanometer and resistance of the wires or other delicate parts of the apparatus, to changes of temperature. The resistance of that part of the leads which is exposed to variations of temperature necessarily changes, and would give rise to serious errors if it were not determined or compensated. The method now generally adopted in accurate work is to compensate the variations of resistance of the leads by an exactly similar pair of dummy leads called the "compensator" and connected as shown diagrammatically in fig. 6. The battery, consisting of a single cell, with wires and reversing key in circuit, is connected to terminals AB of the two equal resistance coils AG, GB, which form the ratio arms of the balance. These coils must be carefully tested for electrical resistance-coefficient, and placed in close proximity to each other so as to be immersed at the same temperature. If they are interwound on the same reel, they must be carefully insulated from each other. In parallel circuit with the ratio coils are connected the compensator CC' and the balancing resistances CE, on one side of the bridge-wire EF, and the compensating resistances FP and the pyrometer and leads PRP' on the other side. The galvanometer is connected to the point G between the ratio coils, and to the sliding contact on the bridge-wire. Since the ratio coils are always equal, the changes of resistance on either side of D are eliminated, and do not affect the balance. Thus the changes of the ratio and leads are balanced by the equal changes of the compensator leads CC' on the other side. As a further refinement, which is of some importance in delicate work, the ends of the compensator leads are connected by a short piece of the same wire as the pyrometer coil. For instance, in observing the variations of temperature of the steam in the cylinder of a steam engine at different points of the stroke with a very delicate thermometer made of wire one-thousandth of an inch in diameter (Proc. Inst. C. E., vol. cxxx., fig. 16, p. 23), the ends of the fine wire attached to the thick leads could not follow the rapid variations of temperature, and it was found necessary to adopt this arrangement. To eliminate the effect of conduction along the leads in the case of the ends of the fine wire coil. The balancing resistances CE are made of some alloy such as manganin or platinum-silver, the resistance of which varies very little with change of temperature. Platinum-silver is probably the best material, as it can be perfectly annealed at a red heat without risk of burning, and is then extremely constant. Unless the box can be kept at an absolutely constant and uniform temperature, which is not impossible but often impracticable, it is necessary to allow for the change of resistance of the balancing coils CE due to change in the temperature of the box. The temperature of the coils cannot be accurately determined with a mercury thermometer unless they are immersed in oil, but it is shown in that case it is necessary to know the temperature-coefficient of each individual coil. A more convenient and accurate method, which eliminates the correction automatically, is to compensate each individual coil of the balancing coils CE by a corresponding compensating coil at FP on the other side of the bridge-wire. The compensating coils are made of platinum, also annealed at a red heat, and each is placed in the box in close proximity to the coil it is intended to compensate. Each balancing coil and its compensator are tested together at various temperatures between 10° and 30° C., and are adjusted until their difference remains a rheostat to the extent that they are in the case of the box. This method of compensation was applied by the writer in 1887, but has not been generally adopted on account of the labour involved in adjusting the coils. The absolute values of these resistances are immaterial, but it is necessary to know the relative values with the greatest possible accuracy. For this reason it is preferable to arrange the resistances in the binary scale, in order to reduce to the smallest possible resistance, or to the sum of all the smaller resistances, the two smallest resistances being made equal. This arrangement permits the greatest accuracy of comparison in the simplest manner with the fewest observations. The bridge-wire EF provides a continuous scale for reading small changes of resistance. Any change of resistance of the pyrometer coil necessitates the movement of the balance point D through an equivalent resistance along the bridge-wire. As the bridge-wire EF provides a continuous scale this can be properly adjusted, by means of a shunt shown in parallel with it in fig. 5, to be an exact submultiple of...
the smallest resistance coil. It is usual also to adjust the resistances of the thermometers so that their fundamental intervals are convenient multiples of this unit, generally either 100, 200, 500, or 1000°. The minimum size of the metal wire in the platinum of the balancing resistances enable the scale to be indefinitely extended. Thus the instrument possesses the great advantage over the mercury thermometer that the most open scale may be easily secured, by allowing the wire to be of double length, and without restricting the range of any thermometer.

26. Errors and Corrections.—It is most instructive to consider the effects of deflections and corrections involved in platinum-resistance thermometers, as they are essentially the same lines as those on which the corresponding errors of the mercury thermometer have already been treated.

1. The changes of zero of the mercury thermometer arise chiefly from the variations of the temperature of the fluid in the bulb of the thermometer and of the inflection of the stem. With the perfect elasticity of the containing tube. In platinum thermometry the containing tube has nothing to do with the reading, and the effect of any possible strain on the wire of the thermometer is minimized by its small dimensions and by the large temperature-coefficient of increase of resistance, which is more than twenty times greater than the coefficient of apparent expansion of mercury in the bulb of the thermometer. It is a complication of the use of a platinum thermometer should be practically negligible, provided that the wire is not strained and contaminated with impurities. It is probable that with ordinary care the changes of zero due to condensation of water, or its evaporation, are not greater than the limit of accuracy of observation, due to other causes at the extreme limit of the range considered.

2. Temperature.—If the thermometer must be regarded as a delicate instrument and be handled with long-continued care. The resistance of the wire will be diminished by using a thermometer, and may be over time; and it is very likely to be greater than the error of the instrument, unless it be well fitted and kept very clean. Mercury cups with large copper terminals, well amalgamated, as used with standard resistance coils, are probably the simplest and most satisfactory method of calibrating the instrument. Accidental thermoelectric effects in the circuit are a possible source of error, as with the thermometer, but they are always very small if the thermometer is properly constructed and is never very important owing to the large error.

3. Pressure.—In every case of thermometer a sufficient safety factor is used, and by reversing the battery. The heating effect of the current through the thermometer is often negligible, but should be measured and allowed for in accurate work. With a current of 0.1 ampere the rise of temperature should not exceed 10° or 12° of a degree. With a delicate galvanometer it is possible to read to the tenth-thousandth of a degree with a current of only 0.002 ampere, in which case the heating effect is generally less than 1/100 of a degree. It can be observed by directing the light from one cell to two, thus doubling the current through the thermometer, and quadrupling the heating effect. The correction is then applied by subtracting one-third of the difference and adding one-third to the correction of one and two cells from the reading with one cell. The correction is always very small, if a reasonably sensitive galvanometer is used, and is frequently negligible, especially in differential work, which is one of the most fruitful applications of the platinum thermometer.

1. Construction of Thermometers.—One of the chief advantages of the platinum thermometer for research work is the endless variety of forms in which it may be made, to suit the particular exigencies of each experiment. It is practically suited for observing the average temperature throughout a length or space, which is so often required in physical experiments. For this reason the wire may be disposed in a straight length, or in a spiral, along the space in question. Again, in observing the temperature of a gas, the platinum wire, on account of its small mass and extremely low rate of heating, is well adapted to any mercury thermometer. The commonest form of platinum thermometer (fig. 7), and the most convenient for laboratory work, is a ½ in. to 2 in. long, wound on a cross of thin mica, and enclosed in a tube, about ½ to 1 in. in diameter, of glass or porcelain according to the temperature for which it is required. The pyrometer contains the conductor, which is placed in the place by passing through mica disks fitting the tube, which serve also to prevent convection currents up and down the tube. The protecting tube of glass or porcelain is fitted with a wooden head A carrying four insulated terminals, PP', CC', to which the pyrometer

27. Electrical Precautions.—The platinum thermometer is so far superior to the mercury thermometer in all the points above enumerated that, if there were no other difficulties, no one would ever think of using the latter, especially in the fields of electrical work. It is essential to obtain the best results. The manipulation and adjustment of a delicate galvanometer present formidable difficulties to the non-electrical observer. Bad contacts, faulty connections, and defective insulation, are not likely to trouble the practised electrician, but present endless possibilities of error to the tyro. A thousand-fold a degree with a current of only 0.002 ampere, in which case the heating effect is generally less than 1/100 of a degree. It can be observed by directing the light from one cell to two, thus doubling the current through the thermometer, and quadrupling the heating effect. The correction is then applied by subtracting one-third of the difference and adding one-third to the correction of one and two cells from the reading with one cell. The correction is always very small, if a reasonably sensitive galvanometer is used, and is frequently negligible, especially in differential work, which is one of the most fruitful applications of the platinum thermometer.
and compensator leads are respectively connected, and which serves the purpose. The instrument of the highest precision these terminals are often omitted, and the leads are directly soldered to a flexible cable in order to avoid possible errors from thermoelectric effects and changes of resistance. The wire may be stranded, but in general the protecting tube must be of porcelain, and the leads of platinum throughout the length of part of the tube which is exposed to high temperatures. The leads must be separate, but if the wire is stranded, the length of the protecting tube is often 5 to 10 ft. In the latter case it is usual to protect the porcelain tubes with an external steel tube, which may be removed for delicate measurements.

In measuring the linear expansion it is a great advantage to employ a thermometer with a bulb or sensitive portion equal in length to the bar or column under test, so as to obtain the mean temperature of the whole length. In measuring the linear expansion of a standard metre or yard, a fine platinum wire enclosed in a glass capillary, or otherwise insulated, is employed, its length being equal to that of the bar.

The same method has been applied by Callendar (Phil. Trans. A, 1887) and Bedford (Phil. Mag., 1898) to the expansion of glass and porcelain at high temperatures, employing a fine wire supported along the axis of the tube under test. An equivalent method, applicable to the expansion of the material itself, is employed by inserting a strip of a platinum tube which is heated by an electric current. This is a very rapid and convenient process, since the mean temperature is not less than 15°. J. J. Joly's melsdometer, which consists of an electrically heated strip for observing the melting-points of metals or other substances in small fragments. If employed in the temperature of a long column of mercury, as in the method of equilibrating columns for determining the absolute expansion of mercury, a platinum thermometer with a bulb equal in length to the column may similarly be employed. In practice this has been employed only on account of the linear instrument is very important because it is practically impossible to ensure perfect uniformity of temperature in a vertical column, 6 ft. or more in length, at high temperatures.

29. Thermocouples.—Where quickness of reading is essential, the mercury thermometer, or the tube form of electric thermometer, is unsuitable. In cases where the thermometer has to be immersed in a conducting liquid or solution, the fine wire forming the bulb may be insulated by enclosing it in a coiled capillary. This method has been employed by Callendar and Barnes and by Jaeger, but the instrument is necessarily fragile, and requires careful manipulation. The radiator may be employed as a null instrument, or the fine wire may be employed with great advantage. This is particularly important in the case of gases owing to the extreme sensitiveness thus obtained and the almost complete immunity from radiation errors. Callendar has used a platinum wire in the form of a flat grid of bare wire mounted on a mica and ebonite frame have been employed by H. Brown (Proc. R. S., 1905, B 76, p. 124) for measuring the temperature of the atmosphere when exposed through a window. They have also employed a thermometer for observing the air-temperature for meteorological purposes in Egypt and Spain with very satisfactory results (Proc. R. S., 1905, A 77, p. 7). The fine wire, owing to its small size and bright metallic surface, very rapidly acquires the temperature of the air, and is very little affected by radiation from surrounding objects, which is one of the chief difficulties in the employment of mercurial thermometers for the observation of the temperature of the air.

For the observation of rapidly varying temperatures, such as those occurring in the cylinder of a gas- or steam-engine, an electrical thermometer is more suitable, but the very fine platinum wire of which any satisfactory instrument is essentially the only available instrument. The temperature at any particular moment may be obtained by setting a mechanical contact-maker to close the circuit at the desired point. The sensitive platinum wire is fixed to the contact-maker in a direction in which it may be moved from half an inch to an inch long, connected by suitable leads to the measuring apparatus as employed by Burstall (Phil. Mag., October 1905) in the gas-engine, and Callendar and Nicolson (Proc. Inst. Mech. Engrs., 1909). Thermocouples of this general character cannot be satisfactorily measured in a gas-engine in this manner, because the radiation error at high temperatures is excessive unless the wire is very fine. The method has been employed by Callendar and Dalby as a dynamical valve (Proc. R. S., A 80, p. 57) for exposing the thermometer only during the admission and compression strokes, and also by Callendar and Lord Rosse (Proc. R. A. Acad., 1896) for the determination of the low temperature sensitivity by an indicator diagram. B. Hopkinsion (Proc. R. S., A 77, p. 387) succeeded in following the course of an explosion in a closed vessel by means of a similar thermometer connected to a galvanometer of short period giving a continuous record on a moving photo-electric galvanometer. The device of Lord Rosse 1200° C. in about 3 of a second, which illustrates the order of sensibility attainable with a fine wire of this size. O. R. Llummer and E. Pringsheim, in their measurements of the ratio of the rate of heat conducts of gold and platinum. In order to sudden expansion, employed a very thin strip of foil with the object of securing greater sensibility. This was a somewhat delicate arrangement, because the fine wire is liable to be injured by air currents, and because the sensibility is not as a matter of fact appreciably improved, whereas the radiation error is increased in direct proportion to the surface exposed. The very thin wire of Nilsson and his assistant, in an improved galvanometer, has been employed for observing rapidly varying temperatures is that the ends of the loop close to the thick leads are affected by conduction of heat to or from the leads, and cannot follow the rapid variations of temperature. This objection may, however, be completely met by first employing the compensating leads with a short length of the same fine wire. The effect is then ended by observing the difference of resistance between two loops of different lengths. Thermocouples of very fine wire have also been employed for similar measurements, but they are more difficult to make than the simple loop of one wire, and the sensibility attainable is much less, owing to the small E.M.F. of a single thermocouple.
THERMOMETRY

The rise of temperature of the grid when exposed to radiation is measured by its increase of resistance in the usual manner. In order to compensate for changes of temperature of the surrounding air the balancing resistance is made adjustable. Two grids are employed, one of which is placed far from the source of radiation, the other first but screened from radiation. The foil should be as thin as possible consistent with strength, in order to secure the maximum sensitivity. For spectroscopic work a single strip or linear heater is employed. For all other work it is usually necessary to absorb the whole radiation admitted through a given area, two grids are placed with the strips of one behind the interspaces of the other.

Absolute Measurement of Radiation.—In many cases the object is not to secure the maximum degree of sensitiveness, but an absolute measurement of the intensity of the radiant energy, it being sufficient to determine the resistance. For this purpose some form of radiation thermometer is generally employed, but the method of procedure is modified. The earlier methods as exemplified in C. S. M. Pouillé’s pyrheliometer, or L. G. Viélo’s actinometer, consisted in observing the rate of rise of temperature of a small calorimeter, or thermometer of known thermal capacity, when exposed to a given area of the radiation to be measured. To secure greater sensitivity F. P. Crova substituted a copper disk with an attached thermocouple for the calorimeter thermometer. The method is very simple and direct, but has the disadvantage that the correction for external losses is not certain. The conditions are steady and the observation depends on rate of change of temperature. For this reason static methods, depending on the steady temperature finally attained, in which the rate of heating is determined, have come more prominently into favour in recent years. In K. J. Ångström’s pyrheliometer (Acta Soc. Upsala, 1893) two similar blackened disks, one of which is adjusted so that the radiations on the two sides are equal, are employed. In a suitable case in such a manner that either may be exposed to the radiation to be measured while the other is simultaneously heated by an electric current. Attached to the backs of the disks are thermocouples which, from the difference of the resistance and area of the strip, by observing the current required to balance the radiation, the instrument is very quick and sensitive in action, and the method is free from any uncertainty with respect to loss of heat, except that it is the same for the two similar strips at the same temperature. The accuracy of the method is limited chiefly by the measurement of the resistance and width of the strips, and by the difficulty of securing exact similarity and permanence in the attachment of the junctions of the thermocouple. Small differences in this respect may be eliminated by interchanging the strips, but there remain outstanding differences in the resistance of the different instruments of the same make which often exceed 5 per cent.

An electric method proposed by F. Kurilbaum (Wied. Ann., 1895, 65, p. 748) consists in determining the rise of temperature of a bolometer grid by employing a network of bolometer strips as in the pattern of a Wheatstone bridge. The chief source of uncertainty mentioned by Kurilbaum lies in possible differences between the effects of radiation and current-heating near the ends of the strips, the area so affected representing a large proportion of the total area. In Ångström’s method this is not so important because the temperature indicated by the couple is that near the middle of the strip. In the case of the bolometer this end-effect may be compensated, as explained by Callen (Phil. Mag., 1877 A, 46, p. 613). In the same manner as for sensitive thermometers, by employing two similar bolometers with strips of different lengths.

An important defect of all the methods so far considered is that the blackness of the strip is that of the same metal as the one with which the receiving surface is coated. The error is probably small, of the order of 1 or 2 per cent., but is difficult to determine accurately, and varies to some extent with the quality of the metal. The use of molybdenum or tungsten, with their high absorption of great wave-length than for visible rays. If we assume that the loss of heat by conduction and convection is independent of the nature of the material, the error may be small. A second method is the following method. Two bolometer strips, one bright and the other black, but otherwise exactly similar, are simultaneously exposed to the radiation to be measured, and are traversed by the same electric current. The strip will only be hotter than the bright, but the rise of temperature of the bright strip due to the current will be greater than that of the black strip because its emissive power is lower. If the current is adjusted until the temperatures of the two strips are equal the losses by convection and conduction will be equal, and also the rate of generation of heat by the current in each strip. The rise of temperature must therefore be such that each strip loses as much heat by radiation to the cold calorimeter as it gains by the current in each strip to be measured. Assuming Kirchhoff’s law, the ratio of the emissive to the absorptive power is the same for all bodies at the same temperature, and is equal to the emissive power of a perfectly black body (so-called Planck body, or the gas thermometer) divided by the temperature to which it is heated. This is attained, will be the same as that of a perfectly black strip under the same conditions of exposure. The electric current in this method is determined by the rise of temperature, and the result is obtained in terms of the observed rise of temperature and the radiation constant for a black body. The method works well for a source at 1000° C.; but, for a high temperature source, in one of the measuring instruments the temperature of the strips may differ appreciably from their emissive powers.

Another electric compensation method of special interest is the method of the "Peltier cross." A small disk of copper is supported by two thermocouples connected by a cross. One of the couples serves to measure the rise of temperature, while the other is traversed by an electric current, which may be employed to measure the radiation by the heat absorption due to the Peltier effect. The advantage of this method is that the Peltier effect is easily determined from an observation of the thermoelectric power (see THERMOELECTRICITY) in absolute measure, and that it is proportional to the radiant energy falling on the heating current, by conduction from the supporting wires, and changes of temperature in the surrounding case, are readily compensated by mounting two similar disks side by side. Small differences between the heating currents may be measured with reversal of the current, so that the irradiated disk is cooled on the other disk heated by the Peltier effect. The current is adjustable to make the rise of temperature of the two equal, as indicated by the second couple connecting the disks.

The method is about equal in sensitiveness to that of Ångström, but it is easier to secure conditions of exact similarity and to measure the loss of heat by conduction, radiation, and convection, namely, the area of the hole through which the radiation is admitted, and the coefficient of the Peltier effect. The uncertainty due to imperfect blackness of the disks may be eliminated by using two such disks which are exactly the same, or whose temperature may be increased by using thermopiles in place of single couples.

33. Optical or Radiation Pyrometers.—Since the intensity of radiation increases very rapidly with the temperature of the source of heat, it is used for measuring temperature, assuming that the laws connecting radiation and temperature are known. The advantage of this method is that the measurement may be made from a distance, without exposing any part of the measuring apparatus to the destructive action of high temperatures. Apart from the difficulty of calibrating the measuring apparatus to give temperature in degrees Centigrade, the chief objection to the application of the method is the emissive power of the source of radiation. The methods principally employed may be divided into two classes:—(1) Radiation methods, depending on the measurement of the intensity of the black body or the bolometer; (2) optical or photometric methods, depending on the colour or luminous intensity of the radiation as compared with a standard.

Of the radiation methods the simplest in theory and practice depends on observing the total intensity of radiation, which varies as the fourth power of the absolute temperature according to the Stefan-Boltzmann law (see HEAT) for a perfectly black body or full radiator. In applying this method it is necessary to allow for the emissive power of the source, in case this does not radiate as a black body. Thus the emissive power of polished platinum at 1000° A. is only 10 per cent., and that of hot iron oxide about 49 per cent., of that of a black body; and the percentage varies quite differently for different bodies with change of temperature, and also (as shown by Callen, ibid., 77 A, p. 46), the observed radiance of a source with the increasing temperature is not proportional to the fourth power, as above supposed for the measurement. Owing to the rapid increase of radiation with temperature the error due to departure from black body radiation is not so serious as might be imagined at first sight. If the object we are to determine is already at a temperature which was estimated by the radiation formula, assuming the constant for a perfectly black body, the error for red light would be about 12°, for green about 100°, and for blue about 75°. Such errors may be compensated by means of an auxiliary thermometer. The temperature is known from previous experiments, but it is preferable to observe, whenever possible, the radiation from the interior of a body which approximates very closely to that of a black body (see HEAT).

Radiation pyrometers of this type are generally calibrated by the method of sighting on the interior of an electric furnace containing a glass thermometer, and the temperature is measured. The gas thermomter has been employed for verifying the law of radiation up to 1500° C., but the difficulties of obtaining accurate results with the gas-thermometer increase so
Thermometry

rapidly above 1200° C. that it is questionable whether any advantage is gained by using it beyond this point. The law of radiation has been so closely verified by observations at lower temperatures that the uncertainty involved in applying it at higher temperatures, in the case of a black body is probably less than the uncertainty of the thermometer itself, and much less than the uncertainty of extrapolating an empirical formula for a thermocouple. Thus L. F. C. Holborn and W. Wien (Wied. Ann., 1895, 46, 303) have extrapolated their thermoelectric formula, found the value 1500° C. for the melting-point of palladium, and 1550° C. for the melting-point of gold, from values of 1535° C. for the calorimetric method, and Callendar and Eumorfopoulos (Phil. Mag., 1899, 48) found 1550° C. and 1550° C. by the methods of the expansion and the change of resistance of platinum respectively. By a later thermoelectric extrapolation Holborn and Henning (Berlin Akad., 1905, 12, p. 311) found 1555° C. for the melting-point of palladium, and 1710° C. for that of platinum, values which were strikingly confirmed by J. A. Harker at the National Physical Laboratory, and by Waidner and Burgess at the Bureau of Standards, U.S.A. Holborn and Valentin employing an optical method, in 1905, 1907, 22, p. 1) found 1562° C. and 1783° C. for palladium and platinum respectively. There can be little doubt that the extrapolation of the parabolic formula for the thermocouple at these temperatures is quite untrustworthy (see Thermoelectricity) and that the values given by the electrical resistance method, or by the laws of radiation, are more likely to be correct. Assuming that the total radiation varies as the fourth power of the absolute temperature, a radiation pyrometer can be calibrated for observing the temperature of a black body, as the melting-point of gold, 1662° C. If a black body is employed as the source; and its indications will probably be accurate at higher temperatures, and with some restriction. If the pyrometer is sighted on the interior of a furnace through a small observation hole it will indicate the temperature of the furnace correctly, provided that the temperature is uniform. But it must be remembered that this condition does not generally exist in large furnaces. Suppose, for instance, that there is a temperature gradient in the molten metal on the hearth of a furnace viewed through a thick layer of furnace gases, which are probably at a much higher temperature. It is evident that the radiation from the intervening flame may be much greater than that from the metal, and may introduce serious errors. The same objection applies with greater force to optical pyrometers, as the luminous radiation from gases may be of a high multiplicity. If, on the other hand, it is required to observe the temperature of metal in a ladle before casting, the surface of the metal must be cleared of scum, and it is necessary to know the emissive power of the metal or oxide exposed.

For scientific measurements of temperature by the radiation method, the thermopile, or bolometer, or radiomicrobeter, previously calibrated by exposure to a black body at a known temperature, is directly connected at a known distance to a known area of the source of radiation. The required result may then be deduced in terms of the area and the distance. The use of extraneous optical appliances is avoided as far as possible on account of selective absorption. For practical purposes, in order to avoid trouble some calculations and measurements, an optical arrangement is employed, either lens or mirror, in order to form an image of the source on the receiving surface. Fig. 8 illustrates Fény's mirror pyrometer, in which a mirror M, focused by the pinion P, forms an image of the source on a disk, supported by wires of constantan and silver forming a thermocouple, connected by the brass strips D and R to the terminals b, b'. Observation hole in the wall of the furnace is sighted through the eyepiece O, and is made to overlap the disk slightly. The rise of temperature of the junction is assumed to be proportional to the intensity of radiation, and is indicated by the deflexion of a delicate galvanometer connected to the terminals b, b'. A lens may be substituted for the mirror at high temperatures, but it is necessary to allow for the selective absorption of the lens, and to a less extent for that of the mirror, by a special calibration of the scale.

Assuming Wien's laws for the distribution of energy in the spectrum (see Heat), the temperature of a black body may also be obtained by solving for the wavelength corresponding to maximum intensity in the normal spectrum, which varies linearly as the absolute temperature, or (2) the maximum intensity itself, which varies as the fifth power of the absolute temperature, or (3) the intensity of the radiation of a definite color temperature, or of radiation or colour, which varies as an exponential function, the exact form of which is somewhat uncertain. Methods (1) and (2) are the most trustworthy optical pyrometers, and most the methods of observing by the intensity of monochromatic light forms the basis in theory of the most trustworthy optical pyrometers.

34. Optical or Photometric Pyrometers.—The change of colour of a heated body from red to white with rise of temperature, and the dependence of intrinsic intensity on the temperature, accompaning the change, are among the most familiar methods of estimating high temperatures. For many processes eye estimation suffices, but a much greater degree of accuracy may be secured by the employment of suitable photometers. In Mesuré and Nouël's pyrometric telescope, the estimation of temperature depends on observing the rotation of a quartz polarimeter required to reduce the colour of radiation to a standard tint. It has the advantage of requiring no auxiliary apparatus, but to the naked eye, and of comparison, its indications are not very precise. In the majority of photometric pyrometers, a standard of comparison for the intensity of black body radiation, either a heated body, or an electric glow-lamp, is employed. The optical pyrometer of H. Le Chatelier (Comptes Rendus, 1892, 114, p. 214) was one of the earliest, and has served as a model for subsequent inventors. The standard of comparison of this pyrometer is a black body, the temperature of which is adjusted in the usual manner and viewed in the same field as the image of the source. The two halves of the field are adjusted for equality of brightness, by means of a cat's eye diaphragm and absorption glasses, and are viewed through a red filter giving nearly monochromatic radiation in order to avoid the difficulty of comparing lights of different colours. Assuming Wien's law, the logarithm of the intensity of the radiation of a black body is a linear function of the reciprocal of the absolute temperature, and the instrument can be graduated by observing two temperatures; but it is generally graduated at several points by comparison with temperatures observed by means of a thermocouple.

The Wanner Pyrometer (Phys. Zeits., 1902, p. 112) is a modification of Konig's spectrophotometer, in which the two halves of the field, corresponding to the source and the standard of comparison, are illuminated with monochromatic red light polarized in planes at right angles to each other. The two halves may be observed alternately, and the circle of which is graduated to read in degrees of temperature. The instrument has a somewhat restricted range of maximum sensitivity, and cannot be used below 1200° C. owing to the great loss of light in the complicated optical system. It cannot be sighted directly on the object, since no image is formed as in the Le Chatelier or Fény instruments, but the methods of securing monochromatic light by a direct vision method (see page 810) and of adjusting the instrument of the analyser, are capable of great precision, and lead to simple theoretical formulae for the ratio of the intensities in terms of Wanner's law.

The Fény Absorption Pyrometer (Journ. Phys., 1904, p. 32) differs from Le Chatelier's only in minor details, such as the replacement of the cat's eye diaphragm by a pair of absorbing glass wedges. The principles of its action and the method of calibration are the same. The pyrometers of Morse, and of L. F. C. Holborn and F. Kuribaum depend on the employment of a glow lamp filament as standard of comparison, the current through which is adjusted to maintain the intrinsic brilliance of the filament equal to that of the source. When this adjustment is made the filament becomes invisible against the image of the source as background, and the temperature of the source may be determined from an observation of the filament required. The filament is either observed, but the lamps remain fairly constant provided that they are not overheated. To avoid this, the source is screened by absorption glasses (which also require calibration) in observing high temperatures. Except at low temperatures the comparison is made by placing a red glass before the eye-piece. At low temperatures a special advantage of the glow-lamp as a standard of comparison is that the red glass is immersed, and thus prevents the minimum temperature occurring, or will register the temperature at a particular time or place. A recording instrument is one constructed to give a continuous record of the temperature, and requires a revolving drum or some equivalent clockwork mechanism.
thermopylae—théroigne de méricourt

for recording the time. The most familiar types of registering thermometers are modifications of the common liquid-in-glass thermometer.

John Rutherford's maximum, invented before 1790, was an ordinary mercurial thermometer placed horizontally; the column provided with a steel wire was laid under the point reached and was drawn down again to the liquid by a magnet when the instrument had to be reset. It is little used now. The Bunsen maximum, invented by Bunsen and made by constructing a section near the bulb, past which the mercury easily expands but cannot return when the temperature falls, since the column breaks at the narrowed point when the fluid in the bulb begins to contract. The instrument is provided with a fresh observed point at the end of the portion of the column back down the tube. The clinical thermometers used by physicians are instruments of this type, and are made with a fairly open scale to read only in the neighbourhood of the patient's rectum or elsewhere the temperature of the body. A Walford maximum a portion of the mercury is separated from the rest by a minute bubble of air. It is placed horizontally and as the temperature rises the detached portion of the column is pushed forward but is not withdrawn when the main column retreats towards the bulb in cooling. It is set for a new observation by bringing it into a vertical position and tapping it slightly. By reducing the length of the index and the bore of the stem this thermometer may be made suitable for use in any position without altering its register.

The minimum thermometer in most common use is that of Phillips and Co. patented in 1790. It is a spirit thermometer, preferably filled with amyl alcohol, to reduce risk of distillation, in the column of which a small porcelain index is included. The instrument is clean and, being graduated, is kept in a horizontal and, when not in use, is drawn back through surface tension by the end of the column. When the temperature rises the liquid flows past the index, which is left at the lowest point attained. To prepare the instrument for use, it is inverted until the index is brought opposite the end of the column. The Six's combined maximum and minimum thermometer (Phil. Trans., 1782) consists of a U-tube, the bend of which is filled with mercury. One leg contains spirit above the mercury and terminates in a bulb also full of spirit. The other leg also contains a column of spirit above the mercury, but terminates in a bulb containing air and vapour of spirit without any increase of pressure in the arm where the bulb expands; the mercury in consequence is pushed round the bend and rises to a greater or less extent in the other leg, carrying before it a steel index which thus marks the maximum temperature. The spirit in the arm of the thermometer moves back carrying with it a second index which marks the minimum temperature. The instrument is set by drawing down the two indices upon the two ends of the mercury column by the means of a magnet.

With a mercury thermometer a continuous record of temperature can only be obtained by the aid of photography, a method which has been used for many years at some meteorological observatories, but which cannot be generally employed on account of the expense and the elaborate nature of the apparatus required. The commonest type of recording thermometer works on the principle of an expansion thermometer. The bulb of a bent, curved metallic tube filled with liquid, the expansion of which with rise of temperature tends to straighten the tube. The movements are recorded on a revolving drum by a pen carried at the end of a link fixed to the tube, or the bulb, or the index of instruments employed for rough work, but it has a very limited range and is unsuitable for accurate work on account of want of sensitiveness and of great liability to change of zero, owing to imperfect elasticity of the metal tube. For accurate work, especially at high temperatures, electrical thermometers possess many advantages, and are often the only instruments available. They are comparatively free from change of zero over long periods, and the thermometer or pyrometer itself may be placed in a furnace or elsewhere at a considerable distance from the registering apparatus. The principal types are the thermocouple and the platinum resistance thermometer, which may be employed for registering purposes, without altering the thermometer itself, by connexion to a suitable recording mechanism. The methods in use for recording the indications of electrical thermometers may be classified as in § 24 under the headings of (1) deflexion methods and (2) balance methods. Deflexion methods, in which the deflexion of the galvanometer is recorded, are more suitable for rough work, and less applicable to accurate measurements. The most delicate and most generally applicable method of recording the deflexions of a mirror galvanometer is by photographing the movements of the spot of light on a moving film. Almost any required sensitiveness may be obtained, but the record cannot be inspected at any time without removal and development. Since the forces actuating the needle of the galvanometer are small, it is necessary to set off a pen or marking point directly to the end of the pointer for recording a continuous trace on a revolving drum, because the errors due to friction with the recording sheet would be excessive. This difficulty has been avoided in many electrical instruments by depressing the pointer so as to mark the paper only at regular intervals. By this means the instrument can be divided into parts, and the record thus obtained is discontinuous, but is sufficient for many purposes. For accurate measurement, or for obtaining an open scale over a particular range of temperature, the instrument is employed by means of a form of balance method as already explained in § 24.

36. Electric Recorder, Balance Method.—The application of the electric balance to thermometry is of great advantage for noting changes of resistance or electromotive force has been effected by employing a galvanometer of the movable coil type as a relay. The deflexion of the galvanometer to right or left, according as the resistance of E.M.F. increases, or diminishes, is magnified by one or other of a pair of motors for moving the contact point on the bridge wire and the recording pen on the drum in the corresponding direction. A continuous record free from friction error may be obtained. The galvanometer does not actuate the pen directly. With an electrical resistance thermometer it is possible in this way to obtain continuous pen-and-ink records on a scale of an inch or more to the degree, reading a few parts practically free from zero error over any desired range from −200° to +1500° C.

With a thermocouple, employing the potentiometer method, the same apparatus can be used with advantage, but it is not possible to obtain a record.

The attainment of sufficient delicacy in the relay mechanism turns on the employment of a rotating or vibrating contact in a manner similar to that employed with the magnetic balance recorder type. This was first successfully effected by Callendar (Trans. R. S. Canad., 1897) for records of radiation and temperature, and by Selfridge for submarine telegraphy by S. G. Brown and by A. Muirhead. The Callendar's electrical recorder, as arranged for temperature measurements, is described and illustrated in Engineering, May 26, 1899, and in a pamphlet on Electric Records, 1902, published by Selfridge. These recording instruments of both types are now coming into extensive use for industrial purposes in the measurement of furnace temperatures, &c., for which they are particularly suitable, because the recording apparatus can be placed at any distance from the furnaces which may be considered most convenient, and can be connected to any one of a set of furnaces in succession whenever it is desired to obtain a record.

Authorities.—There is no special work on the subject of thermometry in English, but most of the principles and methods are described in text-books on heat, of which Preston's Theory of Heat has been very extensively used for the purposes of the present work. In Tutton's Electrical Thermometry the reader should consult the original papers, the most important of which have been cited. The greater part of the recent work on the subject will be found in the publications of the Bureau International des Poids et Mesures (Paris), of the Reichsanstalt (Berlin), of the Bureau of Standards, U.S.A. (Washington), and of the National Physical Laboratory (London). (H. L. C.)

Thermopylae (Gr. θερμόπυλη, hot, and πυλή, gate), a Greek pass leading from Locris into Thessaly between Mount Oeta and the sea (Maiiac Gulf). It is chiefly famous for the heroic defence made by Leonidas, the Spartan king, with 300 Spartan soldiers against the Persian army of Xerxes advancing upon Greece. For details of the campaign see History (and authorities there quoted). In I. C. 63 B.C. Brennus and the Gauls were checked for several months by a Greek army under the Athenian Calippus, and in 191 Antiochus of Syria vainly attempted to hold the pass against the Romans under M'. Aelius Gabrio. In the time of Leonidas the pass was a narrow track (probably about 14 yds. wide) under the cliff. In modern times the deposits of the Spercheios have widened it to a breadth of 1½ to 3 m. broad. The hot springs from which the pass derived its name still exist close to the foot of the hill. There is one large spring used as a bath and four smaller ones, and the water, which is of a bluish green colour and contains lime, salt, calcium and sodium, is said to produce good effects in cases of scrofula, sciatica and rheumatism. The accommodation for bathers is, however, quite inadequate.

For the topography see Grundy, Great Persian War, p. 279-291.

Théroigne de Méricourt, Anne Joseph (1752–1817), a Frenchwoman who was a striking figure in the Revolution, was born at Marcourt (from a corruption of which name she took her usual designation), a small town in Luxembourg, on the banks of the Ourthe, on the 13th of August 1752. She was the daughter of a well-to-do farmer, Peter Théroigne. She
appears to have been well educated, having been brought up in the convent of Robermont; she was quick-witted, strikingly handsome in appearance and intensely passionate in temper; and she had a vigorous eloquence, which she used with great effect upon the mobs of Paris during that short space of her life (1789–93) which alone is of historical interest. The story of her having been betrayed by a young seigneur, and having in consequence devoted her life to avenge her wrongs upon aristocrats, a story which is told by Lamartine and others, is unfounded, the truth being that she left her home on account of a quarrel with her stepmother. In her capacity as a singer she received rapturous applause in Paris in 1785, and in Genoa in 1788, where she was a concert singer. In 1789 she returned to Paris. On the outbreak of the Revolution, she was surrounded by a coterie of well-known men, chief of whom were Pétion and Desmoulins; but she did not play the rôle which legend has assigned her. She took no part in the taking of the Bastille nor in the days of the 3rd and 6th of October, when the women of Paris brought the king and queen from Versailles. In 1790 she had a political salon and spoke once at the club of the Cordeliers. The same year she left Paris to take up residence in London. In 1792, she was back in Paris in 1792, crowned of course with fresh laurels because of her captivity, and resumed her influence. In the clubs of Paris her voice was often heard, and even in the National Assembly she would violently interrupt the expression of any moderating views. Known henceforth as "la belle Lilu," she appeared in public dressed in a riding habit, a plume in her hat, a pistol in her belt and a sword dangling at her side, and excited the mob by violent harangues. Associated with the Girondists and the enemies of Robespierre, she became in fact the "Fury of the Gironde." She commanded in person the 3rd corps of the so-called army of the faubourgs on the 20th of June 1792, and again won the gratitude of the people. She shares a heavy responsibility for her connexion with the riots of the 10th of August. A certain contributor to the journal, the Journal des Apôtres, Suleau by name, earned her hatred by associating her name, for the sake of the play upon the word, with a deputy named Populus, whom she had never seen. On the 10th of August, just after she had watched approvingly the massacre of certain of the national guard in the Place Vendôme, Suleau was pointed out to her. She sprang at him, dragged him among the infuriated mob, and he was stabbed to death in an instant. She took no part in the massacres of September, and, moderating her conduct, became less popular from 1793. Towards the end of May the Jacobin women seized her, stripped her naked, and flogged her in the public garden of the Tulleries. The following year she became mad, a fate not surprising when one considers her career. She was removed to a private house, thence in 1800 to La Salpêtrière for a month, and thence to a place of confinement called the Petites Maisons, where she remained—a raving maniac—until 1807. She was then again removed to La Salpêtrière, where she died, never having recovered her reason, on the 9th of June 1817.

See M. Pellet, Étude historique et biographique sur Théorie de Mercour (1886); L. Lacour, Les Origines du féminisme contemporain. Trois femmes de la Révolution (Paris, 1906); Vincent de Rave, La Vraie Théorie de Mercour (Paris, 1903); E. and J. de Gouv-
court, Portraits intimes du XVIIIe siècle (2 vols., 1857–58); and the play Théorie de Mercour of M. Paul Hervieu, produced at the Théâtre Sarah Bernhardt in 1902.

**THERSITES**

THERSITES, the ugliest man in the Greek camp before Troy, celebrated for his biting tongue. The special objects of his attack were the leaders of the army, and Homer (Iliad, ii. 212) tells how he was chastised by Odysseus for daring to abuse the commander-in-chief. According to a later story, Achilles, after he had slain the Amazonian queen Penthesilea, bitterly lamented her death; for this he was reviled by THERSITES, who even insulted the body of the dead queen. Achilles thereupon slew THERSITES with a blow of his fist (Quint. Smyrn. i. 722). There was a play by Chaeremon called Achilles the Thersites-slayer, probably a satyric drama, the materials of which were taken from the *Antiopeia of Arctinus.*

**THESAURUS**

The word "Thesaurus" in English is derived from the Greek word *Thesaurus,* which means "treasure house," and it is often used to refer to a collection of information or knowledge on a particular subject. It can also refer to a collection of works of art or artifacts. The term is commonly used in the context of a dictionary or lexicon, as being a "treasure house" or store of knowledge.

**Thesaurus**, the great hero of Attic legend, son of Aegeus, king of Athens, and Aethra, daughter of Pittheus, king of Troezen. Thus through his father he was descended from Erechtheus and the original stock of Attica; through his mother he came of the Asiatic house of Pelops. The legend relates that Aegeus, being childless, went to Pittheus, who contrived that Aegeus should have intercourse with his daughter Aethra, and that in due time Aethra brought forth Theseus. It was given out that the child's father was Poseidon, the god of Troezen, and that Aethra raised a temple to Athena Apaturia, at which Troezenian maidens used to dedicate their griddles before marriage. For his tutor and guardian young Thesaurus had one Cnannias, to whom, down to Pindar's time, the Athenians were wont to sacrifice a black ram on the eve of the festival of Theseus. On passing out of boyhood Theseus was sent by his mother to Athens. He encountered many adventures on the way. First he met and slew Periphetes, surnamed Corynetes (Clubman). At the isthmus of Corinth dwelt Sinis, called the Fine-Bender, because he killed his victims by tearing them asunder between two pine-trees. Thesaurus hoisted the Fine-Bender on his own pine-tree. Next Theseus defeated the Crommyonian sow (or boar). Then he flung over a cliff the wicked Sciron, who used to kick his guests into the sea, while perforce they washed their feet. In Eleusis Theseus wrestled with Cercyon and killed him. A little farther on he slew Procrustes, who fitted all comers to his only bed: if his guest was too short for the bed, he stretched him out; if he was too long, he cut him down to the requisite length. As he passed through the streets of Athens, his curls and long garment reaching to his ankles drew on him the derision of some masons, who were putting on the roof of the new temple of Apollo Delphinios: "Why," they asked, "was there such a pretty girl out alone?" In reply Theseus took his trollops out of their cart and flung them higher than the roof of the temple. He found his father married to Medea, who had fled from Corinth. Being a witch, she knew Theseus before his father did, and tried to persuade Aegeus to poison his son; but Aegeus recognized him by his sword and took him to his arms. Theseus was now declared heir to the throne, and the Pallantids, who had hoped to succeed to the childless king, conspired against Theseus, but he crushed the conspiracy. He then attacked the fire-breathing bull of Marathon and brought it alive to Athens, drove the Crommyonian sow (or boar) from the fields of Delphi, and looked down on the house of the Cretan Minotaur (g.r.), whom Theseus slew by the aid of Ariadne (g.r.). While Theseus was in Crete, Minos, 1

1 The story of Theseus is a strange mixture of (mostly fictitious) political tradition, of associations in myth invented to explain otherwise unknown acts of ritual and of a cycle of tales of adventure analogous to the story of the labours of Hercules. All the passages in the Iliad and Odyssey in which his name or allusions to his legend occur are regarded with more or less probability as spurious (but see O. Gropius, Gr. Myth., i. p. 581).

2 The sons of Pallas, the brother of Aegeus.
Theseus wished to see whether Theseus was really the son of Poseidon, flung his ring into the sea. Theseus dived and brought it up, together with a golden crown, the gift of Amphitrite. On the return voyage the ship touched at Naxos, and there Theseus abandoned Ariadne. He landed also at Delos, and there he and his comrades danced the crane dance, the complicated movements of which were meant to imitate the windings of the Labyrinth. In historical times this dance was still danced by the Delians round a horned altar. Theseus had promised Antiope, if he returned successful, the black sail with which the fatal ship always put to sea should be exchanged for a white one. But he forgot his promise; and when Aegeus from the Acropolis at Athens descried the black sail out at sea, he flung himself from the rock and died. Hence at the festival which commemorated the return of Theseus there was always weeping and lamentation. Theseus now carried out a political revolution in Attica by abolishing the semi-independent powers of the separate townships and concentrating those powers at Athens, and he instituted the festival of the Panathenaea, as a symbol of the unity of the Attic race. Further, according to tradition, he instituted the three classes or castes of the eumatrids (nobles), geomori (husbandmen), and demiurgi (artisans). He extended the territory of Attica as far as the isthmus of Corinth.

He was the first to celebrate in their full pomp the Isthmian games in honour of Poseidon; for the games previously instituted by Hercules in honour of Melicertes had been celebrated by night, and had partaken of the nature of mysteries rather than of a festival. Of Theseus’s adventures with the Amazons there were different accounts. According to some, he sailed with Hercules to the Euxine, and there he won the Athenian Antiope as the meed of valour; others said that he sailed on his own account, and captured Antiope by stratagem. Thereafter the Amazons attacked Athens. Antiope fell fighting on the side of Theseus, and her tomb was pointed out on the south side of the acropolis. By Antiope Theseus had a son, Hippolytus. On the death of Antiope, Theseus married Phaedra. She fell in love with her stepson Hippolytus, who, resisting her advances, was accused by her to Theseus of having attempted her virtue. Theseus in a rage imprecated on his son the wrath of Poseidon. His prayer was answered: Hippolytus was cast into the sea, a bull leaped out of the waves terrified his horses, and he was thrown and killed. This tragic story is the subject of one of the extant plays of Euripides.

The famous friendship between Theseus and Pirithous, king of the Lapiths, originated thus. Hearing of the strength and courage of Theseus, Pirithous desired to put them to the test. Accordingly he drove away from Marathon some cows which belonged to Theseus. The latter pursued, but when he came up with the robber the two heroes were so filled with admiration of each other that they swore brotherhood. At the marriage of Pirithous to Hippodamia (or Deidamia) a fight broke out between the Lapiths and Centaurs, in which the Lapiths, assisted by Theseus, were victorious, and drove the

Centaurs out of the country. Theseus and Pirithous now carried off Helen from Sparta, and when they drew lots for her she fell to the lot of Theseus, who took her to Aphidnae, and left her in charge of his mother Aethra and his friend Aphidnus. He now descended to the lower world with Pirithous, to help his friend to carry off Proserpine. But the two were caught and confined in Hades till Hercules came and released Theseus. When Theseus returned to Athens he found that a sedition had been stirred up by Menestheus, a descendant of Erechtheus, one of the old kings of Athens, and Thisbe, younger sister of Chiranthus. Theseus in despair sent his children to Euboea, and after solemnly cursing the Athenians sailed away to the island of Scyros, where he had ancestral estates. But Lycomedes, king of Scyros, took him up to a high place, and killed him by casting him into the sea. Long afterwards, at the battle of Marathon (490 B.C.), many of the Athenians fancied they saw the phantom of Theseus, in full armour, charging at their head against the Persians. When the Persian war was over the Delphic oracle bade the Athenians fetch the bones of Theseus from Scyros, and lay them in Attic earth. It fell to Gimon’s lot in 490 B.C. to discover the hero’s grave at Scyros and bring back his bones to Athens. They were deposited in the heart of Athens, and henceforth escaped slaves and all persons in peril sought and found sanctuary at the grave of him who in his life had been a champion of the oppressed. His chief festival, called Theseia, was on the 8th of the month Pyaneposin (October 21st), but the 8th day of every other month was also sacred to him.

Whatever we may think of the historical reality of Theseus, his legend almost certainly contains recollections of historical events, e.g. the areswode, whether by this we understand the political centralization of Attica at Athens or a local union of previously separate settlements on the site of Athens. The birth of Theseus, then points towards the year 1260 B.C. With this agrees the legend of the contest between Athena and Poseidon for supremacy on the acropolis of Athens, for Theseus is intimately connected with Poseidon, the great Ionian god. As the father of Theseus, has been identified by some modern scholars with Poseidon.

The well-preserved Doric temple to the north of the acropolis at Athens, commonly known as the Theseum, was long supposed to be the sanctuary in which the bones of Theseus repose. But archaeologists have generally abandoned this conjecture. There were several (according to Philochorus, four) temples or shrines of Theseus, of which one stood nominally at Athens, and all scholars have found one of them in the neighbourhood of Peiraeus.

Our chief authority for the legend of Theseus is the life by Plistrollerch, which is a compilation from earlier writers; see also G. Gillot, "Theseus", in "Reisen alterthumer", t. (1892), pp. 305-306; A. Baumeister, "Denkmäler des klassischen Alterthums", ill. (1888).

There is a modern Greek folk-tale which preserves some features of the legend of Theseus and the Minotaur, but for the Minotaur has been substituted a seven-headed snake. See Bernhard Schmidt, "Griechische Märchen, Sagen und Volkslieder" (1877), p. 118 sq.

Among modern monographs on Theseus may be mentioned:

A. Schulz, "De Theseo" (Breslau; 1874); Th. Kaesel, "De Thesei Synkloismo" (Dillingen, 1882); E. Prigge, "De Thesei rebus gatis" (1883); O. Wolf, "Zur Theseumage" (Darmst. 1892); see also O. Gruppe, "Griechische Mythologie", i. pp. 581-608; J. E. Harrison, "Mythology and Monuments of Ancient Athens" (1890); "Der Theseische Synkloismo", in C. F. Hermann's "Lichtbruch der Einehen Wandel des Staatensystems", i. (1892), pp. 305-306; A. Baumeister, "Denkmäler des klassischen Alterthums", ill. (1888).

THESMOPHORIA, an ancient Greek festival, celebrated by women only in honour of Demeter Oerodaphos. At Athens, Abyd, and perhaps Sparta, it lasted three days. At Athens the festival took place on the 11th, 12th and 13th of the month.

The Athenian festival in October, popularly supposed to commemorate the return of Theseus from Crete, is interesting, as some of its features are identical with those of harvest-festivals still observed in the north of Europe. Thus the Athenians at each autumn reaper’s festival baked loaves of bread, &c., which was carried in procession and hung over the door of the house, where it was kept for a year, is the Erntemai (Harvest-may) of Germany. See W. Mannhardt, "Antike Wald- und Feld-Kulte" (1877), p. 212 sq.

See Erläuternder Text to the "Karten von Attika" (Berlin, 1881), p. 37 sq.
The Thesmophoria (24th, 25th and 26th October), the first day being called Anodos (ascent), or, according to others, Kathodos (descent), the second Nesteia (fast), and the third Kalligeneia (fair-born). If to these days we add the Thesmophoria, which were celebrated on the 10th at Halimus, a township on the coast near Athens, the festival lasted four days. If we further add the festival of the Stenia, which took place on the 9th, the whole festival lasted five days. The Stenia are said by Philostratus (Life of Apollonius of Tyana, viii. 34), 16th century, that the women sat on the ground and fasted. As to what place on the Kalligeneia we have no information. Nor can we define the time or nature of the secret ceremony called the "pursuit," or the "Chalidchian pursuit," and the sacrifice called the "penalty." 16 During the Thesmophoria (and for nine days previously, if Ovid, Met., x. 434, is right, and refers to the Thesmophoria) the women abstained from intercourse with their husbands, and to fortify themselves stove their beds with Agnus castus and other plants. The women of Milethus stove their beds with pine branches, and the same custom is observed by Demeter. Whether unmarried women were admitted to the festival seems doubtful; in Lucian's time it would appear that they were. 18 The women of each deme (township) elected two married women of their number to preside over them at the festival; and every married man in the township who possessed property to the value of three talents had to provide a feast for the women on behalf of his wife. 19 During the festival the women seem to have been lodged by twos in tents or huts, probably erected within the sacred precincts of the Thesmophoria. They were not allowed to eat the seeds of the pomegranate or to wear garlands of flowers. Prisoners were released at the festival, 20 and during the Nesteia the law-courts were closed and the senate did not meet. 21 Aristophanes' play on the festival sheds little light on the mode of its celebration. At Thebes the Thesmophoria were celebrated in summer on the acropolis (Cadmeia); at Eretria during the Thesmophoria the women cooked their meat, not at fires, but by the heat of the sun, and they did not invoke Kalligeneia (which seems to mean that they did not celebrate the last day of the festival); at Syracuse during the festival, cakes, called mylloi, made of sesame and honey in the shape of pudenda melobeleia, were handed round. 22 Agrigentum, Ephebus and Dryme, in Phocis, had also their Thesmophoria. 19

The above was nearly all that was known about the Thesmophoria down to 1870. In that year E. Rohde published in his 'Die Festen des Kynoge', 248 sq., the name of Lucian (Dial. Meret., ii. 1), which he discovered in the Vatican MS. Palatinus 73, and which furnishes some curious details about the festival. It also furnishes some corrupt passages of Clemens Alexandrinus and Pausanias, the true history of which had been divined by Lobec (Agaephamus, p. 828). The substance of the scholion is this. When Persephone was carried off by Pluto, a swineherd called Eubules was herding his swine at the spot, and his herd was engulfed in the chasm down which Pluto had vanished with Persephone. Accordingly at the Thesmophoria it was customary, in memory of Eubules, to fling pigs into the chasms of Demeter and Persephone.('These "chasms" may have been natural caverns or perhaps vaults. The scholiast speaks of them also as adyta and megaras'). 23 In these adyta or megaras there were supposed to be serpents, which guarded the adyta and consumed all the flesh of the pigs that were thrown in. The decayed remains of the flesh were afterwards fetched by women called 'drawers' (anuletai), who, after observing rules of ceremonial purity for three days, descended into the caverns, and, frightening away the serpents by clapping their hands, brought up the remains and placed them on the altars. 23 Whoever got a portion of this decayed flesh and sowed it with the seed of the

---

1 [Or, mother of a fair daughter, i.e. Persephone.] Schol. on Aristoph., Thesmophoriae, 80 and 875: Diog. Laërt., ix. 43: Hesychius, s.v. προγλυπος (the reading here is uncertain) and ἄγνως: Aleiphron, iii. 39; Athenaeus, vii. 307 f. Plutarch (Vit. Demet., 30) states that the Nesteia took place on the 16th of Pyanepos, but in this he stands alone.

2 Schol. on Aristoph., Thesm., 80; Photius, Lex., s.v. θεσμομορφος χήμων ὅ (where Naber should not have altered the MS. reading ὅ into ὅ).

3 Thesmophoria at Halimus is mentioned by Pausanias (i. 31, 1).

4 Plut., Solon, 5; for this passage probably refers to the Thesmophoria of Halimus (see Expl. l. c. Text to the Karten von Altika, i. 1 sq.) The Thesmophoria at Halimus is mentioned by Pausanias (i. 31, 1).

5 For Plutarch, Arist., Thesm., 875, suppose that the day was so called because the women ascended to the Thesmophoria, which (according to the scholiast) stood on a height. But no ancient writer mentions a procession from Halimus. For Thesmophoria, see note on scholiast, Eubuleus, Conviv., on the Schol. ad ill. 6. For the statement that at one part of the festival (commonly assumed, by the writers who accept the statement, to be the Anodos) the women carried on their heads the "books of the law," we have only the authority of the scholiast on Theocritus, iv. 25, who displays his ignorance by describing the women as virgins (see below), and saying that they went in procession to Eleusis. The statement may therefore be dismissed as an etymological fiction. Aristophanes, Eccles., 222, is no evidence for the book-carrying.

7 The Boeotian festival of Demeter, which was held at about the same time as the Athenian Thesmophoria, and at which the megaras (see below) were opened, is distinctly stated by Plutarch (De Is. et Osir., 69) to have been a mourning for the descent (Kathodos) of Persephone.

8 Plut., Dem., 34; De Is. et Osir., 69.

9 [It was a day of holiday and rejoicing.]

10 Hesychius, s.v. διογλυπος [perhaps the pursuit of Persephone]; Such pursuit was common at Syracuse, as is shown in Sophocles, Trag. 7, 15: Aelian, Nat. An., ii. 34: Pausanias, i. 24, 4; viii. 53, 3; Diodorus, i. 91: Lobeck, Agaephamus (1829), p. 676; Marquardt, Staatsverwaltung, 2nd ed. (1885), ii. 375.

THESPIAE, an ancient Greek city of Boeotia. It stood on level ground commanded by the low range of hills which runs eastward from the foot of Mount Helicon to Thebes. The deity most worshiped at Thespiae, according to Pausanias, was Eros, whose primitive image was an unwarrought stone. The town contained many works of art, among them the Eros of Praxiteles, dedicated by Phryne in her native place; it was one of the most famous statues in the ancient world, and drew crowds of people to Thespiae. It was carried off to Rome by Caligula, restored by Claudius, and again carried off by Nero. There was also a bronze statue of Eros by Lysippus. The Thespians also worshipped the Muses, and celebrated a festival in their honour in the sacred grove on Mount Helicon. Remains of what was probably the ancient citadel are still to be seen, consisting of an oblong or oval line of fortification, solidly and regularly built. The adjacent ground to the east and south is covered with foundations, bearing witness to the extent of the temple area. The village Thespia on higher ground, was thought by Ulrichs to be probably the site of the ancient Cereus. In 1882 there were discovered, about 1200 yds. east of Eremonakastro, on the road to Arkopodi (Leuctra), the remains of a polyantrion, including a colossal stone lion. The tomb dates from the 5th century B.C., and is probably that of the Thespians who fell at Plataea, for those who fell at Thermopylae were buried on the field.

History.—Thespiae figures chiefly in history as an enemy of Thebes, whose centralizing policy it had all the more to fear because of the proximity of the two towns. During the Persian invasion of 480 B.C. it stood almost alone among Boeotian cities in rejecting the example of treason set by the Thebans, and served the national cause with splendid devotion. Seven hundred Thespians accompanied Leonidas to Thermopylae and of their own free will shared his last stand and destruction. The remaining inhabitants, after seeing their city burnt down by Xerxes, furnished a force of 1800 men to the confederate Greek army at Plataea. In 424 B.C. the contingent which the Thespians had been compelled to furnish sustained heavy losses at Delium, and in the next year the Thespians took part in this temporary enfeeblement to accuse their neighbours of desertion. After the battle of Plataea, the Thespians were evidently no more able to maintain their independence than the Thebans. In 414 B.C. they interfered again to suppress a democratic rising. In the Corinthian war Thespiae sided with Sparta, and between 379 and 372 repeatedly served the Spartans as a base against Thebes. In the latter year they were reduced by the Thebans and compelled to send a contingent to Leuctra (371). It was probably shortly after this battle that the Thebans used their new predominance to destroy Thespiae and drive its people into exile. The town was rebuilt at some later time. In 171 B.C., true to its policy of opposing Thebes, it sought the friendship of Rome. It is subsequently mentioned by Strabo as a place of some size, and by Pliny as a free city.

THESPIS (6th cent. B.C.), Greek poet, of Icaria, in Attica, generally considered the inventor of tragedy, flourished in the time of the Peisistratidae. According to Diogenes Laërtius (iii. 56), he introduced for the first time in the old dithyrambic choruses a person distinct from the chorus, who sang together with the leader, and was hence called ἐποχής ("answerer").

2 According to another explanation, he was so called from repeating of another—what the poet or composer.
His claim to be regarded as the inventor of tragedy in the true sense of the term depends upon the extent to which this person was really an "actor" (see Drama). Suidas gives the titles (of doubtful authenticity) of several of his plays (not confined to the legends of Dionysus, but embracing the whole body of heroic legends), but the fragments quoted in various writers as from Thespis are probably forgeries by Heracleides of Pontus. The statement of Horace (Ars Poetica, 276) that Thespis went round Attica with a cart, on which his plays were acted, is due to confusion between the origin of tragedy and comedy, and a reminiscence of the scurrilous jests which it was customary to utter from a waggon (σκόμματα εἰς ἄμφις) at certain religious festivals. A. and M. Croiset (History of Greek Literature, Eng. tr., 1904), who attach more importance to the part played by Thespis in the development of tragedy, accept the testimony of Horace. According to them, Thespis, actor and manager, transported his apparatus on a cart to the deme in which he intended to produce his drama, formed and trained a chorus, and gave a representation in public.

See Drama; and W. Christ, Griechische Litteraturgeschichte (1898).

**Thessalonians, Epistles to the**, two books of the New Testament. The Christian community in Thessalonica (mod. Salonica) was founded by Paul, Silvanus and Timothy, shortly before the visit to Athens and Corinth. The Gospel preached covered not only the general Christian convictions as to monotheism, belief in Jesus as Messiah Lord, and the impending judgment, but also the specifically Pauline doctrine of the indwelling Christ or Spirit, the earnest of acquittal at the Day of the Lord and of life with Christ for ever. It is the same Gospel as that preached in Galatia, in spite of the fact that the word "justification" does not appear in the Thessalonian letters (cf. 2 Thess. i. 11 f.). The converts, mainly Gentiles and chiefly manual labourers (many of whom, according to the episcopalian narrative of Acts xvii., had already associated more or less loosely to Judaism), suffered persecution from the beginning at the hands of their fellow-countrymen. Some of them, moreover, owing partly to this persecution, but mainly to the belief that the Lord was soon to return, gave up work, thus creating most of the difficulties with which Paul, in these letters, has to cope.

Forced to leave Thessalonica after a brief sojourn (how long is uncertain), Paul hastened to Athens, from which place he sent Timothy back to Thessalonica, being himself unable to go, much as he longed to see his converts. From Athens, Paul went on to Corinth, where Timothy joined him, bringing good news about the Thessalonian converts, especially about their endurance under affliction, and bringing likewise, as Rendel Harris has suggested, a letter from the Corinthians. Of this letter the opening paragraph only is worthy of notice. The sudden departure of Paul, and his failure to return, had been misinterpreted. Some were insinuating that Paul had preached with intent to deceive and as a pretext to cover impure designs (1 Thess. ii. 5); some, perhaps the same people, disregarding Paul's injunction (2 Thess. iii. 10), had remained idle, and had fallen into drunken habits (1 Thess. v. 7), having been tempted to revert to the impure worship of the heathen gods (1 Thess. iv. 3 f.), and, in their lack of funds, had demanded, speaking in the spirit (cf. Didachê xi. 12), money from the church officers, thus disturbing the peace of the church, and causing the soberer mind to question the validity of spiritual gifts (1 Thess. iv. 12 f., v. 12 f.).

Paul's reply, the First Epistle to the Thessalonians, written from Corinth in A.D. 53 or 48, is as tactful as Philemon and as personal as Galatians. In the first three chapters, he reviews his relation to the church from the beginning, commending highly the reception accorded to the Gospel and its messengers, and meeting the insinuations already alluded to by reminding the readers that, although as an apostle he was entitled not only to special respect but to an honorarium, yet he earned his living and loved them as a father. As to his failure to return, he explained that it was not his own fault. He wanted to go back but Satan hindered him. Even now, as he writes, he is praying that they may soon see them face to face. After the prayer, he takes up the points in which they had shown want of faith. To those who are tempted by the heathen worship, he points out that Christian consecration is something ethical, to be won only in the power of the consecrating Spirit. Respect for one's wife is an antidote to this enticement, and marriage with purity becomes better safeguard against adultery. Passing on to other points, he urges that there would be no sham in love of the brethren, if the idlers would work and mind their own business (1 Thess. iv. 1-12). There is no advantage in the Parousia of the living over the dead, for both simultaneously will meet the Lord. The desire for more accurate information about times and seasons is unnecessary, for their present knowledge is accurate enough, viz. that the day is to come suddenly and it is a day of destruction for the wicked. The main thing for them is to be prepared for that day (1 Thess. iv. 13-17). With the specific situation still in mind, he adds his final injunctions. Respect your presiding officers, purposely called "the labourers," and let there be peace. Warn the idlers, encourage those who are impatient of the Parousia, and cling to those tempted by the heathen worship. In spite of the temptation to avenge your persecutors, be patient with them, return good for evil, exemplifying to all what is the Christian good. In spite of affliction, let there be joy, prayer and Thanksgiving (1 Thess. v. 14-18).

The charismata are to be respected, and at the same time esteemed (ibid. 19-22). A prayer for complete consecration, a charge that all should bear the letter read (apparently the leaders were tempted to neglect the idlers and the idlers had threatened not to listen to any epistolary communication from Paul), and a benediction bring the letter to an end (ibid. 23-28).

Such a letter, dominated as it is by the spirit of the Paul we know and fitting nicely the recoverable situation, is unquestionably genuine, and few there be who deny it.

What effect this letter had, it is impossible fully to say. Apparently, it did not quell the excitement for which the idlers were largely responsible. Paul's discussion of the relation of the Second Epistle. On the Parousia seems insufficient. His refusal to go further into times and seasons than the statement "the day comes as a thief in the night," is made the point of departure for the idlers to assert, on the basis of alleged spiritual utterances, corroboration to the dismay of the leaders, by a reference to an anonymous letter reckoned to the account of Paul, that "the day is present." The troubled leaders send post-haste a letter to Corinth stating the situation and asking definite opinions as to the Parousia and the assembling of the saints. Paul is grievously disturbed, both because the first letter, in his judgment, had a dangerous tendency to the future life in Christ, and because the second letter seemed insufficient. A short interval has elapsed, to be reckoned in weeks, when Paul, with the first letter distinctly in mind and with a vivid recollection of his oral teaching on mooted points, hastens with Silvanus and Timothy to write the Second Epistle.

In one long sentence of prayer and thanksgiving (2 Thess. i. 3-12), he insists tactfully that their religious-ethical growth makes it his bounden duty to thank God, in spite of their written remurrer, compels him indeed of his own motion to boast of their faith and endurance, qualities which are the life of the Divine purposes; as to account them worthy of the kingdom for which they, as they wrote, as well as he, are suffering. Suddenly remembering a Pharisaic Psalm, not unlike in proportion to one of the Psalms of Solomon, and admirably adapted to his present purpose, namely, of contrast of the fate of the wicked with that of the righteous at the Parousia, he quotes it, making a few Christian touches in his own style (2 Thess. i. 6-10). Whereupon he prays, as they too prayed in their letter, that God would deem them worthy of the calling, and ensure them of the acquisition at the last day, by giving them in the power of the Spirit that presents life in the Spirit of guidance to the future life in Christ. Then, disregarding the request for more information about the assembling, of which, he thinks, he had spoken sufficiently in his first letter,
he addresses himself to the other question of the "when" of the Parousia, supplementing what was said in the first letter, but adding nothing to what he had already said orally in their presence, and stoutly disclaiming all authority whatever for the statement "the day is present." Briefly and allusively, in language which has nothing specifically Christian in it, he follows the familiar story. The day does not come until the final revolt in heaven and until the lawless one (the man of lawlessness, the son of Perdition) is revealed, which revelation cannot happen, until the controlling or restraining thing or person is removed. Then, however, the tool of Satan will appear, but the Lord will destroy him with the breath of his mouth and annihilate him with the majesty of his presence (2 Thess. i. 1-12).

Following the formal order of the First Epistle, he again thanks God that his converts are chosen to salvation and prays that they may have strength and obey his orders oral or written. Even with a "finality," as in the first letter, he is not quite through, for the second point of the letter remains to be treated—"the idlers." These, he says, must remember both his example (he was never guilty of begging) and his precept ("if any man will not work let him not eat"). They must work quietly and eat their own food. Those who refuse to heed his written orders are to be noted. The test of the genuineness of his letters is his autograph greeting (2 Thess. ii. 13—iii. 18).

The letter meets the known situation excellently. The new material, compared with the First Epistle, is the supplementary discussion of the time of the Parousia (2 Thess. i. 1 ff.) and the fuller treatment of the idlers (2 Thess. iii. 1 ff.), the points about which the leaders sought advice. The style is Pauline even in the adaptation of Jewish apocalyptic material to Christian purposes. Indeed, the outline of the letter is strikingly similar to that of the First Epistle, and many phrases hold over. At the same time there is a freedom of style suggesting not the imitator but the same author. And above all, especially in the treatment of the idlers, the letter reveals a knowledge of the situation which is even more explicit than that of the First Epistle. On such grounds together with the excellent external attestation it is probable, as recent writers hold (e.g. Zahn, Wohlenberg, Harnack, Jülicher, Findlay, Askwith, Charles, Bacon, McGiffert, Moffatt, Milligan, et al.), that the letter is Paul's.

The objection to the Pauline authorship felt by the Tübingen school may, for brevity's sake, be here disregarded. The modern difficulties, expressed mainly by recent German scholars (e.g. Wrede and Holtzmann and others), centre not in the un-Pauline language or in the lack of the personal element, but in the eschatology and the over-Pauline character of the language. As to the first objection, it is realized that in the section i. 1-12 is scarcely an interpolation, since it is one of the two main reasons for the letter; that the material of the section is a distinct allusion to, if not a direct quotation of, a definite bit of Jewish apocalyptic, even if we do not connect it, as Bousset does, with a so-called Antichrist legend; that the alleged inconsistency between the eschatology of the First and the Second Epistle does not exist, for in the first letter Paul says not that the day is present, but that the day, when it comes, comes suddenly "as a thief in the night," while in the second letter he expressly denies the statement attributed to him, namely, that the day is imminent. Wrede, in his brilliant argument against the genuineness of the letter (Die Echtheit des zweiten Thessalonicherbriefes, 1905), inclines to admit that the argument from eschatology is secondary.

As to the second objection, the over-Pauline character of the letter, an objection used with rigour by McGiffert (whose article on these letters in the Ency. Biblica is the most satisfactory discussion known to the present writer), and renewed independently by Wrede, it is to be admitted that the similarity of the second to the first letter is striking, particularly in the formal arrangement of the material. At the same time, however, differences, both in arrangement and in the content of the reminiscences, are not to be overlooked, as McGiffert and after him Wernle (Göth. gel. Anz., 1905, pp. 347-52) have both rightly maintained. Again there should be no disparagement of the new material such as is to be found in Holtzmann's acute discussion (Z. N. T. W., 1901, pp. 97-108). On the whole, the perplexing situation seems to be met on the assumption that Paul writes the Second Epistle either with a letter from Thessalonica before him, which itself suggested the main points of his own epistle, or with a copy or a summary of that epistle before him (cf. Zahn and McGiffert).

The alternative is forgery, as Holtzmann, Wrede and Hollmann (Z. N. T. W., 1904, pp. 28-38) actually hold. The difficulty with this hypothesis is that it does not explain so many facts as the hypothesis of Pauline authorship. As it is improbable that the forger would write during the lifetime of Paul, the date has to be put either shortly after his death, or with Wrede at the end of the century. But this late date creates the insuperable difficulty that iii. 1 ff. gives a more explicit account of the original situation in Thessalonica touching the idlers than does the First Epistle. The purpose moreover of the forgery could not be to discredit the First Epistle as un-Pauline, for the alleged trouble is that the Second Epistle is too Pauline. Hence the purpose is to correct the statements of the First Epistle. If, however, there is no inconsistency between the two letters on the score of eschatology, what is the forger's purpose? The teaching about premonitory signs is not new to Thessalonica, but is assumed as known, hence the allusive character of the second chapter. The statements in ii. 2 and iii. 17 are easily explicable on the hypothesis that the idlers found an anonymous letter and attributed it to Paul, especially when they thought, perhaps in good faith, that the Spirit had indicated that the day is present. Finally, the forger handles Paul's style with miraculous knowledge, not only reproducing phrases from the first letter, but knowing how to amend them to present purposes with singular naturalness. When it comes to putting Christian touches to a Jewish fragment, the touches turn out to be uniquely Pauline, although they are not obviously Pauline (e.g. i. 6-10 'ἐν πυρῷ,' "obey the Gospel thus as was believed"). And even with the thought of Paul, he is curiously at home. So certain is he of the substance of Paul's thought, that he can reproduce it in a concise sentence without recourse to the word "justification" (e.g. i. 11). On the whole, then, the situation created by the literary relation of the two letters is best met by the hypothesis that Paul is the author of the Second Epistle.

In addition to the literature mentioned under Colossians, Epistle to the, and the special literature already named in this letter, attention should be made to the commentaries on these letters by Ellicott (1888), Jowett (1859), Eadie (1877), Hutchinson (1883), Lightfoot (Notes, 1895), Drummond (1889), Findlay (1892 and 1904), Milligan (1908), and Moffatt (1908); and by Schmidt (1885), Zimmer (1884-93), Schmiedel (1892), Zückler (1894), Bornemann (1894), B. Weiss (1896) and Wohlenberg (1903).

**THESSALY**, a district of northern Greece, between Macedonia and the more purely Hellenic countries towards the south, and between the upland region of Epirus and the Aegean Sea. It forms an irregular square, extending for about sixty miles in each direction, and this area, which is for the most part level, is enclosed by well-marked boundaries—by the Cambunian mountains on the north, by the mountains of Pieria on the north-east, by Mount Ossa on the south, and on its western side runs the massive chain of Pindus, which is the backbone of this part of Greece, and towards the east Ossa and Pelion stand in a continuous line; at the north-eastern angle is Olympus, the keystone of the whole mountain system. The elevation of some of the summits in these ranges is considerable, for three of the peaks of Pindus are over 5000 ft., and Olympus, Ossa and Pelion reach respectively the height of 9790, 6398 and 5350 ft. The country that is contained within these limits is drained by a single river, the Peneius, which, together with the water of its numerous confluent, passes into the sea through the Valley of the Tempe.

On the north side of Thessaly there was an important pass from Petra in Pieria by the western side of Olympus, debouching on the
plain northward of Larissa; it was by this that Xerxes entered, and we learn from Herodotus (vii. 173) that, when the Greeks discovered the existence of this passage, they gave up all thoughts of defending Tempe. On the side of Epirus the main line of communication from Thessaly lay to the north of Mount Lacmon, and descended the upper valley of the Peneus to Aeginium in the north-west angle of Thessaly. This was the road of the Thessalians, and the battle of Parnassus was fought by them on this line. Another pass through the Pindus chain was that of Gomphi, farther south, by means of which there was communication with the Ambracian Gulf. The great southern pass was that of Coela, which led to the plain of Megaritis and Thermopylae. The passes of sections which open out into one another, divided by ranges of hills, the principal of these were called Upper and Lower Thessaly, the former was in the central, the latter in the western districts, which contains the higher course of the Peneus and all those of its tributaries that flow from the south—the Enipeus, the Apidanus, the Onocoron and the Pamisos; while the latter, which runs eastward to the foot of Ossa and Pelion, is inundated in parts at certain seasons of the year by the Peneus, the flood-water from which forms the lake Nessos, and, when that is full, escapes again and pours itself out to the lake of Boeotia. The chief city of the latter of these districts is Tricarta; and there were separate districts, one another by a long spur, which runs southwards from the Cambian Mountains on the western side of that city. Again, when Thessaly descends to the plains of Copais and Oropus, there is a plain, containing a small lake, which was formerly called Xynias, intervenes, and a line of low hills has to be crossed before the town of Thaumaki is reached, which, from its commanding position overlooking the plain, has been described by Livy in the following remarkable passage:—

"When the traveller, in passing through the rugged districts of Thessaly, where the roads are entangled in the windings of the valleys, arrives at this city, on a sudden an immense level expanse, resembling a vast sea, is outspread before him in such a manner that the eye cannot easily reach the limit of the plains extended beneath,'" (xvii. 4). To the north-east of this, where a portion of the great plain begins to run up into the mountains, the Plain of Pharsalia is formed, which is intersected by the river Enipeus; and still farther in the same direction is the scene of another great battle. It intervenes between the plains of Thessaly and those of the Thessalian districts, of which Pelasgiaeae the lower plain of the Peneus, and Hestiaeotis and Thessaliotis respectively the northern and the southern portions of the upper plains; while the fourth Phitioiates, which lies towards the south-east, was geographically distinct from the rest of the country, being separated from it by a watershed. The determining feature of this is the Pagasaeus Sinus (Gulf of Volo), a landlocked basin, extending from Pagoae at its head to Apethae at its narrow outlet, where the chain of Pelion, turning at right angles to its axis at the end of Magnesia, throws out a projecting line of broken ridges, while on the opposite side, the spurs of the Olympus range the whole line of the coast, of great importance. It was the birthplace of Greek navigation, for this seems to be implied in the story of the Argonauts, who started from here in the expedition to the land of the Hyperboreans. From it the great Achilles came, and, according to Thucydides (i. 3), it was the early home of the Hellenic race. The site of Iolcos, the centre of so many poetic legends, is at no great distance from the modern Volo. Near that town also, at a later period, Demetrius Poliorcetes founded the city of Demetrias, which was called by Philip V. of Macedon one of the three fetters of Greece, Chalcis and Corinth being the other two.

The history of Thessaly is closely connected with its geography. The fertility of the land offered a temptation to invaders, who carried their impulses all over the Thessalian plains. It was this motive which first induced the Thessalians to leave their home in Epirus and descend into this district, and from this movement arose the expulsion of the Boeotians from Arne, and the settlement in the country subsequently called Boeotia; while another wave of the same tide drove the Dorians also southward, whose migrations changed the face of the Peloponnesus. Again, this rich soil was the natural home of a powerful aristocracy, such as the families of the Aleuadai of Larissa and the Scopaei of Cramnon; and the absence of external defence was a temptation to the four zones of cities, which might have fostered the spirit of freedom and democracy. The plains, also, were suited to the breeding of horses, and consequently the force in which the Thessalian nation was strong was cavalry, a kind of troops which has usually been associated with oligarchy. The wealth and the semi-Hellenic character of the people—for in race, as in geographical position, the Thessalians held an intermediate place between the non-Hellenic Macedonians and the Greeks of pure blood—caused them to be wanting in patriotism, so that at the time of the Persian wars we find the Aleuadai making common cause with the enemies of Greece. When they were united they were a formidable power, but, like other half-organized communities, they seldom combined for long together, and consequently they influenced but little the fortunes of the Greeks.

For several centuries during the middle ages Rumanian immigrants formed so large a part of the population of Thessaly that that district was called by the Byzantine writers Great Wallachia (Μεγάλη Βαλαχία): the Jewish traveller, Benjamin of Tudela, who visited this region in the middle of the 12th century, describes them as then occupying it. At the present day only a few colonies of that race remain, the principal of which are found on the western side of Olympus and in some of the gorges of Pindus. The Turkish inhabitants were settled in the larger towns, and here and there in the country districts, the most important colony being those called Koniarites, who were brought from Konia in Asia Minor shortly before the taking of Constantinople, and planted under the south-west angle of Olympus. The Greeks, however, form the majority of the population, and are either native born or of recent origin. In the country belonged to the Ottomans, Greek was employed as the official language. In accordance with the provisions of the Berlin treaty, Thessaly was ceded to the Greeks by the Porte in 1881, and became a portion of the Hellenic kingdom. Since that time the prosperity of the province has greatly increased. The port of Volo, which is almost the only outlet of the trade of the whole district, has become an important town of 23,000 inhabitants, and daily communication by steamers now exists between it and Athens. The interior of the country has also been opened up by means of railways. One line runs north-westwards from Volo by way of Velestino (the ancient Phocis) to Larissa, which is situated on the Salambria (Peneus), and has a population of 18,000 souls, including 2000 Jews. The Greeks, Turks and Jews here occupy different quarters of the city, but most of the Turkish inhabitants have now quitted the country, so that only four of the numerous mosques remain in use. From Velestino another line branches off to the west by Pharsala (Pharsalos), Domokos (Thaumaki), Karditsa, and Trikala (Trika), to Kalabaka (Aeginion), where the upper valley of the Salambria is enters in the neighborhood of the last-named place, where the Cambanian chain of mountains descends in steep precipices to the plain, the Meteora ("mid-air") monasteries (see METEORA).

THETFORD, a market town and municipal borough of England, mostly in the south-western parliamentary division of Norfolk, but partly in the Stowmarket division of Suffolk, 91 m. N.N.E. from London by the Great Eastern railway. Pope (1901) 4,513; and 1,769 in 1861. The town lies in a level, fertile country at the junction of the river Thet with the Little Ouse. In the time of Edward III. the town had twenty churches and eight monasteries. There are now three churches—St Peter's, St Cuthbert's and St Mary's—principally of Perpendicular flint work; of these St Mary's, on the Suffolk side, is the largest. There are a few monastic remains, the chief being two gate-houses. The most important relic of antiquity is the Castle Hill, a mound 1000 ft. in circumference and 100 ft. in height. The grammar school was founded in 1610. In King Street is the shanck-house occupied as a hunting-lodge by Queen Elizabeth and James I. The chief public buildings are a gild hall and a mechanics' institute; there are several charities. Brewing and tanning are carried on; and there are also manure and chemical works, brick- and lime-kilns, flour-mills and agricultural implement works, engineering works and iron foundries. The Little Ouse is navigable for barges down to
the Great Ouse. Thetford is a suffragan bishopric in the diocese of Norwich. The town is governed by a mayor, 4 aldermen, and 12 councillors. Area, 7,096 acres.

Early antiquaries identified Thetford (Theodoford, Tetford, Teford) with Sitomagus, but modern research shows that there is no conclusive evidence of a permanent settlement before the coming of the Angles. Tradition tells that Uffa, who probably threw up the earthworks called the Castle Hill, established the capital of East Anglia here about 575. Thetford owned a royal mint in the 9th century and was a flourishing town when the Conqueror acquired it. Richard I. granted it to Hamelin, Earl Warenne, and when his heirs failed, it merged in the duchy of Lancaster and so in the crown. About 1290 its principal officers were a mayor and coroner, afterwards assisted by eight burgesses, whom Henry VIII. increased to ten. The town, never very prosperous since the Conquest, had then fallen into great decay, but the petitions of the burgesses for a charter were not heeded till 1573 when Elizabeth incorporated it under a mayor and common council. This charter, restored in 1692 after its surrender to Charles II., remained in force till 1835 when the borough was re-constituted. Thetford returned two members to parliament from 1529 till its disfranchisement in 1868. Its Saturday market, which certainly existed in the 13th century, was granted by the charter of 1573 and also a Magdalen fair (the 22d of July). Fisheries were important in the 13th century.

See A. L. Hunt, Capital of East Anglia (1879); T. Martini, History of Thetford (1779).

THETIS, in Greek mythology, daughter of Nereus, wife of Peleus and mother of Achilles. The chief of the fifty Nereids, she dwelt in the depths of the sea with her father and sisters. When Dionysus leaped into the sea to escape from the pursuit of Lycurgus, king of the Thracian Edones, and Hephæstus was flung out of heaven by Zeus, both were kindly received by Thetis. Again, when Hera, Athena and Poseidon threatened to bind Zeus in chains, she sent the giant Anguron, who delivered him out of their hands. She was married against his will to Peleus (q.v.; see also Achilles). Thetis is used by Latin poets simply for the sea.

THEURIET, CLAUDE ADHÉMAR ANDRÉ (1833-1907), French poet and novelist, was born at Marly-le-Roi (Seine et Oise) on the 8th of October 1833, and was educated at Bar-le-Duc in his mother’s province of Lorraine. He studied law in Paris and entered the public service, attaining the rank of chef de bureau before his retirement in 1886. He published in 1867 the Chemin des bois, a volume of poems, many of which had already appeared in the Revue des Deux Mondes; Le bleu et le noir, bolsmes de la vie réele (1874), Nos isaux (1886), and other volumes followed. M. Theuriet gives nature, simple pictures of rustic and especially of woodland life, and Théophile Gautier compared him to Jaques in the forest of Arden. The best of his novels are those that deal with provincial and country life. Among them are: Le mariage de Gérard (1875); Raymonde (1877); Le fils Mawars (1879); La maison des deux Barbeaux (1879); Sauvagone (1880); Reine des bois (1880); Villa tranquille (1891); Le manuscrit du chanoine (1902). Theuriet received the 3rd prize of the Academy of France, of which he became a member in 1896. He died on the 23rd of April 1907, and was succeeded at the Academy by M. Jean Richepin.

See Emm. Besson, André Théuriet (1890).

THÉVENOT, JEAN DE (1633-1667), French traveller in the East, was born in Paris on the 16th of June 1633, and received his education in the college of Navarre. The perusal of works of travel moved him to go abroad, and his circumstances permitted him to please himself. Leaving France in 1652, he first visited England, Holland, Germany and Italy, and at Rome he fell in with D’Herbelot, who invited him to be his companion in a projected voyage to the Levant. D’Herbelot was detained by private affairs, but Thévenot sailed from Rome in May 1655, and, after vainly waiting five months at Malta, took passage for Constantinople alone. He remained in Constantinople till the end of the following August, and then proceeded by Smyrna and the Greek islands to Egypt, landing at Alexandria on New Year’s Day, 1657. He was a year in Egypt, then visited Sinai, and, returning to Cairo, joined the Lent pilgrim caravan to Jerusalem. He visited the chief places of pilgrimage in Palestine, and, after being twice taken by corsairs, got back to Damietta by sea, and was again in Cairo in time to view the opening of the cataract on the rise of the Nile (on the 14th of August, 1657). In January 1659 he sailed from Alexandria in an English ship, taking Goleta and Tunis on the way, and, after a sharp engagement with Spanish corsairs, one of which fell a prize to the English merchantman, reached Leghorn on the 12th of April. He now spent four years at home in studies useful to a traveller, and in November 1663 again sailed for the East, calling at Alexandria and landing at Sidon, whence he proceeded by land to Damascus, Aleppo, and then through Mesopotamia to Mosul, Bagdad and Mendeli. Here he entered Persia (the 27th of August, 1664), proceeding by Kermanah and Hind to Isfahan, where he spent five months (October 1664-February 1665), and then joined his party with that of the merchant Tavernier, proceeded by Shiraz and Lar to Bander-Abbas, in the hope of finding a passage to India. This was difficult, because of the opposition of the Dutch, and though Tavernier was able to proceed, Thévenot found it prudent to return to Shiraz, and, having visited the ruins of Persepolis, made his way to Basra and sailed for India on the 6th of November 1665, in the ship "Hopewell," arriving at the port of Surat on the 10th of January 1666. He was in India for thirteen months, and crossed the country by Goconda to Masulipatnam, returning open to the sea, from where he sailed to Bander-Abbas and went up to Shiraz. He passed the summer of 1667 at Isfahan, disabled by an accidental pistol-shot, and in October started for Tabriz, but died on the way at Miyana on the 28th of November 1667.

Thévenot was an accomplished linguist, skilled in Turkish, Arabic and Persian, and a curious and diligent observer. He was also well skilled in the natural sciences, especially in botany, for which he made large collections in India. His personal character was admirable, and his writings are still esteemed, though it has been justly observed that, unlike Chardin, he saw only the first picture of the East, and did not find the second. He was posthumously published from his journals in 1674 and 1684 (all 4to). A collected edition appeared at Paris in 1689, and a second in 12mo at Amsterdam in 1727 (5 vols.). There is an indifferent English translation by A. Lovell (London, 1689).

THIAZINES, in organic chemistry, a series of cyclic compounds containing a ring system of four carbon atoms, one nitrogen and one sulphur atom. These may be grouped in three ways, giving the following skeletal structures:

\[ \begin{align*}
(1) & \quad C - C - N \\
(2) & \quad C - C - S \\
(3) & \quad C - N - C \\
(4) & \quad C - S - C 
\end{align*} \]

Members of the first series have not as yet been isolated. Derivatives of the second type have been obtained by A. Luchmann (Ber. 1896, 29, p. 1429) by condensing γ-chlorobutylamine with carbon bisulphide or with mustard oils in the presence of caustic alkali; by M. Kahn (ibid., 1897, 30, p. 1321) on condensing bromhexylamine hydrobromide with thieno-azimide:

\[ \text{CH}_2\text{CH}(_2)\text{CH}(_2)\text{Br} + \text{HS} \rightarrow \text{CH}_2\text{CH}(_2)\text{CH}(_2)\text{S} \]

Benzothiazines are obtained from ortho-aminobenzyl halides and thio-amides:

\[ \text{CH}_2\text{N} + \text{H}_2\text{N} + \text{CS} \rightarrow \text{CH}_2\text{N} \]

The most important thiazines are those derived from class III., thiodiphenylamine, CsHs, being the parent substance of the methylene blue series of dyestuffs. Thiodiphenylamine
is obtained synthetically by heating sulphur with diphenylamine or by the condensation of ortho-aminophenol with pyrocatechin. It is a compound of neutral reaction. The first known dyestuff of this series was Lauth's violet, which was prepared by oxidizing paraphenylene diamine in acid solution in the presence of sulphur. By using dimethyl paraphenylene diamine in place of the simple diamine, methylene blue is obtained. The relationship of these substances to thiophenyldiamine was shown by A. Bernthsen, who, by nitrination of thiophenylamine, obtained a dinitro-compound which on reduction was converted into the corresponding di-aminodervative and this on oxidation yielded Lauth's violet.

Methylene blue is the most important of all blue basic dyes and is put on the market frequently in the form of its zinc chloride double salt, which is soluble in water. Acid oxidents in dilute aqueous solution convert it into methylene azure.

See further A. Bernthsen, Ann., 230, p. 731; 251, p. 1; German Patents 45839 (1887); 47374 (1888). For a discussion as to the constitution of these dyestuffs, whether they are quaternary amomnium salts or a-haloid amides, see A. Ber., 1906, 39, pp. 153, 1365; F. Kehrmann, ibid., 1906, 39, p. 914.

THIAZOLES, in organic chemistry, a series of heterocyclic compounds containing the grouping shown below; the replaceable hydrogen atoms in which are designated a, b and μ. They are prepared by condensing thio-amides with a-haloid ketones or aldehydes, the thio-amide reacting as the tautomeric thio-imino acid. Amino derivatives similarly result from thio-ureas and a-haloid ketones; the o xo derivatives from a-sulphocyanoketones by the action of caustic alkali; and the carboxylic acids from chloro-aceto-acetic ester, &c. and thio-amides. The thiazoles are somewhat basic in character, and combine with the alkyl iodides to form thiazolium iodides.

Dihydrothiazoles, or thiazoline, are obtained by condensing ethylene dibromides with thio-amides; by the action of β-haloid alkylamines on thio-amides (S. Gabriel, Ber., 1881, 24, p. 755; 1896, 29, p. 2610); and by the action of phosphorus pentasulphide on acetyl-β-bromalkylamides (A. Salomon, Ber., 1893, 26, p. 1328). They are much less stable than the thiazoles. The benzothiazoles are a series of weak bases formed by condensing carboxylic acids with ortho-aminophenolhs (A. W. Hofmann, Ber., 1880, 13, p. 1224), by heating the acid anilides with sulphur or by the oxidation of thiazoles. On fusion with caustic alkalis they decompose into their constituent aminothionaphenol and acid. Derivatives of this group are important as substantive cotton dye-stuffs.

THIBAudeau, CLAIR ANTOINE, COMTE (1765-1834), French politician, was born on the 23rd of March 1765, the son of Antoine de Thibaudeau (1739-1813), a lawyer of Poitiers and a deputy to the States-General of 1789. He was admitted to the bar in 1787, and in 1789 accompanied his father to the States-General at Versailles. When he returned to Poitiers in October he immediately set up a local revolutionary club, and in 1792 was returned as a deputy to the Convention.

Thibaudeau joined the party of the Mountain and voted for the death of Louis XVI. unconditionally. Nevertheless he incurred a certain amount of suspicion because he declined to join the Jacobin Club. In May 1793 he was on a special mission in the west and prevented his department from joining the Federalist movement. Thibaudeau occupied himself more particularly with educational business, notably in the organization of the museum of the Louvre. It was he who secured the inclusion of Tom Paine's name in the amnesty of Girondist deputies. Secretary and then president of the Convention for a short period, he served on the Committee of Public Safety and of Generality Security. After the insurrection of 13 Vendémiaire (5th October 1793) he opposed those Thermidorians who wished to postpone the dissolution of the Convention. At the elections for the Corps Législatif he was elected by no less than thirty-two departments. It was only by the intervention of Boulay de la Meurthe that he escaped transportation after the coup d'état of 18 Fructidor (4th September 1797), and he then returned to the practice of his profession. The establishment of the consulate brought him back to public life. He was made prefect of the Gironde, and then member of the council of state, in which capacity he worked on the civil code. He at this time had Napoleon's confidence, and gave him whole-hearted support. He did not entirely conceal his disapproval of the foundation of the Legion of Honour, of the Concordat, and of the Consulate for life, and his appointment as prefect of the Bouches du Rhône, with consequent banishment from Paris, was a semi-dissuage.

A peer of the Hundred Days, he fled at the second Restoration to Lausanne. During his exile he lived in Vienna, Prague, Augsburg and Brussels, occupying himself with his Mémoires sur la Convention et le Directoire (Paris, 2 vols., 1824); Mémoires sur le Consulat: par un ancien conseiller d'état (Paris, 1827); Histoire générale du Napoleon Bonaparte (6 vols., Paris and Stuttgart, 1827-28, vol. iii: not printed); Le Consulat et l'Empire, vol. i, of which is identical with vol. vi. of the Histoire de Napoleon (10 vols., 1834). The revolution of 1830 permitted his return to France, and he lived to become a member of the Imperial Senate under the third empire. He died in Paris on the 8th of March 1854 in his eighty-ninth year.

The special value of Thibaudeau's works arises from the fact that he wrote only of those events of which he had personal knowledge, and that he quotes with great accuracy Napoleon's actual words. His Mémoires sur le Consulat has been translated into English, with introduction and necessary notes, by G. K. Fortescue with the title of Bonaparte and the Consulate (1808). Among the papers left by Thibaudeau were documents of the Moniteur Universel and Mémoires avant ma nomination à la Convention. These were published in a small volume (Paris and Niort, 1875) which includes a list of his works and of the narrative of his life.

THIBAUT (or TRIBAUD) IV. (1201-1253), count of Champagne and Brie, and king of Navarre, French poet, was born at Troyes in 1201. His father, Thibaut III of Champagne, died before his son's birth, and his mother, Blanche of Navarre, was committed to regency. The documents of the period are addressed to Philipp Augustus, king of France, but there is little doubt that the child was acquainted with Chrétien de Troyes and the other trouvères who found patronage at the court of Champagne. Thibaut's verses belong to what is called "courtly" poetry, but they have a personal note that distinguishes them from mere exercises. They are addressed to Blanche of Castille, the wife of Louis VIII., and Thibaut's relations with her have been the subject of much controversy. The count took part with Louis in the crusade against the Albigenenses, but in 1226, with no apparent reason, left the king and returned to Champagne. Three months later Louis died under doubtful circumstances, and Thibaut was accused by his enemies of poisoning him to facilitate his own intrigue with Blanche. The real reason for Thibaut's desertion appears to have been a desire to consolidate his position as heir-apparent of Navarre by an alliance with the disaffected nobility of the south of France, but from this confederation Blanche was skilful enough to detach him. The resentment of the league involved him in a war in which Champagne was laid waste, and his capital saved only by the royal intervention. In 1231 he succeeded his uncle, Sancho VII., as king of Navarre, and from this period date his most fervent songs in praise of his lady. The crusade turned Thibaut's thoughts to religion, and he announced his intention of singing henceforth only in honour of the Virgin. Unfortunately his devotion took darker forms, for before sailing for the Holy Land he ordered and witnessed the burning of a hundred and eighty-three unfortunate men and women convicted of Manichaism. The years 1239 and 1240 were spent in Palestine, and from the time of his return Thibaut devoted
himself to efforts for the improvement of his dominions which he won for him the title of le Bon. He died at Pampeluna on the 14th of July 1253.

Thibaut was the most popular of all the 13th century song-writers, and his work is marked by a grace and sweetness which he alone was able to maintain with the troubadours of the south. He is said to have set his songs to German melodies, and it seems doubtful whether the notes that have come down to us can with justice be attributed to him, but there is no contesting the musical quality of his verse. He was a master beyond the Pyrenees, and Dante admired his poetry. He was one of the most celebrated authors of *jeux-paris*, elaborate discussions between two interlocutors, usually on the subject of love.

Thibaut wrote, was edited in 1851 by T. Tarbé in his Chansonniers de Champagne.

THIBAUT, ANTON FRIEDRICH JUSTUS (1774-1840), German jurist, was born at Hameln, in Hanover, on the 4th of January 1774, the son of an officer in the Hanoverian army, of French Huguenot descent. After passing his school-days in Hameln and Hanover, young Thibaut entered the university of Göttingen as a student of jurisprudence, went thence to Kiel, where he studied under Kant, and afterwards to Kiel, where he worked for a faher-in-law with Niebuhr. Here, after taking his degree of doctor juris, he became a Privatdozent. In 1798 he was appointed extraordinary professor of civil law, and in the same year appeared his *Versuche über einzelne Theile der Theorie der Rechts* (1798), a collection of essays on the theory of law, of which by far the most important was entitled *Über den Einfluss der Philosophie auf die Auslegung der positiven Gesetze*, wherein he sought to show that philosophy without philosophy could not interpret and explain law. In 1799 was published his *Theorie der logischen Auslegung des römischen Rechts*, one of his most remarkable works. In 1802 he published a short criticism of Feuerbach's theory of criminal law, which recalls in many ways the speculations of Bentham. The same year appeared *Über Besitz und Verjährung*, a treatise on the law of possession and the limitation of actions. In 1802 Thibaut was called to Jena, where he spent three years and wrote, in Schiller's summer-house, his chief work, *System des Pandektenrechts* (1803), which ran into many editions. The fame of this book depends before all else upon the fact that it was the first modern complete compendium of the subject, distinguished alike by the accuracy of its sources and the freedom with which subject is handled. It is, in effect, a codification of the Roman law as it was practiced in Germany, modified by Canon law and the practice of the courts into a comprehensive system of Pandect law. At the invitation of the grand-duke of Baden he went to Heidelberg to fill the chair of civil law and to assist in organizing the university; and he never quitted that town, though he received in after years, as his fame grew, invitations to Göttingen, Munich and Leipzig. His class was large, his influence great; and, except Gustav Hugo and Savigny, no civilian of his time was so well known. In 1814 appeared his *Civilistische Abhandlungen*, of which the principal was *Hessbach's* *Thesis*, an essay of so much literature, on the necessity of a national code for Germany (*vide infra*). In 1819 he was appointed to the upper house of the newly constituted Baden parliament. He was also made member of the Scheidungsgericht (divorce court).

In 1836 Thibaut published his *Erörterungen des römischen Rechts*. One of his last works was a contribution in 1838 to the *Archiv für die civilistische Praxis*, of which he was one of the editors (see below). Thibaut married, in 1800, a daughter of Professor Ahlers of Kiel. He died after a short illness, at Kielberg, on the 29th of March 1840.

Thibaut was a man of many matters, and many consistent nature, was much more than a jurist; he deserves to be remembered in the history of music. Palerestia and the early composers of church music were his delight; and in 1824 appeared anony- mously a work in eight vols. entitled *New Finds of the Rhenish Treasure*, in which he eulogized the old music, and especially that of Palerestia. He was an ardent collector of old compositions, and often sent young men to Italy, at his own expense, to discover interesting musical manuscripts or other masterpieces, which holds no mean place. His style is simple and manly, but rich in the happy accidents of expression which come only to true artists.

Most of Thibaut's works have already been mentioned, but his essay on the necessity of a code for Germany (*Über die Notwendigkeit eines allgemeinen bürgerlichen Rechts für Deutschland*), which was inspired by the war of Liberation and written in fourteen days, deserves further notice. Thibaut has explained in the *Archiv für die civilistische Praxis*, in 1838, the origin of this memorable essay. He had realized the change demanded by the war, and had proposed to the Kriegshaupt in the happy future opened up for Germany. The system of small states might be hoped and believed would continue; for the big state he considered crushing to the life of the individual and harmful as concentrating influence on the personal life of a people. This argument the only unity practicable and needful for Germany was that of law; and for this he urged all the German governments to labour.

The framers of the new German civil code (*bürgerliches Gesetzbuch*) in 1879 were indebted for the arrangement of their matter to this work, as it was done beyond the Pyrenees, and beyond this, the code, based on the common law of the several German states, which was adroitly blended by the *ius pandectarium* into an harmonious whole, *vide infra*, reflect his influence. He was one of the earliest to criticize the divorce laws of the time, and, and he carried on with Gustav Hugo a controversy as to these points.

In modern German legal literature Thibaut's influence is not very perceptible. Even at Heidelberg it was quickly superseded by that of his successor, Karl Adolph von Vangerow (1805-1870), and in Germany his works are now little used as text-books. But Thibaut was able to influence his pupil, Savigny, who, who of much to him, describes him as one "who for penetrating acuteness, rectitude of judgment and depth of learning and eloquence of exposition and forcible place...". In short, the controversy belonged to Savigny; the real victory rested with Thibaut.

For further information as to Thibaut's life and work, see Baumbak, Thibaut, Blätter der Erinnerung (1841); Karl Hagemann, *Über den Leben H. Th. und Thibaut, mit Correspondenz*, in die Preuss. Jahrbiicher (1880); Teichmann, in Holtsendorff's *Rechtssikonietz*; and E. Landsberg, in *Allgemeine Deutsche Biographie*, vol. 37.

THIBAW, or HSIPAW, one of the Northern Shan States of Burma. It is called by the Shans, and officially, Hsipaw, and also frequently Üng Pawng (the name of an old capital). It includes four states—Thibaw, the main state, and the sub-states of Möngh Long, Möngh Tung and Thonzh (or Hsimagal). The whole state has an area of 5086 sq. m., and the population in 1910 was 104,700.

The main state lies on the geological fault which runs east and west across the Shan States, from the Salween to Kunlån and beyond to nearly the rim of the Shan tableland at Göktek. It is therefore broken up into a mass of not very well-defined ridges and spurs, crossing and re-entering. The chief plain land is in the valley of the Nam Tu (Myit-nge), near Thibaw town, and the valley or strath of the Pyawng Kawng, Nawng Ping neighbourhood. Elsewhere the valleys are insignificant. The hills on the Möngh Tung border reach their highest elevations in the peaks Loi Pan (6848 ft.) and Loy Htan (6270 ft.); to the north-west of Thibaw town, on the Tawng Peng border, Loy Lam rises to 6386 ft. The valley of the Nam Tu marks the lowest point in the state at Thibaw town, about 1400 ft., and rises on the east in Möngh Tung to a plain level of about 2500 ft., and on the west in Möngh Long to a confused mass of hills with an average height of 4500 ft.; broken up by the Nam Yawn and Nam Kaw valleys, which are about 3000 ft. above mean sea-level.

The chief river is the Nam Tu or Myit-nge, also frequently called by its classical name the Dōktawadi. The main stream rises in the most easterly part of the Shan range, and is divided in two forks; the western fork, the Long Tu, is navigable for 120 ft. above from the falls of Tawnkaw on the Nam Tu to the town of Nam Tu. The eastern branch, the Long Htan, rises on the Nam Tu, and is navigable for 760 ft. above from the falls of Tawnkaw on the Nam Tu to the town of Nam Tu. The valley of the Nam Tu is about 1500 ft. below the general level of the country. Coal is found at various places in the state, but is not of very high quality. There is also a considerable granite quarry near the town, and a large stone quarry at Thibaw (Bawgyo) about 7 m. from Thibaw town. The average maximum temperature at the beginning of April is about 96°, and the minimum
THIELMANN-THIERRY

about the same period 65°. The rainfall averages about 70 in.

for the year. The chief crops are rice, cotton, sesame, tea in the

hills, and thanat, leaf of a tree used for the wrapper of the

Burma, or "green" Cherokee. Cotton cloth was formerly much

made in this country, and a cotton mill is still in operation.

and a cotton mill is also made. Other industries are merely of articles

for local use. The government road to Lashio passes through the

centre of the state, and from this various unmetalled roads

radiate into the different parts of the neighboring states.

The Mandalay-Kunlong railway, now open as far as Lashio, also

passes through the capital. Teak forests exist along the banks of the

River Irrawaddy, and both the Taungthaman and the Bago rivers

are in charge of circles and townships. Each naba-boaing has an

assay, or clerk, and each village has a headman, or kin-man. The

ministers supervise the administration of a certain number of districts.

The system is now being assimilated to that followed in Burma.

The chief Sao Hke was for a time in England. (J. G. Sc.)

THIELMANN, JOHANN ADOLF, FREIHERR VON (1765-

1834), Prussian cavalry soldier, was born at Dresden. Entering

the Saxony cavalry in 1782, he served against the French in the

Revolutionary Wars and in the Jena campaign. When,

after the disaster of Jena, Saxony allied herself with her con-
querror, Thielmann accompanied the Saxony contingent which

fought at the siege of Danzig and at Friedland. In 1809, as

colonel of a Free-Corps, he opposed the advance of the

Austrians into Saxony, and was rewarded for his services with the grade

of major-general, further promotion to lieutenant-general fol-

lowing in 1810. As commander of the Saxon Heavy Cavalry

Brigade he took part in the advance in Moscow two years later.

When his regiment was destroyed, Thielmann was appointed

commander-in-chief of the Saxon army, in which Napoleon,

who took Thielmann into his own suite. His own

sovereign at the same time made him Freiherr. In the war of

Liberation Thielmann took a prominent part; as governor of

Torgau, by his king's orders he at first observed the strictest

neutrality, but on receipt of an order of hand to over the fortress

to the French he resigned his command and, accompanied by

his staff officer Aster, joined the allies. As a Russian general

he was employed in reorganizing the Saxon army after Leipzig,

and in 1814 he commanded the Saxon corps operating in the

Low Countries. Early in the following year he became a

lieutenant-general, and in command of the 3rd army corps he took part in the Waterloo

campaign. From the field of Ligny he retired with the rest of Blücher's

army on Wavre, and when the other corps marched towards

Waterloo, Thielmann covered this movement against Grouchy,

fighting the spirited action of Wavre (June 18-19). He was

later a corps commander at Münster and at Coblenz, and at

the latter place he died in 1834.

(Berlin, 1828); von Holzendorff, Beiträge zur Biographie des

Generals Freiherrn von Thielmann (Dresden, 1830); von Peters-
dorf, General Johann Adolf Freiherr von Thielmann (Leipzig, 1894).

THIERRY, the name of two French historians, the brothers

Augustin and Amédée, both of whom, though their literary

and historical powers were far from being equal, displayed the

same devotion to historical study.

1. JACQUES NICOLAS AUGUSTIN THIERRY (1755-1836),

the elder and more gifted, was born at Blois on the 10th of May

1755. He had no advantages of birth or fortune, but was

greatly distinguished at the Blois Grammar School, and entered

the École normale supérieure (1811). In 1813 he left H, and was

sent as a professor to Compiègne, but stayed there a very short

time. His ardent and generous nature led him to embrace the

ideas of the French Revolution with enthusiasm, and in 1789 he

resigned his post at Compiègne, and devoted himself to

the service of Saint Simon's ideal society of the future. He became

the secretary, and, as he would say himself, the "adopted son"

of the famous visionary (1814-17); but, while most of Saint

Simon's followers turned their attention to the affairs of life,

devoting themselves to the problems, both theoretical and

practical, of political economy, Thierry turned his to history.

His imagination had been powerfully impressed by reading

Les Martyrs, in which Châteaubriand had contrasted the two
civilizations and the two races from which the modern world

was formed. His romantic theories were further nourished by the

works of Sir Walter Scott, and though he did not himself actually write romances, his conception of history

fully recognized the dramatic element. His main ideas on

the Germanic invasions, the Norman Conquest, the formation of

the Communes, the gradual ascent of the nations towards free

government and parliamentary institutions are already

observed in the articles contributed by him to the Censeur

européen (1817-20), and later in his Lettres sur l'histoire de

France (1820). From Fauriel he learnt to use the original

texts, and from Mme. de Beaumont he learned the

collection, as yet very ill understood, of the Anglo-Saxon laws,

he composed his Histoire de la Conquête de l'Angleterre par les

Normands, the appearance of which was greeted with great

enthusiasm (1825). It was written in a style at once precise

and picturesque, and was dominated by an idea, at once
generous and false, that of Anglo-Saxon liberty resisting the

invasions of northern barbarians, and reviving, in spite of

defeat, in the parliamentary monarchy. His artistic talent as

a writer makes the weaknesses and deficiencies of his scholar-

ship and the obvious passion of his ideas of no great

importance. He required several years of hard work, cost Thierry his eye-

sight; in 1826 he was obliged to engage secretaries and in 1830

came quite blind. Notwithstanding, he continued to pro-

duce works. In 1827 he republished his Lettres sur l'histoire de

France, with the addition of fifteen new ones, in which he

described some of the more striking episodes in the history

of the rise of the medieval communes. The chronicles of the

11th and 12th centuries and a few communal charters provided

him, without requiring a great amount of erudition, with

materials for a solid work. For this reason his work on the

communes has not become so out of date as his Norman Con-

quest; but he was too apt to generalize from the facts furnished

by a few striking cases which occurred in a small portion of

France, and helped to spread among the public, and even

among professional historians, mistaken ideas concerning one of

the most complex problems relating to the social origins of

France.

Thierry was ardent in his applause of the July Revolution and

the triumph of liberal ideas; at this time, too, his brother

Amédée was appointed prefect, and he went to live with him

for a few years. He retired, however, from politics, and

devoted himself to an examination of euvres historiques, his first essays in the Censeur

européen and the Courrier français (1834), and composed his Recits des temps mérovingiens,

in which he reproduced a vivid and dramatic form some of the most characteristic stories of Gregory of

Tours. These Recits appeared first in the Revue des deux

mondes; when collected in volume form, they were preceded

by long and interesting Considerations sur l'histoire de France.

From the 7th of May 1830, Thierry had already been a member of the

Académie des Inscriptions et Belles Lettres; in 1841, on

the motion of Villemain, the French Academy accorded to

him the first Prix Gobert, which became a kind of literary

inheritance for him, being renewed in his favour fifteen years in

succession. Moreover, he had been allotted the task of publish-

ing in the series of the Documents inédits a selection of acts

bearing on the history of the Third Estate. By the aid of

zealous collaborators (including Bourquelot and Louandre) he

compiled, in four volumes, a valuable Recueil des monuments

inédits de l'histoire du Tiers État (1850-70), which, however,

bear only on the northern part of France. The preface

appeared afterwards in a separate volume under the title of

Histoire du Tiers État. To Thierry belongs the credit for

inaugurating in France the really critical study of the communal

institutions, and we cannot make him responsible for the

neglect into which it relapsed after his death. The last

years of his life were clouded by domestic griefs and by illness.

In 1844 he lost his wife, Julie de Querengal, an intelligent

woman, who had been to him a collaborator as capable as she

was devoted. The revolution of 1848 inflated on him a final blow.
by overturning that régime of the Liberal bourgeoisie the triumph of which he had hailed and justified as the necessary outcome of the whole course of French history. He began to distrust the rationalistic opinions which had hitherto estranged him from the Church. When Catholic writers animadverted on the "historical errors" in his writings he promised to correct them, and accordingly we find that in the final edition of his Histoire de la Conquête his severe judgments on the policy of the court of Rome, together with some faults of detail, are eliminated. Though he did not renounce his Liberal friends, he sought the conversation of enlightened priests, and just before his death it is said that he had proposed to enter the pale of the Church. He died in Paris on the 22nd of May 1856, after several years of suffering endured by heroism.

II. ANÉDOTE SIMON DOMINIQUE THIERRY (1797—1873) was the younger brother of Augustin, and was born on the 2nd August 1797. He began life as a journalist (after an essay, like his brother, at schoolmastering), was connected with the famous romantic harbingers the Globe, and obtained a small government clerkship. His first book was a brief history of Guizoune in 1825, and three years later appeared the first volume of the Histoire des deux mondes, articles which received was so well-liked from a man, from the royalist premier Martinage, a history professorship at Besançon. He was, however, thought too liberal for the government of Charles X., and his lectures were stopped, with the result of securing him, after the revolution, the important post of prefect of the Haute-Saône, which he held eight years. During this time he published nothing. In 1838 he was transferred to the council of state as master of requests, which post he held through the revolution of 1848 and the coup d'état till 1860, when he was made senator—a paid official, it must be remembered, and, in effect, a lucrative sinecure. He also passed throughout all the ranks of the Legion of Honour, became a member of the Académie des Inscriptions in 1841, and in 1862 received the honorary degree of D.C.L. at Oxford. He had, except during the time of his prefecture, never intermitted his literary work, being a constant contributor to the Revue des deux mondes, his articles (usually worked up afterwards into books) almost all dealing with Roman Gaul and its period. The chief were the Histoire des Gaulois, 3 vols. (1828, 1834, 1845; the 8th vol. I. appeared in 1870); Histoire de la Gaule sous l'administration romaine (3 vols., 1840-47; and ed. 1853), which gave of Aillaud a sousseupier of the establishment of the Hengrosi in Europe (1856; 5th ed. in 1874); Tableau de l'Empire romain (1862; 5th ed. in 1871; now quite out of date); Récits de l'histoire romaine au V e siècle: la lutte contre les Barbares, and les luttes religieuses (1860; 2nd ed. in 6 vols. 1860). He died in Paris on the 27th of March 1873. His son, Gilbert Augustin Thierry (born 1843), who began a literary career by articles on Les Révolutions d'Angleterre (1864) and some Essais d'histoire religieuse (1867), afterwards confined himself to the writing of novels.

THIERS, LOUIS ADOLPHE (1797—1877), French statesman and historian, was born at Marseilles on the 16th of April 1797. His family are somewhat grandiloquently spoken of as "cloth merchants ruined by the Revolution," but it seems that at the actual time of his birth his father was a locksmith. His mother belonged to the family of the Chéniers, and he was well educated, first at the lycée of Marseilles, and then in the faculty of law at Aix. Here he began his lifelong friendship with Mignet, and was called to the bar at the age of twenty-three. He had, however, little taste for law and much for literature; and he obtained an academic prize at Aix for a discourse on Vauvenargues. In the early autumn of 1821 Thiers went to Paris, and was quickly introduced as a contributor to the Constitutionnel. In each of the years immediately following his arrival in Paris he collected and published a volume of his articles, the first on the salon of 1822, the second on a tour in the Pyrenees. He was put out of all need of money by the singular benefaction of Cotta, the well-known Stuttgart publisher, who was part-proprietor of the Constitutionnel, and made over to Thiers his dividends, or part of them. Meanwhile he became very well known in Liberal society, and he had begun the celebrated Histoire de la révolution française, which founded his literary and helped his political fame. The first two volumes appeared in 1823, the last two (of ten) in 1827. The book brought him little profit at first, but became immensely popular. The well-known sentence of Carlyle, that it is "as far as possible from meritng its high reputation," is in strictness justified, for all Thiers's historical work is marked by extreme inaccuracy, by prejudice which passes the limits of accidental unfairness, and by an almost complete indifference to the merits as compared with the antecedents of the facts. Thiers himself did not hesitate to declare that Thiers is "a brisk man in his way, and will tell you much if you know nothing." Coming as the book did just when the reaction against the revolution was about to turn into another reaction in its favour, it was assured of success.

For a moment it seemed as if the author had definitely chosen the lot of a literary man, not to say of a literary hack. He even planned an Histoire générale. But the accession to power of the Polignac ministry in August 1829 changed his projects, and at the beginning of the next year Thiers, with the help of the friends of the previous government, founded and became the editor of a new opposition newspaper. Thiers himself was one of the souls of the actual revolution, being credited with "overcoming the scruples of Louis Philippe," perhaps no Herculean task. At any rate he had his reward. He ranked as one of the Radical supporters of the new dynasty, in opposition to the party of which his rival Guizot was the chief literary man, and Guizot's patron, the duc de Broglio, the main pillar. At first Thiers, though elected deputy for Aix, obtained only subordinate places in the ministry of finance. After the overthrow of his patron Laffitte, he became much less radical, and, after some troubles of June 1832, was appointed to the ministry of the interior. He repeatedly changed his portfolio, but remained in office for four years, became president of the council and in effect prime minister, and began his series of quarrels and jealousies with Guizot. At the time of his resignation in 1836 he was foreign minister, and, as usual, wished for a spirited policy in Spain, which he could not carry out. He travelled in Italy for some time, and it was not till 1838 that he began a regular campaign of parliamentary opposition, which in March 1840 made him president of the council and foreign minister for the second time. But he held the post only six months, and, being unable to force on the king an anti-English and anti-Turkish policy, resigned on the 20th of October. He now had little to do with politics for some years, and spent his time on his Histoire du Consulat et de l'Empire, the first volume of which appeared in 1845. Though he was still a member of the chamber he spoke rarely, till after the beginning of 1846, when he was evidently bidding once more for power. Immediately before the revolution of February he went to all but the greatest lengths, and when it broke out he and Odillon Barrot were summoned by the king; but it was too late. Thiers was unable to govern the forces the king had to call to his aid, and was sent to Aix.

Under the republic he took up the position of conservative republican, which he ever afterwards maintained, and he never took office. But the consistency of his conduct, especially in voting for Prince Louis Napoleon as president, was often and sharply criticized, one of the criticisms leading to a duel with a fellow-deputy, Bixio. He was arrested at the coup d'état, was sent to Mazas, and then escorted out of France. But in the following summer he was allowed to return. For the next decade his history was almost a blank, his time being occupied for the most part on The Consulate and the Empire. It was not till 1863 that he re-entered political life, being elected by a Parisian constituency. For the seven years following he was the chief speaker among the small band of anti-Imperialists in the French chamber, and was regarded generally as the most formidable enemy of the empire. While nominally protesting against its foreign enterprises, he perpetually harped on French loss of prestige, and so contributed more than any one else to stir up the fatal spirit which brought
THIERS 849

on the war of 1870. Even when the Liberal-Imperialist Ollivier ministry was formed, he maintained at first anything but benevolent neutrality, and then an open opposition, and it is impossible to say whether mere "canniness," or something better, kept him from joining the government of the National Defence, of which he was in a manner the author.

Nevertheless the collapse of the empire was a great opportunity for Thiers, and it was worthily accepted. He undertook in the latter part of September and the first three weeks of October a circular tour to the different courts of Europe in the hope of obtaining some intervention, or at least some good offices. The mission was unsuccessful; but the negotiator was on its conclusion immediately charged with another—that of composing an agreement with Bismarck. Thiers had long predeceased him. He had been a member of the Academy since 1834. His personal appearance was remarkable, and not imposing, for he was very short, with plain features, ungainly gestures and manners, very near-sighted, and of disagreeable voice; yet he became (after wisely giving an attempt at the ornate style of oratory) a very effective speaker in a kind of conversational manner, and in the epigram of debate he had no superior among the statesmen of his time except Lord Beaconsfield.

Thiers was by far the most gifted and interesting of the group of literary statesmen which formed a unique feature in the French public history of the 19th century. There are only two who at all comparable to him—Guizot and Lamartine; and as a statesman he stands far above both. Nor is this eminence merely due to his great opportunity in 1870; for Guizot might under Louis Philippe have almost made himself a French Walpole, at least a French Palmerston, and Lamartine's opportunities after 1848 were, for a man of political genius, illimitable. But both failed—Lamartine by reason of his market or mind, and Guizot by reason of his temper at once imperious and intriguing, his invertebrate inclination towards brigue, that is to say, underhand rivalry and Caballing for power and place, showed themselves unfavourably; and his constant tendency to inflame the aggressive and chauvinist part of his country neglected fact, was not based on any just estimate of the relative power and interests of France, and led his country more than once to the verge of a great calamity. In opposition, both under Louis Philippe and under the empire, and even to some extent in the last four years of his life, his worst qualities were always manifested. But with all these drawbacks he conquered England, won a place for France among the smallest, class of statesmen—the class of those to whom their country has had recourse in a great disaster, who have shown in bringing her through that disaster the utmost constancy, courage, devotion and skill, and who have been rewarded by as much success as the occasion permitted.

As a man of letters Thiers is very much smaller. He has not only the fault of diffuseness, which is common to so many of the best-known historians of his century, but others as serious or more so. The charge of dishonesty is one never to be lightly made against men of such distinction as his, especially when their evident solicitude for panegyric, casuistry, and the strength of will which makes them (unconsciously, no doubt) close and keep closed the eyes of their mind to all inconvenient facts and inferences, supply a more charitable explanation. Their vanity retains the claim on the reader from Thiers' dealings with the first revolution to his dealings with the battle of Waterloo, constant, angry and well-supported protests against his unfaithfulness were not made through any lapse of thought. This, in another work in which documents were undoubtedly wide, its results are by no means always accurate, and his admirers themselves admit great inequalities of style in him. These characteristics reappear (accompanied, however, by frequent touches of the epigrammatic power above mentioned, which seems to have come to Thiers more readily as an orator than as a historian) in his speeches, which after his death were collected in many volumes by his widow, Sainte-Beuve, whose notices of Thiers are generally kind, says of him, "M. Thiers sais tout, tranche tout, parle de tout, et cette omniscience et "cocksureness" (to use the word of a prime minister of England contemporary with Thiers), and these monstrosities, are the chief pervading features both of the statesman and the man of letters.

His histories, in many different editions, and his speeches, as above, are easily accessible; his minor works and newspaper articles are not, we believe. Very few, not even Souvenirs, were published years after his death appeared Deux opuscules (1891) and Mélanges littéraire (1892), while Notes et souvenirs, 1870-73, were published in a distinct volume. Among his best works are the "Souvenirs de M. Félicien Donsan. Works of him, by M. Laya, M. de Mazeade, his colleague and friend M. Jules Simon, and others, are numerous.

(G. SA.)

THIERS, a town of central France, capital of an arrondissement in the department of Puy-de-Dôme, 24 m. E.N.E. of Clermont-Ferrand, on the railway between that town and St Étienne. Pop. (1906) town, 12,601; commune, 17,418. Thiers is most picturesque situated on the side of a hill at the foot of
which the Durolle rapidly descends through a narrow valley into the Dore, a tributary of the Allier. The streets rising in steep rows contain a large number of stone and wooden houses, some of which date to the 13th century. A fine view of the peak of Limagne and the Dôme mountain is obtainable from the terraces. The church of St. Genis was built in 575 by Avitus, bishop of Clermont, and rebuilt in the 12th century. It has some curious mosaic work of the Merovingian period and a fine tomb of the 13th century. The church of Le Moutier, which formerly formed part of a Benedictine monastery, dates chiefly from the 11th century. Thiery is the seat of a sub-prefecture and has tribunals of first instance and of commerce, a chamber of commerce, a board of trade arbitration, a commercial college, a commercial and industrial school, and a branch of the Bank of France. Its special industry is the manufacture of cutlery, which employs some 13,000 hands in the town and its vicinity. The manufacture of handles and buttons of bone, pasteboard, stamping, hand-made and other papers and machinery are also carried on.

Thiers was sacked about 531 by the soldiers of Thierry, son of Clovis. About the same period Gregory of Tours speaks of a wooden chapel which may have occupied the site of the present church of Le Moutier. The commercial importance of the town was much increased in the 16th century when the manufacture of cutlery was introduced from the neighbouring town of Châtillon (1833).

THIERSCH, FRIEDRICH WILHELM (1784–1866), German classical scholar and educationist, was born at Kirchseiden- dungen near Freiburg on the Unstrut, on the 17th of June 1784. In 1809 he became professor at the gymnasium at Munich, and in 1826 professor of ancient literature in the university of Landshut, transferred in that year to Munich. He died at Munich on the 25th of February 1860. Thielsch, the "tutor of Bavaria" (praeceptor Bavariae), found an extremely unsatisfactory system of education in existence. The principal violent feud between the Protestants' "north" and the Catholic "south" Germany still continued, and the chiefly old monks, offered violent opposition to his reforms, and an attempt was made upon his life. His schemes, however, were carried out, and have remained the governing principle of the educational institutions of Bavaria. Thielsch was an ardent supporter of Greek independence. In 1832 he visited Greece, and it is said that his influence had much to do with securing the throne of the newly created kingdom for Otto of Bavaria. He wrote a Greek grammar, a metrical translation of Pindar, and an account of Greece (L'Etat actuel de la Grèce, 1846).

Biography by his son, H. W. J. Thielsch. (1866); see also G. M. Thomas, Gedächtnissrede auf Friedrich von Thielsch (1866); articles by A. Baumeister in Allgemeine Deutsche Biographie and O. Zöckler in Herzog-Hauck's Realencyclopädie für protestantische Theologie, u. a. J. E. Sandys, History of Classical Scholarship, iii. (1906).

THIETMAR (DIETMAR OF DITTMAR) OF MERSEBURG (975–1018), German chronicler, was a son of Siegfried, count of Walbeck, and was related to the family of the emperor Otto the Great. Born on the 25th of July 975 he was educated at Quedlinburg and at Magdeburg and became provost of Walbeck in 1002 and bishop of Merseburg seven years later. He took some part in the political events of the time; in 994 he was a hostage in the hands of the Northmen, and he was not unfamilier with the actualities of war. He died on the 1st of December 1018.

Thietmar wrote a Chronicon in eight books, which deals with the period between 906 and 1018. For the earlier part he used Widukind's Res gestae Saxonicæ, the Annales Quedlinburgenses and other sources; the latter part is the result of personal knowledge. It is rough in form and the author shows no power of discriminating between important and unimportant events; yet the chronicle is an excellent authority for the history of Saxony during the reigns of the emperors Otto III. and Henry II. No kind of book could be more useful for tracing the details relating to the bishopric of Merseburg and to the wars against the Wends and the Poles. The original manuscript of the work is preserved at Dresden and has been published in facsimile by L. Schmidt (Dresden, 1906). It has been edited by J. M. Lappenberg in Band III. of the Monumenta Germaniae historica, Scriptores; and by F. Kurze (Hanover, 1899); and has been translated into German by J. Laurent (new ed., revised by W. Wattenbach, Leipzig, 1892). See Kurze, Bischof Thietmar von Merseburg und seine Chronik (Halle, 1890); and W. Wattenbach, Deutschlands Geschichtsquellen, Band 11. (Berlin, 1904).

THIMBLE, an implement for use in sewing, serving as a protective covering for the finger in pushing the needle through the material worked upon. For ordinary purposes the thimble is a bell-shaped cap reaching to the first joint and is usually worn on the middle finger. It is made of silver or other metal, sometimes of horn, ivory or bone. The sail-maker's thimble or "thumrel" is a heavy ring, worn on the thumb, with a disc attached which is the part used to press against the needle. The O.E. thymel, from which the word descends, is formed, with the suffix suffix thums, the thumb, the protective covering having been formerly worn in that dat. The thumb, by etymology means the "thumb" finger, and is to be referred to the root tim, to swell, up, become thick, seen in Lat. tumere, "thumrel," &c. The term "thimble" is used by many mechanical appliances, especially of various forms of sleeve, bushing or joining for the ends of pipes, or shaftings, or as covering for an axile, &c. In nautical usage the "thimble" is a metal ring concave on the outside in which a rope runs; it is a protection against chafing.

THIOPHEN, C₄H₄S, a compound occurring in small quantities in crude coal-tar benzene, from which it was first isolated in 1883 by V. Meyer (Ber., 1883, 16, p. 1465). The method adopted by Meyer to recover the thiophen was as follows: Ten volumes of the purest coal-tar benzene were shaken for four hours with one volume of sulphuric acid, the acid layer was removed and neutralized with lead carbonate, and the lead thiophenolate obtained was distilled with an equivalent quantity of ammonium chloride. The distillate obtained was diluted with one hundred volumes of lignoain (previously purified by shaking with fuming sulphuric acid) and then shaken for one or two more times with the same solvents (using ten volumes of acid to one volume of the distillate). The acid layer so obtained was neutralized with lead carbonate and the lead salt again distilled with an equivalent quantity of ammonium chloride. The distillate is finally rectified. It may be obtained in small quantity by passing ethylen or acetylene into boiling sulphur; by passing ethyl sulphide through a red-hot tube; by heating crotonic acid, butyric acid or erythritic with phosphorus pentasulphide; by heating succinic anhydride with phosphorus pentasulphide or sodium succinate with phosphorus trisulphide (J. Volhard and H. Ermann, Ber., 1885, 18, p. 1784); or by heating succinidihydride with two parts of phosphorus trisulphide (C. Harries, Ber., 1901, 34, p. 1496).

It is a colourless liquid having a faint smell resembling that of benzene and boiling at 84° C. In its chief properties it very much resembles benzene, being readily brominated, sulphonated, and nitrated; also, the side chains in the alkyl thiophens are readily oxidized to carboxyl groups. On passing its vapour through a red-hot tube it yields di-thiényl, C₄H₄S₂. It is completely decomposed by hydriodic acid at 140° C. It condenses with aldehydes (in chloroform solution) in the presence of phosphorus pentachloride and hydrogen cyanogen (A. Nahe, Ber., 1897, 30, p. 2373). It can be readily recognized by the blue colour produced when a trace of thiophen is added to iasxin dissolved in concentrated sulphuric acid (the indophenin reaction). The thiophen ketones may be prepared by the interaction of thiophen and its homologues with acid chlorides in the presence of anhydrous aluminium chloride. The thiophen ketones are best prepared by heating the 1,4-diketones with phosphorus pentasulphide, the diketones reacting in the enolic form: R-C=C=CH₂ + H₂O = R+P₂S₅ + R-C=CH₂, C=C-R. Thietmarrei, or oxymethyl thiophene, is prepared by heating laevulenic acid with phosphorus pentasulphide (W. Kues and C. Paul, Ber., 1886, 19, p. 553). On this group see also V. Meyer, Die Thiophengruppe.
THIRLY (or THIRLEY), THOMAS (c. 1506–1570), English prelate, was born at Cambridge and was educated at Trinity Hall in the university there, becoming a fellow of his college. Through the good offices of his friend, Thomas Cranmer, he was introduced so as to prevent him from pursuing his heretical work, one of whose chaplains he had become, in several ways. Among his numerous public appointments were those of dean of the chapel royal and member of the council of the north. In 1540 he was made bishop of Westminster, being the first and only occupant of that see; in 1550, three years after Henry VIII’s death, he resigned the bishopric, which was dissolved, and became bishop of Norwich. As a diplomatist Thirlby had a long and varied experience; on several occasions he was sent on embassies to the emperor Charles V, and he helped to arrange the peace between England and France in 1559. He appears to have served Edward VI loyally throughout his short reign, both at home and abroad, although it is certain that he disliked the religious changes and he voted against the act of uniformity in 1540. He was thus more at ease when Mary ascended the throne. Translated in 1554 to the bishopric of Ely, he took part in the trial of Cranmer at Oxford and in the consecration of Reginald Pole as archbishop of Canterbury, but he himself did not take severe measures against heretics. When Elizabeth became queen the bishop refused to take the oath of supremacy; he afterwards went to Rome; he was elected to Trinity College, Cambridge, in October 1584, and gained the Craven university scholarship and the chancellor’s classical medal. In October 1581 he was elected to a fellowship, and went for a year’s travel on the Continent. At Rome he gained the friendship of Baron (Christian C. J.) von Bunsen, which had a most important influence on his life. On his return, “distrust of his own resolutions and convictions” led him to abandon for the time his intention of being a clergyman, and he settled down to the study of the law, “with a firm determination not to suffer it to encroach upon the oath of supremacy; in other ways he showed himself hostile to the proposed religious changes, and in 1559 he was deprived of his bishopric. For preaching against the innovations he was arrested in 1560, and he was in honourable confinement at Lambeth Palace when he died on the 26th of August 1570.

THIRLWALL, CONNOP (1797–1875), English bishop and historian, was born at Stepney, London, on the 11th of January 1797. His family was of Northumbrian extraction. He was a precocious boy, learning Latin at three, reading Greek at four, and writing sermons at seven. He went to the Charterhouse school, where George Grubb and John Hinde were among his schoolmates. He entered Trinity College, Cambridge, in October 1814, and gained the Craven university scholarship and the chancellor’s classical medal. In October 1818 he was elected to a fellowship, and went for a year’s travel on the Continent. At Rome he gained the friendship of Baron (Christian C. J.) von Bunsen, which had a most important influence on his life. On his return, “distrust of his own resolutions and convictions” led him to abandon for the time his intention of being a clergyman, and he settled down to the study of the law, “with a firm determination not to suffer it to encroach upon the oath of supremacy; in other ways he showed himself hostile to the proposed religious changes, and in 1559 he was deprived of his bishopric. THIRSK—THIRTY YEARS' WAR

in three volumes (1877–78), two of which are occupied by his charges. His *Letters, Literary and Theological*, with a connecting memoir, were edited by J. J. S. Perowne and L. Stokes (1881). His *Letters to a Friend* (Miss Johnes of Dolaucrothy) are a splendid monument to his memory. Thirsk's work is a revised and corrected edition. For a general view of Thirsk's life and character, see the *Edinburgh Review*, vol. cxliii.; for a picture of him in his diocese, *Temple Bar*, vol. lxxvi.

**THIRSK**, a market-town in the Thirsk and Malton parliamentary division of the North Riding of Yorkshire, England, 22 m. N.W. by N. from York by the N.Y.

*The* Union and the *League* formed.

It lies in a fertile plain W. of the Hambleton Hills, on the Codbeck, a small tributary of the Swale. The church of St Mary, entirely Perpendicular, with parvis, chancel, nave, aisles, porch, and tower 80 ft. in height, is one of the most beautiful churches in the Riding. The original work of oak is especially noteworthy. The moat of the ancient castle built by the Mowbrays about 980 remains. The principal modern buildings are the assembly rooms, mechanics' institute, and court-house. Standing in the fertile district of the Vale of Mowbray, the town has an extensive agricultural trade. Agricultural implements are manufactured. In addition to the manorial engineering, tanning and brick-making are carried on, and there are large flour-mills.

At the time of the Domesday Survey, Thirsk (Treske) was a manor of little importance belonging partly to the king and partly to Hugh, son of Baldric. Soon afterwards it was granted to Robert de Mowbray, who often resided there, and is said to have raised the castle round which the borough grew up. His estates, being forfeited for treason against William Rufus, were restored by Henry I. to Nigel de Albin, Robert's cousin, who took the name of Mowbray. Roger, son of Nigel, took part in the rebellion against Henry II. In 1174, and although he was allowed to retain his estates, his castle at Thirsk was destroyed. The manor remained in his family until the death of John de Mowbray, duke of Norfolk, without issue male in 1475, and after passing through several families was finally sold in 1723 to Ralph Bell, whose descendants thereafter held the manor. Thirsk is first mentioned as a borough in a charter granted by Roger de Mowbray to Newburgh Priory in the reign of Henry II.

*Defeat of the Bohemians.*

It was governed by a bailiff elected by the burgesses at the court leet of the lord of the manor, and never received a charter of Incorporation. The burgesses were represented in parliament by two members in 1295 and again from 1532–53 to 1832, when by the Municipal Reform Act the number was reduced to one. In 1885 the town was disfranchised. Roger de Mowbray held a market by prescription in Thirsk in the 13th century, and by Camden's time (c. 1586) it had become one of the best markets in the North Riding. It is still held by the lord of the manor.

See *Victoria County History: Yorkshire; William Grainge, The Vale of Mowbray: a historical and topographical account of Thirsk and its neighbourhood* (1893).

**THIRTY YEARS' WAR** (1618–1648), the general name of a series of wars in Germany which began formally with the claim of Frederick, archduke of Austria, prince-elector of Bohemia, to the crown of Bohemia, under the treaty of Westphalia. It was primarily a religious war and was waged with the bitterness characteristic of such wars, but at the same time political and feudal quarrels were interwoven with the religious question, with the consequence that the armies, considering themselves as their masters' retainers rather than champions of a cause, plundered and burned everywhere, military violence being in no way restrained by expediency. In a war based on the principle *ejus regio ejus religio* it was vain to expect either the professional or the national type of army to display its virtues.

Fifty years before the outbreak of the war the Convention of Passau had compromised the burning questions of the Reformation, but had left other equally important points as to the secularization of church lands and the consecration of Protestant bishops to the future. Each such case, then, came before the normal government machinery. A Diet was constituted that even though at least half of the secular princes and nine-tenths of their subjects were Protestants, the voting majority was Catholic in beliefs and in vested interests. Moreover, the Jesuits had rallied and disciplined the forces of Catholicism, while Protestantism, however firm its hold on the peoples, had at the courts of princes dissipated itself in doctrinal wrangles. Thus, as it was the princes and the free cities, and by no means the mass of the people, that settled religious questions, the strongest side was that which represented conservatism, peace and Catholicism. Realizing this from the preliminary murrinings of the storm, the Thirties' prince that was called upon promptly answered by the Catholic League. This group was headed by the wise and able Maximilian of Bavaria and supported by his army, which he placed under a soldier of long experience and conspicuously ability, Count Tilly.

The war arose in Bohemia, where the magistrates, roused by the systematic evasion of the guarantees to Protestants, refused to elect the archduke Ferdinand to the vacant throne. Bohemian Protestants, offered it instead to Frederick, the elector palatine. But the aggrandizement of this elector's power was entirely unacceptable to the manufacture of iron and manufactures—forces of Saxony above all. They declared themselves neutral, and Frederick found himself an isolated rebel against the emperor Ferdinand, and little more than the nominal head of an incoherent nobly in his new kingdom.

Even thus early the struggle showed itself in the double aspect of a religious and a political war. Just as the Protestants and their nominee found themselves looked upon askance by the other Protestants, so the emperor himself was unable to call upon Maximilian's Army of the League without promising to aggrandize Bavaria. Indeed the emperor was at first—before Frederick intervened—almost a mere archduke of Austria, waging a private war against his neighbours. Only the incoherence of his enemies saved him. They ordered taxes and levies of soldiers, but the taxes were not collected, and the soldiers, unpaid and unfed, either dispersed to their homes or plundered the country-side. The only coherent force was the mercenary corps of Ernst von Mansfeld, which, thrown out of employment by the termination of a war in Italy, had entered the service of the Union. Nevertheless, the Bohemians were conspicuously successful at the outset. Under Count Thurn they won several engagements, and Ferdinand's army under Longueville, in Bohemia under Prince Eugene of Savoy (1623–1625), was driven back. Thurn appeared before Vienna itself. Moravia and Silesia supported the Bohemians, and the Austrian nobles attempted, in a stormy conference, to wrest from Ferdinand not only religious liberty but also political rights that would have made Austria and Bohemia a loose confederation of powerful nations. Ferdinand firmly refused, though the deputation threatened him to his face, and the tide ebbed as rapidly as it had flowed. One or two small military failures, and the enormous political blunder of bringing in the elector palatine, sealed the fate of the Bohemian movement, for no sooner had Frederick accepted the crown than Maximilian let loose the Army of the League. Spanish aid arrived. Spinola with 20,000 men from the Low Countries and Franche Comté invaded the Palatinate, and Tilly, with no fears for the safety of Bavaria, was able to combine with Buquoy against *Defeat of the Bohemians.*

*Battle of the Wisselberg.*

The resistance was crushed at the battle of the Wissel Berg near Prague (8/18 November 1620). With this the Bohemian war ended. Some of the nobles were executed, and Frederick, the "Winter King," was put to the ban of the Empire.

The menace of Spinola's invasion broke up the feeble Protestant Union. But the emperor's revenge alarmed the Union princes. They too had, more or less latent, the tendency to separatism and they were Protestants, and neither in religion nor in politics could they suffer an all-powerful Catholic emperor. Moreover, the alternative to a powerful emperor was a powerful Bavaria, and this they liked almost as little.
There still remained for the armies of Tilly and Buquet the reduction of the smaller garrisons in Bohemia, and finally expelled railed under Mansfeld, who was joined by the disbanded soldiery of the Protestant Union's short-lived army. Their new strategy was that which was the distinguishing mark of the Thirty Years' War. The control of ramified states had to be, as it were, a law of their own, quite independent of the wishes or needs of the sovereign whose interests they were supposed to serve.  

The conquest of territory upon hostile territory and Mansfeld was so far successful in these for the position of Tilly. 1621 became distinctly unfavourable to the emperor. He had to recall Buquet's army to Hungary to fight against Gabriel Bethlen, the prince of Transylvania, and in an unsuccessful battle at Neunhäuser (July 10) Buquet was killed. Tilly and the League Army fought warmly and did not risk a decision. Thus even the proffered Fresh combat- mediation in the German war might have been accepted but for the fact that in the Lower Palatinate a corps of English volunteers, raised by Sir Horace Vere for the service of the English princess Elizabeth, the fair queen of Bohemia, found itself compelled to accompany the troops under Mansfeld to the country of the nearest probable enemy—in their case the bishop of Spire. This brought about a fresh intervention of Spinola's army, which had begun to return to the Low Countries to prosecute the war. The Emperor, however, had thoroughly eaten up the Palatinate that the magnates of Frederick's own towns begged Tilly to expel his general, decamp into Alsace, where the Palatinate, with the Dutch, was in a state of extreme hunger and in winter safety.  

The winter of 1621–22 proved to be one of the most dangerous negotiations which ever degenerated into an article of war.  

Gottes Freund, der Pfaffen Feind, a plunderer of peasants or priests. Whatever he was the margrave George Frederick of Baden-Durlach, regarded to be of the princes the most skilful sequestor of ecclesiastical lands.  

In April 1622, while Vere garrisoned the central fortresses of the Palatinate, Mansfeld, Christian and George Frederick took the field against Tilly, who at once demanded assistance from Spinola. The latter, though engaged with the Dutch, sent a corps under his subordinate Cordova. Before this arrived Mansfeld and the margrave of Baden-Durlach entered Heidelberg (17/18 April 1622). Nevertheless Tilly's army was not as easily dissolved as one of theirs, and soon the allies had to surrender. And when Cordova came up, and Tilly and the Spaniards combined defeated George Frederick at Wimpfen and Neckar (26 April/6 May). Following up this success, Cordova chased Mansfeld back into Alsace, while Tilly went north to oppose Christian. The 10,500 men of the Majesty of the Holy Roman Empire was almost destroyed by the League Army at Höchst. Mansfeld, and with him Frederick, had already set out from Alsace to join Christian, but when that leader arrived with only a handful of beaten men, the war was practically at an end. Frederick took Mansfeld and Christian back to Alsace, and after dismissing their troops from his employment, retired to Sedan. Henceforth he was a prisoner by powerless exile, and his lands and his electoral dignity, forfeited by the last, went to the prudent Maximilian, who thus became elector of Bavaria. Finally Tilly conquered the Palatinate fortresses, now guarded only by the English volunteers.  

The next act in the drama, however, had already begun with the adventures of the outlaw army of Mansfeld and Christian.  

After Höchst, had it not been for them, the war might have ended in compromise. James I. of England was busy as always with mediation schemes. Spain, being then in close connexion with him, was working to prevent the transfer of the electorate to Maximilian, and the Protestant princes of North Germany being neutral, a diplomatic struggle over the fate of the Palatinate, where the capture of the army supported the arms supported a prisoner in equilibrium, might have ended in a new convention of Passau the same year, which might have regulated the present troubles and left the future to settle its own problems. The struggle would only have been deferred, it is true, but meanwhile the North German Pro- testants, now helpless in an unarmed neutrality, would have taken the hint from Maximilian and organized themselves and their army. As it was, they remained powerless and inactive, while Tilly's army, instead of being disbanded, was kept in hand to deal with the adventurers.  

These, after eating up Alsace, moved on to Lorraine, whereupon the French government "warned them off." But ere long they found the Electorate of Palatinate, who had been reduced, together with Spinola, who was besieging Bergem-op-Zoom, and the States-General invited Mansfeld to relieve it. Time was short and no sooner had the Lower Rhine possible, and the adventurers therefore moved straight across Luxemburg and the Spanish Netherlands to the rescue. Cordova barred the route at Fleurus near the Sambre, but the desperate invaders, held together by the sheer Christian character of their leaders, thrust them out of their way (19/29 August 1622) and relieved Bergem-op- Zoom. But ere long, finding Dutch discipline intolerable, they marched to the rich county of East Friesland.  

Their presence raised a panic in the heads of the Protestant princes of North Germany. In 1623 Mansfeld issued from his Frisian stronghold, and the threat of a visitation from his army induced the princes of the Lower Saxon Circle to join him. Christian was himself a member of the Circle, and although he resigned his bishopric, he was taken, with many of his men, into the service of his brother, the duke of Brunswick-Wolfenbüttel; around the mercenary nucleus gathered many thousands of volunteers, and the towns and the nobles' castles alike were alarmed at the progress of the Catholics, who were reigning Protestant bishops. But this circle was not all that had been by the misadventure of the mercenaries. The authorities of the circle ordered Christian to depart. He returned to Holland, therefore, but Tilly started in pursuit and caught him at Stadthoorn, where on 28 July/6 August 1623 his army was all cut to pieces.  

Tilly's army marched to Friesland, which, like the Bohemians, had ordered collectively to evacuate the country and levies of troops that the members individually furnished either not at all or unwillingly, disbanded their army to prevent originating. So Mansfeld, too, having eaten up East Friesland, returned to Holland in 1624.  

The only material factor was now Tilly's ever-victorious Army of the League, but for the present it was suspended inactive in the midst of a spider's web of European Foreign Inter- vention. Spain and England had quarrelled. The latter became the ally of France, over whose policy Richelieu now ruled, and the United Provinces and (later) Denmark joined them. Thus the war was extended beyond the borders of the Empire, and the way opened for ceaseless foreign interventions. From the battle of Stadthoorn to the pitiful end twenty years later, the decision of German quarrels lay in the hands of foreign powers, and for two centuries after the treaty of Westphalia the evil tradition was faithfully followed.  

France was concerned chiefly with Spain, whose military possessions all along her frontier suggested that a new Austria, more powerful than Charles the Bold's, might arise. To Ger- many, only subsidies were sent, but in Italy the Valtelline, as the connecting link with France, was still in French hands, and Germany, was mastered by a French expedition. James, in conjunction with France, re-equipped Mansfeld and allowed him to raise an army in England, but Richelieu was unwilling to allow Mansfeld's men to traverse France, and they ultimately went to the Low Countries, where, being raw pressed-men for the most part, and having neither pay (James having been afraid to summon parliament) nor experience in plundering, they perished in the winter of 1625. At the same time a Hugenot rising paralysed Richelieu's foreign policy. Holland after the collapse of the French expedition was anxious for her own safety owing to the steady advance of Spinola. The only member of the alliance who intervened in Germany itself was Christian IV. of Denmark, who as duke of Holstein was a member of the Lower Saxon Circle, as king of Denmark was anxious to extend his influence over the North Sea ports, and as Protestant dreaded the rising power of the Catholics. Gustavus Adolphus of Sweden, judging better than any of the difficulties of avaricing the Empire and Spain, contented himself for the present with carrying on a war with Poland.  

Christian IV. raised an army in his own lands and in the Lower Saxon Circle in the spring of 1625. Tilly at once advanced to meet him. But he had only the Army of the League, Ferdinand's
troops being occupied with repelling a new入侵 of Gabriel Bethlen. Then, like a *danes ex machina*, Wallenstein, duke of Friedland, came forward and offered to raise and maintain an army in the emperor’s service. It was an army like Mansfeld’s in that it lived on the country, but its operations were systematic and its products economically used, so that it was possible to feed 50,000 men where Mansfeld and his like had barely subsisted 20,000. This method, the high wages which he paid his own men, his own uniforms and his own discipline, his personality gave it a cohesion that neither a free company nor an army of mere Lower Saxon contingents could ever hope to possess.

In 1625, in spite of Tilly’s appeals, Wallenstein did nothing but levy contributions about Magdeburg and Halberstadt, keeping his new army well away from the risks of battle until he could trust it. It was for this reason that he refused to take part in the siege of Frankfurt, and that he not only disregarded Christian IV, who had been joined by Mansfeld and Christian of Brunswick, had in 1626, 60,000 men. Wallenstein and Tilly together had only a very slight numerical superiority, and behind them was nothing. Even the hereditary provinces of Austria were threatening revolt owing to their having to maintain Maximilian’s troops (the new elector thus recouping his expenses in the Palatinate war) and Gabriel Bethlen was again in the field. But on the other side the English subsidies failed, and the Protestant armies soon began to suffer in consequence. Tilly opposed Christian IV., Wallenstein Mansfeld. The latter, having stood still about Lübeck out of fear that it was fortunate for Brandenburg that the food was exhausted, advanced upon Wallenstein, attacked him in an entrenched position at the Bridge of Dessau and was thoroughly defeated (15/25 April 1626). He then wandered across Germany into Silesia and joined Wallenstein. His resistance was broken up by Mansfeld’s strong positions, compelled Mansfeld and Bethlen to choose between attacking him and starving. So, without the latter, he was unable to live. Wallenstein, according to a later, was disarmed and Mansfeld was required to leave Hungary.

Mansfeld and Christian of Brunswick died soon afterwards, the one in Hungary, the other in Westphalia. King Christian, left alone and unable, without English subsidies, to carry on the war methodically, but took the offensive, as Mansfeld had done, in order to live on the Thuringian countryside. But Tilly, with whom Wallenstein had left part of his army, moved as quickly as the king, brought him to action at Lutter-am-Bärenberge in Brunswick and totally defeated him (17/27 August).

With this, armed opposition to Tilly and Wallenstein in the field practically ceased until 1636. But there was enough danger to prevent the disbandment of their armies, which continued to live on the country. In the intervening years the balance of forces, political and military, was materially altered. France opposed Spain and the emperor in Italy with such vigour as Huguenot outbreaks permitted, England quarrelled with France, but yet like France sent subsidies to the North German Protestants. Gustavus held his hand, while Christian slowly gave up fortress after fortress to the South. Protestant princes in the West and against Gabriel Bethlen, subdued Silesia, where a small part of Mansfeld’s army had been left in 1626, and afterwards drove Christian’s army through Jutland (1627). But Wallenstein, with his dreams of a united Germany free in conscience and absolutely obedient to the emperor, drifted further and further away from the League. Ferdinand thought that he could fulfill the secular portion of Wallenstein’s policy while giving satisfaction to the bishops. The princes and bishops of the League continued to oppose any aggrandizement of the emperor’s power at the expense of the latter. But in the assumption of the character of a last of the embattled, the two Western Protestant cities were strong enough to refuse to admit Wallenstein’s garrisons. In 1628 Wallenstein, who had received the duchy of Mecklenburg on its rightful lord being put to the ban for his share in the Danish war, began to occupy his new towns, and also to spread along the coasts, for his united Germany could never be more than a dream until the possibility of Danish and Swedish invasions was removed. But the Hanse towns rejected his overtures, and Stralsund, second-rate seaport though it was, absolutely refused to admit a garrison of his wild soldiers. The result was the famous siege of Stralsund (February to August 1628), in which, with some slight help from overseas, the citizens compelled the hitherto unconquered Wallenstein army to retire. The siege was, as the result proved, a turning-point in German history. The emperor’s policy of restoring order had practically universal support. But the instrument of the restoration was a plundering army. Even this might have been borne had Wallenstein been able to give them, as he wished, not only peace but religious freedom. But when Christian signed the peace of Lübeck, and the Edict of Restitution (1629) gave back one hundred and fifty northern ecclesiastical foundations to the Catholics, men were convinced that one ruler meant one religion. Rather than endure this the North Germans had called in Gustavus Adolphus, and, just as Gustavus landed, the resentment of the princes of the League against Wallenstein’s policy and Wallenstein’s soldiers came to a head, and the emperor was forced to dismiss him. His soldiers were taken over by Tilly, and for the surprise he disappeared from the scene.

A thoroughly trained and recently recruited army from good yeomen and good soldiers of fortune, paid good wages, and led by a great captain, was a novelty in war that more than compensated for Tilly’s numerical superiority. Gustavus, however, after landing at Peenemünde in June, spent the rest of the year in establishing himself firmly in Mecklenburg and Pomerania, partly for military reasons, partly in view of a future Swedish hegemony of the Baltic, and most of all in order to secure the active support of the more important Protestant princes, so as to appear as an auxiliary rather than a principal in the German conflict. Though Gustavus, and of course his brother, the elector William of Brandenburg joined him, very unwillingly. He was soon afterwards allied with France, by the treaty of Bärwalde (January 1631). John George of Saxony, still attempting to stifle the war by his policy of neutrality, sent a last appeal to Vienna, praying for the revocation of the Edict of Restitution. Meanwhile Tilly had marched into north-eastern Germany. On the 19/20 March 1631, the old general of the League destroyed a Swedish garrison at New Brandenburg, and although Gustavus concentrated upon him with a swiftness that surprised the old-fashioned soldiers, Tilly wasted no time in manoeuvres but turned back to the Elbe, where his lieutenant Pappenheim was besieging Magdeburg. This city had twice defied Wallenstein’s attempts to introduce a garrison, and it was now in arms against the League. But John George, their prince, had not yet decided to join Gustavus. The latter, as yet without active allies, thought it impossible to go forward alone, and could only hope that his sudden and brilliant storm (5/13 April) of Frankfurt-on-Oder would bring back Tilly from the Elbe. But the hope was vain. Tilly and Pappenheim pressed the siege of Magdeburg, and the citizens, directed by Swedish policy, thought desperately that the place was surrounded, sacked and burnt on the night of the 10th of May 1631, amidst horrors that neither of the imperialist generals was able to check, or even to mitigate. The Catholics rejoiced as though for another St Bartholomew’s day, the Protestants were paralysed, and even Gustavus, accused on all hands of having allowed the Magdeburgers to perish without giving them a helping hand, sorrowfully withdrew into Pomerania. But Tilly, in spite of Pappenheim’s remonstrances, turned westward against Hesse-Cassel and other minor principalities whose rulers had declared for Gustavus. The old duke of Brunswick, the elector of Saxony, and the elector of Brandenburg, then George William of Brandenburg joined him, very unwillingly. Pappenheim began the siege of Magdeburg (February 1632), where the army entrenched itself, and, in spite of sickness and famine, stoically awaited the attack. The desired result was achieved. At the end of July Tilly, returning from the west before he had accomplished his reduction, made his appearance and was twice repulsed (13/23 and 18/28 July), losing 6,000 men out of 22,000. Moreover, Ferdinand having in his moment of triumph flatly rejected John George’s appeal against the Edict, Saxony took up arms. Thereupon Tilly, turning away from Gustavus’s entrenchments, invaded Saxony, being reinforced en route by 20,000 men from Italy (the war there being left to the Spaniards). The elector at once made an alliance with the Swedes.

1 In which he exacted life for plunder and plunders for plunder in return for the slaughter at New Brandenburg.
Then Gustavus advanced in earnest. Tilly had taken no measures to hold him off while the invasion of Saxony was in progress, and he crossed the Elbe at Wittenberg. 16,000 Saxons joined the 26,000 Swedes at Dülben, and some of the western Germans had already come in. Tilly had just captured Leipzig, and outside his place was carried away by Pappenheim's enthusiasm, he gave battle on the 7/17 September to the now superior allies. The first battle of Breitenfeld (q.v.) was a triumphant success for Gustavus and for the new Swedish system of war, such a battle as no living soldier had seen. The raw Saxons, who were commanded by Armim, once Wallenstein's lieutenant, were routed by Tilly's men without the least difficulty, and the balance of numbers returned again to the imperialist side. But the veterans of the Leib-Mall were nevertheless driven off the field in disorder, leaving 6000 dead. Tilly himself was thrice wounded, and only the remnant of his own faithful Wallon regiments remained with him and bore him from the field.

All Protestant Germany hailed Gustavus as the liberator. Wallenstein, glad of the defeat of the Catholic army, proposed to co-operate with the Swedes. John George, the Swedish general Horn and the Swedish chancellor Oxenstierna united in advising Gustavus to march straight upon Vienna. Richelieu, who desired to humble Ferdinand rather than to disestablish the power of the Catholic princes, wisely left the matter at large. Gustavus deliberately chose to move into South Germany, there to relieve the Protestants oppressed by Maximilian, to organize the cities and the princes in a new and stronger Protestant Union, the Corpus Evangelicorum, and to place himself in a country full of resources whence he could strike out against the emperor, Tilly, and the Rhine Spaniards in turn. To the Saxons he left the task of rousing the Bohemian Protestants, perhaps with the idea of thoroughly committing them to the war upon Ferdinand. The Swedish army pushed on through Halle, Erfurt, Arnim, Altenburg, and Lübben to the "Pfaffengasse," the long lane of bishops and abbeys along the Main and the Rhine, it wintered in luxury. The Palatinate was reorganized under Swedish officials and the reformed religion established again. In March 1632 the campaign was resumed. Nuremberg and Donauwörth welcomed Gustavus. Tilly's army, rallied and re-organized for the defence of Bavaria, awaited him on the Lech, but after a fierce battle the passage was forced by the Swedes (4/11 April) and Tilly himself was mortally wounded. Augsburg, Munich and all the towns and open country south of the Danube were occupied without resistance. At the same time the John George's army entered Prague without firing a shot.

The emperor had now either to submit or to re-establish Wallenstein. Wallenstein demanded as the price of his services the reversal of the Edict, and power to dethrone every prince who adhered to the Swedes. His terms were accepted, and in April 1632 he took the field as the emperor's alter ego with a new army that his recruiters had gathered in a few weeks. He soon expelled the Saxons from Bohemia and offered John George amnesty. The latter declared the basis of the League of Heilbronn returned to the Palatinate, and while Horn and Banér operated against an imperial army under Aldringen in the Neckar country, Bernhard took Regensburg from Maximilian's army. But it was now late in the year and Wallenstein was intent upon peace. With this object he endeavoured to secure the higher officers of the army, but these were gradually won over by Spanish emissaries; the emperor, having decided to continue the war in alliance with Spain, dismissed his general for the second time. Wallenstein then openly attempted to unite the Swedish, Saxony and other Protestant armies with his own, so as to compel all parties to make peace. But his army would not follow, the coup d'état failed, and Wallenstein was murdered at Eger (15/25 February 1634). All unity, Catholic or Protestant, died with him, and for the
next fourteen years Germany was simply the battle-ground of French, Spanish, Austrian and Swedish armies, which, having learned the complicity and advantages of plunder in the school of Mansfeld and Wallenstal, reduced the country to a state of misery that no historian has been able to describe, save by detailing the horrors of one or other village among the thousands that were ruined, and by establishing the net result that Germany in 1645 was worse off than England in 1485, so much worse that while England was the healthier for having passed through the fever of the Wars of the Roses, Germany remained for 150 years more in the stillness of exhaustion.

Success was for the present with the emperor and Spain. Gallas, now without contesting for the imperial crown, and with his companion from boyhood, whereas Bernhard, the Rupert of the German war, disagreed with Horn. Under the leadership nominally of the king of Spain, the imperialists now overthrew the Spaniards in Catalonia, captured Regensburg and Donauwörth, and when the Spanish Cardinal Infante joined them with 15,000 men on his way from Italy to the Netherlands, they were invincible. Bernhard attacked them in an entrenched position at Nördlingen (27 August, 6 September 1634) and was beaten with a loss of 17,000 men to 2000 of the defenders. Nördlingen was to

Battle of Nördlingen (6 September 1634) and was beaten with a loss of 17,000 men to 2000 of the defenders. Nördlingen was to

**Aggressive policy of France**

The French army numbered 130,000 men in 1635, and 200,000 in the year after. One army assembled in Upper Alsace and another occupied Lorraine, which had been conquered in 1633; a corps under Henri de Rohan was despatched from the south. The most complete and dazzling achievement of fortune met with en route, to expel the enemy from the Valtelline, and so to cut the route to the Netherlands. Another force, co-operating with the duke of Savoy, was to attack the Milanes. Bernhard's army was prepared to defend the Neuf in the last days of October, when the French garrisons holding the places of Alsace. Having thus arranged to isolate the Spanish Netherlands, Richelieu sent his main army, about 30,000 strong, thither to join Frederick Henry of Orange and so to crush the Cardinal Infante. This was strategy on a scale hitherto unknown in the war. Tilly, Wallenstein and Gustavus had made war in the midst of political and religious troubles that hung over centrifugal tendencies. They had made war as they could, not as they wished. Richelieu had unified France under the absolute authority of the king, and his strategy, like his policy, was masterful and clear. But the event proved that his confederates were unable to hold with an unshakable grip the neck of the Spanish power when Gallas and the imperialists were at hand. As a great undertaker in the State and absorbed large forces. But not content with this Richelieu cultivated a climate of pious sentiments and a feeling of sympathy at the same time as he separated them. His forces were not sufficient for these tasks and he was therefore compelled to give battle, both in the Netherlands and in Germany, working with allies whose interests were not his. The army on the Meuse won a victory at Avins, south of Huy, and afterwards joined Frederick Henry in the siege of Nancy. The capture of Nancy and Montmédy in sixties of warfare parted so far from their former associates over the Waal that the inroad of Frederick Henry's army proceeded. Gallas was one of those rare outbursts of a momentary "people's war," which occur from time to time in the world of 18th centuries. The effect of it was that Frederick Henry withdrew to his own country, and in 1636 the French northern army had to face the whole of the Cardinal Infante's forces. In Italy the Franco-Piedmontese army achieved practically nothing, the gathering of the French contingent and its passage of the Alps consumed so much time. But the French took a successful mountain campaign, which even to-day is quoted as a model of its kind.

The Spanish and Lorraine, besides the Spaniards, the dispossessed duke of Lorraine was in the field against the French. Neither side was strong enough to prevail completely. Bernhard waged a desultory campaign in Germany, and then, when supplies gave out, he took refuge with his advancing army on the frontier of Austria, and the year's army was taken into the French service, he himself remaining in command and receiving vague promises of a future duchy of Alsace. Gallas's army from Frankfurt-on-Main pushed far into the Rhine basin, but his strength was not sufficient to compel it to retreat. In eastern Germany the consequences of the peace of Prague were that Saxony, Brandenburg and other states, signing the peace in the spring of 1635, were the first to continue the war. Thus John George turned his arms against the Swedes in his neighbourhood. But their commander Banér was as superior in generalship as he was inferior in numbers, and held the field until the renewal of Gustavus's peace with Poland, which expired in this year, set free a fresh and uncorrupted Swedish corps that had been held ready for eventualities in that country. This corps, under Torstensson, joined him in October, and on the 1st December the Swedes were invested by the imperialists.

Thus Richelieu's great scheme was only very partially executed. The battle of Avins and Rohan's Valletine campaign, the only attempt to re-established the line of battle against the southern French, was one of those accidents within Germany in which within German men were chiefly occupied in considering whether to accept the terms of the peace of Prague. But the land had no rest, for the armies were not disbanded.

In the Netherlands the campaign in 1635 were carried out with energy. John George, aided by an imperialist army, captured Magdeburg, drove back Baner to Lüneburg, and extended his right wing (imperialists) through Mecklenburg into Pomerania, where, however, a Swedish force under the elder Wrangel checked its progress. The Saxons then passed over the Elbe at Tangermünde and joined the imperialists, threatening to interpose between Baner and the Baltic. But Baner was too quick for them. He destroyed an isolated brigade of imperialists at Perleberg, and before the Brandenburg contingent could join John George, brought on a general action at Wittstock (29 September 4 October 1636). The battle was decided in three hours, 27 August, and Baner was able to attack both in front and rear. But while his first entrenchments defied the frontal attack Baner threw the most of his army upon the enveloping force and crushed it. The Wittstock, the king of Denmark, 11,000 killed and wounded, the combined army 11,000 killed and 8000 prisoners. The prestige of so brilliant a victory repaired even Nördlingen, and many North German princes who were about to make peace took fresh heart.

In the west, though there were no such battles as Wittstock, the campaign of 1636 was one of the most remarkable of the whole war. The Cardinal Infante was not only relieved by the retreat of the Dutch, but also reinforced by a fresh army under a famous cavalry officer, Johann von Weert. He prepared, therefore, to invade France from the north-west. Even though the army that advanced at the end of October from the Franche Comté, was delivered to the French, the French were too much scattered to offer an effective resistance, and Prince Thomas of Savoy-Carignan and Johann von Weert, the Cardinal Infante's generals, took Corbie, La Capelle, and some other places, passed the Somme and advanced on Compiègne. For a moment Paris was in danger, but the Cardinal Infante, by ordering Prince Thomas not to go too far in case he was needed to repel a Dutch inroad into Belgium, missed his opportunity. Louis XIII and Richelieu turned the Parisians from panic to enthusiasm. The burghers turned and won a battle at the dilapidated walls, and the old Huguenot marshal, Jacques Nompert, duc de La Force (d. 1642), standing on the steps of the Hôtel de Ville, raised men for the regular army by the hundred. Money, too, was willingly given, and some 12,000 volunteers went to Compiègne, whither Gaston from Orleans, Longueville from Normandy, and Condé, from Franche Comté, brought levies and reinforcements. Thus the army at Compiègne was soon

2 Composed partly of Bavarians who had fought their way from the battle of the Leuth to the Wesser, partly of Cologne troops who had joined the Bavarians against the Protestants of north-west Germany.
In the north-east, the effect of Wittstock proved but transient. Though the Swedes had driven the Hesse-Cassel, after an attempt at resistance, agreed to the treaty of Frankfurt. But the Swedes, taking Erfurt and Torgau found himself the target of several opponents—the Bavarians under Götz, who had remained on the Western Rhine, but had met the Swedes with skill, but had passed into Belgium in 1635, the beaten army of Wittstock, and a potential Brandenburg contingent. The Swedes did no more than defend their own country, but the imperialists and the inhabitants of Belgium, whose defeat he had envisaged, but who had been compelled by the surcease of the Swedes, were left the job of clearing the way for the Swedes, and the conquest of Coburg, which Monsieur’s army recaptured in November.

The gallantry of the defenders, which bore heavily on the townpeople, was rewarded by a singular trait of professionalism. The Swedes had attacked the entrenchments of Maubeuge, in winter quarters, and the garrison of Coburg, it is said, surrendered in good time in order not to be omitted in the allotment of comfortable billets in Belgium.

During the episode of Coburg another storm burst on the eastern frontier of France. The prince of Condé, governor of Burgundy, had in the spring entered Franche-Comté and besieged Dôle, but the inhabitants as well as the Spanish troops vigorously opposed him, and his army ultimately went south to that of Gaston. But, although Duke Charles IV, was active in the north-east, the armistice of the end of the French war with the Low Countries Prince Thomas and Piccolomini repulsed in turn the Dutch and the French. In the south Condé led from Bayonne an army that crossed the Pyrenees and joined the army in the Low Countries. Gaston, however, continued his small war in Lorraine with some success.

The name of Savoy with his own army and a French corps under Créqui advanced to the Ticino, and an action in which both sides lost several thousand men was fought at Tornavento a few miles from the future battlefield of Mantua, for which in its details this affair bears a singular resemblance (June 22, 1636). But the victory of the French was nullified by the refusal of Victor Amadeus, for political reasons, to advance on Milan, and Rohan, who had come down from the Valtelline to co-operate, hastily drew back into his stronghold. On the edges of the western Pyrenees a few towns were taken and retaken.

The campaign of 1637, on the French and Spanish side, was not particularly favorably disposed to either party. From Catalonia a Spanish army invaded Languedoc that was brought to a standstill in front of the rocky fortress of Leucate and defeated with heavy losses by the French relieving army under Schomberg, duke of Schauenburg (July 9th). But in August the Valtelline the Valtelline the lord regiments by Rohan mutinied for want of pay and Rohan had to retire to France. On the Low Countries frontier the cardinal de La Valette captured Câble Cambrai, Landrecies and Maubeuge, and, in the Low Countries, the landgrave of Hesse-Cassel, the duke of Savoy and the duke of Mantua, which occurred almost simultaneously, affected the political foundations of the war but little. The balance, such as it was, however, was unfavourable to France, for the duchess of Mantua went over to the imperialists and the duchess of Savoy was opposed by the princes of her house. On the other hand, Ferdinand III., in spite of Spain, had to concede more power to the electors as the price of the imperial dignity.

On the Rhine and in the adjacent countries Johann von Weert, returning from Belgium with his Bavarians, captured Ehrenbreitstein and marauded the French and expanded small French detachments from the elector of Trier, whose ruler, the archbishop, had been put to the ban by the emperor. Then, passing into the Main valley, he took Hanau. The main imperial army was deployed from Alsenz to the east in order to repair the disaster of Wittstock, and Charles of Lorraine, with his own small force and a detachment of French cavalry, beat them off at the Saône in June, after which Bernhard advanced vigorously against Piccolomini, the imperial commander in Alsenz, and crossed the Rhine at Rheinau. But soon Piccolomini was joined by Johann von Weert, and Bernhard retired again.

1 For the first time in the history of western Europe Cossacks appeared on French territory, and they were marked by extraordinary atrocities. They did not remain long at the front, for their insubordination and misconduct were so flagrant that even Gallas found them intolerable and dismissed them.

In 1638 the French operations in Italy, Belgium and Spain were in the main unsuccessful. In Italy Créqui was killed in an action on the 17th of March, and the Spanish commander in the mouth of the Po, the future duke of Savoy, also princely in the Low Countries Prince Thomas and Piccolomini repulsed in turn the Dutch and the French. In the south Condé led from Bayonne an army that crossed the Pyrenees and joined the army in the Low Countries. Gaston, however, continued his small war in Lorraine with some success.

The campaign of 1637, on the French and Spanish side, was not particularly favorably disposed to either party. But soon Piccolomini was joined by Johann von Weert, and Bernhard retired again.

In 1639, as before, Richelieu’s attacks on Spain, other than those directed upon Alsace and Baden, were unsuccessful. In the north the French devoted this year, as they had devoted 1637 to the siege of Innsbruck, for the purpose of maintaining the view of a future frontière de fer. The two objectives selected, Besin and Thionville, were far apart, and the imperial army to which Piccolomini was posted midway between them. Piccolomini, by a forced march from Liége and Huy through the Ardennes, flung himself upon the besiegers of Thionville before their "circumvallation" became complete, and after a short but hard siege annihilated them (June 7, 1639) before the covering or rescuing army had even passed the Argonne. Then, however, Piccolomini, whose troops had bought the victory dearly, stood still for a time,
Thirty Years' War

and Hesdin, besieged with much pomp by Richelieu's nephew, La Meilleraie, surrendered on the 29th of June. On the side of the Pyrenean Condé as usual showed himself both unlucky and incapable. In Italy Cardinal de La Valette died, after allowing Prince Nino Savelli to take the city of Leggiuno, the most important French post except Casale, Chiavasso and the citadel of Turin taken by Thomas and Legrez.

The return of Harcourt, called by his men "Cadet-la-Perle" on account of his earrings, but a bold and exceedingly competent soldier. Under him served Turenne, hitherto known only as a younger brother of the duke of Bouillon. Harcourt reviewed them for the first time, and asked for the opinion of the review he advanced from Carignano to revisit Casale, detaching Turenne as flank-guard to hold off Prince Thomas on the side of Turin. The enterprise was entirely successful, but Thomas and Legrez was at one moment cut off as Harcourt, in the meantime, out-manoeuvred Legrez bested a defile on the Chiari-Carignano road (whence the action is called the Route de Quiers) while Thomas lay in wait to the north of Turin and the flank-guard sharply repulsed the prince, and by hard fighting the French returned safe and victorious (November 29th).

In Alsace Bernhard was carried off by a fever just as he was prepared to fight his way in a junction with him. He was fortunate in the opportunity of his death, for his dream of a duchy of Alsace had already brought him into conflict with Richelieu, and their conflict could hardly have ended more happily than in the death of the latter. Once took steps to secure his army 1 for the service of France, and Richelieu's officers were placed in charge of the country. But Bernhard had already decided that the long negotiations between the landgrave of Hesse-Cassel and the various powers ended in her allying herself with France and raising an army in return for a subsidy. Another event of importance in this year was the death of the last of the Palatinate princes, Palatine Charles.

Fate of the Spanish fleet.

In 1640 the French still kept up their four wars in Belgium, Germany, Italy and Spain. But the Belgian and Spanish frontiers were no longer directly attacked. On the side of Languedoc there was no further danger from the foolish imposition of strict defensive forms, and equally foolish threats to punish those who did not appear at the rendezvous, caused the Catalans, who were already defending themselves against the French both efficiently and vigorously, to turn their arms against the old enemy Castle. In December 1640 Portugal declared herself independent under a new king of the house of Braganza. In the Low Countries Louis XIII, hitherto unable to give his usual important forces of Arras, which surrendered on the 8th of August.

In Italy, however, Cadet-la-Perle kept the moral ascendancy he had won in the previous year. On the 16th of December 60,000 men he advanced from Carignano against the 20,000 Spaniards who were besieging Casale and attacked their line of circumvallation boldly and openly on the 29th of April. He himself led horseback led his stormers over the parapet.

In Germany Baner's course was temporarily checked. The archduke dialogued from him his few remaining posts in Bohemia, and when at last Bernhard's old army, under the duke de Longueville, crossed the Rhine at Bacharach and joined Baner in Thuringia, the latter, with his small army of 30,000 men, the broken country about Saalfeld until the country would no longer support the combined army. The Weimar and Hesse-Cassel armies retired to the Rhine at Welden, and, in the hope of detaching both German armies, the landgrave of Hesse-Cassel from the Swedish alliance, the imperial general wasted their territories, ignoring Baner. After the departure of the Swedes the imperial army,疗法 aghast to find the French army on their flank, the Swedish general could only watch for his opportunity.

This came in the winter months of 1640-1. Negotiations for peace were constantly in progress, but no result seemed to come out of them. The Swedes were assembled at Reenshausen, and the French army scattered over north-western Germany. Baner suddenly moved south heading for Ratisbon, for the defence of which the Swedes called the young Piccolomini's from the upper Rhine— were hurried up by the emperor. The Weimar Army under Guébriant joined the Swedes on en route, and the combined army reached the objective. But a thorn hindered them and gave them the time to concentrate his forces, and after a series of minor operations Baner's army found itself again in possession of Hesse, Lüneburg, Brunswick, etc. Guébriant's army, however, had again separated from him in order to live, and in May was at Berlin, and the remainder of the army was assembled at Karlsburg, 16 miles south of Schaumburg, to the north of the Rhine. The battle took place on the 20th of May Baner, worn out by fatigue, died, and after some intrigues and consultations the army elected the Count of Turenne to command. The last fortified place held by the Austrians in Lower Saxony, Wolfenbüttel, was now besieged by Torstensson's Swedes and Germans and Guébriant's French and Walenriachers, and the archduke, on the 20th of May, advanced with the army of the United Provinces, and outside the walls on the 29th of June. The war had now receded far from Alsace, which was firmly held by France, and no longer threatened even by Charles of Lorraine, who had made his peace with Louis XIII in the spring, and whose army had followed Guébriant into Germany. The losses of the Germans at Wolfenbüttel caused some of their princes to accept the peace of Prague, but the Holy Roman Emperor, Charles Leopold (Frederick William, the Great Elector) gave up the Austrian alliance and neutralized his dominions.

In 1641 Harcourt thoroughly established his position, without much help from Hungary. The Spanish insurrections continued and the French occupied Barcelona, but underwent a serious reverse at Tarragona. In the north La Meilleraie captured and held some of the Artois towns, but was driven out of the open country by the superior army of the Cardinal Infante. A formidable conspiracy against Richelieu brought about a civil war in which the king's troops were defeated at Marfaie, near Sedan (the fortress of Turenne's discontented brother, the semi-independent duke of Bouillon), by a mixed army of rebels, Spaniards, and Imperialists (July 6th). This, however, led to nothing further and the cardinal further his conquests. But his thanks for having joined the rebels, his newly regained fortresses were reoccupied by the French.

In December 1641 there began at Münster and Osnabrück in Westphalia the peace negotiations which, after eight more years of spasmodic fighting, were to close this ruinous war.

In 1642 Torstensson, having cleared up the war for a moment in the north-west, turned upon Silesia, defeated an imperialist corps at Schweidnitz and took some fortresses, but drove back when the archduke and Piccolomini came up with the main Austrian army. In October, however, he was joined by fresh troops from the north-east, crossed the Elbe and besieged Leipzig. The imperialist army, which was joined by the Saxons when their country was again the theatre of war, marched to the assistance of Torstensson. The battle of Leipzig was of enormous loss in the second battle of Breitenfeld 2 (November 1642).

But, although the Austrians feared an advance on Vienna itself, the victors waited for the fall of Leipzig and then took up winter quarters. Guébriant had throughout the year operated independently of the Swedes. The Bavarians had advanced into the lower Rhine region in order to support, in concert with the Belgian army of Spain, a fresh outbreak in France (Cinq-Mars, 1642). The emperor, with the field army, had driven the French from the Rhine, and before the new offensive Torstensson's army, strengthened and reinforced from the Netherlands, was made not simultaneously but successively, and Harcourt moreover was able to reinforce his army with herds of cattle. The French received fresh troops and a large convoy. The citadel was relieved and the town surrendered soon afterwards. Legrez retired to Milan, Prince Thomas was allowed to take his few remaining troops to Lyons, and recognized the duchess's regency.

"Forstalling others who desired its services, notably the Winter King, who intended to allay his quarrel with Spain and to force the retrocession of the Palatinate"! 3

The emperor executed all the officers and every tenth man of the regiment in which the panic began.

3 The emperor executed all the officers and every tenth man of the regiment in which the panic began.
Melo, the Cardinal Infante's successor, did not profit by his victory, turning back instead to oppose the Dutch and Guébriant. In Italy, Thomas of Savoy and his brother, submitting to the regency of the duchess, led her troops in concert with the French against the Spaniards of the Milanese, and took Tortona. Louis himself conquered the main part of the Casale Marittima and the Mars by executing its leaders, and Marshal de la Motte-Houdencourt held Catalonia and defeated Leganés at Lerida (October 7th).

Before the next campaign opened Louis and Richelieu were dead. One of the last acts of the king was to designate the young duc d'Enghien, son of the incapable Condé, as general of his northern army. Harcourt had strangely failed, Guébriant was far away, and the rest of the French must again experience but incapable of commanding an army.

Yet it was no small matter to put in their place a youth of twenty-one, who might prove not merely inexperienced but also incompetent. But Enghien's victory was destined to be the beginning of the Spanish army of a long hegemony of military Europe.

Melo had selected the Meuse route for his advance on Paris. On it he would meet only the places of Rocroi and Rethel; these mastered, he would descend upon Paris by the open lands between the Marne and the Oise. He hoped by a feint against Landrecies, and under cover of this secretly massed his Sambre and Ardennes corps on the Meuse, while Enghien, having the safety of Landrecies in mind, moved to St Quentin. There, however, the young general learned at the same moment that Louis XIII was dead and that the Spaniards had invested Rocroi. With the resolution and swiftness which was his whole career, he marched at once to offer them battle. Enghien's more experienced counsellors, the generals of the old school, were for delay. To risk the only French army at such a moment, they said, was madness, and even the fiery Gassion asked, "What will become of us if we are beaten?" But Enghien replied, "That will not concern me, for I shall be dead," and his personality overcame the fears of the doubters.

The battle took place on the 10th of May 1643, in a plain before Rocroi, without any marked tactical advantage of position on either side. Melo's cavalry was routed, and nearly all the infantry, 18,000 men of the best regiments in the Spanish army, the old Low Countries tercios, with their general the Conde de Fuentes, a veteran of fifty years' service, in their midst, stood their ground and were assailed on every side. Two hundred and sixty colours and standards went to grace Nâtre Dame.

But even Rocroi, under the existing conditions of warfare, was decisive only in so far as, by the destruction of Spain's superiority in Belgium, it saved France from further inroads from the north. Enghien indeed followed up the débris of Melo's army beyond the Sambre, but on the Rhine Guébriant, who had marched away from the region of Cologne into Württemberg, and there was nothing to prevent the imperialists in the northwest from joining Melo. The thorough establishment of the French on the Rhine and the need of co-operating with the Swedes was considered by the young general to be more important than fighting Melo in front of Brussels, and in spite of the protests of the Regent and Mazarin, he decided to attack Thionville. Taking a leaf out of Melo's book, he threatened Brussels in order to draw all the defenders thither, and then suddenly turned eastward. Enghien arrived on June 18th, a corps from Champagne had already reached the place on the 16th, and on the 8th of August Thionville surrendered. The small fortress of Sierck followed suit (September 8th).

Guébriant meanwhile had attempted without success to cover the French and Protestant posts in Württemberg against the united forces of his old opponents from the lower Rhine (Hatzfeldt's Bavarians) and a fresh Bavarian army under Mercy, and had retired into Alsace. Reaching Enghien he discovered his army was decimated into three-quarters in October, sent him a corps under Josias Ranzau to enable him to recross the Rhine and seize winter-quarters in Germany so as to spare Alase. Guébriant did so, but he was mortally wounded in the siege of Rottweil, a town at the source of the Neckar, and Ranzau, taking over the command, allowed himself to be surprised. This disaster was explained away by Charles of Lorraine (who had again changed sides and now commanded his own, Hatzfeldt's and Mercy's armies). At Tuttlingen on the headwaters of the Danube, Ranzau was taken prisoner, with the loss of 12,000 men, which under Piccolomini manoeuvred for a while to the west of Dresden. But Piccolomini was replaced by Gallas, who, though cherish ing visionary schemes of uniting Hatzfeldt's troops and Lestocq's Cologne-Bavarian-North German army with his own for a decisive blow, had in fact to fall back through Bohemia. The Swedes followed. Taking the small towns and avoiding the large places, Torstensson swept through Bohemia and Moravia in his steps dogged through the devastated country by Gallas, until he reached Brünich. Thence, however, he suddenly retreated to the shores of the Baltic. Christian of Denmark had declared war on Sweden, and threatened to isolate the Swedish forces in Germany. Torstensson, therefore, wintered in Holstein, Gallas, unable to follow him through districts already eaten up, in Saxony. In Italy and Switzerland he carried on the same operations without any result.

In 1644 Gascogne of Orleans, with La Meilleraye and Gassion under him, began the conquest of the Dunkirk region, capturing Gravelines in July. Melo, having no army to oppose them, and having invaded land and water, was forced to retreat. Marshal Plessis-Praslin undertook nothing serious, while Turenne's march in Spain La Motte-Houdencourt lost Lerida, and was ineffective in Italy, also.
cousin the landgrave of Hesse-Cassel. But at this point the army, headed by Bernhard's old colonels, demanded to be put into rest-quarters, and Turenne allowing them to disperse as they wished, was surprised by Mercy and Weert—who brought his courage of nothing else. The battle of Jarnac placed two-thirds of his forces. But Turenne instead of retreating to the Rhine installed himself in the landgrave's country, which was defended by a few Hessians and Swedes, while Engihr hurled up from the Moselle, in pursuit of the Rhine, the disaster. The "Army of Weimar" and the "Army of France" joined forces, as in 1643, almost under the eyes of the enemy. Engihr, pushing the French from Ladenburg, by Heilidelberg, Wimpfen, Rotterburg and Dinkelsbühl. But from day to day the balance leaned more and more on the French and Turenne, after Hadamar, threatening Vienna (April), had drawn off into Moravia, where he was thrown into a desperate struggle. The emperor was able to give Maxilian an Austrian corps to be added to Mercy's army. Mercy therefore, after manoeuvring for some time, Engihr, who was a strong position atAllerhein near Nördlingen, directly barred the way to the Danube. The second battle of Nördlingen (August 3, 1645) was as desperately fought as the first, and had not Mercy been killed at the crisis of the day, Engihr would probably have been disastrously defeated. As it was, the young duke was victorious, but he had only 1500 infantry left in rank and file out of 7000 at the end. Soon afterwards Engihr fell ill, and his army returned to France. Turenne, left with a few thousand men only, attempted in vain to hold his ground in Germany and had to make a hasty retreat before the archduke Leopold William, who had made peace with Rakóczy, and, leaving Torsentsson's successor Wrangel in Bohemia, was driven by the imperialists under their new general, Melander-Holzapfel. As the few obtainable supply of men was not enough to hold the line, the Siemens crossed the Rhine to give the enemy and his army to the enemy's rear-guard, and Melander-Holzapfel was forced to retire before him. Turenne entered Wedberg, and took up the pursuit of the defeated army. But before he settled down into winter quarters he sent a corps to the Moselle, which dislodged the Imperialists from the river and regained the position of his predecessor in the Danube. In Flanders, Gascort of Orleans conquered a number of their strongholds. In Saxony, the Low Countries, and the Danube, the archduke Leopold William and the Bavarians followed suit.

The campaign of 1646 in Hesse up to August was as usual uneventful, each army being chiefly concerned with its food. But at last the archduke retired a little, leaving Turenne and Wrangel free to join their forces. Turenne had no intention of repeating the experiences of Freiburg and Nördlingen. War had by now settled down into the groove whence it did not issue till 1703. It was more profitable to attack the small objects that were sought by manoeuvre than by battle. The archduke Leopold William decided to lay between the Rhine and the enemy's army in their district, and breaking it up by starvation, and pushing one's own army into rich districts regardless of the enemy's army. The usual practice was the first method. Turenne chose the second. Delayed at the opening of the year by orders from Mazarin to stand still—the elector of Bavaria had opened negotiations in order to gain time for the archduke Leopold William to march into the west—Turenne found it impossible to reach Hesse by the short and direct route, and he therefore made a rapid and successful march through the Rhine as far as Wesel, whence, crossing unopposed, he joined Wrangel on the upper Lahn (August 10th). The united armies were only 19,000 strong. Then the Imperialists, fearing to be hemmed in and starved between Turenne and the Rhine, fell back to Fulda, leaving the Munich road clear. The interior of Bavaria had not been fought over for eleven years, and was thus almost the only prosperous land in desolated Germany. Turenne and Wrangel marched straight forward on a broad front. On the 22d of September, far ahead of the pursuers, for whom they left nothing to eat, they reached Augsburg, and for the rest of the year they devastated the country about Munich in order to force Maximilian to make terms. An armistice was concluded in the winter, Maximilian having been finally brought to consent by an ill-judged attempt of the emperor (who desired that Bavaria would go the way of Brandenburg and Saxony) to secure it for his army. The French and Swedes wintered in southern Württemberg.

In Flanders, Gaston of Orleans and Engihr took Dunkirk and other fortresses. In Italy, where the Tuscan fortresses were attacked, the French and Prince Thomas their ally were completely checked at first, until Mazarin sent a fresh army under his son, the Prince of Condé, to replace them. The campaign of 1647 was a battle of the Low Countries Spaniards, concluding with a truce with the Dutch, threw their whole force upon France, but this attack dissipated itself in sieges. In Italy Plessis-Praslin won an unprofitable victory over the viceroy of the Milaneses on the Oglio (July 4th). In Spain Condé, resuming the siege of Lerida, was repulsed with even more loss than Harcourt had been the year before, and had to retire upon the mere appearance of a relieving army. In Germany Turenne and Wrangel parted company. The latter returned to Hesse and Bohemia, but was driven back by the imperialists under their new general, Melander-Holzapfel. As the few obtainable supply of men was not enough to hold the line, the Siemens crossed the Rhine to give the enemy and his army to the enemy's rear-guard, and Melander-Holzapfel was forced to retire before him. Turenne entered Weiden, and took up the pursuit of the defeated army. But before he settled down into winter quarters he sent a corps to the Moselle, which dislodged the Imperialists from the river and regained the position of his predecessor in the Danube. The Weimar Army had refused to follow him to the Meuse, and mutinied for their arrears of pay. Turenne, the campaign of 1648 brought the decision at last. Turenne and Wrangel, having refitted their forces and united in Hesse as in 1646, steadily drove back the imperialists and Bavarians, whose 30,000 combatants were accompanied by a horde of nearly 130,000 hangers-on—men, women and children—to the Danube. For a moment, at Nördlingen, in the French and the Swedes separated, but they soon reunited, moved on to and beyond the Danube, and at Zusmarshausen (May 17th) catching the enemy in the act of manoeuvring, they destroyed his rear-guard, Melander being amongst the dead. The battle of Zusmarshausen was a drama; the Inn, but Piccolomin, was crossed; the Turenne and Wrangel advanced, and the Tabulae Frisonis, iii. and iv.; lives of Turenne, Condé, Wallenstein, Gustavus, &c.; vols. ix. and x. of Clausewitz's works; Lorenzzen, Schwedten Armee im 30jähr. THISTLE—THÖKÖLY

THISTLE, a name, as generally employed, of vague application, being given to almost any herbaceous plant that is of a spiny character. More strictly, it is applied to the species of Cardius. These are Composite herbaceous, which was to be followed by the bracts surrounding a head of purplish-white, tubular, five-parted flowers seated on a pitted and hairy receptacle. The anthers have appendages both at the apex and at the base, and the style has a ring of hairs at the point of bifurcation of the two stigmas. The fruit is surrounded by a tuft of silky-white hairs. The species, chiefly natives of Europe and Western Asia, are numerous, and some are of great beauty, though, not unnaturally, looked on with disfavour by the farmer. The blot and numerous allied species have medicinal properties.

THISTLEWOOD, ARTHUR (1770-1820), an officer; also a political instigator of the Cato Street conspiracy, a plot formed to murder many British ministers in 1820. A son of William Thistlewood, and born at Topham Place in Lincolnshire, young Thistlewood passed his early years in a desultory fashion; he became a soldier and visited France and America, imbuing republican opinions abroad and running into debt at home. Then taking up his residence in London he joined the Spencean Society, a revolutionary body; associated himself with James Watson (d. 1838) and other agitators; and in December 1816 helped to arrange a meeting at Westminster Hall, by which the machine of the Tower of London and the Bank of England, and by a general revolution. The proposed rising was a dismal failure, but the Hebeans Corpus Act was suspended and Thistlewood and Watson were seized, although upon being tried they were acquitted.

Becoming more violent Thistlewood formed other plots, talked of murdering the prince of Wales, and was sentenced to a year's imprisonment for challenging the home secretary, Lord Sidmouth, to a duel. After his release in May 1819, having broken away from Henry Hunt and the more moderate reformers, he prepared a new and comprehensive plot. On the 23rd of February 1820, at a time of great distress and during the unrest caused by the death of George III, the cabinet ministers had arranged to dine at the earl of Harrowby's house in Grosvenor Square. Thistlewood knew of the dinner. With some associates he hired a room in the neighbouring Cato Street, collected arms and made ready to fall upon Harrowby's guests. However, the authorities had been informed of the plot, probably by one of the conspirators named George Edwards; officers appeared upon the scene and arrested some of the conspirators; and although Thistlewood escaped in the confusion he was seized on the following day. Tried for high treason, Thistlewood and four others were sentenced to death, and were hanged on the 1st of May 1820.

See Sir S. Walpole, History of England (1890), vol. i.

THÖKÖLY, IMRE (EMERICH), PRINCE (1657-1705), Hungarian statesman, was born at Késmark on the 20th of September 1657. He lost both parents while still a child. In 1670, fleeing from the dangers of Upper Hungary, where the Protestants and Imperialists were constantly in arms against each other, he took refuge with his kinsman Michael Teleki, the chief supporter of Michael Apafi, prince of Transylvania. Here he came into contact with the Turks, possibly because of his previous hopes of the high-born, highgifted youth who was also a fellow sufferer, a large portion of his immense estates having been confiscated by the emperor. The discontent reached its height when Leopold (Feb. 27, 1673) suspended the Hungarian constitution, appointed Johan Gaspar Ampringen dictator, deprived 450 Protestant clergy of their livings and condemned 67 more to the galleys. Encouraged by promises of help from Louis XIV, the Magyars now rose pro libertate et libellis, and chose the youthful Thököly as their leader. The war began in 1679. Upper Hungary and the Transylvania were soon in Thököly's possession.

In 1681, reinforced by 10,000 Transylvanians and a Turkish army under the pasha of Nagyvârd, he compelled the emperor to grant an armistice. On the 15th of June 1682 he married Helen Zrínyi, the widow of Prince Francis Rákóczi I. Thököly's distrust of the emperor now induced him to turn for help to the sultan, who recognized him as prince of Upper Hungary on condition that he paid an annual tribute of 40,000 florins. In the course of the same year Thököly captured fortress after fortress from the emperor and his allies, but in the end the emperor won. The arrangement by which his son was to receive the title of king offered to him by the Turks. At the two diets held by him, at Kassa and Tálya, in 1683, the estates, though not uninfluenced by his personal charm, showed some want of confidence in him, fearing lest he might sacrifice the national independence to the Turkish alliance. They refused therefore to grant him either subsidies or a levée en masse, and he had to take what he wanted by force. Thököly materially assisted the Turks in the Vienna campaign of 1683, and shared the fate of the gigantic Turkish army. The grand vizier nevertheless exchanged the title of the Hungarian prince for one of the new titles that were made from Adrianople. Thököly was again invited to Adrianople to defend himself before the Diet, but, declining to go, he placed himself in the care of the sultan, who promised to receive him at his next visit to Adrianople.

In 1686 Thököly was released from his dungeon and sent with a small army into Transylvania, but both this expedition and a similar one in 1688 ended in failure. The Turks then again grew suspicious of him and imprisoned him a second time. In 1690, however, the Turks despatched him into Transylvania a third time with 16,000 men and, in September, he routed the united forces of General Heister and Michael Teleki at Zernest. After this great victory Thököly was elected prince of Transylvania by the Kereszténymező Diet, but could only maintain his position against the imperial armies with the utmost difficulty. In 1691 he quitted Transylvania altogether. He led the Turkish cavalry at the battle of Slankamen, and in fact served valiantly but vainly against Austria during the remainder of the war, especially distinguishing himself at Zenta. He was excluded by name from the amnesty promised to the Hungarian rebels by the peace of Karlowitz (Jan. 26, 1699).

After one more unsuccessful attempt, in 1700, to recover his principality, he retired to Galata with his wife. From the sultan he received large estates and the title of count of Wladin. He died in 1705. He was buried in the great Armenian cemetery at Nicosia, but in the course of 1906 his relics were transferred to Hungary.

See Correspondence of Thököly (Hung.), ed. by Kálmán Thaly (Budapest, 1896); V. Frnak, Papii Innocens XI. und Ungarn's Befreiung von der Türkenscherehtschaft (Freiburg, 1902); Memoirs of
THOLOBATE—THOMAR

THOLOBATE (Gr. βλόθος, a circular structure, dome, and βάςison, a base), the architectural term given to the cylindrical drum on which a dome is raised. In the earlier Byzantine churches, the dome rested directly on the pendentives and the windows were pierced in the dome itself; in later examples, between the pendentive and the dome an intervening circular wall was built, in which the windows were pierced, and this is the type which was universally employed by the architects of the Renaissance, of whose works the best-known examples are those of St Peter at Rome, St Paul's in London, and the churches of the Invalides, the Val de Grace and the Sorbonne in Paris.

Another number of German Universities, (1833), come to a university, and, in the 17th century, he was visiting in the 17th century, he was paying some of the earliest examples of those of the beech tombs at Mycenae and in other parts of Greece, which were covered by domes built in horizontal courses of masonry. The Tholos at Epidaurus, built by Polykleitus (c. 400 B.C.), and the Tholos at Olympia, known as the Philippeon, are the most remarkable examples, and in both cases were covered with a sloping roof and not with a dome.

THOLUCK, FRIEDRICH AUGUST GOTTORE (1799-1877), German Protestant divine, was born at Breslau, on the 30th of March 1799. He received his education at the gymnasium and university of his native town, and early distinguished himself by great versatility of mind and power of acquiring languages. A love of Oriental languages and literature led him to exchange the university of Breslau for that of Berlin, that he might study to greater advantage, and there he was received into the house of the Orientalist Heinrich Friedrich von Diez (1750-1817). He was introduced to pietistic circles in Berlin, and came specially under the influence of Baron Hans Ernst von Kottwitz (1757-1843), who became his "spiritual father," and of the historian Neander. Before deciding on the career of theological professor, he went to the East. Meanwhile he was feeling the influence to a certain degree of the romantic school, and of Schleiermacher and Hegel too, though he never sounded the depths of their systems. At length, in his twenty-first year, he finally decided to adopt the academical calling. In 1821 he was Privatdozent and in 1823 became professor extraordinary of theology in Berlin, though he was at the same time active in the work of home and foreign missions. He lectured on the Old and New Testaments, theology, apologetics and the history of the church in the 18th century. In 1821 appeared his first work, Sturms, seine theosophische Persönlichkeit; and following the same line of study he published Blütensammlung aus der morgenländischen Mystik (1825) and Speculative Trinitätstheologie des späteren Orients (1826). His well-known essay on the nature and moral influence of heathenism (1822) was published by Neander, with high commendation, in his Denkwürdigkeiten; and his Commentary on the Epistle to the Romans (1824) secured for him a foremost place amongst the most suggestive, if not the most accurate, Biblical interpreters of that time. Another work, which was soon translated into all the principal European languages, Die wahre Wehe des Zweiflers (1825-1826 ed.), with the title of Das Lied der Lüste (1870), the outcome of his own religious history, procured for him the position which he ever after held of the modern Pietistic apologist of Evangelical Christianity. In 1825, with the aid of the Prussian government, he visited the libraries of England and Holland, and on his return was appointed (in 1826) professor ordinarius of theology at Halle, the centre of German rationalism, where he afterwards became preacher and member of the supreme consistorial council. Here he made it his aim to combine in a higher unity the learning and to some extent the rationalism of J. S. Semler with the devout and active Pietism of A. H. Francke; and, in spite of the opposition of the theological faculty of the university, he succeeded in changing the character of its theology. This he effected partly by his lectures, particularly his exegetical courses, but, above all, by his personal influence upon the students, and, after 1833, his theological position was that of a mild and large-hearted orthodoxy, which laid more stress upon Christian experience than upon rigid dogmatic belief. On the two great questions of miracles and inspiration, he made contributions to modern criticism and philosophy. The battle of his life was on behalf of the mystical and religious experience, in opposition to the externality of rationalism, orthodoxy or sacramentarianism. Karl Schwarz happily remarks that, as the English apologists of the 18th century were themselves infected with the poison of the deists whom they endeavoured to refute, so Tholuck absorbed some of the heresies of the rationalists whom he tried to overthrow. He was also one of the prominent members of the Evangelical Alliance, and few men were more widely known or more beloved throughout the Protestant churches of Europe and America than he. He died in the First in June 1877. As a preacher, Tholuck ranked among the foremost of his time. As a teacher, in the field of theology, he entertained remarkable sympathy and won great success. As a thinker he can hardly be said to have been endowed with great creative power.

After his commentaries (on Romans, the Gospel of John, the Sermon on the Mount and the Epistle to the Hebrews) and several volumes of sermons, his best-known books are Stunden christlicher Andacht (1839-1840; 2nd ed., 1870), intended to take the place of J. H. D. Chazkoff's standard ratiocinative work, Die Frage nach dem unmittelbaren Glauben. In reply to David Strauss's Life of Jesus (Glaubwürdigkeit der evangelischen Geschichte, 1847). He published at various times valuable contributions towards a history of rationalism and of Rationalismus (1853-1866), Geschichte des Rationalismus (1863); and a number of essays connected with the history of theology and especially of apologetics. His views on inspiration were indicated in his work Die Propheten und ihre Weissagungen (1860), in his essay on the "Alte Inspirationslehre," in Deutsche Zeitschrift für christliche Wissenschaft (1850), and in his Gespräche über die vornehmsten Glaubensfragen der Zeit (1846; new ed., 1850).

He also contributed many articles to Herzog's Realencylopädie, and for several years edited a journal (1830-1849), Literarischer Anzeiger.

Tholuck, L. Wittie, by L. Witte (2 vols., 1884-1886); A. Tholuck, ein Lebensbürs, by M. Kähler (1877), and the same author's art. "Tholuck," in Herzog's Realencylopädie; Zur Erinnerung an Tholuck, by C. Siegfried, Protestantische Kirchenzeitung (1885), No. 45, and 1886, No. 47; Karl Schwarz, Zur Geschichte der neuesten Theologie (4th ed., 1869); F. W. F. Nippold's Handbuch der neuesten Kirchengeschichte; cf. Philip Schaff, Germany, its Universities, Theology and Religion (1857), and the article in the Allgemeine deutsche Biographie.

THOMA, HANS (1839- ), German painter, was born at Bernau in the Black Forest. Having started life as a painter of clock-faces, he entered in 1859 the Carlsruhe academy, where he first studied the preparation of colour, and afterwards went to Munich to study and worked, with but indifferent success, in Düsseldorf, Paris, Italy, Munich and Frankfort, until his reputation became firmly established as the result of an exhibition of some thirty of his paintings in Munich. In spite of his studies under various masters, his art has little in common with modern ideas, and is formed partly by his early impressions of the simple idyllic life of his native district, partly by his sympathy with the early German masters, particularly with Altdorfer and Cranach. In his love of the details of nature, in his precise (though by no means faultless) drawing of outline, and in his predilection for local colouring, he has distinct and admirable qualities. Many of his pictures have found their way into two private collections in Liverpool. A portrait of the artist, and two subject pictures, "The Guardian of the Valley" and "Spring Idyll," are at the Dresden Gallery; "Eve in Paradise" and "The Open Valley" at the Frankfurt Museum. Other important pictures of his are "Paradise," "Christ and Nicodemos," "The Flight into Egypt," "Charon," "Pietà," "Adam and Eve," "Solitude," "Tritons," besides many landscapes and portraits. He has also produced numerous lithographs and pen drawings, and some decorative mural paintings, notably in a café at Frankfort, and in the music room of Mr Fringsheim's house in Munich.

THOMAR, a town of central Portugal, in the district of Santarem; on the river Nabão, a tributary of the Zezere, 4 m. from Paialvo railway station, which is 89 m. N.E. of Lisbon.
by the main line to Oporto. Pop. (1900), 6888. Thomar contains examples of the best Portuguese architecture from the 12th century to the 17th. The ruined castle of the Knights Templar, given to that order in 1159, is said to occupy the site of the ancient Nabantia. On the suppression of the Templars, who had done good service against the Moors, King Diniz of Portugal founded the Order of Christ in 1314. The convent palace of the Knights of Christ includes a church and cloister dating from the 12th century. Two cloisters and a chapter-house, added in the 16th century by Prince Henry the Navigator, a very fine 16th-century church built in the Manoelian or Manueline style by João de Castilho, to which the older church served as a chancel, and other buildings erected later. The convent contains Flemish and Portuguese paintings of the 16th century, of the so-called "Grão Vasco" school. Its aqueduct, 3 m. long, was built 1595-1615. Other interesting buildings are the churches of Santa Maria do Ólival, rebuilt in the Gothic style in 1490 on the site of an older Templar foundation; São João Baptista, also Gothic, built in 1490, but with Manoelian additions; Nossa Senhora do Concelho, Renaissance of 1579; and the palace of Prince Henry the most ancient tradition makes the palace of 13th century by Queen Catherine, widow of John III.

THOMAS, ST., one of the twelve apostles. The synoptical Gospels give only his name, associating him in their lists with Matthew (Matt. x. 3; Mark iii. 18; Luke vi. 15); in Acts i. 13 he is coupled with Philip. In the Gospel of John (xi. 16; xiv. 5; xx. 24 seq.; xxii. 2) he appears in a characteristic light, full of personal devotion and ready to die with his Master, but slow to grasp the true significance of the personality of Jesus, and incredulous of the resurrection till direct evidence convinces him of it. In the time of the chancel of its risen Lord John translates the Aramaic name or surname Thomas by the Greek equivalent Didymus (twin). Tradition has it that he was the twin brother of a sister Lyssias (his parents being Diophanes and Rhoa, and his birthplace Antioch; "XII. Apost. Patriae," in Chron. Pasch. ii. 142), or of a brother Eliezer (Hom. Clem. ii. 1), or, according to the Syriac Acta Thomasae (ed. Wright, Eng. trans. pp. 155, 180), of Jesus Himself. The last form of the tradition seems to be derived from the name Judas Thomas, which he bears in Edessene legend (cf. Eusebius, H. E. i. 15, 10), and through the identification of Thomas with Judas, the brother of the Lord. The most ancient tradition makes Thomas the evangelist of Parthia (Eus. H.E. iii. 1, 1); and at Edessa, which claimed to possess his bones, it was related that their missionary Addai (Doctrine of Addai, ed. Phillips, 1876, p. 5), whom Eusebius calls Thaddaeus (H.E. i. 13), was sent to them by him. Later tradition, originating with the Acta Thomasae, and accepted by catholic teachers from the middle of the 4th century, makes him proceed to India and there suffer martyrdom. The Indian king Gundaphor of the Acta is, however, certainly identical with the historical Gundophares, whose dynasty was Parthian, though his realm included regions of loosely reckoned to India. The Parthian and Indian missions of Thomas may perhaps therefore be regarded as derived from a single tradition, but it is very doubtful whether it is based on any historical facts. The oldest extant tradition is that St. Thomas did not suffer martyrdom at all (Heracleon ap. Clem. Alex. Strom. iv. 9). The best investigation of the traditions connecting St Thomas with India is that by W. R. Phillips (Indian Antiquity, 1903, xxxii. 1-15, 145-160). The ingenious conjectures of von Gutschmid (N. Rhein. Mus. xix. 161 seq.) and Sylvain Lévi (Journ. asiatique, 1897, p. 27 seq.) are greatly weakened by the fact that they do not derive the consideration of the names in their original Syriac form. Bishop Medlycott's India and the Apostle Thomas (1903) is wholly untrustworthy.

The Acta Thomasae, very imperfectly published by Thilo (1832) and Tischendorf (1851), have been edited in Greek by Bonnett (Leipzig, 1883, 2nd ed., with new matter, 1903), and in the original Syriac, with an English translation, by W. Wright (Apoecryphal Acts, 1879, 2nd ed.); also by H. K. Schmidt, Die Acta Apostolica, ii. (2nd ed.), 423-425 (Brunswick); F. C. Burkitt in Journ. Theol. St. i. 280 seq., ii. 94. The Acta are said by Photius to be a part of the Henodómos or Apostólos of the Gnostic Leucius Charinus, but this unknown personage is to be thought of as a collector of Gnostic "Acts of Apostles," rather than as the first author. In spite of extensive Catholic revision, the "Acts of Thomas" form one of the most interesting monuments of Syriac Gnosticism. Internal evidence shows them to be of the 2nd century, and the very ancient allegorical hymn about the soul which is preserved in the Syriac text (p. 274 seq., Eng. trans., p. 238 seq.) is perhaps the latest of the Gnostic ones. This hymn was translated into the Greek Acts, along with the rest of the work (Bonnet, pp. 219-224, Anaîl, holländ. xx. 158-164). It is one of the most remarkable pieces in Syriac literature, and has been edited separately by Burkitt (Studi et Fonti, ii. 3 (Cambridge, 1897). A metrical English version is given in F. G. Burkitt's Early Eastern Christianity, p. 218 seq. (London, 1904).

("Clement of St Thomas") is a name often applied to the members of the ancient Christian churches of southern India, which claim him as their first founder, and honour as their second founder a certain bishop named Thomas, who is said to have received the presbyters from Jerusalem to Malabar in A.D. 345.1 According to their tradition, St. Thomas went from Malabar to Mylapur, now a suburb of Madras, where the shrine of his martyrdom, rebuilt by the Portuguese in 1547, still stands on Mt St Thomas, and where a miraculous cross is shown with a Pahlavi inscription which may be as old as the end of the 7th century. We know from Cosmas Indicopleustes that there were Christian churches of Persian (East-Syrian) origin, and doubtless of Nestorian creed, in Ceylon, in Malabar, and at Calliana (north of Bombay) before the middle of the 6th century, when St Thomas, the reputed apostle of Persia, may have been their special advocate. Since the southern India never died out or wholly lost their sense of connexion with their mother church, for we find them sending deputies in 1490 to the Nestorian patriarch Simeon, who furnished them with bishops (Assemani, Bib. or. iii. 1, 590 seq.). Hard pressed by the Moslems, they welcomed the approach of the Portuguese, but proved by no means tractable to efforts to bring them within the Roman obedience. At length a formal union with Rome was carried through in the synod of Diamper (1599). Syriac was to remain the ecclesiastical language, but the service books were corrected and purified from error. A century and a half of foreign Jesuit rule followed, but the loss of independence was not lost. A great schism took place in 1653, and of 200,000 Christians of St Thomas only 400 remained loyal to Rome, though many of their churches were soon won back by the Carmelites. Those who remained independent fell under the influence of the Jacobite Mar Gregorius, styled patriarch of Jerusalem, who reached Malabar in 1665 as an emissary from Ignatius, patriarch of Antioch. From his time the independent Christians have been Jacobites, the counter-efforts of the Nestorians under Mar Gapar have been feeble and unfruitful, and the Jesuits have often come to nothing after his death in 1750. Since the time of Claudius Buchanan, whose Christian Researches in Asia (1811) excited great interest, much has been done for the Christians of India by English missionary effort, and Anglicans have cultivated friendly relations with the clergy of the independent native church, while discouraging dependence on the Jacobite patriarch of Antioch.

A valuable though tedious and ill-arranged history of the Christians of St Thomas is that by W. Germann, Die Kirche der Thomaschristen (Hamburg, 1877). Cross, Histoire du christianisme des Indes (The Hague, 1724); Alexius de Mazaris, Christianismus malabaricae (Latin by F. Raulin, Rome, 1745) (especially for the synod of Diamper); Paulinus a. Bartholomaeo, India orientalis christiana (4to, Rome, 1794); George Milne Rae, The Syrian Church in India (Edinburgh and London, 1892).

THOMAS À KEMPIS (c. 1380-1471), the name by which the Augustinian canon and writer Thomas a Kempis (Hainichen, Malloleus) is commonly known. He was born in 1379 or 1380 in the town of Kempen, lying about 15 miles north-west of Düsseldorf, in one of the many patches of territory between

1 See the sketch in Syriac of the history of the church of Malabar printed and translated by Land, Anec. Syr. i. 24 seq. It was sent to Schaff at Leiden in 1720 by Mar Gabriel, the last Nestorian bishop in Malabar (see Germann, p. 542).
THOMAS (ARCHBISHOP)

the Meuse and the Rhine belonging to the archiepiscopal principal
ipality of Cologne. “Ego Thomas Kempsi,” he says in his chro
icle of the monastery of Mount St Agnes, “scolarisch Daventriensis, ex diocese Colonienisi natus.” His father was a poor hard-worked peasant; his mother “ad custodiam rei domesticae attenta, in opere alaris, in victu sobria, in potu abstemia, in verbo pauca, in factis pudica,” as her son fondly says, kept a dame’s school for the younger children of the town. John and Gertrude Hammerken had two sons, John and Thomas, both of whom found their way to Deventer, and thence to Zwolle and to the convent of Mount St Agnes. Thomas reached Deventer when he was barely twelve years old, and for some
me by a dame the beginnings of his learning, and in a few months
great joy entered the classes of Florentius Radewyn. After the fashion of the time he was called Thomas from Kempen, and the school title, as was often the case then, pushed aside the family name. Thomas Hammerken was forgotten; Thomas à Kempsi has become known to the whole Christian world.

This school at Deventer had become famous long before Thomas à Kempsi was admitted to its classes. It had been founded by Gerhard Groot (q.e.), a wealthy burgher who had been widowed, left a large fortune with which he inhabited his knight’s
broek, the Flemish mystic. It was at Deventer, in the midst of this mystical theology and hearty practical benevolence, that Thomas à Kempsi was trained. Gerhard Groot was his saintly ideal. Florentius Radewyn and Gerhard’s other early disciples were his heroes; their presence was his atmosphere, the measure of their lives his horizon. But he was not like them; he was not an educational reformer like Radewyn, nor a man of affairs like Gerhard. He liked books and quiet corners all his days, he says; and so, when conviction of sin and visions of God’s grace came to him in the medieval fashion of a dream of the anger and forgiveness of the Virgin, Florentius told him that a monk’s life would suit him best, advised him to join the Augustinian order, and sent him to Zwolle to the new convent of Mount St Agnes, where his brother John was prior. Thomas was received there in 1390, he professed the vows in 1407, received priest’s orders in 1413, became sub-prior in 1425 and died on the 8th of August 1471, being ninety-one years old.

The convent of Mount St Agnes was poor, and most of the monks had to earn money to support their household by copying MSS. Thomas was a most laborious copyist: missals, books of hours, illuminated MSS. In addition to these, he wrote or edited a large number of original writings, most of them relating to the convent life, which was the only life he knew. He wrote a chronicle of the monastery and several biographies— the life of Gerhard Groot, of Florentius Radewyn, of a Flemish lady St Louise, of Groot’s original disciples; a number of tracts on the monastic life—The Monk’s Alphabet, The Discipline of Cloisters, A Dialogue of Novices, The Life of the Good Monk, The Monk’s Epitaph, Sermons to Novices, Sermons to Monks, The Solitary Life, On Silence, On Poverty, Humility and Patience; two tracts for young people—A Manual of Doctrine for an Young, and A Manual for Children; and books for edification— On True Compunction, The Garden of Roses, The Valley of Lilies, The Consolation of the Poor and the Sick, The Faithful Dispenser, The Soul’s Soliloquy, The Hospital of the Poor. He also left behind him three collections of sermons, a number of letters, some hymns and the famous Imitatio Christi (though his authorship of this has been disputed). These writings help us to see the man and his surroundings, and contemporary pious records make him something more than a shadow. We see a real man, but a man helpless anywhere save in the study or in the convent—a little man, with wavy locks of red-brown hair, who had a habit of stealing away to his cubiculum whenever the conversation became too lively; somewhat bent, for it is on record that he stood upright when the psalms were chanted, and even rose on his tiptoes with his face turned upwards; genial, if shy, and occasionally given to punning, as when he said that he preferred Psalms to Salmones; a man who perhaps led the most placid uneventful life of all men who ever wrote a book or scribbled letters. It was not that he lived in uneventful

times: it is impossible to select a stormier period of European history, or a period when the stir of the times made its way so well into the obscurest corners. Bohemia, Huss leading, was ablaze in revolt at one end of Europe; France and England, then France and Burgundy, were at death-grips at the other. Two popes anathematized each other from Avignon and from Rome, and zealous churchmen were at their wit’s end to concoct ways and means, by general councils of Constance and Basel and otherwise, to restore peace to a distracted church, and to discipline the clergy into decent living. But Thomas knew nothing about all this. He was intent on his copying, on his books, and on his quiet conversations. His very biographies are colourless. He had not even the common interest in the little world coming up to the convent gate which most monks may be supposed to have. His brethren made him oeconomiae prefectus, but he was too “simple in worldly affairs” and too absent-minded for the post, and so they deposed him and made him sub-prior once more. And yet it is this placid kindly fresh-coloured old man who has come down to us as the author of that book the Imitation of Christ, which has been translated into more languages than any other book save the Bible, and which has moved the hearts of so many men of all nations, characters and conditions of life.

On the controversy as to the author of the Imitatio, see the article Imitatio of Christ in the New Catholic Dictionary. See also James Williams, Thomas of Kempsi (1910). The classical edition of the works of Thomas à Kempsi by Sommalli—Thomas Mallools à Kempsi opera omnia (3 vols. in 1, 1607)—has been many times reprinted. A critical edition in 8 vols. by J. H. Poth, has also been undertaken. The best collection of
ishes of Thomas à Kempsi are those by S. Kettlewell (1882) and F. R. Cruise (1887), written from the Protestant and the Catholic stand-points respectively. A penny tract by F. R. Cruise, entitled Outline of the Life of Thomas & Kempsi (1904), contains substantially all that is known concerning him.

THOMAS (d. 1100), archbishop of York, is a native of Bayeux, and is usually called Thomas of Bayeux. His father was a priest named Osbert, and Samson, bishop of Worcester from 1086 until his death in May 1112, was his brother. Owning largely to the generosity of Odo, bishop of Bayeux, Thomas studied in France, Germany and Spain and became known as a scholar; then he became one of Bishop Odo’s officials and after 1066 one of William the Conqueror’s chaplains or secretaries. In 1070 he succeeded Aldred as archbishop of York, but declining to pay the church fines exacted by the Conqueror, he was exiled by King William, however, induced him to submit and he was consecrated, but his profession of obedience was to Lanfranc personally and not to the archbishops of Canterbury. In 1071 both archbishops travelled to Rome for their palls and while there Thomas wished Pope Alexander II. to decree the equality of the sees of Canterbury and York. The pope, however, referred the dispute to a council of English prelates, and this met at Windsor at Whitson
tide 1072. It was then decided that the archbishop of Canterbury was the superior of the archbishop of York, who had no rights south of the Humber, but whose province included Scot
land. But this decision did not put a period to the dispute. It broke out again, and in 1092 and again in 1093 Thomas protested against what he regarded as infringements of his archiepiscopal rights. The first of these occasions was over the dedication of the cathedral built by Remigius at Lincoln and the second was over the consecration of St Anselm to the archbishopric of Canterbury. In 1100, during Anselm’s exile, Thomas reached London too late to crown Henry I., the ceremony having been hurriedly performed by Maurice, bishop of London, but his anger was stirred up anew when the new king, after his coronation as York, went to the 18th of November 1100. Thomas rebuilt the minster at York, where he appears to have been an excellent archbishop; he knew something of church music and wrote hymns.

Thomas had a nephew, Thomas, the son of his brother Samson, who was also archbishop of York. The younger Thomas became archbishop in 1108 and like his uncle he refused to promise obedi
ence to the archbishop of Canterbury; his consecration was then
THOMAS MAGISTER—THOMAS, A. G.

865

delayed and the dispute was still unsettled when St Anselm died in April 1109. Henry I. and his bishops then decided against Thomas, who was forced to make the necessary promise and was consecrated in London in June 1109. He died at Beverley on the 24th of February 1116.

THOMAS, surnamed Magister (i.e. officium),1 also known as a monk by the name Theodoulos Monachos, a native of Thessalonica, Byzantine scholar and grammarian and confidential adviser of Andronicus II. (1282–1328). His chief work, Έκλογή Ὑφήλιων υἱῶν Αἰτίων, is a selection of collected Attic Attic words and phrases, partly arranged in alphabetical order, compiled as a help to Greek composition from the works of Phrynichus, Anaximenes, Herodias and Moeris. He also wrote scholia on Aeschylus, Sophocles, Euripides (with life), and three of the four plays of Aristophanes; the scholia on Pindar, attributed to him in two MSS, are now assigned to Demetrius Triclinius. His speeches and letters consist partly of declamations on the usual sophistical themes, partly dealt with contemporary historical events: an argument between the fathers of Cynegirus and Callimachus (two Athenians who fell at Marathon) as to which had the better claim to have the funeral oration pronounced over him first; a discussion on the duties of a king and of his subjects; a defence of the Byzantine general Chandrenos addressed to the emperor; a letter on the jurisdiction of the Catalans and Turks in Thessaly and Macedonia; a congratulatory letter to Alexander of Trachonitis, and a version of the Life of Cyril, Bishop of Thessalonica.

Editions of the Έκλογη by F. Ritschl (1832), C. Jacobitz (1833) and C. D. Beck (1836); other works in J. P. Migne, Patrologia graeca, clxv.; see also C. Krumbacher, Geschichte der byzantinischen Literatur (1858)." 

THOMAS OF CELANO, Franciscan friar and disciple and biographer of St Francis of Assisi. Born at Celano in the Abruzzi, he joined St Francis probably about 1214, and he appears to have been one of the first band of friars who went into Germany. He was commissioned by Gregory IX. to write the Life of St Francis, and in 1229 he completed the First Legend; in 1247 at the command of the minister general he composed the Second Legend, and a few years later the Tract on the Miracles of St Francis. He also composed in 1255 the Legend of St Clare; and he is one of those to whom the sequence Dies Irae is attributed.

Thomas of Celano's writings on St Francis have been critically edited by E. d'Alençon in 1906; the value of this work is enhanced by the fact that critical opinion is veering round to the view that Thomas of Celano is not the last authority for the life of St Francis (see Note on the Sources, appended to article FRANCIS OF ASSISI).

An English translation (The Lives of St. Francis of Assisi by Brother Thomas of Celano) by A. G. Ferrers Howell appeared in 1908.

A biography of Thomas of Celano is brought together by Guillaume d'Alençon's Prolegomena; see also Introduction to Ferrers Howell's translation.

(E. C. B.)

THOMAS OF ERCEDOUNE, called also THE RHYMER, and sometimes given the surname of LEARMONT (fl. ? 1220–? 1297), poet and prophet in the legendary literature of Scotland. The historical person of that name figures in two charters of the 13th century, and from this it appears that he owned lands in Ercedoune (now Earlston), in Berwickshire, which were made over by his son and heir on the 2nd of November 1294 to the foundation of the Holy Trinity at Soitra (or Soutra) on the borders of the same county. This would seem to imply that Thomas the Rhymer was already dead, but J. A. H. Murray, who edited The Romance and Prophecies (E.E.T.S., 1875), thinks that he was living three years later in a Cluniac priory in Ayrshire. He figures in the works of Barbour and Harry the Minstrel as the sympathizing contemporary of their heroes, and Walter Bower, who continued the Scolochronicon of Fordun, tells how he prophesied the death of Alexander III. in 1285. Barbour makes the bishop of St Andrews in 1306 express a hope that a prophecy of Thomas referring to Bruce will come true; and Neyman says that he foretold the battle of Kiblance. In the folk-lore of Scotland his name is associated with numerous fragments of verse of a gnomic and prophetic character. The

1For the duties of this important office, see J. B. Bury, Later Roman Empire (1889), i. 45.

romance of Thomas and the elf-queen was attributed to Ercedoune by Robert Mannyng de Brunne, but the earliest text, in the Auchinleck MS. in the Advocates' library, Edinburgh, is in a dialect showing southern forms, and dates from the beginning of the 14th century. It may be based on a genuine work of Thomas, a version by him of the widely diffused Tristan Saga. This text was published in 1804 by Sir Walter Scott, and was by him assigned to the Rhymer. The most widely accepted opinion is that it is a translation of a French original. The Rhymer's lands at Earlston are still identified. In 1840 died the last of a family named Learmont, which claimed descent from the poet. It may be noted that the Russian poet Michael Lermontov claimed Thomas of Ercedoune as his ancestor.

See A. H. Murray's edition of The Romance and Prophecies (E.E.T.S., 1875); Brandis's Thomas of Ercedoune (Berlin, 1829); and Köbling's Die nordische und die englische Version der Tristransage (Heilbronn, 1882); also McNell's Sir Tristan (S.T.S., 1886); Lumby's Early Scottish Prophecies (E.E.T.S., 1870), and the reprint of the Whole Prophecy of Scotland (1603) by the Bannatyne Club (1833).

THOMAS OF MARGA, a Nestorian bishop and author of an important monastic history in Syria, who flourished in the 9th century A.D. He was born early in the century, probably of Persian parents, in the region of Salakh to the north-east of Mosul. As a young man he became in 832 a monk of the famous Nestorian monastery of Beth 'Abbê, which was situated at the confluence of the Great Zab with one of its tributaries, about 25 m. due east of Mosul. A few years later he was acting as secretary to Abraham, who had been abbot of Beth 'Abbê. He then went to Edessa, but was brought back to Beth 'Abbê from 837 to 850. At some date during these 13 years Thomas was promoted by Abraham to be bishop of Marga, a diocese in the same district as Beth 'Abbê, and afterwards he was further advanced to be a metropolitan of Beth Garmâi, a district farther to the south-east in the mountains which border the Tigris basin. It was during the period of his life at Beth 'Abbê and his bishopric that he composed The Book of Governors, which is in the main a history of his own monastery, but includes lives of holy men in other parts of Mesopotamia and the regions east of the Tigris. The work was probably planned in imitation of the famous Paradise of Paradisi, the history of Egyptian monasticism which had become well known to Syria-speaking Christians in the version of 'Anān-Ishā (6th century).

The Book of Governors has been edited with a English translation and a copious introduction by E. W. Budge (2 vols., London, 1893), who claims that "it occupies a unique position in Syrian literature, and is the only work that has come down to us of which it has been already said that it is still regarded by all classes of Nestorians to whom it is known." It gives a detailed history of the great monastery of Beth 'Abbê down to the time of the author, and is at the same time of the highest interest to Nestorian in its few unpretentious but very naive and candid spirit, and it throws much light on the history of Christianity in the Persian dominions. There is a later edition by P. Bedjan (Paris, 1901) (N. M.)

THOMAS, ARTHUR GORING (1850–1892), English musical composer, was the youngest son of Freeman Thomas and Amella, daughter of Colonel Thomas Frederick. He was born at Ratton Park, Sussex, on the 20th of November 1850, and educated at Haileybury College. He was intended for the Civil Service, but delicate health interfered with his studies, and in 1873 he went to Paris to cultivate the musical talent he had displayed from an early age. Here he studied for two years with Émile Durand. In 1875 he returned to England, and in 1877 entered the Royal Academy of Music, where for three years he studied under Ebenzer Prout and Arthur Sullivan, winning twice the Lucas medal for composition. At a later period he received some instruction in orchestration from Max Bruch. His first published composition was a song, "Le Roy Henri," which appeared in 1871. An early comic opera, Don Braggadocio (libretto by his brother, C. I. Thomas), was apparently unfinished; some of the music in it was afterwards used for The Golden Web. A selection from his second opera, The Light of the Harem (libretto by Clifford Harrison), was performed at the Royal Academy of Music on the 7th of November 1879, with such success that Carl Rosa commissioned him to write
THOMAS, C. L. A.—THOMAS, G. H.

Esméralda (libretto by T. Marxials and A. Rendegger), which was produced at Drury Lane on the 5th of March 1834. Two years later it was given (in German) at Cologne and Hamburgh, and in 1790 (in French) at Covent Garden. On the 16th of April 1885 Rosa produced at Drury Lane Thomas's fourth and best opera, Naïscha (libretto by Julian Sturgis), a German version of which was given at Breslau in 1890. A fifth opera, The Golden Web (libretto by F. Corder and B. C. Stephenson), slighter than its predecessors, was produced (after the composer's death) at Liverpool, Feb. 15, and at the Lyric Theatre, London, Mar. 11, 1893. Besides these dramatic works Thomas's chief compositions were a psalm, "Out of the Deep," for soprano solo and chorus, London, 1838; a choral suite, The SeventhCOMMANDER (W. B. S.)

THOMAS, CHARLES LOUIS AMBROISE (1811–1889), French musical composer, was born at Metz on the 9th of August 1811. He studied at the Paris Conservatoire, and won the Grand Prix de Rome in 1832. Five years later (in 1837) his first opera, La Double òchelle, was produced at the Opéra Comique. For the next two or thirty years Thomas's productions were incessant, and most of his operatic works belonging to this period enjoyed an ephemeral popularity. A few of these are still occasionally heard on the continent, such as Le Calè (1849), Le Serçe d'une nuit d'été (1850), Psyché (1857). The overture to Raymond (1851) has remained popular. So far the composer's operatic career had not been marked by any overwhelming success. He occupied a place among the recognized purveyors of operas in the French capital, but could scarcely claim to having achieved European renown. The production of Mignon at the Opéra in 1866, however, marked a turning point. Thomas's elevation to the position of one of the foremost French composers.

Goethe's touching tale had very happily inspired the musician; Mme Galli Mérié, the original interpreter of the title rôle, had modelled her conception of the part upon the well-known picture by Ary Scheffer, and Mignon at once took the fancy of the public, its success being repeated all over the continent. It has since remained one of the most popular operas belonging to the second half of the 19th century. Thomas now attempted to turn Shakespeare's Hamlet to operatic account. His opera of that name was produced with success at the Paris Opéra in 1866, where it enjoyed a long vogue. If the music is scarcely adequate to the subject, it nevertheless contains some of the composer's best work. The scene of the esplanade is genuinely dramatic, the part of Ophelia is poetically conceived, and the ballet music is very brilliant. Ambrose Thomas's last opera, Françoise de Rémimini, was given at the Opéra in 1882, but has not maintained itself in the répertoire. Seven years later La Tempête, a ballet founded on Shakespeare's play, was produced at the same theatre. Ambrose Thomas succeeded Aubier as director of the Paris Conservatoire in 1871. His music is often distinguished by refined touches which reveal a sensitive mind, and there is a distinct element of poetry in his Mignon and Hamlet, two operas that should suffice to keep the composer's memory green for some time to come. He died on the 12th of February 1896.

THOMAS, GEORGE (c. 1756–1802), British military adventurer in India. Thomas was born of poor parentage in Ireland in 1756, deserted from the British Navy in Madras, and made his way north to Delhi, where he took service under the begum Samru of Sardhana. Supplanted in her favour by a Feroe Indian, he transferred his allegiance to Appa Rao, a Mahatra chiefman, and subsequently set up an independent kingdom of his own in Haryana with his capital at Hansi. Thomas was a man of great personal strength and daring, and considerable military genius. In the turmoil of falling kingdoms in the India of that day his sword was always at the service of the highest bidder; but he had the virtues of his profession—he never betrayed an employer, was kind and generous to his soldiers, and was always ready to succour a woman in distress. He cherished dreams of conquering the Punjab and fought one of his best campaigns against the Sikh chiefs; but he was finally defeated and captured by Sindhia's army under General Perron (q.v.). His iron constitution was broken by exposure and excessive drinking, and he died on his way down the Ganges on the 22nd of August 1802.

See Franklin, Military Memoirs of Mr George Thomas (1803); Compton, Military Adventurers of Hindustan (1826).

THOMAS, GEORGE HENRY (1816–1870), American general, was born in Southampton county, Virginia, on the 31st of July 1816. Graduating from West Point in 1840, he served as an artilleryman in the Mexican War. In the battle against the Samuels Indians in Florida (1841), and in the Mexican War at the battles of Fort Brown, Resaca de la Palma, Monterey and Buena Vista, receiving three brevets for distinguished gallantry in action. From 1851 to 1854 he was an instructor at West Point. In 1855 he was appointed by Jefferson Davis, then secretary of war, a major of the 2nd Cavalry. His regimental superiors were A. S. Johnston, R. E. Lee and Hardee. All three resigned at the outbreak of the Civil War and Thomas was long in doubt as to his duty. He finally decided to adhere to the United States. He was promoted in rapid succession to be lieutenant-general on the staff of General Grant, and in the charge of the 9th Army Corps of 50,000 men. He was commander of the division of west Virginia. Under Rosecrans he was engaged at Ring River and was in charge of the most important part of the manoeuvring from Orchard Creek to Fort Donelson. In the rains of the latter part of the year 1862, he was attached to the army of the Cumberland. On the 19th of September 1863 he achieved great distinction, his firmness on that disastrous field, where he gained the name of "The Rock of Chickamauga," being all that saved a terrible defeat from becoming a hopeless rout. He succeeded Rosecrans in command of the Army of the Cumberland shortly before the great victory of Chattanooga (q.v.), in which Thomas and his army played a most conspicuous part, his divisions under Sheridan, Wood and Baird carrying Missionary Ridge in superb style. In Sherman's advance through Georgia in the spring of 1864, the Army of the Cumberland numbered over 65,000 men present for duty. Thomas handled these with great skill in all the engagements and flanking movements from Chattanooga to Atlanta. When J. B. Hood broke away from Atlanta in the autumn of 1864, menaced Sherman's long line of communications and endeavoured to force Sherman to follow him, Sherman determined to abandon his communications and march to the sea, leaving to Thomas the difficult task of dealing with Hood. Thomas hastened back with a comparatively small force, racing with Hood to reach Nashville, where he was to receive reinforcements. At the battle of Franklin on the 30th of November 1864, a large part of Thomas's force, under command of M. Schofield, checked Hood long enough to cover the concentration at Nashville (q.v.). Here Thomas had to organize his force, which was drawn from all parts of the West and included many young troops and even quartermaster's employees. He declined to attack until his army was ready and the ice which covered the ground had melted sufficiently to enable his men
THOMAS, I.—THOMAS, T.

To move. The whole of the North, and even General Grant himself, were impatient of the delay. General Logan was sent with an order to supersede Thomas, and soon afterwards Grant left the Army of the Potomac to take command in person. Before either arrived Thomas made his attack (December 15th-16th, 1864) and inflicted on Hood the most crushing defeat sustained in the open field by any army on either side in the whole war. Hood's army was completely ruined and never again appeared on the field. For this brilliant victory Thomas was made a major-general in the regular army and received the thanks of Congress. After the termination of the Civil War he commanded military departments in Kentucky and Tennessee until 1869, when he was ordered to command the division of the Pacific with headquarters at San Francisco. He died there of apoplexy, while writing an answer to an article criticizing his military career, on the 18th of March, 1869.

Thomas was beloved by his soldiery, for whom he always had a fatherly solicitude. He was a man of solid rather than brilliant attainments; he remained in the army all his life, and never had any ambitions outside of it; the nickname of "Slow Trot Thomas" given him by the cadets at West Point characterized him physically and mentally; his mind acted deliberately, and his temperament was somewhat sluggish; but his judgment was accurate, his knowledge of his profession was complete in every detail, and when he had finally grasped a problem, and the time arrived for action, he struck his blow with extraordinary vigour and rapidity. The only two battles in which he was in chief command—Mill Springs and Nashville, one at the beginning and the other near the end of the war—were signal victories, without defect and above criticism. His service during the intervening three years of almost incessant conflict and manoeuvring was marked by loyal obedience to his superiors, skilful command of his subordinates, and successful accomplishment of every task entrusted to him.

THOMAS, ISAIAH (1749-1831), American printer, was born in Boston, Massachusetts, on the 19th of January 1749. He was apprenticed in 1755 to Zephaniah Fowle, a Boston printer, with whom, after working as a printer in Halifax, Portsmouth, New Hampshire, and Charleston, South Carolina, he formed a partnership in 1770. He issued in Boston the *Massachusetts Spy* three times each week, then (under his sole ownership) as a semi-weekly, and beginning in 1771, as a weekly which soon espoused the Whig cause and which the government tried to suppress. On the 16th of April 1775 (three days before the battle of Concord, in which he took part) he took his presses and types from Boston and set them up at Worcester, where he was postmaster for a time; here he published and sold books, and built a paper-mill and bindery, and he continued the paper until about 1802 except in 1776-1778 and in 1786-1788. The *Spy* supported Washington and the Federalist party. In Boston Thomas published, in 1774, the *Royal American Magazine*, which was continued for a short time by Joseph Greenleaf, and which contained many engravings by Paul Revere; and in 1775-1803 the *New England Almanac*, continued until 1819 by his son. He set up printing houses and book stores in various parts of the country, and in Boston with Ebenezer T. Andrews, published the *Boston Almanac* and *Boston Magazine*, from 1791. At Walpole, New Hampshire, he published the *Farmer's Museum*. About 1802 he gave over to his son, Isaiah Thomas, junr., his business at Worcester including the control of the *Spy*. Thomas founded in 1812 the American Antiquarian Society. He died in Worcester on the 4th of April 1831.

His *History of Printing in America, with a Biography of Printers, and an Account of Newspapers* [2 vols., 1810; 2nd ed., 1874], with a catalogue of American publications previous to 1770 and a catalogue of the works of Isaiah Thomas, by his grandson B. P. Thomas) is important work, accurate and thorough.

THOMAS, PIERRE (1614-1698), sieur du Fossé, French scholar and author, was the son of a master of accounts at Rouen. He was sent as a child to be educated at Port Royal, and there he received his final bent towards the life of a recluse, and even of a hermit, which drew him to establish himself in the neighbourhood of Port Royal des Champs. In 1661 he came to Paris, and in 1666 was arrested along with I. L. Le Maistre (de Sacy), and after a month in the Bastille was exiled to his estate of Fossé. He later made yearly visits to Paris. Apart from his collaboration with de Sacy, Thomas wrote some hagiographic works and left Memorials (1697-1698 and again 1876-1879), which are highly praised by Ste Beuve as being a remarkable mirror of the life at Port Royal.

THOMAS, SIDNEY GILCHRIST (1850-1885), British inventor, was born on the 16th of April 1850 at Canonbury, London. His father, a Welshman, was in the civil service, and his mother was the daughter of the Rev. James Gilchrist. His father's death leaving his family with a considerably reduced income, he gave up his original idea of becoming a doctor and obtained an appointment as a police court clerk, which he held till May 1879. During these twelve years, besides the work of a busy police court, which brought him into intimate contact with social problems, he found time to study chemistry, and attended lectures at the Birkbeck Institute. He set himself to solve the problem of eliminating phosphorus from iron by means of the Bessemer converter, and by the end of 1875 was convinced that he had discovered a method. He communicated his theory to his cousin, F. C. Gilchrist, who was chemist to iron works in Wales, and experiments were made, which proved satisfactory. Edward Martin, manager of the Blaenavon Works, undertook the conducting of the experiments on a larger scale and undertook to help in taking out a patent. In March 1878, the first public announcement of the discovery was made at the meeting of the Iron and Steel Institute, but without attracting much attention; and in September a paper was written by Thomas and Gilchrist on the "Elimination of Phosphorus in the Bessemer Converter" for the autumn meeting of this institute, but was not read till May 1879. Thomas, however, made the acquaintance of E. W. Richards, the manager of Bolckow Vaughan & Co.'s works at Cleveland, Yorkshire, whom he interested in the process, and from this time the success of the invention was assured and domestic and foreign patents were taken out. The "basic process" invented by Thomas was especially valuable on the continent of Europe, where the proportion of phosphoric iron is much larger than in England, and both in Belgium and in Germany the name of the inventor became more widely known than in his own country. In America, although non-phosphoric iron largely predominates, an immense interest was taken in the invention. But Thomas had been overworking for years, and his lungs became affected. A long sojourn and a residence in Egypt proved unavailing for the renewal of his health and he died in Paris on the 1st of February 1883. He had what W. E. Gladstone, in a review of the *Memoirs* published in 1891, described as an "enthusiasm of humanity," and he left his fortune to be used for the promotion of philanthropic work. A police court mission was endowed in his memory.

THOMAS, THEODORE (1835-1905), American musician, was born at Essen, Germany, on the 11th of October 1835. His early musical training was received chiefly from his father. At the age of five he made his first public appearance as a violinist. In 1845 he was taken to America by his parents, and became first violin in the orchestra that accompanied Jenny Lind in 1850, Sonntag in 1852 and Grisi and Mario in 1854. In 1862 he began to organize his own orchestra, and from 1864 to 1878 were performed a series of symphony concerts inaugurated by him in Irving Hall, which were regarded as one of the great musical institutions of New York City. His "summer night" concerts begun in 1866 in Terrace Garden were continued in Central Park. From 1855 to 1868 he took part in a series of chamber music concerts in New York. In the latter year his orchestra made its first tour, and continued to give concerts in various American cities until it was disbanded in 1888. To Theodore Thomas is largely due the popularization of Wagner's
works in America, and it was he who founded the Wagner union in 1872. During most of the seasons from 1877 to 1891 he was conductor of the New York Philharmonic Society, and from 1892 to 1891, of the Brooklyn Philharmonic Society. He was director of the Juilliard College of Music (1878–1879), conductor of the American Opera Company (1887), and for thirty years (1873–1904) the conductor of the biennial May festivals at Cincinnati. In 1891 he removed to Chicago, and became the conductor of the Chicago Orchestra; in 1893 he was musical director of the Columbian Exposition. He died on the 4th of January 1905.

THOMAS, WILLIAM (d. 1554), English soldier and writer, was probably a native of Radnorshire and was educated at Oxford. In 1534 he went to Italy, where he spent the greater part of the next five years, and in April 1550, soon after his return to England, he was made one of the clerks of the privy council; he also taught the science of politics to the young king Edward VI., for whose instruction he wrote some treatises and some "commonplaces of state." Being a strong Protestant he took part in the rising against Queen Mary led by Sir Thomas Wyat in 1554, being captured and thrown into the Tower of London. Having whilst in prison tried to commit suicide and been tortured on the rack in the hope of incriminating the princess Elizabeth, he was found guilty and was hanged at Tyburn on the 19th of May 1554.

THOMASIUS, Christian (1655-1728), German jurist and publicist, was born at Leipzig on the 1st of January 1655, and was educated by his father, Jakob Thomasius (1622-1684), at that time head master of the Thomasschule. Through his father's lectures Christian came under the influence of the political philosophy of Hugo Grotius and Samuel Pufendorf, and continued the study of law at Frankfurt-on-Oder. In 1683 he commenced the career of professor of natural law at Leipzig, and soon attracted attention by his abilities, but particularly by his daring attack upon traditional dogmas in theology and jurisprudence. In 1687 he made the daring innovation of lecturing in German instead of Latin, and in the following year published a monthly periodical (Scherzhaften und ernsthafte, vernünftige und einfältige Gedanken über allerhand lustige und nützliche Bücher und Fragen) in which he ridiculed the pedantic weaknesses of the learned, taking the side of the Pietists in their controversy with the orthodox, and defending mixed marriages of Lutherans and Calvinists. In consequence of these and other views, he was denounced from the pulpit, forbidden to lecture or to write (May 10, 1690), and his arrest was ordered. The latter he escaped, and the elector Frederick III. offered him a refuge in Halle, with a salary of 500 talers and the permission to lecture. He took part in founding the university of Halle (1694), where he became second and then first professor of law and rector of the university. He was one of the most esteemed university teachers and influential writers of his day. He died, after a successful and honourable career, on the 23rd of September 1725.

Though not a profound and systematic philosophical thinker, Thomasius prepared the way above all, in law, literature, social life and theology. It was his mission to introduce a rational, common-sense point of view, and to bring the higher powers of divine and human sciences into close and living contact with the everyday world. He thus created an epoch in German literature, philosophy and law, and Spittler opens with him the modern period of ecclesiastical history. He made it the object of his labours to prepare a modern, comprehensive and lucid system of the control of theology, and fought bravely and consistently for freedom of thought and speech on religious matters. He is often spoken of in German works as the author of the "territorial system," or Ernestian theory of ecclesiastical government. But he taught that the state may interfere with legal or public duties only, and not with moral or private ones. He would not have even atheists punished, though they should be expelled the country, and he came forward as an earnest opponent of the prosecution of witches and of the use of torture. In theology he was not a naturalist or a deist, but a believer in the necessity of revealed religion for salvation. He strongly upholds the theory of the free will of man, a theory dear to Spener, and there was a mystic vein in his thought; but other elements of his nature were too powerful to allow him to attach himself wholly to that party.

Thomasius's most interesting and influential German publications were his periodical already referred to (1688-1689): Erinnerung zur Verurtheilthe (1691, 5th ed., 1710); Vernünftige Gedanken über allerhand auserlesene und juristische Handlungen (1750-1771); Geschichte der Dichter aller Zeiten und aller Länder (1752-1782), and Vorarlbergische Geschichtsquellen und Erinnerungen (1804); H. Dernburg, Thomasius and the Stiftung der Universität Halle (1865); B. A. Wagner, Thomasius, ein Beitrag zur Würdigung seiner Verdienste (1872); Nicoladoni, Christian Thomasius. Ein Beitrag zur Geschichte der Aufklärung (Berlin, 1888); and E. Landsberg, Zur Biographie von Christian Thomasius (1894).

THOMASON, GEORGE (d. 1666), English book and tract collector, was a London bookseller, whose life contains few items of interest save the fact that he was concerned in a royalist plot in 1651. He is famous, however, as the man who brought together the great collection of books and tracts published during the time of the Civil War and the Commonwealth; this was formerly called the "King's Pamphlets," but is now known as the "Thomason Collection." During the years just before the outbreak of war a great number of writings covering every phase of the questions in dispute between king and people were issued, and in 1641 Thomason began to collect these. Working diligently at his task for about twenty years, he possessed nearly 5000 pamphlets. Putting these in order of publication and then arranging them in chronological order he had them bound in 1863 volumes. After many vicissitudes the collection was bought in 1761 from his descendants by George III., who presented it to the British Museum, where it now is (see Newspapers). Thomasian died in London in April (1666).

THOMASVILLE, a city and the county-seat of Thomas county, Georgia, U.S.A., about 200 miles S.W. of Savannah. Pop. (1900), 5322, of whom 3256 were negroes; (1910), 6727. Thomasville is served by the Atlanta, Birmingham & Atlantic, the Atlantic Coast Line and the Florida Central railways. It is attractively situated (about 250 ft. above the sea) on a high plateau, is surrounded by pine forests, and is a well-known winter resort. There are fine drives in the vicinity. Thomasville has a city hospital, a public library (1876) and a good public school system, and is the seat of Young's College (for girls), which was founded by E. Remer Young, a wealthy planter of Thomas county, was incorporated in 1869 and was opened in 1871, and of the Vashon industrial school (1903) for girls, maintained by the Women's Home Mission Society of the Methodist Episcopal Church, South. The city has a large trade in lumber, especially yellow pine; other products are of the citron and of tomatoes, and vegetables. The municipality owns and operates the water-works and electric-lighting plant; the water supply is obtained in part from artesian wells 1900 ft.
THOMOND, EARL AND MARQUESSE—THOMPSON, SIR H. 869

deep. Thomavsville was settled about 1825, was incorporated as a town in 1831, and was chartered as a city in 1880.

THOMOND, EARL AND MARQUESSE OF, Irish titles borne by the great family of O'Brien, the earldom from 1543 to 1741 and the marquessate from 1800 to 1855. Thomond, or Tuaith-Muin, was one of the three principalities of Munster, forming the northern part of the province. Its earls were descended from Turlough O'Brien (c. 1009-1086), king of Munster, and from him through the celebrated king of Ireland, Brian Boruimh. Turlough's descendants, Conchohar O'Brien (d. 1556) and Brian Ruadh O'Brien (d. 1576), kings of Thomond, were both typical Irish chieftains. Conchohar's tomb and effigy with a crown are still to be seen in the ruined abbey of Corcomroe, Co. Clare. His descendant Conor O'Brien (d. 1539), prince of Thomond, took part in the feud between the great families of Fitzgerald and Butler and was the last independent prince of Thomond. It is interesting to learn that in 1534, when he was in some straits, he wrote to the emperor Charles V. offering to submit to his authority. Conor's brother, Murrough O'Brien (d. 1551), prince of Thomond, the succeeding chieftain of the O'Briens, was created a peer of Ireland and granted a pension by Henry VIII. in 1543, when he was created earl of Thomond. By special arrangement the earldom descended, not to his son Dermot, but to his nephew, Donough, who became the 2nd earl. Dermot, however, inherited the barony of Inchiquin, which was conferred upon his father at the same time as the earldom.

Conor O'Brien, the 3rd earl (c. 1534-c. 1582), was for some years at the outset of his career, harassed by the attacks of his discontented kinsmen. Then in his turn he rose against the English, but was defeated and fled to France; in 1571, however, he was pardoned and formally surrendered his lands to Elizabeth. One of his younger sons was Daniel O'Brien (c. 1577-c. 1664) who, after loyally serving Charles I and Charles II., was created Viscount Clare in 1663. His grandson Daniel, the 3rd viscount (d. 1691) served James II. in Ireland, being outlawed and deprived of his estates by the English parliament. The three succeeding viscounts Clare all distinguished themselves in the service of France. Daniel, the 4th viscount, was mortally wounded at the battle of Marsaglia in 1693; his brother Charles, the 5th viscount (1670-1761) after a brilliant military career, was made a marshal of France in 1757. When Charles, the 7th viscount, died in 1774 the title became extinct.

Donough O'Brien, the 4th earl (d. 1624), called the "great earl," was the son and successor of the 3rd earl. He served England well in her warfare with the rebellious Irish during the closing year of Elizabeth's reign and was made president of Munster in 1605. He had two sons, Henry, the 5th earl, (d. 1639) and Barnabas, the 6th earl (d. 1657). During the Irish rebellion of 1641-47 Barnabas showed a prudent neutrality, and then joined Charles I at Oxford, where in 1645 he was created marquess of Billington, but the patent never passed the great seal and the title was never assumed. The succeeding earls were Barnabas's son Henry (c. 1621-1691) and Henry's grandson Henry (1688-1741) who was created an English peer as Viscount Tadcaster. When he died the earldom of Thomond became extinct.

The estates of the earldom descended to the last earl's nephew, Percy Wyndham (c. 1713-1774), a younger son of Sir William Wyndham, Bart. He took the additional name of O'Brien and was created earl in 1756. When he died unmarried the title again became extinct.

In 1880 Murrough O'Brien, 5th earl of Inchiquin (c. 1724-1808), was created marquess of Thomond. He was succeeded by his nephew William (c. 1765-1846) who was created a British peer as Baron Tadcaster in 1826. His brother James, the 3rd marquess (c. 1768-1855), was an officer in the navy and became an admiral in 1833. When he died the marquessate became extinct.

See John O'Donoghue, Historical Memoirs of the O'Briens (Dublin, 1860).

THOMPSON, FRANCIS (1860-1907), English poet, was born at Ashton, Lancashire, in 1860. His father, a doctor, became a convert to Roman Catholicism, following his brother Edward Healy Thompson, a friend of Manning. The boy was accordingly educated at Ushaw College, near Durham, and subsequently studied medicine at Owens College, Manchester; but he took no real interest in the profession of a doctor and was bent on literary production. A period of friendlessness and failure (from the point of view of "practical life") followed, in which he became a solitary creature who yet turned his visions of "the world" into unrecognized verse. It was not till 1893 that, after some five obscure years, in which he was living at the lowest depths of destitution and ill health, his poetic genius became known to the public. Through his sending a poem to the magazine Merrie England, he was sought out by Mr and Mrs Wilfrid Meynell and rescued from the verge of starvation and self-destruction, and these friends of his own communion, recognizing the value of his work, gave him a home and procured the publication of his first volume of Poems (1893). His debt to Mrs Meynell was repaid by a most moving and devoted friendship. It was the attention of sympathetic critics, in the St James's Gazette and other quarters, and Coventry Patmore wrote a eulogistic notice in the Fortnightly Review (Jan. 1894). An ardent Roman Catholic, much of Francis Thompson's verse reminded the critics of Crashaw, but the beauty and splendour though often strange inventiveness of his diction were immediately recognized as giving him a place by himself among contemporary poets, recalling Keats and Shelley rather than any of his own day. Persistent ill health limited his literary output, but State Songs (1899) and New Poems (1897) confirmed the opinion formed of his remarkable gifts. But his health was hopelessly broken down by tuberculosis. Cared for by the friends already mentioned, he lived a frail existence, chiefly at the Capuchin monastery at Tanlarsap, and later at Storrington; and on the 13th of November 1907 he died in London. He had done a little prose journalism, and in 1905 published a treatise on Health and Holiness, dealing with the ascetic life; but it is with his three volumes of poems that his name will be connected. Among his work there is a certain amount which can justly be called eccentric or unusual, especially in his usage of poetically compound terms in his work; but nothing he said or wrote is simply beautiful than "The Daisy," nothing more intimate and reverent than his poems about children, or more magnificent than "The Hound of Heaven." For glory of inspiration and natural magnificence of utterance he is unique among the poets of his time. (H. Cn.)

THOMPSON, SIR HENRY, Bart. (1820-1904), English surgeon, was born at Framingham, Suffolk, on the 6th of August 1820. His father wished him to enter business, but circumstances ultimately enabled him to follow his own desire of becoming a physician, and in 1848 he entered the medical school of University College, London. There he had a brilliant career, and obtained his degree at London University in 1851 with the highest honours in anatomy and surgery. In 1851 he married Miss Kate Loder, a talented pianist, who, though stricken with paralysis soon afterwards, was always a devoted helpmate to him. In 1853 he was appointed assistant surgeon at University College Hospital, becoming full surgeon in 1863, professor of clinical surgery in 1866, and consulting surgeon in 1874. In 1884 he became professor of surgery and pathology in the Royal College of Surgeons, which in 1852 had awarded him the Jacksonian prize for an essay on the Pathology and Treatment of Stricture of the Urethra, and again in 1860 for another on the Health and Morbid Anatomy of the Prostate Gland. These two memoirs indicate the department of medical practice to which he devoted his main attention. Specializing in the surgery of the genito-urinary tract, and in particular in that of the bladder, he went to Paris to study under Civiale, who in the first quarter of the 19th century proved that it is possible to crush a stone within the human bladder, and after his return he soon acquired a high reputation as a skilful operator in that
class of disease. In 1863, when the king of the Belgians was suffering from stone, he was called to Brussels to consult in the case, and after some difficulties was allowed to perform the operation of lithotomy; this was quite successful, and in recognition of his skill Thompson was appointed surgeon-extraordinary to the king, an appointment which was continued by Leopold II. Nearly ten years later he carried out a similar operation on the emperor Napoleon, who, however, died four days after the second crushing, not from the surgical interference, as was proved by the post-mortem examination, but from uraemic poisoning. Besides devising various operative improvements in the treatment of the disease which he was the foremost to study, Sir Henry Thompson wrote various books and papers dealing with them, including *Clinical Lectures on Diseases of the Urinary Organs, Practical Lithotomy and Lithotomy, Tumours of the Bladder, Suprapubic Lothotomy, and Preventive Treatment of Calculous Disease*. Among other books of a medical character that came from his pen were *Food and Feeding, and Diet in Relation to Age and Activity*, both of which passed through a number of editions. In 1874 he took a foremost part in founding the Cremation Society of England, of which he was the first president; and he was active in promoting legislation in connection with the preservation of cemeteries. He also recommended and maintained as a means of disposing of the body after death, but also did much towards the removal of the legal restrictions by which it was at first sought to prevent its practice in England. On various occasions he denounced the slackness and inefficiency of the methods of death-certification prevalent in Great Britain, and in 1892 his agitation was instrumental in procuring the appointment of a select committee to inquire into the matter; its report, published in the following year, in great measure confirmed his criticisms and approved the remedies he suggested. But medicine and hygiene by no means exhaust the list of Sir Henry Thompson's activities. In art he was an accomplished sketcher and, moreover, an amateur of painting whose pictures were hung at the Royal Academy and the Paris Salon. About 1870 he began to get together his famous collection of china, in particular of old blue and white Nanking; this time became so large that he could no longer find room for it, and most of it was sold. A catalogue of it, illustrated by himself and Mr James Whistler, was published in 1878. In his famous "octaves" he may be said to have elevated the giving of dinner parties into a fine art. The number of courses and of guests was almost alike in all, and both were selected with the utmost care and discrimination to promote the "feast of reason and the flow of soul." In literature, in addition to more serious works, he produced two novels—*Charley Kingston's Aunt* (1885) and *All But* (1886)—which met with considerable success. In science he became a devotee of astronomy, and for a time maintained a private observatory in his house at Molesey. He further did much to promote astronomical study in Great Britain by presenting Greenwich Observatory with some of the finest instruments now among its equipment, his gifts including a photoheliograph of 9-in. aperture; a 36-in. reflecting telescope, and a large refracting telescope having an object-glass of 26-in. diameter and a focal length of 23½ ft. The offer of the last instrument was made in 1894. Its manufacture was undertaken by Sir Howard Grubb of Dublin, and its erection was completed in 1897. It added greatly to the instrumental resources of Greenwich, especially for photographic work, and its importance may be gauged from the fact that both in aperture and focal length it is double the size of any instrument possessed by the observatory at the time it was put in place. That Sir Henry Thompson, who was knighted in 1867, received a knighthood in 1894, was probably not unconnected with the presentation of this telescope to the national observatory. Thompson died on the 18th of April 1904. His family consisted of an only son, Herbert, a barrister and well-known Egyptologist, who succeeded to the baronetcy, and two daughters, of whom the elder (author of a valuable *Handbook to the Public Picture Galleries of Europe*, first published in 1877), married Archdeacon Watkins of Durham, and the younger married the Rev. H. de Candole.

---

**THOMPSON, SIR JOHN SPARROW** (1844-1894), Canadian jurist and statesman, was born at Halifax, Nova Scotia, on the 10th of November 1844, of Irish descent. At fifteen he entered a lawyer's office, and in 1865 was called to the provincial bar. In 1871 he incurred much odium by leaving the Methodist Church, in which he had been prominent, and becoming a Roman Catholic, a change dictated solely by religious motives. In 1877 he was elected to the local legislature for Antigonish as a Conservative, and in 1878 became attorney-general. In May 1882 he became premier, but in June was defeated at the general election, though retaining his own seat, and in July was made a judge of the provincial Supreme Court. When in September 1885, he was appointed minister of justice in the federal cabinet, and soon after was elected member for Antigonish. In 1886 he successfully defended in the Federal parliament the hanging of Louis Riel (q.v.), which had greatly angered the French Roman Catholics; in 1887-1888, together with Mr Joseph Chamberlain and Sir Charles Tupper, he arranged a Fisheries Treaty with the American commissioners, which was afterwards thrown out by the United States Senate. During the following years he defended the government with great skill in various offices, as minister of fisheries, and in November 1887 succeeded Sir John Abbott as premier of Canada. The length of time during which the Conservatives had held office had gathered around many parasites, and Thompson was compelled to face charges, some of them true, against prominent Conservatives. He promptly announced his intention to "lop the mouldering branches away," and would probably have reorganized his party, but on the 12th of December 1894 he dropped dead at Windsor Castle, a few minutes after having been sworn in by Queen Victoria as a member of the privy council.

Though a quiet man who did not advertise, few Canadian statesmen have done so much honest and solid work. In 1892 he finished the codification of the Canadian criminal code; in 1893 his firmness and knowledge as British arbitrator at Paris on the Bering Sea dispute between Great Britain and the United States were of great service.

His *Life* has been written by J. C. Hopkins (Toronto, 1895).

**THOMPSON, LAUNT** (1833-1894), American sculptor, was born at Abbeyleix, Ireland, on the 8th of February 1833. In 1847 he emigrated to the United States, and settled with his mother at Albany, New York. After studying anatomy in the office of a physician, Dr Tombs, his acquaintance with William Wilmerforce, he was appointed governor of Sierra Leone in 1868, but was recalled on account of his hostility to the slave trade. In 1872 he returned to his military duties, and, after serving in the south of France, was in 1815 attached as Arabic interpreter to an expedition against the Wahabees of the Persian Gulf, with whom he negotiated a treaty (dated Jan. 1820) in which the slave trade was for the first time declared piracy. He was promoted major in 1825, lieutenant-colonel in 1829 and major-general in...
THOMSON, W. H.—THOMSON, J.

1854. He entered parliament as member for Hull (1833-1837), and afterwards sat for Bradford (1847-1852, 1857-1870). He took a prominent part in the corn-law agitation, his *Catechism of the Corn Laws* (1837) being by far the most effective pamphlet published on the subject. In 1829 he became the proprietor of the *Westminster Review*, to which he contributed a large number of articles, republished in 1842 in six volumes, under the title *Exercises, Political and Others*. His mathematical publications were of a somewhat eccentric kind. He published a *Theory of Parallels* (1842), and was also the author of *Geometry without Axioms*, in which he endeavoured to "get rid of axioms and postulates*. His *History of Jute Manufacture* (1859) was, however, a contribution of great value to the science of musical acoustics, and went through many editions. It may be said to have formed the basis of the tonic sol-fa system of music. He died at Blackheath, near London, on the 7th of September 1869.

THOMPSON, WILLIAM HEPWORTH (1810-1886), English classical scholar and master of Trinity College, Cambridge, was born at York on the 27th of March 1810. He was privately educated before entering the university. In 1834 he became a fellow of Trinity, in 1833 professor of Greek (to which a canonry in Ely Cathedral was then for the first time attached), and in 1866 master of his college. With the exception of the year 1836, when he acted as headmaster of a newly established school in Leicester, his life was divided between Cambridge and Ely. He died at his master’s lodge on the 1st of October 1866. Thompson proved a worthy successor to Whewell; the twenty years of his mastership were years of progress, and he himself took an active part in the abolition of tests and the reform of university studies and of the college statutes. As a scholar he devoted his attention almost entirely to Plato; and his *Phaedrus* (1868) and *Gorgias* (1871), with especially valuable introductions, still remain the standard English editions of these two dialogues. He also edited (1856) from the author’s MSS. *Lectures on the History of Ancient Philosophy* by William Archer Butler (1814-1848; lecturer on moral philosophy at Trinity College, Dublin), the value of which was greatly enhanced by Thompson’s notes. See article by J. W. Clark in *Dict. Nat. Biog.*; and J. E. Sandys, *History of Classical Scholarship* (1853), vol. iii.

THOMSEN, GRIMUR (1820-1876), Icelandic poet and man of letters, was born in 1820. He came in 1837 to the university of Copenhagen, where he first studied law and philology, but later, philosophy and aesthetics. He became an enthusiastic follower of the Pan-Scandinavian movement, although this was not generally favoured by his countrymen. After some years of foreign travel, in 1848 he entered the Danish diplomatic service, and remained in it till 1851, when he returned to Copenhagen, where he became the chief of one of the departments of the Danish foreign office. He retired in 1866 and then went back to Iceland, where he passed the rest of his life, active in the politics and the literature of his native island. He died in 1896. He is the best ballad poet Iceland has produced. His poems are unaffected and mostly free from rhetoric, the besetting sin of Icelandic poets. His subjects are principally taken from Icelandic or Scandinavian history and mythology. He is very unlike most of his contemporaries, both in style and thought: he is Icelandic to the core, and on that account is perhaps the modern Icelandic poet most appreciated by foreigners besides his poems (two separate collections, Reykjavik, 1880, and Copenhagen, 1880), he is the author of numerous critical and historical essays in Icelandic and Danish, and some larger works in Danish, of which his dissertation on Lord Byron (Copenhagen, 1842) deserves to be mentioned. Grímur Thomsen was a warm admirer of Greek literature, and translated a great number of poems from that language into Icelandic. (S. B.)

THOMSEN, HANS PETER JÖRGEN JULIUS (1826-1900), Danish chemist, was born in Copenhagen on the 16th of February 1826, and spent his life in that city. From 1847 to 1856 he was engaged in teaching chemistry at the Polytechnic, of which from 1883 to 1892 he acted as director, and from 1856 to 1866 he was on the staff of the military high school. In 1866 he was appointed professor of chemistry at the university, and retained that chair until his retirement from active work in 1891. His name is famous for his researches in thermochemistry, and, especially between 1869 and 1882, he carried out a great number of determinations of the heat evolved or absorbed in chemical reactions, such as the formation of salts, oxidation and reduction, and the combustion of organic compounds. His collected results were published in 1865-1886 in four volumes under the title *Thermochemische Untersuchungen*, and also a *Résumé* in English, under the title *Thermal Analysis*. In 1866 he established in Copenhagen a process for manufacturing soda from cryolite, obtained from the west coast of Greenland. He died on the 13th of February 1900. His brother, Carl August Thomsen (1834-1894), was lecturer on technical chemistry at the Copenhagen Polytechnic, and a second brother, Thomas Gottfried Thomsen (1841-1901), was assistant in the chemical laboratory at the university till 1884, when he abandoned science for theology, subsequently becoming minister at Norup and Roskilde.

THOMSON, SIR CHARLES WYVILLE (1830-1882), Scottish naturalist, was born at Bonsyre, Linlithgowshire, on the 5th of March 1830, and was educated at Edinburgh University. In 1850 he was appointed lecturer in, and in 1853 professor of, botany at Aberdeen, and in 1853 he became professor of natural history in Queen’s College, Cork. A year later he was nominated to the chair of mineralogy and geology at Queen’s College, Belfast, and in 1860 was transferred to the chair of natural history in the same institution. In 1868 he assumed the duties of professors of botany at the Royal College of Science, Dublin, and finally in 1870 he received the natural history chair at Edinburgh. He will be specially remembered as a student of the biological conditions of the depths of the sea. Being interested in crinoids, and stimulated by the results of the dredgings of Michael Sars (1805-1869) in the deep sea off the Norwegian coasts, he succeeded, along with Dr W. B. Carpenter, in obtaining the loan of H.M.S. "Lightning" and "Porcupine", for successive deep-sea dredging expeditions in the summers of 1868 and 1869. It was thus shown that animal life exists in abundance down to depths of 650 fathoms, that all invertebrate groups are represented (largely by Tertiary forms previously believed to be extinct), and, moreover, that deep-sea temperatures are by no means so constant as was supposed, but vary considerably, and indicate an oceanic circulation. The results of these expeditions were described in *The Depths of the Sea*, which he published in 1873. The remarkable results gained for hydrography as well as zoology, in association with the practical needs of ocean telegraphy, soon led to the granting of H.M.S. "Challenger" for a circumnavigating expedition, and Thomson sailed at the end of 1871 as director of the scientific staff, the cruise lasting three years and a half (see *Challenger Expedition*). On his return he received many academic honours, and was knighted. In 1873 he published two volumes (The Voyage of the Challenger in the Atlantic), of a preliminary account of the results of the voyage, meanwhile carrying on his administrative labours in connexion with the disposition of the special collections and the publication of the monographs dealing with them. His health never robust, was meanwhile giving way; from 1879 he ceased to perform the duties of his chair, and he died at Bonsyre on the 10th of March 1882. See obituary notice in *Proc. Soc. Edin.* (1883); also Thomson and Murray, Reports of the Voyage of H.M.S. "Challenger" (Edinburgh, 1888).

THOMSON, JAMES (1700-1748), English poet, author of *The Seasons*, was born at Ednam, in Roxburghshire, on the 11th of September 1700—the third son and fourth child of Thomas Thomson, minister of that place. His mother, Beatris, was the daughter of Mr Trotter of Fogo, whose wife, Margaret, was one of the Houses of Bassenden. About 1701 Thomas Thomson removed to Southdean near Jedburgh. Here James was educated at first by Robert Riccalltoun, to whose verses on
Winter he owed the suggestion of his own poem. In 1712 he attended a school at Jedburgh, held in the aisle of the parish church. He learnt there some Latin, but with difficulty, and the earliest recorded utterance of the future poet was "Confound the building of Babel." He began very soon to write verses, and we are told that every January he destroyed almost all the productions of the preceding year. And this was just as well, for the little that has escaped the fire contained no promise of him who was not in favour of his own poem. In 1715 he went to the university of Edinburgh. It is said that as soon as the servant who brought him thither had quitted him, he returned full speed to his father's house, declaring that he could read just as well at home; he went back, however, and had not been long at college before he lost his father, who died, according to one remarkable but highly improbable story, in the attempt to lay a ghost. The incident should have left more impression than we can trace upon the mind of the poet, at this date nervous and afraid of the dark; but In his "Winter" he writes of all which stories with a quiet and "whim of horror." He made friends at the university with David Mallock, who afterwards called himself Mallet, and with Patrick Murdoch, his future biographer. In 1719 he became a divinity student, and one of his exercises so enchanted a certain Auditor Benson, that he urged Thomson to go to London and there make himself a reputation as a preacher. It was partly with this object that Thomson left Edinburgh without a degree in March 1725. His mother saw him embark, and they never met again; she died on the 10th of May of that year. There is sufficient evidence that the subject of Thomson's earliest extant declamation, which Dr Johnson attributes to him; and in July 1725 we find him engaged, as a make-shift, in teaching "Lord Binning's son to read." This son was the grandson of Lady Grizel Baillie, a somewhat distant connexion of Thomson's mother. She was the daughter of Sir Patrick Home, whom, after the defeat of Argyll, she fed in his concealment near his own castle; she was also, like other Scottish ladies, a writer of pretty ballads. This heroical and poetical is supposed to have encouraged Thomson to come to England, and it is certain that she procured him a temporary home. But he had other friends, especially Duncan Forbes of Culfin, by whom he was recommended to the duke of Argyll, the earl of Burlington, Sir Robert Walpole, Arbuthnot, Pope and Gay. Some introductions to the literary world he may have owed to Mallet, then tutor in the family of the duke of Montrose.

Thomson's "Winter" appeared in March 1726. It was warmly praised by Aaron Hill, a man of various interests and projects, and in his day a sort of literary oracle. It was dedicated to Sir Spencer Compton, the Speaker, who rewarded the poet, to his great disgust, with a bare twenty guineas. By the 11th of June 1727 a second edition was called for. Meanwhile Thomson was residing at Mr Watts's academy in Tower Street as tutor to Lord George Graham, second son of the duke of Montrose, and previously a pupil of Mallet. "Summer" appeared in 1727. It was dedicated in prose, a compliment afterwards versified, to Bubb Dodington. In the same year Thomson published his "Poem to the Memory of Sir Isaac Newton," with a fulsome dedication to Sir Robert Walpole, which was afterwards omitted, and the verses themselves remodelled when the poet began to inveigh against the ministry as he did in British, published in 1729. "Spring" appeared in 1726, published by Andrew Millar, a man who, according to Johnson, dealt somewhat handsomely by and "raised the price of literature." It was dedicated to the counts of Hertford, afterwards duchess of Somerset, a lady devoted to letters and the patroness of the unhappy Savage. In 1729 Thomson produced "Sophonisba," a tragedy now only remembered by the line "O Sophonisba, Sophonisba, O," and the parody "O Jimmy Thomson, Jimmy Thomson, O," which caused him to remodel the unhappy verse in the form, "O Sophonisba, I am wholly thine." A poem, anonymous but unquestionably Thomson's, to the memory of Congreve who had died in January 1729, appeared in that year. In 1730 "Autumn" was first published in a collected edition of The Seasons. It was dedicated to the Speaker, Onslow. In this year, at the suggestion of Rundle, bishop of Derry, one of his patrons, he accompanied the son of Sir Charles Talbot, solicitor-general, upon his travels. In the course of these he projected his Liberty as "a poetical landscape of countries, mixed with moral observations on their government and people." In December 1731 he returned with his pupil to London. He probably lived with his patrons the Talbots, leisurely meditating on his new poem, the first part of which did not appear until the close of 1734 or the beginning of 1735. But meanwhile his pupil died, and in the opening lines of Liberty Thomson pays a tribute to his memory. Two months after his son's death Sir Charles Talbot became chancellor and gave Thomson a sinecure in the court of chancery. About this time the poet worked for the relief of Dennis, now old and in extreme poverty, and induced even Pope to give a half-contemptuous support to the bitter critic of the Rape of the Lock. Liberty was completed in five parts in 1736. The poem was a failure; its execution did not correspond with its design; in a sense indeed it is a survey of countries and might have anticipated Goldsmith's Traveller. It was not, however, the poem which readers were expecting from the author of The Seasons, who had taken them from the town to the country, and from social and political satire to the world of nature. It is in the main a set of wearisome declamations put in the mouth of the goddess, and Johnson rightly enough remarks that "an enumeration of examples to prove a position which nobody denied as it was from the beginning superfluous, must quickly grow disgusting." The external appearance of the work was for many years perverted by the zeal of partisanship.

He was established in May 1736 in a small house at Richmond, but his patron died in February 1737 and he lost his sinecure; he then "whips and spurs" to finish his tragedy Agamemnon, which appeared in April 1738, not before he had been arrested for a debt of £70, from which, according to a story which has been discredited on quite insufficient grounds, Quin relieved him in the most generous and tactful manner. Quin, it is said, visited him in the sponging-house and "balanced accounts with him" by insisting on his accepting a hundred pounds as a return for the pleasure which the actor had received from the poet's works. The incident took place probably a little before the production of Agamemnon, in which Quin played the leading part. The play is of course modelled upon Aeschylus and owes whatever of dignity it possesses to that fact; the part of Cassandra, for instance, retains something of its original force, pathos and terror. But most of the other characters exist only for the purpose of political innuendo. Agamemnon is too long absent at Troy, as George is too long absent in Germany; the arts of Aegeus the are the arts of Walpole; the declarations of Tantalus are the declarations of Wyndham or Pulteney; Alexander, consoling himself with the muses on his island in Cyclades, is Bolingbroke in exile. Thomson about this time was introduced to Lyttelton, and by him to the prince of Wales, and to one or the other of these, when he was questioned as to the state of his affairs, he made answer that they were "in a more poetical posture than formerly." Agamemnon was put upon the stage soon after the passing of Walpole's bill for licensing plays, and its obvious bias fixed the attention of the censorship and caused Thomson's next venture, Edward and Eleanor, which has the same covert aim, to be proscribed. This was a play generally accepted notice that, like its predecessor, it follows a Greek original, the Alcestis of Euripides. It has also, what Agamemnon has not, some little place in the history of literature, for it suggested something to Lessing for Nathan der Weise, and to Scott for the Talisman. The rejection of the play was defended by one of the ministry on the ground that Thomson had taken a Liberty which was not agreeable to Britannia in any Season. These circumstances sufficiently account for the poet's next experiment, a preface to Milton's Areopagitica. He joined Mallet in composing the masque of Alfred, represented at Cleeveden on the Thames before the prince of Wales, on the 1st of August 1740. There can be little question that "Rule
Britannia," a song in this drama, was the production of Thomson. The music of the song, as of the whole masque, was composed by Arne. In 1744 Thomson was appointed surveyor-general of the Leeward Islands by Lyttelton with an income of £300 a year; but his patron fell into disfavour with the prince of Wales, and in 1747, when Thomson lost, at the close of 1747, the pension he received from that quarter. For a while, however, he was in flourishing circumstances, and whilst completing at his leisure The Castle of Indolence produced Tancred and Sigis- munda at Drury Lane in 1745. The story is found in Gil Bias, and is ultimately to be traced to The Decameron. It owes much to Le Sage in language, plot and sentiment, and the conflict of emotion, in depicting which Thomson had some little skill, is here effectively exhibited. He was assisted herein by his own experience. The "Amanda of The Seasons is a Miss Elizabeth Young, a lady of Scottish birth, whose mother was ambitious for her and forbade her to marry the poet, anticipating that she would be reduced to singing his ballads in the streets. The last years of his life were saddened by this disappointment.

The Castle of Indolence, after a gestation of fifteen years, appeared in May 1748. It is in the Spenserian stanza with the Spenserian archaisms, and is the first and last long effort of Thomson in rhyme. It is not impossible that his general choice of blank verse was partly due to the fact that he had not the southern ear and took many years to acquire it. The great and varied interest of the poem might well rescue it from the neglect into which even The Seasons has fallen. It was worthy of an age which was fertile in character-sketches, and like Gay's Welcome to Pope anticipates Goldsmith's Retaliation in the lifelike presentation of a noteworthy circle. There is in it the same strain of gentle burlesque which appears in Shenstone's Schoolmistress, whilst the tone and diction of the poem harmonize with the hazy landscape, the pleasant land of drowsy head, in which it is set. It is the last work by Thomson which appeared in his lifetime. He was walking from London to his house at Richmond when he became hysteric and took a boat at Hampton-smit; he thus caught a chill with fatal consequences and died on the 27th of August 1748. He was buried in Richmond churchyard. His tragedy Coriolanus was acted for the first time in January 1749. In itself a feeble performance, it is noteworthy for the prologue which his friend Lyttelton wrote for it, two lines of which—

"He loved his friends—forgive the gushing tear!"

"Alas! I feel I am no actor here!

were recited by Quin with no simulated emotion.

It seems, however, that Thomson himself ever quite realized the distinctive significance of his own achievement in The Seasons, or the place which criticism assigns him as the pioneer of a special literary movement and the precursor of Cowper and Wordsworth. His avowed preference was for great and worthy themes of which the world of nature was but one. Both the choice and the treatment of his next great subject, Liberty, indicate that he was imperfectly conscious of the gift that was in him, and might have neglected it but that his readers were wiser than himself. He has many audacities and many felicities of expression, and enriched the vocabulary of the poets who had preceded him, but it is difficult to believe that he was not the better for that training in refinement of style which he partly owed to Pope, who almost unquestionably contributed 'some passages to The Seasons. And, except in The Castle of Indolence, there is much that is conventional, much that is even vicious or vulgar in taste when Thomson's muse deals with that human life which must be the background of descriptive as of all other poetry; for example, his bumpkin who chases the rainbow is as unreal a being as Akenside's more sentimental rustic who has "the form of beauty smiling at his heart."

But if Thomson sometimes lacks the true vision for things human, he retains it always for things mute and material, and whilst the critical estimate of his powers and influence will vary from age to age, all who have read him will concur in the colloquial judgment which only candour could have extorted from the prejudice of Dr Johnson—

"Thomson had as much of the poet about him as most writers. Everything appeared to him through the medium of his favourite pursuit. He could not have viewed those two candles burning but with a poetical eye."

For the day of Thomson's birth see the Aldine edition of his poems (1897). In the same volume (pp. 189 seq.) is discussed the controversy between Pope and Thomson and the question if the handwriting be his, made in an interleaved edition of The Seasons dated 1738, and they were for the most part adopted by Thomson in the edition of 1744; the writer seldom makes more than verbal changes in passages of pure description, but sometimes strikingly enhances the scenes in which human character comes into play, adding, for example, in Autumn, of the fair lady in the Decameron of which the first suggestion for the words can be found in The Rape of the Lock. But whereas many years ago the opinion of experts at the British Museum pronounced the handwriting of these notes to be Pope's beyond a doubt, their successors at the present day are equally positive that it is not. Some account should be taken of the cramping of the hand, due to writing on a curved surface, and of the letter at Blenheim (see Pall Mall Magazine for August 1894), which bear a greater resemblance to the disputed handwriting than any specimens in the British Museum.

The first collected editions of The Seasons bear dates 1730, 1738. By 1746 Lyttelton was talking both with The Seasons and Liberty in editions after his friend's death. Among the numerous lives of the poet may be mentioned those by his friend Patrick Murdoch, by Dr Johnson in Lives of the Poets, by Sir Harris Nicolas (Ald. ed., 1860), by M. Morel, James Thomson, sa vie et ses œuvres (Paris, 1895), and James Thomson, in the English Men of Letters Series, by G. C. Macaulay (1868). See also Dr G. Schmeding's Leben, ein müder Tod, which was a revision of the life prefixed to the Aldine edition of his works in 1897; and an excellent edition of The Seasons in the Clarendon Press Series by J. Logie Robertson. (D. C. To.)

THOMSON, JAMES (1834-1882), British poet, best known by his signature "B.V.", was born at Port-Glasgow, in Renfrewshire, on the 23rd of November 1834, the eldest child of a mate in the merchant shipping service. His mother was a deeply religious woman of the Irvingite sect. On her death, James, then in his seventh year, was procured admission into the Caledonian Orphan Asylum. In 1850 he entered the model school of the Military Asylum, Chelsea, from which he went out into the world as an assistant army schoolmaster. At the garrison at Ballincollig, near Cork, he encountered the one brief happiness of his life: he fell passionately in love with, and was in turn ardently loved by, the daughter of the armour-sergeant of a regiment in the garrison, a girl of very exceptional beauty and cultivated mind. Two years later he suddenly received news of her fatal illness and death. The blow prostrated him in mind and body. Henceforth his health, his method, his gloom, his disenchantment, misfortune, poverty, rarely alleviated by episodes of somewhat brighter fortune. While in Ireland he had made the acquaintance of Charles Bradlaugh, then a soldier stationed at Ballincollig, and it was under his auspices (as editor of the London Investigator) that Thomson first appealed to the public as an author, though actually his earliest publication was in Tait's Edinburgh Magazine for July 1858, under the signature "Crepusculus." In 1860 was established the paper with which Bradlaugh was so long identified, the National Reformer, and it was here, among other productions by James Thomson, that Crepusculus made his appearance for the first time, as "The Ladies of Death," and (1874) his chief work, the sombre and imaginative City of Dreadful Night. In October 1862 Thomson was dismissed the army, in company with other teachers, for some slight breach of discipline. Through Bradlaugh, with whom for some subsequent years he lived, he gained employment as a solicitor's clerk. From 1866 to the end of his life, except for two short absences from England, Thomson lived in a single room, first in Pimlico and then in Bloomsbury. He contracted habits of intemperance, aggravated by his pessimistic turn of mind to dipsomania, which made a successful lawyer increasingly improbable. His "only reputable appearance in respectable literary society," in the acceptance of his long poem, "Sunday up the River," for Fraser's Magazine, on the advice, it is said, of Charles Kingsley.
THOMSON, J.

In 1872 Thomson went to the western states of America, as the agent of the shareholders in what he ascertained to be a fraudulent silver mine; and the following year he received a commission from the New York World to go to Spain as its special correspondent with the Carlisle. During the two months of his stay in that distracted country he saw little real fighting, and was himself prostrated by a sunstroke. On his return to England he continued to write in the Secularist and the National Reformer, under the initials "B.V." In 1875 he severed his connexion with the National Reformer, owing to a disagreement with its editor; henceforth his chief source of income (1875-1881) was from the monthly periodical known as Cope's Tobacco Plant.

Chiefly through the exertions of his friend and admirer, Bertram Dobell, Thomson's best-known book, The City of Dreadful Night, one of the first published in April 1836, and at once attracted wide attention; it was succeeded in the autumn by Vane's Story, and other Poems, and in the following year by Essays and Fantasies. All his best work was produced between 1855 and 1875 ("The Doom of a City," 1857; "Our Ladies of Death," 1861; Weddah and Om-el-Bonain; "The Naked Goddess," 1866-1867; The City of Dreadful Night, 1870-1874). He died at University College Hospital, in Gower Street, on the 3rd of June 1882, and was buried at Highgate cemetery, in the same grave, in unsegregated ground. As his friend Austin Holyoake says:

The productions of James Thomson already mentioned may be added the posthumous volume entitled A Voice from the Nile, and other Poems (1884), to which was prefixed a memoir by Bertram Dobell. This volume contained much that is interesting, but nothing to increase Thomson's reputation. If an attempt be made to point to the most apparent literary relationship of the author of the City of Dreadful Night, one might venture the suggestion that James Thomson was a younger brother of De Quincey. If he has distinct affinity to any writer it is to the author of Suspiria de profundis; if we look further afield, we might perhaps discern shadowy prototypes in Leopardi, Heine and Baudelaire. But, after all, Thomson holds so unique a place as a poet that the effort at classification may well be dispensed with. His was no literary pessimism, no assumed gloom. The poem "Insomnius" is a distinct chapter of biography; and in "Mater Tenebrarum" and elsewhere among his writings passages of self-revelation are frequent. The merits of Thomson's poetry are its imaginative power, its sombre intensity, its sonorous music; to these characteristics may be added, in his lighter pieces, a Heine-like admixture of strange gaiety, pathos and caustic irony. Much the same may be said of his best poems. His faults are few: too infrequent use of mere rhetoric and verbage; and perhaps a prevailing lack of the sense of form; besides an occasional vulgar recklessness of expression, as in parts of Vane's Story and in some of his prose writings.

See the Life, by H. S. Salt (1905 edition).

THOMSON, JAMES (1822-1892), British physicist and engineer, was born in Belfast on the 16th of February 1822, and, like his younger brother, Lord Kelvin, at an unusually early age began to attend the classes at Glasgow University, where his father had been appointed professor of mathematics in 1832. After his graduation he decided to study civil engineering, and for that purpose became a pupil in several engineering offices and works successively; but ill-health obliged him to leave them all, and he had finally to accept the fact that an occupation involving physical exertion was out of the question. Accordingly, from about 1843, he devoted himself to theoretical work and to mechanical invention. To this period belong his well-known researches in thermodynamics, which enabled him to predict by the application of Carnot's theorem that the temperature of the freezing point of substances which expand on solidification must be lowered by the application of pressure, the reverse being the case with substances which contract on solidification; and he was able to calculate the amount by which a given pressure lowers the freezing-point of water, a substance which expands on solidification. His results were experimentally verified in the physical laboratories of Glasgow University under Lord Kelvin's direction, and were afterwards applied to give the explanation of regelation. In 1857 he extended them in a paper on crystallization and liquefaction as influenced by stresses tending to change of form in the crystals, and in other studies on the change of state he continued Thomas Andrews's work on the continuity of the liquid and gaseous states of matter, constructing a thermodynamic model in three dimensions to show the relations of pressure, volume and temperature for a substance like carbonic acid. With regard to his inventions, he devised a clever feathering mechanism for the paddles of steamboats when only a boy of sixteen, and later turned his attention to water-engines. In 1850 he patented his "vortex wind-wheel," and during the next three or four years engaged on inquiries into the properties of "whirling fluids," which resulted in improved forms of blowing-fans and water-turbines (see HYDRAULICS). Settling in Belfast in 1851, he was selected to be the resident engineer to the Belfast Water Commissioners in 1853, and four years later became professor of civil engineering and surveying in Queen's College, Belfast. Thence he removed in 1873 to Glasgow as successor to Macquorn Rankine in the chair of engineering in the university, and retained this position until 1882, when the failure of his eyesight compelled him to resign. He died on the 8th of May 1882 at Glasgow. His contributions to geological science included studies of the parallel roads of Glen Roy and of the prismatic jointing of basalt, as seen at the Giant's Causeway. In 1876 and following years he studied the origin of windings of rivers in alluvial plains and made many experiments with the aid of artificial streams, and the currents of atmospheric circulation afforded him the material for the Bakerian lecture of 1892.

THOMSON, JOHN (1778-1840), Scottish landscape painter—Thomson of Duddingston, as he is commonly styled—was born 1778 at Dailly, Ayrshire. His father, grandfather and great-grandfather were clergymen of the Church of Scotland. He studied for the same vocation in the university of Edinburgh; and, residing with his elder brother, Thomas Thomson, afterwards celebrated as an anti-Jews and feudal lawyer, he made the acquaintance of Francis Jeffrey and other young members of the Scottish bar afterwards notable. During the recess he sketched in the country, and, while attending his final college session, he studied art for a month under Alexander Nasmyth. After his father's death he became, in 1800, his successor as minister of Dailly; and in 1805 he was translated to the parish of Duddingston, close to Edinburgh. He continued, however, to practise art as an amateur, apparently without any detriment to his pastoral duties. Thomson's popularity as a painter increased with his increasing artistic skill; and, having mastered his initial scruples against receiving artistic fees, on being offered £5 for a landscape—reassured by "Grecian" Williams's stout assertion that the work was "worth twice the amount"—the minister of Duddingston began to dispose of the productions of his brush in the usual manner. In 1830 he was made an honorary member of the Royal Scottish Academy. Thomson was also an accomplished performer on the flute, an exact and well-read student of physical science, and one of the writers on optics in the early numbers of the Edinburgh Review. He enjoyed a singularly wide and eminent circle of friends, including, among artists, Turner and Wilkie, and among men of letters, Wilson and Scott—the latter of whom desired that Thomson, instead of Turner, should have illustrated the collected edition of his works. He died at Duddingston on the 27th of October 1840 (not the 20th, as stated by some authorities). Thomson was twice married, and his second wife, the widow of Mr Dalrymple of Cleland, was herself also a skilful amateur artist.

Thomson is fairly represented in the Scottish National Gallery; and the "Aberdaly Bay" of that collection, with the soft infinity of
its clouded grey sky, and its sea which leaps and falls again in waves of sparkling and shadowed silver, is fit to rank among the triumphs of Scottish art.

THOMSON, JOSEPH (1818–1895), Scottish explorer in Africa, was born on the 14th of February 1818 at Penpont, Dumfries-shire, being the fifth son of William Thomson, originally a working stonemason, who had attained the position of a master builder. In 1868 his father removed to Gateheadbridge, where he rented a farm and a quarry. Joseph Thomson was soon attracted by the geological formation and historical associations of Nithsdale. For a short time he worked in his father’s quarry. In 1875 he went to Edinburgh University, where he paid particular attention to geology and botany, and after completing his course in 1878 he was appointed geologist and naturalist to the Royal Geographical Society’s expedition to East Central Africa under Keith Johnston. The latter died at Behobeho, between the coast and the north end of Lake Nyasa, on the 28th of June 1879, and Thomson then took command. Though only twenty-one his coolness and tact were remarkable, and he successfully conducted the expedition across the desolate region of Uhehê and Ubenita to the north end of Lake Nyasa, and then by a hitherto unexplored track to Lake Tanganyika, where he investigated the most question of the Lukuga outlet. From Tanganyika he started to reach the Congo, but troubles with his carriers, who dreaded the warlike Wanza, obliged him to retrace his steps. Going round the south end of Tanganyika he discovered Lake Rukwa, whence he marched via Tabera to the coast at Bagamoyo, reaching London in August 1880. In the following year he published an account of his travels under the title *To the Central African Lakes and Back*. About this time the sultan of Zanzibar, being anxious to develop certain supposed coal beds on the river Rovuma, was advised to obtain independent expert opinion as to their value. Application was made to Thomson, who undertook to survey them, and started from Mikindani, on the 17th of July 1881. The coal, however, turned out to be worthless, and the sultan of Zanzibar, having been sent to Zanzibar, had to endure much delay and vexation through the sultan’s chagrin. For a considerable time the explorer had directed his attention to Masailand, a region of East Africa occupied by a powerful tribe of warriors who had a reputation for savagery and intractability somewhat greater than their actions warranted. Through their territory ran the shortest route from the sea to the headwaters of the Nile. In 1882 the Royal Geographical Society took up the question, and requested Thomson to report on the practicability of taking a caravan through the Masai country, which at first sight the amount of travelling and the severity of the climate seemed to make beyond their power. By undaunted courage and great resourcefulness he succeeded in crossing the Najiri desert and exploring the eastern rift-valley. Thence he went with a picked company through Laikilia to Mt Kenya and Lake Baringo, afterwards traversing the unknown region lying between Baringo and Victoria Nyanza, reached on the 10th of December 1883. On his way back he visited Mt Elgon and discovered there a series of wonderful caves. The account of this adventurous journey appeared in 1884, under the title of *Through Masailand*, and it is a classic in modern travel literature. It was an anathema to Thomson to find that his name began to tell upon Thomson’s exceptionally hard constitution, but in 1885 he undertook an expedition to Sokoto for the National African (afterwards the Royal Niger) Company, and succeeded in obtaining the signatures of the sultans of Sokoto and Gando to treaties with which he had been entrusted by the company, treaties which did much to secure British interests in Nigeria. In 1888, by way of recreation, he travelled through southern Morocco and explored a portion of the Atlas range, and published the results in the following year, under the title *Travels in the Atlas and South-west Morocco*. In 1890 he entered the service of the British South Africa Company and in that and the following year, starting from Quelimane he traversed the region between lakes Nyasa and Bangweulu and the Zambezi. It was a period of great tension between the Portuguese and the British, and Thomson’s party on leaving the Portuguese frontier was fired on by the Portuguese who, too late, realized that they had allowed a treaty-making envoy to pass through their territory in the guise of a peaceful trader. Thomson concluded treaties with native potentates which gave to the Chartered Company political, trading, and indices, communicated to him of the district since known as North-East Rhodesia. This journey, in which he covered nearly a thousand miles of hitherto unexplored country, proved disastrous to a constitution already undermined. In 1893 he visited South Africa in search of health, but unavailingly. He died in London on the 2nd of August 1895. The accounts of his travels not recorded in the books mentioned were published in magazines or in the *Proceedings of the Royal Geographical Society*. Thomson was the last, as he was one of the most successful, of the great geographical pioneers in Africa. He had an extraordinarily keen topographical instinct which enabled him to comprehend at a glance the natural features of the countries he traversed. To undaunted courage and promptness of decision he added a forbearing and patient disposition. “Joseph Thomson,” wrote Sir Clements Markham, “had the high and glorious distinction of never having caused the death of a native. This is a proof of very rare qualities in the leader of an expedition, and places him in the very first rank of explorers.”

THOMSON, THOMAS (1773–1852), Scottish chemist, was born at Crieff, Perthshire, on the 12th of April 1773. He was educated at the universities of St Andrews and Edinburgh, and after taking the degree of M.D. at the latter place in 1799 established himself there as a teacher of chemistry. From 1828 he was professor of the science at the University of Edinburgh. On the death of his success to his elder brother, JAMES THOMSON (1768–1855), who filled that position in 1795–1796, and who in 1805 was ordained to the parish of Eccles, Berwickshire; and the chemical and mineralogical articles which he contributed to the supplement to the third edition formed the basis of his *System of Chemistry*, the first edition of which was published in 1802 and the seventh in 1831. At first this work was merely a compilation, but in the later editions many of his original results were incorporated; the third edition (1827) is noteworthy as containing the first edition of an analytical and theoretical treatise on the constitution of body by John Dalton himself. In 1811 he left Edinburgh, and after a visit to Sweden went to London, where in 1813 he began to edit the *Annals of Philosophy*, a monthly scientific journal which in 1827 was merged in the *Philosophical Magazine*. In 1817 he became lecturer in chemistry at Glasgow University, and in the following year was appointed to the regius professorship. This chair he retained until his death, which happened on the 2nd of July 1852 at Kilmarnock, Ayrshire; but from 1841 he was assisted by his nephew and son-in-law ROBERT DUNDAS THOMSON (1810–1866), who subsequently became medical officer of health for St Marylebone, London, and after 1846 he ceased active work altogether. He was a most energetic professor, and, according to his colleague, but no relation, Lord Kelvin (Sir William Thomson), founded the first chemical laboratory for students at a time when practical work was scarcely recognized as a necessary part of chemical education. He did much to spread a knowledge of Dalton’s atomic theory, and carried out many experiments in its support, but his strong predilections in favour of Prout’s hypothesis tended to vitiate his results, many of which were sharply criticized by J. J. Berzelius. In addition to various textbooks he published a *History of Chemistry* (1830–1851) which has provided material for many chemical biographers, but which, although it reads very plausibly, cannot be regarded as an authority of unimpeachable accuracy. His eldest son, THOMAS THOMSON (1817–1859) graduated as M.D. at Glasgow in 1839, accompanied
THOMSON, W.—THORBECKE

Sir J. D. Hooker on his travels in Sikkim in 1850, and collaborated with him in publishing his Flora indica in 1855 and in 1854 was appointed superintendent of the botanical gardens at Calcutta, also acting as professor of botany at the Calcutta medical college.

THOMSON, WILLIAM (1819-1890), English divine, archbishop of York, was born on the 11th of February 1819 at Whitehaven, Cumberland. He was educated at Shrewsbury and at Queen's College, Oxford, of which he became a scholar. He took his B.A. degree in 1840, and was soon afterwards made fellow of his college. He was ordained in 1842, and worked as a curate at Cuddesdon. In 1847 he was made tutor of his college, and in 1851 was made principal of the hall. In 1851 the subject being "The Atoning Work of Christ viewed in Relation to some Ancient Theories." These thoughtful and learned lectures established his reputation and did much to clear the ground for subsequent discussions on the subject. Thomson's activity was not confined to theology. He was made fellow of the Royal and the Royal Geographical Societies. He also wrote a very popular Outline of the Laws of Thought. He sided with the party at Oxford which favoured university reform, but this did not prevent him from being appointed provost of his college in 1855. In 1858 he was appointed preacher at Lincoln's Inn and there preached some striking sermons, a volume of which he published in 1861. In the same year he edited Aids to Faith, a volume written in opposition to Essays and Reviews, the progressive sentiments of which had stirred up a great storm in the Church of England. In December 1861 he was rewarded with the see of Gloucester and Bristol, and within a twelvemonth he was elevated to the archiepiscopate see of York. In this position his moderate orthodoxy led him to join Archbishop Tait in supporting the Public Worship Regulation Act, and, as president of the northern convocation, he came frequently into sharp collision with the lower house of the church. But he incurred the hostility of the High Church party among the clergy, he was admired by the laity for his strong sense, his clear and forcible reasoning, and his wide knowledge, and he remained to the last a power in the north of England. In his later years he published an address read before the members of the Edinburgh Philosophical Institution (1868), one on Design in Nature, for the Christian Evidence Society, which reached a fifth edition, various charges and pastoral addresses, and he was one of the projectors of The Speaker's Commentary, for which he wrote the "Introduction to the Synoptic Gospels." He died on the 29th of December 1890.

See the Quarterly Review (April 1892).

THOR, one of the chief deities of the heathen Scandinavians. He is represented as a middle-aged man of enormous strength, quick to anger, but benevolent towards mankind. To the harmful race of giants (demons), on the other hand, he was an implacable foe, and many stories are told in the poetic and prose Eddas of the destruction which he brought upon them at various times with his hammer. On the whole his figure is somewhat secondary in the mythology to that of Odin, who is represented as his father. But there is no doubt that in Iceland he was worshipped more than any other god, and the same seems to have been the case in Norway—indeed, perhaps, in all northern countries—except among the royal families. Even in the great temple at Upsala his figure is said to have occupied the chief place. There is evidence that a corresponding deity named Thoron or Thonar was worshipped in England and on the Continent, but little information is obtainable regarding him, except that he was identified with the Roman Jupiter. His name is identical with the Teutonic word for thunder, and even in Sweden the association of Thor with the thunder seems not to have been forgotten. Outside the Teutonic area he has close affinities not only with Jupiter or Zeus, but still more with the Lithuanian god Perkunas, whose name (which likewise means "thunder") appears to be connected with that of Thor's mother (Fiorgyn). The Vanangian god Perun was probably Thor himself under a Slavonic name (Russian perun, "thunderbolt").
been as fully recognized as his political genius has been. As an orator and writer his style was clear and forcible. His very dogmatism brought him many enemies, but at times, especially when he went in advance of his time, he was a much misunderstood man. These misunderstandings, frequently wilful, extended often beyond the domain of pure politics. Thus, by his enemies, Thorebecke was often held up as a pure materialist and no friend of the fine arts, because at a sitting of the states-general in 1862 he had said that it is not the duty of the state, nor in the true interest of art itself, for the government to "protect" art, since all state-aided art must be artificial, like any forced plant. This was popularly condensed into the aphorism, yet current in Holland, that "Art is not the business of the government," and Thorebecke was condemned as the author of it. Again, his adversaries used to call him a dangerous demagogue. As a matter of fact, there was no more ardent royalist than Thorebecke. He believed in constitutional monarchy, as offering the best guarantees both for sovereign and people, and he was bitterly opposed to all forms of state socialism. Long before his death he realized that he had outlived his own principles, and many of his former admirers had commenced to dub him a "rank conservative," whose political aims and reforms were no longer adequate. But Thorebecke's life-work will endure, and the Dutch constitution of 1889 practically embodied his principles, as laid down in the constitution of 1848. The former is the outcome of the latter and could not have been made without it.

The best biographical sketch of Thorebecke we owe to the late Professor Buys, his principal scholar and devoted friend, whose biography appeared in 1876 at Tiel. Another biography which deserves mention was issued in the same year at the Hague, from the pen of Dr. J. A. Levy, an Amsterdam lawyer. (H. Th.)

THOREAU, HENRY DAVID (1817–1862), American recluse, naturalist and writer, was born at Concord, Massachusetts, on the 12th of July 1817. To Thoreau this Concord country contained all of beauty and even grandeur that was necessary to the worshipper of nature; he once journeyed to Canada; he was long on one occasion to embark and explore a few rivers for the rest, he haunted Concord and its neighbourhood as faithfully as the stork does its ancestral nest. John Thoreau, his father, who married the daughter of a New England clergyman, was the son of a John Thoreau of the isle of Jersey, who, in Boston, married a Scottish lady of the name of Burns. This last-named John was the son of Philippe Thoreau and his wife Marie le Gallais, persons of pure French blood, settled at St Helier, in Jersey. From his New England Puritan mother, from his Scottish grandmother, from his Jersey-American grandfather and from his remoter French ancestry Thoreau inherited, distinctively, the least laboring man, a man; above and over and above, the "hauntings of Celtism" were prevalent and potent. The stock of the Thoreaus was a robust one; and in Concord the family, though never wealthy nor officially influential, was ever held in peculiar respect. As a boy, Henry threw his mother's cow to the pastures, and thus early became enamoured of certain aspects of nature and of certain delights of solitude. At school and at Harvard University he in no wise distinguished himself, though he was an intelligent receptive student; he became, however, proficient enough in Greek, Latin, and the more general academic science to enable him to add to a fundamental stock of knowledge. But long before he had become apprenticed to the learning of nature in preference to that of man: when only twelve years of age he had made collections for Agassiz, who had then just arrived in America, and already the meadows and the hedges and the stream-sides had become cabinets of rare knowledge to him. On the desertion of schoolmastering as a profession, Thoreau became a lecturer and author, though it was the labour of his hands which mainly supported him through many years of his life: professionally he was a surveyor. In the effort to reduce the practice of economy to a fine art he arrived at the conclusion that a man must live in Nature as Nature lives, and that the positive demands of necessity, the better for him and for the community at large; he would have had the order of the week reversed—six days of rest for one of labour. It was in 1845 he made the now famous experiment of Walden. Desirous of proving to himself and others that man could be as independent of this kind as the nest-building bird, Thoreau retired to a hut of his own construction on the pine-slope over against the shores of Walden Pond—a hut which he built, furnished and kept in order entirely by the labour of his own hands. During the ten years of his May 1845 to October 1846, Thoreau recorded the exercise of a little surveying, a little job-work and the tillage of a few acres of ground which produced him his beans and potatoes. His absolute independence was as little gained as if he had camped out in Hyde Park; relatively he lived the life of a recluse. He read considerably, wrote abundantly, thought actively if not widely, and came to know beasts, birds and fishes with an intimacy more extraordinary than was the case with St Francis of Assisi. Birds came at his call, and forgot their hereditary fear of man; beasts lipped and caressed him; the very fish in lake and stream would glide, unforear, between his hands. This exquisite familiarity with bird and beast would make us love the memory of Thoreau if his egotism were triply as arrogant, if his often meaningless paradoxes were even more absurd, if his sympathies were even less humanitarian than we know them to have been. His Walden, the record of this fascinating two years' experience, must always remain a production of great interest and considerable psychological value. Some years before Thoreau took to Walden woods he made the chief of his life's work, that with Emerson. He became one of the famous coterie of the transcendentalists, always keenly preserving his own individuality amongst such more or less potent natures as Emerson, Hawthorne and Margaret Fuller. From Emerson he gained more than from any man, alive or dead; and, though the older philosopher both enjoyed and learned from the association with the younger, it cannot be said that the gain was equal. There was nothing electrical in Thoreau's intercourse with his fellow men; he gave off no spiritual sparks. He absorbed intensely, but when called upon to illuminate in turn was found wanting. It is with a sense of relief that we read of his having really been stirred into active enthusiasm and the wrongs done the ill-fated John Brown. With children he was affectionate and gentle, with old people and strangers considerate. In a word, he loved his kind as animals, but did not seem to find them as interesting as those furred and feathered. In 1847 Thoreau left Walden Lake abruptly, and for a time occupied himself with lead-pencil making, the parental trade. He never married, thus further fulfilling his policy of what one of his essayist-biographers has termed "indulgence in fine renoncements." At the comparatively early age of forty-five he died, on the 6th of May 1862. His grave is in the Sleepy Hollow cemetery at Concord, beside those of Hawthorne and Emerson.

Thoreau's fame will rest on Walden; or, Life in the Woods (Boston, 1854) and The Excursions (Boston, 1863), though he wrote nothing which was not deserving of notice. Up till his thirtieth year he dabbled in verse, but he had little ear for metrical music, and he lacked the spiritual impulsiveness of the true poet. His weakness as a philosopher is his tendency to base the laws of the universe on the experience-born, thought-produced conceptions of one man—himself. His weakness as a writer is the too frequent striving after and praise of personal genius without the itch of appearing original, he would have made his fascination irresistible. As it is, Thoreau holds a unique place. He was a naturalist, but absolutely devoid of the pedantry of science; a keen observer, but no retailer of disjointed facts. He thus holds sway over two domains: he had the adherence of the lovers of fact and of the children of fancy. He must always be read, whether lovingly or interestingly, for he has all the variable charm, the strange saturninity, the contradictions, austerities and delightful surprises, of Nature herself.

After Thoreau's death were also published: The Maine Woods (Boston, 1863); Cape Cod (Boston, 1865); A Yankee in Canada (Boston, 1866). In the Atlantic Monthly, in 1862 appeared "Walking", "Autumn Tints" and "Wild Apples"; in 1863, "Night and
Moonlight." The standard editions of his works are The Writings of David Thoreau, Riverside edition (11 vols, Boston, 1894-1895), and Manuscript edition (12 vols, ibid, 1907).

Sanborn, Henry David Thoreau (Boston, 1886), in the "American Men of Letters Series"; H. S. Walt, Life of Henry David Thoreau (London, 1890); Some Unpublished Letters of H. D. and Sophia L. Thoreau, 1842-1860 (J. Russell Smith, My Study Windows; R. L. Stevenson, Familiar Studies in Men and Books; and F. H. Allen, Bibliography of H. D. Thoreau (Boston, 1908).

THORFINN KARLSEFNI, or Karlsefni (fl. 1002-1007), Scandinavian explorer, leader of the chief medieval expedition for American colonization. Thorfinn belonged to a leading Icelandic family and had great success in trading voyages. In 1001 he set sail for Greenland, married Godric, widow of Red Eric's son Thorstein, and put himself at the head of a great expedition now undertaken from Eriksfjord for the further exploration and settlement of the western Vinland (south Nova Scotia?) lately discovered by Leif Ericsson (Q. V.). Three vessels took part in the venture, with 160 men and some women, including Godrid, and Freydís, a natural daughter of Red Eric. They first sailed north-west to the Vesteryrd or "Western Settlement" of Greenland, thence to Bear Island, and thence away to the south till they reached a country they named Helluland (some part of Labrador?) from its great flat slabs of stone, and thence to a thick-wooded land they called Markland (i.e., Woodland, our Newfoundland). Two days after this they sighted land to the right hand, and came to a cape, where they found the keel of a ship—perhaps a relic of some earlier, possibly Scandinavian explorer—and which they called therefore Kialames (Keelness; Cape Breton, or some adjacent point?); the long bleak sandy shores of this coast they called the Wonderstrands (on the east coast of Cape Breton Island?). After passing the Wonderstrands and reaching a coast indented with bays, Thorfinn put in to another island, which he named Færey Islands; Spanish explorers called it Flatey. They explored southwards (see Leif Ericsson), but they returned with grapes and wild wheat, proofs that the Northmen were not far from Vinland. The fleet now stood in to a bay called by the explorers Strömford or Firth of Currents, and wintered there (1003-1004), suffering some privations, and apparently getting no more news of the fruitful country desired. Thorfinn's son Snorri was born this first autumn in the new world. Next spring nine of the party, headed by the chief malcontent Thorhall, Red Eric's huntsman, sailed off southward, intending to come to Vinland by rounding Keelness and thence working round west and north. Adverse winds drove them southward, and somewhere out, but they were enslaved. Meanwhile Thorfinn, with the rest of the venturers, sailed south "for a long time," till they reached a spot they called Hop, at the mouth of a river which flows from a lake into the sea (several estuaries near the southern extremity of Nova Scotia would do equally well here). Here they found the "self-sown" wheatfields and vines of Leif's Vinland, and here accordingly they settled and built their huts above the lake (1004-1005). After a fortnight's swarthy, swarthy and ill-looking, with ugly hair, great eyes and broad cheeks (Beothuk or Micmac Indians?) appeared with many skin canoes; they spring boarding the sailings came back and harried with their visitors. Terrified by a bull belonging to the latter they fled, and after three weeks returned to rest. They were beaten off, but the Northmen narrowly escaped destruction, and two of their number (one a leading settler) were slain. The colony at Hop was therefore abandoned and the whole force returned to Strömford. Thence Thorfinn revisited Hop, staying two months; and also made a voyage northward in search of Thorhall, rounding Keelness and sailing westward (along the north coast of Cape Breton Island?), and apparently southward also, till they came to the mouth of a river flowing from east to west. There Thorhall Ericsson was killed by a (Skraeling?) arrow, and the expedition came back to Strömford where they passed the next winter (1005-1006). Internal dissensions now broke out, mainly about the women of the colony, and in the next summer (1006) the entire project of Vinland settlement was abandoned and the fleet sailed to Markland. Two Skraeling children were captured here and the expedition divided, Thorfinn making Greenland and Ericsson in safety with his own vessel, while the other was lost in the Irish Sea, only half the crew escaping to Ireland in the ship's boat.

It may be noticed that the Flatey Book narrative gives a somewhat different but more slighter account of Thorfinn's expedition, making both Thorvald Ericsson and Freydís undertake separate Vinland ventures—one before, the other after, Karlsfni's enterprise—Thorvald being killed on his (as in Red Eric Saga, but with divergent details), and Freydís on her committing atrocities upon her comrades, the Icelanders Helgi and Finnogi, which are unnoticed in Red Eric. The latter, however, in its main value as the domestic story of which it was woven over the women of the colony in its third winter, points to something which may have been the germ of the highly elaborated Freydís story in Flatey.

On Flatey Book, Red Eric Saga and the whole bibliography for the Vinland voyages, including that of Thorfinn, see Leif Ericsson and Vinland. The six Vinland voyages of Flatey, we may repeat, Red Eric reduces to three, wholly omitting the alleged voyage of Birnir Herjulfsson, and grouping those of Thorvald Ericsson and Freydís with Thorfinn Karlsfni's in one great colonizing venture.

THORIANITE, a rare mineral, discovered by W. D. Holland, and found in the gem-gravels of Ceylon, where it occurs as small, heavy, black, cubic crystals, usually much water-worn. It was so named by W. R. Dunstan, on account of its high percentage of thorium (about 70% ThO₂). It also contains the oxides of uranium, lanthanum, cerium, and didymium. Helium is present, and the mineral is slightly less radio-active than pitchblende. It has been examined for new elements. Miss Evans (Journ. Chem. Soc., 1908, p. 666) obtained what is possibly a new element, whilst M. Ogawa (Journ. Coll. Sci. Tokyo, 1908, vol. 25) found indications of three new species: one which he named Thorocury, another Thoroide, and a third Thorosar.(16) It is a dark green to blue with atomic weight 100; the second with an equivalent of about 16-7; whilst the third yielded a radio-active oxide.

THORITE, a rare mineral consisting of thorium-silicate, crystallizing in the tetragonal system and isomorphous with zircon. The theoretical formula, ThSiO₄, requires 81-5% of thorium, but analyses show only 50-70%, there being also some uranium, cerium, &c. The mineral is almost always altered by hydration and is then optically isotropic and amorphous. Owing to differences in composition and to alteration, the specific gravity varies from 4.4 to 5.4. The colour is usually yellowish or orange, but in the variety known as "orangeite" it is orange-yellow. The mineral occurs as isolated crystals and small masses in the augite-syenite near Brevik in South Norway; also at Arendal, and in the gem-gravels of Ceylon. If found in larger amount it would be an important source of thorium for incandescent gas mantles.

(16) L. J. S.

THORIUM (symbol Th, atomic weight 232.42 [O=16]), a metallic chemical element. It belongs to the group of metals whose oxides are generally denominated "rare earths," and its history is bound up in the history of the group, which is especially interesting from the fact that their utilization for the manufacture of the mantles used in incandescent gas-lighting, and also that the radio-active substances are almost invariably associated with these oxides. The name thoria (after the Scandinavian god Thor) was first given in 1815 by Berzelius to a supposed new earth which he had extracted from several rare Swedish minerals. This "new earth" turned out to be nothing more nor less than a basis yttrium phosphate. In 1828 he gave the name thorite to an earth which he extracted from a mineral found at Lérön. This mineral is the modern thorite. Thorium has proved to be very widely, although extremely sparingly, distributed: pyrochlore, orangeite, monazite, euxenite, gadolinite, orthite, and in fact most of the rare minerals of this type contain it (see B. Szilard, Le Radium, 1909, 6, p. 233). The extraction of thorium salts from these minerals is a matter of much difficulty. Metallic thorium is obtained by
heating potassium thorium chloride or the tetrachloride with sodium.
(see W. von Bolton, R. J. Meyer and H. Karstens, Journ. Chem. Soc. 309, vol. 96). It forms microscopica hexagonal plates having a greenish-white streak. It is very heavy, its density being about 11; it inflames when heated in air and is not attacked by alkalis; readily dissolves in nitric acid and aqua regia, but with difficulty in hydrochloric acid.

In its salts, thorium is tetravalent, and in the periodical classification it occurs in the same sub-group as titanium, cerium and zirconium.

Thorium dioxide or thoria, ThO₂, is the most important compound, being manufactured commercially in comparatively large quantities from thorium oxide (see LIGHTING, GAS). It is an amorphous white powder; but it may also be obtained in crystals isomorphous with cassiterite by heating the ore in a vacuum, or with borax to a very high temperature. An oxide ThO₂ is formed by heating the dioxide.

Thorium fluoride, ThF₄, is obtained as a heavy white insoluble powder by dissolving the hydrate in hydrofluoric acid and evaporating, or precipitating a thorium salt with a fluoride, a gaseous fluoride, ThF₄·4H₂O, is obtained. Acid potassium fluoride precipitates K₂ThF₄·4ThF₄·H₂O from a solution of thorium chloride. Potassium thorofluoride, K₂ThF₄·4H₂O, is a heavy black powder formed by boiling the hydroxide with potassium fluoride and hydrofluoric acid. Thorium chloride, ThCl₄, is obtained as white shining crystals by heating a mixture of carbon and thorium in a current of oxygen at about 1400°. Thiocarbonyl fluoride, ThO₂·2C₃O₂, is not a compound, but a mixture of ordinary compounds, having an atomic weight of 255.6. E. Chauvenet (Compt. rend., 1908, 147, p. 1046) obtains it by heating thorium in a current of carbonyl chloride. Thorium chloride readily dissolves on exposure and forms double salts with alkaline chlorides.

Thorium sulphate, Th₂(SO₄)₄·9H₂O, is obtained by dissolving the oxide in sulphuric acid. It forms several crystalline hydrates. Evaporation of the solutions at ordinary temperatures gives colourless needles or crystals prisms of Th₂(SO₄)₄·9H₂O, which is isomorphous with uranium sulphate, U₂(SO₄)₃·9H₂O. Above 45°, Th₂(SO₄)₄·4H₂O is deposited. B. Ruzoeboom (Zest. phys. Chem., 1890, 5, p. 198) has described several hydrates of thorium sulphate from the alkali sulphates. Thorium nitrate, Th(NO₃)₄·12H₂O, forms white deliquescent tables very soluble in water. It forms double salts such as Mg₂[Th(NO₃)₄·8H₂O], which are isomorphous with the corresponding cerium compounds. Thorium sulphide, Th₂S₄, is obtained by burning the metal in sulphur. It cannot be produced by precipitation.

The atomic weight has been variously given. Berzelius found 235.5; Delafontaine, 229; Cleve, 232-6 by analyses of the sulphate, and 232.2 by analyses of the oxalate. Kruss and Nilson derived the value 230.7 (H.1) from analyses of the carefully purified sulphate.

For the so-called "disintegration of the thorium atom" and the relation of this element to the general subject of radio-active compounds of the alkali metals, see 4.

A number of salts of thorium have been prepared for therapeutic use, including the hydroxide, nitrate, salicylate, oleate and lactate. The oleate has been used in chronic eczema and psoriasis and locally in cancer. Inhalations of thorium oxinates produced from thorium nitrate through a wash-bottle inhaler are said to have a bactericidal action in diseases of the lungs. F. Soddy has used it in phthisis, and Louis Cheyney speaks favourably of the emansions in chronic and acute laryngitis and in tuberculous laryngeal ulcerations.

THORN (Polish Torun), a fortress town of Germany, in the Prussian province of West Prussia, situated on the right bank of the Vistula, near the point where the river enters Prussian territory, 83 m. by rail N.E. of Posen, 92 m. S. of Danzig and 12 m. from the Russian frontier at Alexandrovo. Pop. (1895), 30,314; (1906), 43,435. Its position as a bridge head commanding the passage of the Vistula makes it a point of strategic importance; it was strongly fortified in 1815, and in 1878 was converted into a fortress of the first class. The defensive works consist of a circle of outlying forts, about 25 m. from the centre of the town, the west being on the right and five on the left bank of the river. The "Wasserburg," or new town, was first very long ago to thirty-three years later, were united in 1454, and both retain a number of quaint buildings dating from the 17th and 16th centuries, when Thorn was a flourishing member of the Hanseatic League. The town-hall of the 14th and 16th centuries, the churches of St John of the Virgin, and of St James (all of the 13th-14th centuries), the ruined castle of the Teutonic order (a tower, the so-called "Danksor"), and a leaning tower, the sole remnant of the old environing walls, are among the most interesting of the ancient edifices. Among modern buildings may be mentioned the Artushof, containing concert and assembly halls, the newarrison church (1897), and the new concert hall erected in 1853 to Copernicus, who was a native of Thorn. The ancient wooden bridge, now burned down, at one time the only permanent bridge across the lower Vistula, has been succeeded by a massive railway viaduct, 3300 ft. long. Thorn carries on an active trade in grain, timber, wine, groceries and minerals, and has ironworks, saw-mills, and various other manufactures. It is famous for its Pfefferkuchen, a kind of gingerbread. Part of the trade is carried on by passenger and cargo vessels on the Vistula, which ship small quantities of flour and other provisions.

Thorn, founded in 1231 by the Teutonic order as an outpost against the Poles, was colonized mainly from Westphalia. The first peace of Thorn, between the order and the Poles, was concluded in 1411. In 1454 the townspeople revolted from the knights of the order, destroyed their castle, and attached themselves to the king of Poland. This resulted in a war, which was terminated in 1466 by the second peace of Thorn. In the 15th and 16th centuries Thorn was a Hanse town of importance, and received the titles of "Queen of the Vistula" and "the" Thorn. It opposed the Reformation in 1557, and in 1645 it was the scene of the famous "Torsdags" colloquium betwixt the doctors of the rival creeds, which, however, resulted in no agreement. In 1724 a riot between the Protestant and Roman Catholic inhabitants was seized upon by the Polish king as a pretext for beheading the burgomaster and nine other leading Protestant citizens, an act of oppression which is known as the "blood-bath of Thorn." The second partition of Poland (1793) conferred Thorn upon Prussia; by the treaty of Tilsit it was assigned to the duchy of Warsaw; but since the Congress of Vienna (1815) it has again been Prussian.

Wernicke, Geschichte Thorns (Thorn, 1839-1842); Hoburg, Die Belagerungen der Stadt und Festung Thorn (Thorn, 1860); and the Steinbrecht, Die Baukunst des deutschen Ritterordens in Preussen (1st part, Berlin, 1884); Uebrecht, Thorn (Danzig, 1903).

THORN (O. Eng. Jorn, cf. Du. doorn, Ger. Dorn, &c), in botany, a hard pointed structure, also termed a "spine," generally representing a small branch, as in hawthorn, where a normal branch arising in the axil of a leaf is replaced by a sharply pointed thorn; accessory buds on each side of the thumb and developed in the same leaf-axil will grow in the next season into ordinary leaves. The similarly developed thorns or "honey-locust" (Gleditschia) are branched. In other cases, as the syc or the wild pear, branches become spiny at the apex tapering into a stiff leafless point. On a cultivated tree these branches disappear owing to their more vigorous growth. Leaves may be modified into spines, as in barberry, the leaves of which show every gradation between a leaf with a spiny-toothed edge and those which have been reduced to simple or multiple spines. In some species of Astragalus the petiole of the pinnately compound leaf persists after the fall of the leaflets as a sharp spine. In the false acacia (Robinia) the stipules are represented by spines.

The reduction of the leaf-surface, of which the spiny habit is often an expression, is associated with growth in dry or exposed windy places. Thus, in the gorse, a characteristic plant of exposed localities such as open commons, the smaller branches, instead of being leaf-bearing shoots, are reduced to slender green spines, while the leaves on the main shoots are also more or less spiny in character. As the giving off of water from its surface is one of the chief functions of a leaf, this process is thus reduced to a minimum in such a leaf. This liability to be given off too rapidly. An extreme case is afforded by the cacti and cactus-like euphorbias, which are a characteristic type of desert vegetation where water is extremely scarce. The whole plant is reduced to a simple or branching succulent, leafless, columnar or flattened stem, the branches of which are represented by small clusters of thorns. Incidentally the
thorns protect the plant which bears them from the attacks of animals seeking food. Prickles are structures of less importance from the morphological point of view, being mere superficial outgrowths which may occur anywhere on stem or leaf, or even fruit.

**THORNABY-ON-TEES**

who within separate m. There is a church in the town of Thornaby, and it is also included in the parliamentary borough of Stockton (it is within the Cleveland division of the county), but was incorporated as a separate municipal borough in 1892. It is under a mayor, 6 aldermen and 18 councillors. Area, 1927 acres.

**THORNE**, a market town in the Doncaster parliamentary division of the West Riding of Yorkshire, 10 m. N.E. of Doncaster by the North-Eastern railway, served also by a branch of the Great Central railway. Pop. (1901), 3815. It lies near the river Don, about 4 m. from the North Sea. The river is a fishery and waste, resembling the fens of the eastern counties. Hatfield Chase, a portion of this tract south of Thorne, was partly drained by the Dutch engineer Vermuyden in the 17th century, and there were in the district numerous Dutch settlers. The Chase is generally considered to have been the scene of the battle of Heathfield in 1633, when King Edwin of Northumbria fell before the heathen King Penda of Mercia. The Levels, as this district is generally named, are of remarkable fertility, and Thorne, having water communication with Goole and the Humber, is consequently an agricultural centre of importance; while some large-building and a trade in peel fibre are also carried on. The church of St Nicholas is a fine building of various periods from the 12th century.

**THORNHILL, SIR JAMES** (1675–1734), English historical painter, was born at Melcombe Regis, Dorset, in 1676, of an ancient but impoverished county family. His father died while he was young, but he was befriended by his maternal uncle, the celebrated Dr Sydenham, and apprenticed to Thomas Highmore, sergeant-painter to King William III., a connexion of the Thornhill family. Little is known regarding his early career, except that he visited Holland, Flanders and France, and, having obtained the patronage of Queen Anne, he was in 1719–1720 appointed her sergeant-painter in succession to Highmore, and was ordered to decorate the interior of the dome of St Paul's with a series of eight designs, in chiaroscuro heightened with gold, illustrative of the life of that apostle—a commission for which Louis Laguerre had previously been selected by the commissioners for the repair of the cathedral. He also designed and decorated the saloon and hall of Moor Park, Herts, and painted the great hall at Blenheim, the princeps' apartments at Hampton Court, the hall and staircase of the South Sea Company, the chapel at Wimpole, the staircase at Easton-Neston, Northamptonshire, and the hall at Greenwich Hospital, usually considered his most important and successful work, upon which he was engaged from 1708 to 1727. Among his easel pictures are the altar-pieces of All Souls and Queen's College chapels, Oxford, and that in Melcombe Regis church; and he executed such portrait subjects as that of Sir Isaac Newton, in Trinity College, Cambridge, and the picture of the House of Commons in 1739, in the possession of the earl of Hardwicke, in which he was assisted by Hogarth, who married Jane, his only daughter. He also produced a few etchings in a slight and sketchy but effective manner, and executed careful full-size copies of Raphael's cartoons, which now belong to the Royal Academy. About 1724 he drew up a proposal for the establishment of a royal academy of the arts, and his scheme had the support of the lord treasurer Halifax, but government declined to furnish the needful funds. Thornhill then opened a drawing-school in his own house in James Street, Covent Garden, where instruction continued to be given till the time of his death. He acquired a considerable fortune by his art, and was enabled to repurchase his family estate of Thornhill, Dorsetshire. In 1715 he was knighted by George I., and in 1710 he represented Melcombe Regis in parliament, a borough for which Sir Christopher Wren had previously been member. Having been removed from his office by some court intrigue, and suffering from broken health and repeated attacks of gout, he retired to his country seat, where he died on the 4th of May 1734. His son James, also an artist, succeeded his father as sergeant-painter to George II. and was appointed "painter to the navy."

The high contemporary estimate of Sir James Thornhill's works has not since been confirmed; in the time of Dr Young, "late times do not understand how Raphael's pencil lives in Thornhill's hands." He is weak in drawing—indeed, when dealing with complicated figures he was assisted by Thomas Gibson; and, ignorant of the great monumental art of Italy, he formed himself upon the lower model of Le Brun.

**THORNHILL**, an urban district in the Morley parliamentary division of the West Riding of Yorkshire, England, 2 m. S. of Dewsbury, on the Great Northern, Lancashire & Yorkshire, and London & North Western railways. The church of St Michael has a modern nave, but the chancel with aisles are of good Decorated work, and the tower is Perpendicular. There are interesting monuments of the ancient family of Savile, the site of whose mansion, Thornhill Hall, may be traced near the church. The east window of the church contains fine fragments of stained glass of the 15th century. The large industrial population is employed in the woolen mills and manufactures of shoddy, carpets, &c., which are numerous in this locality.

**THORNBURGH**, a village of the parish of Morton, Nithsdale, Dumfriesshire, Scotland, 14 m. N.N.W. of Dumfries by the Glasgow & South-Western railway. Pop. (1901), 1132. It is beautifully situated in the midst of tree-clad hills and watered by the bountiful Nith and such streams as the Carron, Cample and Crichtoche. Morton parish church lies in the village, and among other buildings are the library and the natural history museum, in the grounds of which there is a statue of Richard Cameron, the covenanter (1686). The weekly sales of livestock are important, and an agricultural show is held every September. Three miles N.N.W. stands Closeburn Castle, a seat of the duke of Buccleuch, a vast edifice of red sandstone in the form of a hollow square, and has 145 ft. of outer walls, which are surmounted with turrets, and capped and spired at the angles. The castle was begun in 1679 and finished in 1689, and cost the first duke of Queensberry an immense sum. He is believed to have spent but a single night under its roof. The fourth duke of Queensberry, Old "Q.," incurred the wrath of Robert Burns and Wordsworth by his wanton destruction of the magnificent woods. On the death of "Old Q." without issue in 1810, Henry, third duke of Buccleuch, succeeded to the dukedom of Queensberry, and the property has since been adequately cared for. Trees, planted on the most extensive scale, have been laid out with exquisite taste; and the vast policy, intersected by the Nith, is one of the finest parks in Scotland. The ruins of Tibber's Castle, dismantled in 1311 by Robert Bruce, stand in the grounds, about 1 m. from the ducal mansion. Two miles and a half N.E. of Thornhill is found another ruined fortress, that of Morton Castle, interesting as the residence of Thomas Randolph, earl of Moray, regent during the early years of the minority of David II., and as belonging afterwards to a branch of the Douglases, who derived from it the title of earl. About 3 m. south-east of Thornhill stands the ruined castle of Closeburn, once a stronghold of the Kirkpatricks. It was Sir Roger of that ilk who helped "mak sikker" the death of John, "Red" Comyn, of Badenoch (1306). In Closeburn parish (pop. 1275) occur cairs, tumuli and a stone circle, besides Roman and prehistoric remains. Two mineral wells give the place the
THORPE, the divided 1873. in Durban) 1798, (Westminster). "It is a great February 1850, (at 1886); a group statues following He from conventional the fountain in favour of a graduated system, and indeed paid his own income tax "on the scale of his ideal, not his legal debt." He was one of the founders of the Sierra Leone Company (see SIERRA LEONE) and its chairman until the colony was taken over by the English government.

THORNTON, THOMAS (1813-1880), English economist, was born at Burnham, Buckinghamshire, on the 14th of February 1813. In 1836 he obtained a clerkship in the London house of the East India Company. In 1838 he became a member of the staff towards the realization of the India Office, which he held till his death. He was created a C.B. in 1873. His works include Over-population and its Remedy (1846), in which he put forward a plan for colonizing Irish wastes by Irish peasants; A Plea for Peasant Proprietors (1848), in which his views were developed in greater detail; On Labour (1860); and Old-fashioned Ethics and Commonsense Metaphysics, a volume of essays, published in 1873.

THORNYCROFT, WILLIAM HAMO (1839- ), British sculptor. A pupil of his father, Thomas Thornycroft, and of the Royal Academy schools, Thornycroft was called upon to assist his father in carrying out the important fountain in Park Lane, London. He accordingly returned in 1871 to England from Italy, where he was studying, and modelled the figures of Shakespeare, Fame and Clio, which were rendered in marble and in bronze. In the following year he exhibited at the Royal Academy "Professor Sharples," in marble, for the memorial in University College; and "Mordant," a relief—a form of art to which he has since devoted much attention. The Fame, already mentioned, was shown in 1873. Believing that the pendulum had overshot its swing from classicism to modernism, Thornycroft turned away from the "fleshy" school towards the Greek, while realizing the artistic necessity for modern feeling. In 1875 his "Warrior Bearing a Wounded Youth from the Field of Battle" gained the gold medal at the Royal Academy schools, and when exhibited in 1876 it divided public attention with the "Tennyson" of Woolner and "Wellington monument," sculptures of Alfred Stevens, now in St Paul's Cathedral. Then followed the dramatic "Lot's Wife," in marble (1878), and "Artemis" (1880), which for grace, elegance and purity of taste the sculptor never surpassed. He was thereupon elected a member of the Royal Academy, and more than justified his election by his "Tennyson" of the following year, a bronze figure of extraordinary distinction which, bought for the Chantrey collection, is now in the National (Tate) Gallery of British Art. It is simple and severe, classic yet instinct with life and noble in form; and in it he touched the high-water mark of his career. Turning to the ideal, in works entirely modern in motive and treatment, Hamo Thornycroft produced "The Mower" (1884) and "A Sower" (1886); the "Stanley Memorial" in the old church at Holyhead partakes of the same character. Among the sculptor's principal statues are "The Bishop of Carlisle" (1895; Carlisle Cathedral), "General Charles Gordon" (Trafalgar Square, London). "Oliver Cromwell" (Westminster), "Dean Colet" (a bronze group—early Italianate in feeling—outside St Paul's School, Hammersmith), "King Alfred" (a colossal memorial for Winchester), the "Gladstone Monument" (in the Strand, London) and "Dr Mandell Creighton, Bishop of London" (bronze, erected in St Paul's Cathedral). Mr Thornycroft's other memorials, such as the "Queen Victoria Memorial" (Karachi), the "War Memorial" (at Dunblane, and the "Armstrong Memorial" (at Newcastle), are well known, and his portraity and statuary and medallions are numerous. He was elected a full academician in 1888, and an honorary member of the Royal Academy of Munich. He was awarded a medal of honour at the Paris Exhibition, 1900. See M. H. Spielmann, British Sculpture and Sculptors of To-day (London, 1901).

THORODDSEN, JON PUR CARSON (1819-1868), Icelandic poet and novelist, was born in 1819 at Reykhol in western Iceland. He studied law at the university of Copenhagen, where he met the Danish sculptor Thoroton, with whom he later lived as a pupil. He has a coat-of-arms, a veritable portrait of Thoroton. His first novel, "Næstróðingur," which was published in 1848, was an immediate success. It was translated into German by H. Holstein, and is a charming picture of Icelandic country life. Still better is Möður og konu ("Man and Wife"), published after his death by his brother, Thoroton, in the Danish language. His other works were not published until after his death, and the best part of his work is in verse. His poems are essentially Icelandic in their character, and so true in their descriptions, that he is justly considered by most of his countrymen not only as the father of the Icelandic novel, but as the best novelist Iceland has produced. His poems, mostly satirical, are deservedly popular; he follows Jónas Hallgrímsson closely in his style, although he cannot reach him in lyrical genius. (S. BL.)

THOROTON, ROBERT (1623-1678), English antiquary, belonged to an old Nottinghamshire family, which took its name from Thoroton, near Newark. He resided mainly at another Thoroton, in the same neighbourhood, in the army, where he practised as a physician and where he lived the life of a country gentleman. He took very little part in the Civil War, although his sympathies were with the royalists, but as a magistrate he was very active in taking proceedings against the Quakers. In 1667 Thoroton, aided by a band of helpers, began to work upon his elaborate Antiquities of Nottinghamshire. This was published in London in 1677; it was dedicated to Gilbert Sheldon, archbishop of Canterbury, and was illustrated by engravings by W. Hollar.

THOROTON, ROBERT (1615-1693), British antiquary. His book Antiquities was published by John Throsby (1740-1803), who added an additional volume. In 1697 the Thoroton Society was founded in honour of the antiquarian, its object being to promote the study of the history and antiquities of Nottinghamshire. The first issues of its Transactions and several volumes of Records have been published and much valuable work has been done. A brass tablet to the memory of Thoroton has been placed in Carl Colston church. See J. T. Godfrey, Robert Thoroton, Physician and Antiquary (1890).

THORPE, BENJAMIN (1782-1879), English Anglo-Saxon scholar, was born in 1782. After studying for four years at Copenhagen University, under the Danish philologist Rasmus Christian Rask, he returned to England in 1830, and in 1832 published an English version of Cædmon's metrical paraphrase of portions of the Holy Scriptures, which at once established his reputation as an Anglo-Saxon scholar. In 1834 he published Analecta Anglo-Saxonica, which was for many years the standard textbook of Anglo-Saxon in English, but his best-known work is a Northern Mythology in three volumes (1851). His was the first complete good translation of the elder Ædda (1866). His other works include Ancient Laws and Institutes of England (1840), an English translation of the laws enacted in the Anglo-Saxon Kings; The Holy Gospels in Anglo-Saxon (1842); Codex Exoniensis (1842), a collection of Anglo-Saxon poetry with English translation; an English translation of Dr Lappenburg's History of England under the Anglo-Saxon Kings (1845); Anglo-Saxon Poems of Beowulf (1855), a translation; an edition for the "Rolls" series of the Anglo-Saxon Chronicle (1861); and Diplomatarius Anglicum oevi saxonici (1865), a collection of
early English charters. Thorpe died at Chiswick on the 10th of July 1870. The value of his work was recognized by the great to him, in 1835, of a civil list pension.

THORPE [or Thork], JOHN (b. 1530–1618), English architect. Little is known of his life, and his work is dubiously inferred, rather than accurately known, from a folio of drawings in the Soane Museum, to which Horace Walpole called attention, in 1780, in his *Anecdotes of Painting*; but how far these were his own is uncertain. He was engaged on a number of important English houses of his time, and several, such as Longleat, have been attributed to him on grounds which cannot be sustained. He was probably the designer of Kirby Hall, Northamptonshire; the Longleat House, Wiltshire; and the oriel in Lord Holland's House, Kensington; and he is said to have been engaged on Rushton Hall, Northamptonshire, and Audrey End, Essex (with Bernard Janssens).

THORWALDSEN, BERTEL (1770–1844), Danish sculptor, the son of an Icelandic who had settled in Denmark, and there carried on the trade of a wood-carver, was born in Copenhagen on the 10th of November 1770. While very young he learnt to assist his father; at the age of eleven he entered the Copenhagen school of art, and soon began to show his exceptional talents. In 1792 he won the highest prize, the travelling studentship, and in 1796 he started for Italy as a Danish man-of-war. On the 8th of March 1797 he arrived in Rome, where Canova was at the height of his popularity. Thorwaldsen’s first success was the model for a statue of Jason, which was highly praised by Canova, and he received the commission to execute it in marble from Thomas Hope, a wealthy English art-patron. From that time Thorwaldsen’s success was assured, and he did not leave Italy for twenty-three years. In 1819 he returned to Denmark, where he was commissioned to make the colossal statues of Christ and the twelve apostles which are now in the Fruenkirche in Copenhagen. These were executed after his return to Rome, and were not completed till 1838, when Thorwaldsen again returned to Denmark. He died suddenly in the Copenhagen theatre on the 24th of March 1844 and bequeathed a great part of his fortune for the building and endowment of a museum in Copenhagen, and also left to fill it all his collection of works of art and the models for all his sculpture—a very large collection, exhibited to the greatest possible advantage. Thorwaldsen is buried in the courtyard of this museum, under a bed of roses, by his own special wish.

On the whole Thorwaldsen was the most successful of all the imitators of classical sculpture, and many of his statues of pagan deities are modelled with much of the antique feeling for breadth and purity of design. His attempts at Christian sculpture, such as the tomb of Pius VII. In St Peter’s and the “Christ and Apostles” at Copenhagen, are less successful, and were not in accordance with the sculptor’s real sympathies, which were purely classic. Thorwaldsen worked sometimes with feverish eagerness; at other times he was idle for many months together. A great number of his best works exist in private collections—especially in England. His not very successful statue of Lord Byron, after being refused a place in Westminster Abbey, was finally deposited in the library of Trinity College, Cambridge. The most widely popular among Thorwaldsen’s works have been some of his bas-reliefs, such as the “Night” and the “Morning,” which he is said to have modelled in one day.

See Eugène Fion, *Thorwaldsen, sa vie, etc.* (Paris, 1868); Andersen, B.: *Thorvaldsen* (Kopenhagen, 1893); Köster, *Der Kupferstich Thorwaldsen’s Abendland* (Copenhagen, 1892); Thiele, “Thorwaldsen’s Leben” (Leipzig, 1852–1856); C. A. Rosenberg, *Thorwaldsen . . . mit 146 Abbildungen* (1869); Künstlermonographien, No. 16; S. Trier, *Thorvaldsen* (1905); A. Wilde, *Erinnerungen an Jerichaos og Thorvaldsen* (1884).

THOTH, the Greek name of the Egyptian god of letters, invention and wisdom (i.e. Thot, Zéthu), the mouthpiece and recorder of the gods, and arbiter of their disputes. Thoth is found on the earliest monuments symbolized by an ibis (Ibis aethiopica, still not uncommon in Nubia), which bird was sacred to him. In the Pyramid texts Thoth is already closely associated with the Osiris myth, having aided the god by his science and knowledge of magic, and demonstrated the justice of his claims in the contest with Set. Thoth presided over writing, measuring and calculation, and is prominent in the scene of the weighing of the soul. He was often identified with the moon as a divider of time, and in this connexion, during the New Empire, the ape first appears as his sacred animal.

Thoth was identified by the Greeks with Hermes, and Hermes Trismegistus (q.v.) is a late development of the Egyptian god. Geographically the worship of Thoth in Lower Egypt centred in [the Hermopolite nome, contiguous to the Busiris and Meïdenian nomes. There is the district, anciently called Zebat, in which his name Zebet was simply “the God of Zebat.” In the ancient Egyptian Thames or Napata, the new capital, and in Hermopolis Magna in Upper Egypt, now Eshmunain, was a city of greater political importance than Hermopolis in Lower Egypt. See E. A. W. Budge, *The Gods of the Egyptians*; and especially *Egypt: Ancient*, § Religion. (F. L. L. G.)

THOU, JACQUES AUGUSTE DE [THOUANUS] (1553–1617), French historian, was the grandson of Augustin de Thou, president of the parlement of Paris (d. 1594), younger son of Christophe de Thou, “first president” of the same parlement, who began to collect a number of books and notes for a history of France which he was never to write (d. 1582), and nephew of Nicolas de Thou, who was bishop of Chartres (1563–1598). In these family surroundings he imbibed a love of letters, a firm and orthodox, though enlightened and tolerant, piety, and an attachment to the traditional power of the Crown. At the age of seventeen he began his studies in law, first at Orleans, later at Bourges, where he made the acquaintance of Hotman, and finally at Valence, where he had Cujas for his master and Scaliger as a friend. He was at first intended for the Church; he received the minor orders, and on the appointment of his uncle Nicolas to the episcopate succeeded him as a canon of Notre-Dame. But his tastes led him in a different direction; not content with a knowledge of books, he wished to know the world and men. During a period of ten years he seized every opportunity for profitable travel. In 1573 he accompanied Paul de Foix on an embassy, which enabled him to visit most of the Italian courts; he formed a friendship with Arnaud d’Ossat (afterwards bishop of Rennes and Bayeux and cardinal, d. 1604), who was secretary to the ambassador. In the following year he formed part of the brilliant cortège which brought King Henry III. back to France, after his flight from his Polish kingdom. He also visited several parts of France, and at Bordeaux met Mme. de Setie. On the death, however, of his elder brother Jean (April 5, 1579), who was *maître des requêtes* to the parlement, his relations prevailed on him to leave the Church, and he entered the parlement and married (1588). In the same year he was appointed conseiller d’état. He served faithfully both the effeminate, bigoted and cruel Henry III. and Henry IV., a sceptic and given to love-intrigues, because they were both the representatives of legitimate authority. He succeeded his uncle Augustin as président à mortier (1595), and used his new authority in the interests of religious peace, negotiating, on the one hand, the Edict of Nantes with the Protestants, while in the name of the principals of the Gallican Church he headed the revolution of the Council of Trent. This attitude exposed him to the animosity of the League party and of the Holy See, and to their persecution when the first edition of his history appeared. This history was the work of his whole life. In a letter of the 31st of March 1611 addressed to the president Jeannin, he himself describes his long labours in preparation of it. His materials for writing it were drawn from his rich library, which he established in the Rue des Poitevins in the year 1587, with the two brothers, Pierre and Jacques Dupuy, as librarians. His object was to produce a purely scientific and unbiassed work, and for this reason he wrote it in Latin, giving it as title *Historia sui temporis*. The first 18 books, embracing the period from 1545–1560, appeared in 1604 (1 vol. folio), and the work was at once attacked by those whom the author himself calls les envieux et les furieux. The second part, dealing with the first wars of religion (1560–1572), was put on the Index librorum prohibitorum
THOUARS—THOUSAND AND ONE NIGHTS

(1657). The third part (up to 1574), and the fourth (up to 1584), which appeared in 1607 and 1608, caused a similar outcry, in spite of the author’s efforts to remain just and impartial. He carried his scruples to the point of forbidding any translation of his book into French, because in the process there might, to use his own words, “be committed great faults and errors against the intention of the author”; this, however, did not prevent the Jesuit Father Machault from accusing him of being “a false Catholic, and worse than an open heretic” (1614); de Thou, we may say, was a member of the third order of St. Francis. As an answer to his detractors, he wrote his Mémoires, which are a useful compilation of the whole history of France up to the death of Henry IV. de Thou met with another disappointment; the queen-regent refused him the position of first president of the parlement, appointing him instead as a member of the Conseil des finances intended to take the place of Sully. This was to him a distinct downfall; he continued, however, to serve under Marie de Medici, and took part in the negotiations of the treaties concluded at Ste Menehoule (1614) and Loudun (1616). He died at Paris on the 7th of May 1617.

Three years after the death of de Thou, Pierre Du Ryer and Nicolas Rigaud, published (1619) a French translation of the second part of the Historia sui temporis, comprising 138 books; they appended to it the Mémoires, also given in Latin (1620). A hundred years later, an Englishman, Samuel Buckley, published a critical and emended version of the third part of the work, in which he ignored the dédication (i.e., the preface) of Thuanus, and, under the pseudonym of Carte, gave a new and enlarged edition of the Mémoires, also in Latin (1620). De Thou was treated as a classic, an honour which he deserved. His history is a model of exact research, drawn from the rich and abundant sources at his command, and it is not great, unfortunately, even for the men of the Renaissance, Latin was a dead language; it was impossible for de Thou, however, to find exact equivalents for technical terms of geography or of administration. As the reason which led de Thou to forbid the translation of his monumental history disappeared with his death, there soon arose a desire to make it accessible to a wider public. It was translated first into German. A Protestant pastor, G. K. L. von Linstow, who had already translated Hittorff’s translation into French, but could not find a publisher. The first translation printed was that of Pierre Du Ryer (1657), but it is mediocre and incomplete. In the following century the abbé Prévost, who was a conscientious collaborator with the Benedictines of Saint-Maur before he became the author of the more profane work Manon Lescaut, was in treaty with a Dutch publisher for a translation which was to consist of ten volumes; only the first volume appeared (1733). But competition, perhaps of an unfair character, sprung up. A group of translators, who had the good fortune of being able to avail themselves of Buckley’s fine edition, succeeded in bringing out a work which was six times that of the first (De Thou, Histoire universelle, Fr. trans. by Le Beau, Le Mascrifer, the Abbé Des Fontaines, 1734). As to the Mémoires themselves, they had been translated as early as 1620, and in this form they have been reprinted in the collections of Petitot, Michaud and Buchon. To de Thou we owe certain other works: a treatise De re accipitoria (1784), a Life, in Latin, of Pamphili, the last of the Popes sacrae.

For his life may be consulted the recollections of him collected by the brothers Dupey (Thoua, vie Excepria J. A. Thouani per f. F. P., 1665; reprinted in the edition of 1735), and the biographies by J. A. Collinson (The Life of Thuanus, 1807), and Dunstan (De Thou’s Leben, 1837). Finally, see Henry Harriese, Le Président de Thou et ses descendants, leur célèbre bibliothèque, leurs armoiries et la traduction française de J. A. Thouani Historiarum sui Temporis (1905).

THOUARS, a town of western France, in the department of Deux-Sévres, on the right bank of the Thouet, 24 m. S. by W. of Saumur on the railway to Bordeaux. Pop. (1906), 5321. A massive stronghold built in the first half of the 17th century by the La Trémoïlle family, and now used as a prison, stands on a rocky eminence overlooking the river, towards which it has a frontage of nearly 400 ft. The adjoining Sainte-Chapelle dating from the early years of the 16th century is in the Gothic style with Renaissance details, and was built by Gabrielle de Bourbon, wife of Louis II. of La Trémoïlle. The church of St. Médard, rebuilt in the 15th century, preserves a doorway of the 12th, and a capital of the church of St. Laurens (14th and 15th centuries) was formerly attached to an abbey, the buildings (17th century) of which serve as town-hall. It has a fine square tower in the Romanesque style and contains the sculptured tomb of the abbot Nicholas. Remains of the ramparts of the town dating from the 13th century and flanked by huge towers are still to be seen, and a bridge of the same period crosses the Thouet. The manufacture of furniture and wooden shoes, and the preparation of veterinary medicine and lime, are carried on. Wine, livestock and agricultural produce are the chief articles of trade.

Thouars, which probably existed in the Gallo-Roman period, became in the 9th century the seat of powerful viscounts, who in later times were zealous supporters of the English. In 1372 the latter were expelled from the town by Bertrand de Guesclin. In 1363 Charles IX. created Louis III., the head of the family of La Trémoïlle, duke of Thouars. In 1793 the Vendeans took the town from the royalists.

THOURET, JACQUES GUILLAUME (1746-1794), French revolutionary, was born at Pont J’Evêque. He was the son of a notaire, and became an avocat at the parlement of Rouen. In 1789 he was elected deputy to the states-general by the third estate of Rouen, and in the Constituent Assembly his eloquence gained him great influence. Like so many lawyers of his time, he was violently opposed to the clergy, and strongly supported the secularization of church property. He also obtained the suppression of the religious orders and all ecclesiastical feudal rights, and contributed to the change of the judicial and administrative systems. He was one of the promoters of the decree of 1790 by which France was divided into departments, and was four times president of the Constituent Assembly. After its dissolution he became president of the court of cassation. He was included in the proscription of the Girondists, whose political opinions he shared, and was executed in Paris. Besides his speeches and reports he wrote an Abrégé des révolutions de l’ancien gouvernement français and Tableau chronologique de l’histoire ancienne et moderne.

His brother, MICHÉL AUGUSTIN THOURET (1748-1810), a pupil of d’Alembert, was a keen advocate of the ideas of Mesmer and a promoter of vaccination in France.

THOUSAND AND ONE NIGHTS. The Thousand and One Nights, commonly known in English as The Arabian-Nights’ Entertainments, is a collection of tales written in Arabic, which first became generally known in Europe in the early part of the 18th century through the French translation by Antoine Galland, and rapidly attained universal popularity. In the Journal asiatique for 1827, p. 273, von Hammer (J. von Hammer-Purgstall) drew attention to a passage in the Golden Meadows of Mas’ud’i (ed. Barbier de Meynard, iv. 89 seq.), written in A.D. 943, in which certain stories current among the old Arabs are compared with “the books which have reached us in translations from Persian, Indian and Greek, such as the book of Hēdr Afṣafnī, a title which, translated from Persian into Arabic, means ‘the thousand tales.’ This book is popularly called The Thousand and One Nights, and contains the story of the king and his vizier and of his daughter Shirazad and her slave girl Dzhāzā. Other book of the same kind are the book of Pers. and Sinās, containing stories of Indian kings and avatars of the book of Sindibād, &c.” Von Hammer concluded that the Thousand and One Nights were of Persian or Indian origin. Against this conclusion Silvestre De Sacy protested in a memoir (Mém. de l’acad. des inscr., 1833, x. 30 seq.), demonstrating that the character of the book we know is genuinely Arabian, and that it must have been written in Egypt at a comparatively recent date. Von Hammer in reply added, in Journ. as. (1839), ii. 173 seq. a passage in the Fihrist (A.D. 987), which is to the following effect—

“...the ancient Persians were the first to invent tales and make books of them, and some of their tales were put in the mouths of animals. The Ashghanians, or third dynasty of Persian kings, and after them the Sassanians, had a special part in the development of this literature, which found Arabic translators, and was taken up by accomplished Arabic litterati, who edited it and improved it. The earliest book of the kind was the Hēdr afṣafnī or Thousand Tales, which had the following origin. A certain Persian king was..."
acquiesced to kill his wives on the morning after the consummation of the marriage. But once he married a clever princess called Shahrazad, who spent the marriage night in telling a story which in the morning reached a point so interesting that the king spared her, and she was permitted to live for another night for the sequel. This went on for a thousand nights till Shahrazad had a son, and ventured to tell the king of her device. He admired her intelligence, loved her, and spared her life. In all this the princess was assisted by the king's vizier, in whose books she has been portrayed as the princess Ḥomāʾī (MSS. Ḥomāʾī), daughter of Bahman. . . . It contains nearly two hundred stories, one story often occupying several nights. I have repeatedly seen the complete book, but it is really a meagre and uninteresting production (Flügel, ed. Flügel, p. 304).

Persian tradition (in Firdousi) makes Princess Ḥomāʾī the daughter and wife of Bahman Ardāshir, i.e. Artaxerxes I. Longimanus. She is described as a great builder, a kind of Persian Semiramis, and is a half-mythical personage already mentioned in the Avesta, but her legend seems to be founded on the history of Atossa and of Parysatis. Firdousi says that she was also called Shahrazad (Mohl v. 11). This name and that of Dinaṭzād both occur in what Masʿūdī tells of her. According to him, Shahrazad was Ḥomāʾī’s mother (ii. 129), a Jewess (ii. 123). Bahman had married a Jewess (i. 118), who was instrumental in delivering her nation from captivity. In ii. 121 this Jewish mother is helped by the Jewess Dinaṭzād, and “the accounts,” says our author, “vary.” Plainly she is the Esther of Jewish story. Tabari (i. 688) calls Esther the mother of Bahman, and, like Firdousi, gives to Ḥomāʾī the name of Shahrazad. The story of Esther and that of the original Nights have in fact one main feature in common. In the former the king is offended with his wife, and divorces her; in the Arabian Nights he finds her unfaithful, and kills her. But both stories agree that thereafter a new wife was brought to him every night, and on the morrow passed into the second house of the women (Esther), or was slain (Nights). At length Esther or Shahrazad wins the king’s favours and becomes queen. The issue in the Jewish story is that Esther saves her people; in the Nights the gainers are “the daughters of the Moslems,” but the old story had, of course, some other word than “Moslems.” Esther’s foster-father becomes vizier, and Shahrazad’s father is also vizier. Shahrazad’s plan is helped forward in the Nights by Dināzād, who is, according to Masʿūdī, her slave girl, or, according to other MSS., her nurse, and, according to the Fihrist, the king’s stewardess. The last account comes nearest to Esther ii. 15, where Esther gains the favour of the king’s chamberlain, keeper of the women. It is also to be noted that Aḥasuerus is read to his queen at night when he cannot sleep (Esther vi. 1). And it is just possible that it is worth notice that, though the name of Aḥasuerus corresponds to Xerxes, Josephus identifies him with Artaxerxes I.

Now it may be taken as admitted that the book of Esther was written in Persia, or by one who had lived in Persia, and not earlier than the 3rd century B.C. If now there is real weight in the points of contact between this story and the Arabian Nights—and the points of difference cannot be held to outweigh the resemblances between the two legends, each of which is necessarily so far removed from the hypothetical form in which the inference is important for both stories. On the one hand, it appears that (at least in part) the book of Esther draws on a Persian source; on the other hand, it becomes probable that the Nights are older than the Sasanian period, to which Lane (ii. 677) refers them.

It is a piece of good fortune that Masʿūdī and the Fihrist give us the information cited above. For in general the Moslems, though very fond of stories, are ashamed to recognize them as objects of literary curiosity. In fact, the next mention of the Nights is found only after a lapse of three centuries. Maqrizi, describing the capital of Egypt, quotes from a work of Ibn Saʿd (c. A.D. 1250), who again cites an older author (Al-Kortob), who, in speaking of a love affair at the court of the caliph Al-ʿAmir (997–1130), says “what is told about it resembles the romance of Al-Bāṭṭāl, or the Thousand and One Nights” (Hitj, Būṣāṣ ed., i. 485, ii. 181).

That the Nights which we have are not the original translation of the Ḥaḍrāʾ Afṣāne is certain, for the greater part of the stories are of Arabian origin, and the whole is so thoroughly Mahommedan that even the princes of remote ages who are introduced speak and act as Moslems. It might be conceived that this is due to a gradual process of modernization by successive generations of story-tellers. But against this notion, which has been entertained by some scholars, Lane has remarked with justice that, much as MSS. of the Nights differ from one another in points of language and style, in the order of the tales, and the division into nights, they are all so much at one in essentials that they must be regarded as derived from a single original. There is no trace of a recursion of the text that can be looked on as starting new “Hāḍrāʾ Afṣāne.” Aid the whole local colour of the work, in point of dialect and also as regards the manners and customs described, clearly belongs to Egypt as it was from the 14th to the 16th century. Some points, as De Sacy and Lane have shown, forbid us to place the book earlier than the second half of the 15th century. Galland’s MS. copy, again, was in existence in 1548. Lane accordingly dates the work from the close of the 15th century or the beginning of the 16th, but this date appears to be too late. For Abūl-Maṣḥān, an Egyptian historian who died in 1470, writing of ʿḤamdi, a famous highwayman of Bagdad in the 10th century, remarks that he is probably the figure who used to be popularly spoken of as Ahmad al-Danaf (ed. Juybni l. 303). Now in the Nights Ahmad al-Danaf really plays a part corresponding to that of the historical Ḥamdi, being now a robber (Lane ii. 404) and again a captain of the guard (Lane ii. 249). It would seem that Abūl-Maṣḥān had read or heard the stories in the Nights, and was thus led to compare the historical with the fictitious character. And, if this be so, the Nights must have been composed very soon after 1450.

No doubt the Nights have borrowed much from the Ḥaḍrāʾ Afṣāne, and it is not improbable that even in the original Arabic text of the Educational work some of the Persian stories were replaced by Arab ones. But that our Nights differ very much from the Ḥaḍrāʾ Afṣāne is further manifest from the circumstance that, even of those stories in the Nights which are not Arabian in origin, some are borrowed from books mentioned by Masʿūdī as distinct from the Ḥaḍrāʾ Afṣāne. Thus the story of the king and his son and the damsel and the seven viziers (Lane, ch. xxl. note 51) is in fact a version of the Book of Sind∂āb,2 while the story of Jalīl ʿĀʾd and his son and the vizier Shammast (M. Naqrīṭen iv. 366 seq.; cf. Lane iii. 530) corresponds to the book of Sin∂āb and another of the same name.3

Not a few of the tales are unmistakably of Indian or Persian origin, and in these poetical passages are rarely inserted. In other stories the scene lies in Persia or India, and the source is foreign, but the treatment thoroughly Arabian and Mahommedan. Sometimes, indeed, traces of Indian origin are perceptible, even in stories in which ʿḤārīn al-Rashīḍ figures and the scene is Bagdad or Baṣra.4 But most of the tales, in substance and form alike, are Arabian, and so many of them have the capital of the caliphs as the scene of action that it may be guessed that the author used as one of his sources a book of tales taken from the era of Bagdad’s prosperity, when the Persian stories were translated by Arab ones.

The late date of the Nights appears from sundry anachronisms. In the story of the men transformed into fish—white, blue, yellow or red according as they were Moslems, Christians, Jews or Magians (Lane i. 99)—the first three colours are those of the

1 The hypothesis of gradual and complete modernization is also opposed to the fact that the other romances used by Cairene storytellers (such as those of Antar and of ʿSaʿīf) retain their original local colour through all variations of language and style.
2 The Soṭarj Sin∂āb, the Greek Sin∂alos, and the Seven Sages of the European West.
3 De Sacy and Lane suppose that the original title of the Arabic translation of the Ḥaḍrāʾ Afṣāne was The Thousand Nights. But MSS. of Masʿūdī already have The Thousand and One Nights, which is also the name given by Maqrizi. Both clichers perhaps mean only “a very great number,” and Fleischer (De glossis Habichtianis, p. 4) has shown that 1001 is certainly used in this sense.
4 Gildemeister, De rebus indicis, p. 89 seq.
the turbans which, in 1501, Mahommeh b. Kala'um of Egypt commanded his Moslem, Christian and Jewish subjects respectively to wear. 1 Again, in the story of the humpback, whose scene is laid in the 9th century, the talkative barber says, “this is the year 653” (= A.D. 1255; Lane, i. 332, writes 653; but see his note), and mentions the caliph Mansur (d. 1242), who is incorrectly called son of Mostad. 2 In the same story several places in Cairo are mentioned which did not exist till long after the 9th century (see Lane i. 379). 3 The very rare edition of the first 200 nights published at Calcutta in 1814 speaks of cannon, which are first mentioned in Egypt in 1383; and all editions sometimes speak of coffee, which was discovered towards the end of the 14th century; but not generally used till 200 years later. 4 One particularly interesting point is the mention of a mosque founded in 1501 (Lane iii. 608), we detect the hand of later interpolators, but the extent of such interpolations can hardly perhaps be determined even by a collation of all copies. For the nature and causes of the variations between different copies the reader may consult Lane, iii. 678, who explains how transpositions actually arise by transcribers trying to make up a complete set of the tales from several imperfect copies.

Many of the tales in the Nights have an historical basis, as Lane has shown in his notes. Other cases in point might be added: the chronicle of Ibn al-Jauzi (d. A.D. 1200) contains a narrative of Kamar, slave girl of Shagb, the mother of Moqtadir, which is the source of the tale in Lane i. 316 seq., and of another to be found in M'Naughten iv. 557 seq.; the latter is the better story, but departs so far from the original that the author must have had no more than a general recollection of the narrative he drew on. 4 There are other cases in the Nights of two tales which are only variations of a single theme, or even in certain parts agree almost word for word. Some tales are mere compounds of different stories put together without any attempt to reconcile them, and occasional cases are found in which the material is added to the book; yet the collector himself was no great literary artist. We must picture him as a professional storyteller equipped with a mass of miscellaneous reading, a fluent power of narration, and a ready faculty for quoting, or at a push improvising, verses. His stories became popular, and were written down as he told them—hardly written by himself, else we should not have so many variations in the text, and such insertions of "the narrator says," "my noble sire," and the like. The frequent coarseness of tone is proper to the condition of Egyptian society under the Mameluke sultans, and would not have been tolerated in Baghdad in the age to which so many of the tales refer. Yet with all their faults the Nights have beauties enough to deserve their popularity, and to us their merit is enhanced by the pleasure we feel in being transported into so entirely novel a state of society.

The Thousand and One Nights became known in Europe through A. Galland's French version (12 vols. 12mo, Paris, 1704-1712): the publication was an event in literary history, the influence of which can be traced far and wide. This translation, however, left much to be desired in point of accuracy, and especially failed to reproduce the colour of the original with the exactness which those who do not read merely for amusement must desire. It was with a special view to the remedying of these defects that E. W. Lane undertook in 1830 this infinitely more elaborate, if somewhat stilted translation, enriched with most valuable notes and a discussion of the origin of the work (new edition, with some additional notes, 3 vols. 8vo, London, 1859). Lane's translation omits the tales which he deemed uninteresting or unfit for a European public. Sir Richard Burton's unexpurgated English translation, with elaborate notes, was issued in 10 vols., 1855-1866, with six supplementary vols., 1867-1880. A new and much more accurate translation undertaken by Herr Max Freyberg was published at Leipzig, 1836): (3) the first Bulaq edition (4 vols., 1862-1863). See also by Edin. Review (July 1886), p. 191 seq.

1 Quatremère, Sultans Mamelouks, ii. p. 177 seq.
2 Lane i. 332, writes "Moustad." for "Mostadir."

THRACE, a name which was applied at various periods to areas of different extent. For the purposes of this article it will be taken in its most restricted sense, as signifying the Roman province which was so called after the district that intervened between the river Ister (Danube) and the Haemus Mountains (Balkan), and the region between the rivers Strymon and Nestus, which included Philippopolis, had been added to Macedonia. The boundaries of this were—towards the N. the Haemus, on the E. the Euxine Sea, on the S. the Propontis, the Hellespont and the region of the Ister; on the W. the Danube. The most distinguishing features of the country were the chain of Rhodope (Despoto-dagh) and the river Hebrus (Maritza). The former separates at its northernmost point from the Haemus, at right angles, and runs southward at first, nearly parallel to the Nestus, until it approaches the sea, when it takes an easterly direction (see Virg. Georg. iii. 351). Several of the summits of this chain are over 7000 ft. in height. The Hebrus, together with its tributaries which flow into it from the north, east and west, drains almost the whole of Thrace. It starts from near the point of junction from Haemus and Rhodope, and at first takes an easterly direction, the chief town which lies on its banks in the earlier part of its course being Philippopolis; but when it reaches the still more important city of Hadrianopolis it makes a sharp bend towards the south, and enters the sea nearly opposite the island of Samothrace. The greater part of the country is hilly and irregular, though there are considerable plains; but besides Rhodope two other tolerably definite chains intersect it, one of which descends from Haemus to Adrianople, while the other follows the coast of the Euxine at no great distance inland. One district in the extreme north-west of Thrace, the Thracian Chersonese, was the most famous of all, Byzantium was the meeting-point of that sea and the Bosporus. Another place which proved attractive to colonists of that race was the curious narrow strip of ground, called the Thracian Chersonese, that intervened between the Hellespont and the Bay of Melas, which penetrates far into the land on its northern side. Among the cities that occupied it the most important were Sestos and Callipolis (Gallipoli). In order to prevent the invasions of the Thracians, a wall was built across its isthmus, which was less than 5 m. in breadth. The north-eastern portion of the Aegean, owing to its proximity to the coast of Thrace, was known as the Thracian Sea, and in this were situated the islands of Thasos, Samothrace and Imbros.

History.—The most striking archaeological monuments of the prehistoric period are the sepulchral mounds, which are found by thousands in various parts of the country, especially in the neighbourhood of the ancient towns. As Roman implements
and ornaments have been found in some of them, it is plain that this mode of burial continued to be practised until a late period. The country was overrun several times by Darius and his generals, and the Thracian Greeks contributed 120 ships to the armament of Xerxes (Herod. vii. 185). The most powerful Thracian tribe was that of the Odrysae, whose king, Teres, in the middle of the 5th century B.C. extended his dominion so as to include the greater part of Thrace. During the Peloponnesian War his son Sitalces was an ally of some importance to the Athenians, because he kept in check the Macedonian monarch, who opposed the interests of the Athenians in the Chersonese. When, in accordance with his own inclinations, we find Cersobleptes, who ruled the southern-eastern portion of the country, exercising an important influence on the policy of Athens. During the early period of the Roman Empire the Thracian kings were allowed to maintain an independent sovereignty, while acknowledging the suzerainty of Rome, and it was not until the reign of Vespasian that the country was reduced to the form of a province (Kalopatathas, De Thracia, provincia romana, 1894; Mommsen, Roman Provinces, Eng. trans., 1880). From its outlying position in the northern part of the Balkan peninsula it was exposed to the inroads of invaders. It was overrun by the Goths on several occasions, and subsequently by the Huns; but its proximity to Constanti- nople caused its fortunes to be closely connected with those of that city, from the time when it became the capital of the Eastern Empire. In the course of the middle ages the northern parts of Thrace and some other districts of that country were occupied by a Bulgarian population; and in 1301 the Turks made themselves masters of Adrianople, which for a time became the Turkish capital. When Constantinople fell in 1453 the whole country passed into the hands of the Turks, and in their possession it remained until 1878, when, in accordance with the provisions of the Treaty of Berlin, the northern portion of it was placed under a separate administration, with the title of Eastern Rumelia; this province has now become, to all intents and purposes, a part of the principality of Bulgaria. The population is composed of Turks, Greeks and Bulgarians. (H. F. T.)

Ancient Peoples.—The name “Thracians,” from being used both ethnically and geographically, has led to confusion. There were the true indigenous Thracians and also Celtic tribes such as the Trebi in the early period, the Getae and Trausi later, and the Gallic it was in contact exposed to the incursions of barbarian Thracians of Greek writers, and they differed not merely in physic and complexion, but also in their customs and religion from the native Thracians (Herod. v. 14). The native ‘Thracians’ were inferior in morals, allowing their girls complete licence till marriage. The chief native deities were Dionysus, Ares and Bendis (Artemis), but many of these tribes had Celtic chiefs, who traced their descent from and worshipped a god called Hermes by the Greeks, but possibly Odin. The substantial features of the ancient Dionysiac rites, including a ritual play by ‘goat-men’ carrying a wooden phallos, may still be seen at Bizye, the old residence of the Thracian kings (see R. M. Dawkins in Hellenic Journal, 1906, p. 191). The true Thracians were part of that dark-complexioned, long-skulled race, which had been in the Balkan peninsula from the Stone Age, closely akin to the Pelasgians (q.v.), the aborigines of Greece, to the Ligurians, the aborigines of Italy, and to the Iberians. The name “Illyrian” (see ILLYRIA) was applied to all the tribes of this stock who dwelt west of the northern extensions of the Findus range and in what was termed Upper Macedonia in later times, and who extended right up to the head of the Adriatic. In Homer the name Macedonia is not yet known, and the term Thracian is applied to all the tribes dwelling from Pteria to the Euxine. There is no well-defined difference between aboriginal Thracians and Illyrians. Thus there was an Illyrian tribe Brygi, a Thracian one Bryges; some of the latter had passed into Asia and settled in the land called from them Phrygia, whence some of them later passed into Armenia; some of the Mysians (regarded by Strabo as Thracians) had also crossed into what was later known as Mysia: closely connected with the Mysians were the Dardanii, of Trojan fame, who had a city Dardania or Dardanus. In Strabo’s time a tribe called Dardanii, then reckoned Illyrian, living next the Thracian Bessi (in whose land was the oldest oracle of Dionysus), were probably as much Thracian as Illyrian. All the Thracian and Illyrian tribes tattooed, thus being distinguished from the Celtic tribes who had conquered many of them. The Thracians differed only dialectically from the Illyrians (Strabo), their tongue being closely allied to Greek. The Thracians of the region from Olympus to the Pangaeian district, usually regarded as rude tribes, had from a very early time worked the gold and silver of that region, and began to strike coins as early as the Greeks, and displayed on them much artistic skill and originality of types. The most famous were the Bisalitae, the Orescii, Odomantes and Edoni. Alexander I. of Macedon on his conquest of the Bisalitae adopted the native coinage, merely placing on it his own name (see, further, NUMISMATICS: Greek, §§ Thrace and Macedonia). They were famous for their skill in music and literature. Orpheus, Linus, Thamyris and Eumolpus were theirs, and in later days the Dardani were noted for their love of music as well as for their uncleanness.

See Herodotus v. 3-8; H. Kiepert, Lehrbuch der alten Geographie (Berlin, 1878); A. Bouët, La Turquie d’Europe (4 vols., Paris, 1840); W. Ridge- way, Early Age of Greece, i. 351 seq. (Cambridge, 1892); Tomasz- chek, Die alten Thraher (1893-1895); Hiller von Gaertingen, De Graecorum fabulis ad Thraes pertinensibus (1886). (W. R.)

THRALL, a slave, a captive or bondman, a term especially applied to the serfs (Lat. servi) of the early northern Teutonic peoples. It only occurs in Old English as a word borrowed from the Norse, the proper term in Old English being “thow” (lowa); the Icel. þoral (Dan. trael, Swed. trul) is probably represented by O. H. Ger. dregel, irisil, shrikel, a slave, and would therefore be derived from the root meaning “to run,” seen in O. Eng. þrunjan, Goth. thagian, Gr. ῥωπενε; Skeat (Eym. Dict., 1889) compares the “trochilus” (Gr. τροχιλος), the small bird that according to Herodotus waits or attends on the crocodile and picks insects out of his teeth.

THRAEA PAETUS, PUBLIUS CLOTIDUS, Roman senator and Stoic philosopher, lived during the reign of Nero. He was the husband of Arria the daughter of Arria (q.v.), father-in-law of Helvidius Priscus, and a friend and kinsman of the poet Persius. He was born at Patavium, and belonged to a dis- tinguished and wealthy family. The circumstances under which he came to settle in Rome are unknown. At first he lived with great consideration by Nero, probably owing to the influence of Seneca, and became consul in A.D. 56 and one of the keepers of the Sibylline books. In 57 he supported in the senate the cause of the Cilician envoys, who came to Rome to accuse their late governor, Cossutianus Capito, of extortion. In 59 Thrasea first openly showed his disquiet at the behaviour of Nero and the obsequiousness of the senate by retiring without voting after the emperor’s letter justifying the murder of Agrippina had been read. In 62 he prevented the execution of the praetor Antistius, who had written a libel upon the emperor, and persuaded the senate to pass a milder sentence. Nero showed his displeasure by refusing to receive Thrasea when the senate went in a body to offer its congratulations on the birth of a princess. From this time (63) till his death in 66 Thrasea retired into private life and did not enter the senate-house again. But his death had been decided upon. The simplicity of his life and his adherence to Stoic principles were looked upon as a reproach to the frivolity and debaucheries of Nero, who “at last yearned to put Virtue itself to death in the persons of Thrasea and Soranus” (Tacitus). Cossutianus Capito, the son-in-law of Tigellinus, who had never forgotten Thrasea for securing his condemnation, and Eprius Marcellus undertook to conduct the prosecution. Various charges were brought against him, and the senate, awed by the presence of large bodies of troops, had no alternative but to condemn him to death. When the news was brought to Thrasea at his house, where he was entertaining a number of friends, he retired to his chamber, and had the veins of both his arms opened. The narrative
of Tacitus breaks off at the moment when Thrasea was about to address Demetrius, the Cynic philosopher, with whom he had previously on the fatal day held a conversation on the nature of the soul. Thrasea was the subject of a panegyric by Anicius Rusticus, one of the tribunes, who, apparently moved to tears by his eloquence, but Thrasea refused to allow him to throw his life away uselessly. Thrasea’s own model of life and conduct was Cato of Utica, on whom he had written a panegyric, one of Plutarch’s chief authors in his biography of Cato.

THRESHING, or THRASHING (from “to thrash.” O. Eng. herscan, cf. Ger. dreschen, Du. dorschen, &c.), the process by which the grain or seed of cultivated plants is separated from the husk or pod which contains it.

Historical.—It is probable that in the earliest times the light grain that was raised was shelled by hand, but as the quantity increased doubtless the grain was beaten out with a stick or the sheaf beaten upon the ground. An improvement on this, as the quantity further increased, was the practice of the Egyptians and Israelites of spreading the grain in a wind and driving oxen 25 to 50 or 100 ft. in diameter, and driving oxen, sheep or other animals round and round over it so as to tread out the grain. This enclosure was placed on an elevated piece of ground so that when the straw was removed the wind blew away the chaff and left the corn. This method, however, damaged part of the grain, and as civilization advanced it was partially superseded by the threshing sledge—the charatus of Egypt and the morag of the Hebrews—a heavy frame mounted with three or more rollers, sometimes spiked, which revolved as it was drawn over the ground corn by two oxen. A common sledge with a ridged or grooved bottom was also used. Similar methods to these were used by the Greeks and are still employed in backward countries.

In Italy a tapering roller fastened to an upright shaft in the centre of the threshing floor and pulled round from the outer end by oxen is still in vogue and would seem to be a descendant of the Roman tribulum or roller sledge.

Doubtless the flail was evolved from the early method of using the stick. It seems to have been the threshing implement in many of the northern European countries, and was the chief means of threshing grain as late as 1860. It was known to the Japanese from the earliest times, and was probably used in conjunction with the stripper, an instrument somewhat resembling a scythe, and used as a sheaf to be carried about and used when the finisher end to allow for the hole for the thong to bind it to the beater. The length of the finisher enabled the operator to stand in an upright position while working. The beater is a wooden rod about 30 in. long, made of ash, though a more compact wood such as horn is less likely to split. This also has a hole at one end for the thong to bind it to the finisher. The shape of the beater was cylindrical, of about 1 in. diameter and constructed so that the edge of the grain of the wood received the force of the blow; 30 to 40 blows or strokes per minute was the average speed.

After the grain had been beaten out by the flail or ground out by rollers, the chaff was raked away and the corn and chaff collected to be separated by winnowing when there was a wind blowing. This consisted of tossing the mixture of corn and chaff into the air so that the wind carried away the chaff while the grain fell back on the threshing floor. This method fell nearest while the lightest grain was carried some distance before falling, thus a very rough-and-ready grading of the grain was obtained. It was also performed when there was no wind by fanning while pouring the mixture from a vessel. Later on a fanning or winnowing mill was invented. All ancient barns were constructed with enclosed areas giving a space to allow the wind and remained that direction of the prevailing winds so that the wind could blow right through the barn and across the threshing floor for the purpose of winnowing the corn. The flail is still in use for special purposes such as winnowing seeds and the wind is so small as to render it not worth while to use a threshing mill.

With regard to the amount of grain threshed in a day by the flail, a fair average of the best heads of corn is in twenty bales of barley, 20 bushels of beans, 8 bushels of rye, and 20 bushels of buckwheat.

There seem to have been many attempts to devise some form of power-driven machine for threshing. In 1732 Michael Meikle, a Scotsman, obtained a patent for a power-driven machine. This was a contrivance arranged to drive a large number of flails operated by water power, but though worked for a time it did not prove successful. The first distinct machine in the right direction was made by a Scottish farmer named Leckie about 1758. He invented what was described as a rotary machine consisting of a set of cross arms attached to a horizontal shaft and ending in a cylindrical case. This machine did not work very well, but it demonstrated the superiority of the rotary motion and pointed out the lines on which threshing machines should be constructed.

Of the really successful of these power-driven threshing machines the most notable is that invented by Joseph Meikle, which is embodied in modern threshers—was invented by another Scotsman named Andrew Meikle in 1786. In this the loosed sheaves were led, first, from a feeding board between two rollers, and beating the grain as it was driven between them. This cylinder or “drum” was armed with four iron-shod beaters or spars of wood parallel to its axle, and these striking the ears of corn as they protruded from the rollers knocked them from the stalks to the revolving drum, which revolved at 200 to 250 revolutions per minute and carried the loose grain and straw on to a concave sieve beneath another revolving drum or rake with pegs which rubbed the straw on to the concave and caused the grain to separate from it. Another revolving rack tossed the straw out of the machine. The straw thus passing under one peg drum and over the next was subjected to a thorough rubbing and tossing which separated the grain and chaff from it. These fell on to the floor, ready for the upcoming part of the process.

A later development of the beater-drum was to fix iron pegs on the framework, and thus was evolved the Scottish “peg-drum,” which speedily became the most popular type for threshing in Great Britain and is found at nearly every farmstead in Scotland as a fixed machine in the barn to the present day, though in many cases unused since the advent of the portable thrasher. Further, it is the type of mechanical part of the “West” are simply modifications of the peg-drum principle. In Great Britain, however, a reversion has been made to the beating or rubbing principle, where the arms of the “drum” rub the straw against an encircling concave framework and thus the grain is separated, and the portable threshing machines now taken from farm to farm are all constructed on this principle. It may be said that about 1860 there was a machine for winnowing, with a beating or rubbing principle, simply a fixed table which worked with a machine to work as part of Meikle’s peg-drum thrasher, and this made a complete separator or thrasher which thrashed, cleaned and delivered the grain at one operation. Still, these machines were stationary, being too heavy to be used on the farm, and the unthreshed corn had to be brought to them. Portable threshing machines operated by horse power were used to a small extent, but the work was very hard on the horses and they were removed when their services were otherwise required on the farm. When steam was developed as a motive power the portable threshing machine became more general.

When Meikle had brought together the peg-drum and concave he had solved the difficulty of mechanical threshing. The development of the machine to the efficiency of the modern thrasher is very gradual, and was in the direction of greater speed to the drum and separation of the wheat and chaff, and the gathering of a clean sample of grain. It is generally supposed that each part was invented and perfected singly, but in reality the early experimenters had tried to make a complete separating machine. In fact they covered the whole ground in theory before any main features were made practical.

The Modern Threshing Machine.—The present-day threshing machine embodies the main features of Meikle’s machine and will thresh up to 16 quarters of oats per hour, depending on the size of the same. There are no fluted rollers, but the beaters are fed straight to the drum; and as the working of these high-speed drums was attended with considerable risk, the Threshing Machine Act 1878 now provides for some sort of guard or safety feature.

In the most modern threshing machine the ordinary routine is as follows: The loosened sheaf is fed in at the feed mouth under the drum guard and passes between the drum beaters.
and the concave; most of the corn falls through the concave on to the corn and chaff receiving board, but some of the corn and chaff remain among the straw; as the “cavings” (the short broken straw and leaf) need to be separated from the straw it is given a thorough tossing up on the shakers, which have an upwards and onwards peristaltic action, and deliver the straw at the end of the machine. The corn, chaff and cavings fall on to a reciprocating board or “upper shoe,” which carries them back to the middle of the machine, where they meet the corn that fell through the concave. The upper shoe passes the cavings, &c., over the end into a “lower shoe,” which thoroughly sifts the corn and chaff from the cavings. The cavings are then carried along to the outside of the machine and emerge at an opening beneath the point where the straw passes out. The corn and chaff fall through the lower shoe or caving riddle on to a receiving board

machine in a roughly dressed condition. The elevator delivers the corn into the awner or “hummeller,” which is fitted with helical blades to rub off the awns or beards which may still adhere to the grain. From here the grain falls on to a second series of sieves, where it meets the blast of air from the second fan, which blows and sifts the light and coarse foreign matter from the grain, delivering this débris on the first corn and chaff receiving board to undergo separation again along with that just fallen from the concave. The corn falls from the sieve of this second dresser into a rotary screen where separations are made producing the clean sample and the tail corn, which are delivered at separate openings below. There are modifications on the machine described—such as single fan-blust instead of double, &c.—but the general principles are the same.

The concave which surrounds the drum is made adjustable, so that it can be regulated according to the nature of the crop to be thrashed. An ordinary machine will thresh all usual farm crops, but great care has to be taken in adjusting the concave or the seed will be injured. Clover, however, is twice passed through a machine of this description, to free the seed from the haulm and afterwards to rub the seed clear from the chaff, but special machines to thresh it all in one operation are made.

The drum is carried on the main shaft and all other pulleys take their motion from it directly or indirectly. Sometimes the main shaft is lengthened to accommodate another pulley and so drive a chaff-cutter behind and chaff up the straw as it leaves the thrasher. In some districts an elevator is driven behind to stack the straw. Others use a truss, which ties the straw into large bundles before delivering it for stacking.

American Machines.—In American machines the straw, cavings, &c., are caught in a blast at the rear end of the machine and blown up in a light iron pipe of about 18 in. diameter on to the top of the stack, and the grain is delivered loose at the side through a spout into a box wagon. As the payment for threshing is per bushel the grain is usually passed through a self-registering weighing apparatus, so that accurate account is kept of the bushels threshed. In Great Britain payment is per quarter of 8 bushels, and as the machine delivers into 4-bushel

sacks this rough-and-ready measure is accepted. On American machines self-feeders are adopted, in which the sheaves are thrown on to a travelling web which carries them under revolving knives to cut the bands and deliver them loose into the
THRASYBULUS

THRASYBULUS, an Athenian general, whose public career began in 411 B.C., when by his resolute behaviour he frustrated the oligarchic rising in Samos (see PELOPONNESIAN WAR), and secured the Athenian armament to the cause of democracy. Elected general by the troops, he effectually the recall of Alcibiades and assisted him in the ensuing naval campaigns. By his brave defence at Cynossema (411) he won the battle for Athens, and in 410 contributed towards the brilliant victory of Cyzicus. In 406 he fought at Arginnae as a simple ship's captain, but after the engagement was commissioned with Thermomenes (q.v.) to rescue some drowning crews. In the subsequent inquiry Thrasybulus successfully disclaimed responsibility for the losses.

In 404, when exiled by the Thirty Tyrants for his services to the democracy, he retired to Thebes and there prepared for a desperate attempt to recover his country. Late in the year, with seventy men, he seized Phyle, a hill fort on Mt Parnes. A force sent by the Thirty was repulsed and routed by a surprise attack. Thrasybulus now gained the Pelopaeus, 1000 strong, and successfully held the steep hill of Munychia against the oligarchs' full force. After this repulse the Thirty gave way to a provisional government of moderate oligarchs. Meanwhile a Spartan fleet, which the latter had summoned, blockaded the Peiraueus, but king Pausanias, commanding the land force, after some skirmishes effected a general reconciliation by which the democracy was restored (October 403). Thrasybulus was now the hero of the people; but a decree by which he secured the franchise for all his followers, including many slaves, was rescinded as illegal.

In 395 Thrasybulus induced Athens to join the Theban league against Sparta, but did not himself take the field till 389, when he led a new fleet of 40 ships against the Spartans at Rhodes. Sailing first to the Bosphorus he effected a democratic revolution at Byzantium and renewed the corn-toll. After a successful descent on Lesbos and the renewal of the 5% import tax at Thasos and Clazomenae he sailed south in quest of further contributions, but met his death in a night surprise by the people of Aspendus. By his executions he had forfeited the confidence both of the allies and of Athens; but after his death the ill-feeling subsided, and he was ever remembered as one of the saviours of his country.

See Thucydides, viii. 75-105; Xenophon, Hellenica; Lysias, c. Erotatis. 55-51 and c. Ergol. 5, 8; and Const. alt. xI. DioDORUS XIII. xiv. Justin v. 9, 10, and Nepos depend almost wholly on Xenophon. Corpus inscr. att. ii. 118 and 142.

THRASYMEDES, of Paros, a Greek sculptor. Formerly he was regarded as a pupil of Pheidias, because he set up in the temple of Asclepius at Epidaurus a seated statue of that deity made of ivory and gold, which was evidently a copy of the Zeus of Pheidias. But an inscription recently found at Epidaurus proves that the temple and the statue belong to the fourth century. (See EPIDAURUS.)

THRESHING, (i) Eng. Pratts, a kind of mill which is twisted, Jute, to 4 twist, or to twist, &c. (ii) 'Throwster', a silk-winder, Ger. drehen, to twist, turn, Du. draad, Ger. Draht, thread, wire), a thin or fine cord of two or more yarns of fibrous substance, such as cotton, silk, wool or flax, tightly twisted together (see SPINNING and COTTON AND COTTON MANUFACTURE).

Thread, whether as silk or cotton thread, is particularly used for sewing, but it is also used in weaving. Lisle thread, a hand-twisted linen thread, originally made at Lille in France, is specially used in the manufacture of stockings (see HOSIERY).

Apart from the figurative sense of that which runs through the body of a subject, there is no speck, cast connecting throughout ideas or purpose, the term is also applied specifically to the spiral part of a screw (q.v.).

THREAT, a menace or intimidation. At common law the employment of threats or other forms of intimidation to induce a person to enter into a contract will give the right to sue for its rescission or avoidance, or to plead the special form of intimidation in answer to any action brought, or to sue for damages occasioned by entering into the contract. (See such headings as CoERCION; CONTRACT; Extortion, &c.)

In criminal law the sending of threatening letters (or causing them to be received), demanding with menaces and without reasonable cause money or other valuable thing, is a felony. So is the sending a letter threatening to burn or destroy any house, barn or other building or to kill or maim cattle. It is also a felony to threaten to accuse a person of a crime for the purpose of extorting money, or merely to demand money or other property, without having any claim to it, by means of a threat.

THREE BODIES, PROBLEM OF, the problem of determining the motion of three bodies moving under no influence but that of their mutual gravitation. No general solution of this problem is possible. As practically attacked it consists in the problem of determining the perturbations or disturbances in the motion of one of the bodies around the principal or central body, produced by the attraction of the third. Examples are the motion of the moon around the earth as disturbed by the action of the sun, and of one planet around the sun as disturbed by the action of another planet.

THREE RIVERS, or Trois Rivières, a city and port of entry of Quebec, Canada, and capital of St Maurice county, situated at the confluence of the rivers St Maurice and St Lawrence. The St Maurice flows in from the north, and, being divided at its mouth by two islands, the channels give the town its name. It is on the line of the Canadian Pacific railway, 78 m. S.W. of Quebec and 92 m. N.E. of Montreal. Founded in 1634 by Champlain, Three Rivers is one of the oldest towns in Quebec. It is the centre of a large lumber trade, which is carried on along the St Maurice and its tributaries. Some miles from the city are the St Maurice forges, where iron wares were manufactured as early as the 17th century. Other industries are furniture- and cabinet-making, boot and shoe making, and those carried on in the brass and lead foundries, saw-mills, and carriage factories. The city is the seat of a Roman Catholic bishopric. A large trade is carried on in lumber, grain, cattle, &c., which are shipped to South America, the West Indies, Great Britain and the United States, and a great development has been caused by the utilization of the water-power of the St Maurice at Shawanegan, Grand Meré and other falls, for the manufacture of wood pulp. As a result, the population, long

Drum, so that while many more bushels of grain are passed per day through an American machine than is done in Great Britain, only about half the men are required at the work.

Threshing Work.—The minimum number of hands required in Great Britain are: An engine-driver, a feeder, a sackman, and ten other men to handle the sheaves, straw, chaff, grain, &c., while half as many more may be needed where the grain has to be carted, as when the threshing is done in the field in harvest time. An 8-h.p. steam engine is the usual motive power, but the development of the oil engine has provided a very satisfactory substitute. The engine is usually of the "traction" type, so that it can move the threshing machine or "crawling" or "walking" a little way over the corn or straw from place to place. The usual quantities threshed with a "double blast finishing machine," as described, in the United Kingdom are, with a 5 ft. wide drum, from 60 to 80 bushels per hour of wheat, and one-third to one-half more of oats and barley.

Sometimes the straw is stacked loose, while sometimes it is tied up with twine by a tier exactly like that on a "string binder" and then stacked up. Where all the straw is used at the farm for fodder, &c., the fixed threshing machine set up in the barn is the most convenient. The sheaf corn has to be carried to it, but, on the other hand, everything is under cover, the work can be done on a wet day, and all the products of threshing in the shape of grain and straw are kept dry. In the great corn districts, however, the portable threshers is most convenient; it is set alongside the stack and only the grain and chaff are carried under a "sackman," who is specially equipped up so that as the work goes on. The farmer finds the coal and the men and horses to cart water to the stack and corn to the barn and pays the proprietor of the threshing outfit, who finds all the other men, about the following rates: wheat, 1s. 10d., oats and barley, 1s. 6d. per quarter.

(P. McC.)
THRENODY, a lament written in verse, a dirge, a funeral ode composed in honour of a dead personage. The word is an adaptation of the Greek θρηνος, a funeral dirge, from θρέω, lamentation, wailing, θρήνος, I cry aloud, and θρήνος, a song, ode, διγραυ, to sing.

THRESHOLD, the door-sill, the piece of stone or wood which is placed at the bottom of a door, gate, or entrance to a house or the building. The word is derived from the Old French, the equivalent of Ger. Schwellde and of Lat. limen, i.e., the lowest limit of sensation, the point at which the intensity of sensation becomes just noticeable. Etymologically threshold (O. Eng. hersold, M. Eng. herswold) has usually been divided into "thresh," i.e., thresh, beat, and weld, weld, weld, wood; the word meaning the pieces of wood beaten or trampled by the feet. The termination, as is shown by the Old English form, has probably no connexion with wald, but is merely a suffix, as in O. H. Ger. driscäfti, threshold. The first part is certainly "thresh," beat; some have supposed that in early times the entrance to a house was used as a threshing-floor.

THRIFT, economy in personal or domestic expenditure, the habit and practice of saving, careful or frugal management in money matters. The word, which is borrowed from Scandinavian languages, meant the condition of one who thrives or prospers (M. Eng. thriwen, Icel. thrifja, to clench, seize, Norw. triva, seize). There are several species of plants, such as the sea-pink, Armeria maritima, or March rosemary (Statice) which from their vigorous growth are often termed "thrift." THRING, EDWARD (1821–1887), English schoolmaster, was the son of John Gale Dalton Thring, rector of Alford, Somerset, and was born on the 19th of November 1821. His elder brother was Henry, afterwards Lord, Thring (1818–1907) the distinguished Parliamentary counsel (1865–1886), who was made a peer in 1886. Edward was educated first at Ilminster grammar school and afterwards at Eton, where he became head of the school, and Captain of Montem in 1841, the last occasion on which that ancient festival was celebrated. He then entered King's College, Cambridge, won the Porson Prize for Greek Verse, and was elected fellow. At that time King's College scholars retained the privilege of proceeding to a degree without examination, but Thring thought the maintenance of this usage inexpedient in the interests of learning and wholly indefensible in principle, and his vigorous protests against it aroused lively academic controversy, and became effective in 1851, when it was abolished. On leaving the university in 1846 he was ordained, and served for a short time as curate in Gloucester. Here he took remarkable interest in the elementary school of the parish, and ever afterwards attributed much of his professional success and his insight into educational principles and methods to the experience he had acquired in imparting the humble rudiments of learning to the children of the poor. After an interval of two or three years, spent partly in private tuition and partly as curate at Cookham Dean, he married in 1853 a daughter of Carl Koch, commissioner of customs at Bonn, and was elected to the mastership of Uppingham School, a post which he retained until his death in 1887. That school had been founded in 1584, was slenderly endowed, poorly housed, and little known. Thring found only twenty-five boys in it, but he succeeded in raising it, both in numbers and repute, to a position in the first rank among English public schools. He had a strong conviction that there should be a limit to the number of pupils entrusted to the care of one head master, and he fixed that limit at 300, although, owing to the increasing popularity of the school, he was under strong temptation to exceed it. Little by little he surrounded himself with a loyal staff of masters, raised money for the building and equipment of a noble schoolroom and chapel, besides class-rooms and eleven boarding-houses. Among the distinctive features of his plans and achievements were: (r) his strong sense of the need for a closer study of the characteristics of individual boys than is generally found possible in large public schools; (2) his absolute adherence to the discipline of the ancient languages, in connexion with English, as the staple of a liberal education; (3) his careful provision of a great variety of additional employments and interests, in studies and in games, to suit the aptitudes of different pupils; (4) the value he attached to the aesthetic side of school training, as evinced in the encouragement he gave to music and to drawing and to the artistic decoration of the schoolrooms; and above all (5) his rebellion against mere routine, and his constant insistence on the moral purpose of a school as a training ground for wholesome habits, rather than as a place solely concerned itself with the acquisition of knowledge. The vigour and intrepidity of his character were conspicuously shown in 1875, when an outbreak of fever made Uppingham for a time untenable, and when, at a few days' notice, he took a disused hotel and some boarding-houses at Borth, on the Cardiganshire coast, and transported the whole 300 boys, with 30 masters and their households, to it, to a city of refuge. Here the school was carried on with undiminished and even fresh zest and efficiency for fourteen months, during which needful sanitary measures were taken in the town. A man of Arnold's stamp and with Arnold's strength and lofty educational aims he was in strong sympathy, he took little or no part in outside controversies, political or ecclesiastical. All the activity of his life centred round the school. His was the first public school to establish a gymnasium, and the first to found a town mission in a district of South London, with a view to interest the boys in an effort to improve the social condition of the poor. He took the first step in 1869 in the formation of the Head Masters' Conference, an institution which has ever since done much to suggest improvements in method and to cultivate a sense of corporate life and mutual helpfulness among the teachers in the great schools of the country. In 1868, he took the bold and unprecedented step of inviting the Association of Head Mistresses to Uppingham, and giving to them a sympathetic address. He also formed an association in Uppingham, with lectures, cookery classes, concerts, and other aids to the intellectual and social improvement of the residents of the little town. He gave valuable evidence before the Schools Inquiry Commission of Lord Taunton in 1866, but it was very characteristic of him that he dreaded the intrusion of public authority, whether of royal commissioners or of the legislature, into the domain of the school. In his view, the term "public school," the liberty and personal inventiveness and enthusiasm of teachers should have full scope and be hindered by no official regulations. His contributions to literature were not numerous, but were all closely connected with his work as a schoolmaster. They were: Thoughts on Life Science (1869), written under the assumed name of Benjamin; Place; Education and School (1864); The Theory and Practice of Teaching (1882); Uppingham School Sermons (1885); The Child's Grammar (1852); The Principles of Grammar (1886); Exercises in Grammatical Analysis (1886); School Songs (1885); Birth Lyrics, poems and translations (1887); and a volume of Miscellaneous Addresses, published after his death in 1887.

The fullest account of his life is that written by G. R. Parkin (1890), containing copies extract from his diary and letters, A Life of Edward Thring. This was followed, in 1887, by a life written by J. H. Skrine, the warden of Glenalmond, who was first a pupil and afterwards an assistant master at the school, presents a vivid and unflattering picture of Thring's active life, and an affectionate and yet discriminating estimate of his character. Other particulars may be found in the chapter devoted to his biography in Sir Joshua Fitch's Educational Aims and Methods, and in Edward Thring, Teacher and Poet, by Canon H. D. Rawnsley. (J. G. F.)

THROAT (O. Eng. frot, prole or brole, possibly from freliam, to press, whence throat, or, with loss of initial s, connected with frin to swell). The term is applied to the front external part of the neck from below the chin to the collar-bone in human and animal anatomy, and to the internal parts, which include the gullet, viz. the faucae, pharynx and oesophagus, and the windpipe, viz. the larynx and trachea (see PHARYNX, ALIMENTARY CANAL, and RESPIRATORY SYSTEM: Anatomy; and for diseases see PHARYNGITIS, LARYNGITIS, DIPHTHERIA, TONSILITIS and OESOPHAGUS).
THROCKMORTON (or THROGMORTON), FRANCIS (1554—1584), English conspirator, was the son of Sir John Throckmorton of Feckenham in Warwickshire, and his wife Margery Puttenham. Sir John had been concerned in Wyatt's rebellion against Queen Mary Tudor, but was afterwards known as a sympathizer with the Roman Catholic party in the reign of Queen Elizabeth, and in 1580 was removed from his office of chief justice of Chester for irregularities in his office, but probably because he was suspected of disloyalty by the government. Francis was educated at Hart Hall, Oxford, which he entered in 1572. In 1576 he was enrolled in the Inner Temple. At Oxford he had come under the influence of the Roman Catholics, whose power was still great in the university, and must have heard of the intrigues of their leaders when he himself entered the university. When Campian and Parsons came to England in 1580 to conduct the Jesuit propaganda against Queen Elizabeth, Francis Throckmorton was one of a society of members of the Inner Temple who united to hide and help them. In that year he went abroad, first to join his brother Thomas, who was engaged with the exiled Roman Catholics in Paris, and then to travel in Italy and Spain. While abroad he consorted with exiled papists, and was undoubtedly engaged in treasonable intrigues. In 1583 he returned to act as the confessional agent of his elaborate conspiracy. After his flight from England he had got his object the invasion of England by a French force under command of the duke of Guise, or by Spaniards and Italians sent by Philip II, for the purpose of releasing the imprisoned Mary Queen of Scots and restoring the authority of the pope. Throckmorton possessed, or occupied, a house on Paul's wharf, London, which served as a meeting-place for the conspirators. Many plots were being carried on alongside of the chief one, and the suspicions of the government were aroused. Throckmorton's constant visits to the Spanish ambassador, Bernardino de Mendoza, attracted attention, and he was arrested in October 1583. He was deciphering a letter to Queen Mary when the constables came upon him suddenly, but he found time to send a casket of compromising papers to a trustworthy maid-servant to Mendoza, and a card in cipher in which he promised to reveal nothing. As he refused to confess when brought before the council, he was put on the rack in the Tower. He resisted a first application of the torture, but his strength and courage failed when he was threatened with a second, and he made a full confession. At a later period he retracted and asserted that his avowals were false and had been extorted from him by pain, or had been put into his confession by the constables. It is possible he made a full confession of his own accord, however, all that is known of his confessions of the conspirators. Many of the conspirators were hanged, but many others escaped, and the conspiracy was not detected until 1586 when the queen was informed of the names of those who had conspired. The queen, however, was not satisfied that they had been sufficiently punished, and she ordered the constables to be searched, and the constables found out a plot to carry off the queen and her attendants. The queen was thus saved from the plot. The queen was saved from the plot, and the conspirators were executed. Throckmorton was executed on the 17th of April 1584. He was brought to trial at the Guildhall on the 17th of April of that year. By eloquence, readiness of wit, and adroit flattery of the jury he contrived to secure his acquittal in the face of the unequivocal statement of the judge—a unimpeachable achievement at a time when the condemnation of prisoners whom the authorities wished to convict was a mere matter of course. The jurymen were fined and sent to prison, and Throckmorton was detained in the Tower till the following year. There was some talk of bringing him to trial again, but he made his peace, and was employed by Queen Mary. After the accession of Elizabeth he rose rapidly into favour. He became chamberlain of the exchequer, and from May 1559 to April 1564 he was ambassador in France. During the latter part of this period he was associated with the English ambassador Sir Thomas Smith, who had at least partly to watch and check his fellow-ambassador. It was in these years that Throckmorton became acquainted with Mary Queen of Scots. He had to conduct the delicate negotiations which accompanied her return to Scotland, and though he was a supporter of the reformers on political grounds, he became her personal friend and was always willing to do her service. As ambassador in France he exerted himself to induce Elizabeth to aid the Huguenots, and took part in the war of religion. He was taken prisoner by the Catholic leader, the duke of Guise. After his return to England he was sent as ambassador to Scotland in May 1565. The principal object of his mission was to prevent Queen Mary's marriage with Darnley, which however he was unable to do. After the murder of Darnley he was again sent to Scotland in June 1567 on a still more hopeless mission than the first. He was instructed to persuade the Scottish barons who had just imprisoned the queen to restore her to her authority. His known friendship for Queen Mary and his constant support of her claim to be recognized as Elizabeth's successor, made him a very unwelcome representative of England in that crisis. Moreover, the queen of England intended to go abroad, and he had to send official messages to the barons, and by contradictory instructions. He cannot have undertaken his task with much zeal, for his own opinion was that Elizabeth would consult her interests best by supporting the barons. In Edinburgh Throckmorton could effect little, but he exerted himself to secure the personal safety of the queen. He offended his mistress by showing his instructions to the Scottish barons, and was recalled in August. In 1569 he fell under suspicion during the duke of Norfolk's conspiracy in favour of Mary, and was imprisoned for a time at Windsor, but was not further proceeded against. He died on the 17th of February 1571. Sir Nicholas married Anne Carew, and his daughter Elizabeth became the wife of Sir Walter Raleigh.

THORNE, a royal, vice-regal, or episcopal chair of state standing upon a dais or platform. Formerly the platform, with the steps leading up to it, was comprised in the significance of the word—hence the familiar expression to "mount the throne." The ceremonial induction of a sovereign into his throne is one of the usual solemnities of a coronation, while enthronization of the bishop in his cathedral is the final observance in the making of a diocesan. The throne, which is of innumerable antiquity, is the universal ancestor of all chairs, which were for long symbols of authority and rule. In early days and in Oriental countries thrones were of barbaric magnificence. Solomon's was of ivory "overlaid with the best gold." There were two figures of lions at the sides, with two other lions on each of the six steps. The remains of a throne in rock-crystal were found in the ruins of Sennacherib's palace. The Persian throne made for Abbas the Great was of white marble. This monarch appears to have had a nice taste in thrones, for in 1605 he presented one to the Russian tsar Boris which is covered with sheets of gold and decorated with precious stones and pearls. Tsar MichaelFeodorovitch, grandfather of Peter the Great, outdid even this magnificence, for his "golden throne" is set with eight thousand turquoises, fifteen hundred rubies, four great amethysts and two large topazes. One of the glories of Delhi, until it was sacked by Nadir Shah, was the "peacock throne," the value
of which was estimated, perhaps with some Eastern exuberance, at twelve millions sterling. It was ascended by silver steps and stood on golden feet set with jewels. It obtained its name from the two open peacocks' tails composed of magnificent diamonds, rubies, and other stones which formed part of its appurtenances. Apparently it was made for Shah Jahan by the French designer of the Taj Mahal. According to that veracious chronicler, Sir John Mandeville, the seven steps of the throne of Prester John were respectively of onyx, crystal, green jasper, amethyst, sardonyx, cornelian and chrysolite. They were bordered with gold and set with pearls. The throne itself was of gold enriched with jewels. Ranjit Singh's golden throne—it is of wood covered with plates of gold—is in the possession of the British Crown. European thrones were usually more ornate and fanciful than the Persian's, and occupied a real or legendary, of the East. The medieval emperors of Byzantium had, however, imbued a good deal of the Orient, and their famous throne, which is supposed to have been imitated from, as well as named after, that of Solomon, was guarded by golden lions, which rose to their feet and roared when some artful mechanism was set in motion. An exceedingly ancient chair of state is the so-called throne of Dagobert (see CHAIR). The most recent writers on this remarkable relic suggest that it is a bronze copy of Dagobert's golden throne. However that may be, there can be no doubt that it possesses at least one illustrious modern association, for Napoleon sat in it when he distributed the first decorations of the Legion of Honour in his camp at Boulogne in 1804. The throne which Napoleon had made for himself was a heavy gilded chair with an abundance of Egyptian ornament, lions' heads and imperial eagles. One of the many curiosities of a conclave for the electing of a Pope is that every cardinal present occupies a throne, since, during the vacancy of the Holy See, each member of the Sacred College is a potential sovereign. When the election has taken place the canopy of every throne is lowered, with the exception of that occupied by the pape. The papal chair—of the great Roman nobles contained—and still in some cases contain—a throne for use in the event of a visit from the pope. The papal throne itself is an antique bronze chair which stands in St Peter's. Embassies frequently contain a throne for the use of the sovereign in whose territory the building technically stands. No ancient throne-chair pertains to the British monarchy; the coronation chair is not, properly speaking, a throne, since it is used only during a portion of the coronation ceremonies. The actual throne of Great Britain is the oaken Gothic chair in the House of Lords occupied by the sovereign at the opening and prorogation of parliament.

THRUM-EYED, a botanical term for flowers which occur in two forms, one of which shows the stamens in the mouth of the corolla, as in the primrose, contrasted with pin-eyed (q.v.).

THRUSH (A. S. Drussca, Icel. Drstr, Norw. Trast, O. H. Ger. Drsche, whence the mod. Ger. Drossel, to be compared with the analogous English form Throstle,¹ now almost obsolete, both being apparently diminutives), the name that in England seems to have been common to two species of birds, the first now generally distinguished as the song-thrush, but known in some districts as the mavis, the second called the mistletoe-thrush, but having many other local designations, of which more presently.

The former of these is one of the finest songsters in Europe, but it is almost everywhere so common that its merits in this respect are often disregarded, and not unfrequently its melody, when noticed, is ascribed to the prince of feathered vocalists, the nightingale (q.v.). In the spring and summer there is hardly a field, a copse or a garden that is not the resort of a pair or more of song-thrushes; and the brown-backed bird with its spotted breast, hopping over the grass for a few yards, then pausing to detect the movement of a worm, and vigorously seizing the same a moment after, is one of the most familiar sights. Hardly less well-known is the singular nest built by this bird—a deep cup, lined with a thin but stiff coating of fragments of rotten wood, ingeniously spread, and plastered so as to present a smooth interior—in which its sea-green eggs spotted with black are laid. An early breeder, it builds nest after nest during the season, and there can be few birds more prolific. Its ravages on ripening fruits, especially strawberries and gooseberries, excite the enmity of the imprudent gardener who leaves his crops unprotected by nets, but he would do well to stay the hand of revenge, for no bird can or does destroy so many snails, set among the ripe berries. To the curious observer on inspection of the stones that it selects against which to dash its capture—interlaced with leaves that are besmeared with the slime of the victims and bestrewn with the fragments of their shattered shells. Nearly all the young thrushes reared in the British Islands—and this expression includes the storm-swept isles of the Outer Hebrides, though not those of Shetland—seem to emigrate as soon as they are fit to journey, and at a later period they are followed by most of their parents, so that many parts of the kingdom are absolutely bereft of this species from October to the end of January. On the continent of Europe the autumnal influx of the birds bred in the North is regarded with much interest, for they are easily ensnared and justly esteemed for the table, while their numbers make their appearance in certain districts a matter of great importance.

The second species to which the name applies is distinguished as the mistletoe-thrush, or, by corrupt abbreviation, the missel-thrush.² It is known also in many districts as the "storm-cock," from its habit of singing in squally weather that silences almost all other birds, and "holm- (i.e. holly-) thrush"; while the harsh cries it utters when angry or alarmed have given it other local names, as "screech," "shrike" and "skirike," all traceable to the Anglo-Saxon Seric.³ This is a larger species than the last, of paler tints, and conspicuous in flight by the white patches on its outer tail-feathers. Of bold disposition, and fearless of the sleet storms of spring, as of predatory birds, the cock will take his stand on a tall tree, "like an enchanter calling up the gale" (as Knapp happily wrote), and thence with loud voice proclaim in wild and discontinuous notes the fervour of his love for his mate; nor does that love cease when the breeding-season is past; since this species is one of those that appear to pair for life, and even when, later in the year, it gathers in small flocks, the North is regarded with much interest, for they have little use for nest and offsprung, too, few birds are more resolute, and the dawn, pie or jay that approaches with an ill intent speedily receives treatment that causes a rapid retreat, while even the marauding cat finds the precincts of the "master of the coppice," (Pen y Bryn), as the Welsh name this thrush, unsuitable for its stealthy operations. The connexion of this bird with the mistletoe, which is as old as the days of Aristotle, is no figment, as some have tried to maintain. Not only is it exceedingly fond of the luscious viscid berries, but it seems to be almost the only bird that will touch them.

The thrushes form a distinct family, Turdidae, of the Oscines division of perching birds, and are now generally divided into sub-families (q.v. Turdinae, or true thrushes and their immediate allies, the ouzel (q.v.), the fieldfare (q.v.), the redwing (q.v.), the rock-thrushes (Monticola), the wheatears, stonechats, willowbirds (see Wheateara), the redstarts (q.v.), robins (see Redbreast), and

¹ There is no doubt of the bird taking its name from the plant mistletoe (Viscum album), about the spelling of which there can be no doubt—A. S. Drossca, Icel. Drstr. etc., "plucked," originally signifying "twig," and surviving in the modern "tine," as of a fork or of a deer's antler.

² It seems quite possible that the word thrush, though now commonly accepted as the equivalent, in an ornithological sense, of Lanius, may have been originally applied to the mistletoe-thrush. In several of the Anglo-Saxon Vocabularies dating from the 8th to the 11th century, as printed by Thomas Wright, the word Seric, which can be hardly anything else than the early form of "shrike," is glossed Turdus.
hedge-sparrows (see Sparrow). In these, as opposed to the warblers, the young are spotted. (2) Myiolecinae, a small group, chiefly South American, with strong bristles round the gape. (3) Sylvinae (see Warblers). (4) Poliopitidae or gnat-catchers of North and South America. Myiarchinae (q.v.), called "babbbling-thrushes" which occur throughout the Old World are usually referred to a distinct family, the Timelidae, characterized by strong bills and feet, and short, rounded and incurved wings. The "ant thrushes" belong to a different family (see Pitta).

(A. N.)

THUCYDIDES (Θουκυδίδης), Athenian historian. Materials for his biography are scanty, and the facts are of interest chiefly as aids to the appreciation of his life's labour, the History of the Peloponnesian War. The old view that he was probably born in or about 471 B.C., is based on a passage of Aulus Gellius, who says that in 431 Hellanicus "seems to have been" sixty-five years of age, Herodotus fifty-three and Thucydides forty (Not. att. xv. 23). The authority for this statement was Pamphila, a woman of Greek extraction, who compiled biographical and historical notices in the reign of Nero. The value of her testimony is, however, negligible, and modern criticism inclines to a later date, about 461 (see Busolt, Gr. Gesch. iii., pt. 2, p. 621). Thucydides' father Olorus, a citizen of Athens, belonged to a family of the highest in the race, and from the possession of gold-mines at Scapté Hyle, on the Thracian coast opposite Thasos, and was a relative of his elder namesake, the Thracian prince, whose daughter Hegesipyle married the great Miltiades, so that Cimon, son of Miltiades, was possibly a connexion of Thucydides (see Busolt, ibid., p. 618). It was in the vault of the Cimonian family at Athens, and near the remains of Cimon's sister Elpinice, that Pindar saw the grave of Thucydides. Thus the fortune of birth secured three signal advantages to the future historian: he was rich; he had two homes—one at Athens, the other in Thrace—so small a aid to a comprehensive study of the conditions under which the Peloponnesian War was waged; and his family connexions were likely to bring him from his early years into personal intercourse with the men who were shaping the history of his time.

The development of Athens during the middle of the 5th century was, in itself, the best education which such a mind as that of Thucydides could have received. The expansion and consolidation of Athenian power was completed, and the inner resources of the city were being applied to the embellishment and ennoblement of Athenian life (see Cixon; Pericles). Yet the History tells us nothing of the growth in the art or the science of life under whose influence its author had grown up. The "Funeral Oration" contains, indeed, his general testimony to the value and the charm of those influences. But he leaves us to supply all examples and details for ourselves. Beyond a passing reference to public "festivals," and to "beautiful surroundings in private life," he makes no attempt to define those "recreations for the spirit" which the Athenian genius had provided in such abundance. He alludes to the newly-built Parthenon only as containing the treasury; to the statue of Athena Parthenos which it enshrined, only on account of the gold which, at an extreme need, could be detached from the immovable. The Protesilaos and other buildings with which Athens had been adorned under Pericles, only as works which had reduced the surplus of funds available for the war. He makes no reference to Aeschylus, Sophocles, Euripides, Aristophanes; the architect Ictinus; the sculptor Phidias; the physician Hippocrates; the philosophers Anaxagoras and Socrates. Herodotus, if he had dealt with this period, would have found countless occasions for invaluable digressions on men and manners, on letters and art; and we might almost be tempted to ask whether his more genial, if lazier, method does not indeed correspond better with a liberal conception of the historian's office. No one can do full justice to Thucydides, or appreciate the true completeness of his work, who has not faced this question, and found the answer to it.

It would be a hasty judgment which inferred from the omission of the History that its author's interests were exclusively political. Thucydides was not writing the history of a period. His subject was an event—the Peloponnesian War—a war, as he believed, of unequalled importance, alike in its direct results and in its political significance for all time. To his task, thus defined, he brought an intense concentration of all his faculties. He worked with a constant desire to make each successive incident of the war as clear as possible. To take only two instances: there is nothing in literature more graphic than his description of the plague at Athens, or than the whole narrative of the Sicilian expedition. But the same temper made him resolute in excluding irrelevant topics. The social life of the Athenian state at that period is not belon to his subject.

The biography which bears the name of Marmelinos states that Thucydides was the disciple of Anaxagoras in philosophy and of Antiphon in rhetoric. There is no evidence to confirm this tradition. But Thucydides and Antiphon at least belong to the same rhetorical school and represent the same early stage of Attic prose. Both writers used words of an antique or decidedly poetical cast; both point verbal contrasts by insisting on the precise difference between terms of similar import; and both use metaphors somewhat bolder than were congenial to Greek prose in its riper age. The deficiencies of the style of Thucydides and that of Antiphon arise chiefly from two general causes. First, Antiphon wrote for hearers, Thucydides for readers; the latter, consequently, can use a degree of condensation and a freedom in the arrangement of words which would have been hardly possible for the former. Again, the thought of Thucydides is often more complex than any which Antiphon undertook to interpret; and the greater intricacy of the historian's style exhibits the endeavour to express each thought. Few things in the history of literary prose are more interesting than to watch that vigorous mind in its struggle to mould a language of magnificent but immature capacities. The obscurity with which Thucydides has sometimes been reproached often arises from the very clearness with which a complex idea is present to his mind, and his strenuous effort to present it in its entirety. He never sacrifices thought to language, but he will sometimes sacrifice language to thought. A student may always be consoled by the reflection that he is not engaged in unravelling a mere rhetorical tangle. Every light on the sense will be a light on the words; and when, as is not seldom the case, Thucydides comes victoriously out of this struggle of thought and language, he is the other hand, by the elegance of his meaning in a sufficiently lucid form, then his style rises into an intellectual brilliancy—thoroughly manly, and also penetrated with intense feeling—which nothing in Greek prose literature surpasses.

The uncertainty as to the date of Thucydides' birth renders futile any discussion of the fact that before 431 he took no prominent part in Athenian politics. If he was born in 455, the fact needs no explanation; if in 471, it is possible that his opportunities were modified by the necessity of frequent visits to Thrace, where the management of such an important property as the gold-mines must have claimed his presence. The treatment in which he refers to his personal influence in that region is such as to suggest that he had sometimes resided there (iv. 195, 1). He was at Athens in the spring of 430, when the plague broke out. If his account of the symptoms has not enabled physicians to agree on a diagnosis of the malady, it is at least singularly full and vivid. He had himself been attacked by the plague; and, as he briefly adds, "he had seen others suffer." The tenor of his narrative would warrant the inference that he had been one of a few who were active in ministering to the sufferers.

The turning-point in the life of Thucydides came in the winter of 424. He was then forty seven (or, according to Busolt, about thirty-six), and for the first time he is found holding an official position. He was one of two generals entrusted with the command of the regions towards Thrace (rā ἐπὶ Θηραίων), a phrase which denotes the whole Thracian seaboard from Macedonia.

1 Christ (Gesch. der griech. Litt.) gives the date of birth as "about 455."

2 See Jebb's Attic Orators, i. 35.
eastward to the vicinity of the Thracian Chersonese, though
often used with more special reference to the Chalcidice penin-
sula. His colleague in the command was Eucleus. About the
end of November 424 Eucleus was in Amphipolis, the stronghold
of Athenian power in the north-west. To guard it with all
possible vigilance was a matter of peculiar urgency at that
moment. The abest of Spartan leaders, Brasidas (q.v.), was in
the Chalcidice peninsula, where he had already gained rapid
success; and part of the population between that peninsula and
Amphipolis was known to be disaffected to Athens. Under
such circumstances we might have expected that Thucydides,
who had the beard of a king—his hair was piled high and
co-operate with Eucleus. It appears, however, that, with his
ships, he was at the island of Thasos when Brasidas suddenly
appeared before Amphipolis. Eucleus sent in all haste for Thucy-
dides, who arrived with his ships from Thasos just in time to
beat off the enemy from Eion at the mouth of the Strymon, but
not in time to save Amphipolis. The profound vexation and
dismay felt at Athens found expression in the punishment of
Thucydides, who was exiled. Cleon is said to have been the prime
mover in his condemnation; and this is likely enough.

His Predecessors.

His Greek predecessors in the recording of events had
been, he conceived, of two classes. First, there were
the epic poets, with Homer at their head, whose characteristic
work was the lyra—Odyssey and Iliad, in the evocative
power, the charm, the splendour of things past. Secondly, there
were the Ionian prose writers whom he calls “chroniclers” (see
Logographos), whose general object was to diffuse a knowledge of
legends preserved by oral tradition and of written documents—usually lists of
officials or genealogies—preserved in public archives; and they published
their materials as they found them, without criticism. Thucydides
approached the study of history by the way of the "γραφή, the difference between the terms answering to that
between compilation of a somewhat mechanical kind and historical
composition in a higher sense. The vice of the "chroniclers,
was that they were more interested in personal details and took no pains to
make their narratives trustworthy. Herodotus was presumably
regarded by him as in the same general category.

In contrast with these predecessors Thucydides has subjected
his materials to the most searching scrutiny, the ruling principle
of his work has been strict adherence to carefully
verified facts. As to the deeds done in the war,
Hearsay from the first informant or on arbitrary
conjecture. My account rests either on personal knowledge or on
the closest possible scrutiny of each statement made by others.
The method of research and the mode of presentation was the
same so far as their cases were given by those who had witnessed the several events, as
partiality swayed or memory served them.

It might be supposed that the speeches which Thucydides has
introduced into his history have this stamp of scientific accuracy; it is,
therefore, well to consider their nature
and purpose rather closely. The speeches constitute
between a fourth and a fifth part of the History. If
they were eliminated, an admirable narrative would indeed remain,
with a few comments, usually brief, on the more striking characters
and events. But we should lose all the most vivid light on the
inner workings of the Greek political mind, on the motives of the actors
and the arguments which they used—all, a word, on the whole
play of contemporary feeling and opinion. To the speeches is due in
particular measure the imperishable intellectual interest of the
History; it is, to use a word, the soul of the
Peloponnesian War. They are so ltit up with keen thought as to become
illustrations of general laws, and to acquire a permanent suggestive-
ness for the student of politics. When Herodotus and Thucydides
hold conversations or deliver speeches, he was following the
precedent of epic poetry; his tone is usually colloquial rather than
rhetorical; he is merely making thought and motive vivid in
the words of a actor or by a word, to a sense of the tradition by which historians were so long held to be warranted in
introducing set speeches of their own composition. His own
account of his practice is given in the following words: "As to
the speeches I made up of the war or in its course, I have
found it difficult to retain a memory of the precise words which
I had heard spoken; and so it was with those who brought me reports

1 Freeman, Historical Essays, 2nd series, vol. iii.; on the general
questions of the structure of the work and the view of the
other which it represents see PELOPONNESEAN WAR; and GREECE;
Ancient History, § Authorities.
THUCYDIDES

895

But I have made the persons say what it seemed to me most opportune for them to say in view of each situation; at the same time I have adhered as closely as possible to the general sense of what was actually said. So far as the language of the speeches is concerned, Thucydides himself, or rather his informants, used the type of language which he found in his sources, or which the historian has given to no other speaker. Such strongly marked characteristics as the curt bluntness of the Spartan ephors Sthenelaidas, or the insolent vehemence of Alcibiades, are also indicated. In the speeches of Thucydides, more than in those of any other writer, the speech is the matter, not in the form. In regard to those speeches which were delivered at Athens before his banishment in 424—and seven such speeches are extant—Thucydides never relies either on his own recollection or on the sources accessible to a resident citizen. In these cases there is good reason to believe that he has reproduced the substance of what was actually said. In other cases he had to trust to more or less imperfect reports or the "general sense"; and in some instances, no doubt, the speech represents simply his own conception of what it would have been "most opportune" to have been said. It is most evident of such instances on the addresses of leaders to the people. The aim in these military harangues—which are usually short—is to bring out the points of a strategical situation; a modern writer would have himself better fitted for the task. Thucydides did not take the speeches of Pericles as the model, or as the parallel to his own, but he used them for the purpose of introducing the battle. The comparative indifference of Thucydides to dramatic verisimilitude in these military orations is curiously shown by the fact that the speech of the general on the sea is written without any reference to the fate of the other general on the other as if they had been delivered in debate. We may be sure, however, that, wherever Thucydides had any authentic clue to the actual words of a speech, he preferred to follow that clue rather than to derive on his own invention.

Why, however, did he not content himself with simply stating, in his own person, the arguments and opinions which he conceived to be essential to the division? The reason must be sought from the standpoint of a Greek in the 5th century B.C. Epic poetry had then for many generations exercised a powerful influence over the Greek mind. Homer had accumulated a wealth of information in his poetry, and the expression of human energy—first, an account of a man's deeds, then an image of his mind in the report of his words. The Homeric heroes are exhibited both in action and in speech. Perhaps the contemporary readers of Thucydides were more habituated to a civic life in which public speech played an all-important part. Every adult citizen of a Greek democracy was a member of the assembly which debated and decided great issues. The law courts, the festivals, the drama, the market-place itself, ministered to the Greek love of animated description. To a Greek of that age a written history of political events would have seemed strangely inappropriate. Poetry had been an established vehicle of expression, especially if it did not offer some mirror of those debates which were inseparably associated with the central interests and the decisive momentousness of the life of the body politic. And, moreover, the reading public might have said, Thucydides confined that oratorical licence to the purpose which is its best justification: with him it is strictly dramatic, an aid to the complete presentation of action, by the vivid expression of ideas and arguments which were really current at the time. Among later historians who continued the practice, Polybius, Sallust and Tacitus most resemble Thucydides in this particular; while in the Byzantine historians, as in some moderns who followed classical precedent, the speeches were usually mere occasions for rhetorical display. Botta's History of Italy from 1780 to 1814 affords one of the latest examples of the practice, which is confined to the wars of Napoleon.

The present division of the History into eight books is one which might well have proceeded from the author himself, as being a natural and convenient disposition of the contents. Book II. contains the speeches of the Peloponnesian War. The first nine years of the war are contained in the second, third and fourth books—three years in each. The fifth book contains the text of the book of Thucydides, for in the first year of the Sicilian expedition fills the sixth and seventh books. The eighth books opens that last chapter of the struggle which is known as the "Peloponnesian Peace." Far more speeches end off abruptly—in the middle of a sentence, indeed—in the year 411.

The principal reason against believing that the division into eight books was made by Thucydides himself is the fact that a division of this kind, or any similar one, did not exist in antiquity, as appears from Marcellinus (§ 58). It is very improbable—indeed hardly conceivable—that this should have been the case if the eight-book division had come down from the hand of the author. We may infer, then, that the division of the work into eight books was introduced at Alexandria—perhaps in the 3rd or 2nd century B.C. That division was already familiar to the grammarians of the Augustan age. Dionysius of Halicarnassus, who recognizes it, has also another mode of indicating the eight-book division by the number of the lines which they contained. Thus, in the MS. which he used, the first 57 chapters of book i. contained about 1700 lines (divalent to about 1700 lines in Bekker's stereotyped text). (On the first division see ALBRECHT DURER'S APOLOGIA, 1525; THUCYDIDES, Ad Init.; and GREECE: Ancient History, § Authorities.)

The division of the war by summers and winters (σαράνθος καὶ ξυνάθροι)—the end of the winter being considered as the end of the season—is perhaps the other which Thucydides himself used, for there is no indication that he made any division of the History into books. His "summer," "autumn" and "winter" were generally speaking, from March or April to the end of September of the following year. His "winter."—November to February inclusive—means practically the period during which military operations, by land and sea, usually or partly suspended. When he speaks of "summer" and "winter" as answering respectively to "half" the year (v. 20, 3), the phrase is not to be pressed: it means merely that he divides his year into these two parts. The mode of reckoning is essentially a rough one, and is not to be viewed as if the commencement of summer or of winter could be precisely fixed to constant dates. For chronology, besides the festivals, he uses the Athenian list of names on the Spartan list of ephors and the Argive list of priests of Hera.

There is no reference to the History of Thucydides in the extant Greek writers of the 4th century B.C.; but Lucian has preserved a tradition of the enthusiasm with which it was studied by Demosthenes and the great orator of Aphiæa for having read it, or even to have learnt it by heart. The Alexandrian critics acknowledged Thucydides as a great master of Attic. Sallust, Cornelius Nepos, Plutarch and Quintilian are among the authors whose admiration for him can be traced in their work, or has been expressly recorded. The most elaborate ancient criticism on the division and composition of Thucydides is contained in three essays by Dionysius of Halicarnassus.

Among the best MSS. of Thucydides, the Codex vaticanus 126 (11th century) represents a recension made in the Alexandrian or Roman age. In the first six books the number of MSS. is almost the same to which the Codex vaticanus belongs, but in book vii. it is somewhat larger; in book viii. it is so large that here the Vaticans, as compared with the other MSS., acquires the character of a revised text. Other important MSS. are the Palatinus 252 (11th century); the Cassianus (A.D. 1752); the Augustanus monacensis 450 (A.D. 1901). A collation, in books i., ii. of two Cambridge MSS. of the 15th century (W. 3. 18; Kx. 5. 19) has been published by Shilleto. Several French MSS. (H. C. A. F.), and a Venetian MSS. (V.) collated by Arnold, also deserve mention. The Aldine edition was published in 1502. It was formerly supposed that there had been two editions. Now, however, it is thought that the first pointed out that the only Juntine edition was that of 1526, and that the belief in an earlier Juntine, of 1506, arose merely from the accidental omission of the word nixema in the Latin translation, made by Rene of Grignion de Montbrun in 1602, as well as from the fact that the editions in Grenfell and Hunt's Oxyrhynchus papyri (1908), vi., which also contains an anonymous commentary (pub. 1st century) on Thuc.

The most generally useful edition is Classen's, in the Weidmann Series (1862-1878; new ed. by Steup, 1882-1892); each book can be obtained separately. Arnold's edition (1848-1851) contains much that is still valuable. For books i. and ii. Shilleto's edition (1872-1877) is a valuable commentary, though not full, and deals admirably with many difficult points. Among other important complete editions, it is enough to name those of Duker, Bekker, Goeller, Popoff, Krüger, and Dippel. For collations and selections of the late (1905) see J. B. Mayor's Guide to the Greek Text (1905). Special mention may be made of those by E. C. Marchant. Latest editions of the text are by H. Stuart Jones (1900-1901), in the Oxford Classical Texts (1919), by C. H. Hutton (1901; ed. minor, 1903). Béâtant's lexicon to Thucydides (1843) is well executed. Jowett's translation (1853) is supplemented by a volume of notes. Dale's version (Bohn) also deserves mention (London, 1859). Lastly, Jowett's edition (London, 1880) contains an essay on "The Speeches of Thucydides," which has been translated into German (see Eduard Meyer, Forschungen zur alten Geschichte, Bd. ii. pp. 426-436). The best clue to Thucydidean names is in E. B. Schemmann, Thucydides in Ancient History (1893), and supplemented by the articles by G. Meyer, in Bursian's Jahrbücher, (1895) lxix., (1897) lxviii. Busolt, Griechische Geschichte, iii. (1912), and E. C. Marchant, "Thucydides," in Witz-Moellendorf, "Die Thukydidische-Legende," Hermes, (1878) xliii., is all important. All works on ancient Greek History contain discussions of Thucydides, and an interesting criticism is that of J. B. Bury, Ancient Greek Historians (1905). F. M. Cornford.
THUGS—THUGUT, BARON

Thucydides myhistoricus (1907), sought to prove that the History is really only an historical tragedy, i.e. a dramatized version of the facts, but this view has not been adopted. (R. C. J.; J. M. M.)

THUGS. That the Sanskrit root stho (Pali, thak), to cover, to conceal, was mainly applied to fraudulent concealment, appears from the noun sthaga, a cheat, which has retained this significance in the modern vernaculars, in all of which it has assumed the form tha (commonly written thug), with a spelling-common in Thugs. The Thugs were a predatory fraternity of professional assassins, who in gangs of whom 10 to 100 travelled in various guises through India, wormed themselves into the confidence of wayfarers of the wealthier class, and, when a favourable opportunity occurred, strangled them by throwing a handkerchief or nose round their necks, and then plundered and buried them. All this was done according to certain ancient and rigidly prescribed forms and after the performance of special religious rites, in which the consecration of the pickaxe and the sacrifice of sugar formed a prominent part. From their using the noose as an instrument of murder they were also frequently called Phansighars, or "noose-operators." Though they themselves trace their origin to seven Mahomedan tribes, Hindus appear to have been associated with them at an early period; at any rate, their religious creed and practices as stanch worshippers of Kalî (Devi, Durga), the Hindu goddess of destruction, had certainly no flavour of Islam in them. Assassination for gain was with them a religious duty, and was considered a holy and honourable profession. They had, in fact, no idea of doing wrong, and their moral feelings did not come into play. The will of the goddess by whose command and in whose honour they followed their calling was revealed to them through a very complicated system of omens. In obedience to these they often travelled hundreds of miles in company with, or in the wake of, their intended victims before a safe opportunity presented itself for executing their design; and, when the deed was done, rites were performed in honour of that tutelary deity, and a goodly portion of the spoil was set apart for her. The fraternity possessed also a jargoon of their own (Ramosai), as well as certain signs by which its members recognized each other in the remotest parts of India. Even those who from age or infirmities could no longer take an active part in the operations continued to aid the cause as watchers, spies, or dressers of food. It was owing to their thorough organization, the secrecy and security with which they went to work, but chiefly to the religious garb in which they showered their murders, that they could, unmolested by Hindu or Mahomedan rulers, recognized as a regular profession and paying taxes as such, continue for centuries to practise their craft. Both the fractions into which they were divided by the Nerbudda river laid claim to antiquity; while the northern, however, did not trace their origin further back than the period of the early Mahomedan kings of Delhi, the southern fraction not only claimed an earlier and purer descent, but adhered also with greater strictness to the rules of their profession.

The earliest authenticated mention of the Thugs is found in the following passage of Ziau-d din Barni's History of Firoz Shah (written about 1356): "In the reign of that sultan, that is, about 1290, some Thugs were taken in Delhi, and a man belonging to that fraternity was the means of about a thousand being captured. But not one of these did the sultan have killed. He gave orders for them to be put into boats and to be conveyed into the lower country, to the neighbourhood of Lakhnauti, where they were to be set free. The Thugs would thus have to dwell about Lakhnauti till they could not troubles written thugs of Delhi any more." (Sir H. M. Elliot's History of India, iii. 147.) The first European travellers who speak of them without mentioning their name are Thévenot (1665) and Fryer (1753). Though instances of Thagi (Thuggee) had been known to the English rulers in India for many years, and sporadic efforts had been made by them towards the extinction of the gangs, it was not till Lord W. Bentinck (1828-1833) took vigorous steps in this matter that the system was gradually unmasked, and finally all but stamped out. His chief agent, Captain (afterwards Sir William) Sleeman, with several competent assistants, and the co-operation of a number of native states, succeeded in completely grappling with the evil, so that up to October 1835 no fewer than 1562 Thugs had been committed, of which number 382 were hanged and 986 transported or imprisoned for life. According to the Thuggee and Dacoity Report for 1879, the number of registered Punjabi and Hindustani Thugs then still amounted to 344; but all of these had already been registered as such before 1852. Thuggee in the United Provinces of the Gangetic Provinces in 1852, 1837-1838. The Thuggee and Dacoity department continued to exist until 1904, though its operations had long been confined to the suppression of organized robbery in native states. Its place is now taken by the Central Criminal Intelligence Department.

THUGUT, JOHANN AMADEUS FRANCIS DE PAULA, BARON (1736-1818), Austrian diplomatist, was born at Linz on the 24th of May 1736. His origin and name have been the subject of legends more or less malicious and probably the inventions of enemies. It has been said that the correct form of his name was Thumichtgut, or Thenichtgut (do no good), and was altered to Thugut (do good) by Maria Theresa. Tunicotta has been given as a variation. But Thugut was the name of his grandfather, who belonged to Budweiss in southern Bohemia. He was the legitimate son of Johann Thugut, an army paymaster, who married Eva Maria Mösbauber, daughter of a miller near Vienna. The paymaster, who died about 1760, left his widow and children in distress, and Maria Theresa took charge of them. Johann Amadeus was sent to the school of Oriental languages. He entered the Austrian foreign office as an interpreter and was appointed dragoman to the embassy at Constantinople. In 1769 he was appointed Chargé d'Affaires, and in that capacity secured a grant of money and a promise of the territory of Little Wallachia from the Turks during the negotiations connected with the first partition of Poland (see Poland: History). In 1771 he was appointed Intermnunci at Constantinople and was actively engaged, under the direction of Prince Kaunitz, in all the diplomacy of Austria in Turkey and Poland until he secured the cession of the Bukovina on the 7th of May 1775. During these years Thugut was engaged in a mean intrigue. His salary as dragoman was small, and his needs great. He therefore agreed to receive a pension of 13,000 livres, a brevet of lieutenant-colonel, and a promise of a safe refuge in case of necessity from the king of France, Louis XV. The condition on which the pension was granted was that he took advantage of his position as an Austrian official to render secret services to France. The only excuses to be made for him are that such hidden arrangements were not uncommon before and in his time, and that as a matter of fact he never did render France any real service, or betray his masters at Vienna. Yet the terror of discovery disturbed him at several periods of his life, and when Louis XV. died in 1774 he showed a strong disposition to take refuge in France, and would have done so if Louis XVI. would have given him a promise of employment. His pension was continued. It seems to be tolerably certain that an interval of a few years belonged to the emperor Francis II. His services at Constantinople were approved by Prince Kaunitz (q.v.), who may possibly have been informed of the arrangement with the French secret diplomatic fund. It is never safe to decide whether these treasons were single or double. When Thugut was appointed Intermunici he was also ennobled, being raised to the Ritterstand. After 1775 he travelled in France and Italy, partly on diplomatic service. In 1778 he was the agent through whom Maria Theresa entered into direct negotiations with Frederick the Great, in order to stop the Bavarian War. In 1790 he was Austrian envoy in
Warsaw, but in 1783 he applied for leave and satisfied his hankering after France by living for four years in Paris. It was in this time that his savings, made during his years of service at Constantinople, by means which would probably not bear investigation, were invested, and in France, Thugut became acquainted with many of the leaders in the Revolution. From 1787 to 1789 he was minister at Naples, and showed great tact in managing the queen, Maria Carolina, a daughter of Maria Theresa. In 1790 he was sent by the emperor Joseph II. to Bucharest, nominally as commissioner with the hospodar of Wallachia, but in reality in order that he might open negotiations for peace with the Turks. Until 1792 he was much in France and Belgium, partly as a diplomatic agent, but largely because he was anxious to secure his investments, which were ultimately lost. His personal grievances may have had a share in creating the hatred of the Revolution and the Jacobins, for which he was afterwards famous. In 1792 he was associated with Mercy Argenteau, formerly Austrian ambassador in France, as diplomatic agent at the headquarters of the allied army. The mismanagement of the invasion of France excited his anger. He came back to Vienna to report the facts to Francis II., to whom he presented a statement on the 27th of December. On the 19th of January 1793 he was appointed armé-diplomat at headquarters, largely, it is said, by the intrigues of Philip Cobenzl and Spielmann, who wished to have him out of the way. But he never invested, for at this time Russia and Prussia were parts of Poland. Austria, entangled in the war with France, was left empty-handed (see POLAND: History). The emperor, dissatisfied with the ministers who had not prevented this misfortune, dismissed them, and after some delay Thugut was named "director of the foreign affairs of Austria" on the 23rd of March 1793. When Prince Kaunitz died in the following year Thugut was appointed to "discharge the duties of the office of house, court, and state chancellor." His promotion to the foremost place in the Austrian administration met with much opposition, from which he was rescued by the return of Maria Theresa of Naples. The Austrian government was by tradition very aristocratic. The empress Maria Theresa, mother of Francis II., though she valued the services of Thugut, had consented with reluctance to make him commander of the order of St Stephen, and had only yielded to the urgent requests of Kaunitz and of her son Joseph II. She thought the promotion excessive for a man of his plebeian origin. The nobles, who thought that the great offices of state should go to themselves, were of the same opinion. Thugut, who had a large fund of vanity, resented their insolence, and did nothing to disarm their hostility. He was unimportant, dull in conversation, and the discharge of his duties he took counsel with nobody. All the confidential work of his department was done by himself with the help of two clerks he could trust, and he took all important papers directly to the emperor, keeping no copies in his own office. He had his own experience to teach him how easy it was to baffle the officials of Austria. The nobles, who regarded themselves with good cause as the supporters of the Crown, and who expected to be consulted, resented his indifference and secrecy as the arrogance of an upstart. They were his constant enemies and critics. A bitter quarrel broke up between Thugut and his opponents on personal grounds, but with these exceptions Thugut had no friends in Austria. Out of it, he was commonly regarded as the representative of all that was most unscrupulous and self-seeking in the methods of the Austrian government. He had inherited from his master Prince Kaunitz the firm conviction that Prussia was the worst enemy of Austria. From him, too, he had learnt that the first duty of an Austrian minister was to be an increaser of the empire, even at the expense of allies, and that excuses for annexation were to be made when they could not be found. His hatred of France, and of the Revolution, was no doubt sincere. But while prepared to defend Europe from French aggression, it was with the implied intention that Austria should be rewarded for her exertions by increases of territory, and should be made the absolute mistress of Germany. The history of his policy from 1793 to 1800 is the history of Europe. The conflicting objects which he kept before him, resistance to French aggression on the west, and to Russian and Prussian aggressions on the east, and the pursuit of more territory for Austria, compelled him to divide his exertions and his forces. Thus in 1793-94 he recalled troops from the west to participate in a partition of Poland, thereby taking pressure off Austria doing much to open the way for her subsequent victories. Some of his actions cannot be described as other than criminal. He was certainly responsible for the murderous attack on the French envoys at Rastadt in April 1799. He may have intended that they should only be robbed, but he must be held responsible for the acts of his agents. So again he has to answer for the perverse policy of Austria in 1799 when Suvarov (q.v.) and the Russians were recalled from northern Italy for no visible reason except that Austria should be left in sole possession of the dominions of the king of Sardinia, with a good excuse for retired from public life. The correspondence of Joseph de Maistre shows how bitterly the continental allies of Austria resented her selfishness, and how firmly they were persuaded that she was fighting for her own hand. That Thugut believed that he was doing his duty, and that he was carrying on the traditional policy of Austria, may be true. Yet his methods were so extreme, and his attitude so provocative as to justify the judgment passed on him by Kaunitz—namely, that he required the control of a strong hand if good results were to be obtained from his ability. After the defeats of Austria in Italy in 1796-97 and the Peace of Campo Formio, it became fixed object of the French, and with a growing party in Austria who held him responsible for the disasters of the war, to secure the removal of Thugut. He found no support, except from the British government, which considered him as a sure ally and had great influence at Vienna as paymaster of subsidies. The death of the empress Catherine of Russia deprived him of a friend at court. During the campaigns of 1799 and 1800 Thugut was the advocate of war "to the knife." At the end he was kept in office only by the vigorous support of England. The battle of Hohenlinden on the 3rd of December 1800 made his position untenable. He retired from public life.

THUIN, a town of Belgium, in that part of the province of Hainaut called "entre Sambre et Meuse." Pop. (1904), 6198. It is situated on the Sambre about 9 m. S.W. of Charleroi. The old part of the town, which dates back to the 10th century, occupies a narrow promontory between the Sambre and a small stream called the Biesmelle. The ruined tower called after him is all that remains of the fortress constructed by Bishop Notger of Liége. It was successfully defended against the Normans and long afterwards against the French under Marshal de Lorges in 1654. Although the town itself retains something of its medieval appearance it is the centre of a great manufacturing and mining district, the banks of the Sambre being lined with factories and coal-yards.

THULE, the Greek and Roman name for the most northerly known land in the north Atlantic. The first to use the name was the Greek navigator Pytheas (about 300 B.C. probably). He called it the most northerly of the British Isles and says that he reached it after six days' sail from Britain: it was inhabited, but produced little; corn grew there sparingly and ripened ill; in summer the nights were long and bright. This account of his travels is lost save for fragments, and the few surviving fragments
do not determine where his Thule was, but Müllenhoff is probably right in thinking it was the Shetlands. The Faeroes, Iceland and Norway have also been suggested, but are for various reasons much less likely. After Pythagoras, the name of the Thule is lost for the fact that local Thules Agricolae’s first in u. B.C. sailing up the east coast of Scotland is said to have espied but not to have reached Thule (“dispecta est Thule”) but the phrase is merely literary. The actual point meant to be the Orkneys or the Shetlands, or even some fragment of Scotland seen across the water. In some later writers (Procopius, &c.) Thule seems sometimes used to denote Scandinavia. The phrase “ultima Thule” is commonly used to describe the farthest limit possible.

(Th. B. C.)

THÜMML, MORITZ AUGUST VON (1738–1817), German humorist and satirical author, was born on the 27th of May 1738 at Schönhof near Leipzig. Educated at Rossleben and the university of Leipzig, where he studied law, he held from 1761 till 1783 various offices in the ducal court of Saxo-Coburg, where he became privy councillor and minister of state. He retired in 1783 and died at Coburg on the 26th of October 1817. He wrote a comic prose epic, Wilhelmine, oder der vomäßliche Pedant (1764); and Die Invasion der Liebe (1771), a tale in verse. His most famous work is his Reise in die mitländischen Provinzen von Frankreich, Holland, Norwegen (1795), in six volumes, in which the influence of Wieland is unmistakable. Schiller, who found this work wanting in aesthetic dignity, yet allowed that the keen knowledge of men and things it displays makes it a valuable contribution to literature. Thümmel’s other writings are unimportant.

His collected works were published at Leipzig in six volumes (1812), and again in 1820 (7 vols), with a biography by E. von Gruner. The most recent edition is that of 1855 (8 vols). See also F. Bobertag, Erzählende Prosa der klassischen Periode vol. i. (Kürschner’s Deutsche Nationalliteratur, vol. cxxxi., 1886). Wilhelm von Gruner has also been edited by R. Rosenbaum (1894). (Th. B. C.)

THUN (Fr. Thoune), a picturesque little town in the Swiss canton of Bern, built on the banks of the Aar, just as it issues from the Lake of Thun, and by rail 15 m. S.E. of Bern, or 17½ m. N.W. of Interlaken. It is the capital of the Bernese Oberland, the snowy peaks of which are well seen from it. It has 6,600 inhabitants, mostly German-speaking and Protestants. The 18th-century parish church and the 15th-century castle rise in a striking fashion above the town, in the chief street of which are arcades (locally called Lauben) as in Bern. There is a museum in the tower of the castle, while in and near the town (in the Heimberg, the Belp, the Aar, etc.) there are fine old homes. It is the capital of the lords it belonged to 1127 to the house of Zähringen, and on its extinction (1218) to the counts of Kyburg. The heiress of that family brought Thun (and Burgdorf) in 1273 to the cadet or Laufenburg line of the Habsburg family, her mother having (1264) granted the town a charter of liberties that confirmed an earlier grant of 1256. In 1375 the town was mortgaged to Bern, to which it was sold outright in 1384. From 1708 to 1802 Thun was the capital of the canton Oberland of the Helvetic Republic. (W. A. B. C.)

THUN, LAKE OF, in the Swiss canton of Bern, the second lake (after Lake Neuchâtel that of Brienz) into which the river Aar (q.v.) expands. It lies in a deep hollow between (N.W.) the town of Thun (q.v.) and (E.) the plain on which Interlaken (q.v.) is built between this lake and that of Brienz. It is 11½ m. in length, 2 m. in width, and its maximum depth is 712 ft., while its area is 18½ sq. m., and its surface is 1837 ft. above sea-level. Most splendid views of the great snowy peaks of the Bernese Oberland range are obtained from the lake, while the beauty of its shores renders it a formidable rival in point of picturesque ness to the Lake of Lucerne. Its chief feeder is the Kander (swollen shortly before by the Simme), which in 1714 was diverted by a canal into the lake (south-western end). On or above the south-western shore (along which runs the railway from Thun to Interlaken, 17½ m.) are Spiez (a picturesque village with an ancient castle, and the starting-point of railways towards the Gemini and Montreux) and Aeschi (admirably situated on a high ridge). On the other shore of the lake are Oberhofen and Gunten (above which is Sigriswil), and Meriligen, while above the lake, near its east end, are the wooded heights of St Beatenberg, well known to summer visitors. The first steamer was placed on the lake in 1815. (W. A. B. C.)

THUNBERG, KARL PETER (1743–1828), Swedish naturalist, was born at Jönköping on the 11th of November 1743, and became a pupil of Linnaeus at the university of Upsala. After graduating in medicine there in 1770 he obtained an appointment as surgeon in the Dutch East India Company, and sailed to the Cape of Good Hope in 1772. He spent three years there, and then went to Japan, where he remained till 1776, engaged in making collections of plants. On his return in 1779 he visited England, and made the acquaintance of Sir Joseph Banks. Thunberg was appointed to the professorship of botany in 1784. He published his Flora japonica in 1784, and in 1788 he began to publish his travels. He completed his Prodromus plantarum in 1800, his Icones plantarum japonicarum in 1805, and his Flora capensis in 1813. He published numerous memoirs in the transactions of many Swedish and other scientific societies, of sixty-six of which he was an honorary member. He died near Upsala on the 8th of August 1828. A genus of tropical plants (Thunbergia), of the natural order Acanthaceae, which are cultivated as evergreen climbers, is named after him.

THUNDER, the noise which accompanies or follows a flash of lightning, due to the disturbance of air by a discharge of electricity (see LIGHTNING; ATMOSPHERIC ELECTRICITY and METEOROLOGY). The Old English word is thaner, also the name of the Scandinavian god Thor (q.v.), which is cognate with Dutch donder, German Donner. The root is than-, Indo-European tan-, cf. Latin tonare, teniru. This root is apparently another form of stam, as in skr. stam, to sound, thunder, Gr. στηνησ, to grunt, Eng. "stam.

THUN-HOHENSTEIN. The family of Thun-Hohenstein, one of the wealthiest of the Austrian nobility, which has for more than 200 years settled at Tetschen, in Bohemia, has given several distinguished members to the Austrian public service. Of the three sons of Count Franz, the eldest, FRIEDRICH (1810–1881), entered the diplomatic service; after holding other posts he was in 1850 appointed president of the restored German Diet at Frankfort, where he represented the anti-Prussian policy of Schwarzenberg, and often came into conflict with Bismarck, who was Prussian envoy. He was afterwards ambassador at Berlin and St Petersburg. After his retirement from the public service in 1863 he supported in the Bohemian Landtag and the Austrian Reichsrat the federal policy of his brother Leo. In 1879 he was made hereditary member of the Upper House. In this position he was on his death, on the 24th of September 1881, succeeded by his eldest son FRANZ ANTON (b. 1847). Like the rest of his family, he belonged to the Federalist party, and his appointment in 1885 as governor of Bohemia was the cause of grave dissatisfaction to the German Austrians. He took a leading part in the negotiations of 1860 for the Bohemian settlement, but the elections of 1891, in which the young Czechs who were opposed to the feudal party gained a decisive victory, made his position a very difficult one. Contrary to expectation, he showed great energy in suppressing disorder; but after the proclamation of a state of siege his position became untenable, and in 1895 he had to resign. On the resignation of Badeni in 1896 he was made minister president, an office which he held for little more than a year, for, though he succeeded in bringing to conclusion the negotiations with Hungary, the support he gave to the Czechs and Slovenians increased the opposition of the Germans to such a degree that parliamentary government became impossible, and at the end of 1899 he was dismissed.

The third son of Count Franz, LEOPOLD or LEO (1811–1888), was one of the leading Austrian statesmen. After studying at the university of Prague he travelled through Europe, and among other countries he visited England, where he became acquainted with James Hope (afterwards Hope-Scott) and other leaders of the Tractarian party. He was much affected by the romantic
movement and the Ultramontane revival, and after his return home interested himself greatly in the revival of Czech language and literature and the growth of the Bohemian national feeling. He formed a personal friendship with Palacky and others of the Czech leaders; he helped in the foundation of schools in which Czech should be taught, and set himself to acquire some knowledge of the language. He was also interested in prison reform, on which he wrote, and other philanthropic work. After serving under Stadion in Galicia, he was in 1848, after the outbreak of the revolution, appointed president of the administration and acting Stadthalter in Bohemia. He had scarcely entered on his duties when the rebellion of June broke out in Prague. In order to avoid bloodshed, he went down to the insurgents on the barricade, but was seized by them, imprisoned, and for some time his life was in danger. On his release he vigorously supported Windsichgrätz, who was in command of the troops, in the restoration of order, but thereby lost his popularity and was superseded. He still defended the Bohemian national movement, and in one of his writings laid down the principle that nationality was one of the greatest and first claims of the people, and was the controlling force of the state. Notwithstanding this, in 1849 he accepted the office of minister of religion and education, which he held in 1850 under the autocratic and centralizing administration of Schwarzenberg and Bach. At first he threw himself with great energy into the task of building up an adequate system of schools. He summoned experienced teachers, Protestant as well as Catholic, from Germany, established middle and higher schools in all parts of the empire, superseded the antiquated textbooks and methods of instruction, and encouraged the formation of learned societies, for the growth of a professional spirit and independence among the teachers. It is noticeable that at this time he insisted on the use of German in all schools of higher education. As minister of religion he was to a certain extent responsible for the concordat which again subjected the schools to the control of the Church: to a certain extent he thereby undid some of his work for the extension of education, and it was of him that Grillparzer said, "I have to announce a suicide. The minister of religion has murdered the minister of education." But during his administration the influence of the church over the schools was really much less than, by the theory of the concordat, it would have appeared to be. The crisis of 1860, by which the office he held was abolished, was the end of his official career; for the rest of his life he was very prominent as the leader of the Federalist party in Bohemia. His high social position, his influence at court, his character, as well as his undoubted abilities and learning, not often in Austria found in a man of his rank, gave him great influence. He supported the claims of Bohemia to a full autonomy; he strongly attacked both the February constitution and the Ausgleich with Hungary; what he desired was a common parliament for the whole empire based on a settlement with each one of the territories. With the old Czechs he refused to recognise the constitution of 1867; he helped to draft the declaration of 1868 and the fundamental articles of 1871, and took a leading part in the negotiations during the ministry of Potocki and Hohenwar. In order to found a strong Conservative party he established a paper, the Vaterland, which was the organ of the Clerical and Federalist party. It is needless to say that he protested against the ecclesiastical legislation of 1867 and 1873. He married in 1847 the countess Clâm-Martinc, but there was no issue of the marriage. He died in Vienna on the 17th of December 1888.

See the very full article by Freuchenberg in the Biographie, which superseded his earlier biography. (J. W. He.)

THURET, GUSTAVE ADOLPHE (1817-1873), French botanist, was born in Paris on the 23rd of May 1817. He came of an old Huguenot family, which had sought refuge for a time in Holland after the revocation of the Edict of Nantes. A trace of Dutch influence still persists in the pronunciation of the family name in which the final t is sounded. Thuret's mother was brought up in England; English was the first language that he learnt, and he appears to have retained strong sympathies with Great Britain throughout life. As a young man he studied for the law; in his leisure time he was an ardent musician, and it was from a musical friend, de Villers, that he received, in 1837, his first initiation into botany. Beginning simply as a collector, he soon came under the influence of Joseph Decaisine (1809-1882), whose pupil he became. It was Decaisine who first encouraged him to undertake those botanical studies which were to become the chief work of his life. Thuret twice visited Constantinople in company with the French ambassador, M. de Pontois, and was for a time attached to the French embassy there. His diplomatic career, though of short duration, gave him a valuable opportunity of studying the Oriental flora. After travelling in Syria and Egypt in the autumn of 1841, he returned to France. Giving up his intention of entering the civil service, he retired to his father's country house at Rentilly, and thenceforth devoted himself to scientific research. He had already, in 1840, published his first scientific paper, "Notes sur l'antherè de Chara et les animalcules qu'elle renferme," in which he first accurately described the organs of motion of the "animalcules" or spermatozoïds of these plants. He continued his studies of the zoözoïds of such cells of algae and other Cryptaephyrae, and the exact knowledge of these remarkable motile stages in vegetable life is largely due to his labours. He spent a great part of his time, up to 1857, on the Atlantic coast of France, assiduously observing the marine Algae in their natural habitat and at all seasons. In conjunction with his friend Édouard Borne, he became the recognized authority on this important group of plants, of which the two colleagues acquired an unrivalled knowledge. Their work, while remarkable for taxonomic accuracy, was more especially concentrated on the natural history, development and modes of reproduction of the plants investigated. The discovery of sexual reproduction in seaweeds is almost wholly the work of these two men. The researches on the fecundation of the Fucaceae were published by Thuret in 1853 and 1855; the complicated and difficult question of the sexual reproduction in Florideae was solved by the joint work of Thuret and Borne (1867). These great discoveries—of far-reaching biological significance—stand out as the chief, but every group of marine Algae was elucidated by the researches of Thuret and his colleague. There are few scientific authors whose work has so completely stood the test of subsequent investigation and criticism. Thuret's style in expounding his results was singularly clear and concise; he was a man of wide education, and possessed the power of expressing his ideas with literary skill. Unfortunately, much of his best work remained unpublished during his life. A portion of the material accumulated by himself and his colleague was embodied in two magnificent works published after his death—the Notes algologiques (1876-1880), and the still fuller Études physiologiques (1878). These volumes, as well as earlier memoirs, are illustrated by drawings of unequalled accuracy and beauty by the hand of the artist Ricour, whom Thuret employed. In 1857 Thuret removed to Antibes on the Mediterranean coast, where, on a once barren promontory, he established a botanical garden which became famous throughout the scientific world. Since his death the Antibes establishment has been placed at the disposal of botanical workers as an institute for research. Thuret died suddenly, while on a visit to Nice, on the 10th of May 1875, when he had scarcely completed his fifty-eighth year. He was a man of considerable wealth, who devoted his money as freely as his time and labour to the advancement of science, but his high reputation rests on the brilliancy of his personal investigations.

The best and fullest account of Thuret's career is that by his friend and fellow worker Borne, published in the Annales des sciences naturelles for 1876. An English notice of his life, by Professor W. G. Farlow, will be found in the Journal of Botany for the same year. (D. H. S.)

THURGAU (Fr. Thurgovie), one of the cantons of north-eastern Switzerland, bordering on the Lake of Constance and the Rhine as it issues from that lake. Its total area is 399-9 sq. m., of which 326-9 sq. m. are reckoned as "productive" (forests covering 69-3 sq. m. and vineyards 4-4 sq. m.); of the "unproductive"
Thurible

portion most (593 sq. m.) consists of the cantonal share of the Lake of Constance. The canton is partly made up of the central portion of the valley of the Thur (which rises in the Toggenburg), with its affluent the Murg, and partly of the level stretch along the west shore of the Lake of Constance and left bank of the Rhine. Low ranges of wooded hills separate the lake from the Thur valley and the latter from that of the Murg, as well as from the cantons of Zürich and of St. Gall, the highest point in the canton being situated at its southern extreme. The area is much increased by the donation of the 13th century, of 1272, Hörnli (1727 ft.), itself wholly in Zürich. The small outlying district of Horn is an "enclave" in the canton of St. Gall, because it was acquired in 1463 by the bishop of Constance, who incorporated it with the bailiwick of Arbon, the fate of which it has followed. In 1798 the lower portion of the Stammheim glein was given to Zürich, as well as the Diessenhofen region to Schaffhausen, but the latter region came back to Thurgau in 1800. The main railway line from Winterthur to Romanshorn (with a branch to St. Gall) runs right through the canton, while on its north edge the direct line along the left bank of the Rhine from Constance to Schaffhausen. A network of well-made roads traverses the canton in every direction, some of them being now served by public motor cars. It is a prosperous region, the population being mainly engaged in agriculture, and in cotton-spinning, which is often combined with it at home. The orchards are so splendid that Thurgau has been called "the garden of Helvetia." The vineyards produce a number of highly esteemed wines (the best known is the red Bachtobler), which are said to retain their strength for eight or ten years, this being attributed to the influence of the east wind to which the vineyards are much exposed. In 1800 the population was 11,221, of whom 119,845 were German-speaking, 18,677 Italian-speaking, and 332 French-speaking, while there were 17,210 Protestants, 33,824 Romanists and 113 Jews. Its capital is Frauenfeld (q.v.), while other important places are Arbon (pop. 5,677), Kreuzlingen (1,752), practically a suburb of Constance, and Romanshorn (q.v.), the chief port of the canton on the Lake of Constance. Till 1814 it was in the diocese of Constance, and since 1828 in that of Basel. The canton is divided into eight administrative districts, which comprise 212 communes. In 1869 the very advanced College of Constance was adopted, by which the "initiative" (or right of 250 electors to propose a law to the cantonal assembly to take any subject into consideration), and the "obligatory referendum," taking place twice a year (by which all laws passed by the cantonal assembly, and all financial resolutions involving a capital expenditure of 50,000 francs or an annual one of 10,000, must be submitted to a popular vote), were introduced. The cantonal government consists of a legislative assembly or Grossrat (one member to every 250 electors, or fraction over 125) and a Regierungsrat or executive council of five members, both elected directly by the people and holding office for three years; 3,000 electors can at any time call for a popular vote on the question of the dismissal of either one or the other. Further, to show the very democratic character of the (1869) constitution, it may be added that members of both houses of the Federal assembly are in Thurgau elected directly by the people, and hold office for three years. The "communes" in Thurgau are of no less than eleven or twelve varieties. The division of the lands, &c., of the old "burgher communes" between them and the new communes, consisting of all residents (with whom political power rests), was carried out (1572) in all the 212 communes; but there are still 38 guilds or corporations with special rights over certain fiefs, &c.

The Thurgau originally took in all the country, roughly speaking, between the Reuss, the Lake of Lucerne, the Rhine and the Lake of Constance; but many smaller districts (Zürichgau, Toggenburg, Appenzell, St Gall) were gradually carved out of it, and the county was reduced to about the size of the present canton when in 1764 it passed by the gift of the last count of Kyburg to his nephew Rudolph of Habsburg, chosen emperor in 1723. In 1415 the count, Duke Frederick of Austria (a Habsburg), was put under the ban of the empire by the emperor Sigismund for having aided Pope John XXIII, to escape from Constance, and the county was overrun, Sigismund in 1417 mortgaging to the city of Constance the appellate jurisdiction in all civil and criminal matters ("Landgericht" and "Bluttarn") arising within the county, which he had declared to be forfeited in consequence of Frederick's conduct. In 1460 some of the Confederates, now becoming very eager for conquests, overran and seized the county. Winterthur was saved, but in 1461 Frederick's son, Duke Sigismund, had perforce to cede the county to the Confederates. Henceforth it was ruled as a "subject district" by seven members of the League—Bern occupied in the west, not being admitted to a share in the government till 1712, after one of the wars of religion. It was only in 1499 that the Confederation (then consisting of ten members) obtained from the emperor (the claims of Constance being passed over in silence) the supreme jurisdiction, through the mediation of the duke of Milan, but there were still 105 minor jurisdictions belonging to various lords spiritual (particularly the bishop of Constance) or secular (the abbots of Reichenau) and temporal, which went on till 1798 and greatly limited the power of the Confederates. Thurgau had hoped, but in vain, to be admitted in 1499 a full member of the Confederation.

At the time of the Reformation many of the inhabitants became Protestants, and bitter quarrels ensued between the Protestant and Catholic (the latter having a large majority) members of the Confederation who had rights over Thurgau, with regard to the toleration of the new doctrines in the "subject districts," such as Thurgau. By the first peace of Kappel (1529), the majorit in each "commune" was to settle the religion of the "subject commune"; but by the second (1531, after Zwingli's death) both religions were to be allowed side by side in each "commune." Thurgau thus became a "canton of parity," as it is to this day. Its rulers, however, continued to watch other each very closely, and Killian Kesslerling, one of the chief military commanders in Thurgau, was in 1633, on suspicion of having connived at the advance of the Swedes through Thurgau on Constance, seized by the Catholic cantons and severely punished. In 1798 Thurgau became free, and was one of the nineteen cantons of the Helvetic republic, being formally received as the other, "subject of St. Gall" (and the abbey of Reichenau) and temporal, which went on till 1798 and greatly limited the power of the Confederates. Thurgau had hoped, but in vain, to be admitted in 1499 a full member of the Confederation.

portable vessel in which burning incense (g.s.) can be carried.

The censer, to use the more general term, is a vessel which contains burning charcoal on which the aromatic substances to be burned are sprinkled.

The early Jewish portable censer would seem to have been a bowl with a handle, resembling a ladle. A similar form was used by the ancient Egyptians long prior to the Jewish use. There are various representations on the monuments; in some the censer appears as a small cup or bowl held by a human hand to which a long handle is attached on which is a small box to hold the incense. The Greek and Roman censers (θυραιρός and ταφύραμα or taphuríboum) are of different shape. They are small portable braziers (foculis) of bronze or sometimes of silver and of highly ornate design. One type took the form of a candelabrum with a small flat brazier on the top. They were carried in processions and were lifted by cords. Terra cotta censers have also been found of a similar shape. The censers or thuribles in Christian usage have been specially adapted to be swung, though there are in existence many early specimens of heavy weight and made of gold or silver which were obviously not meant to be used in this way and have handles and not chains. The thurible, the procession; peace was made with Cretona, and also, after a period of war, with Tarentum, and Thurii rose rapidly in power and drew settlers from all parts of Greece, especially from Peloponnesus, so that the tie to Athens was not always acknowledged. The oracle of Delphi determined that the city had no founder but Apollo, and in the Athenian War in Sicily Thurii was at first neutral, though it finally helped the Athenians. Thurii had a democratic constitution and good laws, and, though we hear little of its history till in 390 it received a severe defeat from the rising power of the Lucanians, many beautiful coins testify to the wealth and splendour of its days of prosperity. In the 4th century it continued to decline, and at length called in the help of the Romans against the Lucanians, and then in 282 against Tarentum. Thenceforward its position was dependent, and in the Second Punic War, after several vicissitudes, it was Populated and plundered by Hannibal (204). In 194 a Roman colony was founded, with Latin rights, known for a time as Copiae, but afterwards by the old name of Thurii. It continued to be a place of some importance, the situation being favourable and the region fertile, and does not seem to have been wholly abandoned till the middle ages. The site of the original Greek city is not accurately known, though that of the Roman town, which probably though not certainly occupied the same site, is fixed by insinuative ruins as being 4 m. to the east of Terranova di Sibari, and as occupying an area some 4 m. in circuit. The tombs found in 1879-1880 (see Sybaris) lie a little to the east of the site.

The Thurii-Thuringia is strictly designated only that district in upper Saxony that is bounded by the Werra, the Harz Mountains, the Saale and the Thuringian Forest; in common parlance, however, it is frequently used as equivalent to the Thuringian states, i.e. the group of small duchies and principalities lying between Prussia, Hesse-Nassau, Bavaria and the kingdom of Saxony. Such Thuringian states are Saxe-Weimar-Eisenach, Saxe-Coburg-Gotha, Saxe-Meiningen, Saxe-Altenburg, Schwarzburg-Rudolstadt, Schwarzburg-Sondershausen, and the two principalities of Reuss, all of which are separately described. Besides these, the term Thuringia also, of course, includes the various "ex-Prussian" Saxony, Bavaria and Bohemia which lie embedded among them.

The Thuringian are first mentioned by Vegetius Renatus about A.D. 420 when they occupied the district between the Harz Mountains and the Thuringian Forest. They were probably descended from the Hermunduri, a Suevic people referred to by Tacitus as living in this region during the 1st century. They were tributary to Attila the Hun, under whom they served at the battle of Châlons in 497. They were governed by kings, whose realm in the early 6th century touched both the Danube and the lower Elbe. At this time King Basin divided Thuringia among three sons: first, Heraklaz, who obtained sole possession by the help of Theuderich I., king of Austrasia, but having refused to pay the price he had promised for this assistance, was defeated by Theuderich in a series of battles and murdered by him in 531. The northern portion of the kingdom was given to the Saxons who had joined him against Hermannfried; the southern part was added to Austrasia; and the name of Thuringia was confined to the district bounded by the Harz Mountains, the Werra, the Thuringian Forest and the Saale. It remained under the direct rule of the Frankish kings until 954, when Radulf was appointed duke of the Thuringians by King Dagobert I. Radulf made himself practically independent of the Franks, in spite of an attack made on him by Sigebert III., king of Austrasia. About this time the conversion of the Thuringians to Christianity was begun by British missionaries and continued by St Boniface, who founded a bishopric at Erfurt. They were again reduced to dependence on the Franks by Charles Martel, who abolished the office of dukedom and divided the country among Frankish counts. About 804 Charlemagne, in order to defend the line of the Saale against the Slavs, founded the Thuringian mark, while the monastery was practically coextensive with the former duchy. In 849 King Louis the German recognized Thukulf as duke (dux Sorabitë limitis), and some of his successors bore the title of margrave until the death of Burkhard in 908, when the country was seized by Otto the Illustrious, duke of Saxony. Thuringia was retained by Otto's son and successor, Henry I. the Fowler, in spite of the opposition of the German king, Conrad I., and ceased for a time to enjoy a separate political existence. It appears to have been united with Meissen for some time, and this was certainly the case from 1046 to 1067, when both countries were ruled by William and Otto, counts of Weimar. During the 11th century the Thuringians refused to pay tithes to Siegfried, archbishop of Mainz, and this was probably one reason why they joined the rising of the Saxons against the emperor Henry IV. in 1073.

About this time a new dominion was founded by Louis the Bearded, who by purchase, gift or marriage obtained several counties in Thuringia. These passed on his death in 1056 to his son Louis the Springer (d. 1123), who took part in the Saxon risings against the emperors Henry IV. and Henry V., built the castle of the Wartburg near Eisenach, which was the residence of his family for nearly 200 years, and remained in close alliance with the emperors. Louis the Springer paid tribute to the emperors of Reinhardsbrunn, where as a monk he passed his last days. His son Louis was appointed landgrave of Thuringia in 1130 by the emperor Lothair II.; by his marriage with Hedwig of Gudensberg in 1137 he obtained a large part of Hesse. He was succeeded in 1140 by his son Louis II. the Hard, who married Judith, a sister of the emperor Frederick I., and on his behalf took a leading part in the opposition to his powerful neighbour Henry the Lion, duke of Saxony. In 1172 he was succeeded

See F. Lenormant, La Grande-Grece i, 317 (Paris, 1881). (T. As.)
by his son Louis III, the Pious. He acquired the Saxon palatinate in 1179, on the death of Adalbert, count of Sommerschenburg, went to Italy to assist Frederick I. in 1157, joined in the war against Henry the Lion in 1180, and distinguished himself at the siege of Acre in the Third Crusade, on the return from which he died at Cyprus in 1180. He was succeeded by his brother Hermann I., during whose reign Thuringia suffered greatly from the ravages of the adherents of Philip, duke of Swabia, and also from those of his rival Otto of Brunswick. The next landsgrave (1217-1257) was his son Louis IV. the Saint, who succeeded his father Hermann, and entered into hostile relations with Hungary, and acted as guardian for his kinsman Henry III. the Illustrious, margrave of Meissen. This Louis, who is celebrated in story, destroyed many robber-castles in Thuringia and died at Otranto while accompanying the emperor Frederick II. on crusade. The next ruler was Henry Raspe, who made himself regent on behalf of his nephew Hermann II. from 1227 to 1238 and in 1241 succeeded his former ward as landsgrave. Henry was appointed regent for King Conrad IV., but he soon transferred his allegiance from the emperor to Pope Innocent IV., and the latter in 1246 was chosen as the new king of Thuringia. The son of the latter, Henry VII., was in turn landsgrave of Thuringia, and was married to his son Albert the Degenerate, who sold it in 1293 to the German king Adolph of Nassau for 12,000 marks of silver. Albert's sons Frederick the Undaunted and Dietrich contested this transaction, and the attempts of Adolph and his successor Albert I. to enforce it led to the infliction of great hardships upon the Thuringians. Frederick defeated Albert decisively and in 1314 was formally invested with Thuringia by the emperor Henry VII. His son Frederick II. the Grave (1333-1349) consolidated the power of his dynasty against rebellious vassals and the neighbouring counts of Weimar and Schweizburg. His son Frederick III. the Strong (1349-1381) and his grandson Balthasar (1381-1406) further extended their dominion by marriage and conquest, and the latter of these founded the university at Erfurt (1392). Balthasar's son, Frederick the Peaceful, became landsgrave in 1406 but left the government largely to his father-in-law Günther, count of Schwarzburg. He died childless in 1440, and Thuringia then passed to the electoral dynasty of Saxony. After a joint rule by Frederick II. and his brother William, the latter in 1445 became sole landsgrave as William III. and died without sons in 1452. In 1455 his nephews and heirs Albert and Ernest made a division of their lands, and Thuringia was given to the Ernestine branch of the family of Wettin, with which its subsequent history is identified (see SAXONY).

Wegele and R. von Lillencrutz (Jena, 1854-1859) and Regesta diplomatum mediæ aevi Thüringiae, published by O. Dobenecker, vols. i. and ii. (Jena, 1896-1900).

THURINGIAN FOREST—THURLOE, a range of hills in Germany, extending in an irregular line from the neighbourhood of Eisenach in the N.W. to the Lobenstein Kulm on the Bavarian frontier on the S.E. On the S.E. it is continued directly by the Frankenwald mountain to the Fichtelgebirge, while on the N.E. it approaches the Harz Mountains, and thus takes its place in the great Sudetic chain of central Germany. The length of the Thuringian chain is 70 m., and its breadth varies from 6 to 22 m. It nowhere rises into peaks, and only a few of its rounded summits reach 3000 ft.; the successive hills form a continuous comb; the north-west slopes are precipitous and seamed with winding gorges. This range encloses many charming valleys and glens; the most prominent feature of its scenery is formed by the forests, chiefly of pines and firs. The north-west part of the system is the loftier and the more densely wooded as well as the more beautiful; the highest summits are the Grosser Beerberg (3225 ft.), Schneekopf (3200 ft.) and the Waldstein (3257 ft.). The crest of the Thuringian Forest, from the Werra to the Saale, is traversed by the Rennsteig or Rainsteig, a broad path of unknown antiquity, perhaps referred to in a letter of Pope Gregory III. dated 738. The name means probably "frontier-path"; and the path marks in fact the boundary between Thuringia and Franconia. It may be also regarded as part of the boundary line between north and south Germany, for dialect, customs, local names and costume are different on the two sides. The rocks are largely volcanic, the stratification being complex. The mineral resources have been nearly exhausted, but the district is an important centre of small industries (glassware, earthenware, meerschaum-ware, iron castings and toys being among its principal products) and a favourite resort for tourists.

THURLES, a market town of Co. Tipperary, Ireland, pleasantly situated on the Suir, and on the main line of the Great Southern & Western railway, 87 m. S.W. of Dublin. Pop. (1901), 4411. Thurles is the seat of the Roman Catholic archdiocese of Cashel; and the cathedral of St Patrick is a beautiful building. The town is the seat of other important Catholic establishments, including an Ursuline convent; a Presbyterian convent; St. Patrick's Catholic College (1859) for ecclesiastical students, where was held in 1850 the synod of Thurles; and an establishment of Christian Brothers, who devote themselves to the instruction of boys on the Lancastrian method. The town has a considerable agricultural and retail trade, and there is a monthly horse fair largely attended by English and continental buyers. Thurles is governed by an urban district council.

Originally the town was called Duras O'Fogarty. In the 10th century it was the scene of a defeat of the Irish by the Danes. A preceptory was founded here by the Knights Templars, who possessed themselves of a castle, of which there are remains, erected early in the 13th century. A castle was subsequently erected by James Butler, first lord patrician of Tipperary, of which the keep collapsed in 1868. There were several other strongholds in the vicinity. South-west of the town, at a distance of 33 m., stands the Cistercian abbey of Holy Cross, one of the finest ruins in Ireland. It was founded by Donnell O'Brien, king of Thomond (1176-1194); and owes its foundation and name to the presentation to his family of a portion of the true Cross, which attracted numerous pilgrims. The shrine of this relic is in the Ursuline convent at Blackrock, Co. Cork. The ruins, beautifully placed on the bank of the river, embody a cruciform church, transitional Norman in style, and exhibiting the carving of the period in its highest development. There is a fine Perpendicular tomb in the choir. A large portion remains of the adjoining buildings, including chapter-house, sacristy, cloisters and dormitory.
of Oliver Thurlow, John, through whose interest he was appointed a
secretary to the parliamentary commissioners at Uxbridge in
January 1645. He was admitted to Lincoln’s Inn in 1647; and
in March 1648 he received the appointment of receiver of the
custor’s fines, worth £350 a year. He took no part in the
subsequent historical events or in the king’s death. In March
1651 he attended St John and Sir Walter Strickland as secretary
in the Court of Carousal and in the same year he was appointed
secretary to the council of state, being apparently
also elected a member thereof about the same time. His duties
included the control of the intelligence department and of
the posts, and his perfect system of collecting information and
success in discovering the plans of the enemies of the administration
astonished his contemporaries. By his means, it was said,
“Cromwell carried the secrets of all the princes of Europe at
his girdle.” On the 10th of February 1654 he was made a
bencher of Lincoln’s In.
In the parliaments of 1654 and of 1656 he represented Ely; he was appointed a member of Clarendon’s
second council in 1657; and in 1658 was raised to the
peerage on the Charterhouse in the same year; and in 1658 became chancellor of
Glasgow University. Thurlow was elected to Cromwell as a
man and admired him as a ruler, and Cromwell probably placed
more confidence in the secretary than in any one of those
who surrounded him. Thurlow, however, by no means directed
Cromwell’s policy. He was in favour of the protector’s assump-
tion of the royal title, and was opposed to the military party
who obtained the ascendancy. After Oliver’s death he sup-
ported Richard Cromwell’s succession and took a prominent part
in the protectorate, by his advice and direction all international
transactions, and by his exhortations and courtesies to
foreigners. His relations with the Senate in Rome, and his
renunciation of power in 1659, as member for Cambridge University.
Attacked by the republicans on the ground of arbitrary imprisonments and
transportations during the Protectorate, he succeeded in vindicat-
ing his conduct; but the breach between the army and the
parliament, and the ascendancy obtained by the former, caused
his own as well as Richard’s downfall. Nevertheless, being
indispensable, he was reappointed secretary of state on the
27th of February 1660. He appears to have steadily resisted
the Restoration, and his promises of support to Hyde in April
inspired little confidence. On the 15th of May 1660 he was
arrested on the charge of high treason, but was released on the
20th of June, subject to the obligation of attending the secretary of
state “for the service of the state whenever they should
require.” He subsequently wrote several papers on the subject
of foreign affairs for Clarendon’s information. He died on the
21st of February 1668 at his chambers in Lincoln’s Inn, and is
buried under the chapel there. Thurlow twice married, and by his second wife Anne, daughter of Sir John Lyttoce of
East Moulsey in Surrey, he had four sons and two daughters.

His extensive correspondence, the originals of which are in the
Bodleian Library at Oxford and the British Museum (Add. MSS.
4156, 4157, 4158), is one of the chief sources of information for the
period. A portion was published with a memoir by T. Birch
in 1742, and other correspondence is printed in R. Vaughan’s
lectione of Oliver Cromwell (1836). See also Die Politik des Pro-
tекторates Oliver Cromwell in der Auffassung und Thätigkeit . . . des
Staatssekretärs John Thurlow, by Sigismund, Freiherr von Bährillos-
hausen (1899); Eng. Hist. Rev., xiii, 527 (Thurlow and the post
office); Notes and Queries, 11th series, vol. viii. p. 83 (account of his
death); A Letter to a Friend . . . on the Publication of Thurlow’s
State Papers (1742); Clarendon’s History of the Rebellion; Gardiner’s
History of the Commonwealth.

THURLOW, EDWARD THURLOW, 1ST BARON (1731–1806),
English lord chancellor, was born at Bream Ash, in the county of
Norfolk, on the 6th of December 1731. He was the eldest
son of the Rev. Thomas Thurlow. He was educated at a private
school and at the grammar school of Canterbury, where he was
considered a bold, refractory, clever boy. In 1743 Thurlow
entered Caius College, Cambridge, but an act of insubordination
necessitated his leaving Cambridge without a degree (1751).
He was for some time articled to a solicitor in Lincoln’s Inn
along with the poet Cowper, but in 1754 was called to the bar
at the Inner Temple, and subsequently went on the western
Robinson v. The Earl of Winchelsea (1758) Thurlow came into
collision with Sir Fletcher Norton, afterwards 1st Baron Grantley
(1716–1780), then the terror of solicitors and the tyrant of the
bar, and put down his arrogance with dignity and success. From
this time his practice increased rapidly. In 1761 he was made
a king’s counsel, through the influence of the duchess of Queens-
berry. In 1762 he was elected a bencher of the Inner Temple. 
Thurlow now with some hesitation entered himself into the
ranks of the Tory party. In 1766 he became member for Tam-
worth. In 1769 the Douglas peerage case came on before the
House of Lords, and Thurlow, who had drawn the plead-
ings some years before (Notes and Queries, 3rd series, vol. iii.
p. 122), led for the appellant in a speech of great analytic power.
In 1770, as a recognition of his defence in the previous January
of the expulsion of Wilkes, Thurlow was made solicitor-general
on the resignation of Dunning, and in the following year, after
he had enhanced his reputation with the government by attack-
ing the rights of juries in cases of libel (Rex v. Miller, 20 St.
Tr. 370–806) and the liberty of the press (16 Partly. Hist.
174). Thurlow, acting as the king’s adviser, and in accordance with
his public life as factious as his youth had been daring. His
hatred of the American colonists, and his impudent assertion
that as attorney-general he might set aside by scire facias as
forfeited every charter in America (debate on the American
Prohibitory Bill, 18 P.H. 999); his speech in aggravation of
punishment in the case of Horne Tooke (20 St. Tr. 777–783),
when he alleged that the prisoner ought to be pilloried, because
imprisonment was no penalty to a man of sedentary habits
and a fine would be paid by seditious subscription; and his
opposition to the measures of the ministry in the Jacobites.
In 1778 Thurlow became lord chancellor and Baron
Thurlow of Ashfield, and took his seat in the House of Lords,
where he soon acquired an almost dictatorial power. He
opposed the economical and constitutional reforms proposed
by Burke and Dunning. Under Rockingham he clung to the
chancellorship, while conducting himself like a leader of
the opposition. To the short-lived ministry of Shelburne he gave
consistent support. Under the coalition of Fox and North (April
to December 1783) the great seal was placed in commission,
and Lord Loughborough was made first commissioner. But
Thurlow, acting as the king’s adviser, and in accordance with
his wishes, harassed the new ministry, and ultimately rejected
the rejection of Fox’s India Bill (24 P.H. 226). The coalition
was at once dissolved. Pitt accepted office, and Thurlow again
became lord chancellor (Dec. 23, 1783). At first he supported
the government, but soon his overbearing temper asserted itself.
Imprudently relying on the friendship of the king, and actuated
by scarcely disguised enmity to Pitt, Thurlow passed rapidly
from occasional acts of hostility to secret disaffection, and finally
to open revolt. He delivered himself strongly against a bill,
introduced without his privy, for the restoration to the heirs
of attainted owners of estates forfeited in the Jacobite rebellion
of 1745. Partly to please the king and queen, partly from dislike
to Burke, and partly perhaps from a real belief in the ground-
lessness of the accusation, he supported Warren Hastings on
every occasion “with indecorous violence.” His negotiations
with the Whigs during the discussion of the Regency Bill
(1788–Feb. 19, 1789) were designed to secure his seat on the
woolsock in the event of Fox being called to power. The climax
was reached in 1792, when he attacked Pitt’s Bill “to establish
a sinking fund for the redemption of the national debt,” not on
account of the economic objections to which it was liable, but
on the trivial ground that it was an unconstitutional attempt
to bind further parliaments. The bill was carried, but only by
a narrow majority, and Pitt, feeling that co-operation with such
a colleague was impossible, insisted successfully on his
dismissal (June 15, 1792). The ex-chancellor, who had a few days
before been created Baron Thurlow of Thurlow, with remainder to
his brothers and their male descendants, now retired into private
life, and, with the exception of a futile intrigue, under the auspices
of the prince of Wales, for the formation of a ministry from
which Pitt and Fox should be excluded, and in which the earl of
Motra should be premier and Thurlow chancellor (1797), finally
abandoned hope of office. In 1795 he opposed the Tennis and Sedition bills without success. In 1801 he spoke on behalf of Horne Tooke—now his friend—when a bill was introduced to render a priest in orders ineligible for a seat in the House of Commons. He died at the age of thirty-five in the House of Commons, and was burried at the nearby church.

Sir Thomas was never married, but left three natural daughters, for whom he made a handsome provision. The title descended to his nephew, son of the bishop of Durham.

Lord Thurlow was a master of a coarse caustic wit, which habitually expressed itself with the force and vividness of the public press. He was also gifted in his profession, and the great legal merits of Eldon Thurlow's personal appearance were striking. His dark complexion, harsh but regular features, severe and dignified demeanour, and bushy eyebrows, doubtless contributed to his professional and political eminence and provoked the sarcasm of Fox that he looked wiser than any man ever saw. Yet he was far from being an impartial judge of his own profession through his bias, and he possessed all the qualities which command success. His speeches in the trial of the duke of Kingston for bigamy (20 St. Tr. 375-455) are vigorous and statesmanlike. His charge to the Grand Jury at Dublin in 1782, and his argument for the Crown in Campbell v. Hall (30 St. Tr. 312-316) show that he might have rendered high service to the judicial literature of his country had he relied more upon his own industry and less upon the learning of Hargrave and Kenyon.

THURMAN, ALLEN GRANBERY (1813-1895), American jurist and statesman, was born at Lynchburg, Virginia, on the 13th of November 1813. In 1819 he removed with his parents to Chillicothe, Ohio, where he attended the local academy for two years, studied law in the office of his uncle, William Allen, and in 1835 was admitted to the bar, becoming his uncle's law partner. He began to take an active part in politics in 1842, and in 1843-44 was a delegate to the Democratic convention in Cincinnati, where he advocated the Wilmot Proviso. From 1851 to February 1856 he was an associate justice of the state supreme court, and from December 1854 was chief justice. He was Democratic candidate for governor of Ohio in 1857, and was defeated by Rutherford B. Hayes by a majority of less than 3000 votes; but the Democrats gained a majority in both branches of the state legislature, and Thurlow was elected to the United States Senate, where he served from 1861 until 1865 during the 46th Congress (1879-1881) as president, pro tem. Here he became the recognized Democratic leader in Congress, and was chairman of the judiciary committee. He contested the constitutionality of the Civil Rights Bill, opposed the resumption of specie payments, advocated the payment of the public debt in silver and supported the Bland-Allison Act. He introduced the Thurlow Bill, for which he was chiefly responsible, which became law in May 1878, and readjusted the government's relations with the bond-aided Pacific railways. Thurlow was a member of the Electoral Commission of 1871, and was one of the American delegates to the international monetary conference at Paris in 1881. In 1876, 1880 and 1884 he was a candidate for the presidency, and in 1888 he was nominated for vice-president on the ticket with Grover Cleveland, but was defeated in the election. He died at Columbus, Ohio, on the 12th of December 1895.

THURSDAY ISLAND, one of the smallest of the Prince of Wales group, N. of Cape York, in the Torres Strait, attached to Somerset county, Queensland, Australia. (Pop. (1901), 1534. It has an excellent harbour, Port Kennedy, and is a port of call for mail steamers and the centre of the bêche-de-mer and pearl fisheries of the Torres Strait. It is a fortified coaling station for the British navy. The neighbouring Friday Island is the quarantine and leper station for Queensland.

THURSO, a municipal and police burgh, and seaport of Caithness, Scotland. (Pop. (1901), 3723. It is situated at the mouth of the Thurso, on Thurso Bay, 21 m. N.W. of Wick, and 319 m. N. of Edinburgh by the North British and Highland railways, the most northerly town in Scotland. Coaches run daily to Mey and Wick and every day a mail-car goes to Tongue, in Sutherlandshire, about 40 m. west.

In Mac donnal Square, laid out with ornamental walls, there is a statue of Sir John Kinross. A promenade along the sands was opened in 1882. The town-hall contains a public library and museum, which possesses the geological and botanical specimens of Robert Dick (1811-1866), the "Thurso baker," as well as a large collection of northern birds. In the neighbourhood are quarries for Caithness flags, which are cut and dressed in the town. They constitute the leading export, but the trade of the port is hindered by the inconvenience of the harbour. There is, however, communication daily from Scrabster pier, 2 m. north-west, with Scapa and Stromness in Orkney (Orkneys). The train to Inverness passes through Thurso, and goes on to Inverness and Leith; and occasionally in summer with Liverpool. To the east is Thurso Castle, the residence of the Ulster branch of the Sinclairs, and near it is Harold's Tower, built over the grave of Earl Harold, once owner of half of Caithness, and half of the Orkneys and Shetlands, who fell in battle with Earl Harold the Wicked in 1090. About three-quarters of a mile west stand the ruins of the bishop's palace, which was destroyed by fire in 1222. Thurso was the centre of the Norse power on the mainland when at its height under Thorfinn (1014), and afterwards till the battle of Largs (1265). Count Thorfinn appointed his brother-in-law Orm I> for a time at Thurso and despoiled it till he was surprised and slain by Thorfinn in 1046. In the time of Malcolm II. Earl Edgar resided in the town. In 1633 it was created a burgh of barony, and was the seat of the sheriff courts of the county till they were removed to Wick in 1828.

THURSTAN, or TURSTIN (d. 1140), archbishop of York, was the son of a certain Anger, or Auger, prebendary of St. Paul's, London, and a brother of Audoen (d. 1130), bishop of Ely. He himself was a prebendary of St. Paul's, and was also a clerk (the voice of) at Winchester; once a week at York; and finally at Dunfermline, where he was once archbishop. He was installed archbishop of York in 1130, but was also murdered by the people of York. His murder was an event in the history of the archbishopric, and his death was an event in the history of York. He was a man of great learning, and a great patron of learning, and was one of the most famous archbishops of the Middle Ages. He was a man of great learning, and a great patron of learning, and was one of the most famous archbishops of the Middle Ages.

He was a man of great learning, and a great patron of learning, and was one of the most famous archbishops of the Middle Ages.
in August 1138. Early in 1140 he entered the order of the Cluniacs at Pontefract and here he died on the 6th of February 1140. Thurstan was generous to the churches of his diocese and was the founder of several religious houses.

See his life in the Fasti eboracenses, edited by J. Raine (1863).

**THYLACINE** *(Thylacinus cynocephalus).* The only known living species of this genus, though smaller than a common wolf, is the largest predaceous marsupial existing. It is confined to the island of Tasmania, although fragments of bones and teeth found in caves afford evidence that a closely allied species on the mainland of Australia already existed. The general colour of the thylacine is grey-brown, but it has a series of transverse black bands on the hinder part of the back and loins, whence the name of “tiger” frequently applied to it by the colonists. It is also called “wolf,” and sometimes, though less appropriately, “hyena.” Owing to the havoc it commits among the sheep-folds, it has been nearly exterminated in all the more settled parts of Tasmania, but still finds shelter in the more mountainous regions of the island. The female produces four young at a time. (See MARSUPIALS.)

**THYROSTRACA.** The genus *Thyrostraca* (nat. ord. Labiatae) comprises a number of fragrant aromatic undershubs, with very small leaves and whorls of small purple honey-bearing flowers in the axes of the leaves or at the ends of the branches. The common garden thyme, a native of the Mediterranean region, is *Thymus vulgaris*; the wild thyme of English banks is *T. serpyllum*. Marjoram (*Origanum*) is also closely allied. All these plants are remarkable for their essential oil, to which their fragrance is due. From this oil is produced by distillation the substance known as thymol.

**THYMOIL,** C₆H₅OH or C₆H₅(OH) (CH₃) (C₆H₅) \[ 1:3:6 \], a methylisopropylphenol isomerically with carvacrol (q.e.), is an aromatic substance found with the hydrocarbons cymene, C₆H₄(1), and thymene, C₆H₄(1) in oil of thyme (*Thymus vulgaris*) and in other essential oils, e.g. *Carum coticum*, from which it may be extracted by shaking with potassium hydroxide, filtering and precipitating the phenol with hydrochloric acid. It can be prepared from dibrom-menthol (obtained by brominating menthol in chloroform solution) by eliminating two molecules of hydrobromic acid. Thymol crystallizes in large colourless plates, which melt at 44°C and boil at 230°C. On distillation it loses its volatile constituents. Mere isolation has a strong odour of thyme and a pungent taste, and is freely soluble in alcohol, ether, chloroform or olive oil, but almost insoluble in cold water. It is a more powerful antiseptic than carbolic acid and is used in the Malacetic acid as being used for the same purposes. A saturated solution (1 in 1000 of warm water), thymol gauze and an ointment are used. Externally it is anti-parasitic, and is used in certain stages of eczema and psoriasis, and the alcoholic solution has been used in ringworm; internally it has been employed as an internal antiseptic in typhoid fever. Its chief use is as an anthelmintic to destroy the *Ankylostoma duodenale*. Thymol may colour the urine green. Thymol iodide, official in the United States, is a compound of iodine and thymol; it is also known as aristol or anidril. It was introduced as a substitute for iodine and is stated to be less toxic. *Glycyphymin* is a proprietary preparation, used in the treatment of catarrhal conditions of mucous membranes, while a mixture of naphthalene, camphor and thymol is sold under the name of thymolpin.

**THYROID** *(Gr. θυροεδής, shield-shaped, from θύρα, a door, δέσμη, and ἔσσω, form),* in anatomy, a term applied (1) to the largest of the cartilages of the larynx (see RESPIRATORY SYSTEM), (2) to one of two arteries which lie near the thyroid cartilage and gland (see ARTERIES), and (3) to the vascular ductless gland, which rests on the larynx and upper part of the trachea (see DUCTLESS GLANDS). The thyroid gland is used in medicine in two forms. *Thyroidium siccatum* is a light dull brown powder, prepared by drying the thyroid gland of a sheep. Its chief constituent is a protein known as thyroglobulin, the active principle of which contains 9-3% of iodine and 0-5% of phosphorus, and is known as idothyrin or thyroidin. The dried gland easily becomes damp and deteriorates. *Liquor thyroidei* is a pink turbid liquid made by macerating the fresh gland of a sheep with glycerin and phenol.

Thyroid gland administered to man increases the pulse rate, causes increased and unfeebled cardiac beat and leads to increased metabolism, consequently to hunger, and to a feeling of restlessness and loss of weight; it therefore reduces the body weight. Glocosuria develops from the inability of the body to ingest glucose. Overdoses of thyroid cause rapid pulse, headache and vomiting, diarrhea, and dizziness, with inanition and weakness. These symptoms are known as *thyroidism*.

Thyroid gland was introduced for the treatment of patients suffering from goitre, myxoedema and cretinism, in which effusions and degenerations of the tissues are dependent on the use of thyroid; it therefore reduces the body weight. Glocosuria develops from the inability of the body to ingest glucose. Overdoses of thyroid cause rapid pulse, headache and vomiting, diarrhea, and dizziness, with inanition and weakness. These symptoms are known as *thyroidism*.

THYROSTRACA

("Challenger" Reports, "Cirripedia," 1883, viii, 8-11.), gives a brief geological summary down to 1882. In that year J. M. Clarke (Am. Jour. Sci. and Arts, 1884) described a new species of Plumbulites (Barrande, 1872), remarking that the species in question, P. devonis, is interesting in being the first representative of fossil barnacles, and that it appears to have a new relation to the Plumbulites and Anatifopsis, as well as the Turritopsis of Woodward, being from the Upper and Lower Silurian, and Plumbulites janes (Hall and Whitt., Pal. Ohio, vol. ii.) from the Hudson River group. Since Plumbulites was a synonym of Terrulipes (not Turritopsis), the species Turritipes wrighti (Woodward, 1862), from the Upper Silurian of Dudley, did not long enjoy an isolated eminence as the oldest known cirripede. As pointed out by Dr. Bathr. (Geo. Mag. 1890, p. 149), who translated his Pygoma con- taceum, 1865, to a new genus Brachypteras (fig. 1), and a new family from the Devonian, intermediate between the Rhaetic Pollicipes and the modern Balanus. Among other fossil genera of recent instiga- tor of the Alcanides, Lepas, Rhizop. Squama, Stemnum can only be mentioned as incentives to research. Long living forms, added by Wettner to the Catalina. It may be noticed Kolelepas willei, from the Loyalty Islands (Stebbing, in Willey's Zool. Results (1900) pt. v., p. 577. This was found in a Turbo shell, occupied also by Pagonurid, and coated with Actinians. The cirripede, which has an elastic peduncle, a crested capitulum, but no valves, and the first cirri longer than the rest, are strikingly similar in external form, the name given by Wettner in place of the preoccupied Gymnolepas (Aurivillius). In the new genus Scalpellum, S. giganteum, Grun. (Trans. Zool. Soc.) is compared with S. stearnsii (fig. 2), Pilsbury, 1890, which shall be accounted the greater. The latter is found in open sea, and the former in the Baltic. Aus den Tiefen des Weltmeeres, 1900, p. 502.

The horizontal distribution of barnacles over all seas is fully explained by Darwin. The bathymetric range of sessile as well as pedunculate forms down to such depths as twelve or eighteen thousand feet—Verruca quadrangularis, Hook. 1900 fathoms; Scalpellum regium, Wyville Thomson, 2850 fathoms—is a more recent discovery. Grivel (Recherches sur l'ant. 1886) found that the species frequenting sea sur- face or shallow water, notwithstanding their feeble powers of vision, cannot live long on land. Saccocoma, which some small species, especially in the genus Discelisopus, occupy the very jaws of large crustaceans. It is generally supposed that cirripedes are confined to salt water, and, generally speaking, that in the Baltic. Peduncules larger than the base of the foot. Balanus amphitrite (Darwin?) from roots and stems of mangroves in the Congo, where, says, "it follows the mangroves as far as their vegetation extends along the stream, to six seas-miles from the mouth." Darwin notes B. improvisus as quite tolerant of water not saline. Why the Thyrostraca, so hardy, so widely dispersed and from one area to another, show such a large number of species, have made so extended and more independent incursions into fresh water remains a problem. Though the Orthiolepas australis (Taylor of Bass Strait) is certainly the only the cirripedia of a cirripede, it still shows one of the many facilities for dispersion which these creatures enjoy. A striking instance of their abundance is cited by Aurivillius (1864) from the coast of Issas, and another by Eekelaar (Dutch East Indies) observed great masses of Lepas fuscicostata forming broad belts in the North Sea. Aurivillius himself examined a humpback whale which had as many as fifty specimens of Coronula diadema on its belly, something of an oddity, for whales do not frequent this part of the sea; it is sometimes seen not only in the North Sea, but in the North Sea, and off the coast of the Yellow Sea, and the Shantung, a most unusual sight. The author has seen some species of the cirripede, especially those of the small genus Lepas, in the Baltic, where they are sometimes seen to be in great numbers, though not in large masses.

Fig. 2. Scalpellum stearnsii. (Two-thirds nat. size.)

when entirely debarred from water, it is of no great moment that abysmal forms have gradually acquired such toleration of darkness as makes their health independent of the sun. Among other singularities of the deep sea, which some small species, especially in the genus Discelisopus, occupy the very jaws of large crustaceans. It is generally supposed that cirripedes are confined to salt water, and, generally speaking, that in the Baltic. Peduncules larger than the base of the foot. Balanus amphitrite (Darwin?) from roots and stems of mangroves in the Congo, where, says, "it follows the mangroves as far as their vegetation extends along the stream, to six seas-miles from the mouth." Darwin notes B. improvisus as quite tolerant of water not saline. Why the Thyrostraca, so hardy, so widely dispersed and from one area to another, show such a large number of species, have made so extended and more independent incursions into fresh water remains a problem. Though the Orthiolepas australis (Taylor of Bass Strait) is certainly the only the cirripedia of a cirripede, it still shows one of the many facilities for dispersion which these creatures enjoy. A striking instance of their abundance is cited by Aurivillius (1864) from the coast of Issas, and another by Eekelaar (Dutch East Indies) observed great masses of Lepas fuscicostata forming broad belts in the North Sea. geradise (Lacaze-Duthiers, 1885), sends such rootlets into its host as would justify the term Rhizothoracida. The small sinuose segmented body is enclosed, except for one small opening, in an enormous sac-like carapace, between the lamellae of which are protruded from the body the ovary and "liver," both large, bifurcate and ramified. It is this sac-like and not valvular carapace, therefore, that justifies the term Ascothoracida. But Synagoga mira, Norman, 1888 (Brit. Assoc. Report for 1887), has the body covered by two nearly circular valves instead of a sac. Petaraca bakhchidzis, G. H. Fowler (Quart. Journ. Mic. Sci., 1889, vol. xxx. pt. ii. p. 115), has a bilobed carapace, ventrally open; Denenageraster asterica, Knipovich (Bidopptica Centralblat, 1891, x. 207), is a multibulibar, with apparently indistinct segmentation of the body proper on the dorsal side. For this highly problematic group the original authorities should by all means be consulted. The student may then be asked to compare the account of Synagoga mira both with the figure of the cypris-stage of Denenageraster asterica and with the figure of the "indeterminate animal found on Gerardia," about which Lacaze-Duthiers asks, "Is it the cypris-stage of Laura?" (Mém. Acad. Sci., 1883, xlii. 160, pl. i, fig. 102). S. mira was found, like Laura geradise (fig. 3), in the Mediterranean, and found like it attached to an antipatharian. Its six pairs of limbs are not like the bare and simple feet of the Laura, but two-branched and setose as in the ordinary cypris-stage of the cirripede. The conclusion, therefore, from these facts and from the suggested comparisons, seems at least extremely probable that the question asked by H. Lacaze-Duthiers should be answered in the affirmative, and that S. mira is either the cypris-stage of Laura geradise or of some congeneric species. In Lacaze-Duthiers's highly-elaborated memoir it should be noticed that he uses the term "cirrhes" rather misleadingly, not for cirriform heaps, but as the equivalent of setae. Also he gives two different reckonings of the segmentation, counting first eleven body segments without the caudal furca (p. 40), and then the caudal furca as itself the eleventh segment (p. 41). Of Petaraca the development is not yet known. The points of agreement and difference between it and Laura are carefully drawn out in the essay by Dr. G. H. Fowler, who inclines to favor a close relationship between the Thyrostraca and Ostracoda. To the extreme development of the carapace in Laura, as compared with the segmented body, it would be difficult to find among crustaceans any analogy more striking than that of the great ovaial expansions in Nicopee estaci, the little copepod parasite of the common lobster. The compactness of the class Cladocera is generally admitted; of the precise affinities of its subdivisions there is still much uncertainty.

THYRSUS (the latinized form of Gr. δήφως, a stem or stalk) the wand or staff of Dionysus (Bacchus), the Bacchants and Maenads and the votaries taking part in his orgiastic rites. As commonly represented on the monuments it was a straight staff terminating in a pine cone, a ribbon or fillet being attached to the head below it. Another form terminated in a bunch of grapes and vine leaves, or ivy-berries and leaves. The pinecone or bunch of leaves was sometimes supposed to cover the head of a spear, and the thyrsus was termed θυρόφσακες (see Diovoeuses and Mystax).

THYSANOPTERA (θῦσαν, a fringe, and πτερόν, a wing), a term used in zoological classification for a small order of the class Hexapoda (q.v.). The minute insects included in it, which haunt blossoms and leaves, are fairly well known to gardeners by the name Thrips, a generic term used by Linnaeus for the four species of the group which he had examined and relegated to the order Hemiptera. The term Thysanoptera was first used by the Irish entomologist A. H. Haliday (1836), who made a careful study of the British species and recognized that their structural peculiarities required ordinal separation. H. Burmeister in 1838 also considered that these insects should form a distinct order, for which he proposed the name Physopoda, with reference to the bladder-like outgrowths (fig. 3) on the feet. Since then various authors have incorporated the Thysanoptera with one of the larger orders, some, following Linnaeus, regarding them as Hemiptera, others grouping with them the Orthoptera or "Pseudoneuroptera." But all recent students agree with Haliday and Burmeister in allowing the Thysanoptera to rank as a distinct order, ranking affinities on the one hand with the Corroentia (beetles and biting lice) and on the other with the Hemiptera (crickets, bugs, &c.).

Characters.—The Thysanoptera, small insects with firmly chitinized cuticle, are recognized by the combination of imperfectly suctorial jaws—the mandibles acting as pickers and maxillae retaining their palps (see fig. 2)—with the presence of two pairs of excessively narrow wings (fig. 1), which are partly or completely surrounded by elongate delicate bristles forming a fringe. Other important structural features are mentioned below. In their life-history the Thysanoptera belong to the Exopterygote division of the Hexapoda (q.v.). Thenewly hatched insect closely resembles the parent, and the wing-rudiments appear originally on the second and third thoracic segments; but before the final moult the nymph remains quiescent, taking no food. Its condition thus recalls the pupal instar of the higher (Endopterygote) Hexapoda; and the Thysanoptera, though few in number, are seen to be of great interest to the student, exhibiting at once a transition between the biting and the suctorial mouth, and the passage from "incomplete" to "complete" metamorphosis.

Structure.—The head is usually quadrangular in form with small but prominent compound eyes (fig. 2), whose facets are relatively large and convex; three ocelli may also be present on the vertex. The feelers are inserted close together (fig. 2). The extreme front of the head; they exceed the head in length, but they are composed of only six to nine segments, which are beset with prominent spines, some of the latter appearing to be organs of special sense. The mouth, with its jaws, forms a conical outgrowth which projects backwards, so that its apex lies beneath the prothorax. The labrum (fig. 2 e), which encloses the cone in front, is irregularly triangular in shape. Behind the mouth the two maxillae of the second pair are intimately

![Fig. 3.—A, Laura geradise; B, Carapace ait open to show the body proper.](image-url)
THYSANOPTERA

associated to form the labium (fig. 2 b), whose appendicular nature is shown only by a median furrow and by short, cylindrical palps (fig. 2 i) with two or four segments. The maxillae of the first pair (fig. 2 j) enclose the mouth at either side. They are broad at the base, but narrower toward the tip (fig. 2 i) and divided into three segments. Within the mouth lie a pair of slender piercers (fig. 2 d), while a single piercer (fig. 2 e) is situated asymmetrically on the left side. The nature of these structures has been much disputed. H. Uzel, with the major authority, believes that the mandibles of the left mandible, the right mandible being absent. C. Börner, however, has shown that the unpaired piercer is attached directly to the base of the left maxilla. He therefore regards it as the inner lobe (locusia) of that maxilla, comparing it with the piercing organs of Lepidoptera, the book-lice (see Copeognatha in article NEUROPTERA). The pair of piercers, connected by muscles with the base of the maxillae, but attached directly to the head skeleton, into which they can be withdrawn, are regarded by former authors as mandibles.

Turning to the thorax we find that the first segment (prothorax) is distinct and free, with a wide dorsal sclerite. The mesothorax and metathorax are rather intimately fused together. Most remarkable in this order is the structure of the feet; there are never more than two dorsal segments, and the claws, usually so conspicuous in insect feet, are reduced (fig. 3 a) or absent, and the legs carry: pelligerous spines, and the terminal dorsal segment is cup-shaped at the end; from this hollow a delicate bladder (fig. 3 b) can be protruded, which at the same time has a direct communication with the blood-pressure, and by means of this bladder—acting as a sucker—the insect obtains nutrition from any surface that the foot touches. The narrow, delicate, fringed wings have already been described; each wing may be surrounded by a transparent "wing-bladder," or by a transparent film, the longitudinal nervurs, or the nervuration may be altogether degenerated. A fair number of species are wingless (fig. 3 d), and in both winged and wingless the occurrence of winged females with wingless males is noteworthy.

Ten segments are recognizable in the abdomen, which is elongated in some cases, and in many families the females of Thysanoptera have a conspicuous ovipositor (fig. 4) with serrate processes, projecting from the ventral surface of the abdomen. The number of spiracles is greatly reduced; in the adult a pair is present on the mesothorax, sometimes also on the metathorax, and there is always a pair on the first and another pair on the eighth abdominal segment. These processes belong to the remarkable honeycomb-like structures, and perforations to the tracheal tubes have not been demonstrated. The internal structure of the abdomen has been studied by K. Jordan. They possess a long, tubular gullet and a highly concentrated nervous system; in addition to the subesophageal ganglion, there are two thoracic ganglia and a single abdominal nerve-mass which is situated far forward. In this condensation of the nervous system several authors have been led astray by the presence of four Malpighian (excretory) tubes the Thysanoptera resemble the Hemiptera.

Development and Habitats. Many species of Thysanoptera are known to be habitually parthenogenetic. The eggs are laid on the food-plant, those females possessed of an ovipositor cutting through the epidermis and placing their eggs singly within the plant-tissues; a single female may take possession of the entire plant. The young insect resembles its parent in most points, but the head is disproportionately large; the anterior abdominal spiracles are on the second segment instead of on the first, and the foot has only a single segment. At first the eyes consist of a few distinct facets on either side of the head; they increase in number as growth proceeds, and become aggregated to form the curious compound eye of the adult. From two to four mouth parts—tentacles, maxillae, and proboscis—are formed. The "imaginal stage" is reached, which in the insect is moderately active and possesses wing-rudiments reaching to the second abdominal segment. After another moult the insect passes into the passive nymphal form "pupal tube" and remains in this condition in some safe hiding-place, such as the soil at the base of its food-plant or the hollow of a leaf-stalk. During this stage the cuticle draws in for the imaginal article which is forming beneath, ultimately becoming separated as a thin transparent pellicle through which the form of the adult can be seen.

Thysanoptera are found on the leaves and in the blossoms of plants. According to Hinds they feed chiefly on the green tissues, but they can also be procured by piercing mouth-parts and the sap withdrawn by suction. The traces are almost always irregular streaks of dry, whitened cells. It has been stated that when present in blossoms they feed on nectar, but it is more probable that the stems of the flowers and the fruits of many trees and others periodically migrate to roots. While the majority of the Thysanoptera are thus vegetarian in their diet, and are frequently associated with the blossoms, some species, when occurring in large numbers in the soil, adopt a predacious habit, killing aphids and small mites (so-called "red-spiders") and sucking their juices. There are even records of an Anaphothrips, when cut off from its normal vegetable food, of the becoming cannibalistic and feeding on its own species. The usual variations in habit that characterize plant-feeding insects are exhibited by the Thysanoptera some species being found only on one particular food-plant, while others thrive indifferently on a large assortment. Some members of this order spend the winter in the adult state, others in the "larval" or "pupal" condition. They shelter in crevices of the bark of trees, in the dried stems of grasses, in the dry leaves of bulbs, and fallen leaves on the ground.

Hinds states that the hibernating individuals live for more than six months. During summer there may be eight or nine successive generations when conditions are favorable and food abundant.

Distribution and History. The Thysanoptera are probably world-wide in their range, but they have hardly been studied outside Europe and North America. Fossil insects referable to the order have been found in amber, the White River Oligocene of North America, and the Baltic amber, but nothing is known as to the previous history of the group.

Classification.—Only about 150 species of Thysanoptera are known, and but a few of these have a more or less restricted distribution. They are described by Uzel, the North American by Hinds. These writers both follow the classification of Haliday, who divided the order into two groups or sub-orders.

1. Terebrantia: In this division (fig. 1, 4) the abdomen is cylindrical, the female is provided with a ventral ovipositor and has the terminal abdominal segment conical; the corresponding segment of the male is usually flattened. The forewings have at least a single longitudinal nervure—often one reaching from base to tip of the wing. The maxillary palps have usually three, the labial either two or four segments. There are two families of Terebrantia: (a) the Aedoeothrieidae, whose females have nine segments; whose wings, relatively broad and rounded at the tip, have a few cross nerves, and whose ovipositor is curved backwards; and (b) the Thripidae, whose females have from six to eight segments, the maxillary and labial palps, and the narrow acuminate wings have no cross nerves, and whose ovipositor is curved forwards. The latter family contains the great majority of the order.

2. Tubulifera: This division comprises a single large family, the Phloeothripidae; the species are not numerous, but some of them are of large size for Thysanoptera, as much as 8 mm. (one-third inch) in length. These insects have the abdomen flattened, with its terminal segment narrow and cylindrical. The palps, both maxillary and labial, have two segments. There is no ovipositor, and the wings are either without nervature, or a single degraded longitudinal nervure does not reach to the tip. While the Terebrantia are often winged and are hibernating in the ground (fig. 5), Megalothrips lati- tubuliferus are slow and deliberate. ventris, female, Europe. (According to Hinds, "they never 16")

RUNNING SPRING!

BIBLIOGRAPHY.—The number of important writings on the Thysanoptera is not large. A. Haliday's papers in Entom. Mag., 1836-1837, vols. iii. and iv., are still valuable and contain nearly all the information on this group, and after them have been studied (Zeits. wiss. Zool., 1888, vol. xxvii.) are valuable and the descriptions of the jaws by H. Garman (Amer. Nat., 1896, vol. xxxiv.), and C. Börner (Zeits. f. Zool., 1904, etc.), and the descriptions of the others are H. Uzel's Monographie der Ordnung Thysanoptera (Koniggratz, 1853; in the Czech language, but with a German summary), and W. E. Hinds's Monograph of the North American species (Proc. U. S. Nat. Mus., 1899, vol. xxvii.).

(G. H. C.)
THYSANURA, the name applied by P. A. Latreille to the primitive wingless insects known as springtails and bristletails. Sir J. Lubbock (Lord Avebury) separated the springtails as a distinct order, the Collembola, and by many students this separation has been maintained. It is better, on the whole, to regard the Thysanura and Collembola as sub-orders of a single order, the Aptera (q.v.). The Thysanura are recognizable by their elongate feelers and tail-processes ( cerci). Campodea (q.v.) Mecistus and Lepisia—to which belongs the "silver-fish"—are the best known genera. (See also HEXAPODA and Aptera.)

THYSAGETAE, an ancient tribe described by Herodotus (iv. 22, 123) as occupying a district to the north-east of Scythia separated from the Budini by a desert seven days' journey broad—perhaps the Voguls. From their land four rivers flowed into the Maeotis, but as one of them, the Oaurus, is almost certainly the Volga, there must be some mistake about this. They seem to have held the southern end of the Uralis about Ufis and Orenburg. (E. H. M.)

TIAN-SHAN, or CELESTIAL MOUNTAINS, one of the most extensive mountain systems of Asia. In the western prolongation, the system extends from the E. edge (in about 65° E.) of the Aral-Caspian depression in the W. to the great bend of the Hwang-ho (about 103° E.) in the E. The Chinese geographers, however, appear to have confined the term to that part of the system which falls between the conspicuous mountain-knot of Khan-tengri (8° 11' E. and 42° 15' N.) and the Otun-koza or Barkul depression in 92°-93° E., where the northern ranges of the system abut upon the Ektagh Alatai; and this conception and limitation of the term are more or less accepted by some European geographers, e.g. Dr Max Friedrichsen and G. E. Grum-Grahimalo. On the other hand P. P. Semenov (or Semyonov), one of the earliest scientific explorers of the system, applies the name to the ranges which lie immediately west of Khan-tengri, including Khan-tengri itself. The Tertiary Mountains and their north-western continuation, the Chinghiz-tau, are sometimes considered to belong orographically to the Alatian system; but there are good reasons for regarding them as an independent range. Excluding these mountains, the northernmost member of the Tien-shan system is the Dzungarian Alatau in 45°-46° 30' N. The southernmost range is the Trans-Alai, or eastern W.S.W. prolongation, Peter the Great's accretion in Karsteghin (Bokhara), though some geographers (e.g. Max Friedrichsen) assign both the Alai and Trans-Alai Mountains to the Pamirs.

General Orographical Description.—The Tien-shan consists almost everywhere of "sheaves" of parallel ranges, having their strike preponderantly east and west, while the Terek-tau, that is the main west of Khan-tengri and to the E.S.E. east of 92° E., thus describing as it were a wide flattened arc open to the south. The principal constituent ranges are accompanied by another set of ranges which break away from the main axes in a southerly direction giving rise to saps, and bounding them run from five to seven ridges as broad as the basin and rising by gentle slopes to 13,000-16,000 ft. The ridges run for long distances parallel to each other, and on many miles the sky-line is an almost straight crest, from which the rounded slopes of pure white snow-fields descend towards the basin. The crest line is notched by high passes only 1000-2000 ft. below the top of the crest. Often the summits of the ridge are broken into individual mountains, broadly flat-topped and of nearly equal elevation. . . . (Since late Tertiary times erosion has had but little effect in altering the country from the state to which it was brought by the great Tertiary "depressions." The result of these geological changes is that, although the internal structure of the Tien-shan region is highly mountainous, its external appearance is of a peneplain.) The valleys of the Tien-shan are often deeply incised between the ranges, and on the west side of the mountains the valleys are carried down into a narrow flat plain or intermontane basin, which often fills up to the elevation of 10,000 ft., and is consequently called a "matttormer." The loftiest range is that to the north, which exceeds 16,000 ft., and the altitude increases generally from west to east as far as the Bedel pass in 78° 30' E., where the route crosses from Ak-su and Uch-Turfan to the valley of the Naryn and Ferghana. At its south-western extremity the Kokshal-tau merges in the Kokya Mountains (16,000-18,000 ft.), which at their other end are merged in the Trans-Alai and Eastern and Northern Tien-shan.—The mutual relations and exact orographical connexions of several of the ranges east and north of the Khan-tengri group are not yet elucidated. The region east of the Bokhara Alatau was explored during the second quarter of the 19th century, by P. K. Kozlov, V. A. Obручев, the brothers G. E. and M. E. Grishmalo, V. I. Rebrovov and Sven Hedin. The system is known there locally as the Barkul Mountains and the valley of Ferghana against the Aralo-Caspian desert. The other arm of the bifurcation, situated farther south, and beginning at the Terek-tau, is double; it consists of the Alai and Trans-Alai transverse mountain ranges, divided by the low Bashkirs and Turkistan ranges, though orographically the Trans-Alai ought probably to be described as the border-ridge of the Pamir plateau. Thus the Tien-shan is as a whole narrowest in the east and spreads out again in the west.

Khan-tengri and the Central Tien-shan.—The peak of Khan-tengri, which according to Max Friedrichsen's observations is not so high as had generally been supposed, being 22,800 ft. instead of 24,000 ft., stands at the back of the Tien-shan range, as the crest of the watershed of the south-west. Its lofty summit on the actual watershed, according to G. Merz-Beck, seems to rise to 22,000 ft. (about 20,670 ft.); its altitude he puts at 20,670 ft. But the general altitude of the crest of the watershed he estimates at about 16,500 ft., and it is overtopped by peaks (e.g. Dr von Almasy's peak Edward Vil.) rising to 20,670 ft. and 21,720 ft.

Closely connected with the Khan-tengri knot are the Khalyk-tau on the east, and on the west three diverging lines of elevation, namely the Terskei Alatau, the Kirghiz Alatau, and between them the high Naryn rise, which is really in the Trans-Alai and the westernmost of the three. Thus the main mountain barrier seems to be divided into three sections, the eastern or Karatau, the middle or Naryn, and the western or Pamir.
TIAN-SHAN

Karylyk-tagh, which stretches from W.N.W. to E.S.E. Its middle parts are snow-clad, the snow lying down to 12,000 ft. on the north side, while the peaks reach altitudes of 14,000-15,000 ft., but the range is divided by a steppe and desert land lying between the east, where there are passes at 9600 ft. and 10,600 ft. (Belu-daban). Towards the east, the Karlyk-tagh radiates outwards, at the same time decreasing in altitude, though it rises again in the rocky Emir tagh, a line of peaks stretching from near the town of Chui to Karlyk Lake. The range belongs to the Chol-tagh. The Chol-tagh marks the northern escarpment, as the Kuruk-tagh, farther south, marks the southern escarpment, of the great massif. From the Chol-tagh to the south lies the Murz Sems (southern range, described under Gont) are apparently eastern prolongations, the former of the Khaidyk-tagh or Khaidu-tagh, and the latter, of the Kok-teke Mountains, which enclose on north and south respectively the Terek and the Lake of Baskunchak. These ranges terminate at the Kok-teke, on to the Khalyk-tau of the Khen tengri group. The Khaidyk-tau, which are crossed by the passes of Tash-againsn (770 ft.) and Ketyl (9900 ft.), are not improbably connected by the right hand continuation of the Ala-tau, as the two parallel range, the Khungie Ala-tau, in the west, in that they are an eastern prolongation of the latter. The Narat-tau appear to form a diagonal (E.W. to W.S.W.) link between the Khaitzhi tau and the Khalyk-tau and are crossed by passes which V. I. Roborovski estimates at 10,800 ft. (Sary-tyur) and 11,800 ft. (Mukhdurul). The Jambé pass in this same range lies at an altitude of 11,000 ft. and the Cholkhe pass 11,710 ft.

At the west end of the Barkul range is the gap of Otunkoza (2390 ft.), by which the Hami-Barkul caravan road crosses into the valley of Dzungaria, and at Urumqai (87° 30' E.), over 200 m. farther west, the east and west branches of the range converge and create the oasis of Turfan and Dzungaria. Between these two gaps stretches the snow-clad range of the Bogdo-olai, which runs at an average altitude of 17,000-18,000 ft. in the conspicuous double peak of Turpanat-tagh or Topotar-aule, a mountain which the Mongols regard with religious veneration. On the north side of this range the snow-line runs at an altitude of 2000 ft., and the steeps, which according to the Chinese are known as the "stony slopes of the Karlyk-tau," reach at 8000 ft. the snow-capped peaks of the Alatau, which lie at an altitude of 14,900 ft. In the south the Bogdo-olai is flanked by the nearly parallel range of the Jargab, a range which, in contrast to most of the common ranges, carries no perpetual snow. But its altitude does not exceed 10,100 ft., and its steep rocky slopes meet in a sharp, denticulated crest. West of the Urumqai gap, the Bogdo-olai is continued in the dangling range of the Karlyk-tau, which, rising both north and south, make a curious curve to the north-west and finally, under the name of the Talki Mountains, merge into the Boro-khor range. The Iren-khabirga, like the Bogdo-olai and the Terskei Ala-tau, are capped with perpetual snow. They culminate in the peak of Ala-megen-or at an altitude of 20,000 ft. The more southerly of the twin ranges, the Avral-tau, in which is the Arystan-daban pass at an altitude of 10,800 ft., terminates in 82° E. over against the confines of the Kizhik and 12,740 ft. The Boro-khor Mountains, with an average elevation of at least 11,900 ft., have all the characteristics of a border-range. This range, the slopes of which are alternately rounded and steep, is divided into two branches by the 89° 60' meridian. The south branch of the range, rising at 9000 ft., separates the valley of Kula (II) on the south from the depressions of Zairam-nor (6820 ft.) and Ehi-nor (670 ft.) in the valley of the Borotala on the north, the said valley opening out into the Karalai-Karakul basin. The valley of the Borotala, which is flanked by the Boro-khor lie at an altitude of 9000 ft., and the Terskei Ala-tau, which is parallel to another one and also to the lake and to the Terskei Ala-tau. The two chains are connected by the lofty transverse ridge of Amurad, Almata or Almatinka. The mountain chain of the Karakul-Ala-tau, which is joined to the Terskei Ala-tau, swings away to the north-west, and is continued in the elevated ranges of Kandyk-tau, Kulja-bashi, Khan-tau and the Chu-lii Mountains, the general altitudes of which lie between 4000 and 5000 ft. In the middle of the Trans-ili Ala-tau rises the Pamir or Pamir massif. This is a dome-shaped massif of the Pamir massif, which rises abruptly from the desert and lifts its snow peaks to an altitude of 15,000-16,000 ft., separating the river Syr-darya from the river Pamir. The Trans-ili becomes it Mel Taigar at an altitude of 4990 ft. The Trans-ili is a river of the Pamir massif. The Trans-ili rises near 8900 ft. above the Issyk-kul and lifts its summits higher than 13,000 ft. The passes across the twin

1 It may however eventually turn out that these ranges, together with the Mechin-ola, farther to the north-east and intimately connected with the Karlyk-tau, belong to the Altai system.
Indeed, the evidences, so far as they have been examined, appear to warrant the conclusion that the region of the Western Tian-shan, from Lake Issyk-kul southwards, was in great part the scene of probably five successive glacial periods, each being less severe than the preceding. It is probable that the glacial stream, at the head of the lake, or five large glaciers stream down the shoulders and embed themselves in the hollow flanks of Khan-tengri—the Semenov at altitudes of 12,410-12,800 ft., the Mushtekhet at 11,910-11,920 ft., the Inylchik glacier, and the Barson. The Inylchik glacier is composed of a length of about 45 m. glaciers. Occur also on Baiman mount to the south of the town of Auz, a by no means uncommon region there and other places. Formerly, the Fedchenko and Shishky's glaciers south of peak Kham. Generally speaking, the snow-line runs at 11,500-12,800 ft. above sea-level, and all ranges the peaks of which shoot up above 12,000 ft. are covered with a considerable amount of snow. Towards the plateau, the altitudes are 10,500 ft. A feature generally characteristic of the Tian-shan as a whole is that the absolute elevation of the ranges increases gradually from north to south, and from the centre decreases towards both the east and the west. At the same time the relative altitudes, or the heights of the mountain ranges above the valleys which flank them, decrease from north to south. For instance, in the Dzungarian Alai-tau, the valleys going south lie successively... in altitudes of 4300 ft. in the Borteilin, at 5600 ft. in the Urtasaryk and at 6820 beside the Zairam-nor. Again, while the III (Kulja) valley lies at 1300 ft. the Issyk-kul has an altitude of 5300 ft., the lower reaches of the Shishkys tend to the Chinghiz at 1500 ft. 6070 ft. the Son-kul valley 9430 ft. the Ak-sai valley, farther east, 10,000 to 11,150 ft., and the Charyk-kul on the north side of the Terek Mountains 11,200 ft. In the elevated regions of this part of the mountainous region, the snow-line rises above 12,000 ft. and the snow-line runs at a higher level than is usual elsewhere, namely at 12,900 ft. and even at 13,000-13,800 ft. on the Kokkii Mountains. "It is the middle of June," says one authority, "when the first snow is seen in the range."

The snow-line in the middle of July is 5000 ft. in most of the higher ranges is both milder and moister than on the south and east, and accordingly the precipitation in the former is relatively heavier, namely 10 to 20 in. annually. It used to be supposed that the snow-line in the central part of the range would be much lower in 20th century, and approximately the present snow-line would be 10,000 ft. The vegetation becomes luxuriant. According to P. P. Semenov, the following vegetable zones may be distinguished on the northern slopes of the Tian-shan: 1) at about 1575-3400 ft. are the zone of cultivation, 4300-8100 ft. the zone of coniferous trees, 8100-9500 ft. alpine pastures, 9500-11,900 ft., the higher alpine regions, and above the last limit is the region of perpetual snows. The range has a very abrupt gradient and desolate below the 10,000 ft. limit and above that it is dotted with scanty patches of grass and bush vegetation. Its general aspect is that of rugged slopes of bare rock, seeded with the beds of dry torrents choked with gravel (sees farther Turkestan, West)."
that of Benedict XII. (d. 1342), of which the head is preserved in the museum at Avignon, while an effigy of the same pope in the crypt of St Peter's at Rome has a tiara with only two crowns. Since Benedict XII. the triple-crowned tiara has appeared regularly on the monuments of the popes. The tiaras are essentially uniform, though the ornament varies (leaves or spikes).

Outside Rome it was still a considerable time before the triple-crowned tiara appeared in representations of the popes, and as late as the 15th century they are sometimes pictured with the single-crowned tiara. The reason for the addition of the third crown is unknown. The symbolism now attached to the triple crown (authority over heaven, earth and hell, or the temporal power and the power of binding and loosing) is certainly not the original explanation.

Several baseless hypotheses have been advanced as to the origin of the papal tiara. In all probability the camesacuum, the oldest form of the tiara, came into use under the Greek and Syrian popes of the 7th, or the beginning of the 8th century, perhaps even under Pope Constantine himself. The prototype of the camesacuum must undoubtedly be sought at Constantinople in the head-ornament forming part of the Byzantine court costume.

TIARET (Toherit), a town of Algeria, in the Tell Atlas, department of Oran, 122 m. S.E. of Mostaganem by rail. It occupies a fine open plateau 800 ft. above the sea at an elevation of 1552 ft. Pop. (1906), 5778, of whom 3433 were Europeans. The Wadi Tiaret flows through the town in a series of cascades. The upper town, the residential quarter, is on the right bank of this stream. The citadel occupies a separate hill on the other side of the wadi. The chief business centre is the lower town where are also the principal public buildings. On another hill opposite the citadel is the native town.

The citadel occupies the site of a Roman station believed to be that of Thurturia. Tiaret (Berber for "station") was a town of note at the time of the Arab invasion of North Africa in the 7th century and is stated by Ibn Khaldun to have offered a stubborn resistance to Sidi-Okba. In 767 it was taken by Abdurrahman ibn Rostem, the founder of the dynasty of the Beni Rustam (Rostem). Their empire, which during the reign of Abdurrahman (761-784) and his son Abdul Wahab (784-823) extended over the greater part of the modern Algeria, was known as the Ibadite Empire from Abdullah ibn Ibad, the founder of the heretical sect to which Abdurrahman belonged. The Ibadites represented the moderate section of the Kharjites (q.v.), and under the rule of the Beni Rustam the empire was a well-governed community. The dynasty was overthrown by the Fatimite general al Shiil in 829. Two years later Tiaret was captured by Massali ibn Habip of the Miknas dynasty of Morocco, and after his death in 924 two other princes of the same house maintained their independence, but in 933 the Fatimites again gained the mastery. The Ibadites, after being expelled from the Tell, took refuge in Wargla. They were driven thence in the 11th century and migrated to Mzaab, where their descendants still profess the Ibadite doctrines (see Mzabites). After its second capture by the Fatimites, Tiaret ceased to be the capital of a separate state. For a long period it was included in the sultanate of Tiemcen, and in the 16th century fell to the Turks. It was one of the chief towns of Abd el Kader, but was occupied by the French in 1843. At Takedempt, 6 m. west of Tiaret, Abd el Kader had his principal arsenal. About a mile from Takedempt are ruins of a town supposed to be the remains of the Ibadite capital. Eighteen miles S.S.W. of Tiaret are the sepulchral monuments known as the Jedars (see Algeria: § Archaeology).

TIBBU, or TIBBU (" Man of Tu", "i.e." of the rocks"), a nomadic tribe of the western Sahara, their tribe is very constant westward with that of the Tuareg Berbers. Roughly, their domain is some 200,000 sq. m. Their westernmost settlements are the oasis of Agram, Kawar and Jebabo, their northernmost the district of Gatron (Qatrun) within the Fezzan frontier, while south and south-east they merge gradually in the negroid populations of Kanem, Bornu (Chad basin), Wadai and north-west Darfur. But the bulk of the nation is concentrated in the region of Tibesti or Tu, hence their name. There are two main divisions—the northern Teda, or lessnegroid, Tiaret, and the southern Daza, or more negroid, Tiabb. Some what more distinctly connected with the same family are the Baelie of the eastern and south-eastern oases and the Zoghawa (Zaghwa) of Darfur. The Tiabb are variously estimated as numbering from 60,000 to 100,000, but their districts are so little known that these figures are not to be relied on.

The Tiabb are usually identified with the Garamantes of Herodotus (iv. 183), whose capital was Garama (Idrisi’s Germa) in Phazzania (Fezzan). The Hellenic name of what are now the Beni N'agatesians (Negroes ?) : ‘Οντας ἐν καὶ κατὰ τὸν ἤλιον Λαμπάς (i. 8). But Leo Africanus transfers them to the Berber connexion, whose fifth great division he deals with under the names of Gumeri (Garama, Germa), the Allied Bardacan, and the Zaghawa tribes, or negroes of the Tibesti. Lastly Heinrich Barth on linguistic grounds grouped them with the Kanaari of Bornu, who are undoubtedly negroes; and since his time (1854-1853) they have been regarded by most ethnologists as a negro people. Gustav Nachtigal, who studied them carefully (1870-1875), although his own inferences are somewhat vague, supplies sufficient evidence for a solution of the question. And more recently, as Kadum (1907), or negroes, or, in the time of the, the Teda, or true Tiabb, probably identical with the Tedamansil, a branch of the Garamantes, placed by Ploemey south of the Samamisci in Tripolitana,4 physically resemble their western Tuareg neighbours. Their language with general terms, without doubt, has undergone no perceptible change in their rocky homes, and are still distinguished by the regular features, long black ringlety hair, naughty bearing and fierce expression common to so many of the negro people, and, while they are finely proportioned, except the somewhat small hands and feet, with lighter complexion than that of the southern Daza, and no trace of beard, a little more robust, or, in the case of women, the third language characteristics of the true negro. “ Their women are charming while still in the bloom of youth " (Keane’s Reclus, xxii. 429). But there has been a general displacement of the race southwards; and, while a few Tiabb are still found in the Wadi Al Tana in the Nohla, the numbers have since medieval times penetrated into the Kanem, Bornu, Wadai and Darfur regions of central Sudan. Here they have everywhere merged in the natives, so that in the Daza, Kanembo, Kordofan and Darfur their people and language are mingled with all the shades of transition between the true negro and the true Berber. The same transitional stages are observed in the Tiabb forms of speech, which constitute a wide-spread linguistic family, whose most archaic and purest branch is the Tedaga of Tibesti (Nachtigal). Through the southern Dazaga the Tedaga merges in the more highly developed, and more recent Kanem, Bornu (Kanuri), Ennedi (Fadila) and Darfur (Zoghawa) dialects, which, owing to the absence of grammatical gender and some other structural features, are usually classed as negro languages. But a negro tongue could not have attained its present isolation without the care of a people who have carefully preserved it and explained the expression of this linguistic difficulty is obviously the same as that of the physical puzzle. The negro affinities of the southern Tedaga and the negro linguistic features of the original and now partly displaced negro idioms of central Sudan. There remains the final difficulty that Tedaga itself has nothing in common with the Berber or any Hamitic tongue. If, therefore, it is not Hamitic, how is it a negro group?. Its negro characteristics have been largely assimilated to the Sudanese negro dialects.

Lying on the tract of the great caravan route between Fezzan and Lake Chad, the Tiabb have always been a predatory race, levying blackmail on the caravans passing through their country, maintaining inter-tribal feuds and carrying on constant

**TIBER** (anc. *Tiberis*; Ital. *Tevere*), a river of central Italy. It traverses the Tuscan Apennines—in which it rises at a point some 12 m. N. of Fieve San Stefano, 4160 ft. above sea-level—in a series of picturesque ravines, skirts the west foot of the Sabine Mountains in a broad shallow valley, then crosses the Roman Campagna, cutting its way through Rome, and finally enters the Tyrrhenian (Mediterranean) Sea by two arms at Ostia and Fiumicino, the latter artificial. Its principal tributaries are the Paglia, the Nera and the Anio or Teverone, and it is generally navigable by boats up to the confluence of the Nera, a distance of 104 m., though, owing to the rapidity of the current, there is very little navigation above Rome. The total length of the river is 240 m., of which 21 m. lie between Rome and the sea. This latter portion of the river's course is tortuous, but in spite of this, and although the depth varies from only 7 to 20 ft., and in places at low water does not exceed 3 ft., it is navigable by vessels up to 180 tons burden and proposals have been made to extend its navigable channel so as to increase this depth to 8 ft. at least, or to build a ship canal up to Rome. The area of the Tiber basin is 6845 sq. m. The stream is heavily charged with sediment, and from that circumstance got its ancient epithet of *fluvius* (tawny). It does not, however, form a delta proportionate to the volume of its water, owing to a strong sea current flowing northwards close to the shore, to the sudden sinking of the sea to a great depth immediately off the mouth of the river, and possibly also to the far more southward current of the Italian coast from the Tiber mouth southwards to Terracina. Still it has advanced at each mouth about 2 m. since Roman times, while the effect of the sediment it brings down is seen on the north-west coast as far as Palo (anc. *Alismum*), and on the south-east beyond Tor Paterno (see LAURENTINA Via) in the gradual advance of the coast. The rate of advance at Fiumicino is estimated at 13 ft. per annum. From Rome to the sea the fall is only 6-5: 1000. The arm which reaches the sea at Fiumicino is a canal dug by Claudius and improved by Trajan (see PORTUS), which partially silted up in the middle ages, and was reopened for navigation by Paul V. in 1612, 28 m. long, 50-130 ft. wide, and with a minimum depth of 5 ft. The lower course of the Tiber has been in part taken from the earliest ages subject to frequent and severe inundations; of more recent ones, those of 1598, 1879 and 1904 have been especially destructive, but since the year 1876 the municipality of Rome, assisted by the Italian Government, has taken steps to check, and possibly to prevent these calamities within the city by constructing embankments of stone, resting on caissons, for a total distance (counting in both sides of the river) of 6 miles. The flood of 1900 carried away about 1 m. of the new embankments, but it is the arm opposite the island owing to the faulty planning of the course of the river at that point, which threw the whole of the water into the right arm, and except in flood time, left the left arm dry—a fault which has since been corrected.

In the prehistoric period the mouth of the Tiber must have been situated at the point where the hills which follow it on each side cease, a Point 12 m. below Rome. On the right bank they are of Pleistocene gravel, on the left of tufa; and on the latter, a cliff rising above the river (the ancient *Pulita saxa*) stood Ficana (marked by the farmhouse of Dragoncello), which is said to have owed its origin to Ancus Marcius. Beyond these hills the low coast belt formed by the solid matter brought down by the river begins; and on each side of the mouth in the flat ground were salt marshes (see Ostia). The flood of 1900, when the river both above and below Rome flowed over the length of its valley, from hill to hill, and over most of the low ground at its mouth, gave an idea of the conditions which must have existed in prehistoric days.

**TIBERIAS** a town on the western shore of the sea of Galilee (to which it gives its modern Arabic name, *Ba’ar Tubariya*, i.e. Sea of Tiberias). It has a population of about 4000, more than half of whom are Jews (principally Polish immigrants). It stands in a fertile but fever-stricken strip of plain between the Galilean mountains and the Lake of Tiberias. For many centuries it was the seat of a kainmakam or sub-governor, subordinate to the governor of 'Akka. There are Latin and Greek hospices here, as well as an important mission, with hospital and schools, under the United Free Church of Scotland. The pre-Herodian history of the city is not certain. There is a rabbinical tradition that it stands on the site of a city called Rakka, but this is wholly imaginary. Josephus (Ant. xviii. 2, 3) describes the building of Tiberias by Herod Antipas near a village called Emmaus, where are hot springs. This is probably the Hammath of Jos. xix. 35. The probability is that Herod built an entirely new city; in fact, the circumstance that it was necessary to disturb an ancient graveyard proves that there were here no buildings previously. The graveyard was probably the cemetery of Hammath. Owing to this necessity Herod had a difficulty in peopling his city, and, indeed, was compelled to use force (Jos. Ant., loc. cit.) to cause any but the dregs of the populace to incur defilement by living in a place thus unclean. On this account Tiberias was long regarded with aversion by Jews, but after the fall of Jerusalem it was settled by them and rose to be the chief centre of rabbinic learning.

The building of the city falls between A.D. 16 and A.D. 22. It was named in honour of the emperor Tiberius, and rapidly increased in luxury and art, on entirely Greek models. Probably because it was so completely exotic in character it is passed over in almost total silence in the Gospels—the city (as opposed to the lake) is mentioned but once, as the place from which came boats with sight-seers to the scene of the feeding the five thousand, John vi. 23. There is no reason to suppose that Christ ever visited it. The city surrendered to Vespasian, and was given by him to Agrippa, a famous rabbinic school. Here lived Rabbi Judah ha-Kadosh, where he edited the Jerusalem Talmud, and here are the tombs of Rabbi Aqiba and Maimonides. Christianity never succeeded in establishing itself here in the Byzantine period, though there was a bishopric of Tiberias, and a church built by Constantine. In 637 the Arabs captured the town. The crusaders under Tancred retook it, but lost it to Saladin in 1187. In the 16th century the city was rebuilt by Joseph ben Arud, subvented by Doña Gracia and Sultan Suleiman. An attempt was made to introduce the silk industry. In the 18th century it was fortified and occupied by the famous independent sheikh Dhahir el-Amir.

Tiberias is notoriously dirty and proverbial for its fleas, whose king is said by the Arabs to hold his court here. Most of the town was ruined by the earthquake of 1837. The most interesting buildings are the ruins of a fortress, perhaps Herodian, south of the town, and an ancient synagogue on the sea-coast. The hot springs mentioned by Josephus (and also by Pliny) are about half an hour's journey to the south. (R. A. S. M.)

**TIBERIUS [TIBERIUS CAIUSIAZIT NOER]** (42 B.C.—A.D. 37), Roman emperor, was born near the town of Betar (Qabri), the son of the father, who bore the same name, who was an officer of Julius Caesar, who afterwards proposed to confer honours on the assassins, then joined Mark Antony's brother in his mad attack on Octavian, took refuge with Mark Antony, and returned to Rome when the general amnesty was proclaimed in 39 B.C. Livia, the mother of Tiberius, was also of the Claudian family, out of which her father had passed by adoption into that of the Livii Drusi. Early in 38 Livia was amicably ceded to Octavian (the future Augustus), and three months after her new marriage Drusus, brother to Tiberius, was born. Livia had no children by Augustus, and therefore devoted all her remarkable gifts to the advancement of her sons. Tiberius passed through the list of state offices in the usual princely fashion, beginning with the quaeestorship at the age of eighteen, and attaining the consulate for the first time at twenty-nine. From the great capacity for civil affairs
which he displayed as emperor it may be inferred that he applied himself with determination to learn the business of government.

But from 22 to 6 B.C. and again from A.D. 4 to 10 by far the greater part of Tiberius’s time was spent in the camp. His first service was as legionario tribune in one of the desperate and arduous wars which led to peace in the Spanish peninsula through the decimation, or rather the extermination, of the rebellious tribes. In 20 B.C. Augustus sent Tiberius with an army to seat Tigranes of Armenia on the throne as a Roman vassal. When Tiberius approached the frontier of Armenia, he found its throne vacant through the assassination of the king, and Tigranes stepped into his place without a blow being struck. Tiberius crowned Tigranes king with his own hand. Then the Partian monarch was laden with spoils beyond the standards of three Roman armies.\footnote{Horace, Odes, iv. 14.}

The senate offered a thanksgiving such as was usually celebrated in honour of a great victory. The following year was passed by Tiberius as governor of Transalpine Gaul. In the next year (13) he was despatched to aid his brother Drusus in subjugating the Retai and Vindelic, peoples dwelling in the mountainous region whence the Rhine, Rhone and Danube take their rise.\footnote{Drusus attacked from the eastern side, while Tiberius operated from the upper waters of the Rhine, and by stern measures the mountain dwellers were reduced to a state of quietude, and could no longer cut communications between northern Italy and Gaul, nor procreate their raids in both countries.} In 12 B.C. Agrippina, the great general of Augustus, died at the age of fifty-one, leaving Julia, the emperor’s only child, a widow. Agrippina, daughter of Agrippa by an earlier marriage, was wife of Tiberius, and had borne him a son, Drusus, afterwards father of Germanicus. Livis, with great difficulty, prevailed upon Augustus to replace Agrippa by Tiberius, who was compelled to exchange Agrippina for Julia, to his bitter grief. During the year of mourning for Agrippa, which delayed his new marriage, Tiberius was occupied with a protracted campaign against the Pannonians, followed by successful expeditions in the three succeeding summers.\footnote{His victories in the Danube regions, the emperor conferred on him the distinctions which flowed from a military triumph in republican times (now first separated from the actual triumph), and he enjoyed the “ovation” or lesser form of triumphal entry into the capital.} On the death of Drusus in the autumn of 9 B.C. Tiberius, whose reputation had hitherto been eclipsed by that of his brother, stepped into the position of the first soldier of the empire. The army, if it did not warmly admire Tiberius, entertain[ed a loyalty confidence in a leader who, as Velleius (the historian who served under him) tells us, always made the safety of his soldiers his first care. In the campaign of the Rhine, Drusus’s death Tiberius traversed all Germany between the Rhine and the Elbe, and met with slight opposition. But it would be too much to believe the statement of Velleius that he “reduced Germany almost to the position of a tributary province.” He was rewarded with the full triumph, the military title of “imperator,” and his second consulship, though the opposition of the powerful Sugambri had been only broken by an act of treachery, the guilt of which should perhaps be laid at the door of Augustus. In 7 B.C. there was another but insignificant campaign in the province of Cisalpine Gaul. In 6 B.C. Augustus bestowed on his stepson the tribunician authority for five years. Tiberius was thus in the most formal manner associated with the emperor in the conduct of the government on the civil side; but Tacitus (Ann. iii. 56) goes too far when he says that this promotion marked him out as the heir to the throne.

Tiberius now suddenly begged permission to retire to Rhodes and devote himself to study. He seems to have declined absolutely at the time to state his reasons for this course, but he obstinately adhered to it, in spite of the tears of Livia and the lamentations of Augustus to the senate that his son had betrayed him. The departure from Italy was as secret as it could be made. Years afterwards, when Tiberius broke silence about his motives, he declared that he had retired in order to allow the young princes, Gaius and Lucius, sons of Agrippa and Julia, a free course. There was perhaps a portion of the truth wrapped up in this declaration. Like Agrippa, who retired to Mytilene to avoid the young Marcellus, Tiberius had clearly no taste to become the servant of the two children whom Augustus had adopted in their infancy and evidently destined to be joint emperors after his death. But it may well be believed that Tiberius, unlike Agrippa, had no burning ambition to see himself in the place destined for his stepsons; and it may have been in his eyes one of the attractions of exile that it released him from the obligation to aid in carrying out the far-reaching designs which Livia cherished for his sake. But the contemporaries of Tiberius were no doubt right in believing that the scandal of Julia’s life did more than all else to render his position at Rome intolerable. His conduct to her from first to last gives a strong impression of his dignity and self-respect. When at length the emperor’s eyes were opened, and he inflicted severe punishment upon his daughter, her husband, now divorced by the emperor’s act, made earnest intercession for her, and did what he could to alleviate her suffering. At Rhodes Tiberius lived simply, passing his time mainly in the company of Greek professors, with whom he associated on pretty equal terms. He acquired considerable proficiency in the studies of the day, among which was astrology. But his attempts at composition, whether in prose or verse, were laboured and obscure. After five years’ absence from Rome, he begged for leave to return; but the boon was anxiously refused, and Livia with difficulty got her son made nominally a legate of Augustus, so as in some degree to veil his disgrace. The next two years were spent in solicitude and gloom. Then, on the intercession of Gaius, Augustus allowed Tiberius to come back to Rome, but on the express understanding that he was to hold aloof from all public functions—an understanding which he thoroughly carried out.

He had scarcely returned before death removed (A.D. 2) Lucius, the younger of the two princes, and a year and a half later Gaius also died. The emperor was thus left with only one son to succeed him, his only child, Julia, and still a boy. Four months after Gaius’s death Augustus adopted Agrippa and at the same time Tiberius. The emperor now indicated clearly his expectation that Tiberius would be his principal successor. The two essential ingredients in the imperial authority—the \textit{proconsulare imperium} and the \textit{tribunicia potestas}—were conferred on Tiberius, and not on Agrippa, who was too young to receive them. Tiberius’ career as a general now began anew. In two or three safe rather than brilliant campaigns he strengthened the Roman hold on Germany, and established the winter camps of the legions in the interior, away from the Rhine.

In A.D. 5 it became necessary to attack the formidable confederacy built up by Marobodius, with its centre in Bohemia. At the most critical moment, when Pannonia and Dalmatia broke out into insurrection, and an unparalleled disaster seemed to be impending, Marobodius accepted an honourable peace. The four serious campaigns which the war cost displayed Tiberius at his best as a general. When he was about to celebrate his well-won triumphs, the terrible catastrophe to Varus and his legions (A.D. 9) turned the rejoicing into lasting sorrow, and produced a profound change in the Roman policy towards Germany. Although Tiberius with his nephew and adopted son Germanicus made in A.D. 9 and 10 two more marches into the interior of Germany, the Romans never again attempted to bound their domain by the Elbe, but clung to the neighbourhood of the Rhine. Tiberius was thus robbed in great part of the fruit of his campaigns; but nothing can deprive him of the credit of being a chief founder of the imperial system in the lands of Europe. From the beginning of 11, when he celebrated a magnificent triumph, to the time of the emperor’s death in 14 Tiberius remained almost entirely in Italy, and held rather the position of a joint emperor than of that of expectant heir. Agrippa Postumus had died, and his place was beyond his reach; he had been banished to a desolate island. In all probability Tiberius was not present when Augustus died, although Livia
spread reports (eagerly amplified by Velleius) of an affectionate interview and a lingering farewell.

Tiberius ascended the throne at the age of fifty-six. What struck his contemporaries most was his absolute impenetrability. All his feelings, desires, passions and ambitions were locked behind an impassable barrier, and had to be interpreted by the very uncertain light of his external acts. It is recorded of him that only once did he as commander take counsel with his officers concerning military operations, and that was when the destruction of Varus’s legions had made it imperatively necessary not lightly to risk the loss of a single soldier. The penalty of his incurtnability was widespread dislike and suspicion. But behind his defences there lay an intellect of high power, cold, clear, and tenacious, in which every department of the state more by virtue of instinct and application than by genius. His mind moved so slowly and he was accustomed to deliberate so long that men sometimes made the mistake of deeming him a wavering. He was in reality one of the most tenacious of men. When he had once formed an aim he could wait patiently for years till the favourable moment enabled him to achieve it, and if compelled to yield ground he never failed to recover it in the end. The key to much of his character lies in the observation that he had in early life set before himself a certain ideal of what a Roman in high position ought to be, and to this ideal he rigorously adhered. Agrippa Postumus, sternness, silence, simplicity of life and frugality as he deemed that they had been practised by the Fabrici, the Curii and the Fabii. That Tiberius’s character was stained by Vice before he became emperor, no one who fairly weighs the records can believe. The persuasion entertained by many at the end of his life that he had been always a monster of wickedness, but had succeeded in concealing the fact till he became emperor, has slightly discoloured the narratives we possess of his earlier years.

The change which came over him in the last years of his life seems to have been due to an inward conviction of the spiritual powers that had made him the elder Pliny call him “the gloomiest of mankind,” and disposed him to brood over mysteries and superstitions. As this gloom deepened his will grew weaker, his power tended to fall into the hands of unworthy instruments, terrors closed in around his mind, and his naturally clear vision was perturbed.

The change of masters had been anticipated by the Roman world with apprehension, but it was smoothly accomplished, Tiberius was already invested with the necessary powers, and it may even be that the senate was not permitted the satisfaction of giving a formal sanction to his accession. Agrippa Postumus was put to death, but Livia may be reasonably regarded as the instigator of this crime. Livia indeed expected to share the imperial authority with her son. At first Tiberius allowed some recognition to the claim; but he soon shook himself free, and later became estranged from his mother and held no communication with her for years before her death. The history of Tiberius’s relations with other members of his family is hardly less miserable. Perhaps with any other commander than Germanicus the dangerous mutiny of the troops on the Rhine which broke out soon after Tiberius’s accession would have ended in a massacre of the discontented legions upon the capital. The perilous episode of Arminius caused the recall of Germanicus and his despatch to the East on an honourable but comparatively inactive mission. The pride and passion of Agrippina, the grand-daughter of Augustus and wife of Germanicus, tended to open a breach between the husband and the emperor. In his Eastern command Germanicus found himself perpetually watched and even violently opposed by Piso, the governor of Syria, who was expected to have received secret orders from Tiberius. When Germanicus died at Antioch in A.D. 19, the popular wish combined with Agrippina in demanding vengeance upon Piso; and the emperor was forced to disown him. The insinuation, conveyed by Tacitus, that Piso poisoned Germanicus on orders from Tiberius, will not stand criticism. The death of Germanicus was followed four years later by that of the emperor’s son Drusus. These two princes had been firm friends, and Livilla, the wife of Drusus, was sister to Germanicus. Years afterwards it was found that Drusus had fallen a victim to the treachery of his wife Livilla, who had joined him to that of the emperor’s executor the state Sejanus. When Drusus died, Tiberius nominated two of Agrippina’s sons as his heirs. But Sejanus had grown strong by nursing the emperor’s suspicions and dislike for the household of Germanicus, and the mother and the princes were imprisoned on a charge of crime. In his memoirs of his own life Tiberius declared that he killed Sejanus because he had discovered that he entertained a mad rage against the sons of Germanicus. But the destruction of Sejanus did not save Agrippina and her two children. The third son Gaius Caesar (Caligula), lived to become emperor when Tiberius died in 37.

Throughout his reign Tiberius strove earnestly to do his duty to the empire at large. But he lived through the last century of exceptional upheaval and with an almost superstitious reverence the constitutional forms which had been constructed by Augustus. Only two changes of moment were introduced. The imperial guard, hitherto only seen near the city in small detachments, was by the advice of Sejanus encamped permanently in full force close to the walls. By this measure the turbulence of the populace was kept in check. The officer in command of the guard became at once the most important of the emperor’s lieutenants. The other change was the practically complete abolition of the old comitia. But the state was treated with an almost hypocritical deference, and a pedantic observance of forms as the essential principles of ancient Roman forms was observed towards the senatorial magistrates. The care expended by Tiberius on the provinces was unremitting. His favourite maxim was that a good shepherd should shear the flock and not slay it. When he died he left the subject peoples of the empire in a condition of prosperity such as they had never known before and never knew again. Soldiers, governors and officials of all kinds were kept in wholesome dread of vengeance if they oppressed those beneath them or encouraged irregularity of any kind. Strict economy permitted light taxation and the state was permitted almost without any reluctance the use of noble families and the revenue of the publicans. Public security both in Italy and abroad was maintained by a strong hand, and commerce was stimulated by the improvement of communications. Jurisdiction both within and without the capital was on the whole exercised with steadiness and equity, and the laws of the empire were at many points improved. The social and moral reforms of Augustus were upheld and carried further. Such risings against the emperor’s authority as occurred within the Roman domain were put down with no great difficulty. The foreign or rather the frontier policy was a policy of peace, and it was pursued with consider-
shrouded himself in mystery, and such stories are probably the result of unfriendly attempts to penetrate the darkness. If history ventures to doubt the blackness of Theodora, that of Tiberius grows continually lighter under the investigations of criticism. Suetonius makes the emperor’s condition to have been one of mania, issuing frequently in the abandonment of all moral restraint. But in that case the authority of Tiberius, which was as firmly upheld during the years spent at Capreae as it had been earlier, must have fallen to pieces and come to an end. With respect to Sejanus, it is impossible to acquit Tiberius of blame. If he was deceived in his favourite he must have been willing to be deceived. He conferred on Sejanus a position as great as had been held by Agrippa during the reign of Augustus, and the minister was actually, and all but formally, joint emperor. Of the administrative ability of Sejanus there can be no question; but the charm and secret of his power lay in the use he made of those apprehensions of personal danger which seem never to have been absent from his master’s mind. The growth of “delation,” the darkest shadow that lies on the reign, was mainly a consequence of the supremacy and the arts of Sejanus. Historians of Rome in ancient times remembered Tiberius chiefly as the sovereign under whose rule prosecutions for treason on slight pretexts first became rife, and the hateful rule of informers was first allowed to fatten on the gains of judicial murder. Augustus had allowed considerable licence of speech and writing against himself, and had made no attempt to set up a doctrine of constructive treason. But the history of the state trials of Tiberius’s reign shows conclusively that the straining of the law proceeded in the first instance from the eager flattery of the senate, was in the earlier days checked and controlled to a great extent by the emperor, and was by him acquiesced in at the end of his reign, with a sort of contemptuous indifference, till he developed, under the influence of his fears, a readiness to shed blood.

The principal authorities for the reign of Tiberius are Tacitus and Suetonius. The Annales of Tacitus were not published till nearly eighty years after the death of Tiberius. He rarely quotes an authority by name. In all probability he drew most largely from other historians who had preceded him; to some extent he availed himself of oral tradition; and of archives and original records he made some, but comparatively little, use. In his history of Tiberius two influences were at work, in almost equal strength: on the one hand he strived continually after fairness; on the other the bias of a man steeped in senatorial traditions forbids him to attain it. No historian more frequently refutes himself. Suetonius was a biographer rather than an historian, and the ancient biographer was even less given to exhaustive inquiry than the ancient historian; moreover Suetonius was not gifted with great critical faculty, though he told the truth so far as he could see it. His Lives of the Twelve Caesars was written nearly at the time when Tacitus was composing the Annales, but was published a little later. Velleius Paterculus is by far the oldest authority for any part of Tiberius’s life. He had been an officer under Tiberius, and he eulogizes his old general enthusiastically—feeling it necessary, however, to do less than justice to the achievements of Germanicus. To Velleius all defenders of Tiberius have eagerly appealed. In truth it is his silence alone which affords any external aid in repelling the charges of Tacitus and Suetonius, and the fact that Velleius published his work in the lifetime of his master deprives that silence of its value. The eulogy of Sejanus which is linked with that of Tiberius must needs shake faith in the scrupulousness of the author. It is still doubtful whether Dio Cassius (whose History ended with the year 239) in his narrative of the reign of Tiberius is to any great extent independent of Tacitus. In recent times a considerable mass of inscriptions has added to our knowledge of the administration of this emperor. The chief account of Tiberius in English is that contained in Dean Merivale’s History of the Roman Empire. Professor E. S. Beesly has written an interesting defence of him in his Catoine, Cleodius and Tiberius (1878). The best recent history of this period is Hermann Schiller’s Geschichte der römischen Kaiserzeit (Gotha, 1883). Much historical information is given in the editions of the Annales of Tacitus, of which the best in English is that of Furneaux (Oxford, 1884); Freytag, Tacitus and Tactius (Berlin, 1870) (following Stahli, Tiberius, Berlin, 1863), exposes the inconsistencies of Tacitus’ account. Many monographs have since appeared, written on similar lines, among which may be mentioned Jhne, Zur Erekreitung des Kaisers Tiberius (Strassburg, 1902); Gentile, L’Intrepide Tiberio secondo la moderna critica storica (1887); J. C. Varner, Tiberius the Tyrant (1902). The principles of the imperial administration of the provinces by Tiberius have been treated by Mommsen in the fifth volume of his History of Rome, translated into English by W. P. Dickson (1888).

**TIBESTI—TIBET**

TIBESTI, a mountainous and little known region of the central Sahara, inhabited by the Tibbu (q.v.). The country was partly explored in 1876 by Gustav Nachtigal; it had not been again visited by Europeans up to 1910, though French officers had reached Borku on its southern borders. By the Anglo-French declaration of the 21st of March 1899 Tiberist was included in the French sphere of influence in North Africa.

TIBET, or THIBET, a country of central Asia. It is the highest country in the world, comprising table-lands averaging over 16,500 ft. above the sea, the valleys being at 12,000 to 17,400 ft., the peaks at 20,000 to 24,600 ft., and the passes at 10,000 to 15,000 ft. It is bounded on the N. by Turkestan, on the E. by China, on the W. by Kasmir and Laos, and on the S. by India, Nepal and Bhutan. It has an area of over 1,000,000 sq. m., and an estimated population of about 3,000,000, being very sparsely inhabited.

**Origin of Name.**—The Tibetans call their country Bod, which
word in colloquial pronunciation is aspirated into Bhôd or Bhôt, and in the modern Lhasa dialect is curtailed into Bhô. Hence the country is known to Indians as Bhôti, and the inhabitants as Bhôt-îas.

This territory came to be known as Europeans as "Tibet" evidently because the great plateau with its uplands bordering the frontiers of China, Mongolia and Kashmir, through which travellers communicated with this country, is called by the natives Zhô-bhôt (written stod-bod) or "High Bod," or "Tibet," which designation in the loose orthography of travellers assumed a variety of forms. Thus in Chinese annals are found Tu-bol (5th century, a.d.), Tu-po-le, Tu-bul, Tu-bo-le (1018 and 1050 A.D.), etc. Bushell shows, being the same Chinese character which had formerly the sound of po); in Mongolian, Tôbô, Tobôt; in Arabic, Tôbet; in Jetib; J. de Plano Carpini (1247), Thôbet; Rubruquis (1253), Marco Polo (1298), Tébet; Ibn Batuta (1340), Thûtâb; Ibn Haukul (1376), Al Biruni (1020), Ovodic of Purdone (c. 1328), Orazio della Penna (1370), Tébet, which is the form now generally adopted. The inhabitants of Tibet call themselves Bod-po (pronounced usually Bhôd-po), or people of Bod. Owing to the rarefied air the men are somewhat taller than the flowery native writers are. "The Icy Land" (Gangs-Can) and the "Country of the Red Faces" (Gong-mar-gyi-yul). The Chinese name for central Tibet is Wei-T'sang, which is a transcription of the Tibetan designation of the two provinces U and Tsang (spelt dows-gisang) that constitute central Tibet. Among the Mongols, Tibetans are called "Tangutu" and the country Baromitala or the "right side," in contradistinction to Deonitala or the left side, which was their own name for Mongolia itself.

Geography of Tibet. A large part of Tibet is divided into three parts, the lake region in the west and north-west, and the river region, which spreads out on three sides of the former on the east, south, and west. The lake region extends from the Pangong t'so (t'so-lake) in Ladak, near the source of the Indus to the sources of the Salween, the Mekong and the Yangtse. This region is called the Chang-tang (Byang-lang) or "Northern Plateau" by the people of Tibet. It is extensive, elevated, and of the most barren appearance. From its great distance from the ocean it is extremely arid, and possesses no river outlet. The mountain ranges are spread out, rounded, disconnected, separated by flat valleys relatively of little depth. The country is dotted over with large and small lakes, generally salt or alkaline, and intersected by streams, and the soil is boggy and covered with tufts of grass, thus resembling the Siberian tundra and the Pamirs. Its average altitude is over 10,000 feet above sea-level, and it is highly diversified, and fresh-water lakes are intermingled. The lakes are generally without outlet, or have only a small effluent. The deposits consist of soda, potash, bcrax and common salt. This last is frequently found in large quantities. The mines of gold, silver, and copper are mentioned, but probably the result of the action of wind and intense cold. The loftiest lake so far as observed is Hosga t'so, near the Lingshi pass, at an elevation of 17,500 feet, and 27 miles in circumference. The lake region is noted for a vast number of hot springs, which are widely distributed between the Himalayas and 34° N., but are most numerous to the west of Tengri Nor (north-west of Lhasa). So intense is the cold in Tibet that these springs are sometimes represented by columns of ice, the nearly boiling water having frozen in the act of ejection. The southern portion, from Lake Pangong to Tengri Nor, is inhabited by pastoral tribes of Tibetans, and possesses a few hamlets, such as Ombo, Rukud and Senja. The river region comprises the upper courses of the Brahmaputra (Yaru Tsangpo), the Salween (Gyama nyul chu), the Yangtse (Dre chu), the Mekong (Nanga chu), and the Salween (Ma chu). Amidst the mountains there are numerous narrow valleys and ravines, from an altitude of 12,000 ft. downwards, with here and there fine forests covering the mountain sides. Villages of high stone-built houses, are numerous, yet enough to afford a little space for agriculture. The northern portion of Tibet is an arid and wind-swept desert; but in the southern portion the valleys of Lhasa, Shigatse, Gyansitse and the Brahmaputra extend over a good soil and groves of trees, well irrigated and richly cultivated.

The valley of the Brahmaputra (q.v.), or Yaru Tsangpo or simply Tsang-po, is the river as various local names—is the great waterway of central Tibet. On its north bank rises the Indus, by the Himalayas, on the north by a mountain system still more vast. This mountain-system was only vaguely known, in fact its existence was doubted by the little knowledge. During his journeys in 1900-1908, crossed it at several points. He found the system to form the chief physiographical feature of southern Tibet, and stated it to be "on the whole the most massive range on the crust of the earth, its average height above the sea-level being greater than that of the Himalayas. Its peaks are 4000 to 5000 feet lower than Mount Everest, but its passes average 3000 feet higher than the Himalayan passes." Its extreme breadth is almost as great as that of the great basin of the central area, by the chain of lakes running N.W. and S.E. between 30° and 33° N., beyond which the mountains of central Tibet are much lower. The system at no point narrows to a single range; generally there are three great chains, and the valleys are everywhere broad. As across its breadth on the north and south is a great range of mountains, the watershed between rivers flowing to the Indian Ocean—the Indus and its tributaries, Brahmaputra and its tributaries, and Salween—on which different systems flowing to the Indian Ocean are separated. The principal ranges in the system are the Nien-chên-tang-la, called Kanchen-gangri in the west, the Targo-Gangri-Laphching range, the very lofty Humpo-Gangri range, the Dingla range, &c. The Targo-Gangri system is the one that had been studied always by Hedin's discoveries, and named Gangri; Hedin proposed for it the name of Trans-Himalaya.

Geology and Mineral Wealth.—Little is known of the geological structure of the central regions of Tibet. The observations of Strachey, Godwin-Austen and of Griesbach and other members of the Geological Survey of India only extend to the southern edge or rim of the great plateau, where vast alluvial deposits in horizontal strata have been farmed out. These mines are used by Russian explorers but have superficially examined the mountain regions of the north and north-east, and the British mission to Lhasa in 1904 only observed the country lying along the trade-route to that city. The general structure of the Trans-Himalaya and the western mountain system indicate that the main axis of upheaval of the whole vast mass of the Tibetan highlands is to be found on two approximately parallel ridges, which are separated by the Kukim-Yong-tso (10200) lake which is more or less coincident with the watershed between Indus and the central lake region, extending from Lake Pangong to Tengri Nor, the plateau enclosed between the two being wrinkled into parallels of ranges, of which there are two large sets of higher and lower, averaging from 1000 to 1500 ft. The strike of these folds is usually east and west and roughly parallel to the axes of elevation of the mountains. A most remarkable and noteworthy economic feature is the almost universal distribution of gold throughout Tibet. The gold-digging is referred to in some way mythical terms by Herodotus. Every river which rises in Tibet washes down sand impregnated with gold; this sand is not sought, but the miners, from the nature of the intervening strata, but must have existed previously in the crystalline rocks of the main axes of upheaval. In western Tibet the gold mines of Jahang have been worked since 1885. They have been visited by a number of the members of the Indian Survey, who report that much gold was produced and remitted twice a year under a Chinese guard to Peking. The Tibetans diggers collected together at the mines chiefly during the winter, when the frost assisted to bind the loose alluvial sand and render excavation easy. These mines are within 200 m. of the Ladak frontier, near the sources of the Indus, at an elevation which cannot be less than 15,000 ft. above sea-level. These aboriginal gold-digging villages of the Ladak frontier have been abandoned owing to the exorbitant levies levied on gold production by Chinese and Tibetan officials. Between the Ladak frontier and Lhasa the plateau region teems with evidences of abandoned mines, where the Indians have worked over large areas which had been abandoned by the exorbitant levies of past centuries. The gold-diggers are Chinese and Tibetan officials. Between the Ladak frontier and Lhasa the plateau region teems with evidences of abandoned mines, where the Indians have worked over large areas which had been abandoned by the exorbitant levies of past centuries. The gold-diggers are Chinese
desolation is unsolved by the existence of trees or vegetation of any size, and where the wind sweeps unchecked across vast expanses of arid plain. All the western region is but slightly affected by the monsoon. The central plateau is also characterized by extreme dryness in autumn, winter and spring, with an abundant rain in summer, whilst the eastern mountain region, extending to China south of the Dang la (which, with an altitude of 5,000 ft., or 1,525 m., is the highest point on the road to Lhasa), is subject to intense heat in summer and intense cold in winter. In March snow still lies deep in the Tsaidam passes, whilst Welby found the heat oppressive in June on a journey of observation on the plateau south of the He Kun, and a temperate climate prevailing about the sources of the Dré chu (Yangtze) in August.

All travellers testify to the perpetual wind currents from the west, which, in the case of the Tsaidam (9,000 ft.) and through the higher valleys of eastern Tibet, is a prevailing feature throughout Tibet at certain seasons of the year, as it is in the Pamirs, in Turkestan, in western Afghanistan and in Persia. The climate of southern Tibet, however, subject to considerable modifications from that of the northern and central regions, owing doubtless to its geographical connexion with northern India. Here, at an elevation of 13,000 ft., about the great Lango Dung, we hear of crops being richly cultivated; the class of barley is fully represented, and the more prominent kinds are Chusum and Kham-ling. Western and southern Tibetan flora were partially explored previously to the advent of these travellers. Professor Maximowicz concludes from an analysis of the Pjeyval's collection that the flora of Tibet is peculiarly rich in the number of species, and that it is chiefly composed of immigrants from the Himalaya and Mongolia. There is also a large percentage of endemic species. Chinese and European plants follow in the process of immigration. Those species which are distinctive of the eastern border ridges are found to reach the plateau, but do not spread westwards, so that a botanical separation or distinction is found to exist between the true plateau of Tibet and the adjacent tracts of the Pamirs. These farther to the east than the flora of Tibet on the whole as belonging to the Arctic-Alpine section of the great northern division, but containing a purely endemic element. Two typical species are Lysichiton spathularis, which occurs in the Pamirs, and the smaller form, L. pallasianus, an endemic fern specimen obtained by Lüttledale (Polypodium hastatum) is indicative of eastern China. Of the fifty or sixty genera obtained by Dr. Waddell from a single plant are, as a rule, perhaps indicating many of the most characteristic mountain forms. In the higher regions of northern and western Tibet the conditions under which vegetation exists are extreme. Here there are no trees, no shrubs, nor any plants above a foot high. Welby says he saw nothing higher than an onion. The peculiar form of tussocky grass which prevails in the Pamirs is the characteristic feature of the Tibetan Chang-tang of the Tsaidam plains and of the bogs north-east of Lhasa. Of grasses indeed there are many forms, some peculiar to Tibet, but no trees or shrubs at any elevation higher than 15,000 ft., except in the Kharo Pass of central Tibet, where Waddell has recorded the height of 16,300 ft. A flowering plant (Sussurra iridactyla) was discovered by Bower at an elevation of 19,000 ft. In south-eastern Tibet, where Himalayan conditions of climate prevail, we have a completely different flora. Of the list of plants in Rockhill's 'Tibet' the 'hot lands' (Tsari) in southern and south-eastern Tibet, extending even to Batang, peaches, apricots, apples, plums, grapes, water-melons, &c., and even pomegranates, are raised; most of Tibet on the other hand is a land of rice, wheat, barley, or such as parsnips, beans, cabbages, onions, &c. The principal cereals raised are barley and buckwheat, wheat in small quantities, and a little oats. A few localities in the extreme southern portions of the country, and the Lahul Valley, produce tea, a plant much esteemed on the mountainous ridges of the north. A variety of mountain bamboo is found in southern and parts of eastern Tibet, and is much used for basket work. Tibet produces a large number of valuable plants obtainable in China and Mongolia, among others the Cordyceps sinensis, the Coptis teeta, Wall., and Pickorrhiza kurroa, Royle, &c. Rubarb is also found in great quantities in eastern Tibet and Amdo; it is largely exported for European use, but does not appear to be used medicinally in the country. The trees most commonly found are the plane, poplar, maple, walnut, oak, the Cupressus funebris, the Pinus nepalensis, the Ephedra tamariscina, and the Salix smithii. Some of the most valuable plants are obtained in the mountains of southern and south-western Tibet, yielding the excellent yellow and red colours used to dye the native cloths. Waddell gives a list of 164 species of plants collected during his journey between Lhasa and Tashkashim.

Fauna.—The fauna of Tibet has been by no means exhaustively investigated, especially the rodents and smaller species of animals. Among domesticated animals to be found the horse, mule, ass, goat, sheep, yak, oxcart, camel, donkey, and the increased use of the cow is noticeable. Ovis aries and Equus caballus are the commonest species of the domesticated race of the Angora goat, and of the horse, in Tibet, whilst the others are found only as birds of passage. In eastern Tibet, on the Chinese border, varieties of the pheasant tribe abound, some of which are rare. Among them are the white pheasant, the Cerinthus temminckii, two kinds of eared pheasants, and the beautiful Lophura rubriventris. Moreover, the snowcock, the splitird (Tetraogallus tibetanus) are occasionally met with in the uplands, while the ordinary pheasants (Perdix hodgsoni) is common in the region, but there are no partridges.

People.—The Tibetan race, which probably belongs to the Turko-Mongol stock, is divided between the nomadic tent-dwelling Tibetans of the lake region and transition zone between it and the river region, and the settled sedentary population of the valleys. The tent-dwelling Tibetans, called Dokpa or Drupa (spelt kbro-ga), or 'steppe-dwellers,' are generally of a more Mongolized type than the people of the lowlands. The males measure about 5 ft. 5 in., except in eastern Tibet, where 5 ft. 9 in. is a common stature; the females are appreciably less. The head is mesaticephalic, verging on brachycephalic in the case of many of the Dokpa; the hair is black and somewhat curly; the eyes are usually of a clear brown, in some cases even hazel; the cheek-bones are high, but not so high as with the Mongols; the nose is thick, sometimes depressed at the root, in other cases prominent, even aquiline, though the nostrils are broad. The teeth are strong but irregular; the ears, with tolerably large lobes, stand out from the head, but to a less degree than with the Mongols. The mouth is broad, the lips not full, and, among the people of the lower altitudes, decidedly thin. The beard is sparse, and, with the exception of the moustache, which is sometimes worn, especially in central Tibet, it is plucked out with tweezers. The shoulders are broad, the arms round; the legs are not well developed, the calf is especially small. The foot is somewhat small but broad, the hand coarse. The women are usually stouter than the men. The colour of the skin of the Tibetans is a light brown, sometimes so light as to show ruddy cheeks in children; where exposed to the weather it becomes a dark brown. Their voices are full, deep and powerful. They can endure exposure without much apparent inconvenience; and though the nature of the food they use is such that they cannot stand absolute privation for any considerable length of time, they can exist for long periods on starvation rations, if eked out with weak soup or buttered tea, which is drunk at frequent intervals. The sedentary population of Tibet is of the same general type, except in less degree; the same physical traits as the Dokpa, but as one approaches China, India or the border lands generally, one observes that the admixture of foreign blood has considerably modified the primitive type. Among the customs of the Tibetans, perhaps the most peculiar is polyandry, the brothers in a family having one wife in common. Monogamy, however, seems to be the rule among the pastoral tribes, and polygamy is not unknown in Tibet, especially in the eastern parts of the country.

Their religion is described under Lamaism.

(L. A. W; T. H. H.)
TIBET

Language.—The language of Tibet bears no special name, it is merely known as "The Speech of Bod or Tibet," namely, Bod-skud (popularly known as "The language of the Tibetans and transplanted in the P. T. genus"), in contradistinction to the rje-sa or "polite respectful speech," of the educated classes, and the chos-skud or "the style in which the scriptures and other classical works are written.

It is not a uniform speech, but comprises several dialects which have been classed by Jaeschke into three groups, namely, (1) the central or Lhasa dialect, which is the language of the Tibetan peninsula, Tsang (including Spiti) which is the lingua franca of the whole country, (2) the western dialects of Ladak, Lahul, Baltiistan, and Purig, and (3) the eastern dialects of the provinces of Khams. In addition to these, there are many other dialects of Tibetans, which are spoken in the frontier Himalayan districts and states outside Tibet, namely, in Kunawar and Bashahr, Garwhal, Kumaon, Nepal, including Sikkim and Bhutan, and the Bhotanta dialect of Nepal. For the most part, these are not considered as dialects of Tibetan, but are spoken by the Nepalese or Sikkimese, who are not considered as such, and therefore not as a separate people. The language is spoken in the central and the Sifan dialects of a group of dialects on the Chinese frontier, which includes the Minyak, Sungpan, Lianfo, and Tochu dialects. On the north bordering on Turkestan the dialect of the nomadic Hor-pa tribes is much mixed with Turkic ingredients. The number of speakers of Tibetan dialects is probably not far short of eight millions.

Linguistically, Tibetan is allied to the Burman languages, and forms with them a group of languages known as Tungus-Burman-Tibet, and sometimes called "Tibeto-Burman" (q.v.), the unity of which family was first recognized by William Hodgson in 1828, and indeed several of the dialects of Tibetan are still only known through the Burman and Chinese sources mentioned above. The former, of which a knowledge was known of the Tibetan language before Hodgson's time was mainly derived from the writings of the Romish friars who resided in Lhasa in the 17th century, and who are called "the authors of the 18th century." The first serious European student of Tibetan was Csoma de Koros (1784-1842), an indefatigable Hungarian, who devoted his life to the study of this language and the ancient Buddhist literature in it. His name is still remembered today; for he was not known by his full name: Cora, which was a kind of cap he wore, a kind of fur cap which is still common in the Himalayas. The Tibetan characters were drawn by Della Penna and engraved by Ant. Fontanita in 1738. In 1820 Abel Remusat published his Recerches sur les langues tartares, a chapter of which was devoted to Tibetan.

1 The Capuchin friars who were settled in Lhasa for a quarter of a century from 1719 studied the language; two of them, Francesco Orsi and Giovanni Battista Lampugnani, were known as "the two European Capuchins of the Antarctic," and spoke Tibetan, and Cassian di Macerata sent home materials which were utilized by the Augustinian friar Aug. Ant. Geografi of Romana (1711-1797) in his Alphabetai tibetum (Rome, 1762, 4to), a ponderous and rather unemotional work in which some words, especially verbs, were transcribed with great caution. The Tibetan characters were drawn by Della Penna and engraved by Ant. Fontanita in 1738. In 1820 Abel Remusat published his Recerches sur les langues tartares, a chapter of which was devoted to Tibetan.

2 The first Tibetan dictionary for Europeans was a Dictionary of the Bhutana or Bhotan Language, published at Serampur near Calcutta in 1828. It was, however, crude and unedited and contained many serious mistakes, having been taken from the MS. notes of an unknown Italian priest (now believed to be Father Juvalal of Agra, who had been stationed near the frontier of Bhutan), whose MS. was translated into English by Fr. G. Schroeter and published without supervision by any Tibetan scholar; and Csoma was unaware of its existence when compiling his dictionary. As an example of the defective Vol. 1, pp. 247-249. He employed the Tibetan-Deutsche Wörterbuch in 1841, and these corrections of these works which he transcribed in a new, simplified language, and of the general form of the language which has been made by Dr. G. A. Bells in 1841. Meanwhile, the dictionary published by his student Walter, the collection Dictionary of Western Tibet. In 1902 was brought out at Calcutta a Tibetan English Dictionary with Sanskrit synonymes, introduced in 1839 and published by E. S. D. Schier in 1841, and the P. T. deutsches-deutsches Wörterbuch in 1841, and these corrections were made by a number of Chinese, Tibetans, and Missionaries of the English Bible Society. In 1858 a Grammata tibetana, a comprehensive grammar, was prepared by Meilhat, and published by the Press of the Missionary Society of Edinburgh, and edited by Graham Sandberg and the Moravian missionary A. H. Heydey. The Tibetan Manual by W. A. V. Donaldson (1935) is a useful work, and so is the Manual of Tibetan Grammar by C. A. Bell (Cambridge, 1919), which has full English-Tibetan vocabularies, and I. S. B. Survey of India (1908). As regards native philology, the most ancient work extant is a grammar of the Tibetan tongue preserved in a manuscript in the library of the P. T. in St. Petersburg. There are other works of the same kind, dictionaries by later writers, translations of many Sanskrit works on grammar, vocabulary, &c., and bilingual dictionaries, Sanskrit and Tibetan. As separate publications there are several dictionaries in Chinese and Tibetan: Chinese, Manchu, Mongol, Oelot, Tibetan and Turkish; Tibetan, Sanskrit, Manchu, Mongol and Chinese.

The language was first reduced to writing with the assistance of Indian Buddhist monks in the middle of the 7th century A.D. by a Chinese named Sabin, and was first used in the printed form of the Indian Sanskrit charact}
The verb, which is properly a kind of noun or participle, has no element analogous to the English verb "to be." In this respect, Tibetan is like the Anglo-Saxon. In both languages the sentence "I am," /*are/*/*is*, is expressed as an external and internal inflection, or the addition of auxiliary verbs and suffixes when the stem is not susceptible of inflexion, so that instead of saying "I go," "a Tibetan says" /*my go*/. The conditions which cause the prefix to be used are not easily and clearly stated, and imperative are marked either by aspiration of the initial or by one of the five prefix consonants according to the rules of euphony, and the whole looks like a former system thrown into confusion and misapplication of some accidental word order so that the prefix a or e in the present tends to become a in the imperative, the e changing to a in the past and future; and u are less liable to change. Which case then it is difficult to indicate certainly which of the number of verbs are capable of four changes; some cannot assume more than three, some two, and many only one. This deficiency is made up by the addition of auxiliaries or suffixes. There are no new words formed by assonance and consonantial changes, and languages of eastern Asia, though words expressive of a collective or integer are often used after the tens, sometimes after a smaller number. A good deal of new research on the grammar is to be found in Grisewood's "Linguistic Survey of India," part III., 1908. In scientific and astrological works, the numerals, as in Sanskrit, are expressed by symbolic words. In the order of the sentence the substantive precedes the adjective and the verb last; the object and the adverb precede the verb, and the genitive precedes the noun on which it depends; this contrasts with the order in the isolating Chinese, where the order is subject, verb, object. An accent has been assigned to the nouns in the nominative case, which goes only before a neuter or intransitive verb. The chief differences between the classical language of the Tibetan translators of the 9th century and the vernacular, as well as the language of the present day, are vocabulary, grammar and grammatical structure, and arose from the influence of the translated texts.

The Tibetan language, presenting such marked differences between its written and spoken forms, has a great interest for philologists, *Philology*. On account of its bearing on the history of the monosyllabic languages of eastern Asia, with their so-called "Isolation," or "Foreign," or "Intransitive," or "Nominal," or "Consonantal," or "Consonatical" forms. Is the Tibetan a monosyllabic language passing to agglutinative, or the reverse? The question has turned mainly upon the elucidation of the phenomenon of the silent letters, generally prefixed, which differentiate the meaning of words, without their pronunciation, in the central dialect or current speech of Lhasa. Rémusat rather dubiously suggested, while Schmidt and Schlegel, in the "Voyage en Chine," have been led to the view that the Tadji is a monosyllabic language of two parts, or in the order of the language, "Isolation," with the superimposition of "Consonantal," or "Consonatical," forms. Is the language monosyllabic, or "Isolated," or "Nominal," or "Foreign," or "Intransitive," or "Consonantal," or "Consonatical," as the case may be? The question of whether the pronunciation is that of a written, or the written that of a spoken, language is a problem of great interest.

The question of whether the language is "Isolated," or "Foreign," or "Intransitive," or "Consonantal," or "Consonatical," or "Nominal," or "Isolated," or "Foreign," or "Intransitive," or "Consonantal," or "Consonatical," as the case may be, is a problem of great interest. account just given stands good whatever solution the question of prefixes may receive in future.

**Literature.**—The religious literature, which is very considerable, is the source of almost all our information about the legends and folk-tales and superstitions of the Tibetans. A number of Tibetan religious treatises, with a few monastic and other works, have been translated into English, and a few of the more popular and classical Buddhist works have been published in the vernacular (Tibetan). Most of the Buddhist literature of Tibet is divided, probably owing to the printing being in the hands of the priests. One of the most popular and widely circulated books is called *The Hundred Thousand Songs of the Vajra Song* (Dzongs i lha). This name is usually ascribed to Mila, although this book (ascribed to his disciple), often called Mila, was a Buddhist ascetic of the 11th century, who, during the intervals of meditation travelled through the upper part of the country, and thus became acquainted with the people by their improvisations in poetry and song, proselytizing, refuting and converting heretics, and working manifold miracles. His legends are not without wit and poetical merit. An equally popular and instructive work is *Sgrungs rgyags* (At the Feet of the Dissipated Young Dalai Lama who was deposed in 1701 (see LILASA). There are a number of poems written in an elevated style, also dramatic works chiefly alluding to characters of mystic lore and the history of the Tibetan race. The Tserig Epic, which has been translated by A. H. Francke under the title of the *Kesar Saga*, is a widely known tale of a heroic warrior king of northern Asia named Kesar (believed by some to be a transcription of "Czar") but it is not found as a printed book. Several collections of folk-songs have also been published by A. Francke from Ladak. A long story book, called the *Dijiang yi* (*Sjugro ba giungs*), and regarded as the national epic in Khiam, has been partly seen by Dreogol and Baber. It is in prose; but the dialogue, interspersed with songs, is metrical, and is much more extensive than the prose framework. Religious literature includes instructions alternative with comic episodes. It includes three divisions—the *Dijiang ling*, which describes the invasion of part of Tibet by the Dijiang or Moso; the *Hor ling*, which recounts the conquests of the Hor (Turk tribe) from that country; and the *Dijiang ling* (Chinese division), which narrates a contest of unknown date between the Tibetans and the Chinese. This work has apparently never been published, and even the titles of the three divisions cannot, says Baber, be obtained in a complete form. But every Tibetan, or at least every native of Khiam, who possesses any education, is able to recite or to chant passages of the work. Another Tibetan story, Khaur, the *Gyjaldrug*, praises Dzigolme, a famous warrior who subdued the savage men of Khiam. Dramatic works exist, as also a version of the *Ramayana* in the first volume of the *Bsdilogs* of the Peking University.

**Writing.**—Writing was not introduced until the 7th century. Notched sticks (shing-chram) and knotted cords were in current use, but the latter contrivance is only faintly alluded to in the Tibetan records, whilst of the other there are numerous examples. No mention is anywhere made of a hieroglyphical writing, but on the eastern frontier the medicine-men or *lomba* of the Moso have a peculiar pictorial writing, which is known in Europe from two published MSS. (In Journ. Roy. Asiatic Soc., 1855, xvi.), though apparently now confined solely to purposes of witchcraft, it perhaps contains survivals of a former extensive system superseded by the Tibetan letters. According to Baber, writing, as it now exists, is a development or confused mixture of the old Sanskrit and modified Sanskrit "writing in thirty characters" (already detailed under Language and six of which do not exist in Sanskrit) in two styles, the thick letter and the thin letter, the latter being the more common, and is used in printed books, and the half-cursive "cornered letters," so called from their less regular heads. The former are traditionally said to have been derived from the Landza character. The Landza of Nepal, however, is certainly not the origin of the Tibetan letter, but rather an ornamental development of the parent letter. The close resemblance of the Tibetan characters "with heads" to the Gupta inscriptions of Allahabad shows them to be of the same parentage, and the monumental writing of the four main divisions of the Dravidian family, and various arguments appear to show that the other Tibetan letters came from the same Indian character in the style in which it was used in common India. The "half-cursive" or "headless" (a-med) characters, of which there are several styles. The ancient manuscripts discovered by Dr. M. Aurel Stein in Khotan seem to include very early, if not the oldest, forms derived from the script. (A. W. & C. L., Tibet.)

**Political Divisions.**—Tibetans divide their country into five provinces: (1) Amo, which comprises that part of the Chinese province of Kanshu which is inhabited by Tibetans, and Koko Nor region, extending southwards to the Yellow river and westwards as far as the Tasaidam. Amo is inhabited in its eastern part by Tibetans, called Rongga or "razheng-folk," who are agriculturists, and in the western by pastoral tribes, collectively called Panaka or the Three Panakas. (2) Khams or Khamde, which includes all eastern Tibet between the Chinese provinces of Szechuan and Yunnan, and the district of Lhong, which forms the eastern border of the Lhasa-governed territory. This province is divided into the five Horba tribes, the eighteen Nyarong states in the valley of the upper Yalu, and the districts of Litang, Batang, Derge, Gartok Chiamdo and Draya. In Khamdo, but subject to the direct rule of Lhasa, are several small districts, the principal are Nyarong, Tsarang, and Mar Khams or "Lower Khamdo." Most of these districts are governed by *daba* or chiefs, while a few have kings or *gyalpo*, the most powerful of the latter being the king of the Litang district, who is the head of Chagla, or, as it is better known, Tachenlu, as it is called by the Chinese or the Dartsenmo of the Tibetans, the headquarters of the ten trade with China. Khamdo is under the direct rule of the Chinese provincial authorities of Szechuan. Some of its rulers send also tribute missions to Peking. For convenience of classification we may include in Khamdo a long strip of country extending along the northern border of the Lhasa territory of Lhong-jong and Larego as far as Tengri Nor, and bounded to the north by the Tang-la mountains, which is designated by Tibetans as *Gyuda* or "the Chinese province." This strip of country has its own native chiefs, but is under the control of a high Manchu officer stationed at Lhasa, known colloquially as the "superintendent of savage tribes." (3) The third political division is *U* (written Dhus), meaning "Central." It includes Lhasa and a large number of outlying districts in south-eastern Tibet, such as Po, Pemakothen, Zayul. The pastoral or Dokpa tribes, north and north-east of Tengri Nor, are also under its rule. (4) The fourth division of Tibet, called *Tsung*, includes all south-west Tibet from the Lhasa or Central frontier to the Indus. (5) The fifth division, called *Nari* (Mngah-ri) by the Tibetans or *Hande* by the Indians, who call the inhabitants Haniyias, comprises the whole country around the sources and along the upper course of the Indus and the Sutlej, and also all north-western Tibet generally, as far as Ladak and the border of Kashmir. Tsang and Nari are under the rule of Lhasa, all the high civil and military authorities in these provinces holding their offices from these. These provinces, however, do not include the elevated steppes of Tsaidam (extending between the Kuen-lun and the Altyn Tagh), inhabited by a mixed race of marauding people, Tunguts and Mongols. Yet Tsaidam is geographically a northern extension of the great Tibetan plateau, and in most of its essential physical features it is more closely allied to the Chang-tang of the south than to the sandy depressions of Chinese Turkestan or Mongolia on the north.

**Government.**—Though the whole of Tibet is under the suzerainty of China, the government of the country is divided into two distinct administrations, the one under the rule of the Dalai Lama of Lhasa, the other under local kings or chiefs, and comprising a number of fields or fiefs immediately controlled by the high Chinese officials residing at Lhasa, Sining Fu, and the capital of the Chinese province of Szechuan. North-eastern Tibet or Amo, and also a portion of Khamdo, are under the supervision of a high official (Manchu) residing at Sining Fu in Kanshu, whose title is Imperial Controller-General of Koko Nor. The native chiefs of the Panaka and other Tibetan tribes of this region are styled *phesa* ("official") or "headman") by both the natives and the Chinese. The region under the supervision of the imperial controller includes all the countries north of the upper course of the Dere-chu (Yar-khol). They pay to China a tax of some 3d. to any other impost; they also pay a small tax in kind, sheep, butter, &c., to their chiefs. The province of Khamdo, including all eastern Tibet, is governed by local chiefs, styled *gyalpo*, "king," and *daba*, "chief," succession to the chieftainship being usually assured to the eldest son not a lama. Each chief appoints a certain number of civil and military officers to assist in the government of the country, and each village has its headman or *besa*, also an hereditary office. None of these officials receive salaries; they are only exempt from taxation, and some have grants of land made to them. The only tax paid to China is a so-called "horse-tax" of about 3d. for each family. Once in every five
years the chiefs send a tribute mission to the capital of Szechuen, and once every ten years to Peking, but the tribute sent is purely nominal. The Chinese maintain a few small military posts with from six or eight to twenty men stationed in them; they are under the orders of a colonel residing at Tachienlu. There are also a few lama chiefs.

The part of Tibet under the rule of Lhasa, by far the largest and wealthiest, includes the central province of Ī, Tsang, Nari, and a number of large outlying districts in southern and eastern Tibet. The central government at Lhasa, all of the province is at Lhasa; the nominal head is the Dalai lama or grand lama. The Tashi lama or head of the monastery of Tashihunpo near Shigatse is inferior to the Dalai lama in secular authority, of which, indeed, he has little—much less than formerly—but he is considered by some of his worshippers actually superior to him in religious rank. The person next in consideration to the two great lamas is the regent, who is an ecclesiastic appointed during the minority of each Dalai lama. Under him are four ministers of state (sha-po or kalön), who divide among themselves, under the immediate control of the chief minister, the management of all secular affairs of the country. There is also a Tsong-du or National Assembly, divided into a greater assembly, including all government officials, and called together only to decide on matters of supreme importance, and a lesser assembly, consisting of certain high officials of Lhasa, noblemen, and delegates from the monasteries of Debung, Sera, and Galdan, and fairly constantly in session. The Tsong-du discusses all matters of importance, especially relating to foreign policy, and its decisions are final. The army is under the command of the senior Chinese amban, a Tibetan generalissimo or mag-pön, and six Tibetan generals (dak-pön or de-pön). The military duties of the generals are slight, but their political status is high. Under the dak-pön are six rü-pön or colonels, and a number of subordinate officers. The regular army consists (in theory) of 6,000 men, on active service for three years, and at home on half-pay for three years. After the six years they pass into the reserve or militia (yul-mag). The taxes paid to the Lhasa government are mostly in kind, sheep, ponies, meal, butter, wool, native cloth, &c., and the coin paid is said to be about 30,000 ounces of silver a year. Chandra Das states that the crown revenues of Lhasa amount to about 3,000,000 rupees annually.

All high Tibetan officials, whether ecclesiastics or laymen, are appointed subject to confirmation by the Chinese government. The administrative subdivisions of the Lhasa country, of which there are fifty-four, are called jong, or "prefecture," each of which is under the rule of two jong-pön, the one a lama, the other a layman. They collect all taxes, are responsible for the levy of troops, the courier service, corvées, &c., and exercise judicial functions, corresponding directly with Lhasa. There are 123 sub-prefectures under jong-nyer. Under them are village headmen or tsö-pön, headmen or mi-pön, and elders or gya-po. All are appointed for indefinite periods by the prefects.

Industries and Trade.—The industries are confined to the manufacture of woolen cloth of various degrees of fineness and colour. and called iruk, irma, and lams, to that of small rugs, pottery of an inferior quality, utensils of copper and iron, some of which show considerable artistic design, and to such other small trades as are essentially the banks of the province. The best artisans are Nepalese and Chinese, the former being the best workers in metal and dyers.

The great trade routes are, first, that which, starting from Cheng-tu, the capital of the Chinese province of Szechuen, passes by way of Tachenlur or Dartsedo, Litang, Batang, Chiamdo, Larego, Lhasa, Gyantse, Shigatse, reaches the Nepalese border at Nielam and goes thence to Katmandu. This route is called Gya-lam, "the China road" (or "high road"); the great bulk of Tibetan travel goes over it. Minor roads go from Sinping Fu in the Chinese province of Kansu via Tsialdam and the Tachenlur to the Tsangpo valley at Nielam or "northern road," which was much used by traders till the middle of the 19th century, when the Mahommadedan rebellions in northwestern China practically closed it. Another road starts from Szechuen and follows the river Szechuen, by way of the Yarrow River, joins the Gya-lam at Chiamdo; it is little used, as it passes through the country of the wild marauding Golok. Still another route starts from Tachenlur, and by the valley of the Yalung and the Dzo chu runs to Yekundo, and thence to Chiamdo. From this point it leads to Kirocho, and then through Gyade or Chinese province, thence to Lhasa and Lhasa. An important trade route from Sikhim Fu in Yarkandese region (Guiedad of the French missionaries) joins the Gyamal at Batang.

The most direct route from India to Lhasa, and that most frequented by the traders of Lhasa, is by the Chumbi Valley, and was opened by Sir Robert Brown in 1851. It runs from the British station of the Tang Pass (15,200 ft.), and thence proceeds via Gyantse (13,200 ft.) and the Khargo Pass (16,500 ft.), Yamdok Lake (15,000 ft.) to the Tsang-po (12,100 ft.), and crossing the river which runs up along the Kyi Chu, on the general level of the Chumbi, down to the Wei, 250 miles from Lhasa. The road from Simla goes 200 miles about midway between Lhasa and Lake Mansarowar. Further west Tibet may be reached from Kumaon by one of a group of passes (of which the best known is the Milam) leading to Lake Mansarowar. The lake becomes a sort of obligatory post on all routes to Tibet which lie between Ladak and Nepal. The Shipki road from Simla, which strikes the Sutlej at Totling (where there is a bridge), leads up to Manasarowar, coinciding with the high road (Changlow) after passing Totling. The remarkable area of gold-mining industry which lies to the north-east of Gartok is reached by another route from Leh, which, crossing the Chang-la close to Leh, passes by Rudok and goes to Katmandu. One of the most important lands of Tibet is the Chinese brick-tea, which even passes as currency. The tea imported from Szechuen is for the most part of inferior quality, estimated at 35% tea-leaves and 65% twigs and other material. It is compressed into large bricks, and costs two-thirds of a penny per pound. Efforts have been made by the planters of the Duars to prepare Indian brick-tea for the Tibetan market, which it is essential to counteract the European invasion of the market.

Money.—It is curious that Tibet, though using coined money, seems never, strictly speaking, to have had a coinage of its own. Till nearly the end of the 18th century the coinage had for a long time been derived from Nepal. That valley prior to the Gurkhas' domination (1766) was divided into four states (Kathmandu, Patan, and Katmandu), and these struck silver mohurs, as they were called, of the nominal value of half a rupee. The coins were sometimes struck with silver and copper, strung together in necklaces. These latter bore (obverse) a Nepalese emblem surrounded by eight fleurons containing the eight sacred Buddhist jewels, and (reverse) an eight-petalled flower surrounded by eight fleurons containing the names of the eight jewels in Tibetan characters. Portions of Chinese silver were sent from Lhasa with a small proportion of gold dust, and an equal weight in mohurs was returned, leaving to the Nepal rajahs, between gold dust and alloy, a good profit. The trade in these coins (which we may perhaps consider as almost the last to deteriorate) is said to have been a small addition to wealth. But the Gurkhas were mistrusted and their coin refused. A coinage was then issued which appeared only once in Tibet for domestic circulation, and was known as "kang-kow, i.e. miskangyung ("cash") are cut into aliquot parts, and in commerce are known as "la-poch," or "la-choo," the Chinese silver, stamped with the imperial seal, are also used. But of late years there has been an enormous influx of Anglo-Indian rupees, so that these have become practically the currency of the
country, even to the frontier of China, and are now counted, instead of being valued as bullion. They are called Piting tanka, (foreign coins), from the Hindi tanka, a rupee.

**Weights and Measures.**—The weights and measures in use are practically those of China. Desideri remained in the west till employed at the court of Lhasa, and the jealousies of the people are, the bre or bo of about four pints and the chush of twenty bo; the capacity of the bo varies according to localities. The most commonly used measures of length are the span (mto), the cubit (brau), and the arm’s-length or fathom (doppa).

**Exploration.**—Tibet was a terra incognita to Europeans. It is difficult of access on all sides, and everywhere difficult to traverse. Its great elevation causes the climate to be rather arctic than tropical, so that there is no gradual blending of the climates and physical conditions of India and Tibet, such as would tend to promote intercourse between the inhabitants of these countries. On the contrary, there are sharp lines of demarcation, in only a few points, and in the social aspects and conditions of life on either side. No great armies have ever crossed Tibet to invade India; even those of Genghis Khan took the circuitous route via Bokhara and Afghanistan, not the direct route from Mongolia across Tibet. Added to this was the religious exclusiveness of the Tibetans themselves. Thus it was no easy matter for the early European travellers to find their way into and explore Tibet. Frater Odoric of Pordenone is supposed to have reached Lhasa via the Tangrung, Cathay; but this visit is doubtful. On the strength of certain statements in his narrative, and of other accounts, Mendes Pinto, some authorities hold that he may have visited Lhasa in the course of his journeys in the middle of the 14th century. The Jesuit Antonio Andrade, a native of Portugal (1586-1634), travelling from India, appears to have entered Tibet on the west, in the Manasarowar Lake region, and made his way across to Tangut and north-western China; in 1661 the Jesuit fathers Johann Guebier (an Austrian) and Albert D’Orville (a Belgian) travelled from Peking via Tangut to Lhasa, and thence through Nepal to India. The extracts from Guebier’s narrative, given by Gabet, in his Kitab-i-burj (1667), are accompanied by a good drawing of Potala. During the first half of the 18th century various Capuchin friars appear to have passed freely between Calcutta and Lhasa (1708) by way of Nepal. They even founded a mission in Lhasa, which, after failing at first, was more firmly established in 1715 and lasted till 1733.

In 1716 two Jesuits, P. Ipolito Desideri, of Pistoia, and P. Freyre, a Portuguese, reached Lhasa by way of Kashmire, Ladakh, and the enormous journey from Ladakh by the holy lakes and the valley of the Tsangpo. The Jesuit at Lhasa till April 1721, witnessing the capture of Lhasa successively by Dzungar and Chinese. Of the moderation of the latter, and their abstinence from all outrage or plunder, he speaks highly. His departure was due to controversies between the Jesuits and Capuchins at Rome, which caused an order to be issued for his retirement from Tibet. An interesting letter from him, dated the 10th of April, 1716, is printed in the Lettres édifiantes, rec. xv., and he left a large MS. volume of his observations. The next European visitor was Samuel Van de Putte, of Flushing, an LL.D. of Leiden, whose thirst for travel carried him through India to Lhasa (1731), where he is said to have resided a long time, to have acquired the language, and to have become intimate with some of the lamas. After travelling from Lhasa to Peking with a Lama mission he returned, again by Lhasa, to India, and was an eyewitness of the sack of Delhi by Nadir Shah in 1737. Unhappily he ordered papers to be burnt after his death, and the knowledge that such a traveller must have accumulated died with him. In 1745 the Capuchin mission finally collapsed after a revival had been attempted in 1741 by a party under Orazio della Penna, of which Cassiano Bellettagi was chronicler. We possess some of the results collected by this mission in an excellent short treatise on Tibet by P. Orazio himself, as well as in the Alphabeta Tibetana of the Augustine monk A. Georgi (Rome, 1762). Some fifty volumes, the relics of the mission library, were in 1847 recovered from Lhasa by Brian Hodgson, through the courtesy of the Dalai Lama himself, and were transmitted as an offering to Pope Pius IX. The first Englishman to enter Tibet was George Bogle, a writer of the East India Company, in 1774, on an embassy from Warren Hastings to the Tashi lama of Shigatse. In 1783 Lieut. Samuel Turner was despatched on a mission similar to that of Bogle, and reached Shigatse, 1811-1812 the first English visit to Lhasa occurred. The travelled was Thomas Manning, a Cambridge man of Calius College, who had been long devoted to Chinese studies, the “friend M.” of Charles Lamb, from whom “Elia” professes to have got that translation of a Chinese MS. which furnished the dissertation on roast pig. After residing some years at Canton, Manning went to Calcutta, bent on reaching the interior of China through Tibet, since from the seaboard it was sealed. He actually did reach Lhasa, stayed about five months, and had several interviews with the Dalai Lama but was not destined to go further. He never published anything regarding his journey, and its occurrence was unknown to few, when his narrative was printed, through the zeal of Mr (afterwards Sir) C. Markham, in 1876. The account, though containing some passages of great interest, is disappointing. Manning was the only Englishman known to have reached the sacred city without the aid of an army. But the Abbé Huc states that William Moorcroft, an Englishman who made a journey into Tibet in the neighbourhood of Lake Manasarowar in 1812, and who afterwards went to Kashgar in 1824, lived in Lhasa for twelve years disguised as a Mussulman, and then went to the Afghan frontier in 1825 on his second journey; but if Huc’s statement is true he reached Lhasa in 1826, and did not leave it till 1838, being assassinated on his homeward journey, when maps and drawings were found on him, and his identity was for the first time suspected by the Tibetans. During the 19th century Europeans were systematically prevented from entering the country or speedily expelled if found in it. In 1844-1846 the French missionaries, Évariste Régis Huc and Joseph Gabet, made their way to Lhasa from China. They travelled from China the route followed by Guebier and Van de Putte, and reached Lhasa on the 29th of January 1846. On the 15th of March they were sent off under escort by the rugged road to Szzechueh. Huc’s book, Souvenirs d’un voyage, &c, is one of the most delightful books of travel. Huc was, indeed, not only without science, perhaps without accurate knowledge of any kind, but also without that geographical sense which sometimes enables a traveller to bring back valuable contributions to geographical knowledge though unable to make instrumental observations. He was, however, amazingly clever as a narrator and sketcher of character. It was Ke-sien, a well known Chinese statesman, who was dispatched for the purpose of keeping peace with the English at Canton in 1841, and was then on a special deputation to Lhasa, who ostensibly expelled them. The Tibetan regent, with his enlightened and kindly spirit, is painted by Huc in most attractive colours, and Markham expressed the opinion that the native authorities were then willing to receive strangers, while the jealousy that excluded them was Chinese only. The brothers Henry and Richard Strachey visited Manasarowar Lake in 1846 and 1848 respectively. In 1866 the Abbé Desgodins travelled through portions of eastern Tibet and reached Chiamdo (in Khâm), but was prevented from approaching any closer to Lhasa.

Beginning in 1863 a number of native Indian explorers were sent by the government of India into Tibet, for the purpose of surveying the country and collecting information about its inhabitants. These men were specially trained at Dehra Dun in the work of surveying, and entered Tibet with a strong wooden box with a specially concealed secret drawer for holding observing instruments, a prayer wheel with rolls of blank paper instead of prayers in the barrel on which observations might be noted, and lamaze rosaries by the beads of which each hundred passes might be counted. As may be imagined, they carried their lives in their hands in case of discovery. The best known of these men were Pundit Nain Singh, Pundit Krishna, originally known as A.-K. (from the first and last letters of his name transposed) and Uyen Gyaoto, or U.-G. Nain Singh reached Lhasa in the course of two remarkable journeys. In the first, after an ineffectual attempt by Nepal, he
travelled by the Manasarowar Lake, and the road thence eastward, parallel to the course of the Tsango, reaching Lhasa on the 10th of January 1866, and leaving it on the 21st of April 1867. On the second journey (1874) he started from Ladak, crossing the vast and elevated plateau by the Tengri Nor and other large lakes, and again reaching Lhasa on the 18th of November. Nain Singh gave an account of his journeys, and of his residence there, which, though brief, is full of intelligence and interest. This enterprising and deserving man, on the completion of his journey in 1875, was rewarded by the Indian government with a pension of information and land, and afterwards received the silver medal of the Royal Geographical Society and the Companionship of the Star of India. He died early in 1882.

In 1878 A.-K also revisited Lhasa, stayed a year, and afterwards continued into Tsaidam, not returning to India till 1882. Lama Ugyen Gyatsa, a semi-Tibetan, who was originally a teacher of Tibetan in a Darjeeling school, was trained by the Indian Survey Department as a surveyor, and being deputed to take tribute from his monastery to Tashilhunpo, he secured permission in 1879 from the Tashilhunpo authorities for Sarat Chandra Das, Bengal schoolmaster at Darjeeling, to visit that monastery, where his name stood as a vacancy. It was the opportunity for a series of valuable exploratory journeys through the Tibetan provinces adjoining the Indian and Nepalese frontiers, which added greatly to our stock of information about Lhasa and the districts surrounding that city. In their first journey the travellers set out from Jogni in Sikkim, and traversing the north-east corner of Nepal, crossed into Tibet by the Chatang la, and travelled northwards to Shigatse and Tashilhunpo. They returned by much the same way to near Khamba jong, and re-entered Sikkim by the Donkya pass. The journey was fruitful of information and of land, for mapping. Ugyen Gyatsa undertook another journey in 1883 to complete and extend his former surveys. Travelling by way of Khamba jong directly to Gyantsé and Shigatse, he turned eastwards at the latter town, finished the survey of the Yamdok tso, and crossed the Himalaya into the valley of the Lobratsangpo or Upper Manas river. At Shakhang jong he was arrested, and his true character discovered. He managed, nevertheless, to extricate himself, and turning north-eastwards he passed through Chetang, and reached Lhasa by way of Samye monastery. From this city he started for Darjeeling, which he reached on December 15th, 1882, into Central Tibet made a second journey in 1881, with the intention of reaching Lhasa. He travelled by way of Tashilhunpo, lay dangerously ill for some time at Samding monastery, duly reached Lhasa, where he visited the Dalai Lama, but owing to small-pox in the city could remain there only a fortnight, though he made full use of this time. During a journey home occupying nearly half a year he collected much further valuable information. Sarat Chandra Das's reports of his two journeys were published by the Indian government, but for political reasons were until 1890 kept strictly confidential. In 1899 they were edited by the Royal Geographical Society and in 1902 published. They contain valuable information on the superstitions, ethnology and religion of Tibet. Chandra Das also brought back from his journeys a large number of interesting books in Tibetan and Sanskrit, the most valuable of which have been edited and published by him, some with the assistance of Ugyen Gyatsa and other lamas.

The Russian explorer Prjevalsky, although he was not, strictly speaking, an explorer of Tibet, did much industrially towards determining the conformation of its north-eastern and eastern mountain systems. His third journey, into Central Asian wilds, which lasted from March 1879 to October 1880, included the sources of the Hwang Ho, or Yellow river, till then unmapped and unknown. His fourth journey, between November 1883 and October 1885, covered much of northern Tibet, and established the true character of Tsaidam. It was when setting out in 1888 to make an attempt to reach Lhasa that he died.

After Prjevalsky's death, V. I. Roborovski, with several companions, explored the western ranges of the Kuen-lun, and crossed southwards into Tibet, tracing the course of the Kiria river to the north-western plains of the central plateau. The distinguishing feature of these explorations, led by Russian officers, is their high scientific value and the contributions they have offered to the botany, natural history, geology and meteorology of the regions under investigation in addition to the actual geographical data attained. The Kuen-lun is known in their writings as the Russian Range.

In 1888 Mr W. W. Rockhill, an American possessing the unique qualifications for Tibetan exploration of a profound knowledge of the language and history of the country, coupled with the instincts and training of a scientific explorer, with the lamasery of Kumbum in north-western Tibet, took with three Chinese servants and a small caravan, proceeded round the north shore of Koko Nor, crossed eastern Tsaidam, and explored some of the rivers and lakes directly south of that region. Leaving Barong Tsaidam, he travelled south by way of the sources of the Yellow river, till he reached the Dre chu (upper Yangtsze-kiang), which he crossed to the north of the important trading centre of Yekundo. From this point he followed the valley of the Dre chu till about lat. 30° 31', where he passed into the basin of the Yelung river, traversed the Hornu basin, and finally reached Tachienlu by the Gi la and the valley of the Darchu.

In 1891 Mr Rockhill, starting again from Kumbum with three Chinese, passed south of Koko Nor through the country of the pastoral Panaka Tibetans, and by a very difficult pass (Vahon jamkar la) entered again the basin of the Tsaidam. He then turned west, followed the base of the south Tsaidam range as far as the Naichi Gol, where he entered the southern mountainous region forming the northern borderland of Tibet. From this point the traveller followed a general south-westerly direction around the heads of all the feeders of the upper Dre chu, and thence into the lake region of northern central Tibet, crossing Bonvalot's route south of the Chi-chang tso and that of Bower a few days farther south. Here, just north of the Namur tso his farther progress south was arrested and he was compelled to take an easterly course. After making a long détour north, often crossing the roads previously travelled by Bonvalot and Bower, and passing by Riwoche, he came to Chimdo and Tachienlu. The results of Mr Rockhill's two journeys were important and valuable.

Messrs A. D. Carey and A. Dalgleish in 1885–1887 made a protracted journey from Ladak, in the course of which they crossed the Aksai Chin, reached Khotan, entered the Tarim basin, and subsequently made their way eastwards and then southwards across the Alyn Tagh and the Tarim Khotian, and other ranges to the Tsaidam region. Finally a second journey was made into the north-west, through the Humboldt range, and by Hami, Urumchii, and Yarkand to Ladak again.

Bonvalot, accompanied by Father Dedeken of the Belgian Catholic Mission and Prince Henri d'Orléans, left Charkhil, south-west of the Lob Nor, in November 1889, and taking a very nearly due southerly course, reached on the 13th of February 1890 the eastern end of the Tengri Nor. Then pushing southwards, he crossed the Nienchen-tang-la and entered the Dam district near the Lhasa-Sining high road. Here the party was stopped by Tibetan authorities and forced to take the tea route through Chinese Tibet (Gyade) by way of Batasumdo, Chebotenchin, Riwoche, Chiamdo to Changka, near the upper Yangtsze-kiang, whence they proceeded to Tachienlu by Batang and Litang. Bonvalot noted some extinct volcanoes in the northern Tibet desert.

Accompanied by Dr W. G. Thorold, of the Indian Medical Service, and a native sub-surveyor, Captain Hamilton Bower, I.S.C., set out from Leh on the 1st of June 1891, and crossed the Lanak la and the Ladak frontier on the 3rd of July. From this point the party took a general easterly direction past the Mangtza tso, Horpa tso, Charol tso, and around the northern end of the Aru tso, all important lakes, at an average altitude of about 16,500 ft. From the Aru tso the travellers took a south-easterly direction...
TIBET

across the great northern plateau or Changtang till they reached the south-eastern side of the Garing t'so, in about 31° 30' N. and 89° 10' E. At this point Bower was stopped by some of the headmen of the Tibetan pastoral tribes (here under the rule of Lhasa), and obliged to make a long circuit to the north west well out of Lhasa territory, and then eastward—till he struck the road to Chiamdo through Gyade or Chinese Tibet. Crossing the Sining-Lhasa road a little south of the Dang la range, and about two days' journey north of Nagchuka, Captain Bower crossed the Su chu, and following a course parallel to the Giama-nu chu, he made his way to Rwoche and thence to Chiamdo, from which town he followed the Lhasa-Tachienlu high road to the latter town, which he reached on the 18th October. The results of Captain Bower's journey were all of first-class importance.

Miss Annie R. Taylor, an Englishwoman of the China Inland Mission, started from Tao-chow (Kansuh) in September 1892, accompanied only by five Asiatics. Passing by the famous lamasery of Labrang, south of the yellow river, she crossed the river and traversed the southern part of the country inhabited by the predatory Tibetan tribes called Golok. Thence, after crossing the upper Yalung, which flows by the town of Kanze, she pursued the junction of the upper and lower roads of the Vangpo-shiang (Dre) crossing that river somewhere near where A.-K. had crossed it in 1881 and Rockhill in 1889, and then came to the town of Gye-Yekundo. From this point she seems to have followed the Chiamdo road to near that town, when she turned westwards and continued in that direction till she came on the high road from Lhasa to Sining Fu somewhere north of Nagchuka. Here, like all other European travellers who have tried to reach Lhasa from the north, she was stopped by the Lhasan authorities. She appears to have followed about the same route on her way back to China, for she again went to Yekundo and thence by the high road followed previously by A.-K. and Rockhill, to Tachienlu in Sze-ch'uen, where she arrived on the 12th of April 1893.

In 1893 MMJ L. Dutreuil de Rhins and Fernand Grenard, both Frenchmen, left Chercen, with Lhasa as their objective. After crossing the Kara muren davan in the Arkha Tagh, they entered the lake region of north Tibet and followed a general southerly direction across low ranges of hills and plateaus, and by numerous small lakes till they arrived in 31° 30' N., where they changed direction to east-south-east, passing to the north of the Chargut and Ziling lakes. The travellers were able to push on as far as the north-eastern bank of the great Tengri Nor, which they reached on the 30th of November 1893. Here they were finally stopped by the Tibetans, and after a delay of six weeks passed in vain attempts to obtain permission to go to Lhasa, they were only allowed to proceed to Nagchuka on the Sining-Lhasa road, and to continue by the Gyade route to Yekundo, near the upper Dre chu, and thence to Sining in Kansuh. From Nagchuka the travellers followed a heretofore unexplored road through the Gyade country, crossing Rockhill's route in the Pse-Sangyl districts near Tashiilin (their Tachi gompa). The road followed by them to Yekundo is called by Tibetans the upper road (gong lam), and had apparently been followed previously by Miss Taylor. Reaching Yekundo (or Gergundo) on the 21st of May 1894, the travellers started for the Koko Nor and Sining on the 1st of June; but the party was attacked near Tungbhumdo (Tumbumbo of previous travellers), and Dutreuil de Rhins was killed on the 5th of June. M. Grenard after a few days resumed his march, passed east of the Noring t'so, the eastern extremity of Tousu Nor, and thence by the south-eastern corner of Koko Nor to the town of Sining Fu in Kansuh. The results of this exploration were a large number of maps and a report of great scientific importance. Mr Littledale, an Englishman, accompanied by his wife, left Khotan in the early part of 1895, and travelling thence to St George R. C. Cherchen, he turned southwards, and following up Littledale, 1895.

the course of the Cherchen darya to a point near its source, he continued in that direction between 87° and 89° E. across the northern plateau of Tibet till he reached the Zilling (or Garing) t'so. Pursuing, amid great difficulties, his southerly course, he finally reached the western bank of Tengri Nor. Pushing rapidly on in the direction of Lhasa, when not over 50 m. away from the city (camp, 35° 12' 13' N.) he was finally stopped by the Lhasan authorities and obliged, in great part on account of the severe illness of Mrs Littledale, to give up the attempt to reach Sikkim, and to take a direct trail to Ladak. In the latter part of this remarkable journey Littledale's route lay parallel but to the south of the routes followed previously by Nain Sing, and more recently by Bower. Passing by Rudok, the party re-entered Ladak at the village of Shushal on the 27th of October 1895, and left on the 2nd of November. Mr Littledale returned to Europe by a journey between Khotan and Shushal, and brought back a valuable collection of plants, which, added to those collected by other travellers in this part of Tibet, enabled botanists considerably to extend their scanty knowledge of this region.

Accompanied by Lieut. N. Malcolm of the 53rd Highlanders, Captain Welby, of the British army, left Lhasa on the 4th of May 1896. The travellers were compelled to enter Tibet by way of the Lighten t'so in 35° 5' N. From this point they turned due east and continued, accompanied by the usual incidents experienced by all travellers in those regions—cold, storms, lack of food and of grass, loss of ponies and pack animals, &c.—until they reached the northern branch of the Dre chu, the Chumar. Passing into the valley of the Nomorong Gol, south of the Tsaidam, they made their way by Barong Tsaidam to Donkyr and Sining Fu by the high road along the northern shore of the Koko Nor.

Captain Deasy, of the British army, left Lhasa on the 27th of May 1896, and crossing the Lanak la, passed by the Mangtza t'so, north of the Horpa t'so, to Yeshil kul. Thence he endeavoured to proceed due east, but was obliged to turn south by the nature of the country to turn south, crossing Bower's route on the west side of the Aru t'so. He finally completed a valuable survey of an important part of western Tibet.

In 1898 a Dutch missionary in China named Rijnhart started with his wife from the vicinity of Koko Nor, with the intention of reaching Lhasa, but at the upper Mekong, to the east-north-east of the city, he was murdered, and his wife reached the Chinese province of Sze-ch'uen with great difficulty alone.

Sven Hedin, a Swede (1857- ), left Kopa, a point about 100 m. south of Cherchen, and after crossing the Arkha Tagh took an easterly course between that range and the western continuation of the Kokoshili range till he entered the valley of the most northerly feeders of the Dre chu, when he passed into the valley of the Naichi Gol and entered the Tsaidam. His careful observations concerning the meteorology of this region are of great value, and his surveys between Kopa and the Naichi Gol were in a country not previously explored. During his second and more important journey in Central Asia (1899-1902), Sven Hedin left Charikhik, on the edge of the Taktalanak desert, in May 1901, intending to cross Tibet in a diagonal direction to the sources of the Indus. He made crossings of the lofty Arkha Tagh and other parallel ranges to the south (running east and west). On his final penetration southward, arriving within fourteen days of Lhasa, he left the bulk of his caravan and pushed rapidly on towards that city, but was stopped when about five days from it (Aug. 5, 1901). Rejoining his caravan he turned westward, and passing through the country previously traversed by Bower and Littledale he reached Lhasa on the 20th of December 1901. His careful and detailed maps, lake soundings, hydrographic, geological, meteorological and other investigations gave him the highest rank among modern explorers.

On a third journey (1906-1908) he travelled by way of Turkish Armenia, Persia, Baluchistan and India, and entered Tibet by way of the Aksai Chin. Proceeding south-east, or diagonally across the country, he traversed 840 m. of unknown country, investigating the lake Ngannon t'so or Ngantse t'so, which had hitherto been only hypothetically mapped, and marched thence
over the watershed between this and the Tsangpo. This watershed was found to lie much farther north than had been supposed, and to consist of very lofty mountains, in complicated ranges from which large tributaries descend to the Tsangpo (Brahmaputra). After a journey of half a year Hedin reached Shigatse; on leaving it he turned north again, intending to explore the large sacred lake Dangra-yumso, west of Ngantse, but when within sight of it he was prevented by Tibetans from approaching it. He now followed a deviuous route to Lake Manasarowar, entering Nepal for a short distance from Tradum, discovering the main source of the Brahmaputra in a great mass of glaciers called Kubiang-tse, near the northerning of the Himalayas. He next investigated the sources of the Sutlej, made hydrographic investigations of the Manasarowar lakes, with the neighbouring underground waterways, and proceeded to Gartok. He confirmed the existence, long suspected, of a lofty mountain chain extending right across the country from the lake Tengri Nor (i.e. about 90° E.) to the district north of Gartok (about 81° E.). He reached to Ladak in 1908. He was then elected a K.C.I.E. in 1910.

In May 1900 Koslov, in command of the Russian Geographical Society’s expedition to Central Asia and Tibet, left Baron Tschudin and Captain varma), and took to the Dre chu (his Ndu chu, or Blue river), at about the same point as Rockhill in 1889. Assisted by the old chief of Nyamtsa, he crossed the river and reached Yokundo (his Jarku Lomba). One stage beyond this place he left the route followed by former travellers and pushed northwards to near the town of Chamdo, where a sharp fight with the natives he turned eastwards. The winter was passed in the valley of the Ra chu, a tributary of the Chamdo chu (his Dza chu), and encampments were made as far as Derge drencher. In the spring of 1901 the expedition resumed its march eastwards along the Dre chu and the Ja chu (Yalung river), followed up the left bank of the latter and got back to Russian Lelu (Oriente’so) on the 30th of May 1901.

In 1903 Captain C. G. Rawling and Lieut. A. J. G. Harleagues of the Serbian Light Infantry, starting from Leh as a base, carried out careful survey work (their chief object being to extend that of Captain Desay) in the territory lying east of the British frontier, i.e. about 80° to 83° 1' E., and 34° N.

The British expedition of 1904 performed a brilliant feat of marching and reached Lhasa, whose mysteries were thus unveiled, but this exploit belongs to the section dealing with history, below.

History.—Previous to the 7th century A.D. there was no indigenous recorded history of the country, the people being steeped in barbarism and devoid of any written language. The little that is known of this prehistoric period is gathered from the legends and the more trustworthy sidelights of contemporary Chinese records.

From the 11th century B.C. the Chinese used to call by the name of Kiang (or Shepherds) the tribes (about 150 in number) of nomads and shepherds in Koko Nor and the north-east of present Tibet; but their knowledge continued to be confined to the border tribes until the sixth century of our era. In the annals of the Tang dynasty it is said that the population of the country originated from the Bat-Kian or Fah Kiang; and, as the information collected in the first part of the notice concerning Tu-bat, afterwards Tu-ban, the modern Tu-fan, dates partly (as is proved by internal evidence) from a time anterior to the Tang dynasty (A.D. 618), some degree of reliance may be placed on it. There we are told that Fanning, a son of the southern Lian dynasty of the Tu-bat family (which flourished from 397 to 415 at Lia-n-chow in Kansuh), who had submitted to the northern Lian dynasty, fled in 433 with all his people from his governorship of Lin-sung (in Kan-chow) westwards across the Yellow river, and founded beyond Tibshih ("heavy stones") a state amidst the Kiang tribes, with a territory extending over a thousand li. By his mild and just rule he was soon enabled to establish his sway over an immense territory. His original state was apparently situated along the upper course of the Yalung river, an affluent of the Khin-ha-kiang.

Through the exertions of Prinsep, Csooa de Koros, Emil Schlag-}

Lundwe, Chandra Das, Rockhill, Huth, Waddell and others, we have copies of many of the annals of Tibet from the legendary beginnings between the 5th and 2nd century B.C. down to the end of the monarchy in 914. But the several interruptions (both in our knowledge of the Likiu and translated by Schlaghamph and Rockhill. The first king, Gnyah-khi bsan-po, is said to have been the fifth son of King Prasenajit of Kosala, and was born with "seven different heads." He fled north of the Himalayas into the Bod country, where he was recognized by the leaders of the tribes of southern and central Tibet. He took up his residence in the Yarlung country south of Lhasa. This Yarlung, which borrowed its name from the Yalung of the state of Hedin, is a river which flows into the Yar-lo tsangpo (Brahmaputra). The first king and his six successors are known as the seven celestial kings; the next series consists of six kings known as the earthly deities and they were followed by eight territories ded. This three-fold succession is apparently an imitation or a debased form of the ancient legend of heavenly, earthly and human rulers, which was carried into Persia and China, and from the latter country into Japan. In the Samy-tam—the relative number of kings being altered in the last-named countries to suit local convenience and the small amount of truth which they contain. Whilst giving an Aryan descent from the first king, the Bhutanese legends also. The Liko kings were followed by four rulers simply called bsam ("mysterious").

Then occurs a break in the lineal descent and the king next in order (c. 460) may be the Tatar Fanni Tu-bat, but most probably his son and successor. His name was Lha-tho thori gnyan-tsam, otherwise Gyan-tsam of Lha-tho thori, according to the custom of his family, was a daughter of his father and his princesses a divine origin, and called them lhama, "goddess." The gynaecocratic habits of the race are manifested in the names of all these kings, which were formed by a combination of those of their ancestors, the "roc" and the "crown." The Liko kings were followed by four rulers simply called bsam ("mysterious").

In the year 680 the country was divided into two kingdoms, each represented by a sovereign, and this division was to continue to the present time.

Koko-Nor, from the name of a small lake to the north of the Lhasa, was in the possession of the Tais, who called it Jangts'a ("salt").

The Chinese annals do not mention the discovery of the inexhaustible salt mine called Chang-gi-tsa'wa (Byang-gi-tsa'wa "northern salt"), which still supplies the greater portion of Tibet. The reign of his illustrious son, Grom-bha gam-po, was marked by the establishment of Buddhism, and the art of writing from India, and was the founder (in 639) of Lha-ldan, afterwards Lha-sa. He was greatly helped in his prosecution of these two by his two wives, one a Nepale princess, daughter of King Gyantse, another a daughter of Dzil Khori ("black woman"); his son and only child, who was childless, he took two more princesses from the Ru-yang ("left corner") and Mön (general appellative for the nations between Tibet and the Indian plains) countries. As a conqueror he extended his sway from the still unsubdued Kiang tribes of the north to Ladak in the west, and in the south he carried his power through Nepal to the Indian side of the Himalayas. How far southward this dominion at first extended is not known; but in 703 Nepal and the country of the Brahmanas rebelled, and the Tibetan king, the third successor of Grom tsan gam-po, was killed while attempting to restore his power. It is rather curious that Koko-Nor is said of him, while other conquerors of the Koko-Nor in 665, and attacked the Chinese; after some adverse fortune the latter took their revenge and penetrated as far as Lhasa, where they burnt the royal palace (Yumbo-lagang). Khri Imdun, a grandson of the second king, and the eldest son of Tashi, was made king in succession from him, promoted the spread of Buddhism and obtained for his son, Jangts'a Lhamon, who was famous for the beauty of his person, the hand of the accomplished princess Kuyim-tsho, and put to death the female conqueror (Ko-lo) of the Imdun (? Taih) tsung. But the lady arrived after the death of her betrothed, and after long hesitation became the bride of the father. She gave...
The Mongol dynasty of China passed away, the Ming confirmed and enlarged the territory of Tibet, and by 1450, the Tsang-pa family was the most important monastery to visit him. This lama was Sodnam rGyamtso, the third successor of Gedun grub, the founder of the first Dalai Lama in 1447, who had been elected to the most important abbots of Dalai Lama near Lhasa, and he paid a visit to the great, afterwards Dalai. The immediate successor of Gedun grub, who ruled from 1475 to 1541, had appointed a special officer styled to help the civil administration of the country. To Sodnam rGyamtso the Mongol khans gave the title of Vaja Dalai Lama in 1576, and this is the first use of the widely known title of Dalai Lama. During the minority of the fifth (really the third) Dalai Lama, when the Mongol king Tengri To, under the pretext of supporting the religion, intervened in the affairs of the country, the Pan-ch'en Lo-sang Chö-kyi Gyal-ten'ang lama obtained the throne by the support of the Chinese, who paid him the indemnity, and then applied for help to the first Manchu emperor of China, who had just ascended the throne. This step enraged the Mongols, and the advance of Gushri Khan, son and successor of the Great Khan, caught the Dalai Lama. The Chinese, princes, including the king of Tsang, and, after having subjugated the whole of China, made the fifth Dalai lama supreme monarch of all Tibet, in 1645. The Chinese government in 1653 confirmed the Dalai Lama in his authority, and he paid a visit to the emperor at Peking. The Mongol Khoshotes in 1706 and the Sungura in 1717 interfered again in the succession of the Dalai Lama, but the Chinese army finally conquered the country in 1710, and the present system of government was established. It is probable that the isolation of Tibet was inspired originally by the Chinese, with the idea of creating a buffer state against European aggression.

In 1872-1873 some attempt was made by Indian officials to open up trade with Tibet; further attempts followed in 1884, and in 1886 a mission was organized to proceed to Lhasa. The Chinese, however, although they had at first granted a passport to this mission, later objected to its advance, and it was abandoned. The Tibetans assumed this to show England's weakness; they invaded Sikkim, and in 1888 it was necessary to send a force under General Graham to expel them. In 1890 a treaty was concluded, and trade regulations under this treaty in 1893; but the Chinese authorities, and the lamas, considering themselves to have received insufficient recognition, repudiated them and offered further insults. A new development presently appeared in the situation. A lama, a Mongolian Buriat by birth and a Russian subject, whose Russianized name was Dorjiev, had come to Lhasa about 1880. When subsequently visiting Russia, he appears to have drawn the attention of the authorities towards Tibet as a field for their statecraft, and he established himself as the unofficial representative of Russia in Lhasa. He obtained a commanding influence over the Dalai Lama, and in 1893 he was ordered to threaten Tibet from England, and suggested the desirability of securing Russian protection and even the possibility of converting the tsar and his empire to Buddhism. The Dalai Lama assented, and was even prepared to visit St. Petersburg, but was checked by the Tsong-dü (assembly). He therefore sent a representative of high rank, who had audience of the tsar, and returned with proposals for a treaty and for the residence of a Russian royal prince in Lhasa in order to promote friendly relations. But both the Chinese authorities in Lhasa and the Tsong-dü were averse to all but the most limited relations inspired by Dorjiev, now took steps to bring on a crisis by provoking England. He felt sure of Russian support. Russian arms had been imported into Lhasa. It was suspected, although denied, that a treaty was in draft under which Russia should assume the suzerainty of Tibet. A further encroachment on
of the frontier states of Nepal, Bhutan and Sikkim must be respected. To the Dalai Lama, who had attempted to obtain British intervention at Peking, it was made clear that he personally had no claim to this, as the British government could only recognize the de facto government in Tibet.

**TIBETO-BURMAN LANGUAGES.**

The Tibeto-Burman family comprises a long series of dialects spoken from Tibet in the north to Burma in the south, and from the Ladakh wazārat of Kashmir in the west to the Chinese provinces of Sze-ch'uen and Yunnan in the east. In the first place we have the various Tibetan dialects, spoken all over Tibet and in the neighbouring districts of India and China. Another series of dialects, the Himalayan group, is spoken in the southern Himalayas, from Lahul in the west to Bhutan in the east. Some of these dialects approach Tibetan in structure and grammatical principles, while others have struck out new lines of development, probably under the influence of the dialects spoken by an older population. East of Bhutan, to the north of the Assam valley, we find a third small group, the North Assam group, which consists of three dialects. A fourth group, the Bodo group, can be followed in a series of dialects from Bhutan in the north to the Tippeerca state in the south. They have at one time extended over most of Assam west of Manipur and the Nāgā hills, and even far into Bengal proper. To the west of the Bodos, in and in the neighbourhood of the Nāgā hills we find a fifth group, the so-called Nāgā group. It comprises dialects of very different kinds. Some of them approach Tibetan and the dialect of the North Assam group. Others are more or less akin to the Bhutan languages, and others again connect the Nāgā dialects with the Sino-Tibetan languages of the west south and east. To the south of the Nāgā hills, in the long chain of hills extending southwards under various names such as the Lushai hills, the Chin hills and the Arakan Yoma, we find a sixth group, the Kuki-Chin dialects. The old Meitei language of Manipur lies midway between this group and the easternmost branch of the Tibeto-Burman family, the Kachin group. The Kachins inhabit the tract of country to the east of Assam and to the north of Upper Burma, including the headwaters of the

**British**

An advance was made to Tuna, where part of the expedition wintered. A further advance being made on the 31st of March 1904, the first hostile encounter took place at Guru, when the Tibetans (the aggressors) were defeated. With the fall of Guru further the expedition reached and occupied Gyanwest on the 12th of April; here some of the British forces were subsequently beleaguered, and the most serious fighting took place. In fact the advance to Lhasa, resumed after the storming of the Gyanwest fort (on the 5th of July), met with comparatively little opposition, and the capital was reached on the 3rd of August. The Dalai Lama had fled with Dorijev. Partly on this account, and in spite of the attempts of the Chinese authorities to bring about a settlement, there was some delay owing to the attitude of the lamas, but finally a treaty of peace was concluded on the 7th of September. The principal provisions were—the Sikkim frontier violated by the Tibetans was to be respected; marts were to be established for British trade at Gyantse, Gartok and Yatung; Tibet was to pay an indemnity of £300,000 (subsequently reduced to one-third of this sum); and no foreign power was to receive any concession in Tibet, territorial or mercantile, or to concern itself with the government of the country. The expedition left Lhasa on the 23rd of September and reached India again at the close of the following month. The treaty was slightly modified later in matters of detail, while the adhesion of China to the treaty was secured by an agreement signed on the 1st of October 1906.

The Anglo-Russian convention of 1907 determined the following conditions with respect to Tibet—the recognition of the suzerain rights of China and the territorial and administrative integrity of the country; that no official representative at Lhasa should be appointed either by England or by Russia, and that no concessions for railways, mines, &c., should be sought by either power. An annex to the convention provided that, except by arrangement between England and Russia, no scientific expedition should be allowed to enter the country for three years.

In January 1908 the final instalment of the Tibetan indemnity was paid to Great Britain, and the Chumbi valley was evacuated. The Dalai Lama was now summoned to Peking, where he obtained the imperial authority to resume his administration in place of the provisional governors appointed as a result of the British mission. He retained in office the high officials then appointed, and pardoned all Tibetans who had assisted the mission. But in 1909 Chinese troops were sent to operate on the Sze-ch'uen frontier against certain insurgent lamas, whom they handled severely. When the Dalai Lama attempted to give orders that they should obey, his authority was disputed by his government, and summoned the Chinese troops to enter the city. They did so, and the Dalai Lama fled to India in February 1910, staying at Darjeeling. Chinese troops followed him to the frontier, and he was deposed by imperial decree. The British government, in view of the apparent intention of China to establish effective suzerainty in Tibet, drew the attention of the government at Peking to the necessity of strictly observing its treaty obligations, and especially pointing out that the integrity
TIBIA

Chindwin and the Irrawaddy. The Kachins have not as yet settled down, and are still pushing southwards. The Kachins and the Kuki-Chins gradually and finally merge into Burmese, the language of the ancient kingdom of Burma.

It is impossible to bring the relationship existing between all these various groups under one single formula. The dialects spoken in the Himalayas and in Assam can be described as a double chain connecting Tibetan with Burmese, which are the two principal languages of the family. In the first place the Kachin group runs from the easternmost Tibetan dialects in Sze-ch'uen down to the Burmese and Assamese. The second chain, the Assam valley, appears to possess in the north. We can trace one line from the North Assam group, the Naga, Bodo and Kuki-Chin groups. Another line can be followed from Tibetan through the Himalayan and Bodo groups into Kuki-Chin. The latter dialects finally merge into Burmese.

The original home of the Tibeto-Burman race seems to have been on the Upper Hwangho and the Upper Yangtsze-kiang in the Chinese provinces of Sze-ch'uen and Yunnan. The oldest invaders followed the Tsangpo into Tibet and became the Tibetans of the present day. Other hordes crossed the Brahmaputra and set up camps in the southern slopes of the Himalaya range. From the headwaters of the Irrawaddy and the Chindwin successive waves entered Assam and Further India. Some followed the course of the Brahmaputra and settled in the hills to the south and east of the great bend of the river. Others entered the Naga hills, while numerous tribes must have followed the Chindwin into Manipur and the hills to the south. The inhabitants of Burma have probably come down along the Chindwin and the Irrawaddy, and the latest immigrants, the Kachins, have only in modern times begun their wanderings southwards through the hills. The tribes living in the hills not only occupy a mixed character. Their home can be considered as a kind of backwater which has been overflowed by the waves of successive invasions.

In their original home the Tibeto-Burmans were the neighbours of Chinese and Tai tribes. Their languages are also closely related to Chinese and Tai, more closely to the former than to the latter. The agreement is apparent in the phonetical system, in vocabulary and in grammar. The principal point in which they differ is the order of words. The Tibeto-Burman family arranges the words of a sentence in the order of subject, object, verb, while the order in Chinese and Tai is subject, verb, object. Together and separately the languages form one great family, which is usually called Indo-Chinese.

The Indo-Chinese family is usually considered as a typical instance of the so-called isolating languages. The single words do not consist of more than one syllable. They are incapable of inflexion because there are no form-words, which merely denote relation in time and space. Grammatical relations are therefore not indicated by prefixes, but simply by putting together, according to fixed rules, words of which each retains its independence. Thus a sentence such as "the father struck the boy" would be translated "father agent son striking completion." This state of affairs, which is the prevailing condition in Chinese, is not, however, the original one. While the bases of the words are monosyllabic, i.e. each word consists of one syllable, comparative and superlative forms are generally formed by adding a suffix, as in Burmese. As a result the meaning of which cannot always be ascertained, but which modified the meaning of the base in the same way as the terminations of other languages. Such prefixes were not accentuated, and in the course of time they were commonly reduced and often dropped altogether, so that each word (i.e. the prefix plus base) itself came to be monosyllabic. Such words were then pronounced in a higher tone, and this gave rise to the development of a complicated system of tones in Chinese, Tai and some Tibeto-Burman languages.

The existence of old prefixes can therefore still be inferred from the tones.

This discussion will be followed in the Tibeto-Burman languages. They have, to some extent, retained the old prefixes. This is, for example, the case in Old Tibetan and some modern Tibetan dialects, while the prefixes have been dropped in the modern dialects of the Indo-Chinese. In the Burmese, the Kuki-Chins and the Assamese there is no trace of these prefixes, while in Central Tibetan there has developed a system of tones corresponding to that prevailing in Chinese. The same
TIBULLUS is a Latin elegiac poet. The information which is also pass about him is extremely meager. We know the poems themselves—that is to say, the first and second books—we have only a few references in later writers and a short Life of doubtful authority. We do not know his praenomen; his gentile name has been questioned; nor is his birthplace ascertained. His station was not improbably that of a Roman knight (so the Life affirms); and he had inherited a very considerable estate. But, like Virgil, Horace and Propertius, he seems to have lost the greater part of it in 41 amongst the confiscations which Antony and Octavian found expedient to satisfy the rapacity of their victorious soldiery. Tibullus's chief friend and patron was M. Valerius Messalla Corvinus, himself an orator and poet as well as a statesman and a commander. Messalla, like Maecenas, was the centre of a literary circle in Rome; but the bond between its members was that of literature alone. They stood in no relations to the court; and the name of Augustus is not once to be found in the writings of Tibullus. About 30 B.C. Messalla was dispatched by Augustus to Gaul to quell a rising in Aquitania and restore order in the country, and Tibullus may have been in his retinue. On a later occasion, probably in 36, they are said to have accompanied him on a mission to the East, but he fell sick and had to stay behind in Corcyra. Tibullus had no liking for war, and though his life seems to have been divided between Rome and his country estate, his own preferences were wholly for the country life. His first love, the subject of book i., is called Delia in the poems, but we learn from Apuleius (A pol. 10) that her real name was Plania. Delia seems to have been a woman of middle station. It is impossible to give an exact account of the intimacy. The poems which refer to her are arranged in no chronological order. Now she appears as single, now as married, and her name bears various modifications, little of her husband's death. It is clear, however, that it was the absence of her husband on military service in Cilicia which gave Tibullus the opportunity of making or renewing the acquaintance. It was not dropped when he returned. It was not difficult to deceive the simple soldier; and Delia was an apt pupil in deception—too apt, as Tibullus saw with dismay when he found that he was not the only lover. His entreaties and appeals were of no avail; and after the first book we hear no more of Delia. In the second book the place of Delia is taken by Neaera, which is itself a fictitious name. Nemesis (like the Cynthia of Propertius) was a courtesan of the higher class; and she had other admirers besides Tibullus. He complains bitterly of his bondage, and of her rapacity and heartlessness. In spite of all, however, she seems to have retained her hold on him until his death. Tibullus died prematurely, probably in 19, and almost immediately after Virgil. His death made a deep impression in Rome, as we learn from his contemporary Domitius Marsus and from the elegy in which Ovid (Amores, iii. 19) has enshrined the memory of his predecessor. The character of Tibullus is reflected in his poems. Though not an admirable he is certainly an amiable one. He was a man of generous impulses and a gentle unsquishee disposition. He was loyal to his friends to the verge of self-sacrifice, as is shown by his leaving Delia to accompany Messalla to Asia, and constant to his mistresses with a constancy but ill deserved. His tenderness towards them is enhanced by a refinement and delicacy which are rare among the ancients. Horace and the rest taunt the cruel fair with the retribution which is coming with the years. If Tibullus refers to such a fate, he does it by way of warning and not in any pettish spirit of triumph or revenge. Cruelly though he may have been treated by his love, he does not invoke curses upon her head. He goes to her little sister's grave, hung so often with his garlands and wet with his tears, and bemoans his fate to the dumb ashes there. Tibullus has no leanings to an active life; his ideal is a quiet retirement in the country with the loved one at his side. He has no ambition and not even the poet's yearning for immortality. As Tibullus loved the country life so he clung to its faiths, and in an age of crude materialism and the grossest superstition, he was religious in the old Roman way. As a poet he reminds us of Collins and Longfellow. His clear, finished and yet unaffected style made him a great favourite with his countrymen and placed him, in the judgment of Quintilian, at the head of their elegiac writers. And certainly within his own range he has no Roman rival. For natural grace and tenderness, for exquisiteness of feeling and expression, he stands alone. He has far fewer faults than Propertius, and in particular he rarely overloads his lines with Alexandrian learning. But, for all that, his range is limited; and in power and compass of imagination, in vigour and breadth of style, he is inferior. In the variegation of his treatment, he is much his rival's inferior. The same differences are perceptible in the way the two poets handle their metre. Tibullus is smoother and more musical, but liable to become monotonous; Propertius, with occasional harshnesses, is more vigorous and varied. It may be added that in many of Tibullus's poems a symmetrical composition can be traced, although the symmetry must never be forced into a fixed and unelastic scheme.

It is probable that we have lost some of the genuine poems of Tibullus. On the other hand, much has come down to us under his name which must certainly be assigned to others. Only the third book of the second hundred lines is genuine; the rest consists of poems written at various times between 30 and 26. About the second book we can only say that in all likelihood it was composed between 36 and 26, and, though containing only 428 verses, and apparently incomplete. In both books occur poems which give evidence of internal disorder; but scholars cannot agree upon the remedies to be applied. The third book, which contains some of the most beautiful lines, is much inferior hand. The writer calls himself Lygdamus and the fair that he sings of Neera. He was born in the same year as Ovid, but there is nothing Ovidian about his work. He has little poetical power, and he seems to be chiefly marked by the stern judgment and the mischievous and imitations of Tibullus and Propertius; and they are not always happy. The separation of the fourth book from the third has no ancient authority. It dates from the revival of letters, and is due to the Italian scholars of the 15th century. The fourth book consists of poems of very different quality. The first is a composition in 211 hexameters on the achievements of Messalla, and is very poor. The author is unknown; but he was certainly not Tibullus. The poem itself was written in 31, the year of Messalla's consulship. The next eleven poems relate to the love of Sulpicia and Cerinthus. Sulpicia was a Roman lady of high rank; his name is not certainly accurate. Cerinthus seems to have been a relations of Valeria, Messalla's sister. She had fallen violently in love with Cerinthus, about whom we know nothing but what the poet tells us. About Book iv. we have a bit more certain, for it is divided into two groups. The first comprises iv. 2-6, containing ninety-four lines, in which the theme of the attachment is worked up into five graceful poems. The second, iv. 8-12 (to which 7 short stanzas are added) is the author's own letters. They are very short, only forty lines in all; but they have a unique interest as being the only love poems by a Roman woman that have escaped the ravages of time. Their frank and passionate outpourings remind us of Catullus. The style and metrical handling betray a novice in poetical writing. The thirteenth poem (twenty-four lines) claims to be by Tibullus; but it is hardly more than a cento from Tibullus and Propertius. The fourteenth is a little epigram of four lines with nothing to determine its authorship. Last of all comes the epigram or fragment of Domitius Marsus already referred to. To sum up: the third and fourth books appear in the accepted tradition, and they contain poems which are divided by different authors in different styles, none of which can be assigned to Tibullus with any certainty. The natural conclusion is that we have here a collection of scattered compositions relating to Tibullus, and the collection, which has been added as an appendix to the genuine relics of Tibullus. When this "Messella collection" was made cannot be exactly determined; but it was done after the death of Tibullus, 19 B.C., and probably between 15 and 2 B.C. Besides the foregoing, two pieces in the collection called Priscus (one an epigram and the other a longer piece in lambs) have been attributed to Tibullus; but there is little external evidence of his authorship (see Hiller in Hermes, xxvii. 343-349).

The value of the short Vita Tibulli, found at the end of the Athosian, Vatican and inferior MSS., is also questioned. There is little in it that we could not once infer from Tibullus himself and from what Horace says about Albius, though it is
TIBUR

possible that its compiler may have taken some of his statements from Sue tonius's book De poesi; it is as follows: "Albius Tibullus essentially follows Propertius in his (Propertius's) "cuiusque" (cf. MSS. the corruption regulus), insignis forma cultuque corpori observabili, ante alios Curvini Messaliam Oratorem (MSS. Or., since he is so closely associated with Tiberian and Augustan times, is 3, 6; 7). It is rejected, the authority of the Life is considerably impaired.

Ovid, Trist., lv. 10, 53 seq., "successor fuit hic [Tibullus] tibi, Galle, Propertius iii, quartus ab his serie temporis iapae ful. In the preceding couplet he had said, "Verum vidit tantum nec amara Tibullus tempus amicitiae data dedecre meae." Ovid was born in 43, would be only twenty-four at Tibullus's death if it occurred in 19. The loss of Tibullus's landed property is attested by himself (3, 19 seq.), "Felicitas quadram, nam panicis auribus custodes" (cf. 41, 42). Its cause is only an inference, though a very probable one. That he was allowed to retain a portion of his estate for his personal consumption (182, 290). Grainger does not press this point, and it is quite possible that Tibullus may have been Messalla's contubernialis in the Aquitanian War (Via Tib. and Tib. l. 7, 9 seq., a poem composed for Messalla's triumph), and may have received militia dona (Vita Tib., Epist. ii. 2, 18).

"Tibullus ... and tibi ..." As regards her station, it should be noticed that she was not entitled to wear the toga, the dress of Roman matrons (i. 6, 68). Her husband is mentioned as absent (i. 2, 67 seq.). She eludes the custodes placed over the temple gates of the temple of Venus, and is allowed to enter the temple of Venus, of whom she speaks in very affectionate terms (i. 6, 57 seq.). For Tibullus's illness at Corcyra, see i. 3, 1 seq., 55 seq. The fifth elegy was written after Tibullus's death and just before the return of the husband and during Delia's double indecency. Ovid, writing at the time of Tibullus's death (Am. iii. 9, 31), says: "Sic Nemesis longum, sic Delia, nomen habebunt, altera cura reperiet, siquid non secatur, Nenia vis, si Dianam i. 3, 4, 6. The mention of a lena (ii. 6) settles her position. The connexon had lasted a year when ii. 5 was written (see ver. 109). It is worth noticing that Martial selects Nemesis as the source of their malady (II. 7, 31; cf. Elegies of Ovid).

Specimens of Tibullus at his best may be found in i. 1, 89-94; 5, 19-26; 9, 45-68; ii. 6. Quintilian says (Inst. x. 1, 93), "Elegia quoque Graecas provocamus, cuiusque mihi tersus esse elegans maxime sidetor autor Tibullus; sunt qui Propertium malit; Ovidius utoque lascivior, sicut durior Gallus." Charissia (pp. 66 and 105) quotes part of a hexameter which is not from any of the four books of Tibullus.

Lydamus is probably the real name of the author of the first six elegies in book iii, but little further is known about him. His elegies and the other poems in the third book (' third " and " fourth " book) have been examined by various scholars. There are two passages between i. 5, 15-20, and three passages of Ovid, Ars. i. ii. 669 seq.; Tr. iv. 10, 6; "cum ceddit fato consilium uteque par" (Lydamus and others), are quoted in the same sense (for the year of their birth, the consularis of Hirtius and Pansa) and Am. xii. 4, 23 seq., much too close to be accidental. We do not know when they were added to the genuine poems of Tibullus.

Most scholars since Lachmann have condemned the "Panegyric on Messalla." It is an inflated and at the same time tasteless declaration, entirely devoid of poetic merit. The language is often absurdly exaggerated, e.g. 190 seq. The author himself seems to be conscious of his own deficiencies (i. seq. 177 seq. Like so many of his contemporaries, he had been reduced to poverty by the loss of his estates (181 seq.) If we could set the question of poetical merit aside, we might reasonably conclude that he was not Propertius as in fact is done by Némethy (op. cit. below). The date is fixed by 121 seq. Sulpicia was the daughter of Servius Sulpicius (iii. 16 iv. 10), and she seems to have been under the guardianship of Messalla, her uncle by marriage (Haupt, Opuscule, iii. 502 seq.).

Some scholars attribute i. ii. 8-12 iv. 2-6 to Tibullus himself; but the style is different, and it is best to answer the question, an open one.

The direct ascription of i. 19-iv. 13 (verse 13, "nunc licet e caelo mitatur amica Tibullo") to Tibullus probably led to its inclusion in the collection and later to the addition of the title to the poet's name. For the evidence against the ascription, see Postgate, Selections, app. C.

Manuscripts.—The two best MSS. of Tibullus are the Ambrosianus (Ambro. 706) and the Vaticanus (Vat. lat. 221) and most of the 19th century. Besides these we have a number of extracts from Tibullus in Florilegium Parisianum, an anthology from various Latin writers which probably goes back to the 11th century, and the Excerpta frisingensia, preserved in an 11th-century MS. now at Munich, unfortunately very few in number. Also excerpts from the lost second book of Tibullus (1819). The two best editions are those of Teuffel's (1871) and Postgate's (1872). An Essay towards a New Edition of the Elegies of Tibullus, with a Translation and Notes (London, 1872), contains only 1. i. and 4, 29-48. C. A. Elton's Selections of the Classic Poets (London, 1871-71) contains only 1. i. ii. iv. 2-4, 6, 36 to end, iv. 2, 3. To these should probably be added Tibullus, with other Translations from Ovid, Horace, &c., by Richard Whiffen (London, 1874). Cranston's is the only complete version of merit; but it is inferior to the translation of Elton. P. Fr.

TIBUR (mod. Tivoli, q.v.), a pleasant town of Latium, 18 m. E.N.E. of Rome by the Via Tiburtina (see Tiburtina, Via), it is finely situated at the point where the Anio forms its celebrated falls; it is protected on the E., N., and N.W. by the river and it commands the entrance to its upper course, with an extensive view over the Campagna below. The modern town is in part built upon the terraces of a large temple of Hercules Victor, the chief deity of Tibur, of which some remains exist: many small votive objects in terra-cotta were found in the gorge of the Anio below the town on the north-west in 1898. Below it, on the cliffs above the Anio, is a large building round a colonnaded court, the Opus cubicaturum, built over the Via Tiburtina (caves under it in an arched passage), generally known as the villa of Maecenas, but shown by the discovery of inscriptions to have been in reality the meeting place of the Herculean Augustales, connected probably with the temple.

In an ancient hall at one side of the modern cathedral two mensae ponderarie—marble tables with holes in them for measuring solids—erected by one M. Varesius Diphilus, a freedman, a magister herculaneus, were found in situ in 1833, and in 1902 two vases of statues erected by Diphilus, as inscriptions showed, in honour of his patron, and a bas-relief of a bearded Hercules entirely draped in a long tunic with a lion's skin on his shoulders.

Remains of two small temples—one circular, with Corinthian columns, the other rectangular with Ionic columns—stand at the north-east extremity of the town, above the waterfalls. They are traditionally, but without foundation, attributed to Vesta and the Sibyl of Tibur (Varro adds Albucena, the water goddess worshipped on the banks of the Anio as a tenth Sibyl to the nine mentioned by the Greek writers).

The so-called Tempio della Tosse, an octagonal domed structure just below the town, is probably a tomb of the 4th century B.C. Two Roman inscriptions in close vicinity were found after the falls in 1826.

Tibur was a favourite place of resort in Roman times, and both Augustus and Maecenas had villas here, and possibly Horace also. It is certain that a house was shown as being his in the time of Suetonius; and this has been identified with a villa of the Augustan period, the site of which is now occupied by the monastery of S. Antonio. In his poems he frequently mentions Tibur with enthusiasm. Catullus and Statius, too, have rendered it famous by their poems. The abundance of
TIBURTINA, VIA—TICHBORNE CLAIMANT

water from aqueducts and springs and the falls of the Anio were among its chief attractions. The remains of villas in the district are numerous and important (see T. Ashby in Papers of the British School at Rome, iii.1). The largest is that of Hadrian, situated in the low ground about 2 m. to the south-west of Tibur, and occupying an area of some 160 acres. The remains are extensive and well preserved, though the identifications of the existing buildings with those mentioned by Spartianus who records that Hadrian gave to them the names of various well-known edifices at Athens and elsewhere, cannot in most cases be treated as certain. A large number of statues have been found in the villa, and costly foreign marbles and fine mosaic pavements, some of the last being preserved in situ, while among others may be named the mosaic of the dove in the Capitolium and that of the masks in the Vatican. Of the fresco and stucco decorations of the walls and ceilings, less is naturally preserved. Excavations have gone on since the 16th century, the last having been carried on by the Italian government to which the greater part of the site now belongs: but little has been done since 1884.1

The ancient Tibur was founded, according to tradition, by Tiburtus, Corax and Catillus, grandsons of Amphiarous. Though on the edge of the Sabine Mountains, it was a member of the Latin League. The site is remarkable for ancient roads and outlying forts in its territory dating from the period of its independence. It allied itself with the Gauls in 361 B.C., and in the war which followed the towns of Empulum and Saxula were destroyed (their sites are unknown) and triumphs over Tibur were celebrated in 360 and 354 B.C., and again in 338, when its forces were defeated, with those of Praeneste. It did not, however, lose its independence, but became an ally of Rome, as is shown by an inscription, probably of the 2nd century B.C., in which it is recorded that the ambassadors of Tibur successfully cleared themselves before the Roman senate of a suspicion that they were not Romans. In 115 A.D. they were granted Roman citizenship in 90 B.C., though some of its citizens gained the franchise previously. Syphax, king of Numidia, died in the territory of Tibur as a captive in 202 B.C.; and in A.D. 273 Zenobia, queen of Palmyra, was assigned a residence here by Aurelian. Its prosperity during the imperial period was mainly due to the favour in which it stood as a summer resort. During the siege of Rome by Narses, Belisarius occupied Tibur: it was afterwards treacherously surrendered to Totila, whose troops plundered it, but who rebuilt it in A.D. 542.

See H. Dessau in Corp. inscrit. latin. xiv. 365 sqq. and reff. (T. As.)

TIBURTINA, VIA, an ancient road of Italy, leading E.N.E. from Rome to Tibur, a distance of about 18 m. It must have come into existence, as a track at any rate, during the establishment of the Latin League. Though it afterwards became an important thoroughfare, the first portion of it always retained its original name, that of Via Valeria (see VALERIA, VIA) being applied only to the portion of the road beyond Tibur. The road is in the main followed by a modern highroad. There is, however, a difficulty about the last portion of its course from the Albanæ Aquæ (q.v.) to Tibur; whereas, according to the milestones and itineraries, it should be 20 m. from Rome to Tibur, it is impossible to make the distance more than 18 m. along any probable line.

See T. Ashby in Papers of the British School at Rome, iii. 84 sqq. (T. As.)

TICHBORNE CLAIMANT, THE. Roger Charles Tichborne (1829–1854), whose family name became a household word on account of an attempt made by an impostor in 1868 to personate him and obtain his inheritance, was the eldest grandson of Sir Edward Tichborne, the 6th baronet, of a very ancient Hampshire family. Sir John de Tichborne, sheriff of Southampton, was created a baronet by James I. in 1621, and from him his descendants inherited great wealth and the position of one of the leading Roman Catholic families in the south of England. Roger Charles, born at Paris on the 5th of January 1829, was the eldest son of James Francis Doughty-Tichborne (who subsequently became 10th baronet and died in 1862) by Henriette Felicité, natural daughter of Henry Seymour of Knoule, in Wiltshire. This lady, who hated England, was intent upon bringing up her son as a Frenchman; the result was that he got hardly any education until he went in 1846 to Stonyhurst, whence he proceeded in 1849 to Dublin and joined the 6th Dragoon Guards. His eccentricity and his French accent made him a butt in his regiment, and, being disappointed of war service, he sold out in 1852, spent the next four years in the United States of America, and sailed in March 1853 from Havre for Valparaíso, whence he crossed the Andes, reaching Rio de Janeiro in 1854. In April of that year he sailed from Rio in the "Bella" and was lost at sea, the vessel foundering with all on board. His insurance was paid and his will proved in July 1855. The baronetcy and estates passed in 1862 to Roger's younger brother, Sir Alfred Joseph Doughty-Tichborne, who died in 1866. The only person unconvinced of Roger's death was his mother the dowager Lady Tichborne, from whom every tramp-sailor found a welcome at Tichborne Park. She advertised largely and incessantly for her nephew, and in November 1865, when her 86th birthday, sent, through an agency in Sydney, that a man "answering to the description of her son" had been found in the guise of a small butcher at Wagga Wagga, in Queensland. As a matter of fact, the supposed Sir Roger did not correspond at all to the lost heir, who was slim, with sharp features and straight black hair, whereas the claimant was enormously fat, with wavy, light-brown hair. His first letter to Lady Tichborne was not only ignorant and illiterate, but appealed to circumstances (notably a birth-mark and an incident at Brighton) of which she admitted that she had not recollection. But so enchanted was she by his theory that she soon overcame the first qualms of distrust and advanced money for the claimant to return to Europe. Like all pretenders, this one was impelled by his own purse, who regarded him in the light of an investment. He himself was reluctant to move, but the credulity of persons under the influence of a romantic story soon came to his aid. Thus an old friend of Sir James Tichborne's at Sydney, though puzzled by the claimant's answers, was convinced by a resemblance to his supposed father. At Sydney, too, he made the acquaintance of Bogle, a negro freedman, who reproduced a portion of the manuscript in Sydney in the summer of 1866, and coached him in the rudiments of the rôle which he was preparing to play. On reaching London on Christmas Day 1866 the claimant paid a flying visit to Tichborne House, near Aldershot, where he was soon to obtain two important allies in the old family solicitor, Edward Hopkins, and a Winchester antiquary, Francis J. Baignet, who was intimately acquainted with the Tichborne family history. He next went over to Paris, where in an hotel bedroom on a dark January afternoon he was promptly "recognised" by Lady Tichborne. This "recognition" naturally made an enormous impression upon the English press; but it was not the kind that the Lady Tichborne was a monomania. That such a term is no exaggeration is shown by the fact that she at once acquainted in her supposed son's absolute ignorance of French. She allowed the claimant £1000 a year, accepted his wife, a poor illiterate girl, whom he had married in Queensland, and handed over to him the diaries and letters written by Roger Tichborne from South America. From these documents the claimant now carefully studied his part; he learnt much, too, from Baignet and from two carabiniers of Roger's old regiment, whom he took into his service. The villagers in Hampshire, a number of the county families, and several of Tichborne's fellow officers in the 6th Dragoons, became eager victims of the delusion. The members of the Tichborne family in England, however, were unanimous in declaring the claimant to be an impostor, and they were soon put upon the track of discoveries which revealed that Tom Castro, as the claimant had been called in Australia, was

identical with Arthur Orton (1834–1898), the son of a Wapping butcher, who had deserted a sailing vessel at Valparaiso in 1850, and had received much kindness at Melipilla in Chile from a family named Castro, whose name he had subsequently elected to bear during his sojourn in Australia. It was shown that the claimant, on arriving in England from Sydney in 1866, had first of all directed his steps to Wapping and inquired about the surviving members of his family. It was discovered, too, that Roger Tichborne was never at Melipilla, an assertion to which the claimant, transferring his own adventures in South America to the account of the man whom he impersonated, had committed himself in an affidavit. These discoveries and the deaths of Lady Tichborne and Hopkins were so discouraging that the "claimant" would gladly have "retired" from the baronetage; but the pressure of his creditors, to whom he owed vast sums, was importunate. A number of "Tichborne bonds" to defray the expenses of litigation were taken up by the duces of the imposture, and an ejectment action against the trustees of the Tichborne estates (to which the heir was the 12th baronet, Sir Henry Alfred Joseph Doughty-Tichborne, then two years old) finally came into the hands of the Justices, who, on the 28th of February 1874, during a trial that lasted over one hundred days the claimant exhibited an ignorance, a cunning and a bulldog tenacity in brazening out the discrepancies and absurdities of his depositions, which have probably never been surpassed in the history of crime. Over one hundred persons swore to the claimant's identity, the majority of them—and they were drawn from every class—being evidently sincere in their belief in his cause. It was not until Sir John Coleridge, in a speech of unparalleled length, laid bare the whole conspiracy from its inception, that the result ceased to be doubtful. The evidence of the Tichbornes finally convicted the jury, who declared that they wanted no further evidence, and on the 5th of March 1875 Sergeant Ballantine, who led for the claimant, was non-suited. Orton was immediately arrested on a charge of perjury and was brought to trial at bar before Chief Justice Cockburn in 1873. The defendant showed his old qualities of impudence and endurance, but the indiscretion of his counsel, Edward Kenealy, the testimony of his former sweetheart, and Kenealy's refusal to put the Orton sisters in the box, proved conclusive to the jury, who, on the one hundred and eighty-eighth day of the trial, after half-hour's deliberation found that the claimant was Arthur Orton. Found guilty of perjury on two counts, he was sentenced on the 28th of February 1874 to fourteen years' penal servitude. The cost of the two trials was estimated at something not far short of £200,000, and of this the Tichborne estates were mulcted of fully £50,000. The claimant's better-class supporters had deserted him before the second trial, but the people who had subscribed for his defence were stanch, while the populace were convinced that he was a persecuted man, and that the Jesuits were at the bottom of a deep-laid plot for keeping him out of his own. There were symptoms of a riot in London in April 1875, when parliament passed the Orton (by Kenealy) Bill for restoring the Tichborne case to a royal commission, and the military assisted, and when Orton emerged from gaol in 1884 the fickle public took no interest in him. The sensation of ten years earlier could not be galvanized into fresh life either by his lectures or his alternate confessions of imposture and retractions of innocence, and Orton sank into poverty and oblivion, dying in obscure lodgings in Marylebone on the 2nd of April 1898.

**TICINO (Gen. Tessin, anc. Ticinum), a river of Switzerland and north Italy, which gives its name to the Swiss canton of Ticino (q.v.), and gave in classical times to the town of Ticinum (Pavia).** It rises at the foot of the Gries Pass to the west of Airolo; from Airolo to the Lago Maggiore its valley bears the name of Val Leventina, and is followed as far as Bellinzona by the St Gotthard road and railway. It flows through Lago Maggiore, leaving it at its south end at Sesto Calende, and thence flows S.S.E. into the Po which it joins a little west of Pavia.

**TICINO (Fr. and Ger. Tessin), a canton of Switzerland, the only one situated almost wholly on the southern slope of the Alps and inhabited by a population of which the majority is Italian-speaking. It takes its name from the Ticino river, the whole upper course of which (the Val Leventina, with its side glen of Val Belino, the so-called Riviera, extending from Biasca to near Bellinzona, and the bit beyond Bellinzona), till it swells into the Lago Maggiore, is within the canton. Not far from the head of the lake the elevation of the land is increased by the Maggia torrent which is formed by the junction of the waters from the mountain glens known as the valleys of Locarno, save the Val Verzasca, the stream from which falls into the lake without joining the Maggia. The third portion of the canton is that called Monte Ceneri, including the hilly region between Bellinzona on the Ticino and Lugano, together with most of the lake of that name, and stretching on the south as far as Mendrisio, not far from Como. These three districts were all formerly part of the duchy of Milan till conquered by the Swiss, and in 1803 were joined together to form a Swiss canton, of which the most artistic Blend (Como, opposite Lugano, is still an Italian "enclave"). Its total area is 1087.1 sq. m., of which 721.9 sq. m. are reckoned as "productive" (forests covering 267.2 sq. m. and vineyards 19.9 sq. m.), while of the rest part is taken up by the Lake of Lugano (the Swiss share of which is 73 sq. m.), and those of the Lago Maggiore (Swiss share 161 sq. m.), and by 134'4 sq. m. of glaciers. In point of size the canton is surpassed by only four other cantons (Bern, the Grisons, the Valais, and Vaud), while only Vaud can boast of a larger vine-growing district. The highest points in the canton are two of the loftiest summits of the two halves of the Leopontine Alps. The highest in the south is the Piz Pizurin (11,149 ft.) in the Adjula Alps. Save the Ticino valley between Biasca, Bellinzona and Locarno, and the environs of Lugano, the canton is principally composed of hills and mountains, and is therefore poor from the material point of view, though rich in fine scenery.

The canton is traversed from end to end, from Airolo at the southern mouth of the St Gotthard tunnel to beyond Mendrisio (about 74 m.), by the main line of the St Gotthard railway, many of the marvellous engineering triumphs of which occur between Airolo and Biasca. From Bellinzona there is a short branch railway to Locarno (14 m.), whence the line runs across the north end of the Italian Switzerland, and at the head of one of the side glens of the Val Maggia, and colonized before 1253 from the neighbouring Tosa or Pommat valley (now politically Italian), which is inhabited by German-speaking emigrants from the canton of the Valais. In 1900 there were in the canton 75,731 women to 62,907 men, the men being in the habit of emigrating in search of work. Up to 1881 Bellinzona, Locarno and Lugano were alternate capital cities, though Bellinzona is the permanent capital. Yet it is but the second town in size, being surpassed by Lugano (q.v.), while after it come Locarno (q.v.) and Mendrisio (3338 inhabitants). Bellinzona is by far Italy's most important industrial town, and the canton has produced many sculptors, painters and architects. But its industrial development is backward, though the opening of the St Gotthard railway has attracted many foreign travellers. Yet the region is in another respect a great source of wealth, as coffee-house keepers (such as Delmonico, of New York), waiters in cafés, messengers, plasterers, labourers, navvies, &c. Fruit, chestnuts and wine are among the principal exports. The canton is divided into 8 administrative districts, which comprise 265 communes. The cantonal constitution is still that of 1830, which, however, has been almost mended out of sight owing to the political struggles.
that have raged in the canton. The legislature (Grundbesitz) is composed of members elected (since 1880) in the proportion of one to 15,000 of the Swiss and holding office for four years. The executive (Consiglio di stato) is (since 1892) elected directly by the people, is composed (since 1875) of five members, and holds office for four years. Since 1883 500 citizens have the right (as to bills passed by the legislature, since 1892) to vote as to bills passed by the legislature, thus (since 1892) 5000 citizens have the right of "initiative" in legislative matters, though 7000 signatures are required in case of a proposal to revise the cantonal constitution. In 1891 the system of proportional representation was introduced for elections to the cantonal legislature and the communal assemblies. In 1904 a very complicated system of proportional representation was adopted, of which the major fraction of the people of Ticino. In elections to the cantonal legislature all fractions below that required to secure a member in the entire canton are added together and then divided by the number of members of the cantonal legislature, the resulting number, selected being, as far as possible, assigned to the constituencies in which they have obtained most votes (the point remains obscure). In 1904 also the "limited vote" was adopted as to the election of members of the executive, no one being allowed to vote for more than four out of the five members. In 1896, by a strange anomaly only to be explained by the previous political history of the canton, non-resident citizens were given a vote in all cantonal and communal matters, though residence is strictly required for all voters in Federal matters. The two members of the federal Ständerath and the seven members of the Federal Nationalrat are elected by a popular vote.

The canton is made up of all the permanent conquests (with one or two trifling exceptions) made by different members of the ancient confederacy, in a line south of the Alps. From an historical point of view Italian Switzerland falls into three groups: (1) the Val Leventina conquered by Uri in 1440 (previously held from 1403 to 1422); (2) Bellinzona (previously held from 1419 to 1422); the Riviera and the Val Blenio, all won in 1500 from the duke of Milan by men from Uri, Schwyz and Nidwalden, and confirmed by Louis XII. of France in 1503; (3) Locarno, Val Maggia, Lugano and Mendrisio, seized in 1512 by the Confederates when fighting for the Holy League against France, ruled by the twelve members then in the league, and confirmed by Francis I. in the treaty of 1516. These districts were governed by bailiffs holding office two years and purchasing it from the members of the League; each member of group 3 sent annually an envoy, who conjointly constituted the supreme appeal in all matters. This government was very harsh and is one of the darkest pages in Swiss history. Yet only one open revolt is recorded—that of the Val Leventina against Uri in 1755. In 1798 the people were distracted by the Swiss and "Cisalpine republic" parties, but sided with the Swiss. On being freed from their hated masters, they were formed into two cantons of the Helvetic Republic—Bellinzona (which included the Lago di Lugano) and Ticino. These districts were formed into one canton—Ticino—which became a full member of the Swiss Confederation. From 1810 to 1813 it was occupied by the troops of Napoleon. The carriage road over the St Gotthard (1820-1830) was made under the constitution of 1814. But many of the old troubles reappeared, and were only done away with by the constitution of the 23rd of June 1830. In 1848, on religious grounds and owing to fears as to customs duties, the canton voted in the minority against the Federal constitution of that year; but in 1874, though the people voted against the revised constitution, the legislature adopted it, and thus it was a triumph of the majority. Since 1830 the local history of the canton has been very disturbed owing to the fact that, though Roman Catholicism is the state religion, and all the population are Roman Catholic (the few Protestants having been expelled from Locarno in 1555), they are divided between the Radical and Ultramontane parties. Since 1876 the intervention of Federal troops (already known in 1870) has been frequent in consequence of conflicts of the local authorities inter se, or against the Federal Assembly. The political troubles of Ticino were increased in 1888 by the formation of the see of Lugano, considered by the Radicals as illegal; it freed the district from both foreign ecclesiastical rule. Hence in September 1890 the Radicals carried out a bloody revolution, which necessitated Federal intervention, but at a state trial at Zürich in July 1891 the leaders were acquitted. Political passions still run high in the canton, as the Radicals and Conservatives are nearly balanced in point of numbers.

TIKELL, Thomas (1585-1746), English poet and man of letters, the son of a clergyman, was born at Bridgwater near Carlisle in 1586. After a good preliminary education he went (1707) to Queen's College, Oxford, taking his M.A. degree in 1709. He became fellow of his college in the next year, and in (T. A. S.)
TICKET—TICKING

1711 university reader or professor of poetry. He did not take orders, but by a dispensation from the Crown was allowed to retain his fellowship until his marriage in 1726. Tickell's success in literature, as in life, was largely due to the friendship of Addison, who procured for him (1717) an under-secretaryship of state, to the chaplain of Richard Steele, who thenceforth bore Tickell no goodwill. During the peace negotiations with France Tickell published in 1713 the Prospekt of Peace. In 1715 he brought out a translation of the first book of the Iliad contemporaneously with Pope's version. Addison's reported description of Tickell's version as the "best that ever was in any language" aroused the anger of Pope, who assumed that Addison himself was the author, or had at any rate the principal share in the work. Addison gave Tickell instructions to correct his works, which were printed in 1722 under Tickell's editorship. In 1724 Tickell was appointed secretary to the lords justices of Ireland—a post which he retained until his death, which took place at Bath on the 23rd of April 1740.

Kensington Gardens (1729), his longest poem, is inflated and pedantic. It has been said that Tickell's poetic powers were awakened and sustained by his admiration for the person and genius of Addison, and undoubtedly his best work is the sincere and dignified elegy addressed to the earl of Warwick on Addison's death. His ballad of Colin and Mary was long the most popular of his poems. Tickell contributed to the Spectator and the Guardian.

See "T. Tickell," in Johnson's Lives of the Poets; the Spectator; Ward's English Poets. His Works were printed in 1749 and are included in Chalmers's and other editions of the English Poets.

TICKET (O. Fr. esquiset, also esquitte, mod. étiquette, from Ger. stechen, to stick up), by origin a small bill stuck up for the purpose of giving notice or information, hence a small printed or written card or slip, containing a notice, order or the like, and more particularly such an one as embodies the terms under which the party issuing the ticket grants some right, privilege or licence to the party to whom it is issued; where there has been valuable consideration for such given by the holder the ticket is the method by which the parties enter into a contract. The most familiar of this last class of tickets is the passenger's ticket issued by railway companies, tramways or "common carriers" in general. The ticket does not usually contain the whole terms of the contract, but refers to the conditions under which it is issued, to which the holder is subjected if sufficient notice of them is given. A ticket of admission issued for a theatre, or place of entertainment, constitutes a licence to the holder to occupy and use a seat, whether particularized or not, and such parts of the building as may be open to him. Such a licence can be revoked by the issuer, and the holder may be ejected as a trespasser, subject to his right to bring an action for damages.

TICKET-OF-LEAVE, a term first invented for the "emancipists" in the days of Australian transportation (see Deportation); in the English penal system, a document or "pass" handed to a convict who has completed the second stage of his sentence and is about to enter the third and last, that of conditional or semi-freedom, in which he goes at large to earn his freedom, under certain restrictions and with less independence of the community. The "ticket" or "licence" is the outward sign of "remission" gained by industry and blameless conduct in prison (see Prison), and it may be forfeited for disobedience or neglect of certain conditions endorsed upon the licence. Convicts are by law required to report themselves at an appointed place within forty-eight hours after liberation and again every succeeding month at the police station nearest to their place of abode, between the hours of nine in the morning and nine in the evening. They must get their living by honest means and regular employment, and must reside—that is to say, sleep—at the address notified by them to the police in order that they may be found at once if required for any legal and justifiable purpose. If they change their address or withdraw from any known police district, they must give notice of their removal at the police station at which they have been reporting, stating the place to which they are going, and, as far as practicable, their address there, and also at the nearest police station within forty-eight hours of arriving in any other police district in any part of the United Kingdom. They must produce their licences whenever, they are called upon to do so by a police officer.

This treatment of offenders who have already expiated their crimes has been deemed to bear heavily on any who are anxious to turn over a new leaf. To be ever subject to the watchfulness of the police must often increase the licence-holder's difficulty of leading an honest life. The struggle is known to be often severe; employers of labour are not too ready to accept the services of "gaol birds," and free workmen often resent the admission of an old convict amongst their number. Private charity has come forward to diminish or remove this hardship, and many societies have been called into existence for the purpose of assisting discharged prisoners. They are to be found in most of the principal cities of the United Kingdom. London alone has those of the Church Army, the St Giles's Christian Mission, the Salvation Army, the Catholic Aid Society and the Royal Society for the Assistance of Discharged Prisoners, which was established in 1856 and has done a vast and meritorious work. It labours chiefly in the metropolis; it receives contributions from private subscriptions, but it has control also over the gratuities of the licencees who accept its aid. The prisoners on release are first examined at the society's office as to their prospects and wishes; they are given some pocket-money out of their own gratuities; and their "liberty clothing," a present from the prison, is changed for more suitable clothes. They are then placed in respectable lodging-houses until employment is obtained for them, after which the society undertakes the reporting to the police and by its own agents exercises a watch over its protégés. There are upwards of sixty-five societies, all certified by the secretary of state, of which the number is increasing; every year the subscriptions increase, more money is expended, more cases are aided and more ex-convicts are rehabilitated. Unfortunately a large number of those who solicit help belong to the class of "lazy loafers who like neither work nor honesty," and who, when the first is found, will not adhere to the latter. Most of the societies employ agents who act as intermediaries between employers and ex-convicts and fill a place analogous to that of the "probation officers" in parts of the United States (see Probation); but the probation officer generally interposes at an earlier stage and shields the first offender from the consequences of his act, by sparing him a visit to the gaol. In a speech on Prison Reform in the English House of Commons on the 20th of July 1910, the home secretary outlined a proposed scheme for abolishing ticket-of-leave altogether, and entrusting the after-supervision of released prisoners to a central agency of semi-official character.

Ticking, a strong linen or cotton fabric usually woven in stripes of colour; blue and pink with white being the most common. The name is derived from a word "tick," common in various forms to many languages, signifying a case or sheath.

1 See Warton's note in the Bathos (ed. Pope and Elwin, x. 388), where he quotes from Tickell's version and from Addison and says the same author.
TICKNOR, G.—TICKS

Ticking is used for mattresses, awnings and tents. In some qualities it is also used as a foundation for embroidery.

White, grey, or brownish warp threads are usually flax, while the coloured threads are often cotton. The weft is flax or tow. The warps of many of the cheaper kinds are made entirely of cotton, and jute is used for warps in the cheapest grades. A feather tick should be made of fine flax yarns set close, and there should also be a large number of weft threads per inch. Sometimes the inside of the tick is waxed in order to prevent the feathers from working out.

The structure of the fabric is termed a twill, of which four varieties, each showing four units, are illustrated. Fig. 1, the ordinary three-leaf twill, is more extensively used than any other. Occasionally the pattern or twill is in one direction only, but more often the direction is reversed at intervals, thus producing what is technically termed a "herring-bone" or an "arrow-head" twill. Fig. 2 complete on twenty-four threads and three picks such a pattern, where the twill is reversed every twelve threads. Figs. 3 and 4 are the four-thread and five-thread straight twills respectively, while fig. 5 is the five-thread seaten twill. These latter twills require a great number of threads and picks per inch, and are used only in the finest ticks. The plain weave is occasionally used for cheaper varieties.

Mattress ticks and awnings are woven with the same twills, but the colouring of these, especially of the former, is more elaborate.

TICKNOR, GEORGE (1791-1871), American educator and author, was born in Boston, Massachusetts, on the 1st of August 1791. He received his early education from his father, Elisha Ticknor (1757-1821), who had been principal of the Franklin public school and was a founder of the Massachusetts Mutual Fire Insurance Company, of the system of free primary schools in Boston, and of the first New England savings bank. In 1805 the son entered the junior class at Dartmouth, where he graduated in 1807. During the next three years he studied Latin and Greek with Rev. Dr John Sylvester Gardiner, rector of Trinity, Boston, and a pupil of Dr Samuel Parr. In 1810 Ticknor began the study of law, and he was admitted to the bar in 1813. He opened an office in Boston, but practised for only one year. He went to Europe in 1815 and for nearly two years studied at the university of Göttingen. In 1817 he became Smith professor of French and Spanish languages and literatures (a chair founded in 1816), and professor of belles-lettres at Harvard, and began his work of teaching in 1819 after travel and study in France, Spain and Portugal. During his professorship Ticknor advocated the creation of departments, the grouping of students in divisions according to proficiency, and the establishment of the elective system, and reorganized his own department. In 1835 he resigned his chair, in which he was succeeded in 1836 by Professor H. W. Longfellow; and he was again in Europe in 1835-1838. After his return he devoted himself to the chief work of his life, the history and criticism of Spanish literature. In many respects a new subject at that time in Europe, there being but inadequate treatment of the literature as a whole in Spanish, and both Bouterwek and Sismondi having worked with scanty or second-hand resources. Ticknor developed in his college lectures the scheme of his more permanent work, which he published as the History of Spanish Literature (New York and London, 3 vols., 1849). The book is not merely a story of Spanish letters, but, more broadly, of Spanish civilization and manners. The History is exhaustive and exact in scholarship, and direct and unpretentious in style. It gives many illustrative passages from representative works, and copious bibliographical references.

It was soon translated into Spanish (1851-1857) by de Gayangos and de Vedia; French (1864-1872), a poor version by Magnabahal; and German (1852-1867), by N. H. Julius and Ferdinand Wolf. The second American edition appeared in 1854; the third corrected and enlarged, in 1863; the fourth, containing the author's last revision, in 1872, under the supervision of George S. Hillard; and the sixth in 1888. Ticknor had succeeded his father as a member of the Primary School Board in 1832, and held this position until 1825; he was a trustee of the Boston Athenæum in 1833-1834, and was vice-president in 1833; and was a director (1827-1823) and vice-president (1841-1854) of the Massachusetts Hospital Life Insurance Company, and a trustee of the Massachusetts General Hospital (1826-1830) and of the Boston Provident Institution for Savings (1838-1850), the bank that his father had helped to found. He was especially active in the establishment of the Boston Public Library (1852), and served in 1821-1866 on its board of trustees, of which he was president in 1865. In its behalf he spent fifteen months abroad in 1856-1857, at his own expense, and it to he gave at various times money and books; a special feature of his plan was a free circulating department. He left to the library his own collection, which was particularly strong in Spanish and Portuguese literatures. He died in Boston on the 26th of January 1871.

Ticknor's minor works include, besides occasional reviews and papers, Syllabus of a Course of Lectures on the History and Criticism of Spanish Literature (1823); Outline of the Principal Events in the Life of General Lafayette (1823); Remarks on Changes lately Proposed or Adopted in Harvard University (1825); The Remains of Nathan Appleton Haven, with a Memoir of his Life (1827); Remarks on the Life and Writings of Daniel Webster (1831); Lecture on the Best Methods of Teaching the Living Language, delivered before the American Institute of Education; and the Life of William Hickling Prescott (1864).

See Life, Letters and Journals of George Ticknor (2 vols., 1876), by George S. Hillard and Mrs Anna (Eliot) Ticknor and Miss Anna Eliot Ticknor. This book was edited, with a critical introduction, in 1909, by Ferris Greenslet.

TICKS, the common name for Arachnida (q.v.) belonging to the order Acari, of which they constitute the two families, Ixodidae and Argasidae. Collectively the Ixodidae and Argasidae may be distinguished from other Acari by the presence of a median probe, armed with recurved hooks, which project forwards towards the mouth and extend the spiracular area above and usually behind the base of the fourth leg on each side. As compared with the majority of Acari, ticks are of large size, distended female specimens of some of the species measuring half an inch or more in length, while even the newly hatched young can hardly be regarded as microscopical. The integument is tough, leathery or horny. The mouth parts consist of two small retractor mandibles, of a pair of short palpi and of the toothed probe above mentioned. The palpi and probe or hypostome are attached to a movable sclerite or horny plate called the capitulum. The capitulum, with its associated structures, is sometimes called the rostrum, whereas sometimes the term rostrum is restricted to the hypostome alone. It is by means of the hypostome that ticks pierce the integument and firmly adhere to the host whose blood they suck for food. The two families Argasidae and Ixodidae may, be distinguished as follows. In the Argasidae the anterior portion of the dorsal surface of the body is extended forwards above the capitulum, so that this structure is concealed from above; the integument is fairly uniformly granular or coriaceous above and below; the palpi are simple and unmodified; there is a sucker beneath the claws in the adult, and there is only a slight structural difference between the sexes. In the Ixodidae the capitulum is not overlapped by a forward extension of the dorsal area, which is smooth and firmly chitinised either in front or all over; the palpi are usually modified, that is to say, their second and third segments are usually excavated internally to form a sheath for the hypostome; there is a distinct sucker beneath the claws and the difference between the sexes is well marked, the males having the dorsal integument thickly and continuously chitinised, whereas in the females only its anterior
portion bears a chitinous plate, the rest of the integument being soft to admit of its distension by the blood which is imbibed in quantity by members of this sex. For a longer or shorter period of their lives ticks are parasitic upon vertebrate animals of various kinds; but although the belief that the bite of certain tropical species is poisonous has long been held by the natives of the countries they infest and has been recorded with corroborative evidence in the European literature, it is only of recent years that accurate information has been acquired of the part played by these Arachnids in transmitting from one host to another protozoal blood-parasites which cause serious or fatal diseases to man and other animals.

Both the Argasidae and Ixodidae contain pathogenic species, of which the best known are the following: Ornithodoros moubata, belonging to the Argasidae, and called bbe in Uganda, monbata in Angola, and tampan on the Zambezi, is widely distributed in tropical Africa from Uganda in the north to the Transvaal in the south. This first was recorded as poisonous by Livingstone and is now known to be the carrier of the Spirochaete of relapsing fever in man, known as tick fever. Although Europeans suffer from this disease far more severely than negroes, death seldom or ever follows. An allied species, O. turecata, occurs in Mexico and Texas, which causes considerable destruction amongst poultry and is a pest to mankind as well. A similar bad reputation attaches to other species in different parts of the world, in America; while Argas minutus has been proved to be the carrier of the Spirochaete causing spirillosis in fowls in Rio Janeiro, and also in New South Wales whether it has been introduced with imported poultry. Argas persicus has been introduced in the same way into South Africa from Europe. As its name indicates, it was first discovered in Persia, where the belief in the venomous nature of its bite to human beings is both widespread and historical. It is held that the Argasidae, which are for the most part parasitic upon birds, contain the only species of ticks, especially O. moubata, which are known to be seriously harmful to mankind; whereas amongst the Ixodidae no human pathogenic species has been ascertained to be parasitic. The only species which have been proved to be highly destructive to domestic mammals of different species. The most important of these are the following: Dermacentor reticulatus, a species widely distributed in Europe, Asia and America, infects dogs in Europe with the haematozoon disease known as "biliary fever," and has been asserted to be answerable for the so-called spotted or tick fever in man in the Rocky Mountains.

The same canine disease results in South Africa from the bite of the Haemaphysalis leachi. Amblyomma hebraeum, the brown tick of the Cape Colonists, infects sheep with the Sporozoon causing "heart-water" sickness, and in Europe sheep are inoculated with the disease by the bite of Argas persicus, its European name, and is called "coast fever" in cattle in South Africa is conveyed by two distinct species of the genus Rhipicephalus, namely R. appendiculatus and R. simus, which are locally known respectively as the "brother tick" and the "sister tick." Finally Margarops annulatus, of which there are several geographical races, is the carrier of the germs causing the destructive cattle-disease variously known in India as "tick fever," 's Fokien fever, and "bursa" fever in Africa, South America, Australia and South Africa. In the United States alone an annual animal loss in cattle stock occasioned by the ravages of this tick disease was computed in 1907 at one hundred million dollars. With one or two possible exceptions, like Argas septentironis, which has only been observed from European bats, no species of tick is known to be confined to a particular host. The common sheep-tick (Ixodes ricinus) of England, for example, infects cattle and dogs as well as sheep; and the pathogenic mite, with above mentioned, occurs parasitically upon other mammals than those to which they convey the diseases specified. Reptiles are infested as well as mammals, and many insects, including lice, are occupied by Ixodidae of various kinds adherent to tortoises, snakes and lizards. Ticks belonging to the Ixodidae differ to a certain extent in their life-histories.

Mature males and females are found together upon the same host. Parallel with the sexual development the spermatophores penetrate into the genital orifice of the female by means of his proboscis. The gorgeted and fertilized female quits her hold of the host, and falling to the ground, proceeds after a short delay to lay her eggs in some sheltered place. The egg is a transparent, homogeneous, oval, colorless or whitish body, which assumes the position putting it at twenty thousand. After oviposition, which may extend over several weeks, the female dies. The newly-hatched young has only three pairs of legs and is without spiracular and genital orifices. These young or larvae, as they are called, after the integument has hardened by exposure to the air, climb up the stalks of grain or herbage and cling with outstretched legs waiting for passers-by to whom they hold on with a cover called brushes, by which, and crawling to a suitable place become engorged with blood. After about a week's feeding they drop to the ground, lie dormant for a month, during which time they acquire their fourth pair of legs and spiracles, and, molting, emerge from their old skin as nymphs. Nymphs repeat the behaviour of the larvae, and finally moult into the adult, showing the generative orifice, which is the mark of maturity. The adult secures a host in the same way as the young. Both sexes feed upon blood; whereas the male alters but little in appearance, the female becomes enormously distended.

From the foregoing it appears that many species, Rhipicephalus appendiculatus for example, it is evident that every individual tick has to find a host on three occasions, namely, as larva, nymph and adult. In R. bursa, however, the moth that

![Fig. 1](image_url) - *Hyalomma aegyptium* Savigny. Undistended female: a, Rostrum or hypostome; b, b, Palpi; c, Capitulum; f, Abdomen.

![Fig. 2](image_url) - The same, under side: a, Rostrum or hypostome; b, Palpi; e, Genital aperture; d, Anal orifice; e, e, Ventral surface of capitulum; g, Sternum; 1-7, segments of leg.

transforms the larva into the nymph takes place on the host, and in *Margarops annulatus* the transformation of larva into nymph and nymph into adult is effected without the temporary sojourn on the ground. Another species, *Hyalomma aegyptium*, the so-called camel-tick of Egypt and Arabia, is alleged to be parasitic only in its mature stage. Again, in *Ornithodoros moubata*, which is parasitic apparently only at night, the young does not hatch from the egg until it has attained the nymphal stage.

It is an interesting and important fact that the newly hatched young of certain species, *Margarops annulatus* for instance, before it has fed, if produced by a female carrying the germs of spirillosis, can infect healthy organisms with the disease. From this it is evident that the Spirochaetes pass directly from the mother tick to her offspring.

Duration of life in ticks depends upon the conditions of their existence. Under favourable conditions, when food is obtainable, growth is rapid, the time from the hatching of the young until it reaches maturity and dies after oviposition being, for example, about eleven weeks in *R. appendiculatus* and only about three weeks in *M. annulatus*. On the other hand, when food is not obtainable, life may be indefinitely prolonged if the tick be guarded from enemies and from atmospheric conditions iminical to existence. Examples of *Ixodes ricinus* have been kept for two years and three months without feeding, and specimens of *Argas persicus* were still alive after four years' starvation.

**TICONDEROGA**, a village in the township of Ticonderoga, Essex county, New York, U.S.A., on the outlet of Lake George, 100 m. by rail N. by E. of Albany. Pop. (1890), 2267; (1900), 1911; (1905), 1740; (1910), 2475. Ticonderoga is served by the Delaware & Hudson and the Rutland railways. The water
TIDE

from Lake George falls here about 30 ft., providing water-power, and among the manufactures are paper pulp, paper-making machinery and lumber. Flake graphite was discovered in this vicinity as early as 1815, and for years two mines (with quartzite veins, respectively 1-5 and 2-15 ft. thick) at Ticonderoga were the principal source of supply of good crystalline graphite. Commanding a portage on the line of water communication between Canada and the English colonies, Ticonderoga was a place of considerable strategic importance during the Seven Years' War. On a commanding elevation overlooking the present village and Lake Champlain the French began building a fort of earth and timber in 1755 and called it Fort Carillon; later it was named Fort Ticonderoga. Sir William Johnson led an expedition in the same year against this fort and Crown Point; though he failed to capture the forts he defeated Baron Ludwig August Dieskau in the battle of Lake George and erected at the head of the lake Fort William Henry, which was captured by the marquis de Montcalm in 1757. On the 8th of July 1758 less than 4000 Frenchmen were confronted at Fort Carillon by about 6000 British regulars and 10,000 provincials under Lt.-Gen. James Abercrombie and Brigadier-General George A. Howe, but Howe, the controlling spirit of the British force, had been killed on the 6th of July, and Abercrombie, after an ineffectual attack which cost him nearly 2000 men killed or wounded, retreated. In 1758, however, when Montcalm had gone to Quebec to oppose Wolfe and a force of only 400 men was left at Ticonderoga, Lord Amherst with 11,000 men invested it, and on the 26th of July the garrison blew up and abandoned the fortifications. At the beginning of the War of Independence, on the 10th of May 1775, the fort was surprised and captured by Ethan Allen. It was recovered by the British on the 4th of July 1777, during Burgoyne's campaign, was abandoned immediately after Burgoyne's surrender in October 1777, but was re-occupied by the British in 1780. After the close of the war it was allowed to fall into ruins. In 1909, on the occasion of the tercentenary celebration of the discovery of Lake Champlain, the restoration of the fort was begun under the direction of the owner of the site. The settlement of this region was begun soon after the close of the Seven Years' War, and the township of Ticonderoga was set apart from the township of Crown Point in 1804. The village of Ticonderoga was incorporated in 1889. The name "Ticonderoga" is a corruption of an Indian word said to mean "sounding waters."

TIDE (O. Eng. tid, cf. Ger. Zelt, time or season, connected with root of Sanskrit a-diti, endless), a term used generally for the daily rising and falling of the water of the sea, but more specifically defined below.

I.—GENERAL ACCOUNT OF TIDES AND TIDAL THEORIES

§ 1. Definition of Tides.—When, as occasionally happens, a ship in the open sea meets a short succession of waves of unusual magnitude, we hear of tidal waves; and the large wave caused by an earthquake is commonly so described. But the use of the adjective "tidal" appears to us erroneous in this context, for the tide is a rising and falling of the water of the sea produced by the attraction of the sun and moon. A rise and fall of the sea produced by a regular alternation of day and night, by regular rainfall and evaporation, or by any influence which the moon may have on the weather cannot strictly be called a tide. Such alterations may be inextricably involved with the rise and fall of the astronomical tide, but we shall here distinguish them as meteorological tides. It is well known that there are strongly marked diurnal and semi-diurnal inequalities of the barometer due to the sun's heat, and they may be described as atmospheric meteorological tides. These movements both in the case of the sea and in that of the atmosphere are the result of the action of the sun, as a radiating body, on the earth. True astronomical tides in the atmosphere would be shown by a

regular rise and fall in the barometer, but such tides are undoubtedly very minute, and we shall not discuss them in this article, merely referring the reader to the Mécanique céleste of Laplace, bks. i. and xii. We shall in the present article extend the term "tide" to denote an elastic or viscous periodic deformation of a solid or viscous globe under the action of tide-generating forces.

§ 2. General Description of Tidal Phenomena.—If we live by the sea or on an estuary, we see that the water rises and falls nearly twice a day; speaking more exactly, the average interval from high-water to high-water is about 12h 25min, so that the average retardation from day to day is about 50min. The times of high-water are then found to bear an intimate relation with the moon's position. Thus at Ipswich high-water occurs when the moon is nearly south, at London Bridge when it is south-west, and at Bristol when it is east-south-east. For a very rough determination of the time of high-water it is sufficient to add the solar time of high-water on the days of new and full moon (called the "establishment of the port") to the time of the moon's passage over the meridian, either visibly above or invisibly below the horizon. The interval between the moon's rise and fall of water is also subject to great variability. On the days after new and full moon the range of tide is at its maximum, and on the day after the first and third quarter at its minimum. The maximum range is called "spring tide" and the minimum "neap tide," and the range of spring tide is usually nearly three times as great as that of neap tide. At many ports, however, especially non-European ones, two successive high-waters are of unequal heights, and the law of variability of the difference is more a matter of opinion; a statement of that law will be easier when we come to consider tidal theories. In considering any single oscillation of water level we find, especially in estuaries, that the interval from high to low-water is longer than that from low to high-water, and the difference between these two intervals is greater at springs than at neaps.

In a river the current continues to run up stream for some considerable time after high-water is attained and to run down similarly after low-water. Much confusion has been occasioned by the indiscriminate use of the term "tide" to denote a tidal current and a rise of water, and it has often been incorrectly inferred that high-water must have been attained at the moment of cessation of the upward current. The distinction between "rising and falling" and "flowing and ebbing" must be maintained in rivers, whilst it is unnecessary at the seaboard. If we examine the progress of the tide-wave up a river we find that high-water occurs at the sea earlier than higher up. If, for instance, on a certain day it is high-water at Margate at noon, it is high-water at Gravesend at a quarter past two, and at London Bridge a few minutes before three. The interval from low to high-water diminishes also as we go up the river; and at some time up the river, for example, the Severn—the rising water spreads over the flat sands in a roaring surf and travels up the river almost like a wall of water. This kind of sudden rise is called a "bore" (p. 96). In other cases where the difference between the periods of rising and falling is considerable there are, in each high-water, two or three rises and falls. A double high-water exists at Southampton.

When an estuary contracts considerably, the range of tide becomes largely magnified as it narrows; for example, at the

1 Lord Kelvin shows that the attraction of the sun on these tides must produce an excessively small acceleration of the earth's rotation. See Société de physique (September 1881), or Proc. Roy. Soc. Edin. (1881-1882), p. 356.

3 See a series of papers bearing on this kind of wave by Sir W. Thomson (Lord Kelvin) in Phil. Mag. (1886-1887).
entrance of the Bristol Channel the range of spring tides is about 18 ft., and at Chesport about 50 ft. This augmentation of the height of the tide-wave is due to the concentration of the energy of motion of a large mass of water into a narrow space. At oceanic ports the tidal phenomena are much less marked, the range of tide being usually only 2 or 3 ft., and the interval from high to low-water sensibly equal to that from low to high-water. The changes from spring to neap tide and the relation of the time of high-water to the moon’s transit are, however, the same both on the open coast and in rivers.

In long narrow estuaries such as the English Channel, the tide in the inland-channel follows the same law as at a station near the mouth of a river, rising and falling in equal times; the current runs in the direction analogous to up-stream for three hours before and after high-water, and down-stream for the same period before and after low-water. But near the sides of channels and near the mouths of bays the changes of the currents are very complex; and near the headlands separating two bays there is usually at certain times a very swift current, termed a race.

In bays and sounds, such as the Mediterranean, the tides are nearly insensible except at the ends of long inlets. Thus at Malta the tides are not noticed by the ordinary sailors, whilst at Venice they are conspicuous.

The effect of a strong wind on the height of tide is generally supposed to be strongly marked, especially in estuaries. In the case of an exceptional gale, when the wind veered round appropriately, Airy states that the water has been known to depart from its predicted height at London by as much as 5 ft. The effect of wind will certainly be different at each port. The discrepancy of opinion on this subject appears to be greatest—so much so that we hear of some observers concluding that the effect of the wind is insensible. Variations in barometric pressure also cause departures from the predicted height of water, high barometer corresponding to decrease of height of water. Roughly speaking, an inch of the mercury column will correspond to about a foot of water, but the effect seems to vary much at different ports.

Mariners and hydrographers make use of certain technical terms which we shall now define and explain.

The “establishment of the port,” already referred to above, is the average high-water or low-water mark of the moon’s transit across the meridian, at full moon and at change of moon, and the occurrence of high-water. Since at these times the moon crosses the meridian at twelve o’clock either of those days the term “establishment” is the hour of the clock of high-water at full and change.

It has already been remarked that spring tide occurs at most places a day or a day and a half after full and change of moon. Now it is more important in the theory of the tides to know what occurs at spring tide than what occurs at full and change of moon. Thus the term “the corrected establishment of the port” is used to denote the interval in hours elapsing at spring tide between moon’s transit and high-water. The difference between the ordinary and the corrected establishments is of small amount. At any other state of the moon, except full and change, the “interval” or “lunital interval” is the interval between the moon’s upper or lower transit and high-water.

The average interval elapsing between full or change of moon and spring tide is called the “age of the tide”; as already remarked this interval is commonly about a day or a day and a half, but it may be twice as great in some places. The use of this term arises from the idea that spring tides are generated at some undefined place exactly at full or change of moon, and that an interval of time denoted the “age” to reach the place of observation. The term is not altogether satisfactory, since it implies a theory, but it must be referred to as in general use.

The phrase “spring tide” is used at high and low-water marks is called “the spring rise”; the similar height at neap tides is however, called “the neap range.” “Neap rise” is used to mean the average height between high-water of neap tides and low-water of spring tides. This term “rise” refers to the rise above the level of low-water at spring tide. French hydrographers call half the spring rise “the unit of height.”

The “diurnal inequality” of the tide denotes the fact that successive high-water and successive low-water are unequal to one another. In England the diurnal inequality scarcely exists. When the phase of the moon is at either the first or last quarter, the tide is transferred to “medium low-water mark of ordinary spring tides.” This datum is found by taking the mean of all the available observations of spring tides, excluding, however, from the mean any spring tides which may be considered at fault, and then, if necessary, correcting the mean of the whole by linear interpolation. If the tide still persist, we may use a different procedure; if not, then, the tide is used for the mean of the high and low water, which is defined as being below mean sea-level by the sum of the ordinates of the tides M, S, K₁, O (see §§ 24, 25 on Harmonic Analysis below).

In ordinary parlance sailors very commonly use the term “tide” when they mean what may be more accurately described as a tidal current.

§ 3. Tidal Observation: the Tide-gage.—Tide prediction is only possible when accurate observations have been made of the phenomena to be predicted; and the like is true of verification after prediction. It was formerly thought sufficient to note the heights of the water at high and low-water, together with the times of those events, and the larger part of the observations which exist are still of this character, but complete investigation of the law of tidal oscillations demands that the height of the water should be measured at other times than at high and low-water.

With whatever degree of thoroughness it is proposed to observe the tides the procedure is much the same. The simplest sort of observation is to note the height of the water on a graduated staff fixed in the sea, with such allowance as may be possible for wave-motion. It is, however, far preferable to sink a tube into the sea into which the water penetrates through small holes; and the wave motion is thus annulled. In the calm water inside the tube there lies a float, to which is attached a cord passing over a pulley and counterpoised at the end. The motion of the counterpoise against a scale is observed. In either case the observations may be made every hour, or the times and heights of high and low-water may be noted.

In more careful observations than those referred to above the tidal record is automatic and continuous and is derived by means of an instrument called a tide-gage.

This gauge should be placed in a place where we may obtain a fair representation of the oscillation of the surrounding sea. In such a site a well or tank is built on the shore communicating by a channel with the sea. At the mouth of this channel water meters, artificially constructed well may be dispensed with, where some lagoon or pool exists near to the sea as to permit junction with the sea by means of a narrow channel. The water in that channel is measured by an instrument which is always in a vertical position. When the tide is rising the water is provided rising and falling with the tide, without much wave-motion. A cylindrical float, usually a hollow metallic box or a block of greenheart wood, hangs and floats in the well, and is of such density as just to sink without support. The float hangs under very light tension by a platinum wire, or a metallic ribbon, or by a chain. The suspension wire is wrapped round a wheel, and imparts to it rotation proportional to the rise and fall of tide. By a simple gearing this wheel drives another, by which the range is reduced to any convenient extent. A fine wire wound on the final wheel of the train drops a pencil or pen up and down and to and fro, so as to literally to represent the wave motion by a line that is lightly pressed against a drum, which is driven by clockwork so as to make one revolution per day. The pen leaves its trace or tide-curve on paper wrapped round the drum. The paper is fixed to the drum with the edges of the paper at the XII o’clock line, and the record of a fortnight may be taken without change of paper. An example of a tide-curve for Apollo Bunder, Bombay, from the 1st to the 15th of January 1884, is shown in fig. 1.

We have chosen an example from a sub-tropical region because it illustrates the remarkable regularity of the tides in a region where the weather is equable. Further, if the reader will note the successive maxima or minima of the tides, he will see on any one day, he will see a strongly marked “diurnal inequality,” which would have been barely perceptible in a European tide-curve.

2 See J. N. Shoobridge on datum levels, Brit. Assoc. Reports (1879).
§4. Tide-Tables and the Degree of Accuracy in Tidal Prediction.

The connexion between the tides and the movements of the moon and sun is so obvious that tidal predictions were regularly made and published long before mathematicians had devoted their attention to them; and these predictions attained considerable success, although they were founded on empirical methods. During the 18th century, and even in the earlier part of the 19th, the art of prediction was regarded as a valuable family secret to be jealously guarded from the public. The best example of this kind of tide-table was afforded by Holden's tables for Liverpool, founded on twenty years of observation by a harbour-master named Hutchinson.

About 1832 the researches of W. Whewell and of Sir John Lubbock (senior) pointed the way to improvement on the empirical tables prepared by secret methods, and since that time the preparation of tide-tables has become a branch of science.

A perfect tide-table would tell the height of the water at the place of observation at every moment of the day, but such a table would be cumbrous; it is therefore usual to predict only the times and heights of high-water and of low-water. The best kind of tide-table contains definite forecasts for each day of a definite year, and we may describe it as a special table. Although the table is only made for one definite place, yet it is often possible to give fairly accurate predictions for neighbouring ports by the application of corrections both for time and height. Special tide-tables are published by all civilized countries for their most important harbours.

But there is another kind of table, which we may describe as a general one, where the heights and times are given by reference to the time at which the moon crosses the meridian. Although such a table is only applicable to a definite place, yet it holds good for all time. In this case it is necessary to refer to the Nautical Almanac for the time of the moon's transit, and a simple calculation then gives the required result. In a general tide-table the heights and times are tabulated according to the hour of the clock at which the moon will cross the meridian at the place of observation, distinguishing between the visible and invisible transits. Certain simple corrections have also to be applied. A considerable degree of elaboration has to be given to the table, in order that it may give accurate results, and it would occupy some half-dozen to a dozen pages of a book, its extension varying according to the degree of accuracy aimed at.

It might occupy about five minutes to extract a prediction from the more elaborate form of such a table. There are many ports of considerable commercial importance where, nevertheless, it would hardly be worth while to incur the great and repeated expenditure involved in the publication of special tables. But this kind of elaborate general table has been used in few cases, and the information furnished to mariners usually consists either of a full prediction for every day of a future year, or of a meagre statement as to the average rise and interval, which must generally be almost useless.

The success of tidal predictions varies much according to the place of observation. In stormy regions the errors are often considerable, and the utmost that can be expected of a tide-table is that it shall be correct with a steady barometer and in calm weather. But such conditions are practically non-existent, and therefore errors are inevitable.

Notwithstanding these perturbations, tide-tables are usually of surprising accuracy even in northern latitudes; this may be seen from the following table showing the results of comparison between prediction and actuality at Portsmouth.

The importance of the errors in height depends, of course, on the range of the tide; it is well, therefore, to note that the average ranges of the tide at springs and neaps are 13 ft. 9 in. and 7 ft. 9 in. respectively.

Prediction at such a place as Portland is difficult, on account of the instability of the weather, but, on the other hand, the tides in themselves are remarkably simple in character. Let us now turn to such a port as Aden, where the weather is very uniform, but the tides very complex on account of the large diurnal inequality, which frequently obliterates one of two successive high-waters. The short series of comparisons between actuality and prediction which we give below may be taken as a fair example of what would hold good when a long series is examined. The results refer to the intervals 20th of March to the 9th of April and the 12th of November to the 12th of December 1884. In these two periods there should have been 118 high waters, but the tide-gauge failed to register on one occasion.

Darwin, "Tidal Prediction," quoted above. This kind of table has been applied with some success at Cairns in North Queensland, where there is a large diurnal inequality.
so that one comparison is lost. We thus have 117 cases to consider, but on one occasion the diurnal inequality obliterated a high-water, leaving 116 actual comparisons. The maximum range of the tide at Aden is 8 ft. 6 in., and this serves to give a standard of importance for the errors in height.

It would be natural to think that when a prediction is erroneous by as much as fifty-seven minutes it is a very bad one, but such a conclusion may be unjust. There was one case in which the high-water was completely obliterated by the diurnal inequality, but there were many others in which there was nearly complete obliteration, so that the water stood nearly stagnant for several hours. A measure of the degree of stagnation is afforded by the amount of rise from low to high-water. Now, on examining all the eleven cases where the error of time was equal to or over twenty minutes, we find five cases in which the range from low to high-water was less than 8 in., and these include the errors of fifty-six and of fifty-seven minutes. There is one case of a rise of 17 in. with an error of twenty-two minutes; one of 19 in. rise with thirty-three minutes error. The remaining three cases have rises of 2 ft. 10 in., 3 ft. 9 in., 3 ft. 11 in., and errors of twenty-two, twenty-three, twenty minutes. Thus all the very large errors of time correspond with approximate stagnation, and are unimportant. It is fair to conclude, therefore, that the predictions as to time are very good. The predictions as to height are obviously good, for more than half were within 1 in., and only eleven had an error of as much as 4 in.

When it is considered that the incessant variability of the tidal forces, the complex outlines of the coast, the depth of the sea, the earth's rotation and the perturbations by meteorological influences are all involved, it should be admitted that the success of tidal prediction is remarkable. If further evidence were needed, we might appeal to tidal prediction as a convincing proof of the truth of the theory of gravitation.

§ 5. General Explanation of the Cause of Tides.—The moon attracts every particle of the earth and ocean, and by the law of gravitation the force acting on any particle is directed towards the moon's centre, and is jointly proportional to the squares of the particle and of the moon, and inversely proportional to the distance between the particle and the moon's centre. If we imagine the earth and ocean subdivided into a number of small portions or particles of equal mass, then the average, both as to direction and intensity of the forces acting on these particles is equal to the force acting on that particle which is at the earth's centre. For there is symmetry about the line joining the centres of the two bodies, and, if we divide the earth into two portions by an ideal spherical surface passing through the earth's centre and having its centre at the moon, the portion remote from the moon is a little larger than the portion towards the moon, but the nearer portion is under the action of forces which are a little stronger than those acting on the farther portion, and the resultant of the weaker forces on the larger portion is exactly equal to the resultant of the stronger forces on the smaller. If every particle of the earth and ocean were being urged by equal and parallel forces there would be no cause for relative motion between the ocean and the earth. Hence it is the departure of the force acting on any particle from the average which constitutes the tide-generating force. Now it is obvious that on the side of the earth towards the moon the departure from the average is a small force directed towards the moon; and on the side of the earth away from the moon the departure is a small force directed away from the moon. Also these two departures are very nearly equal to one another, that on the near side being so little greater than that on the other that we may neglect the excess. All round the sides of the earth along a great circle perpendicular to the line joining the moon and earth the departure is a force directed inwards towards the earth's centre. Thus we see that the tidal forces tend to pull the water towards and away from the moon, and to depress the water at right angles to that direction.

If it were permissible to neglect the earth's rotation and to consider the system as at rest, we should find that the water was in equilibrium when elongated into a prolate ellipsoidal or oval form with its longest axis directed towards and away from the moon.

But it must not be assumed that this would be the case when there is motion. For, suppose that the ocean consisted of a canal round the equator, and that an earthquake or any other cause were to generate a great wave in the canal, this wave would travel almost along it with a velocity dependent on the depth. If the canal were about 15 miles deep the velocity of the wave would be about 1000 miles an hour, and with depth about equal to the depth of our seas the velocity of the wave would be about half as great. We may conceive the moon's tide-generating force as making a wave in the canal and continually outstripping the wave it generates, for the moon travels along the equator at the rate of about 1000 miles an hour, and the sea is less than 13 miles deep. The resultant oscillation of the ocean must therefore be the summation of a series of partial waves generated at each instant by the moon and always falling behind her, and the aggregate wave, being the same at each
TIDE

instant, must travel 1000 m. an hour as to keep up with the moon.

Now it is a general law of frictionless oscillation that, if a slowly varying periodic force acts on a system which would oscillate quickly if left to itself, the maximum excursion on one side of the equilibrium position occurs simultaneously with the maximum force in the direction of the excursion; but, if a quickly varying periodic force acts on a system which would oscillate slowly if left to itself, the maximum excursion on one side of the equilibrium position occurs simultaneously with the maximum force in the direction opposite to that of the excursion. An example of the first is a ball hanging by a short string, which we push slowly to and fro; the ball will never quit contact with the hand, and will agree with its excursions. If, however, the ball is hanging by a long string we can play at battledore and shuttlecock with it, and it always meets our blows. The latter is the analogue of the tides; for, in a free wave in our shallow canal goes slowly, whilst the moon's tide-generating action goes quickly. Hence, when the system is left to settle into steady oscillation it is low-water under and opposite to the moon, whilst the forces are such as to tend to make high-water at those times.

If in this case we consider the moon as revolving round the earth, the water assumes nearly the shape of an oblate spheroid or orange-shaped body with the shortest axis pointed to the moon. The rotation of the earth in the actual case introduces a complexity which it is not easy to unravel by general reasoning. We can see, however, that if water moves from mid-night to a higher latitude it arrives at the higher latitude with more velocity from west to east than is appropriate to its latitude, and it will move accordingly on the earth's surface. Following out this conception, we see that an oscillation of the water to and fro between south and north must be accompanied by an eddy. The solution of the difficult problem involved in working out this idea will be given below.

The conclusion at which we have arrived about the tides of an equatorial canal is probably more nearly true of the tides of a globe partially covered with water than if we were to suppose the ocean at each moment to assume the prolate figure of equilibrium. In fact, observation shows that it is more nearly low-water than high-water when the moon is on the meridian. If we consider how the oscillation of the water would appear to an observer carried round with the earth, we see that he will have low-water twice in the lunar day, somewhere about the time when the moon is on the meridian, either above or below the horizon, and high-water half-way between the low waters.

If the sun be now introduced we have another similar tide of about half-hour duration and this lunar diurnal tide, giving a low-water somewhere about noon and a lower, to the ocean at each moment to assume the prolate figure of equilibrium. In fact, observation shows that it is more nearly low-water than high-water when the moon is on the meridian. If we consider how the oscillation of the water would appear to an observer carried round with the earth, we see that he will have low-water twice in the lunar day, somewhere about the time when the moon is on the meridian, either above or below the horizon, and high-water half-way between the low waters.

In fact, observation shows that it is more nearly low-water than high-water when the moon is on the meridian. If we consider how the oscillation of the water would appear to an observer carried round with the earth, we see that he will have low-water twice in the lunar day, somewhere about the time when the moon is on the meridian, either above or below the horizon, and high-water half-way between the low waters.

If the sun be now introduced we have another similar tide of about half-hour duration and this lunar diurnal tide, giving a low-water somewhere about noon and a lower, to the ocean at each moment to assume the prolate figure of equilibrium. In fact, observation shows that it is more nearly low-water than high-water when the moon is on the meridian. If we consider how the oscillation of the water would appear to an observer carried round with the earth, we see that he will have low-water twice in the lunar day, somewhere about the time when the moon is on the meridian, either above or below the horizon, and high-water half-way between the low waters.

the tides on the English coasts would be profoundly modified if the Straits were completely closed.

It will be noticed that between Yarmouth and Holland the cotidal lines cross one another. Such an intersection of lines is in general impossible; it is indeed only possible if there is a region in which the water neither rises nor falls, because at such a place the cotidal line ceases to have a definite meaning. A set of observations by Captain Hewitt, R.N., made in 1840, appears to prove the existence of a region of this kind at the part of the chart referred to.

![Diagram of Cotidal Lines in British Seas]

(From Berghaus's Atlas.)

**Fig. 3.**—Cotidal Lines in British Seas.

§ 7. **Historical Sketch.**—The writings of various Chinese, Arabic and Icelandic authors show that some attention was paid by them to the tides, but the several theories advanced are fantastic. It is natural that the writings of the classical authors of antiquity should contain but few references to the tides, for the Greeks and Romans lived on the shores of an almost tideless sea. Nevertheless, Strabo quotes from Posidonius a clear account of the tides on the Atlantic coast of Spain, and connects the tides correctly with the motion of the moon. He also gives the law of the tide in the Indian Ocean as observed by Seleucus the Babylonian, and the passage shows that Seleucus had unravelled the law which governs the diurnal inequality of the tide in that sea.

We shall not give any details as to the medieval speculations on the tides, but pass on to once to Newton, who in 1687 laid the foundation for all that has since been added to the theory of the tides when he brought his grand generalization of universal gravitation to bear on the subject. Johann Kepler had indeed at an early date recognized the tendency of the water of the ocean to move towards the centres of the sun and moon, but he was unable to submit his theory to calculation. Galileo expresses regret that so acute a man as Kepler should have produced a theory which appeared to him to reintroduce the occult qualities of the ancient philosophers. His own explanation referred the phenomenon to the rotation and orbital motion of the earth, and he considered that it afforded a principal proof of the Copernican system.

In the 19th corollary of the 66th proposition of bk. i. of the *Principia*, Sir Isaac Newton introduces the conception of a canal circling the earth, and he considers the influence of a satellite on the water in the canal. He remarks that the movement of each molecule of fluid must be accelerated in the conjunction and opposition of the satellite with the centre; that is to say when the molecule, the earth's centre and the satellite are in a straight line, and retarded in the quadratures, that is to say when the line joining the molecule and the earth's centre is at right angles to the line joining the earth's centre and the satellite. Accordingly the fluid must undergo a tidal oscillation. It is, however, in propositions 26 and 27 of bk. iii. that he first determines the tidal force due to the sun and moon. The sea is here supposed to cover the whole earth and to assume at each instant a figure of equilibrium, and the tide-generating bodies are supposed to move in the equator.

Considering only the action of the sun, he assumes that the figure is an ellipsoid of revolution with its major axis directed towards the sun, and he determines the ellipticity of such an ellipsoid. High solar tide then occurs at noon and midnight, and low-tide at sunrise and sunset. The action of the moon produces a similar ellipsoid, but of greater ellipticity. The superposition of these ellipsoids gives the principal variations of the tide. He then proceeds to consider the influence of latitude on the height of tide, and to discuss other peculiarities of the phenomenon. Observation shows, however, that spring tides occur a day and a half after full and change of moon, and Newton falsely attributed this to the fact that the oscillations would last for some time if the attractions of the two bodies were to cease.

The Newtonian hypothesis, although it fails in the form which he gave to it, may still be made to represent the tides if the lunar and solar ellipsoids have their major axes always directed toward a fictitious sun and moon, which are respectively at constant distances from the true bodies; these distances are such that the full and change of the fictitious moon as illuminated by the fictitious sun occur about a day or a day and a half later than the true full and change of moon. In fact, the actual tides may be supposed to be generated directly by the action of the real sun and moon, and the wave may be imagined to take a day and a half to arrive at the port of observation. This period has accordingly been called "Tide of the Sun." The Age of Tide.

In 1738 the Academy of Sciences of Paris offered, as a subject for a prize, the theory of the tides. The authors of four essays received prizes, viz. Daniel Bernoulli, Leonhard Euler, Colin Maclaurin and Antoine Cavalleri. The first three adopted not only the theory of gravitation, but also Newton's method of the superposition of the two ellipsoids. Bernoulli's essay contained an extended development of the conception of the two ellipsoids, and, under the name of the equilibrium theory, it is commonly associated with his name. Laplace gives an account and critique of the essays of Bernoulli and Euler in the *Mécanique céleste*. The essay of Maclaurin presented little that was new in tidal theory, but is notable as containing certain important theorems concerning the attraction of ellipsoids. In 1746 Jean-le-Rond D'Alembert wrote a paper in which he treated the tides of the atmosphere; but this work, like Maclaurin's, is chiefly remarkable for the importance of its applications.
interesting account of the manner in which he was led to attack the problem. We shall give below the investigation of the tides of an ocean covering the whole earth; the theory is substantially Laplace's, although presented in a different form, and embodying an important extension of Laplace's work by S. S. Hough. This theory, although very wide, is far from representing the tides of our ports. Observation shows, in fact, that the irregular distribution of land and water and the various depths of the ocean in various places produce irregularities in the oscillations of the sea of such complexity that the rigorous solution of the problem is altogether beyond the power of analysis. Laplace, however, rested his discussion of tidal observation on this principle—The state of oscillation of a system of bodies in which the primitive conditions of movement have disappeared through friction is coteriodic with the forces acting on the system.

Hence if the sea is acted on by forces which vary periodically according to the law of simple oscillations (a simple time-harmonic), the oscillation of the sea will have exactly the same period, but the moment at which high-water will occur at any place and on any important of the coast will be derived from observation. Now the tidal forces due to the moon and sun may be analysed into a number of constituent periodic parts of accurately determinable periods, and each of these will generate a corresponding oscillation of the sea of unknown amplitude and phase. These amplitudes and phases may be found from observation. But Laplace also used another principle, by which he was enabled to effect a synthesis of the various oscillations, so that he does not discuss a very large number of these constituent oscillations. As, however, it is impossible to give a full account of Laplace's methods without recourse to technical language, it must suffice to state here that this procedure enabled him to discuss the tides at any port by means of a combination of theory with observation. After the time of Laplace down to 1870, the most important workers in this field were Sir John Lubbock (senior), William Whewell, and Sir G. B. Airy. The work of Lubbock and Whewell (see § 33 below) is chiefly remarkable for the co-ordination and analysis of enormous masses of data at various ports, and the construction of trustworthy tide-tables and the attempt to construct cotidal maps. Airy contributed an important lesson to the tide theory. He also studied profoundly the theory of waves in canals, and explained the effects of frictional resistance on the progress of tidal and other waves.

The comparison between tidal theory and tidal observations has been carried out in two ways which we may describe as the synthetic and the analytic methods. Nature is herself synthetic, since at any one time and place we only observe one single tide-wave. All the great investigators from Newton down to Airy have also been synthetic in their treatment, for they have sought to represent the oscillation of the sea by a single mathematical expression, as will appear more fully in chapter V. below. It is true that a presupposed analysis lay behind and afforded the basis of the synthesis. But when at length tide-gauges, giving continuous records, were set up in many places the amount of data to be co-ordinated was enormously increased, and it was found that the simple formulae previously in use had to be overloaded with a multitude of corrections, so that the simplicity became altogether fictitious. This state of matters at length led Lord Kelvin (then Sir William Thomson) to suggest, about 1870, the analytic method, in which the effort is to represent the whole synthesis is frankly abandonded and the complex whole is represented as the sum of a large number of separate parts, each being a perfectly simple wave or harmonic oscillation. All the best modern tidal work is carried on by the analytic method, of which we give an account below in chapter IV.

Lord Kelvin's other contributions to tidal theory are also of profound importance; in particular we may mention that he established the correctness of Laplace's procedure in discussing the dynamical theory of the tides of an ocean covering the whole

earth, which had been impugned by Airy and by William Ferrel. We shall have frequent occasion to refer to his name hereafter in the technical part of this article.

Amongst all the grand works which has been bestowed on the theory of this difficult subject, Newton, notwithstanding his errors, stands out first, and next to him we must rank Laplace. However original any future contribution to the science of the tides may be, it would seem as though it must perforce be based on the work of these two.

§ 8. The Tide-Predicting Instrument.—In the field of the practical application of theory Lord Kelvin also made another contribution of the greatest interest, when in 1872 he suggested that the laborious task of constructing a tide-table might be effected mechanically. Edward Roberts bore a very important part in the first practical realization of such a machine, and a tide-predictor now in regular use at the National Physical Laboratory for the Indian government was constructed by Léger under his direction. We refer the reader to Sir William Thomson's (Lord Kelvin's) paper on "Tidal Instruments" in Inst. C.E., vol. lv., and to the subsequent discussion, for a full account and for details of the share borne by the various persons concerned in the realization of the idea.

Fig. 4 illustrates diagrammatically the nature of the instrument. A cord passes over and under a succession of pulleys, every other pulley forming a fixed support. A wheel C sliding in a slot attached to the pulley frame. All the wheels and the drum are geared together so that, as the drum turns, all the movable pulleys rock up and down. The gearing is of such a nature that if one revolution of the drum were made each side of the dent in the frame represents one of the simple constituent oscillations or tides into which the aggregate tide-wave is analysed. The nature of the gearing is determined by theoretical considerations derived from the motions of the sun and moon and earth, but the throw of each crank, and the angle at which it has to be set at the start are derived from observation at the particular port for which the tide-curve is required. When the tide-predictor has been set appropriately, it will turn off a complete tide-curve for a whole year; the curve is subsequently measured and the heights and times of high and low water are tabulated and published for a year or two or three in advance.

The Indian instrument possesses about 20 units, so that the tide-curve is regarded as being the sum of 20 different simple tides; and tide-tables are published for 40 Indian and Oriental ports. A tide-predictor has been made for the French government under the supervision of Lord Kelvin and is in use at Paris; another has been made by the United States Coast Survey at Washington; in India the work was undertaken at the request of the British government. These instruments, although differing considerably in detail from the Indian predictor, are essentially the same in principle.

§ 9. Tidal Friction.—All solid bodies yield more or less to stress; if they are perfectly elastic they regain their shapes after the stresses are removed, if imperfectly elastic or viscous they yield to the stresses. We may thus feel certain that the earth yields to tide-generating force, either with perfect or imperfect elasticity. Chapter VIII. will contain some discussion of this
subject, and it must suffice to say here that the measurement of the minute elastic tides of the solid earth has at length been achieved. The results recently obtained by Dr O. Heck at Potsdam constitute a conspicuous advance on all the previous attempts.

The tides of an imperfectly elastic or viscous globe are obviously subject to frictional resistance, and the like is true of the tides of an actual ocean. In either case it is clear that the system must be losing energy, and this leads to results of so much general interest that we propose to give a short sketch of the subject, referring to chapter VIII. A more rigorous investigation. It is unfortunately impossible to give even an outline of the principles involved without the use of some technical terms.

In fig. 5 the paper is supposed to be the plane of the orbit of a satellite M revolving in the direction of the arrow about the planet C, which rotates in the direction of the arrow about an axis perpendicular to the paper. The rotation of the planet is supposed to be more rapid than that of the satellite, so that the day is shorter than the month. Let us suppose that the planet is either entirely fluid, or has an ocean of such depth that it is high-water under or nearly under the satellite. When there is no friction, with the satellite at r, the planet is elongated into the ellipsoidal shape shown, and an ocean of the same is drawn with much exaggeration and the satellite is shown as very close to the planet in order to illustrate the principle more clearly. Now, when there is a deflection of the direction of motion, the tide is retarded, and high-tide occurs after the satellite has passed the meridian. In this case, as in the previous one, the same figure to represent the tidal deformation, the satellite must be at M, instead of at N, and if we number the four quadrants as shown, the satellite must be in quadrant 1. If the force acting on the satellite far from C than it would be dragged back by the central force towards C. The satellite would describe a spiral, the coils of which would be very nearly circular and very nearly coincident. Now if we resolve the central component force along CM tangentially and perpendicular to the spiral, the component tends to retard the velocity of the satellite, whereas the disturbing force, already considered, tends to accelerate it. With the gravitational force as the disturbing influence, the central component must prevail over the acceleration. The action of tidal friction may appear somewhat paradoxical, but it is the exact converse of the acceleration of the linear velocity and the diminution of the angular momentum occurring when a body moving through a resisting medium. The latter result is generally more familiar than the action of tidal friction, and it may help the reader to realize the result in the present case. Tidal friction then diminishes planetary frequency, increased frequency of oscillation being the consequence of increased friction. The angular velocity decreases, and the orbital angular velocity diminishes the orbital angular velocity. The comparative rate of diminution of the two angular velocities is generally very different. If the satellite be close to the planet, the rate of increase of the satellite's periodic time or month is large compared with the rate of increase of the period of planetary rotation or day; but if the satellite is far from the planet the month a little longer than the day, since the satellite

recedes, the month soon increases so that it contains many days. The effect of this is to increase the rate of planetary rotation and to diminish the rate of the satellite's rotation; but if too small compared with the rate of increase of the period of planetary rotation or day; if the satellite is far off the converse is true. Hence, if the satellite starts very near the planet, with the moon a little longer than the days, since the satellite

8 This way of presenting the action of tidal friction is due to Sir George G. Stokes.

9 See that work (ed. 1835), § 83; P. H. Cowell, M. N. R. A. Soc. (1905), b.xvi. 861.

whole 1889, and with important changes (1901, 1911); (Boston, 1988); translations: German, by A. Pockels (Leipzig, 1902, 1911); Italian, by G. Magrini (Turin, 1905), with appendices by translator; Magyar, by Rádó von Kövesligethy (Budapest, 1904), with appendices by translator.
TIDE

B in 1904. This work contains an enormous mass of useful work, and gives not only complete technical developments both on the theoretical and practical sides but also has chapters of general interest. The present writer feels it his duty, however, to dissent from Mr. Harris's courageous attempt to construct the cotidal lines of the various oceans.

The work contains the most complete account of the history of tidal theories of which we know. Laplace's admirable history of the subject down to his time can be seen in the Bibliography, summarized in § 7. Dr. Giovanni Magriani has an appendix to his translation of Darwin's book, entitled La Conoscenza della maree nell'antichità, founded on the researches of the Observatorio Almagia. Dr. Almagia himself gives the results of his researches more fully in a memoir, presented to the Accademia dei Lincei of Rome (5th series, vol. v. fascic. x., 1905, 137 pp).

Another paragraph on tides, treating especially the mathematical developments, is Maurice Levy's La Théorie des marées (Paris, 1898). Colonel Baird's Manual of Tidal Observation (1886) contains instructions for the installation of tide-gauges, and auxiliary tables for harmonic analysis.

Dr. Almagia's article on Tides and Waves in the Ency. Metrop., although superseded in many respects, still remains important. Harris's Manual contains a great collection of results of tidal observations made at ports all over the world.

The article "Die Bewegung der Hydrospheäre" in the Encyklopädie der mathematischen Wissenschaften (vi. 1, 1908) gives a technical account of the subject, with copious references. The same article is given in English in vol. iv. (1911) of C. H. Darwin's collected Scientific Papers; and vols. i. and ii. contain reprints of the several papers by the same author referred to in the present article.

Since the date of the 9th edition of the Ency. Brü. some technical discussion of the tides has appeared in textbooks, such as H. Lamb's Hydrodynamics. 1 That work also reproduces in more modern form Airy's investigation of the effects of friction on the tides of rivers.

We are unable to abide the present article, but we shall present the extension by Hough of Laplace's theory of the tides of an ocean-covered planet, which is still only to be found in the original memoirs.

II.-TIDE-GENERATING FORCES

We have already given a general explanation of the nature of tide-generating forces; we now proceed to a rigorous investigation. If a planet is attended by a single satellite, the motion of any body relatively to the planet's surface is found by the process described as reducing the planet's centre to rest. The planet's centre will be at rest if every body in the system has impressed on it a velocity equal and opposite to that of the planet's centre; and this is accomplished by impressing on every body an acceleration equal and opposite to that of the planet's centre.

Let $M$, $m$ be the masses of the planet and the satellite; $r$ the radius vector of the satellite, measured from the planet's centre; $\rho$ the radius vector, measured from the same point, of the particle whose motion we wish to determine; and $z$ the angle between $r$ and the radius vector of the particle whose motion we wish to determine. We may set $\mathbf{a}_r = \mathbf{a}_s$, the acceleration relative to the planet's centre of the satellite is $(M+m)\mathbf{a}_r$ towards the planet along the radius vector $r$. Now the acceleration of interest of the planet and satellite remains fixed in space, and the centre of the planet describes an orbit round that centre of inertia similar to that described by the satellite round the planet but with linear dimensions reduced in the proportion of $m$ to $M+m$. Hence the acceleration of the planet's centre is $m\mathbf{a}_r$ towards the centre of inertia of the two bodies. Thus, in order to reduce the planet's centre to rest, we apply to every particle of the system an acceleration $m\mathbf{a}_r$ parallel to $r$, and directed from satellite to planet.

Now take a set of rectangular axes fixed in the planet, and let $Mx, My, Mz$ be the co-ordinates of the satellite referred thereto; and let $x, y, z$ be the co-ordinates of the particle whose radius vector is $\rho$. Also, the component accelerations for reducing the centre of inertia to rest are $-mMx/\rho^2$, $-mMy/\rho^2$, $-mMz/\rho^2$, and since these are the differential coefficients with respect to $\rho, \phi, \psi$ of the function

$$-m \frac{M}{\rho^2} \left( Mx + MMy + MMz \right),$$

and since $z = Mx + MMy + MMz$, it follows that the potential of the forces by which the planet's centre is reduced to rest is

$$-m \frac{M}{\rho^2} z.$$

1 The theory as presented in the Mécanique céleste is unnecessarily difficult, and was much criticized by Airy. Before the publication of the 9th edition of this dictionary, air was considered as an entirely new subject, and the student to read a number of controversial papers published all over the world in order to get at the matter.

Now let us consider the other forces acting on the particle. The planet is spheroidal, and therefore does not attract equally in all directions; but in this investigation we may make abstraction of the ellipticity of the planet and of the ellipticity of the ocean due to the planetary rotation. This, which we set aside, is considered in the theories of gravity and of the figures of planets. Outside its body, then, the planet contributes forces of which the potential is $M/p$. Next the direct attraction of the satellite contributes forces of which the potential is the mass of the satellite divided by the distance between the point $P$ and the satellite; this is

$$m \frac{1}{\sqrt{r^2 + p^2 - 2rp \cos z}}.$$

To determine the forces from this potential we regard $\rho$ and $z$ as the variables for differentiation, and we may add to this potential any constant we please. As we are seeking to find the forces which urge $P$ relatively to $M$, we add such a constant as will make the whole potential at the planet's centre zero, and thus we take as the potential of the forces due to the attraction of the satellite

$$m \frac{1}{\sqrt{r^2 + p^2 - 2rp \cos z}} - \frac{M}{p}. $$

It is obvious that in the case to be considered $r$ is very large compared with $\rho$, and we may therefore expand this in powers of $\rho/r$. This expansion gives us

$$m \left( \frac{p^2}{r^4} + \frac{p^4}{r^6} + \frac{p^6}{r^8} + \cdots \right),$$

where $p = \cos z$, $p = \frac{1}{2} \cos^2 z - \frac{1}{4}$, $p = \frac{1}{3} \cos^3 z - \frac{1}{6} \cos z$, &c.

The reader familiar with spherical harmonic analysis of course recognizes the spherical harmonic functions; but the result for a few terms, which is all that is necessary, is easily obtainable by simple algebra.

Now, collecting together the various contributions to the potential, and noticing that $\frac{m^2}{\rho^2} p^2 = \frac{m^2}{\rho^2} \cos z$, and is therefore equal and opposite to the potential by which the planet's centre was reduced to rest, we have as the potential of the forces acting on a particle whose co-ordinates are $\rho$, $\phi$, $\psi$;

$$\frac{M}{\rho} + m \frac{p^2}{r^4} \left( \frac{1}{2} \cos^2 z - \frac{1}{4} \right),$$

and thus

$$V = \frac{m^2}{\rho^2} \left( \cos z - \frac{1}{2} \right).$$

(2)

as the tide-generating potential. 1

1 The first term of (1) is the potential of gravity, and the terms of the series, of which two only are written, constitute the tide-generating potential. In all practical applications this series converges so rapidly that the first term is amply sufficient, and thus we shall generally denote

$$V = \frac{m^2}{\rho^2} \left( \cos z - \frac{1}{2} \right).$$

(2)

As the surface of the earth $\rho$ is equal to $a$ the earth's radius.

§ 12. Form of Equilibrium.—Consider the shape assumed by an ocean of density $\epsilon$, on a planet of mass $M$, density $\delta$ and radius $a$, when acted upon by the potential $\phi$. This potential has a harmonic character, and its coefficients are found as in the previous section. Let $S_i$ denote a surface spherical harmonic of order $i$, such a potential is given at the point whose radius vector is $\rho$ by

$$V = \frac{m^2}{\rho^2} \left( \cos z - \frac{1}{2} \right),$$

(3)

In the case considered in § 11, $i = 2$ and $S_i$ becomes the second zonal harmonic $\cos z - \frac{1}{2}$. The theory of harmonic analysis tells us that the form of the ocean, when in equilibrium, must be given by the equation

$$\rho = a - e \cos S_i,$$

(4)

Our problem is to evaluate $e$. We know that the external potential of a layer of matter, of depth $eS_i$ and density $\epsilon$, has the value

$$\frac{4\pi e}{21 + 1 \left( \frac{1}{2} \right)^2} S_i,$$

(5)

Hence the whole potential externally to the planet and up to its surface is

$$\frac{M}{\rho} + \frac{m^2}{\rho^2} \left( \cos z - \frac{1}{2} \right),$$

(6)

The first and most important term is the potential of the planet, the second that of the disturbing force, and the third that of the departure from sphericity.

The ocean must stand in a level surface, the expression (5) equated to a constant must be another form of (4). Hence, if we put $\rho = a - e \cos S_i$ in the first term of (5) and $e = a$ in the second and third terms, (5) must be constant; this can only be the case if the
coefficient of $S$ vanishes. Hence on effecting these substitutions and equating that coefficient to zero, we find
\[ M = 2\pi a^2 = gS, \]
where $g$ is gravity, and therefore
\[ e_i = -\frac{2\pi a^2}{2gr^2} \]
\[ = -\frac{3\pi}{(2\pi + 1)^2}. \quad (6) \]

In the particular case considered in §11 we therefore have
\[ \rho = a \left[ 1 + \frac{3\pi a^2}{2gr^2} \left( \cos z - 1 \right) \right] \]
\[ = 1 + 3\pi \left( \cos z - 1 \right). \quad (7) \]

The axis of $C$ is taken as the polar axis, and $AB$ is the equatorial plane, so that the functions of $\xi$, $\eta$, $\zeta$ are functions of the latitude and longitude of the point $P$, at which we wish to find the potential. The functions of $M_1$, $M_2$, $M_3$ depend on the moon's position, and we shall have occasion to develop them in two different ways—first, in terms of her hour-angle and declination, and secondly (§25) in terms of her longitude and the elements of the orbit.

Now let $A$ be on the equator in the meridian of $P$, and $B$ go east of $A$ on the equator. Then, if $M$ be the moon, the inclination of the plane $MC$ to the plane $CA$ is the moon's easterly hour-angle.

\[ \hat{h}_a = \text{Greenwich westward hour-angle}; \]
\[ \hat{h}_d = \text{the west longitude of the place of observation}; \]
\[ \lambda = \text{the latitude of the place}; \]
\[ \delta = \text{moon's declination}; \]
\[ \text{then we have} \]
\[ M_1 = \cos \delta \cos (\hat{h}_2 - \hat{h}_1), \]
\[ M_2 = \cos \delta \sin (\hat{h}_2 - \hat{h}_1), \]
\[ M_3 = \sin \delta, \]
\[ \hat{h}_2 = \text{the longitudes}, \quad \eta = \text{a constant}. \quad (9) \]

Also the radius vector of the place of observation on the earth's surface is $a$. Whence we find
\[ V = \frac{3\pi a^2}{2r^2} \left( \cos \theta - 1 \right) \]
\[ \times \left[ \cos \hat{h}_2 \cos 2(\hat{h}_2 - \hat{h}_1) + \sin 2\theta \sin \hat{h}_2 \cos \theta \right] \]
\[ + \left[ \cos \theta \sin \hat{h}_1 + \sin \theta \sin \hat{h}_2 \right]. \quad (10) \]

The tide-generating forces are found by the rates of variation of $V$ for latitude and longitude, and also for radius $a$, if we care to find the radial disturbing force.

The westward component of the tide-generating force at the earth's surface, where $\rho = a$, is $dV/a \cos \theta$, and the northward component in the equatorial plane is the cross product of the $z$-axis and $\rho$ with the attraction due to $a$. These are the forces which produce a constant heaping up of the water at the equator; or, in other words, the moon's attraction has the effect of causing a small permanent ellipticity of the earth's mean figure. This augmentation of ellipticity is of course very small, but it is necessary to mention it.

If we consider the motion of a pendulum-bob under the influence of these forces during any one day, we see that in consequence of the semi-diurnal changes of level it twice describes an ellipse with its greatest axis east and west and its minor axis north and south; when developed shows that the ratio of axes is equal to the sine of the latitude, and the linear dimensions proportional to $\cos^3 \theta$.

It describes once a day an ellipse whose north and south axis is proportional to $\sin 2\phi$ and whose east and west axis is proportional to $\sin 2\phi \sin \lambda$. Obviously the latter is circular in latitude $30^\circ$.

When the moon is on the equator, the maximum deflexion occurs when the moon's local hour-angle is $45^\circ$, and is then equal to
\[ \frac{3\pi a^2}{2M^2} \left( \cos \lambda ight). \]

This angle is equal to $0.017^\circ \cos \lambda$. Attempts actually to measure the deflexion of the vertical have at length proved successful (see Seismometer).

III.—Dynamical Theory of the Tides.

§14. Recent Advances in the Dynamical Theory of the Tides.—The problem of the tidal oscillation of the sea is essentially dynamical. In two papers in the second volume of Liouville's Journal (1860) H. Poincaré has considered the mathematical principles involved in the problem, where the ocean is interrupted by land as in actuality. He has not sought to obtain numerical results applicable to any given configuration of land and sea, but he has aimed rather at pointing out methods by which it may some day be possible to obtain such solutions.

Even when the ocean is taken as covering the whole earth, the problem presents formidable difficulties, and this is the only case in which it has been solved hitherto.

Laplace gives the solution in bks. i. and iv. of the Mécanique céleste; but his work is unnecessarily complicated. In the 9th edition of the Encyc. Brit. we gave Laplace's theory without these complications, but the theory is now accessible in H. Lamb's Hydrodynamics and other works of the kind. It is therefore not reproduced here.

In 1867 and 1889 S. S. Hough undertook an important revision of Laplace's theory and succeeded not only in introducing the effects of the mutual gravitation of the ocean, but...
also in determining the nature and periods of the free oscillations of the sea. A dynamical problem of this character cannot be regarded as fully solved unless we are able not only to discuss the "forced" oscillations of the system but also the "free." Hence we regard Mr. Hough's work as the most important contribution to the dynamical theory of the tides since the time of Laplace. We shall accordingly present the theory briefly in the form due to Mr. Hough.

The analysis is more complex than that of Laplace, where the mutual attraction of the ocean was neglected, but this was perhaps inevitable. Our first task is to form the equations of motion and continuity, which will be equally applicable to all forms of the theory.

§ 15. Equations of Motion.—Let \( r, \theta, \phi \) be the radius vector, colatitude and east longitude of a point with reference to an origin, a polar axis and a zero-meridian rotating with a uniform angular velocity \( \eta \) from west to east. Then if \( R, H, \Xi \) be the radial, colatitudinal and longitudinal accelerations of the point, we have

\[
R = \frac{\partial^2 \phi}{\partial t^2} - \frac{\partial (\partial \phi / \partial t)}{\partial t} - r \sin \theta \left( \frac{\partial^2 \phi}{\partial t^2} + \eta \right),
\]

\[
\Xi = \frac{\partial^2 \phi}{\partial t^2} - r \sin \theta \cos \phi \frac{\partial^2 \phi}{\partial t^2} + \frac{\partial^2 \phi}{\partial t \partial \phi} + \frac{\partial \phi}{\partial t} \frac{\partial \phi}{\partial t}.
\]

If the point were at rest with reference to the rotating meridian we should have

\[
R = -r^2 \sin \theta, \quad \Xi = -r^2 \sin \theta \cos \phi, \quad H = 0.
\]

When these considerations are applied to the motion of an ocean relative to a rotating planet, it is clear that these accelerations, which still remain when the ocean is at rest, are annulled by the permanent oblateness of the ocean. As then they take no part in the oscillations of the ocean, and as we are not considering the figure of the planet, we may omit these terms from \( R \) and \( \Xi \) for this being so we must replace \( \frac{\partial^2 \phi}{\partial t^2} \) as it occurs in \( R \) and \( \Xi \) by \( \frac{\partial \phi}{\partial t} \frac{\partial \phi}{\partial t} \).

Now suppose that the point whose accelerations are under consideration never moves far from its zero position, and that its displacements \( \xi, \eta \) in colatitude and longitude are very large compared with \( \rho \) its radial displacement. Suppose, further, that the velocities of the point are so small that their squares and products are negligible compared with \( \rho^2 \); then we have

\[
r \sin \theta \frac{\partial \phi}{\partial \eta} = \text{a very small quantity};
\]

\[
r \sin \phi \frac{\partial \phi}{\partial \xi} = \left( \frac{\partial \phi}{\partial \xi} \right) / \sin \theta .
\]

Since the radial velocity always remains very small it is not necessary to concern ourselves further with the value of \( R \), and we only require the two other components which have the approximate forms,

\[
\Xi = \frac{\partial^2 \phi}{\partial t^2} - 2n \sin \theta \cos \phi \frac{\partial^2 \phi}{\partial t^2} + \frac{\partial \phi}{\partial t} \frac{\partial \phi}{\partial t},
\]

\[
H = \sin \phi \frac{\partial^2 \phi}{\partial t^2} + 2n \sin \theta \cos \phi \frac{\partial^2 \phi}{\partial t^2} .
\]

We have now to consider the forces by which an element of the ocean is urged in the direction of colatitude and longitude. These forces are those due to the external disturbing forces, to the pressure of the water, surrounding an element of the ocean, and to the attraction of the ocean itself. The latter denotes the equilibrium height of the tide, it is a function of colatitude and longitude, and may be expanded in a series of spherical surface harmonics \( \epsilon_i \). Thus we may write the equation to the equilibrium tide in the form

\[
r = a + \epsilon = a + \Xi + \epsilon.
\]

Now it appears from (10) and (11) that the value of the potential, at the surface of the sphere where \( r = a \), under which this is a figure of equilibrium, is

\[
V = \Xi + \epsilon.
\]

We may use this as supplying the external disturbing force due to the known attractions of the moon and sun, so that \( \epsilon_i \) may be regarded as known.

But in our dynamical problem the ocean is not a figure of equilibrium, and we may denote the elevation of the surface at any moment of time by \( b \). Then the equation to the surface may be written in the form

\[
r = a + b + \epsilon = a + b + \Xi + \epsilon,
\]

where \( \epsilon \) denotes a spherical harmonic just as \( \epsilon_i \) did before.

3 Phil. Trans., 189 A, pp. 201—258 and 191 A, pp. 139—185.
Solving (20), we have
\[
(2b_a(x)) \left( f^2 - \cos^2 \theta \right) \int \frac{d}{d\theta} \left[ (1 + \frac{b_a}{b_b}) \sin \theta \right] \left( f^2 - \cos^2 \theta \right) \left( \frac{d}{d\theta} \left[ \frac{b_a}{b_b} \sin \theta \right] \right) \left( f^2 - \cos^2 \theta \right).
\]
This is almost the same as Laplace's equation for tidal oscillations in an ocean whose depth is only a function of latitude. If indeed we treat \(b_a\) as unity (thereby neglecting the mutual attraction of the water) and replace \(b_a\) and \(b_b\) by \(u\) and \(e\), we obtain Laplace's equation.

When \(b_a\) is found from this equation, its value substituted in (21) will give \(x\) and \(y\).

§ 17. Zonal Oscillations.—We might treat the general harmonic oscillations first, and proceed to the zonal oscillations by putting \(x = 0\). These waves are, however, comparatively simple, and it is well to begin with them. The zonal tides are those which Laplace describes as of the first species, and are now more usually called the tides of long period. As we shall only consider the case of an ocean of uniform depth, \(y\) the depth of the sea is constant. Then since in this case \(x = 0\), our equation (22), to be satisfied by \(u\) or \(k - \epsilon\), becomes
\[
\frac{d}{d\theta} \left[ \sin \theta \left\{ \frac{d}{d\theta} \left[ \frac{b_a}{b_b} \sin \theta \right] \right\} \right] = \frac{4ma}{\gamma} \sin \theta \frac{dK}{d\theta} = 0.
\]
This may be written
\[
\frac{d}{d\theta} \left[ \sin \theta \frac{d}{d\theta} \left[ \frac{b_a}{b_b} \sin \theta \right] \right] = \frac{4ma}{\gamma} \sin \theta \frac{dK}{d\theta} = 0,
\]
where \(A\) is a constant.

Let us assume
\[
h = C_P i, \quad \epsilon = E_P i,
\]
where \(P_i\) denotes the 7th zonal harmonic of \(\cos \theta\). The coefficients \(C_P\) are unknown, but the \(E_P\) are known because the system oscillates under the action of known forces.

If the term involving the integral in this equation were expressed in terms of differentials of harmonics, we should be able to equate to zero the coefficient of each \(dP_i/d\theta\) in the equation, and thus find the conditions for determining the \(C_P\).

The task then is to express \(f^2 - \cos^2 \theta\) in terms of \(P_i\) and \(d\theta\) in differentials of zonal harmonics.

It is well known that \(P_i\) satisfies the differential equation
\[
\frac{d}{d\theta} \left( \sin \theta \frac{d}{d\theta} \right) P_i = \frac{2 \epsilon_i}{\sin \theta} P_i, \quad \text{and} \quad \frac{d}{d\theta} \left( \sin \theta \frac{d}{d\theta} \right) dP_i = \frac{2 \epsilon_i}{\sin \theta} dP_i.
\]

If we differentiate (25) and use (24) we have
\[
\frac{d}{d\theta} \left[ \frac{d}{d\theta} \right] P_i = P_i \frac{d}{d\theta}\left( \frac{d}{d\theta} \right), \quad \text{and} \quad \frac{d}{d\theta} \left[ \frac{d}{d\theta} \right] dP_i = \frac{d}{d\theta}\left( \frac{d}{d\theta} \right) P_i.
\]

Multiplying (25) by \(\sin \theta\) and using (26) twice over,
\[
\sin \theta \frac{d}{d\theta} P_i = \frac{2 \epsilon_i}{\sin \theta} P_i, \quad \text{and} \quad \sin \theta \frac{d}{d\theta} dP_i = \frac{2 \epsilon_i}{\sin \theta} dP_i.
\]

Then we have
\[
\sin \theta \frac{d}{d\theta} \left[ \frac{d}{d\theta} \right] P_i = P_i \frac{d}{d\theta}\left( \frac{d}{d\theta} \right), \quad \text{and} \quad \sin \theta \frac{d}{d\theta} \left[ \frac{d}{d\theta} \right] dP_i = \frac{d}{d\theta}\left( \frac{d}{d\theta} \right) P_i.
\]

This expression, when multiplied by \(4ma/\gamma\) and with \(C_P\) and \(\epsilon_P\) and summed, is our second equation of motion.

The first term is
\[
\sum_{b_i}(C_i - E_i) \frac{dP_i}{d\theta}.
\]
In order that the equation may be satisfied, the coefficient of each \(dP_i/d\theta\) must vanish identically. Accordingly we multiply the whole by \(\gamma/4ma\) and equate to zero the coefficient in question, and obtain
\[
\sum_{b_i}(C_i - E_i) \frac{dP_i}{d\theta} = 0.
\]
equilibrium tide $\epsilon$, which is as we know equal to $E_2 P_4 \cos (3\nu t + \alpha)$.

Whence we find
\[
b = \frac{\delta h_{S3}}{P_3} \left[ 3 \cos \theta P_3 + 1.5 \cos \theta (\cos \theta + \sin \theta) \right].
\]

The number $b$ is a fraction such that its reciprocal is twice the number of sidereal days in the period of the tide. The greatest value of $f$ is that pertaining to the lunar fortnightly tide (M in notation of harmonic analysis), and in this case $f$ is in round numbers $1/28$, or more exactly $f = 0.0113$. The ratio of the density $\sigma$ of sea-water to $\delta$ the mean density of the earth is $18003$; which gives us
\[
b = 1.3 \times 10^{-3}.
\]

The quantity $m$ is the ratio of equatorial centrifugal force to gravity, and is equal to $1/289$. Finally, $\gamma$ is the depth of the ocean expressed as a fraction of the earth's radius.

With these numerical values Mr Hough has applied the solution to determine the lunar fortnightly tide for oceans of various depths. Of his results we give two:

First, when $\gamma = 0.0562$ ft. = 1210 fathoms, which makes $\gamma / \delta m = 1/40$, he finds
\[
b = 1.04 \times 10^{-2} P_3.
\]

Thus we see how widely the dynamical solution differs from the equilibrium value.

Secondly, when $\gamma = 0.0808$ ft. = 9680 fathoms, and $\gamma / \delta m = 1/5$, he finds
\[
b = 1.04 \times 10^{-2} P_3.
\]

From this we see that the equilibrium solution presents some sort of resemblance to the dynamical solution; and it is clear that the equilibrium solution would be fairly accurate for oceans which are still quite shallow when expressed as fractions of the earth's radius, although far deeper than the actual sea.

The tides of long period were not investigated by Laplace in this manner, for he was of opinion that a very small amount of friction would suffice to make the ocean assume its form of equilibrium. In the arguments which he adduced in support of this view the friction contemplated was such that the integral effect was proportional to the velocity of the water relatively to the bottom. It is probable that proportionality to the square of the velocity would have been nearer the truth, but the distinction is unimportant.

The most rapid of the oscillations of this class is the lunar fortnightly tide, and the water of the ocean moves northward for a week and then southward for a week. In oscillating systems, where the resistances are proportion to the velocities, it is usual to specify the resistance by a "modulus of decay," namely the time in which a velocity is reduced by friction to $e^{-4}$ or $1/2.78$ of its initial value. Now in order that the result contemplated by Laplace may be true, the friction must be such that the modulus of decay is short compared with the semi-period of oscillation. It seems certain that the friction of the ocean bed would not reduce a slow ocean current to one-third of its primitive value in a day or two. Hence we cannot accept Laplace's discussion as satisfactory, and the investigation which has just been given becomes necessary. (See § 34).

§ 18. Tesserla Oscillations.—The oscillations which we now have to consider are those in which the form of surface is expressible by the tesserall harmonics. The results will be applicable to the diurnal and semi-diurnal tides—

Laplace's second and third species.

If we write $a \cdot \sigma$ the equation (22) becomes
\[
d \left[ \sin \sigma \frac{D}{D} \sin \sigma \cos \theta \right] + \left[ \sigma \cos \theta \frac{D}{D} \sin \sigma \cos \theta \right] + \frac{1}{2} \left( \frac{\delta h_{S3}}{P_3} \right) \sin \theta \Sigma h_{S3} = 0.
\]

If we write $D$ for the operation $\sin \sigma \frac{D}{D} \sin \sigma \cos \theta$ the middle term may be arranged in the form
\[
\sigma \cos \theta D + \sigma \cos \theta \sin \theta \Sigma h_{S3} = 0.
\]

Therefore on multiplying by $\sin \theta$ the equation becomes
\[
\frac{D}{D} \sigma \cos \theta \left( D + \sigma \cos \theta \right) \left( \Sigma h_{S3} \right) = 0.
\]

We now introduce two auxiliary functions, such that
\[
\Sigma h_{S3} = \mu(1 - P_3) C \cos \theta + (\mu - P_3) \sin \theta \cos \theta \Phi.
\]

It is easy to prove that
\[
(D + \sigma \cos \theta) (D + \sigma \cos \theta) = D^2 - \sigma^2 \cos \theta \sin \theta + (\sigma^2 - \sigma^2 \cos \theta) \sin \theta.
\]

Similarly
\[
(D - \sigma \cos \theta) (D - \sigma \cos \theta) = D^2 - \sigma^2 \cos \theta \sin \theta + (\sigma^2 - \sigma^2 \cos \theta) \sin \theta.
\]

Also
\[
(D + \sigma \cos \theta) (D + \sigma \cos \theta) = D^2 - \sigma^2 \cos \theta \sin \theta + (\sigma^2 - \sigma^2 \cos \theta) \Phi.
\]

Now perform $D + \sigma \cos \theta$ on (31), and use the first of (32) and (33), and we have
\[
\frac{d}{d} \left( \sigma \cos \theta \right) \left( \Sigma h_{S3} \right) = \frac{1}{2} \left( \frac{\delta h_{S3}}{P_3} \right) \sin \theta \cos \theta \Phi.
\]

The functions $\Phi$ and $\Phi$ are as yet indeterminate, and we may impose another condition on them. Let that condition be
\[
(D^2 - \sigma^2 \sin \theta) \Phi = 2 \sigma^2 \sin \theta \cos \theta \Phi.
\]

Then (34) may be written
\[
\frac{d}{d} \left( \sigma \cos \theta \right) \left( \Sigma h_{S3} \right) = \Phi + (D + \sigma \cos \theta) \Phi.
\]

Substituting from this (30), and using the second of (32), the function $\Phi$ disappears and the equation reduces to
\[
(D^2 - \sigma^2 \sin \theta) \Phi = \frac{1}{2} \left( \frac{\delta h_{S3}}{P_3} \right) \sin \theta \cos \theta \Phi.
\]

Since by (35) $\sigma \cos \theta \Phi = \frac{1}{2} \left( \frac{\delta h_{S3}}{P_3} \right) \sin \theta \cos \theta \Phi$, (31) may be written
\[
\Sigma h_{S3} = \frac{1}{2} \left( \frac{\delta h_{S3}}{P_3} \right) \sin \theta \cos \theta \Phi.
\]

The equations (35), (36), and (37) define $\Phi$ and $\Phi$, and furnish the equation which must be satisfied.

If we denote $\cos \theta$ by $\mu$ the zonal harmonics are defined by
\[
P_1 = \frac{1}{2} \left( \frac{d}{d} \right) \left( D^2 - \sigma^2 \sin \theta \right) \Phi.
\]

The following are three well-known properties of zonal harmonics:
\[
d \left[ \frac{1}{2} \left( \frac{d}{d} \right) \left( D^2 - \sigma^2 \sin \theta \right) \Phi \right] = (D - \sigma \cos \theta) \left( \Sigma h_{S3} \right).
\]

If $P_{i1}$ are the two tesseral harmonics of order $i$ and rank $s$, it is also known that
\[
P_{i1} \sin \theta = \frac{1}{2} \left( \frac{d}{d} \right) \left( D^2 - \sigma^2 \sin \theta \right) \Phi.
\]

Let us now assume
\[
h_i = C_i P_{i1}, \quad e_i = P_{i1}, \quad \Psi = 2 \sigma \Phi P_{i1}, \quad \Phi = 2 P_{i1} \Phi.
\]

These must now be substituted in our three equations (35), (36), and (37), and the result must be expressed by series of the $P_{i1}$ functions.

It is clear then that we have to transform into $P_{i1}$ functions the following functions of $P_{i1}$, namely
\[
\frac{1}{2} \left( \frac{d}{d} \right) \left( D^2 - \sigma^2 \sin \theta \right) \Phi = \frac{1}{2} \left( \frac{d}{d} \right) \left( D^2 - \sigma^2 \sin \theta \right) \Phi.
\]

If we differentiate (36) $s$ times, and express the result by means of the operator $D$, we find
\[
(D - \sigma \cos \theta) P_{i1} + (i + s) P_{i1} = 0.
\]

Again, differentiating (39) $s$ times and using (40), we find
\[
(i - s + 1) P_{i1} + (i + s + 1) \sigma \cos \theta P_{i1} + (i + s + 1) P_{i1} = 0.
\]

Lastly, differentiating (41) once and using (38), (40) and (43)
\[
P_{i1} = \frac{2}{21} \left( D^2 - \sigma^2 \sin \theta \right) \Phi.
\]

By means of (42), (43) and (44) we have
\[
\frac{1}{2} \left( \frac{d}{d} \right) \left( D^2 - \sigma^2 \sin \theta \right) \Phi = \frac{1}{2} \left( \frac{d}{d} \right) \left( D^2 - \sigma^2 \sin \theta \right) \Phi.
\]

Therefore the equations (35), (36), (37) give
\[
\Sigma \left[ e_i \right] \left( i - s + 1 \right) P_{i1} + 2 \sigma \Phi P_{i1} \left( i - s + 1 \right) P_{i1} = 0.
\]

\[
\Sigma \left[ e_i \right] \left( i - s + 1 \right) P_{i1} + 2 \sigma \Phi P_{i1} \left( i - s + 1 \right) P_{i1} = 0.
\]

\[
\Sigma \left[ e_i \right] \left( i - s + 1 \right) P_{i1} + 2 \sigma \Phi P_{i1} \left( i - s + 1 \right) P_{i1} = 0.
\]
Since those equations must be true identically, the coefficients of $P'_i$ in each of them must vanish. Therefore

$$a_i[i-(i+1)-3]+b_i[i-(i+1)+3]+c_i[i-(i+1)-1]=0,$$

$$-b_i[i-(i+1)+1]+i_0 C_i=0. \tag{45}$$

$$b_i(C_i-E_i)+a_i[i-(i+1)-(i-2)]+c_i[i-(i+1)+(i-2)]\beta_i^2=0.$$

If we eliminate the $a_i$'s and $b_i$'s from the third equation (45), by means of the first two, we find

$$L_i^2=\frac{3-2b_i}{35} \text{ and } \zeta_0=0.$$

The equation (46) for the successive $C_i$'s is available for all values of $i$ provided that $C_4$, $E_1$, $E_2$, $E_3$, $E_4$ are regarded as being zero.

As in the case of the semi-diurnal oscillations, the equations with odd suffixes separate themselves from those with even suffixes, so that the two series may be treated independently of one another. Indeed, as we shall see immediately, the series with odd suffixes are all equal and independent, but $i$ and $s$ are rigorously integers, whereas $\eta$ depends on the "speed" of the tide; accordingly in the case referred to we must regard terms involving $i-(i-2)$ as vanishing in the limit when $\eta$ approaches to equality with $i-(i-1)$. For this particular case we find

$$L_i^2=\frac{3-2b_i}{35} \text{ and } \zeta_0=0.$$
It must be premised that when the profile of a wave does not present the simple harmonic form it is convenient to analyze its shape into a series of partial waves superposed on a fundamental wave; and generally the principle of harmonic analysis is adopted in which the actual wave is regarded as the sum of a number of simple waves.

Suppose that the water is contained in a straight and shallow canal of uniform depth $h$, and that at one end the canal debouches on to the open sea. Suppose further that in the open sea there is a forced oscillation of water level, given by this formula

$$
\eta = H \sin \pi n \left(1 - \frac{x}{\sqrt{gk}}\right).
$$

where $\eta$ is the elevation of the water at time $t$ above its mean level, $2\pi h$ the period of the oscillation and $H$ the amplitude of the oscillation.

Waves will clearly be transmitted along the canal, and the problem is to obtain a formula which shall represent the oscillations of level at any distance $x$ measured from the mouth of the canal.

The mathematical investigation shows that, if $g$ denotes gravity, the formula for the oscillation of water level at the point defined by $x$ is

$$
\eta = H \sin \left(\frac{\pi n x}{\sqrt{gk}} - \frac{2\pi h n}{\sqrt{gk}} \sin \frac{2\pi n x}{2\pi h} \right).
$$

The second of these terms is proportional to $x$, and if the canal were infinitely long it would become infinite. The difficulty thus occasioned may be eluded by supposing the canal to debouch on a second sea in which a second appropriate oscillation is maintained. In actual friction gradually annuls all motion, and no such difficulty arises.

The first term of the formula is called the fundamental tide, the second gives what is called the first over-tide; and further approximation would give second and third over-tides, &c. All the over-tides (as he the river tide, for instance) are distinct from the fundamental, but they have double, treble, quadruple frequencies or "speeds," and the ratio of the amplitude of the first over-tide to the fundamental is

$$
\frac{3H}{4\sqrt{gk}}.
$$

As a numerical example, let the range of tide at the river mouth be 20 ft., and the depth of the river 50 ft. The "speed" of the semi-diurnal tide, which is an angular velocity, is 28.98° per hour or 11/9 radians per hour; $\sqrt{gk} = 27$ miles per hour; hence $\frac{3H}{4\sqrt{gk}} = \frac{1}{342}$. Therefore 34 miles up the river the over-tide is 1/10th of the fundamental and has a range of 2 ft. If the river shallows very gradually, the formula will still hold, and we see that the height of the over-tide varies as (depth)⁻¹.
Fusion of Terms affected by Motion of Moon's Node

TIDE

Let the axes fixed in the earth be taken as follows: the axis C the north pole axis; the axis A through the earth's center and a point on the equator on the same meridian as the place of observation; the axis B at right angles to the two eastward of A. Then if $\lambda$ be the latitude of the place of observation

$$\xi = \cos \lambda, \eta = \sin \phi, \zeta = \sin \lambda$$

With these values we have

$$\cos^2 z - 1 = \frac{1}{2} \cos \lambda (M_1 + M_3 - M_2) + \sin 2\lambda M_4$$

$$+ \frac{1}{2} (1 - \sin^2 \phi) (M_1 + M_3 - 2M_2)$$

In fig. 7 let ABC be the axes fixed in the earth; XYZ a second set of axes, XY being the plane of the moon's orbit; M the projection of the moon's node on the earth's surface at $\phi = 2\pi / 3$; the obliquity of the lunar orbit to the equator; $x = AX = BCY$; $l = MX$, the moon's longitude in her orbit measured from X, the descending node of the equator on the lunar orbit, hereafter called the "intersection."

Then

$$M_1 \cos \phi \cos x + \sin \phi \cos \lambda = \cos \phi \cos (\chi - \phi) + \sin \phi \cos (\chi + \phi)$$

$$M_2 = \cos \phi \sin x + \sin \phi \cos \lambda = - \cos \phi \sin (\chi - \phi) \cos \phi \sin (\chi + \phi)$$

When these expressions are substituted in $M_1^2 - M_3^2, M_2M_4, M_1^2 + M_3^2 - 2M_2$, it is clear that the first will have terms in the cosine of $2(\chi - \phi), 2x, 2(x+\phi)$; the second in sines of $2\chi - 2x$, $x + \phi$, the third in $\cos 2l$, together with a term depending only on $l$.

Now let $e$ be the moon's mean distance, $\epsilon$ the eccentricity of her orbit, and let

$$X = \left[\left\{1 - (\epsilon^2)\right\}M_3 \right]Y, \quad Y = \left[\left\{1 - (\epsilon^2)\right\}M_3 \right]X_2 = \left[\left\{1 - (\epsilon^2)\right\}M_5 \right]$$

Then we have for the lunar tide-generating potential at the place of observation

$$V = \frac{r_0^2}{(1 - \epsilon^2)^2} \left[\left(\cos^2 \phi \cos \lambda (X^2 + Y^2) + \sin 2\lambda XZight.ight. \left.\left.\right. + (1 + \sin^2 \phi) (X^2 + Y^2 - 2Z^2)\right]$$

The only parts of this expression which are variable in time are the functions of $X, Y, Z$.

To complete the development the formulae of elliptic motion are introduced in these functions, and terms which appear numerically negligible are omitted. Finally, the three $X, Y, Z$ functions are often divided into component semi-diurnal and diurnal terms, the components of the sines and cosines being linear functions of the earth's rotation, the moon's mean motion, and the longitude of the moon's perigee. The next step is to pass, according to the principle of forced oscillations, from the potential to the height of the generated forces by the forces corresponding to that potential. The $X, Y, Z$ functions being simple time-harmonics, the principle of forced oscillations allows us to conclude that the first of the generating terms in the oceans of the same periods and types as the terms in $V$, but of unknown amplitudes and phases. Now let $X \neq 0, Y, Z,$ $(X^2 + Y^2 + 2Z^2)$ be three functions having respectively similar forms to those of

$$X' = X - Y, \quad Y' = \left(1 - \epsilon^2\right)^2 X, \quad Z' = \left(1 - \epsilon^2\right)^2$$

but differing from them in that the argument of each of the simple time-harmonics has some angle subtracted from it, and that the term is multiplied by a numerical factor. Then, if $g$ be gravity and $h$ the height at the place of observation, we must have

$$h = \frac{r_0^2}{(1 - \epsilon^2)^2} \left[\left(\cos^2 \phi \cos \lambda (X' - 2Y' - 2Z') + (1 - \sin^2 \phi) (X' - 2Y' - 2Z')\right)\right]$$

The factor $r_0^2/g$ may be more conveniently written $3m/(2gR)$, where $R$ is the earth's mass. It has been shown that if the equilibrium theory of tides were fulfilled with water covering the whole earth, the numerical factors in the $X, Y, Z$ functions would each unity and the alterations of phase would be zero. The terms in $(X^2 + Y^2 + 2Z^2)$ require special consideration because of the function of the latitude being $\cos^2 \phi$, and the higher terms of the southern hemisphere. It is best to adopt a uniform system for the whole earth, and to regard high-tide and high-water as
TIDE

consentaneous in the equatorial belt, and of opposite meanings outside the critical latitudes. We have conceived the function always to be written \(\sin^k\), so that outside the critical latitudes high-tide is low-water. We may in continuing the development write the \(X, Y, Z\) functions in the form appropriate to the equilibrium theory with water covering the whole earth, for the actual case it is only then necessary to multiply by the reducing factor, and to subtract this from the already given unknown constants for each place, they would only occur in the development as symbols of quantities to be deduced from observation. It will be understood, therefore, that in the following schedules the "argument" is that part of the argument which is derived from theory, the true complex argument being the "argument" \(-\theta\), where \(\kappa\) is derived from observation.

Up to this point we have supposed the moon's longitude and the earth's position to be measurable from the "intersection" \(l\); but in order to pass to the ordinary astronomical formulæ we must measure the longitude and the earth's position from the vernal equinox. Hence we shall now write down the result in the form of a schedule; but we must first state the notation employed: \(e, \epsilon\) = eccentricities of lunar and solar orbits; \(l, \omega\) = obliquities of equator to lunar orbit and ecliptic; \(p, \psi\) = longitudes of lunar and solar positions; \(s, \delta\) = mean sun's and sun's mean longitudes; \(a, \varepsilon\) = hourly increments of \(s, \delta\); \(i\) = local mean solar time reduced to angle; \(\gamma - \pi = 15^\circ\) per hour; \(\lambda = \) latitude of place of observation; \(\xi, \eta\) = longitudes in lunar orbit, and R.A. of the intersection: \(N = \) longitude of moon's node; \(i\) = inclination of lunar orbit. The "speed" of any tide is defined as the rate of increase of its argument, and is expressible, therefore, as a linear function of \(\gamma, \eta, \xi, \delta, \varepsilon\); for we may neglect \(\sigma\) as being very small.

The following schedules, then, give the height of tide. The arrangement is as follows. First, there is a universal coefficient \(\frac{3}{2} \frac{M}{a} (\frac{2}{\pi})^5\), which multiplies every term of all the schedules. Secondly, there are general coefficients, one for each schedule, viz. \(\cos^2\) for the semi-diurnal terms, \(\sin 2\lambda\) for the diurnal, and \(\frac{1}{2} - \sin^2\lambda\) for the terms of long period. In each schedule the third column, headed "coefficient," gives the functions of \(J\) and \(\epsilon\). In the fourth column is given the mean semi-range of the corresponding term in numbers, which is approximately the value of the coefficient in the first column when \(I = \omega\), but we pass over the explanation of the mode of combination of the values. The fifth column contains argument linear functions of \(l, \omega, s, p, \psi, \xi, \eta\). In \(A, A, i, j\) \(\pm 2(\pi - r)\) and in \(A, ii, j\) \(\pm (\pi - r)\) are common to all the arguments. The arguments chosen for the coefficients of subsequent columns, respectively subsequent columns, are chosen so as to give the most convenient form for the coefficients. Lastly, the sixth is a column of speeds, being the hourly increases of the arguments in the preceding column, estimated in degrees per hour. It has been found practically convenient to determine the whole of those tables of hourly coefficients by an initial argument, arbitrarily chosen. In the first column we give a descriptive name for the tide, and in the second the arbitrarily chosen initial.

The schedule for the solar tides is drawn up in precisely the same manner, the only difference being that the coefficients are absolute constants. In order that the comparison of the importance of the solar tides with the lunar may be complete, the same universal coefficient \(\frac{3}{2} \frac{M}{a} (\frac{2}{\pi})^5\) is retained, and the special coefficient for each term is made to involve the factor \(\frac{1}{2}\). Here \(r, \frac{M}{a}, \frac{1}{2}\), \(\frac{1}{2}\), \(\frac{1}{2}\) being the sun's mass. With

\[
\frac{M}{a} = 81.5, \quad \frac{M}{a} = 46035 = 2^{-17226}
\]

To write down any term, take the universal coefficient, the general coefficient for the class of tides, the special coefficient and multiply by the cosine of the argument. The result, taken with the positive sign, is a term in the equilibrium tide, with water covering the whole earth. The translation to the actual case by the introduction of a factor and a delay of phase (to be derived from observation) has been already explained. The sum of all the terms is the complete expression for the height of tide at any place. It must be remarked that the coefficient of tides is here largely abridged, and that the reader who desires fuller information must refer to the Brit. Assoc. Report for 1853, or vol. i. of G. H. Darwin's Scientific Papers, or to Harris's Manual of Tides.

From the fourth columns we see that the coefficients in descending order of magnitude are \(M, K, K_1\) (both combined), \(S, K, K_1\) (lunar), \(N, P, K\) (solar) \(K_2\) (both combined), \(K_3\) (lunar), \(M_1, Q, K_3\) (solar). Ssa.

The tides which we omit from the schedules are relatively unimportant, but nevertheless commonly evaluated in accurate tidal work, viz. the following semi-diurnal tides: the smaller elliptic tide \(L\), the larger and smaller ejectional tides \(v, \lambda\), the variational tide \(\mu\). Also the following diurnal tides, viz. the smaller elliptic tide \(M\), a tide of speed \(\gamma - \beta - \theta\) called \(J\). Also amongst the tides of long period, the luni-solar fortightly called MSF.

The tides depending on the fourth power of the moon's parallax

\[4\text{The mean value of this coefficient is }\left(1 + \frac{1}{E^2}\right)\left(1 - \sin^2\epsilon\right) \approx 0.25,\] and the variable part is approximately \(1 - \frac{1}{E^2}\sin \omega \cos \omega \cos \epsilon = N - 0.0236\cos N.\]
TIDE
955

come out the same from each year's reductions. It is only
when the results are presented in such a form as this that it will be possible
to judge whether the harmonic analysis is yielding satisfactory results.
This method of presentation is also essential for the use of a tide-predicting machine
(see § 8).

We must now show how to determine $H$ and $\kappa$ from $R$ and $\gamma$. It
is obvious that
\[ H = -1883 \kappa + 1883 \gamma \]

and that
\[ \kappa = 1883 \kappa + 1883 \gamma \]

so that
\[ \kappa = \frac{1}{2} \gamma + \frac{1}{2} H \]

Thus the rule for the determination of $\kappa$ is: \textit{Add to the value of $\gamma$ the value of the argument $\alpha$ of the first day.}

The results of harmonic analysis are usually tabulated by giving
$H$ and $\kappa$ at the initial time and the results are then comparable
from year to year. 1 For the purpose of using the
tide-predicting machine the process of determining
$H$ and $\kappa$ from $R$ and $\gamma$ has simply to be reversed,
with the difference that the instant of time to which to refer
the argument is $\kappa$ of the first day of the new year, and we must
have note of the different values of $\kappa$ and $\gamma$ for the new year.

1. Tables may be computed for $\kappa$ and $\gamma$ for all longitudes of the tidal
node and for each kind of tide, and the mean longitudes of moon,
sun, and lunar perigee may be extracted from any ephemeris.

Thus when the mean semi-range $H$ and the retardation $\kappa$ of
any tidal factor is given in terms of the geocentric co-ordinate,
the tidal height of water above the datu at every mean solar
hour. The period chosen for analysis is about one year and the
first measurement corresponds to noon.

If $T$ be the period of any one of the diurnal tides, or the double
period of any one of the semi-diurnal tides, it approximates more
or less nearly to 24 solar hours, and if we divide it into 24 equal
parts, we find that the corresponding hourly tide will fall at all hours of any other special
day.

The final outcome is that we obtain the height of water at each
of the 24 T-hours of a T-day, freed from the influence of all the other
tides. We may see that it is thus possible to isolate the T-tide
when this has been done let $t$ denote T-time expressed in T-hours,
and let $n$ be $\frac{\pi}{2}$. Then we express the height $h$ as given by the
average process above indicated by the formula
\[ h = A_s + A_n \cos (n + 1883 \kappa) + A_n \cos (n - 1883 \gamma) \]

or $h = A_s + A_n \cos (n + \kappa) + A_n \cos (n - \gamma)$.

An actual numerical example of harmonic
analysis of tidal observations is given in the \textit{Admiralty Scientific Manual} (1886) in the article "Tides," or G. H. Darwin's \textit{Scientific Papers}, vol. i.

V.—SYNTHETIC METHOD
§ 29. On the Method and Notation.—The general nature of the
synthetic method has already been explained; we now propose
to show how the expressions for the tide may be developed from the
result as expressed in the harmonic notation. If it should be
desired to make a comparison of the results of tidal observation
as expressed in the synthetic method with those of the harmonic
method, or the converse, or to compute a tidal table from the
harmonic constants by reference to the moon's co-ordinates and parallelly to the analytical expressions founded on
a procedure indicated in the following sections are necessary.

In chapter iv. the mean semi-range and angle of retardation of
anomalous of each of the tides as a T-tide by $H$ and $\kappa$. We shall
here, however, require to introduce several of the $H$'s and $\kappa$'s into
the same expression, and they must therefore be distinguished
from one another. This may in general be done conveniently by
calling $H_m, \kappa_m$ will be taken to denote the $H$ and $\kappa$ of the tidal
node. This notation does not suit the $K_s$ and $K_t$ tides.

1 See, for example, a collection of results by Baird and Darwin, Proc. Roy. Soc. (1885), No. 239, and a more extensive one in Harris's \textit{Monthly Weather Review} (London, 1867).
3 See Darwin's \textit{Tides} for an account without mathematics.
and we shall therefore write $H^*$, $x^*$ for the semi-diurnal $K_h$ and $K_s$, $x^*$ for the diurnal $K_t$ tide. These two tides proceed according to the mean time and arise from the sun and moon tides, and the synthesis of the two parts of each is effected in the harmonic method, although that synthesis is not explained in chapter iv. It is now necessary to reverse this part of the method, in order to obtain a more complete one. We must therefore note that the ratio of the solar to the lunar part of the total $K_h$ tide is $0.683$; so that $0.683 H^*$ is the lunar portion of the total $K_h$. There will be no occasion to separate these portions of the tide, and we shall retain the synthesis which is effected in the harmonic method.

Mean Longitudes and Elements of the Planetary Nuclei

§ 30. Semi-Diurnal Tides.—The process adopted is to replace the mean longitudes and elements of the orbit in each term of the harmonic development of the schedules of § 25 by hour-angles, declinations, and parallaxes.

At the time 1 (mean solar time of port reduced to angle) let $\psi$ be the $K_h$, $R$, and $H$, and $\nu$ the longitude measured from the "intersection." These and other symbols when written with a subscript accent are to apply to the sun. Then $\varphi$ being the $R$, $A$, of the intersection, we have from the rightangled spherical triangle of which the sides are $l$, $a$, $r$ the relations

$$\tan (a-r) = \cos t \tan l, \quad \sin \delta = \sin l \sin \varphi$$

Now $s = \varphi$ is the $s$'s mean longitude measured from the intersection and $\varphi - r$ is the mean anomaly; hence approximately

$$s = \varphi - e \sin \varphi - \sin (\varphi - r)$$

From (49) and (50) we have approximately

$$\begin{align*}
a &= \frac{e^2}{2} (e - \cos \varphi) + e \sin \varphi - \sin (\varphi - r) \\
\nu &= \frac{e^2}{2} (e - \cos \varphi) + e \sin \varphi - \sin (\varphi - r)
\end{align*}$$

Next, if $h$ be the $\lambda$'s mean longitude, $1+h$ is the sidereal hour-angle, and

$$\varphi = \frac{1+h-s-r}{2}$$

Again, if we put

$$\begin{align*}
s &= \cos \delta = 1 - \sin \delta^2 \\
\cos \Delta &= \cos (s-r) \\
\sin \delta &= \cos \delta \sin \delta \\
\cos \Delta &= \cos (s-r)
\end{align*}$$

Obviously $\Delta$ is such a declination that $\sin \Delta$ is the mean value of $\sin \delta$ during a lunar month. Again, $F$ is the ratio of the $\varphi$'s parallax to her mean parallax, the equation to the ellipse described

$$\begin{align*}
\varphi &= \frac{1}{1+F} \varphi - e \sin \varphi - \sin (\varphi - r) \\
\varphi &= \frac{1}{1+F} \varphi - e \sin \varphi - \sin (\varphi - r)
\end{align*}$$

Now it appears in schedule A of § 25 that the arguments of all the lunar semi-diurnal tides are of the form $2(t-h-r) = 2(s-r) + 4n + \sigma$, and $a = e \sin \varphi$. From this, the arguments of such angles may be given by the relations (51), (52), (53) by Expressions in hour-angles, declinations and parallaxes. Also by means of (52) we may introduce $\Delta$ in place of $I$ in the coefficients of each term. An approximate formula for $\Delta$ is

$$\Delta = 1 + e \cos \varphi + \frac{e^2}{2} (e - \cos \varphi) + e \sin \varphi - \sin (\varphi - r)$$

and $\Delta = 1 + e \cos \varphi + \frac{e^2}{2} (e - \cos \varphi) + e \sin \varphi - \sin (\varphi - r)$. Obviously $\Delta$ is such a declination that $\sin \Delta$ is the mean value of $\sin \delta$ during a lunar month. Again, $F$ is the ratio of the $\varphi$'s parallax to her mean parallax, the equation to the ellipse described

$$\begin{align*}
\varphi &= \frac{1}{1+F} \varphi - e \sin \varphi - \sin (\varphi - r) \\
\varphi &= \frac{1}{1+F} \varphi - e \sin \varphi - \sin (\varphi - r)
\end{align*}$$

Reference to Moon's Transit.

Let us write them

$$\begin{align*}
M &= \frac{P \cos \theta}{\cos \delta} \\
M &= \frac{P \cos \theta}{\cos \delta}
\end{align*}$$

Then we find that the height $h^2$ of the complete lunar and solar semi-diurnal tides is represented by the expression

$$\begin{align*}
h^2 &= M \cos \theta \left(\psi + \mu\right) + M \cos \theta \left(\psi - \mu\right) \\
h^2 &= M \cos \theta \left(\psi + \mu\right) + M \cos \theta \left(\psi - \mu\right)
\end{align*}$$

The first of these is the lunar tide, and it will be observed that the height $\Delta$ depends on the angle of the moon's parallax at a time earlier than that of observation by the "age of the lunar parallactic inequality," and that it depends also on the angle of the moon's declination at a time earlier by the "age of the declination inequality of the moon, represented by the angle $\Delta$, also has a declinational inequality.

The second term is the solar tide, and it also has parallactic and declinational inequalities.

The formulae (53), (54) have been used in an example from the computation of a tide-table given in the Admiralty Scientific Manual (1889).

§ 31. Synthesis of Lunar and Solar Semi-Diurnal Tides.—Let $A$ be the excess of $\mu$'s over $Q$'s R.A., so that $A = q - a$,

$$\begin{align*}
\mu &= \frac{A + M \cos \theta (\psi + \mu) + M \cos \theta (\psi - \Delta)}{M} \\
\mu &= \frac{A + M \cos \theta (\psi + \mu) + M \cos \theta (\psi - \Delta)}{M}
\end{align*}$$

and $\mu = q + M \cos \theta (\psi + \mu) + M \cos \theta (\psi - \Delta)$.

The synthesis is then completed by writing $H \cos 2 (\theta - \psi) = M + M \cos 2 (\theta - \Delta)$, or

$$\begin{align*}
H &= M + M \cos 2 (\theta - \psi) - \mu - M \cos 2 (\theta - \Delta) \\
H &= M + M \cos 2 (\theta - \psi) - \mu - M \cos 2 (\theta - \Delta)
\end{align*}$$

The height $H$ of the sun is given in degrees, is the "interval" from the moon's transit to high water.

The formulae for $H$ and $\psi$ may be written

$$\begin{align*}
H &= \frac{M^2 + M \cos 2 (\theta - \psi) - \mu - M \cos 2 (\theta - \Delta)}{M} \\
H &= \frac{M^2 + M \cos 2 (\theta - \psi) - \mu - M \cos 2 (\theta - \Delta)}{M}
\end{align*}$$

Since $A$ goes through its period in a lunation, it follows that $H$ and $\psi$ have inequalities with a period of half a lunation.

These are called the "fortnightly inequalities in the height and interval.

Spring tide obviously occurs when $A = \mu - \mu$. Since the mean value of $\mu$ is $h$ (the difference of the mean longitudes), and since the mean value of $\mu$ and $\mu_0$ are $h$, $\mu$, it follows that the mean value of the period elapsing after full moon and change of moon up to spring tide is $(h - h)/2 (\eta - \eta)$. The association of spring tide with full and change is obvious, and a fiction has been adopted by which the tide is calculated in those configurations of the moon and sun, but takes some time to reach the port of observation. Accordingly $2 (\eta - \eta)/2 (\eta - \eta)$ has been called the "age of the tide." The average age is about 36 hours as far as observations have been made. The age of the tide appears not in general to differ very much from the ages of the declinational and parallactic inequalities.

The spring- and spring tide is found practically convenient not to use $A$, which is the difference of R.A.'s at the unknown time of high-water, but to refer the tide to $A$, the difference of R.A.'s at the time of the moon's transit. We have already remarked that $\phi (\eta - \eta)/2 (\eta - \eta)$ is the interval from transit to high-water, and hence at high-water

$$\begin{align*}
A &= \frac{A + \sin \Delta - \sin \Delta}{\cos \Delta - \cos \Delta} \phi \\
A &= \frac{A + \sin \Delta - \sin \Delta}{\cos \Delta - \cos \Delta} \phi
\end{align*}$$

As an approximation we may attribute to all the quantities in the second term their mean values, and we then have

$$\begin{align*}
A &= \frac{A + \sin \Delta - \sin \Delta}{\cos \Delta - \cos \Delta} \phi \\
A &= \frac{A + \sin \Delta - \sin \Delta}{\cos \Delta - \cos \Delta} \phi
\end{align*}$$

This approximate formula (61) may be used in computing from (59) the fortnightly inequality in the "height" and "interval." In this investigation we have supposed that the declinational and parallactic corrections are applied to the lunar and solar tides before they are synthesized; but it is obvious that the process may be reversed, and that we may find a table of the fortnightly inequality based on mean values $H_0$ and $H_1$ and afterwards apply corrections. This is the process usually adopted, but it is less exact. The labour of computing the fortnightly inequality, especially by graphical methods, is not great, and the plan here suggested seems preferable.

§ 32. Diurnal Tides.—These tides have not been usually treated.
with much completeness in the synthetic method. In the tide-
tables of the British Admiralty we find that the tides at some ports are ‘affected by diurnal inequality’; such a statement may be interpreted to mean that the time of high-water at that port is not the time of high-water at the same port at another time of the day. The information given in the so-called tide-table. The diurnal tides are indeed complex, and do not lend themselves easily to a complete synthesis. In the harmonic notation the three important tides are represented by the series

\[ T \approx \sum_{j} A_{j} \cos(j \omega t + \phi_{j}) \]

where \( T \) is the tide, \( A_{j} \) is the amplitude of the \( j \)-th harmonic, \( \omega \) is the angular frequency, and \( \phi_{j} \) is the phase angle. These equations represent a series of oscillations, with amplitudes, frequencies, and phases. The method of Laplace by taking into account all the observed tides, and not merely those appertaining to certain configurations. He divided the observations into a number of classes. First, the tides is divided into paroxysms, one for each month; then each paroxysm is divided into a number of semi-diurnal tides, and then into the diurnal tides. This method was followed in the treating of the tides of London, Brest, St Helena, Plymouth, Portsmouth and Sheerness. Whewell (Phil. Trans. 1834, seq.) did much to reduce Laplace's results to a mathematical form, and to extend the synthesis to include the introduction of graphical methods by means of curves. The method explained above is due to him. A review of Whewell's papers that they appear to be the best specimens of reduction of new observations that we have ever seen.

VI.—TIDAL DEFORMATION OF THE SOLID EARTH

§ 34. Elastic Tides.—The tide-generating potential varies as the square of the distance from the earth's centre, and the corresponding forces act at every point throughout its mass. No solid matter possesses the property of absolute rigidity, and we must therefore admit the probable existence of tidal elastic deformation of the solid earth. The problem of finding the state of strain of an elastic sphere under given conditions first was solved by G. Lamé; he made, however, but few physical deductions from his solution. An independent solution was found by Lord Kelvin, who drew some interesting conclusions concerning the phenomenon.

His problem, in as far as it is now material, is as follows. Let a sphere of radius \( a \) and density \( \varrho \) be made of an elastic material and limited by a rigid and rigidly fixed and rigidly fixed to the origin of the co-ordinates. This sphere is not considered as subject to forces due to a potential equal to \( r^{-2} \sin^2 \lambda \), where \( \lambda \) is latitude. Then it is required to find the strain of the sphere. We refer the reader to the original sources for the methods of solution applicable to spherical shells and to solid spheres. The investigation applies either to tidal or to rotational stresses. In the case of tides \( r^m \varrho a^3 \), \( m \) being the mass of the moon and distance, and in the case of rotation \( r^{-\varrho} \), \( \omega \) being the angular velocity about the polar axis. The equation to the surface is found to be

\[ r = \frac{a}{1 + \frac{2\varrho}{1 - \varrho} \left( 1 + \frac{\sin^2 \lambda}{1 + \frac{k^2}{1 - k^2}} \right) \Delta } \]

In most solids the bulk modulus is considerably larger than the rigidity modulus, and in this discussion it is sufficient to neglect \( k \) compared with \( \varrho \). With this approximation, the ellipticity of the surface becomes

\[ e = \frac{2\varrho}{1 - \varrho^2} \]

Now suppose the sphere to be endued with the power of gravitation, and write

\[ e = \frac{g}{1 + \frac{g}{1 + \frac{2\varrho}{1 - \varrho}} \left( 1 + \frac{\sin^2 \lambda}{1 + \frac{k^2}{1 - k^2}} \right) \Delta } \]

where \( g \) is gravity at the surface of the globe. Then, if there were no elasticity, the ellipticity would be given by \( e = r^2 \varrho \), and without gravitation by \( e = r^2 \varrho^2 \). And it may be proved in several ways that, gravity and elasticity co-operating,

\[ e = \frac{2\varrho}{1 - \varrho^2} \]

If \( \mu \) be the rigidity of steel, and if the globe have the size and mean density of the earth, \( r^2 = 2 \), and with the rigidity of glass \( r^2 = 1 \). Hence the ellipticity of an earth of steel under tide-generating forces would be \( \frac{1}{2} \) of that of a fluid earth, and the fraction for glass would be \( \frac{1}{2} \). If an ocean be superposed on the globe, the visible tide will be the excess of the fluid tide above the solid tide. Hence for steel the oceanic tide would be reduced to \( \frac{1}{2} \), and for glass to \( \frac{1}{0} \) of the tides on a rigid earth.

It is not possible in general to compute the tides of an ocean lying on an unyielding nucleus. But Laplace argued that friction would cause the tides of long period (§ 17) to conform to the equilibrium law, and thus be amenable to calculation. Acting on this belief, G. H. Darwin discussed the tides of long period as observed during the years 1833-1840, and found a simple relation between the tidal force as on an unyielding globe, indicating an elasticity equal to that of steel. Subsequently W. Schwedler repeated the calculation from 184 years of observation with nearly the same result. But as Laplace's approximation, to be used in (§ 37), the conclusion seems to be of doubtful validity. Yet subsequently Lord Rayleigh showed

that the existence in the ocean of continental barriers would have the same effect as that attributed by Laplace to friction, and thus help to explain the similar peculiarities of the tides of the two large oceans.

A wholly independent estimate derived from what is called the variability of the tide, the tides of an elastic planet, *mutatis mutandis*, that of the tides of a viscous spheroid. The reader who desires to know more of this subject and to obtain references to original memoirs may refer to C. G. Darwin.

VII.—TIDAL FRICTION

§ 35. Investigation of the Secular Effects of Tidal Friction.—We have indicated in general terms in § 9 that the theory of tidal friction leads to an interesting speculation as to the origin of the moon. We shall therefore investigate the theory mathematically in the complex of the earth as a planet, and one or more satellites moving in a circular orbit, and rotating about an axis perpendicular to that orbit. In order, however, to abridge the investigation we shall only consider the case where the planetary rotation is more rapid than the satellite.

Suppose an attractive particle or satellite of mass *m* to be moving in a circular orbit, with an angular velocity *ω*, round a planet of mass *M* and suppose the planet to be rotating about an axis perpendicular to the plane of the orbit, with an angular velocity *n*; suppose, also, the mass of the planet to be partially or wholly imperfectly elastic or viscous, or that there are oceans on the surface of the planet; then the attraction of the satellite on the planet by a spheroid moving in an orbit and rotating about an axis perpendicular to the plane of the orbit, and that motion must be subject to friction, or, in other words, there must be frictional tidal forces. The system must accordingly be losing energy by friction, and its configuration must change in such a way that its whole energy diminishes.

Such a system does not differ much from those of actual planets and satellites, and, therefore, the results deduced in this hypothetical case must agree pretty closely with the actual course of evolution, provided that time enough has been and will be given for such changes. Let *C* be the moment of inertia of the planet about its axis of rotation, *r* the distance of the satellite from the centre of the planet, *h* the resultant moment of momentum of the whole system, *e* the whole energy, both kinetic and potential, of the system. It is assumed that the figure of the planet and the distribution of its mass are such that the attraction of the satellite on the planet causes no couple about any axis perpendicular to that of rotation. A special system of units of mass, length and time will now be adopted such that the tidal forces can be reduced to their simplest forms. Let the unit of mass be *Mm/(M+m)*. Let the unit of length *γ* be a distance such that the moment of inertia of the planet about its axis of rotation may be equal to the moment of inertia of the planet and satellite, treated as particles, about an axis of inertia, when distant *γ* apart from another. This condition gives

\[ M \frac{M}{M+m} + m \frac{m}{M+m} = C; \]

Let the unit of time *e* be the time in which the satellite revolves through 57°3′ about the planet, when the satellite's radius vector is equal to *γ*. This system of units will be found to make the following functions each equal to unity, viz.

\[ \mu^2 M (M+m)^2, \mu Mm, \text{ and } C, \]

where *μ* is the attraction of the earth's mass about the earth and the earth's moment of inertia as 3/4\( M^2 \) (as is very nearly the case), it may easily be shown that the unit of mass is 3/4 of the earth's mass, the unit of length 5-26 earth's radii or 33,506 kilometres (20,807 miles), and the unit of time 2 hrs. 41 mins.

In these units the present angular velocity of the earth's diurnal rotation is expressed by 0-7044, and the angular velocity of a spheroid is equal to the angular velocity of the earth, the earth's moment of inertia is the earth's moment of inertia about an axis of inertia, and the earth's moment of inertia about an axis of inertia is the earth's moment of inertia about an axis of inertia, and the earth's moment of inertia about an axis of inertia is 3-384. Adding to this the rotational momentum of the earth, which is 0-704, we obtain 4-088 for the total moment of momentum of the moon and earth. The ratio of the orbital to the rotational momentum of the earth is 4-8, so that the total moment of momentum of the system would, but for the obliquity of the elliptic, be 5-80 times that of the earth's rotation. Again, the kinetic energy of orbital motion is

\[ \frac{1}{2} \frac{1}{2} \frac{M}{M+m} \omega^2 + \frac{1}{2} \frac{m}{M+m} \omega^2 = \frac{1}{2} \frac{Mm}{M+m} \omega^2 = \frac{1}{2} \gamma^2. \]

The kinetic energy of the planet's rotation is 1/2\( C \). The potential energy of the system is \(-\mu Mm/r\). Adding the three energies together, and transforming into the special units, we have

\[ 2e = n^2 - 1/r. \]

Now let

\[ x = r/E. \]

It will be noticed that *x*, the moment of momentum of orbital motion is equal to the square root of the satellite's distance from the planet. Then equations (62) and (63) become

\[ h = y + x \]

\[ y^2 - 1/e^2 = (h - x)^2 - 1/e^2 \]

(64) is the equation of conservation of moment of momentum, or, ably, the equation of momentum; (65) is the equation of moment of momentum.

Now consider a system started with given positive moment of momentum *h*; and we have all sorts of ways in which it may be started. If the two rotations be of opposite kinds, it is clear that we may start the system with any amount of energy, however great, but the true maxima and minima of energy capable with the given moment of momentum determined by *h* / \(1/2 C\) = 0, or

\[ x^2 - h^2 + 1 = 0. \]

We shall presently see that this quartic has either two real roots and two imaginary, or all imaginary roots. The real roots may be derived from the equation for the satellite may move round the planet so that the planet shall always show the same face to the fact, that they move as parts of one rigid body. The condition is simply that the satellite's orbital angular velocity *ω* = the planet's angular velocity of rotation, or *Y* = 1/\(k^2\), since *π* and \(r = x - y \). By substituting this value of *Y* in the equation of momentum (64), we get as before

\[ x^2 - h^2 + 1 = 0. \]

At present we have only obtained one result, viz. that, if with given moment of momentum it is possible to set the satellite and planet moving as a rigid body, it is possible to do so in two ways, and that these two ways require a maximum amount of energy and the other a minimum; from this it is clear that one must be in general rotation with the satellite near the planet and the other a slow one with the satellite remote from the planet. Of the three equations (64), (65) and (66) is the equation of momentum, (68) that of energy, and (69) may be called the equation of rigidity, for it indicates that the two bodies move as though parts of one rigid body.

To illustrate these equations geometrically, we may consider a mass *x*, which is fixed to the axis of revolution, and a mass *y*, which is the moment of momentum of the planet's rotation, so that the axis of *y* may be called the axis of rotational momentum. For (68) we may take as ordinate *Y*, which is the energy of the system, so that the axis of *y* may be called the axis of energy. Then, as it will be convenient to exhibit all three curves in the same figure, with a parallel axis of *x*, we must have the axis of energy identical with that of rotational momentum. It will not be necessary to consider the motion when the moment of momentum is negative, because this would only be equivalent to reversing all the rotations, and is therefore to be taken as essentially positive. The line of momentum whose equation is (65) is a straight line inclined at 45° to one axis, having positive values on both axes. The curve of rigidity whose equation is (69) is clearly of the same nature as a rectangular hyperbola, but it has a much more rapid rate of approach to the axis of orbital momentum than to that of rotational momentum. The intersections (64) and (65) and (66) may be as ordinates to the *y* the ordinate of 0 on the axis of rotational, and a straight line parallel to the *y* through the origin. Then, since *Y* = *h* - *x*, the intersection which is the result of the integration with the satellite is remote from the planet; the other gives the configuration where the satellite is closer to the planet. We have already learnt that these two correspond respectively to minimum and maximum energy. When *x* is very large the equation to the curve is *y* = *(h - x)*, which is the equation to a parabola with a vertical axis parallel to *y* and distant *h* from the origin, so that the axis of the parabola passes through the intersection of the line of momentum
with the axis of orbital momentum. When $z$ is very small, the equation becomes $Y = e^z$. Hence the axis of $Y$ is asymptotic on both sides to the curve of energy. If the line of momentum intersects the curve of rigidity, the curve of energy has a maximum vertically underneath the point of intersection near the origin and a minimum underneath the point more remote. But if there are no intersections, it has no maximum or minimum.

Fig. 8 shows these curves when drawn to scale for the case of the earth and moon. The points $a$ and $b$, which are the maximum and minimum of the curve of energy, are supposed to be on the same ordinates as $A$ and $B$, the intersections of the curv of rigidity and the line of momentum. The intersection of the line of momentum with the axis of orbital momentum is denoted by $D$, but in a figure of this size it necessarily remains indistinguishable from $B$. As the zero of energy is quite arbitrary the origin of the axes of curv and $O$ and the radii corresponding to the points $a$ and $b$ prevent the two curves from crossing one another in a confusing manner.

On account of the limitation imposed we neglect the case where the quartic has no real roots. Every point of the line of momentum gives by its abscissa and ordinate the square root of the satellite's distance and the rotation of the planet, and the ordinate of the energy curve gives the energy corresponding to each distance of the satellite. Part of the figure has no physical meaning, for it is impossible for the satellite to move round the planet at a distance less than the sum of the radii of the planet and satellite. For example, the moon's diameter being about 2200 m. and the earth's about 8000 m., the moon could not in reality be on the line $o$.

The actual value of $k$ for the moon and earth is about 4; hence, if the moon-earth system were started with less than $\frac{1}{k}$ of its actual moment of momentum, it would not be possible for the two bodies to move so that the earth would always show the same face to the moon. Again, if we travel along the line of momentum, there must be some point for which $y^2 = 1$, and this is a maximum when $z = \frac{h}{k}$ and the maximum number of days in the month $n = \frac{2\pi}{\sqrt{k/2}}$.

Maximum

$$n = \frac{2\pi}{\sqrt{k/2}}$$

$\text{Maximum Number of Days in Month.}$

$$h^2 = 4/4^2, or k = 4/4 \approx 1.75.$$ The actual value of $k$ for the moon and earth is about 4; hence, if the moon-earth system were started with less than $\frac{1}{k}$ of its actual moment of momentum, it would not be possible for the two bodies to move so that the earth would always show the same face to the moon. Again, if we travel along the line of momentum, there must be some point for which $y^2 = 1$, and this is a maximum when $z = \frac{h}{k}$ and the maximum number of days in the month $n = \frac{2\pi}{\sqrt{k/2}}$.

Discussion of Figure.

We will now consider the physical meaning of the figure. It is seen that the energy of the moon-earth system corresponds to a positive rotation. Now imagine two points with the same abscissa, one on the momentum line and the other on the energy curve, and suppose the one on the energy curve were to move along the momentum line and the energy must degrade, however the two points are set initially on the point on the energy curve must always slide down a slope, carrying with it the other point. Looking at the figure, we see that there are four slopes in the energy curve, two running down to the planet and two down to the minimum. There are no line of momentum curves except the nearest one of Mars. The satellite was placed in the condition $A$—that is to say, moving rapidly On a planet which is a satellite—the condition is clearly dynamically unstable, for the least disturbance will determine whether the system shall degrade down the slopes $ac$ or $a$, that is to say, whether it falls into or recedes from the planet. If the equilibrium is broken down by the satellite receding, the recession will go on until the system has reached the state corresponding to $B$. It is clear that, if the intersection of the edge of rigidity of the system is identical with the point A, which indicates that the satellite is just touching the planet, then the two bodies are in effect parts of a single body in an unstable configuration. If, therefore, the moon was originally part of the earth and moon, there is no curve drawn to scale to represent the earth and moon, there is so close an approach between the edges of the shaded band and the intersection of the line of momentum and curve of rigidity that it would be impossible to distinguish them. Hence, there seems a probability that the two bodies once formed parts of a single one, which broke up in consequence of some kind of instability. This conclusion is confirmed by the author of the paper in the "Proc. of a Viscous Spheroid," already referred to, and subsequent papers, in the Phil. Trans. 1 § 50. Effects of Tidal Friction on the Elements of the Moon's Orbit.

"The effects of the tides on the orbit of the earth and the satellite at the present time are so slight as to be unimportant; the limits of the present article to discuss completely the effects of tidal friction; we therefore confine ourselves to certain general considerations which throw light on the nature of those effects. We have in the preceding section supposed that the planet's axis is perpendicular to the orbit of the satellite, and that the latter is circular; we shall now suppose the orbit to be oblate to the equator and the satellite to be that of the earth, and the satellite the moon. The complete investigation was carried out on the hypothesis that the planet was a viscous spheroid, because this was the only theory of frictionally resisted systems that had been proposed. We may say, then, that practically the same for any system of frictionally resisted tides, we shall speak below of the planet or earth as a viscous body. We shall show that if the tidal retardation is small the obliquity of the ecliptic increases, the earth's rotation is retarded, and the moon's distance and periodic time are increased.

Obliquity of the Ecliptic Increases.

The expressions of the tidal force, the moon's orbit and the earth's rotation are given in the paper. The dotted lines indicate the energy of various parts of the figure which are below the plane of the paper. If the moon were cut in two and one half retained at the place of the moon and the other transported to a point diametrically opposite to the first half with reference to the earth, there would be no material change in the tide-generating forces. It is easy to verify this statement by reference to § 11. These two halves may be described as moon and anti-moon, and suppose a satellite to be placed between them. Let $M'$ be the directions of the moon and anti-moon to the terrestrial sphere. If the fluid in which the tides are raised were perfectly frictionless, or if the earth were a perfect fluid or perfectly elastic, the apices of the tidal spheroid would be at $M$ and $M'$. If, however, there is internal friction, due to any sort of viscosity, the tides will lag, and we may suppose the tidal apices to be at $T$ and $T'$. Now suppose the tidal protuberances to be replaced by two equal and opposite circles at $T$ and $T'$, which are instantaneously rigidly connected with the earth. Then the attraction of the moon on $T$ is greater.

Footnotes:

1. For further consideration of this subject see a series of papers by G. H. Darwin in Proc. of a Viscous Spheroid. 1879. Trans. of the Royal Society from 1879, vol. i. of Thomson and Tal' i's Nat. Phil. (1883) or Scientific Papers, vol. ii.

2. These explanations, together with other remarks, are to be found in the abstracts of G. H. Darwin's memoirs in Proc. Roy. Soc., 1880.
than on $T'$, and that of the anti-moon on $T'$ is greater than on $T$. The result of these forces is clearly a pair of forces acting on the earth in the direction TM, T'M'. These forces cause a couple about the axis in the equator, which lies in the same meridian as the moon and anti-moon and in the equator and the ecliptic. But the couple is curved arrows at L'L'. If the effects of this couple be compounded with the existing rotation of the earth according to the principle of action and reaction, then the earth is forced to move northwards to approach M'. Hence, supposing the moon to move in the ecliptic, the inclination of the earth's axis to the ecliptic diminishes, or the obliquity increases. Next the forces TM, T'M' clearly produce precession, as in the simple case. This precession is the one recognized by the earth's polar axis, which tends to retard the diurnal rotation.

This general explanation remains a fair representation of the state of the case so long as the different harmonic constituents of the precession are not different from the different modes of retardation; and this is the case so long as the viscosity is not great. The rigorous result for a viscous planet shows that in general the obliquity is constant, and does not vary with the period of rotation of the planet, the obliquity increases, and vice versa. Hence, zero obliquity is only dynamically stable when the period of rotation of the satellite is less than two periods of the planet's rotation.

It is possible, by similar considerations, to obtain some insight into the effect which tidal friction must have on the planet of the lunar orbit, but as the subject is somewhat complex we shall pass over this tied in with the necessary, but not the said explanation. It must suffice to say that in general the inclination of the lunar orbit must diminish. Now let us consider the reposition of a satellite in the precessional motion of the moon, which has a periodic time which is long compared with the period of rotation of the planet; and suppose that frictional tides are raised in the planet. The major axis of the tidal spheroid is now perpendicular to the axis of the satellite, and the TIDE

87.—Cosmogonic Speculations Founded on Tidal Friction.

§ 57. History of the Earth and Moon.—We shall not attempt to discuss the mathematical methods by which the complete history of a planet, attended by one or more satellites, is to be traced from the laws indicated in the preceding sections show that there is such a problem, and that it may be solved, and we refer to G. H. Darwin's paper entitled "The Earth and the Moon," 1879. It may be interesting, however, to give the various results of the investigation of a sketch of the possible evolution of the earth and moon, followed by remarks on the other planetary systems and on the solar system as a whole.

We begin with a planet not very much more than 8,000 m. in diameter, and probably partly solid, partly fluid, and partly gaseous. It is rotating about an axis inclined at about 11° or 12° to the normal equator. Suppose that this planet is subject to forces of rotation, which is revolving about the sun with a period not much shorter than our present year. The rapidity of the planet's rotation causes so great a compression of its figure that it cannot continue to exist in an ellipsoidal form with stability; or else it is so nearly unstable that complete instability is induced by the solar tides. The planet then separates into two masses, the larger of which becomes the earth, and the smaller mass becomes more or less conglomérated and finally fused into a spheroid, perhaps in consequence of impacts between its constituent meteorites, which were once part of the prævalent planet. Up to this point we have not attempted to define the mode of separation, or to say whether the moon was initially a chain of asteroids. An investigation of the conditions of instability in such a case surpasses the powers of the mathematician. We have now the earth and moon nearly in contact with one another, and rotating nearly as though they were one body, and the solar tide, which was the subject of dynamic investigation. As the two masses are not rigid, the attraction of each does not act upon the other; and they do not move rigorously with the same periodic time, each raises a tide in the other. Also the sun raises tides in both. In consequence of the frictional resistance to these tidal motions, such a system is dynamically unstable. If the moon and moved orbitally a little faster than the earth rotated, she must have fallen back into the earth; thus the existence of the moon compels us to believe that the equilibrium broke down by the moon revolving orbitally a little slower than the earth, and the increase of the tangential motion of the moon system the moon was conglomérated into a spheroidal form, and acquired a rotation about an axis nearly parallel to that of the earth.

The axial rotation of the moon is retarded by the attraction of the earth on the tides raised in the moon, and this retardation takes place at a far greater rate than the similar retardation of the earth of the rotation. As soon as the moon rotates around its axis with the angular velocity with which she revolves in her orbit, the position of her axis of rotation (parallel with the earth's axis) becomes dynamically unstable. The obliquity of the lunar equator to the plane of the moon's orbit increases a maximum, and then diminishes. Meanwhile the lunar axial rotation is being reduced towards identity with the orbit rotation. Finally, her equator is nearly coincident with the plane of the orbit, and the tides cease. By the history of the rates into a permanent ellipiticity of the lunar equator, causes her always to show the same face to the earth. All the must have taken place early in the history of the earth, to which we now return. At first the moon is identical with the day, and as both these increase in length the lunar orbit will retain its circular form until the month is equal to 1° days. From that time the orbit begins to eccentric, and the eccentricity increases thereafter up to its present magnitude. The plane of the lunar orbit is at first practically identical with the earth's equator, but as the moon recedes from the earth less of the perigees are visible to the observer on the earth, and they shall not attempt to trace the complex changes by which the plane of the lunar orbit is affected. It must suffice to say that the present small inclination of the lunar orbit to the ecliptic accords with the supposed neglect.

As soon as the earth rotates with twice the angular velocity with which the moon revolves in her orbit, a new instability sets in. The moon is then about twelve of our present hours, and the day above six such hours in length. The inclination of the equator to the ecliptic now begins to increase and continues to do so until finally it reached its present value of 23°. All these changes continue, and no new phase now supervenes, and at length we have the system in its present configuration. The minimum time in which the changes from first to last can have taken place is 54,000,000 years. There are other collateral results which must arise from a supposed principle of possibility of the history of the earth's moon, and for this course of evolution the earth's mass must have suffered a screwing motion, so that the solar regions have allowed a little from west to east relatively to the earth-equator. This affords a possible explanation of the north and south trend of our great continents. The whole of this argument reposes on the imperfection of solids and on the adhesion of the moon to its original place as a cause. Thus of changes of the kind here discussed must be going on, and must have gone on in the past. And for this history of the earth and moon to be true throughout, it is necessary that there should not be an intrinsic gravity, and that there is not enough matter diffused through space materially to resist the motions of the moon and effects of the sun, of 54,000,000 years. It seems hardly too much to say that, given these two postulates, and the existence of a

1 See criticism, by Noll, Genesis of Moon (Melbourne, 1885); also Nature (Feb. 18, 1886).
TIDORE 961

The primeval planet such as that above described, a system would necessarily be developed which would bear a strong resemblance to its own. The long period of the moon was deferred until a late epoch in the history of the terrestrial mass, the mass of the moon relatively to the earth would be likely to differ from the mass of other satellites which may have their planet in the solar system, and this must be almost completed before the genesis of the satellite, tidal friction will thereafter be the great cause of change in the system; and thus the hypothesis that it is the sole cause of change will give an apparent explanation of the motion of the terrestrial satellite at any subsequent time. We have already seen that the theory that tidal friction has been the ruling power in the evolution of the earth, and moon co-ordinates the present motions of the two bodies. If our hypothesis is correct, then it would be impossible for the separate existence as a satellite; and the initial configuration of the two bodies is such that we are led to believe that the moon is a primeval earth detached by rapid rotation or other causes.

Let us now turn to the other planetary sub-systems. The satellites of the larger planets revolve with short periodic times; for the smallness of their masses would have prevented tidal friction from being a very efficient cause of change in the dimensions of their orbits, and the largeness of the planet’s masses would have caused them to proceed slowly in their evolution. The satellites of Mars present one of the most remarkable features in the solar system, for, whereas Mars rotates in 24h. 37m., Deimos has a period of 30h. 18m., and Phobos of only 7h. 39m.

The theory of tidal friction would explain the shortness of the period of one of these of Phobos and their ellipticity of the rotation of the planet, or the that the dimensions of their own orbits have been much changed.

We may say, that given the tidal friction on a contracting planetary mass, we have been led to assign a cause for the observed distribution of satellites in the solar system, and this again has itself afforded an explanation of how it happened that the moon so originated that the tidal friction of the lunar tides in the earth should have been able to exercise so large an influence. We have endeavoured not only to set forth the influence which tidal friction may have, and probably has had in the history of the system, if sufficient time be granted, but also to point out what effects it cannot have produced. These investigations afford no grounds for the rejection of theories more recently proposed; but, on the other hand, an elimination of explanations of considerable importance. Tidal friction is a cause of change of which Laplace’s theory took no account; and, although the discovery of radio-activity and the consequent remarkable advances in physics throw grave doubt on all such arguments, and we believe that it is still beyond our powers to assign definite numerical limits to the age of the solar system.

Laplace (Principes de la Mécanique Céleste; vol. ii. (1910) Capture Theory) rejects the applicability of tidal friction to the cosmogony of the solar system, and argues that the satellites were primitively wandering bodies and were captured by the planet. This position has been considered by Dr See to be a necessary result of the presence in space of a resisting medium; but the present writer does not feel convinced by the arguments adduced.

and of a Dutch controleur (commissioner or agent). By an agreement of 1879 the sultan exercises authority over some parts of Halmahera, the Papuan Islands, the western half of New Guinea and the islands in Godlind Gulf. The sultanate is included in the residency of Teine (Ternate). The population of Malaita, Tana and Malakula in religion, is about 8000. They live by agriculture (cotton, tobacco, nutmegs, etc.) and fishing.

**TIECK, JOHANN LUDWIG** (1772–1833), German poet, novelist and critic, was born in Berlin on the 31st of May 1773, his father being a rope-maker. He was educated at the Friedrich-Werdensche Gymnasium, and at the universities of Halle, Göttingen and Erlangen. At Göttingen Shakespeare and the Elizabethan drama were the chief subjects of his study. In 1794 he returned to Berlin, resolved to make a living by his pen. He contributed to a number of periodicals (1795–1798) to the series of Straußfelder, published by the bookseller C. F. Nicolai and originally edited by J. K. A. Musius, and wrote *Abdallah* (1796) and a novel in letters, *William Lovell* (3 vols. 1795–1796). These works are, however, immature and sensational in tone. Tieck’s transition to romanticism is to be seen in the series of plays and stories published under the title *Volksmärchen von Peter Lehrbrec* (3 vols. 1797), a collection which contains the admirable fairy-tale *Der blonde Eckbert*, and the witty dramatic satire on Berlin literary taste, *Der Bildner* (1797). Tieck’s friendship with W. H. Hackenroeder (1777–1798), he planned the novel *Franz Sternbolds Wanderungen* (vols. i–ii. 1798), which, with Hackenroeder’s *Hersenergis- sungen* (1798), was the first expression of the romantic enthusiasm for old German art. In 1798 Tieck married and in the following year settled in Jena, where he, the two brothers Schlegel and Novalis were the leaders of the new Romantic school. His writings between 1798 and 1804 include the satirical drama, *Prinz Zerzub* (1799), and *Romantische Dichtungen* (2 vols. 1799–1800). The latter contains Tieck’s most ambitious poetic experiments, like *Leichte Übung in die Natur* (1799) and *Leben und Tod des kleinen Rotkäppchens*, which were followed in 1804 by the remarkable “comedy” in two parts, *Kaiser Oktavius*. These dramas, in which Tieck’s poetic powers are to be seen at their best, are typical plays of the first Romantic school; although formless, and destitute of dramatic qualities, they show the influence of both Calderon and Shakespeare. *Kaiser Oktavius* is a poetic glorification of the middle ages.

In 1801 Tieck went to Dresden, then lived for a time near Frankfort-on-the-Oder, and spent many months in Italy. In 1803 he published a translation of *Menandros*, and the following year, a translation of *Phantasus*. In this collection he published the stories *Der Kunen- burg, Die Elfen, Der Pokal*, and the dramatic fairy tale, *Fortuna*. In 1817 Tieck visited England in order to collect materials for a work on Shakespeare (unfortunately never finished) and in 1819 he settled permanently in Dresden; from 1825 on he was literary adviser to the Court Theatre, and his semi-public readings from the dramatic poets gave him a wide popularity which extended far beyond the Saxon capital. The new series of short stories which he began to publish in 1822 also won him a wide popularity. Notable among these are *Die Gemälde, Die Reisenden, Die Verlobung, Des Lebens Überfluss*. More ambitious and on a wider canvas are the historical or semi-historical novels, *Dichter- leben* (1826), *Der Aufruhr in den Cevennen* (1826, unfinished), *Der Tod des Dichters* (1834); *Der junge Tischlermeister* (1836; but begun in 1811) is an excellent story written under the influence of Goethe’s *Wilhelm Meister*; *Vittoria Accorambona* (1840), in the style of the French Romanticism, shows a falling off. In later years Tieck carried on a varied literary activity as critic (Dramaturgische Blätter, 2 vols. 1825–1826; Kritische Schriften, 2 vols., 1848; he also edited the translation of Shakespeare by A. W. Schlegel, who was assisted by Tieck’s daughter Dorothea (1799–1841) and by Graf Wolf Heinrich Baudissin (1789–1858); Shakespeare’s *Vorschule* (2 vols., 1825–1826); the works of H. von Kleist (1826) and of J. M. R. Lenz (1828). In 1841 Friedrich Wilhelm IV. of Prussia invited him to Berlin where he enjoyed a pension for his remaining years. He died on the 28th of April 1853.

Tieck’s importance lay rather in the readiness with which he adapted himself to the new ideas which arose at the close of the 18th century, than in any conspicuous originality or genius. His importance as an immediate force in German poetry is restricted to his early period. In later years it was as the helpful friend and adviser of others, or as the well-read critic of wide sympathies, that Tieck distinguished himself.

Tieck’s *Schriften* appeared in 20 vols. (1828–1846), and his *Gesammelte Werke* in 12 (1822–1854). Nachgelassene Schriften were published in 2 vols. in 1855. There are several modern editions—*Ausgewählte Werke* by H. Wehl (8 vols., 1886–1888); by J. Minor (in Kirschner’s *Deutsche Nationalliteratur*, 144, 2 vols., 1883); by G. Kies (with an excellent biography, 3 vols., 1892), and G. Wittkowski (4 vols., 1903). *The Elves and The Cabinet* were translated by Carlyle in *German Romance* (1827), *The Pictures* and *The Betrothal* by Bishop Thirlwall (1829). A translation of *Vittoria Accorambona* was published in 1845. Tieck’s *Letters* have not yet been collected, but *Briefe an Tieck* were published in 4 vols. by K. von Hostel in 1864. See for Tieck’s earlier life R. Köpke, *Ludwig Tieck* (1851), and *Tieck: Erinnerungen* (2 vols., 1871); also A. Stern, *Ludwig Tieck in Dresden* (Zur Literatur der Gegenwart, 1876); J. Minor, *Tieck als Nationaldichter* (1884); B. Steiner, *L. Tieck und die Volkskabare* (1893); H. Rautenstrauch, *Tieck als Dramaturg* (1897); W. Miessler, *Tiecks Lyrik* (1902).

**TIEDEMANN, FRIEDRICH** (1781–1861), German anatomist and physiologist, eldest son of Dietrich Tiedemann (1748–1803), a philosopher and psychologist of considerable repute, was born at Cassel on the 23rd of August 1781. He graduated in medicine at Marburg in 1804, but soon abandoned practice. He devoted himself to the study of natural science, and, betaking himself to Paris, became an ardent follower of Baron Cuvier. On his return to Germany he maintained the claims of patient and sober anatomical research against the prevalent speculations of the school of Lorenz Oken, whose foremost antagonist he was long reckoned. His remarkable studies of the development of the human brain, as correlated with his father’s studies on the development of intelligence, deserve mention. He spent most of his life as professor of anatomy and physiology at Heidelberg, a position to which he was appointed in 1816, after having filled the chair of anatomy and zoology for ten years at Landsluth, and died at Munich on the 22nd of January 1861.

**Tiel, a town in the province of Gelderland, Holland, on the right bank of the Waal (here crossed by a pontoon bridge), 25 m. by rail west of Nijmegen. Pop. (1900), 10,788. It possesses fine streets and open places, but of its fortifications the Kleiberg Gate (1647) alone remains. The principal buildings are St. Martin’s church (15th century), the town hall, court-house and the historical castle of the family of van Arkel. In 1892 a harbour was built, but the shipping of Tiel is now chiefly confined to craft for inland navigation. It carries on a flourishing trade, especially in fruit, and is an important market for horses and cattle. It also manufactures agricultural implements and makes fine flour.

Five miles W.N.W. of Tiel is the small town of Buren, which contains some interesting old houses and is an important market for horses. Buren was the seat of an independent lordship which is mentioned as early as 1152. In later times it was held in fief, first from the dukes of Brabant, then from the dukes of Gelderland. In 1492 the emperor Charles V. raised it to a countship, and in 1551 it passed by marriage to Prince William of Orange Nassau. The title is now sometimes used by the royal family of the Netherlands when travelling inconspicuously. The castle was destroyed in the beginning of the 19th century, and the site of it is now marked by the park on the west side of the town. It contained not less than 170 apartments and was memorable for the imprisonment within its walls of Arnold duke of Gelderland (d. 1473), and as the birthplace of Philip William of Orange in 1544.
TIELE—TIEPOLO

TIELE, CORNELIS PETRUS (1830-1902), Dutch theologian and scholar, was born at Leiden on the 16th of December 1830. He was educated at Amsterdam, first studying at the Atheneum Illustre, as the communal high school of the capital was then named, and afterwards at the seminary of the Remonstrant Brotherhood. He was destined for the pastorate in his own brotherhood. After steadily, declining for a considerable period, this had increased its influence in the second half of the 19th century by winning the interests of the author, in the History of Methodists, which had caused many of the liberal clergy among the Lutherans and Calvinists to go over to the Remonstrants. Tiele certainly had liberal religious views himself, which he early enunciated from the pulpit, as Remonstrant pastor of Moor-drecht (1853) and at Rotterdam (1856). Upon the removal of the seminary of the brotherhood from Amsterdam to Leiden in 1873, Tiele was appointed one of its leading professors. In 1877 followed his appointment at the university of Leiden as professor of the history of religions, a chair specially created for him. Of his many learned works, the Verkeerdeschis van de egyptische en mesopotamische Godsdiensten (1872), and the Geschiedenis van den Godsdienst (1876; new ed. 1891), have been translated into English, the former by James Ballingall (1887-1882), the latter by J. Estlin Carpenter (1877) under the title "Outlines of the History of Religion" (French translation, 1885; German translation, 1893). A French translation of the Comparative History was published in 1882. Other works by Tiele are: De Godsdienst van Zarathustra, van het Ontstaan in Bokhri, tot den Val van het Oud-Persische Rijk (1864) a work now embodied, but much enlarged and improved by the latest research. In 1881 he published the History of Religions (vol. ii, part ii, Amsterdam, 1901), a part which appeared only a short time before the author's death; De Vrucht der Assyrialogie voor de vergelijkende geschiedenis der Godsdiensten (1877; German ed., 1878); Babylonisch-assyrische Geschiede (two parts, Leipzig, 1886-1888); Western Asia, according to the most Recent Discoveries (London, 1894). He was also the writer of the article "Religions" in the 9th edition of the Ency. Brit. A volume of Tiele's sermons appeared in 1865, and a collection of his poems in 1863. He also edited (1866) the poems of Petrus Augustus de Géneset. Tiele was best known for his Outlines by his Outlines and the Gifford Lectures "On the Elements of the Science of Religion," appearing in 1866-1868 at Edinburgh University. They appeared simultaneously in Dutch at Amsterdam, in English in London and Edinburgh (1897-1899, 2 vols.). Edinburgh University in 1900 conferred upon Tiele the degree of D.D. honoris causa, an honour bestowed upon him previously by the universities of Dublin and Bologna. He was also a fellow of at least fifteen learned societies in Holland, Belgium, France, Germany, Italy, Great Britain and the United States. He died on the 11th of January 1902. In 1901 he had resigned his professorship at Leiden University. Tiele's zeal and power for work were as extraordinary as his vast knowledge of ancient languages, peoples and religions, upon which his researches, according to F. Max Müller, have shed a new and vivid light. With Abraham Kuenen and J. H. Scholten, amongst others, he founded the "Leiden School" of modern theology. From 1867 he assisted A. Kuenen, A. D. Loman and L. W. Rauwenhoven editing the Theologisch Tijdschrift.

His brother PIETER ANTON TIELE (1834-1888) acted for many years as the librarian of Utrecht University, and distinguished himself by his bibliographical studies, more especially by his several works on the history of colonization in Asia. Among these the most noteworthy are: De Opkomst van het nederlandsch Genoot in Oost-Indië (1886); De Vestiging der Portugeseen, in Indie (1875), and other books on the early Portuguese colonization in the Malay Archipelago.

TIENSTINS, the largest commercial city in Chih-li, the metropolitan province of China. Pop. (1907), about 750,000. It is situated at the junction of the Peiho and the Hun-ho, which is connected by the grand Canal with the Yangtze-kiang. It is a prefectural city, and has, since the conclusion of the foreign treaties, become the residence of the viceroy of the province during a great portion of the year. The town is built on a vast alluvial plain, which extends from the mountains beyond Peking to the sea, and through which the Peiho runs a circuitous course, making the distance by water from Tientsin to the coast about 70 m. as against 30 m. by railway.

The appearance of the city has greatly changed since the Boxer rising in 1900. After the event of the city, which measured about three-quarters of a mile each way, were razed, wide streets were made, the course of the river straightened, electric lighting and tramways introduced and a good water service supplied. Among the public buildings are a university (in which instruction is given in western learning) and an arsenal. There are several cotton mills and important rice and salt markets. The city has always been a great commercial depot; a wharf nearly two miles long affords ample facilities for vessels able to cross the bar of the Peiho, over which there is a depth of water varying from 9 to 12 ft.

In 1907 the imports amounted to 22,500,000 taels (a tael in 1907 averaged 38.30d.); viz. foreign imports 61,200,000, native imports of 17,500,000 taels. In 1907 the value of foreign trade was about 7,250,000. Valuable cargoes of tea are landed here for carriage overland, via Kalgan and Khiakhta, to Siberia. During the winter months the river is frozen. Here the Peiho and the Kiangyin, which is brought by the canal to the east of Tientsin; its output in 1883 was 181,099 tons and in 1904 28,926 tons.

The importance of Tientsin has been enhanced by the railways connecting it with Peking on the one hand and with Shanghai, Kwan and Manchuria on the other. The British concession, in which the trade centres, is situated on the right bank of the river Peiho both for the native city, and occupies some 200 acres. It is held on a lease in perpetuity granted by the Chinese government to the British Crown, which sublets plots to private owners in the same way as is done at Hankow. The local management is entrusted to a local company, the Tientsin and Peking Railway (1899) which obtains a dividend out of the receipts of the railway. Besides the British concession the French, Germans, Russians, Japanese, Austrians, Italians and Belgians have separate settlements, five miles in all, the river front being governed by foreign powers.

In 1853 Tientsin was besieged by an army of T'ai-p'ing rebels, which had been detached from the main force at Nanking for the capture of Peking. The defences of Tientsin, however, saved the capital, and the rebels were forced to retreat. Five years later Lord Elgin, accompanied by the representative of France, steamed up the Peiho, after having forced the barriers at Taku, and took possession of the city. Here the French treaty was signed. But in 1860, in consequence of the treacherous attack made on the British plenipotentiary the preceding year at Taku, the city and suburbs were occupied by an allied British and French force. Afterward the Russians were held here by the Chinese. The last open port. On the establishment of Roman Catholic orphanages some years later the pretensions of the priests so irritated the people that on the occurrence of an epidemic in the schools in the year 1870 they attacked the French and Russian establishments and murdered twenty-one of the foreign inmates, besides numbers of their native followers. The Chinese government suppressed the riot, paid 180,000 in compensation and sent a representative to Europe to apologize for the outbreak.

During the period 1874-1894, when Li Hung-Chang was viceroy of Chih-li and ex efficio superintendent of trade, he made Tientsin into a centre for the control of his empire's foreign trade and naval education. As a consequence the city became the chief focus of enterprise and foreign progress. Having arrogated to himself the right of judicial control of the foreign policy of the nation, Li's yamen became the scene of many important negotiations, and attracted distinguished visitors from all parts of the globe. The loss of prestige consequent on the Japanese War brought about the collapse of this position, which he had so skilfully created. Both the foreign concessions and the native city suffered severely during the hostilities resulting from the Boxer movement in June-July, 1900. (See CHINA: History § B.)

TIEPOLO, GIOVANNI BATTISTA (1692-1768), Italian painter, was born at Venice, and acquired the rudiments of his art from Gregorio Lazzarini, and probably from Piazzetta, though the decisive influence on the formation of his style was the study of Paolo Veronese's sumptuous pictures. When hardly out of his teens he developed an extraordinary facility of brushwork, and proved himself, as a fresco-painter, a colourist of the first
order, though this early mastery of technique made him frequently neglect form and composition. The more solid qualities of Paolo Veronese—depth of thought and balance of design—are frequently wanting in his work, but he approaches the earlier master in richness of colour and in the management of difficult effects of lighting. He decorated many Venetian churches and palaces with ceilings and frescoes full of turbulent movement and rich colour, extending his operations to the near cities of the mainland and to Bergamo (Colleoni Chapel) and Milan (ceiling at Palazzo Chierici). In 1750 he proceeded to Würzburg to paint the magnificent ceilings and frescoes at the archbishop's palace. From 1753 to about 1759 he worked again at Venice and in the cities of north-east Italy, until he was summoned to Madrid by Charles III. to paint some frescoes for the royal palace. He died at Madrid in 1766. He was the last important figure in Venetian art, and at the same time the initiator of the baroque period.

Tiepolo's altarpieces and easel pictures show more clearly even than his frescoes how deeply he was imbued with the spirit of Paolo Veronese, for in these smaller works he paid more attention to the balance of composition, whilst retaining the luminosity of his colour harmonies. The majority of his works, both in fresco and in oils, are to be found in Venice in the churches of S. Aloise, SS. Apostoli, Gesuati, SS. Giovanni e Paolo, in the Scalzi, and the Scuola del Carmine, the Academy, and the Palazzi Labia, Rezzonico, and Quirini-Stampaia, and the Doge's Palace. Besides the cities already mentioned, Padua, Udine, Pordenone and Vicenza boast of fine examples of his work. At the National Gallery are two altarpieces, for altarpieces, and the Marriage of Marie de Médicis. Two versions of "Christ and the Adulteress" are in the collection of Dr L. Richter. Other easel pictures by Tiepolo are at the Louvre, and at the Berlin and Munich galleries. His paintings in Madrid belong to the closing years of his life and show signs of waning power. Tiepolo also executed some notable work with the etching-needle, the list comprising some fifty plates. His two sons, Giovanni Domenico (about 1725-1804) and Lorenzo, did not attain to his excellence.

TIENEY, GEORGE (1761-1830), English Whig politician, was born at Gibraltar on the 20th of March 1761, being the son of a wealthy Irish merchant of London, who was living there as prize agent. He was sent to Eton and Peterhouse, Cambridge, where he took the degree of LL.B. in 1784, and was called to the bar; but he abandoned law and plunged into politics. He contested Colchester in 1788, when both candidates received the same votes, but Tieney was declared elected. He was, however, defeated in 1790. He sat for Southwark from 1796 to 1806, and then represented in turn Athlone (1806-1807), Bandon (1807-1812), Appleby (1812-1818), and Knaresborough (1818-1830). When Fox seceded from the House of Commons, Tieney became a prominent opponent of Pitt's policy. In 1797 Wilberforce noted in his diary that Tieney's conduct was "truly Jacobinical"; and in May 1798 Pitt accused him of want of patriotism. A duel ensued at Putney Heath on Sunday, the 27th of May 1798; but neither combatant was injured. In 1803 Tieney, partly because peace had been ratified with France and partly because Pitt was out of office, joined the ministry of Addington as treasurer of the navy, and was created a privy councilor; but this alienated many of his supporters among the middle classes, and offended most of the influential Whigs. On the death of Fox he joined (1806) the Grenville ministry as president of the board of control, with a seat in the cabinet, and thus brought himself once more into line with the Whigs. After the death of George Ponsonby in 1817 Tieney became the recognized leader of the opposition in the House of Commons. It was Ponsonby's ministry he was master of the mint, and when Lord Goderich succeeded to the lead Tieney was admitted to the cabinet; but he was already suffering from ill-health and died suddenly at Savile Row, London, on the 25th of January 1819.

Tieeny was a shrewd man of the world, with a natural aptitude for business. His powers of sarcasm were a cause of terror to his adversaries, and his presence in debate, even when his arguments were felicitous, and his choice of language was the theme of constant admiration. Lord Lytton, in his poem of St Stephen's, alludes to "Tieeny's airy tear," and praises his "light and yet vigorous" attack, in which he inferred, "with a placid smile," a fatal wound on his opponent.

TIERRA DEL FUEGO, an archipelago at the southern extremity of South America, from which it is separated by Magellan Strait, at the First Narrows and other points scarcely a mile wide. The group lies between 52° 40' and 55° 59' S. and 63° 30' and 74° 30' W. stretching nearly in a line with the Patagonic Andes for 400 m. N.W. and S.E., between Capes Pillar (Desolation Island) and Horn, and for about 270 m. W. and E. from Cape Pillar to Catherine Point on the north of the main island of Tierra del Fuego. Southwards it tapers to 120 m. between Capes Horn and San Diego, east of which extends Staten Island, which terminates in Cape St John. The boundary between A and C has once been settled in such a manner that Argentina holds that part of the main island of Tierra del Fuego which is situated east of the meridian of Cape Espiritu Santo, the frontier striking the north shore of Beagle Channel about its centre; and Chile holds the western part of the main island and the other numerous islands to the west and to the south of Beagle Channel. The Argentine side is known as the Territory of Tierra del Fuego (including Staten Island), and the Chilean forms part of the Territory of Magallanes. Although on ordinary maps this region presents to the eye a hopelessly confused chaos of islands and fjord-like inlets, it is nevertheless clearly disposed in three main sections: (1) the main island; (2) the islands to the south, from which it is separated by Beagle Channel; (3) the islands to the west, marked off from those to the south by the Brecknock Peninsula.

Knowledge of these lands increased considerably during the later years of the 19th century, and their reputation for dreariness has been favourably modified. The climate in the eastern and southern regions is not so rigorous as was believed, there are no barren lands, the soil is fertile and can support fruitful industries, and the aborigines are far from being so dangerous as they were once considered to be. The greater part of the main island of Tierra del Fuego is formed by the continuation of the Tertiary beds of the Patagonian tableland cut by the transversal depression of Magellan Strait and by the low land extending from Useless Bay on the west to San Sebastian Bay on the east, of so recent origin that there exist still some salt lakes, this depression being represented in the old charts as an inter-oceanic passage for small boats. Although in 1880 numerous prospectors discovered extensive deposits of alluvial gold, its exploitation was not generally successful, and farms took the place of mines. By the end of the 19th century 200 square miles had been occupied by cattle and sheep on the Argentine side, and about the same extent on the Chilian; and the cattle industry proved very profitable.

The undulating tableland has an average height of 300 ft. above the sea, and its climate, however cold in winter—in 1892 and 1893 the temperature reached 12-6° F.—allows of the cultivation of barley, oats and occasionally potatoes, which, however, grow better south of Beagle Channel; there are more lakes and rivers, and more broken, being drained by the Silva and Grande, among smaller rivers, the Grande being navigable in some parts by small craft. To the west and south-west the general character of the land changes; the hills and larger ranges extend to Cape Horn, and its depth reaches 700 ft. To the south of the lake rises the south-eastern prolongation of the Cordillera of the Andes, with ridges of a uniform height of 3500 ft., in which predominates crystalline schists which are less broken than the mountains to the north, but the slopes collapse and the uniformity, such as Mt Sarmiento (7200 ft.), Mt Darwin, of which two peaks have been measured (6201 and 7054 ft.), and Mt Olivia (4524 ft.), Sarmiento, the culminating point of
The archipelago, was generally supposed to be volcanic, but it presents such extremely precipitous flanks that John Ball considered it most likely to be a mole, a great force of the axis of the Andean chain during the long ages that preceded the great volcanic outbursts that have covered the framework of the South America.

Martin Conway, who ascended it, ascertained that it was a volcano. This is altogether a region with numerous snow-clad summits and glaciers descending down to the sea. Deep valleys, which seem to be only the precursor channels and the floor of the large extinct igneous lakes, have been dissected, and alluvial gold is washed principally at Sloggett Bay. These regions, as they become more known, may even invite the attention of tourists by their sublime scenery. Stanley Island to the east of Tierra del Fuego has been settled by the Argentine government; there are a prison and lighthouse at St John Harbour, and a first-class permanent meteorological and magnetic station.

The dissection of the archipelago to the south of Beagle Channel includes the islands of Hoste, Navarin, Gordon, Londonderry Stewart, Wollaston and numerous islets, disposed in triangular form with the mainland and Isla Grande de Tierra del Fuego being the vertex of Cape Horn. At its west end Beagle Channel takes the name of Darwin Sound, which leads to the Pacific at the Londonderry and Stewart Islands. Partial exploration in this region was conducted by Dr. Darwin and Capt. John Byron in 1801. The foundations of the southern islands are granite and basic volcanic rocks. The western group of islands, demarcated by Brecknock Peninsula, includes Clarence Island and Captain Cook's Desolation Land, with Darwin Island and several small islets. Desolation Land was supposed by Cook to form a continuous mass stretching from the western entrance of Magellan Strait to Cockburn Channel, but it actually consists of several islands. Small islands separated from each other by very narrow channels, flowing among these islands have shown that several of the larger islands are cut by channels which separate them into smaller parts, while elsewhere the low valleys which unite the mountains and hills are the result of postglacial depressions that have filled part of the former channels, these islands being the summits of an old continuous half-submerged mountain chain. At Dawson Island the Chilian government has established settlements, and a Roman Catholic mission has carried on work among the Alakaluf Indians.

Climate.—At Ushuaia ten years' meteorological observations have shown a mean annual temperature of 42.84° F., with a winter mean of 42.2° F., and they confirm the observations of Charles Darwin that tolerably mild winters (as a whole, apart from the extremes of cold already indicated) are followed by cool summers, both seasons being accompanied by overcast skies, constant and sudden changes from calm to a gale. Philip Parker Snow (1855), while living in the same winds (prevailing throughout the year) endangers the navigation of the intricate inland channels. The precipitation during ten years at Ushuaia has been 29.80 inches. Beagle Sound, forming the southern seaward islands, under the influence of the prevalent westerly and south-westerly winds, it is very much heavier, and reaches 59 in. at Staten Island.

Flora.—In the main island of Tierra del Fuego, the low-lying plains with their rich growth of tall herbage are frequented by the rhea, guanaco and other animals common to the adjoining mainland. In the southern and western islands the fauna is restricted mainly to coatis, rats, bats, mice, the sea otter, the penguin and other aquatic birds, and various cetaceans in the surrounding waters.

Inhabitants.—To the three geographical divisions correspond three well-marked ethnical groups—the Onas of the main island, the Yagans (Yahgens) of the south and the Alakalufs of the west. With the settlement of the main island, which is now sometimes called Charles Darwin, having taken place, the Onas of Patagonia, the Onas tribe has become fairly known. Their origin, like that of the other groups, is obscure. Undoubtedly among these Indians are many that recall some Patagonian types; if so, it seems almost as if the same species have been driven, in what they pertain to one of the races that in earlier times existed in Patagonia. Their language is closely allied to that called Old Tehuelche; it is a hard, slow-spoken speech, not at all resembling the soft, rapidly-spoken language of the Yagans, which has many points of similarity with that of the Alakalufs. The isolation of the Onas is peculiarly marked, inasmuch as they are an insular people, living upon the flesh of the guanaco, and using only tussock-roots and wild celery for vegetable food. Their skill in and necessary to the chase influence their whole mode of life; "their moral code is based upon the chase. A man who has not suffered a serious injury to his stock is considered a disgrace, though certain legends are preserved. They have maintained their stock untainted, and have withstood the influence of the white man to a remarkable degree (for example, they use no spiritual drink); their scanty gold has never been subject to any other form of currency, or even to a medium of exchange, but is always kept in a bush or under a rock, 'the food,' they venture naked in small canoes into the treacherous seas; their life is a constant battle with starvation and a rude climate, and their characters have become rude and low in consequence. They have no higher social unit than the family. On the authority of Charles Darwin they have been held by many to be cannibals, but they are not, although those suffering from incurable ailments are sometimes killed for their meat. Although tall and on the Negritos of the eastern hemisphere (4 ft. 10 in. to 5 ft. 4 in.), the Yagans present in some respects a more debased type—characteristic of the same genus—prominent zygomatic arches, large gum lips, flat nose, loose wrinkle on the back of the neck. They have been considered coarse black unskirted hair, and head and chest disproportionately large compared with the extremely slender and outwardly curved body. The Yagans are of considerable size, and have about 30,000 words, although the numerals stop at five, already a compound form, and although the same word expresses both hand and foot. It is argued that it was not a human language in this total are compounds. Comparatively little is known about the Alakalufs. They have a reputation for treachery, and for absurdities on shipwrecked ships. They are hunters both on land and on the water, using the bow and arrow like the Onas, and building canoes often of considerable size.

The aborigines are decreasing rapidly in the whole archipelago, and the Roman Bishop Thomas Bridges, who, as missionary first and then as farmer, resided thirty years there, calculated the population to be 10,000 when he arrived, towards the close of the 19th century it was estimated to be little more than 1000.

Tierra del Fuego was discovered by Fernández de Magellan in 1520, when he sailed through the strait named after him, and called this region the "Land of Fire," either from now extinct volcanic flames, or from the fires kindled by the natives along parts of his course. In 1578 Sir Francis Drake first sighted the point which in 1616 was named Cape Horn (anglicized Horn) by the Dutch navigators Jacob Lemaire and Willem Cornelis Schouten (1615-1617), and which the Dutch navigators A. de Bille (1624) and B. de Lace (1643) circumnavigated the archipelago, which was afterwards visited at intervals by Captain Sir John Narborough (1670), M. de Gennes and the Sieur Friger (1666), Commodore John Byron (1764), Samuel膀 (1768), and Philip Parker Snow (1813-1836). The latter expedition (Voyage of the "Beagle") was accompanied by Charles Darwin, then a young man. To these admirable surveys is due most of the present geographical and historical knowledge of the archipelago. Subsequently the work of exploration was continued by Dumont d'Urville (1837), Charles Wilkes (1839), Parker Snow (1852), various later travellers, a selection of whose works are quoted below, and British, American and Roman Catholic missionaries and settlers.

TIETJENS

democratic joins an the 48', 1812-1814, 1789, Russian American and 1796 1835, the Samuel the K. extracted, government October was 1906 Sir the magnificent Tiffany (Mr. Tiffany) made the of Cleveland. 1812. "1

Made into a decision, Tiffany, the firm having the principal address in London, was 1877), (Stockholm, 1895), xxi.; K. Skottsberg, Vegetationsbilder aus Feuerland, &c., parts iii. and iv. in G. Karsten and J. Schenck's Vegetationsbilder (Jena, 1906); R. Crawshaw, The Birds of Tierra del Fuego (London, 1907).

TIETJENS, THÉRÈSE JOHANNE ALEXANDRA (1831-1877), Hungarian soprano vocalist, was born at Hamburg on the 17th of July 1831. Her voice was trained at Hamburg, where she soon made a success. She left in 1849 as Lucretia Borgia in Donizetti's opera. Thence she proceeded to Frankfort and Vienna. She sang for the first time in London in 1858, appearing as Valentine in Les Huguenots. Her success was so great that for the rest of her life she made England her home, and soon gained as brilliant a reputation in concert and oratorio work as she had already won upon the stage. Her voice was a dramatic soprano of magnificent quality, and her powers as an actress were supreme. Her most famous parts were Fidelio, Medea (in Cherubini's opera) and Donna Anna (in Don Giovanni). She died in London on the 3rd of October 1877, having enjoyed as much success with the English people as much by her private virtues as by her artistic gifts.

TIPPANY, CHARLES LEWIS (1812-1902). American jeweler, was born at Killingly, Connecticut, on the 15th of February 1812. At fifteen he became a clerk in his father's store, but removed to New York City in 1837, and with John B. Young opened a fancy goods store. In 1847 the firm began to manufacture gold jewelry, and in 1858, when the political unrest in Europe caused great depreciation in the price of precious stones, Tiffany invested heavily in diamonds, which were sold at a Test price a few years later. The firm became Tiffany, Young & Ellis in 1851 and was reorganized as Tiffany & Co. (Mr. Young and Mr. Ellis retiring) in 1853. In 1851 the firm had established the sterling silver standard of 925 fine, subsequently adopted by other jewelers; and in the same year had founded a branch house in Paris. In 1858 Tiffany bought the unused portion of the Atlantic telegraph cable which he made into cane handles or sold in sections. At the beginning of the Civil War, foreseeing that the jewelry business would suffer, he turned most of his capital to the manufacture of swords, medals and similar war material. In 1868 the company was incorporated, and branches were established in London and at Genova. Tiffany made a specialty of importing historic gems, jewelry and art works, and in 1857 bought some of the crown jewels of France, paying for them about half a million dollars. He was made a chevalier of the Legion of Honour in 1878. He died in New York on the 18th of February 1902.

TIPPANY, LOUIS COMFORT (1848- ), American artist, son of Charles L. Tiffany, was born in New York City, on the 18th of February 1848. He was a pupil of George Inness and of Samuel Coleman, New York, and of Léon Bailly, Paris. He became a member of the Society of American Artists, 1880, of the National Academy of Design (1880), of the American Water Color Society, and of the Société Nationale des Beaux Arts, Paris. He travelled extensively in Europe, and painted in oil and water-colour, but subsequently devoted himself to decorative glass work. He became president and art director of the Tiffany Glass and Decorating Co., and produced a "Favellite" glass, of unusual beauty of colour.

TIPPANY, a city and the county-seat of Seneca county, Ohio, U.S.A., on the Sandusky river, about 40 m. S.S.E. of Toledo. Pop. (1900, 18,904, of whom 1,804 were foreign born. (Last census), 11,894. Tiffany is served by the Baltimore & Ohio, the Cleveland, Cincinnati, Chicago & St. Louis and the Pennsylvania railways, and by an electric line to Fostoria, about 12 m. west. It is the seat of an Ursuline College for girls, founded in 1863 and incorporated with power to confer degrees in 1878; and of Heidelberg University (Reformed Church), founded in 1859, incorporated as Heidelberg College in 1851 and reincorporated under its present name in 1890. The Heidelberg Theological Seminary was conducted here from 1850 to 1907, not removed to Warrenton. There are a Roman Catholic college and a Norwegian Lutheran College, Collegeville, Pennsylvania, to form the Central Theological Seminary of the Reformed Church in the United States, which in 1908 was removed to Dayton, Ohio. In Tiffin are the St Francis Home (1869), and the National Orphans' Home (1897). The city had 87 factories in 1905, of which 54-2% were owned by individuals, and the value of the factory products was $2,434,502. Tiffin was settled in 1817, incorporated as a town in 1835, and chartered as a city in 1850, when the village of Ft. Balli, on the opposite side of the Sandusky, was consolidated with it. It was named in honour of Edward Tiffin (1766-1829), a native of Carlisle, England, who emigrated to the United States. He graduated at the University of Pennsylvania in 1789, removed in 1796 to Chillicothe, Ohio, where he practised medicine and was a local Methodist preacher. He was speaker of the House of Representatives of the Northwest Territory in 1799, president (1802) of the convention which framed the first constitution of Ohio, the first governor of the state (1803-1807), a Democratic member of the United States Senate in 1807-1809, first commissioner of the United States General Land Office in 1813-1814, and surveyor-general of public lands north-west of the Ohio River in 1814-1829.

TIFLIS, a government of Russian Transcaucasia, occupying the eastern portion of the great valley which stretches between the main Caucasus range and the Armenian highlands, from the Meskes Mountains eastward, and extending up into the higher regions on both north and south. The district of Akhalkalik lies actually on the Armenian highlands. The government is rich in minerals, but only copper is extracted, at Alaverdi and Akhtal; petroleum and other mineral springs are abundant. The government is drained by the Kura and its tributaries (Lyakhka, Aragva, Yora and Alazan), all of whose waters are largely used for irrigation; but in the lower parts of the valley there are extensive waterless steppes, Shirak and Karayaz, on the left bank of the Kura, which are chiefly inhabited by nomad Tatars. The area of the government is 15,601 sq. m. (17,140 with the Zakataly district), and the estimated population in 1906 was 1,681,600. The government is divided into nine districts, the chief towns of which are Tiflis, Akhalkalaki, Akhalkalikh, Dushet, Gori, Signakhi and Telav. Agriculture is the principal occupation. Good soil is produced, especially in the province of Akhalkalak, the Black Sea and the Black Sea bight, and the grains are carried on the steppes. About one-fourth of the area is under forest. The natives exhibit remarkable skill in the manufacture of leather and metallic goods, felt, woollen stuffs (e.g. carpets and shawls) and gold embroidery.

TIFLIS, a town of Russian Caucasus, capital of the government of the same name and of the governor-generalship of Caucasus, picturesquely situated (44° 48' E., 41° 42' N.) at the foot of bare high mountains, on both banks of the river Kura, 300 ft. above the Black Sea. It is connected by rail with Poti and Batum (217 m.) on the Black Sea, with Baku on the Caspian (432 m.), with Kars (187 m.) and Tiflis (189 m.) and Petrovsk, with the railway system of European Russia, which it joins at Beslan, near Vladikavkaz. Omnibuses also run regularly across the main range to Vladikavkaz, which by this route is only 133 m. distant. The best in summer is excessive (mean, 73.4° F.), owing to the confined position; but the surrounding hills (1500 to 2400 ft.) shelter the town effectively from the cold winds of winter (mean, 34.7°). A large square, cathedrals, handsome streets, gardens, bridges, many fine buildings—among them the grand-ducal palace, the opera-house and the museum—mark the seat of an important national university. In the departmental offices, there are evidence of Western civilization. Among the modern public buildings are the Hall of Fame (1885), the Caucasian Museum, a
cathedral of the Catholic Greek Church, and a curiositario museum. The chief of the older edifices is the (Sion) cathedral, which traces back its origin to the 3rd century. Other churches date from the 14th and 15th centuries, the Armenian cathedral of Van from 1480, and the Catholic church from the 14th century. At Tiflis are the Caucasian branch of the Russian Geographical Society, an astronomical and a physical observatory, a botanical garden and museum, and a public library. There are cotton and silk factories, tanneries, soap-works and brick-works. The artisans of Tiflis are renowned as silversmiths, gunsmiths and sword-makers. Tiflis is the chief centre for the export of raw silk and silken goods, raw cotton, cottons, woollens, boots, tobacco, wine, carpets, and dried fruits from Persia and Transcaucasia, while manufactured wares are imported from Russia.

The city has considerably developed, and had in 1897, 160,645 inhabitants, as compared with 104,024 in 1883. They include Georgians, Russians, Germans, Persians and Tatars.

In the old division of Tiflis three distinct towns were included—Tiflis, Kala (the fort) and Isni; subsequently Tiflis seems to have been known as Aulahar. Kala and Isni possessed citadels; that of the former contained the church of St Nicholas and a royal palace; that of the latter the church of the Holy Virgin and the residence of the archimandrite. The town is now divided into Russian quarters: the Russian (the finest of all), the German, the Armenian, and that in which are congregated Jews, Mahomedans and the mass of Orientals.

The Georgian annals put the foundation of Tiflis back to A.D. 379. In the later half of the 5th century the chieftain of Georgia, Wakhlong, Gurgashan, transferred his capital from Mtskhet to the warm springs of Tphlis, where he erected several churches and a fortress. In 570 the Persians took the place and made it the residence of their rulers, but retained it only for ten years. Tiflis suffered successive plunderings and devastations at the hands of the Greeks in 626, of one of the commanders of the Caliph Omar in 731, of the Khazars in 828, and of the Arabs in 851. The Georgians, however, always managed to return to it and to keep it in their permanent possession. In the course of the succeeding centuries Tiflis fell repeatedly into Persian hands; and it was plundered by the Mongol conqueror Tamerlane towards the end of the 14th century. Afterwards the Turks seized it several times, and towards the end of the 17th century the Lesghians attacked it. In 1705, when the shah of Persia plundered Tiflis, Russia sent troops to its protection, and the Russian occupation became permanent in 1799.

Perhaps one of the fullest accounts of Tiflis is contained in Brossot's edition of the Description géographique de la Géorgie (St Petersburg, 1842), by the illegitimate son of Wakhlong VI., king of Georgia (q.v.), who became a pensioner of Peter the Great.

TIGELLINUS, SOPHONIUS, minister and favourite of the emperor Nero, was a native of Agrigentum, of humble origin and possibly of Greek descent. During the reign of Caligula he was banished (A.D. 39) for adultery with the emperor's sisters, but recalled by Claudius (41). Having inherited a fortune, he bought land in Apulia and Calabria and devoted himself to breeding race-horses. In this manner he gained the favour of Nero, whom he aided and abetted in his vices and cruelties. In 63 he was promoted to the pretorship of the praetorian guards. In 64 he made himself notorious for the orgies arranged by him in the Basin of Agrippa, and was suspected of incendiarity in connexion with the great fire, which, after having subsided, broke out afresh in his Aemilian gardens. In 65, during the investigation into the abortive conspiracy of Piso, he and Poppaea formed a kind of imperial privy council. In 67 he accompanied Nero on his tour in Greece. When the emperor's downfall appeared imminent, Tigellinus deserted him, and with Nymphophilus Sabinus brought about the defection of the praetorians. Under Galba he was obliged to give up his command, but managed to save his life by lavishing presents upon Vinius, the favourite of Galba, and his daughter. Otho on his accession (69) determined to remove one so universally detested by the people. While in the baths at Sinussa, Tigellinus received the news that he must die, and, having vainly endeavoured to gain a respite, cut his throat.

TIGELLINUS—TIGER

See Tacitus, Annals, xiv., xv., xvi.; Hist. i. 72; Dio Cassius lix. 23, liii. 13, 15, 27, lixii. 12, 21, lixiv. 3; Suetonius, Galba, 15; Plutarch, Galba, Other; ancient authorities quoted by Mayor on Juvenal, i. 135; B. W. Henderson, Life and Principate of the Emperor NERO (1893).

TIGER (Felis tigris), an animal only rivalled by the lion in size, strength and ferocity among the cat-like beasts of prey (see Carnivora). Almost everything that is stated in the article Lion concerning the structure of the skeleton, teeth and claws of that animal will apply equally well to the tiger, the difference between the two lying mainly in the skin and its coverings. A tiger's skull may, however, always be distinguished from that of a lion by the circumstance that the nasal bones extend higher on the forehead than the maxillae, instead of stopping on nearly the same line. Although examples of both species present considerable variations in size, it is ascertained that the length of the largest-sized Bengal tiger may exceed that of any lion. Much larger specimens are recorded, but 10 feet from the tip of the nose to the end of the tail is no unusual length for a large male tiger. The female is somewhat smaller and has a lighter and narrower head. The tiger has no mane, but in old males the hair on the cheeks is rather long and spreading. The ground-colour of the upper and outer parts of the head, body, limbs and tail is bright rufous fawn; and these parts are beautifully marked with transverse stripes of a dark, almost black colour. The markings vary much in different individuals, and even on the two sides of the same individual. The under-parts of the body, the inside of the limbs, the cheeks and a large spot over each eye are nearly white. The tigers which inhabit hotter regions, as Bengal and the south Asiatic islands, have shorter and smoother hair, and are more richly coloured and distinctly striped than those of northern China and Siberia, in which the fur is longer, softer and lighter-coloured. The Siberian tiger is F. tigris mongolica, and the Persian F. tigris virga. Black and white phases have been recorded, but they are rare. The tiger is exclusively Asiatic, but has a very wide range in that continent, having been found in almost all suitable localities south of a line drawn from the river Euphrates, passing along the southern shores of the Caspian and Sea of Aral by Lake Balkal to the Sea of Okhotsk. Its most northern range is the territory of the Amur, its most southern the islands of Sumatra, Java and BAli. Westward it reaches to Turkish Georgia and eastward to the island of Sakhalin. It is absent, however, from the great elevated plateau of Central Asia, nor does it inhabit Ceylon, Borneo or the other islands of the Indo-Malay Archipelago, except those named. The principal food of the tiger in India is cattle, deer, wild hog and peafowl, and occasionally human beings. The regular "man-eater" is generally an old tiger whose vigour is past, and whose teeth are worn and defective; it takes up its abode in
the neighbourhood of a village, the population of which it finds an easier prey than wild animals. Though chiefly affecting grassy plains or swamps, tigers are also found in forests, and seem to be fond of haunting the neighbourhood of old ruins. As a rule, they do not climb trees; but when pressed by fear, or during an inundation, they have been known to do so. They take to the water readily and are good swimmers. The tigers of the Sundarbans (Ganges delta) continually swim from one island to the other to change their hunting grounds for deer. The following extract from Sir J. Fayer's "Royal Tiger of Bengal" (1875) may complete this notice of the tiger's habits.

The Tigress gives birth to from two to five, even six cubs; but three is a frequent number. She is most affectionate and attached to her young, and will defend her cubs against her youth with the most watchful solicitude. They remain with her until nearly full-grown, or about the second year, when they are able to kill for themselves and look after their own food. As soon as they begin to require other food than her milk, she kills for them, teaching them to do so for themselves by practising on small animals, such as deer and young pigs. When they are about three years old and have become too large for her to carry them, and are too strong to be held, they are driven away from her. The young tigers are more destructive than the old. They will kill three or four cubs at a time, while the older and more experienced rarely kill more than one, and this at intervals of from three or four days to a week. For this purpose the tiger will leave its retreat in the dense jungle, proceed to the neighbourhood of a village or gowrie, where cattle feed, and during the night steal on and strike down a bullock, drag it into a secluded place, and then remain near the "murrie" or "kill," for several days, until it has eaten it, when it will proceed in search of a further supply, and, having found good hunting ground in the vicinity of a village or in the course of its rovages, will devour one or two cows or buffaloes a week. It is very fond of the ordinary domestic cattle, which in the plains of India are generally weak, half-starved, undersized creatures. One of these is easily struck down and carried or dragged off. The smaller buffaloes are also easily disposed of, but the buffalo bulls, and especially the wild ones, are formidable antagonists, and have often been known to beat the tiger off, and even to wound him seriously. (W. H. F.; R. L. *)

TIGER-CAT, typically *Felis tigrina*, an American wild cat ranging from Mexico, on the east of the Andes to Paraguay and the central forest region of Argentina. Together the head and body measure something over 30 in., of which the tail counts for a third. The fur is grizzly grey, with black spots that do not form chains. The name is also applied to the Ocelot (*P. tigrina*), and often used of any small striped or spotted wild cat, either from the western or eastern hemisphere.

TIGER-FLOWER, known botanically as *Tigridia*, a genus of bulbous plants (natural order Iridaceae), native in Mexico, Central America, Peru and Chile. They have long narrow plicate-veined leaves springing from the bulb and a stem bearing two or three scattered smaller leaves and above a few flowers emerging from a spathe. The flowers are spotted (whence the name tiger-flower or tiger-iris) and have free segments springing from a tube; the three large outer segments are concavely spreading, the three inner are much smaller and more erect. *T. pavonia* (Flower of Tigris) has large flowers with a golden orange, white or yellow ground colour.

TIGHE, MARY (1772-1816), Irish poet, daughter of the Rev. William Tighe, who was born on the 9th of October 1772. In 1793 she contracted what proved to be an unhappy marriage with her cousin, Henry Tighe, of Woodstock, Co. Wicklow. She died on the 24th of March 1810, at Woodstock, Co. Kilkenny, and was buried at Inistioge. Mrs Tighe was the author of a poem of unusual merit, *Psyche or the Legend of Love*, printed privately in 1803 and published posthumously in 1811 with some other poems. It is founded on the story as told by Apuleius, and is written in the Spenserian stanza. The poem had many admirers, and high praise is awarded it in a contemporary notice in the *Quarterly Review* (May 1811).

TIGLATH-PILESER I, the son of Assur-ris-isi, ascended the throne c. 1120 B.C., and was one of the greatest of Assyrian conquerors. His first campaign was against the Moschi who had occupied certain Assyrian districts on the Upper Euphrates; then he overran Commagen and eastern Cappadocia, and drove the Hittites from the Assyrian province of Subharti north-east of Malatia. In a subsequent campaign the Assyrian forces penetrated into the Kurdish mountains south of Lake Van and then turned westward, Malatia submitting to the invader. In his fifth year Tiglath-Pilesar attacked Comana in Cappadocia, and placed a record of his victories engraved on copper plates in a fortress he built to secure his Cilician conquests. The Aramaeans of north Syria were the next to be attacked, and he thrice made his way as far as the sources of the Tigris. The command of the high road to the Mediterranean was secured by the possession of Cilicia and Pamphylia. Tiglath-Pilesar crossed the Tigris, and held the fortress of Birt Marduk, by which he compelled his enemy to submit. In the following year the Assyrians penetrated into the Syrian states, and compelled the kings of Damascus and Arpad to surrender. Tiglath-Pilesar then turned south to Tarsus, and was called to Damascus by a message from the King of Arpad, and the party who had fled thither from the Assyrian invaders. In the fall of this year Tiglath-Pilesar died, and was succeeded by his son Esarhaddon.

TIGLATH-PILESER II, or III., son of Hadad-nirari II., appears to have reigned from about 930 to 930 B.C., but nothing is known about him.

TIGLATH-PILESER III. or IV., was a successful general who was over the Assyrian throne on the 73th of Lykar 745 B.C., after the fall of the older dynasty, and changed his name of Pulu to that of the famous conqueror of earlier times. In Babylonia, however, he continued to be known as Pulu. He was a man of great ability, both military and administrative, and initiated a new system of policy in Assyria which he aimed at making the head of a centralized empire, bound together by a bureaucracy who derived their power from the king. The empire was supported by a standing army and an elaborate system of finance. The first task of Tiglath-Pilesar was to reduce the Aramaean tribes to order, and so win the gratitude of the Babylonian town of Nisibin. The army at the junction of the Euphrates and the Tigris was thereby sent to the eastern frontiers of the kingdom by a campaign which extended into the remotest parts of Media. Next came the defeat of a northern coalition headed by Sar-duris of Ararat, no fewer than 72,050 of the enemy being captured along with the city of Arpad, where the Assyrian king received the homage of various Syrian princes. Arpad revolted soon afterwards, but after a siege was taken in 740 B.C. The following year Azariah of Judah appears among the enemies of Tiglath-Pilesar, who had overthrown his Hamathite allies and annexed the nineteen districts of Hamath. The conquered peoples were now transported to distant parts of the empire. In 737 B.C. Tiglath-Pilesar again marched into Media, and in 735 he invaded Ararat and wasted the country round the capital Van to a distance of 450 miles. In 734 B.C. he was called to the help of Yahu-khaz (Ahaz) of Judah, who had been attacked by Pekah of Israel and Rezon (Rasun) of Damascus. Rezon, defeated in battle, fled to his capital which was at once invested by the Assyrians, while with another portion of his army Tiglath-Pilesar ravaged Syria and overran the kingdom of Samaria. Ammon, Moab, Edom and the queen of Sheba sent tribute, and Teima in northern Arabia was prized by the Assyrian troops. In 732 B.C. Damascus fell; Rezon was put to death, and an Assyrian viceroy appointed in his stead. Tyre also was made tributary. The next year Tiglath-Pilesar entered Babylonia, but it was not until 729 B.C. that the Chaldaean prince Uzin-zer (Chinzirus) was driven from Babylon and Tiglath-Pilesar acknowledged as its legitimate ruler. In the early part of Tebet 727 B.C. he died, after having built two palaces, one at Nineveh, the other at Calah.

See P. Rost, *Die Keilschrifttexte Tigl-Pileser III. (1893)*; also *Babylonia and Assyria, § v. History* ("Second Assyrian Empire"); and authorities quoted in § viii. Chronology.
TIGRANES—TIGRIS

TIGRANES, or Dikran, king of Armenia (c. 95-52 B.C.). Armenia had by the conquests of Alexander the Great become a province of the Macedonian Empire; but it was never thoroughly subjected to the foreign rule. A Persian family, that of Hydarnes, one of the associates of Darius Hystaspis, which possessed large domains in Armenia and had been invested with the satrapy for several generations, was dominant in the country, and assumed the royal title in defiance of the Seleucids. Antiochus III. The Great put an end to this dynasty (about 212 B.C. and divided the kingdom between his two grandsons, testing their loyalty and ability to govern. Later, he subdivided it among his younger sons, and assumed the title of king of kings. The new king was subjected to a number of Persian origin, the district of Sophene in the west (on the Euphrates and the sources of the Tigris) to Zariades, the eastern part, called Armenia Major (round the lake of Van) to Artaxias. After the battle of Magnesia (190) both remained independent; Artaxias conquered the valley of the Araxes, where he founded his new capital Artaxata ("town of Artaxias," said to be built by the advice of Hannibal, Strabo xii. 528; Plut. Lec. 37). He was defeated and taken prisoner by Antiochus IV. Epiphanes in 165 (Appian, Syr. 45, 66), but soon became independent again in the troubles of Mithradates, his death (cf. Diod. xxi. 274); and his successors extended their power even farther against Media and the districts on the Kur. But from 140 the Parthians became the dominant power east of the Tigris. King Artavasdes of Armenia was attacked by Mithradates II. The Great about 105 B.C. (Justin xii. 2). He had to give his son Tigranes (b. 140 B.C. according to Lucian, Macrobr. 15; by Appian, Syr. 48, he is called "son of Tigranes"); if that is correct, he probably was the nephew of Artavasdes) as hostage to the Parthians, and he obtained his freedom only by ceding seventy valleys bordering on Media (Strabo xi. 524 cf. xvii. 321). During his first war with Rome, Mithradates was supported by Tigranes, although he abstained from interfering openly. But he meanwhile began war with the Parthians, whose empire was weakened after the death of Mithradates II. (about 88) by internal dissensions and invasions of the Scythians. Tigranes reconquered the valleys which he had ceded, and laid waste a great part of Media, down to Ecbatana (Isidor. Charac. 6), and the districts of Nineveh and Arbela; the kings of Artaxata, Gordyene (the country of the Carduchi, now Bohtan), Ardabene (the former Assyria) and Orsoene (Edessa) became his vassals, who attended him like slaves wherever he went; northern Mesopotamia also was taken from the Parthian Empire (Strabo xi. 529, 747; Plut. Lec. 32). In 83 he invaded Syria, defeated the last successors of Seleucus and occupied Cilicia, of which the eastern parts still belonged to the Seleucids (Justin xi. 13; Appian, Syr. 48; Plut. Lec. 14, 21). In 81 he was in battle with Mithradates and Sulla and he did not interfere, but after the death of Sulla (78) he occupied Cappadocia again and expelled King Ariobarzanes I., the vassal of the Romans (Appian, Mihr. 67; Strabo xii. 539). During the next years wars are mentioned in Syria, when the princes Cleopatra Selene attempted to establishe herself in the Seleucid rule, but was besieged in Acco and afterwards killed (Joseph. Ant. xiii. 16, 4; Strabo xvi. 749), and in Cilicia, where he destroyed the Greek town of Soli (Plut. Pompeu. 28; Dio Cass. xvi. 37). Tigranes now had become "king of kings" and the mightiest monarch of Asia. So he built a new royal city, Tigranocerta, on the borders of Armenia and Mesopotamia, between Mt. Masius and the Tigris, where he accumulated all his wealth and to which he transplanted the inhabitants of twelve Greek towns of Cappadocia, Cilicia and Syria (Plut. Lec. 21, 26; Appian, Mihr. 67; Strabo xi. 522, 532, 539; Plin. vi. 26 seq.; for the situation, which is much disputed, cf. Tac. Ann. xiv. 24, xv. 5, ed. Furneaux). He also transplanted many Arabic tribes into Mesopotamia (Plut. Lec. 21; Plin. vi. 142). But the Romans could not tolerate encroachment upon their sphere of power, and in 69 Lucullus invaded Armenia. Tigranes was beaten at Tigranocerta on the 6th of October 69, and again near Artaxata in September 68. The recall of Lucullus gave some respite to the two kings, who even invaded Asia Minor again. But meanwhile a son of Tigranes and Cleopatra, called Tigranes, like his father, rebelled against him (as the old man had already killed two of his sons, he had reason enough to be afraid for his life) and found refuge with the Parthian king Phraates III., whose daughter he married and who sent him back with an army (Appian, Mihr. 104; Plut. Pompeu. 33; Dio Cass. xxxvi. 21). The old king now gave up all hope of resistance; he put a price on the head of Mithradates, and when Pompey advanced into Armenia and united with the younger Tigranes, he surrendered himself to the Roman general (66 n.c.). Pompey now changed his policy; he received the old Tigranes graciously and gave him back his diadem, while he treated the son very coolly and soon made him prisoner. The younger Tigranes was led in triumph into Rome, where he found his death when he tried to escape from his confinement by the intrigues of P. Clodius in 58 (Dio Cass. 38, 30). The father after his defeat ruled about ten years longer over Armenia, as vassal of the Romans. He died about 56, and was succeeded by his son Artavasdes. (See also Mithra- datcs.)

TIGRIS, a northern province of Abyssinia; one of the principal divisions of the country, the others being Amhara or Gondar in the centre and Shoah in the south. The seat of power of Tigris has been often a more powerful potentate than the nominal emperor. Tigris contains the town of Axum (q.v.), capital of the ancient Ethiopic Empire. Adua (Adowa, q.v.) is the capital of the province. (See Abyssinia.)

Tigrina, the dialect spoken in Tigré and Lasta, is nearer the ancient Geez than is Amharic, the official and more widely diffused language of Abyssinia. See J. Schröber, Manuel de la langue tigris (Vienne, 1887-1893); and L. de Vito, Grammatica della lingua tigrina (Rome, 1895).

TIGRIS (Old Persian Tigr, Diklat of the cuneiform inscriptions, Hiddekel of the Old Testament, Diglath of the Targum, Digla of the Arabs), a great river of western Asia, rising from two principal sources. The more western of these is about 15 m. S. of Lake Uegulik (Cholchis of the ancients), at an altitude of 550 ft., some 2 or 3 m. only from the channel of the Euphrates, which here forms a peninsula by a great bend (38° 40' N., approximately 30° 20' E.). The eastern source, which joins the main stream at Til (37° 45' N., 41° 46' E.), is itself divided into two branches, or rather it may be said to consist of a network of small streams, the most northerly of which has its origin in about 38° 40' N. to the west of Lake Van, and close to the headwaters of the Murad Su, the eastern branch of the Euphrates, where the most easterly point is situated in a region about 42° 30' E., southward of the same lake. The two sources together drain the region south as the Euphrates drains the region north of the Taurus mountains. After the junction of the two branches the river pursues a winding course, generally south-east, for about 800 m. to the point of union with the Euphrates at Garmat Ali, whence it is known as the Shatt-el-Arab until it emptied into the Persian Gulf some 70 m. lower down. For some five or six centuries before 1908-1909 the junction with the Euphrates was at Kokan, some 70 m. to the west of Garmat Ali. On the western side there are no tributaries at the present day. As late as 1858, however, the Arabian geographers mention a tributary, the Tharthar, navigable in flood time, which flowed from the Jahgah branch of the Khabur, a tributary of the Euphrates, to the Tigris. Ormsby, in 1853, also reported a river, the Asas Amir, as coming down from the Sinjar hills and joining the Tigris near Kal-iat Shergat, about 35° 30' N.; but this seems now to be a dry bed. On the eastern side of the river, on the other hand, there are several important tributaries descending from the Persian
mountains; the Kabur, a little north of 37° N., navigable for rafts; the Great Zab, at 36° N., just below Nimrud, the ancient Calah; the Little Zab, about 35° 15' N.; the 'Adhem at 34° N. and the very large and important Diyalu, a little below Bagdad, at 33° 15' N.

The course of the Tigris is much shorter than that of the Euphrates, about 1,500 m., as compared with 1,800 m., but its volume of water is greater, at least in its lower course. At Bagdad it has an average breadth of about 200 yards and a current in flood time of about 41 ft. per sec., navigable for almost all kinds of boats except above the mouth of the Great Zab, about 30 m. south of Mosul, at which point navigation is blocked by two ancient dams, erected, apparently, to control the river for the Assyrian city of Calah, the ruins of which are still visible and which they conceive to be the work of that mythical hero. Were it not for these dam steemers might reach Mosul itself, at an elevation of 345 ft. above the Persian Gulf. All the great lines of communication of the English and Turkish, furnish an inadequate service between Basra and Bagdad, but there is no steam navigation on the river above the latter city. Small sailing craft navigate upwards as far as Samarra; above this all navigation is downward, and by raft. For rafts the river is navigable from Diarbekir and is termed by the natives "the cheap camelier." The rafts used are the so-called keelless, of wood supported on inflated skins, which are broken up at Bagdad, the wood sold and the skins carried back by caravans.

Near the source of the Tigris, at Arghanna-Ma'den, are copper mines, and at Hamshahr is a large iron. Bagdad and its vicinity are important for some distance, occur sulphurous and bituminous springs. There are also in that neighbourhood famous marble quarries. This part of the river's course, the ancient Assyria, is also a rich agricultural region.

From a little above the confluence of the Great Zab downward, the banks of the river are absolutely uninhabited, and the river flows through a desert until Tekr is reached. Beginning shortly below Tekrit there are indications of considerable civilization, both for the purpose of irrigating country remote from the river, and also for shortening the course of the river for navigation. In ancient times the country on both sides of the river was occupied by tribes so situated below this point, the waters of the Tigris were under thorough control, and it and its lower tributaries, the 'Adhem and the Diyalu, were made, by means of huge canals, to furnish great water-ways for commerce. While it and its smaller branches flow through the maritime plains of the Persian Gulf, and these canals are the best known, and probably the greatest, was the Nahrawan, which, leaving the Tigris, on its eastern side, above Samarra, over 100 m. north of Bagdad, rejoined it below Kut-el-Amarah, equal distance to the south. None of these canals is serviceable at the present time, and few carry water in any part of their course, even in flood time.

A little south of Samarra the stony plateau of Mesopotamia ends, and the alluvial plain of Irak, ancient Babylonia, begins. Here the palm groves begin also, and from this point on is a little beyond Bagdad the shores of the river are well cultivated. At the point just above Bagdad the Tigris seems to have lost the maritime face and bed of the river, and be lower than that of the Euphrates, so that the canals run from the latter to the former stream. At Bagdad the Tigris and Euphrates are less than 35 m. apart, then they run side by side, the Tigris being eastward of and a little north of the Euphrates; at Shat-el-Hai they are separated by almost 100 m. From Bagdad downward, the course of the Tigris is peculiarly serene and shifting. The mud brought down by it, estimated to 7190 lb. an hour at Bagdad, is not deposited in marshes to form alluvium, as in the case of the Euphrates, but although in flood time the river becomes at places an inland sea, rendering navigation extremely difficult and uncertain, the bulk of the mud is deposited in banks, shoals and islands in the stream of the river, and is finally carried out into the Persian Gulf. At Kut-el-Amarah, approximately half way from Bagdad to Korna, the bed of the Tigris is higher than that of the Euphrates, and according from the former to the latter, its waters flow into the Euphrates and not vice versa.

Shortly below Kut-el-Amarah all traces of ancient canalization on the Tigris are lost; it would appear as though the great plain of the region, now largely under water at flood time, constituted an inland sea. On the west side, however, there are the remains of some canals or channels, some still carrying water, one of which, the Shat-el-Hai, is said to have been navigable for munitions during the Tigris at Kut-el-Amarah, and emptying into the Euphrates at Nasireh, is still navigable. Indeed, in the time of the caliphate this was the channel of the Tigris, and on its banks stood the important city of Aiwa, much more recently the great city of Lagash stood by on its banks. In the time of the Sasanian kings, however, as at the present time, the Tigris occupied a more easterly course. Indeed, the lower course of the Tigris, leaving the Tigris at Kut-el-Amarah, and emptying into the Euphrates at Nasireh, has been subject to change. Below the Shatt-el-Hai the country on both sides of the river is practically a swamp, except where the palm groves have formed land.

The Tigris begins to rise about the middle of November and is highest in May and June, and lowest in September and October. The principal towns on its banks are Diarbekir (anc. Amida), on the western branch; Bitlis, on the eastern branch; Mosul; Tekrit, a town dating from Persian days, said to have been founded by Shapur I. son of Ardashir I., formerly important, but now relatively insignificant; Samarra, also called Samira, the capital of the caliphate from A.D. 827 to 892, a place of pilgrimage of the Shia Moslems, containing magnificent tombs of two of their Imams the tenth and eleventh, with another much venerated shrine of the twelfth, as well as some interesting ruins; and Bagdad. While the Tigris never played the same rôle historically as the Euphrates, numerous remains of antiquity are to be seen along its course. Cuneiform inscriptions and bas-reliefs have been found at the sources of both the western and eastern Tigris, as well as at various points on the cliffs along the upper course of both branches. Opposite Mosul are the ruins of ancient Nineveh, the last capital of Assyria, and 20 m. below that the ruins of Calah, the second capital; while 35 m. farther south, on the opposite bank, lies Kal'at-Shergat, the ancient Assur, the original name-place and capital of the Assyrian Empire. A little south of Samarra are found remains of the Median Wall, which stretched south-west towards the Euphrates near Sahlawych, marking the edge of the Babylonian alluvial plain. In this neighbourhood also stood the ancient Opis. At Bagdad, besides the memorials of the caliphate, may be seen a few remains of the old Babylonian city of Bagdadu, and a dozen miles southward, on the eastern bank of the river, stands Tukah, the modern town of Teesup, the two are connected by a causeway that recedes in a river, on the lowest part of the river, the low mound remains of ancient Seleucia.

TILBURG, a town in the province of north Brabant, Holland, and a junction station 13½ m. by rail E. by S. of Breda. A steam tramway connects it northwards with Waalwijk. Pop. (1905), 49,317. Tilburg has risen into importance since the separation of Belgium from Holland as one of the chief industrial centres of the south. It has Roman Catholic and Protestant churches, a synagogue, a cloth hall, a higher-burgher school, an art and music school, and a Roman Catholic seminary. The woollen manufacture is the chief industry, besides which there are leather, soap, oil and tobacco factories, as well as breweries, tanneries and iron foundries.

TILBURY DOCKS, on the north shore of the Thames, in the county of Essex, England. They lie opposite Gravesend 25 m. below London Bridge and about the same distance from the Nore, being thus within the port of London. They were constructed by the South Essex and Thames Iron Works Company, and were later owned by the London & India Docks Company. The docks are four in number, having, with tidal basin and entrance locks, a total area of 74 acres. The depth of water in the tidal basin is 25 ft. at low tide and 44 ft. at high tide. The length of quayage is about 2½ m., and there is extensive warehousing as well as accommodation for passengers, as the largest passenger steamers trading with the Port of London lie here. Railway communication is provided by the London, Tilbury & Southend line, and there is direct connexion for goods traffic with all the northern lines.

TILDEN, SAMUEL JONES (1814–1886), American statesman, was born at New Lebanon, New York, on the 9th of February 1814. In 1834 he entered Yale University, but soon withdrew on account of ill health, and later studied in the University of the City of New York. He was admitted to the bar in 1841, and rose rapidly to the front rank. In the financial troubles between 1850 and 1860 it is said that more than half the railways north of the Ohio river and between the Hudson and the Missouri rivers were at some time his clients. In spite of his activity at the bar, Tilden maintained an interest in politics, serving in the State legislature in 1846 and in the state constitutional conventions of 1846 and 1867. In 1848, largely on account of his personal attachment to Martin Van Buren, he participated in the revolt
of the "Barnburner" or free-soil faction of the New York Democrats, and in 1855 was the candidate of the "softshell," or anti-slavery, faction for attorney-general of the state. During the Civil War, although he opposed several of the war measures of President Lincoln's administration, he gave the Union cause his heartfelt support. In 1866 Tilden became chairman of the Democratic state committee, and soon came into conflict with the notorious "Tweed ring" of New York City. As the "ring" could be destroyed only by removing the corrupt judges who were its tools, Tilden, after entering the Assembly in 1872 to promote the cause of reform, took a leading part in their impeachment. By analysing the bank accounts of certain members of the "ring," he obtained legal proof of the principle on which the spoils had been divided. His fame as a reformer brought him to the governor's chair in 1874, and he at once gave his attention to a second set of plunderers—the "canal ring," made up of members of both parties who had been systematically robbing the state through the maladministration of its canals—and succeeded in breaking them up. In 1876 the Democrats nominated him for the presidency, the Republicans nominating Rutherford B. Hayes of Ohio. The result was the disputed election of 1876, when two sets of returns were sent to Washington from the states of Florida, Louisiana, South Carolina and Oregon. As the Federal Constitution contained no provision for settling a dispute of this kind the two houses of Congress agreed to the appointment of an extra-constitutional body, the "Electoral Commission" (q.v.) which decided all the contests in favour of the Republican candidates. Tilden counselled his followers to abide quietly by the result. In 1878 the New York Tribune (Republican) published a series of telegraphic despatches in cipher, accompanied by translations, by which it attempted to prove that during the crisis following the election Tilden had been negotiating for the purchase of the electoral votes of South Carolina and Florida. Tilden denied emphatically all knowledge of such despatches, and appeared voluntarily before a Congressional sub-committee in New York City to clear himself of the charge. The attempts to implicate him in corrupt transactions were not successful; but his political opponents endeavoured to make capital in subsequent campaigns, out of the "Cipher Despatches." The remainder of his life was spent in retirement at his country home, Greystone, near Yonkers, New York, where he died on the 4th of August 1886. Of his fortune (estimated at $5,000,000) approximately $4,000,000 was bequeathed for the establishment and maintenance of a "free public library and reading-room in the City of New York"; but, as the will was successfully contested by relatives, only about $2,000,000 of the bequest was applied to its original purpose; in 1893 the Tilden Trust was combined with the Astor and Lenox libraries to form the New York Public Library.

Tilden (2 vols., New York, 1908), both edited by John Bigelow; also Bigelow's Life of Samuel J. Tilden (2 vols., New York, 1895); and E. Haworth's The Hayes-Tilden Disputed Presidential Election of 1876 (Cleveland, 1906).

TILE (O. Eng. tile, Fr. tuile, connected with Lat. tegula), the name given to flat slabs of baked clay or other material used for a great variety of architectural purposes, such as covering roofs, floors and walls.

1. Roofing Tiles. In the most important temples of ancient Greece the roof was covered with tiles of white marble, fitted together in the most perfect way so as to exclude the rain. In most cases as in the Athenian Parthenon and the existing temple of Aegina the tiles were large slabs of marble, with a flange along each side over which joint tiles (αργυρία) were accurately fitted (see A. in fig. 1). In the temple of Apollo at Bassae, though the main building was of limestone, the roof was covered with very beautiful tiles of Parian marble, which are especially mentioned by Pausanias as being one of the chief beauties of the temple. Some of these were found by Mr Cockerell during his excavations at Bassae early in the 19th century. In design they resemble the other examples mentioned above, but are peculiar in having a joint piece worked out of the same slab of marble as the adjacent tiles (see B in fig. 1) at great additional cost of material and labour, in order to secure a more perfect fit. Fig. 2 shows the

1 In Egypt and Assyria temples and palaces were mostly roofed with stone, while inferior buildings had flat roofs covered with beaten clay (see also Terra Cotta).
3 Marble tiles are said to have been first made by Byzas of Naxos about 620 B.C.; see Pausanias v. 10, 2.
TILE

edge of the next tile and the joints were covered with a semi-circular joint tile (imbrex). Rows of terra-cotta antefixae were set along the eaves of the roof, and were often moulded with very beautiful reliefs. In localities which supply laminated stone, such as Gloucestershire and Hampshire in Britain, the Romans often roofed their buildings with stone tiles fastened

brick-clay exists. In some places pan-tiles are still used and have a very picturesque effect; but they are liable to let in the rain, as they cannot be securely nailed or well bedded in mortar. In Gloucestershire, Yorkshire, north-east Lancashire and other counties of England, stone tiles are still employed, but are rapidly going out of use, as they require very strong roof timbers to support them, and the great extension of railways has made the common purple slates cheap in nearly every district. The green slates of the Lake District are now extensively used for this purpose, often with excellent effect.

Some of the mosques and palaces of Persia are roofed with the most magnificent, enamelled, lustred tiles, decorated with elaborate painting, so that they shine like gold in the sun. They were specially used from the 13th century to the 18th. In style and manufacture the finest of them resemble the frieze shown in fig. 5.

2. Wall Tiles.—These are partly described under MURAL DECORATION (p. 446). In most oriental countries tiles were used in the most magnificent way throughout the middle ages especially in Constantinople, Broussa, Damascus, Cairo, Moorish Spain, and in the chief towns of Persia. Fig. 4 shows a fine example from a mosque in Damascus. From the 11th to the 16th century a special kind of lustred tiles was largely employed for dadoes, friezes and other wall surfaces, being frequently made in large slabs, modelled boldly in relief with sentences from sacred books or the names and dates of reigning caliphs. The whole was picked out in various, usually dark or turquoise blue, on a ground of cream-white enamel, and in the last firing minute ornaments in copper lustre were added over the whole design, giving the utmost splendour of effect (see fig. 5). Great skill and taste are shown by the way in which the delicate painted enrichments are made to contrast with the bold decoration in relief. These lustred tiles sometimes line the prayer-niche in houses and mosques; in such cases the slabs usually have a conventional representation of the kaaba at Mecca, with a lamp hanging in front of it and a border of sentences from the Koran. The mosques of Persia are specially rich in this method of decoration.

The Victoria and Albert Museum, London, contains many fine examples of the early as well as of the later sorts, like those shown in fig. 4.
magnificent examples existing at Natenz, Seljuk, Tabriz, Isfahan and other places. Indian tile-work is specially described in the article KASHMIR.

Stamped Spanish tile decoration in its earliest form was an imitation of mosaic, whereof enameled tile of various colors being arranged in geometrical patterns, or combined with glass or stone for the purpose. In the 14th and 15th centuries this process was supplanted by one in which the variously shaped and colored sections of tile were separated by means of narrow bands of the same material, enameled in white and disposed in various combinations of geometrical interlacing. Of this kind are the bulk of the Alhambra tiles. But the tediousness of the process gave rise, about 1450, to what is known as the cuerda seca (or "dry cord") method, in which narrow fillets at the edges of the separating interlacings were first stamped. After the tiles were fired, these being fired (thus forming a "dry cord" or line) formed shallow compartments which were in turn filled with colored enamel, white being used for the interlacings themselves. The process was much in vogue in Andalusia and Castile until about 1550, when there arose the method de cuenca in which the parts of the design to receive different coloured enamels were stamped, slightly concave (cuenca—a bowl or socket), their edges alone being left in relief. This process lasted until about the commencement of the 18th century.

At Manises, Paterna and elsewhere in Valencia, soon after the middle of the 14th century there commenced an extensive production of white enameled tiles painted with designs in blue (more rarely in lustre and manganese) for wall and pavement decoration. This manufacture continued throughout the 15th century and produced some of the finest freestanding tile designs that are known to-day. The motifs included figure compositions, animals, plants, coats of arms, &c., drawn with great skill and facility. Most of these tiles are to be found in old houses in the city and province of Valencia.

In Catalonia, in the 16th century, blue and white painted tiles were produced in imitation of those of Valencia. For the most highly finished of these stencils were employed to block out the designs. Polychrome painting upon tiles in the Italian manner was introduced into Spain by Niculoso Francisco of Pisa, who settled at Seville (1503-1508) and executed altar-pieces and architectural details in tile work. This imported Italian style was much affected for armorial decoration.

In the 16th and 17th centuries tiles of a coarse kind of majolica were used for wall decoration in southern Spain; some rich examples still exist at Seville. These were the work of Italian potters who had settled in Spain.

J. de Osma, Apuntes sobre cerámica morisca: textos y documentos valencianos, No. 1 (1906), and Los Letreros ornamentales en la cerámica morisca del siglo XV, in the review Cultura española, No. II., 1906); J. Font y Guma, Rijolos valencianos y catalanas (1905); J. Gestoso y Perez, Historia de los barro virdiados sevillanos (1904).

3. Floor Tiles.—After the development of painted and lustred tiles in Spain and Italy for the decoration of wall surfaces, they were also introduced, during the latter part of the 15th and the first part of the 16th centuries, as pavements, especially in the chapels of the famous cathedrals of those countries. Comparatively few examples of these pavements now exist, as the majolica enamel was too soft to stand the wear of the feet of worshippers. The earliest known pavement of this type is that in the church of San Giovanna Carbonara in Naples, which is dated, approximately, 1440. The tiles, square and hexagonal in shape, are coated with white enamel and are painted chiefly in dark blue, with touches of green and purple. The British Museum, the Louvre and other museums have secured odd examples of these tiles. It seems probable from the technical methods of the work that it was produced by a Spanish or even a Moorish hand. It is well known that Moorish tile-makers did travel both into Italy and into France to embellish the palaces of great nobles or the chapels they founded. There is the well-known instance of the Moorish potter, Jean de Valence, who, in 1354, was brought to France by Jean de Berry to make tiles for the adornment of his ducal palace at Poitiers. One of the most important of these early majolica pavements is that made for the Convent of San Paolo at Parma, now in the museum of that town, which was probably laid down in 1482. One of the south chapels in the church of S. Maria del Popolo in Rome has a very fine pavement of painted tiles, executed probably at Forli, about 1460, for Cardinal della Rovere (Julius II.), whose arms—a oak tree—are repeated over and over again among the rich decorations. A still more magnificent tile floor, in the uppermost of Raphael's Vatican loggie, is mentioned in the article DELLA ROBBIA, where also are described the exquisite, enameled tiles which Luca della Robbia made as a border for the tomb of Bishop Federighi at Fiesole near Florence. Fine examples of tile pavements of 1486 exist in the basilica of S. Petronio at Bologna. The chapel of St Catherine at Siena and the church of S. Sebastiano at Venice have majolica pavements of about 1510. Fig. 6 shows an example of about this date from

**Fig. 6.—Majolica Paving Tiles from Siena, made in 1509.**

The Petrucci Palace in Siena, now in the Victoria and Albert Museum. In the early part of the 16th century majolica tiles from Spain were occasionally imported into England. At the south-east of the mayor's chapel at Bristol there exists, though much worn, a fine pavement of Spanish tiles dating from about 1520. Others have been found in London, at Newington Butts, and in other places.

Long before the southern nations of Europe were introducing their painted majolica tile pavements, a much more practical type of flooring tile was in use in Germany, France and England; of these the English encaustic tile pavements, dating from the early years of the 13th century to the end of the 16th century, are particularly important and beautiful. These Northern peoples had no knowledge of enamels and colours such as was possessed by the contemporary tile-makers of Moorish Spain or of Italy, and they were confined to the native red-brick earths and white pipeclays for their materials. The method of decoration was as simple and homely as the materials. Slabs of ordinary red-brick clay freed from pebbles, but not from grit or sand, were shaped by pressing cakes of clay into a mould of wood or baked clay, carved in such fashion that when the clay was just hard and dry enough to be removed from the mould the important elements of the design were formed as sunk cells divided by broad raised outlines. While this red tile was still soft and plastic, a thickish paste of pipeclay or other light-burning clay was poured into the cells and allowed to stiffen.
When the whole had dried sufficiently the surface was scraped level, with a thin sharp tool, with the result that the tile appeared with a kind of close-knit design, the cloisons or boundaries of the cells being, of course, the upstanding ridges of the moulded red tile. Over the surface of the tile finely powdered galena (native sulphide of lead) was freely dusted, and the whole was fired at one operation with the resulting production of a tile or tiles bearing a yellowish white pattern relieved against red or chocolate, and glazed with a natural lead glaze, which was much harder and better adapted to resist wear than the majolica glazes of Spain or Italy. The origin of this type of pavement tile is still obscure; one idea is that they were a development of the Roman Mosaic pavement, for, in examples discovered at Lambeth, and at Lambeth and the Abbey Church of Westminster, in which the tiles were of great variety of form and size, and, instead of the patterns being wholly inlaid in the tiles themselves, the design is, to a large extent, produced by the outlines of the individual pieces, which, in the later examples, are cut to the forms required to be represented, including the subject of the "Temptation of Adam and Eve," trees, lions, &c., the tesserae being also enriched with what may be more strictly called encaustic decoration. The more probable origin of this method of work seems, however, to be a development of the pavement tiles with simple incised designs which were made in the northern parts of England, in the Rhine Valley and in Flanders. Most interesting examples of these incised tiles are to be found in the cathedral of St Omer, which are known to be of the 12th century, and it seems impossible to resist the conclusion that such incised work forms the starting-point of the English encaustic tile-makers. A similar piece of work exists in Canterbury Cathedral, where we have stone tiles engraved with pictorial designs, the sunk parts being filled with a dark cement—this pavement also belongs to the 12th century.

Four styles of decoration are found on medieval Gothic tiles (1) incised (2) raised (3) inlaid (4) slip-painted. It is to the third of these groups—the inlaid—that the name of "encaustic" tiles had been particularly given. The manufacture of medieval Gothic tiles was apparently the secret of certain religious houses in England, belonging either to the Benedictine or the Cistercian Orders. The earliest date at which we have tangible proof of the existence of this art is 1237, in which year it was ordered that the king's little chapel at Westminster should be paved with "painted tile": "mandatum est etc., quod Parvum capellam apud Westm. regina piceta decenter pavocti faciatis," Rot. Claus. 27, Henry III. M. 10, A.D. 1237-38. During the 14th century, tiles were used in the church of the Abbey of Westminster, and, in the 15th century, a pavement of this kind was exposed in the chapter-house of Westminster, which is to view a tile pavement in good preservation which, though it can hardly be the pavement in question, is evidently of contemporary manufacture.

The finest and most artistic of these early English tiles were those found in Chertsey Abbey in Surrey. They were found in a very fragmentary condition on the Abbey site, but have been to a great extent pieced together by Mr. H. H. Shurlock. Practically all the tiles that have been recovered are now in the British Museum (a number of them were formerly in the architectural museum at Westminster). They constitute a remarkable series of illustrations from the English romance of Sir Tristram and of events in the history of Richard Coeur-de-Lion (see Hobson's Catalogue of English Pottery in the British Museum, pl. ii.). Mention should also be made of the tile pavement discovered at the abbey of Halesowen in south Staffordshire. Many of these tiles are of very similar design to those of Chertsey, while some appear to have been made from the same moulds. From the evidence of inscriptions it would appear that this pavement was laid down in the latter part of the 13th century.

Combinations of tiles forming a cross were frequently used as mortuary slabs; an example is in Worcester Cathedral in situ, whilst detached component tiles of similar slabs are to be found in other ancient churches.

Encaustic tiles are almost exclusively used for pavements, but an interesting instance of their employment for wall decoration occurs in the Abbey Church of Great Malvern, where these tiles have probably been originally used to form a reredos, and bear designs representing Gothic architecture in perspective, have introduced into them the sacred monogram "I.H.S.," the crowned monogram of "Maria," the symbols of the Passion, the Royal Arms and other devices. This example is also interesting as bearing the date of its manufacture on the margin "Anno R. R. H. VI. XXXVJ," that is the thirty-sixth year of the reign of Henry VI. (1457-1458).

Kilns for tile-burning have been found at Bawsey, near Lynn, Norfolk; Malvern, containing some 15th-century tiles; Repton; Farringdon Street, London; and Great Saredon, in Staffordshire, with tiles of the 16th century.

LITERATURE.—John Gough Nicholls, Examples of Encaustic Tiles (1845); Henry Shaw, Specimens of Tile Pavements (1848); T. Oldham, Ancient Irish Pavement Tiles; Frank Renaud, The Use and Teachings of Ancient Encaustic Tiles; Lancashire and Cheshire Antiquarian Society, vol. ix.; W. W. Pocock's article in The Surrey Archaeological Collections (1868); J. R. Holiday on "Halesowen Tiles," in Transactions of the Birmingham and Midland Institute (1871); Mr. J. C. Medcalf, Shurlock. Tiles from Chertsey Abbey (1895); Major Heales, F.S.A., The Chertsey Tiles (1886); W. Burgess, in The Builder (July 24, 1858).

With the downfall of the monasteries in the reign of Henry VIII. the making of encaustic tiles in England appears to have come to an end, and for nearly two centuries foreign tiles were imported from Germany, the Netherlands, Italy and Spain, or workmen from those countries must have practised their art here. There are in evidence the well-known glazed tiles in the British Museum which, if made in England at all, were obtained from America. The use of encaustic tiles, however, continued until the 17th century, and many of the tiles used in the house of Sir Nicholas Bacon (c. 1500-1579) are obviously the work of an Italian majolist, whether they were made in Italy or in England. Increasing intercourse with the Netherlands brought into this country and, during the 17th century into the American colonies, the famous Delft tiles, painted either in blue, or in blue and manganese purple, on a tin enamel ground like that of the contemporary Delft pottery. From the 16th century onwards every country in Europe continued to make tiles by methods strictly analogous with their contemporary pottery (see CERAMICS). Thus we have in Italy and Spain, throughout the 17th and 18th centuries, wall tiles in the style of the debased Italian majolica; in Germany a continuation of the ancient German stove tiles, either glazed with green, brown or black glaze, or bearing painted designs in the crude colours characteristic of the contemporary German pottery; in France there were, first, the painted tile pavements of Massicot Abaquesne of Rouen (1542-1557), and later the decorative tiles produced at Rouen, Nevers, Marseilles and elsewhere, always in the style of the current pottery of the same centuries, and painted for decoration of fireplaces and for use as wall panels formed a considerable part of the output of the Dutch factories. Wherever imitations of Delftware were made, in England, Germany or the north of France, the manufacture of similar tiles naturally followed; and at Lambeth, Liverpool and Bristol, the chief centres of this industry in England, large quantities of tiles were made, especially during the 18th century. The tiles produced at Lambeth and Bristol factories were invariably painted after the manner of their Dutch prototypes, but during the latter half of the 18th century Liverpool became famous for its printed tiles, in which designs, mostly in black, transferred from engraved copper plates, took the place of hand-painting. Fine examples of all these 18th-century English tiles are to be found in the British Museum; the Guildhall Museum; the Victoria and Albert Museum, London; and in the museums at Liverpool and Bristol.

During the 17th and 18th centuries the old painted and
decorated pavement tiles seemed to have been entirely replaced by the common buff or red terra-cotta "quarries" so largely used in farmhouse kitchens, dairies, &c., and it is to the painted tiles for walls and fireplaces that we have to look for the progress of the art.

The modern revival of tile-making in Europe dates from about 1830, when Samuel Wright, a potter of Shelton, near Stoke-upon-Trent, was granted a patent for the manufacture of tiles by mechanical means. His patent was extended for fourteen years, and in 1844 was purchased, in equal shares, by Herbert Minton—head of the famous firm of Minton, of Stoke-upon-Trent—and Fleming St John, of Worcester. In 1848 the firm of Minton acquired the sole right of the patent, and many of their designs were produced by such famous architects as Pugin, Gilbert Scott, Street, &c., so that between 1850 and 1880 encaustic tiles had a great vogue for pavement work not only in England, but in all civilized countries, and fine examples of the rich encaustic pavements made at Minton's, Maw's, or Godwin's of Hereford, are to be found in many of the restored cathedrals and churches of this period.

Side by side with the revival of this ancient process, there was developed an essentially modern process of manufacturing by compressing pulverized clay in metal dies under a screw press. This was the outgrowth of a patent granted to Richard Prosser in 1840, and worked out and perfected at the works of Minton at Stoke-upon-Trent. The advantages of this method of manufacture consist in (a) greater rapidity in execution than can be effected by the greater mechanical, and (b) the greater mechanical accuracy of the finished tile due to the steel dies used in shaping the tile and to the diminished contraction in drying and firing. This essentially modern method of tile-making is really an outcome of the methods introduced in the manufacture of English earthenware (see Ceramics), and it has not only been extensively developed in England, but has been adopted, practically without modification, in all the leading countries of Europe and in the United States.

The manufacture of tiles by the compression of powdered clay rendered possible the introduction of many varieties—plain, inlaid, embossed and incised. The designs in these cases, though generally based on old work, are so different, especially in mechanical finish, that they form a class of tiles entirely distinct from old work. Economically, and for all practical purposes, they afford a style such as the world has never before seen, but, like many modern productions—perfect in execution and finish—they lack the spontaneity and artistic charm of the work of bygone days.

Since the middle of the 19th century artist-potters in many countries have gone back to the ancient methods of production for highly painted tiles, and, in this connexion, productions of Deck in France, William de Morgan and Pilkington’s in England, mark a distinct departure from contemporary modern work.

The extended use of tiles for interior decoration has created a large trade in these articles, either for wall or floor decoration. Among the most important firms engaged in this branch of the ceramic industry must be mentioned Minton’s, Hollins & Co., Maw & Co., and Pilkington’s in England; Villeroy & Boch in Germany; Utschneider & Co. in France; Boch Frères in Belgium; Thoofit & Labouhere at Delft, Holland; and the American Encaustic Tile Co., in the United States.

Literature.—Besides the works mentioned in connexion with special sections in the text a good deal of information about tiles in general, and modern tiles in particular, will be found in Furnival, Leadless Decorative Tiles, &c.; L. L. Jewitt, Ceramic Art of Great Britain; see also Porter, Geschichte der europäischen Fliesen-Keramik.

(T. B.*

TILLEMONT, Sébastien Le Nain de (1637-1698), French ecclesiastical historian, was born in Paris on the 30th of November 1637. His father, a wealthy member of the legal class, being a devoted Jansenist, the boy was brought up in the little schools of Port Royal. Here his bent towards historical study was warmly encouraged, and in 1660 he was made a tutor in the seminary of Buzenval, Jansenist bishop of Beauvais. Ten years later he came back to Paris, and was eventually persuaded (1676) to enter the priesthood, and become a chaplain at Port Royal. In 1679 the storm of persecution drove him to settle on his family estate of Tillemont, between Montreuil and Vincennes. There he spent the remainder of his life, dying on the 10th of January 1698. He was buried at Port Royal; in 1711, on the desecration of the cemetery, his remains were transferred to the church of St André des Arcs in Paris.

From the age of twenty he was at work on his two great books—the Mémoires pour servir à l'histoire ecclésiastique des six premiers siècles, and the Histoire des empereurs de l'Empire Romain, during the same period. Both works began to appear during his lifetime—the Histoire in 1690, the Mémoires in 1693—but in neither case was the publication...
finished till long after his death. To his modesty Bossuet bears witness, when he told him to stand up sometimes, and not be always on his knees before a critic. Gibbon vouches for his learning, when (in the 47th chapter, On the erudition, veracity, diligence, and scrupulous minuteness.) There is a full account of his life in the 4th volume of Sainte-Beuve's Port Royal.

TILLEY, Sir Samuel Leonard (1618-1690), Canadian statesman, was born at Gagetown, New Brunswick, on the 28th of May 1618, the son of Samuel Tilley, an American Loyalist, who had settled in St. John in 1783. In 1850 he was elected to the local legislature as a Liberal representative of St. John. He soon became prominent from his opposition to the liquor traffic, and in 1853 persuaded the assembly to pass a prohibitory law, which proved a failure, and was repealed. From 1860 to March 1865 he was premier of the province, and was prominent in organizing the conference on the union of the maritime provinces, which met at Charlottetown in 1864, and which soon widened into a discussion of Canadian federation. In 1856 he was defeated in a general election on the federation question, but returned to power in 1866, partly through an intrigue of the colonial office. From 1868 till November 1873 he held various portfolios in the Dominion cabinet; from 1873 to 1878 he was lieutenant-governor of New Brunswick, but in 1878 was again elected as member for St. John, and entered the Conservative cabinet as minister of finance. Later in 1878 he introduced and carried through parliament the "national policy" of protection, on which issue the election of 1878 had been won. The tariff so introduced became the basis of Canadian financial policy. In October 1883 ill health forced him to retire from the cabinet, and he was again appointed lieutenant-governor of New Brunswick, which position he held till 1893. He died on the 25th of June 1896. In 1879 he was created K.C.M.G. His kind and honourable private character was admitted by all; his political merits are judged differently by advocates and opponents of the policy of protection which he introduced, but of his financial ability and grasp of detail there is no doubt.

His Life, by James Hannay (1907), forms one of the "Makers of Canada" series.

TILLODONTIA, a group of mammals of uncertain position, typified by Tillemium from the Middle Eocene of Wyoming,

and perhaps including Esthonyx from the Lower Eocene of the same district, and other genera from the same horizon in both North America and Europe. In Tillemium the skull is decidedly rodent-like, with an elongated cranial and a short facial portion, and a small brain-cavity; the jugal bone occupying the middle of the zygomatic arch. The dentition, of which the formula is $i, I, c, I, p, I, m, I$, also approximates to the rodent type, the canines being minute and functionless, and the first pair of incisors large and chisel-like. On these and other grounds it has been suggested that Tillemium (of which the greater part of the skeleton is known) indicates the ancestral form of the Rodentia. Professor Max Weber considers, that such a view has but little justification. Relationship with the Ungulata and Carnivora has also been suggested; if there be any with the latter, it must have been with the most primitive forms, as the plantigrade feet are furnished with five toes carrying long pointed claws.

(From Marsh.)

Skull of Tillemium fodiens. (1 nat. size.)

Possibly Platychroerm richardsoni, from the Lower Eocene London Clay, belongs to the group. (R. L. *)

TILLOTON, John (1630-1694), English archbishop, was the son of a Puritan clothier in Sowerby, Yorkshire, where he was born in October 1630. He entered as a pensioner of Clare Hall, Cambridge, in 1647, graduated in 1650 and was made fellow of his college in 1651. In 1656 he became tutor to the son of Edmond Prideaux, attorney-general to Cromwell. About 1661 he was ordained without subscription by T. Sydserf, a Scottish bishop. Tillotton was present at the Savoy Conference in 1661, and renounced the Presbyterian creed in the preamble to the Act of Uniformity in 1662. Shortly afterwards, he became curate of Cheshunt, Herts, and in June 1663, rector of Kedington, Suffolk. He now devoted himself to an exact study of biblical and patristic writers, especially Basil and Chrysostom. The result of this reading, and of the influence of John Wilkins, master of Trinity College, Cambridge, was seen in the general tone of his preaching, which was practical rather than theological. He was a man of the world as well as a divine, and in his sermons he exhibited a tact which enabled him at once to win the ear of his audience. In 1664 he became precentor of Lincoln's Inn. The same year he married Elizabeth French, a niece of Oliver Cromwell; and he also became Tuesday lecturer at St Lawrence, Jewry. Tillotton employed his controversial weapons with some skill against atheism and popery. In 1663 he published a characteristic sermon on "The Wisdom of being Religious," and in 1666 replied to John Sergeant's Sure Footing in Christianity by a pamphlet on the "Rule of Faith." The same year he received the degree of D.D. In 1670 he became prebendary and in 1672 dean of Canterbury. In 1675 he edited John Wilkins's Principles of Natural Religion, completing what was left unfinished of it, and in 1682 his Sermons. Along with Burnet, Tillotton attended Lord Russell on the scaffold in 1683. He afterwards enjoyed the friendship of Lady Russell, and it was partly through her that he obtained so much influence with Princess Anne, who followed his advice in regard to the settlement of the crown on William of Orange. He possessed the special confidence of William and Mary, and was made clerk of the closet to the king in March 1689. It was chiefly through his advice that the king appointed an ecclesiastical commission for the reconciliation of the Dissenters. In August of this year he was appointed by the chapter of his cathedral preacher at Lincoln's Inn. The same year he married Elizabeth of Canterbury during the suspension of Sancroft. He was also about the same time named dean of St Paul's. Soon afterwards he was elected to succeed Sancroft; but accepted the promotion with extreme reluctance, and it was deferred from time to time, at his request, till April 1691. In 1693 he published four lectures on the Socinian controversy. His attempts to reform certain abuses of the Church, especially that of clerical non-residence, awakened much ill-will, and of this the Jacobites took advantage, pursuing him to the end of his life with insult and reproach. He died on the 22nd of November 1696.

For his manuscript sermons Tillotton's widow received 2500 guineas. Ralph Barker edited some 250 of them together with the "Rule of Faith" (1695-1704). In 1752 an edition appeared in 3 vols., with Life by Thomas Birch, compiled from Tillotton's sermons, theological papers, and letters. Various selections from his sermons and works have been published separately, e.g. by G. W. Weldon in 1886.

TILLY, Johann Tserclaes, Count of (1550-1632), general of the Catholic League in the Thirty Years' War, was born in 1559 at the chateau of Tilly in Braissant. He was destined for the priesthood and received a strict Jesuit education. But, preferring the career of a soldier, he entered Span's infantry and foot regiment about 1574 as a volunteer, and in the course of several campaigns rose to the command of a company. This being reduced, he again became a simple pikeman, and as such he took part in the famous siege of Antwerp by Parma, whose army afforded the best training in the art of war then obtainable. He distinguished himself by his bravery, and the duke of Lorraine gave him the governorship of Dun and Villefranche, which he held from 1590 to 1594. Henry IV. made tempting
offers, which were refused, to induce him to enter the service of France. Somewhat later he left the Spanish service for that of Austria to fight against the Turks. In 1602 he became colonel in the imperial army, and raised a regiment of Walloon infantry, which he commanded in the assault on Budapest, receiving a severe wound. In 1604 he was made general of artillery, and handled his new force with conspicuous success; the campaign of this year showed Tilly as a soldier of great capacity, and in 1605 he was made a field-marshall. His part in the dissensions in Austria, which preluded the 'Thirty Years' War, was marked by unswerving loyalty and devotion to the emperor and the Catholic religion. In 1610 he left the service of the emperor to enter that of Maximilian, duke of Bavaria, the head of the Catholic League. It was not, however, until 1620 that he became lieutenant-general to Maximilian and commander-in-chief of the field forces.

With the great victory of the Weisser Berg near Prague (1622) the new army and its leader became celebrated throughout Germany, and the long and weary campaigns against Christian, Mansfeld and the Protestant princes of the north-west established their reputation. The chief battles were Wimpfen (1622), Stadtlohn (1623), Wiesloch (1622), Höchst (1622), the last being a great victory for the Catholic forces, and winning for Tilly the title of count, which was given by the emperor himself (1622). The military operations of the Thirty Years' War will be found described under that heading. With the intervention of the King of Denmark, the struggle entered upon a new phase, and on the 26th of May, Tilly, after a four-days' stay at Wallenstadt, appeared on the scene, though it was the army of the League which won the great success of the war at Lutter-am-Barenberge (1626). Throughout these arduous campaigns Tilly had other than military difficulties with which to contend. The military superiority of his veterans, trained as they were to their own ideal of "a ragged soldier and a bright musket," may be held to explain his victories over superior numbers, but the energy which he displayed in the midst of political difficulties was not less conspicuous than his leadership and strategy. On two occasions, at least, he was thwarted by orders from the League; once the Protestants were allowed to escape into Holland, once the army of Wallenstein was left to its own resources in the presence of the enemy. That the League achieved the successes which it actually did, was to the credit of Tilly and his men rather than to any action of the allied princes. It may be that Tilly cannot be considered as great a soldier as Wallenstein; it should, however, be borne in mind that the League army never possessed the prestige of an imperial force: that Tilly was repeatedly thwarted by political considerations, and that, even so, the hardest part of the task was achieved by the League and its allies.

The defeat of King Christian was soon followed by the intervention of Gustavus Adolphus, a great captain at the head of the finest troops in Europe. But Tilly was the best general of the old school; the League troops were trained after the Spanish model, and the opening stages of the campaign did not display any marked superiority of the Swedes. At this time Tilly was commander of the imperial forces as well as of his own army. The first great contest was for the possession of Magdeburg (1631). After one of the fiercest struggles of the war, the town was taken by storm on the 20th of March, and the sack which followed was accompanied with every sort of atrocity. For this the old general has been held responsible, yet it was rather the magnitude of the catastrophe than its special cruelties which made it the most striking example of military barbarity in modern history. Tilly's personal exertions saved the cathedral and other religious buildings from pillage and fire. Four months later Tilly and Gustavus, the representatives of the old and the new art of war, met in the battle of Breitenfeld (q.v.). The victory of Gustavus was complete, though the imperial general, severely wounded as he was, managed to draw off his men in good order. A few more months of campaigning brought the two armies to the Lech, where Gustavus was again victorious, and Tilly received a mortal wound. He died on the 30th of April 1632, in Ingolstadt, and was buried in the church at Altenmünster in Bavaria.

**TILSIT,** a town of Germany, in the Prussian province of East Prussia, situated on the left bank of the Memel or Niemen, here crossed by an iron railway bridge, 57 m. S.E. of Memel and 72 N.E. of Königsberg by rail. Pop. (1905), 37,148. The town has a number of handsome modern buildings, including a town hall, a post office, law courts, and a large hospital. It contains four Protestant churches, among them the German church, with a handsome steeple, and the curious circular Lithuanian church, a Roman Catholic church, a Jewish synagogue and a classical school (*Gymnasium*). The manufactures include machinery, chemicals, soap, leather, shoes, glass and other articles, and there are iron-foundries, breweries, and steam flour and saw-mills. Tilsit carries on trade in timber, grain, hemp, flax, herrings and coal; but its trade with Russia, at one time considerable, has fallen off since the construction of the railway from Königsberg to Kovno. The river is navigable for the whole of the town, and steamboat communication with Königsberg, Memel and Kovno.

Tilsit, which received civic rights in 1552, grew up around a castle of the Teutonic order, known as "the Schaulauer Haus," founded in 1288. It owes most of its interest to the peace signed here in July 1807, the Peace of Tilsit, by which the emperors Alexander and Napoleon on a raft moored in the Memel. This treaty, which constituted the kingdom of Westphalia and the duchy of Warsaw, registers the nadir of Prussia's humiliation under Napoleon. The poet Max von Schenkendorf (1784–1817) was born at Tilsit.

**TIMAEUS** (c. 345-c. 295 B.C.), Greek historian, was born at Tauromenium in Sicily. Driven out by Agathocles, he migrated to Athens, where he studied rhetoric under a pupil of Isocrates and lived for fifty years. During the reign of Hiero II. he returned to Sicily (probably to Syracuse), where he died. While at Athens he completed his great historical work. The *Histories*, in at least 38 (Bury says 33) books, was divided into unequal sections, containing the history of Italy and Sicily in early times; of Sicily alone; of Sicily and Greece; of the cities and kings of Syria (unless the text of Suidas is corrupt); the lives of Agathocles and Tychrus, king of Ephesus. The chronological sketch ("Ολυμπιουσικά, the victors at Olympia) perhaps formed an appendix to the larger work. Timaeus was bitterly attacked by other historians, especially by Polybius, and indeed his unfairness towards his predecessors, which was attributed to his being a disciple of Isocrates ("fault-finder," though some authorities render this "old woman," in allusion to his fondness for trivial details), is preferable to the rationalistic interpretation under which it had become the fashion to disguise them. Timaeus also devoted much attention to chronology, and introduced the system of reckoning by Olympiads, with which he compared the years of the Attic archons, the Spartan ephors, and the priestesses of Argos. This system, although not adopted in everyday life, was afterwards generally used by the Greek historians. Although a pupil of Isocrates and a disciple of Isocrates, Timaeus is a representative of the Asiatic style of Hegesias of

---

TIMANThES—TIMBER

Mognesia rather than of the Attic (see Norden, Griech. Kunstprosa i. 186). Both Démyus of Halicarnassus and the pseudo-Plutarch regarded him as a model of "frigidity" (Syrupus), although the latter admits that in other respects he is a competent writer. Cicero, who was a diligent reader of Timaeus, expresses a far more favourable opinion, specially commending his copiousness of matter and variety of expression. Timaeus was one of the chief authorities used by Trogus Pompeius, Diodorus Siculus and Plutarch in his life of Timoleon.

BIBLIOGRAPHY.—Fragments and life in C. W. Müller, Frag. hist. grece, i. iv.; frags. of bks. i., ii., ed. J. Gficklen, Timaeos: Geographie des Westens (1882); Polybius xii. 3-28; Diod. Sic. xxi. 17; Cicero, De Orat. ii. 14; J. B. Bury, Ancient Greek Historians (1909), 167 seqq.; F. Susemihl, Geschichte der griech. Litt. in der Alexanderreise, with references to authorities (1891); W. Christ, Griechische Litteraturgeschichte (1898); H. Rothe, De Timaei Tauromonieta vita et scriptis (Breslau, 1874); C. Clasen, Historisch-kritische Untersuchungen zu Timaeos von Tauromenion (Kiel, 1883); E. Schwartz in Hermes (1899), xxxiv. p. 481.

TIMANThES, of Cythnos or Sicyon, a Greek painter of the 4th century B.C. The most celebrated of his works was a picture representing the sacrifice of Iphigienia, in which he finely depicted the emotions of those who took part in the sacrifice; but despairing of rendering the grief of Agamemnon, he represented him expressing his joy at seeing his face. A painting discovered at Pompeii, and now in the Museum at Naples, has been regarded as a copy or echo of this painting (Helbig, Wandgemälde Campaniens, No. 1304).

TIMARU, a seaport of Geraldine county, New Zealand, on the E. coast of South Island, 100 m. S.W. of Christchurch by rail. Pop. (1906), 7015. The slight inward sweep of the coast forms the Canterbury Bight, and the shore-line northward from Timaru is called the Ninety-mile Beach. The harbour is formed by breakwaters enclosing a space of 50 acres. Chief exports are wool, flour and frozen meat, and the industries are in connexion with these. Opals are found in the district. The Anglican church of St Mary is built of Oamaru and bluestone, with a roof of kauri wood. Caroline Bay, to the north, is a bathing resort. The volcanic soil is highly fertile. Timaru is the chief town in South Canterbury district, and the seat of the supreme and district courts. A branch railway traverses the inland agricultural district.

TIMBER, the term given to wood cut and shaped for building purposes, or growing wood suitable for such purposes; in English law the tenant for life may not cut such trees (see Wood). The word occurs in all the early Latin, Greek, and Gothic languages, meaning originally material to be used for building purposes; in the case of Ger. zimmer, and Du. timmer, both meaning "room," the word has been transferred to the structures made of this material. The root is seen in Gr. ἔξω, to build, and Lat. domus, house.

The wood used in building is obtained from trees of the class known to botanists as exogens, or those trees which grow larger by the addition each year of a layer of new wood on their outer surface. A transverse section of a tree of this class shows it to consist of three distinct parts: the pith or medulla, the wood, made up of annual rings or layers, and the bark. The pith is in the centre of the tree and around it the wood is disposed in approximately concentric rings; that part near the pith is hard and close in grain, and from its position is termed heart-wood. The sap-wood is made up of the outer layers or rings, and these are softer than the heart and generally more open grain. Each annual ring is made up of two parts—an inner soft portion light in colour, and a hard, dark-coloured outer portion. The inner portion is formed early in the season and is termed "spring wood," the darker part being called "autumn wood." The medullary rays extend radially from the centre of the tree to the bark at right angles to the grain of the wood, and serve during life to bind the whole together as well as to convey nourishment from one part of the tree to another. The greatest care should be exercised in the selection of trees for felling. If the tree is too young the proportion of sap-wood is large, and the heart-wood is not so hard as that of a tree of mature age. The wood of an old tree, on the other hand, has lost a great part of its toughness, and is of bad colour, brittle and often predisposed to decay. In trees that have arrived at a mature age the heart-wood is in its largest proportion and the sap-wood is firm and elastic; and the timber from such trees is of the strongest, toughest and most durable character. The age at which the northern pine and Norway fir arrive at maturity is between seventy and one hundred years. The larch, elm and ash should be felled when the trees are between the ages of fifty and one hundred years. The oak should be about one hundred years old when it is cut. The best time of the year for felling timber is in midsummer or midwinter, when the sap of the tree is at rest; it is not desirable to cut timber in the spring or autumn. By some authorities it is considered a good plan to remove the bark in the early spring and fell the tree in the ensuing winter.

As soon as possible after felling, logs should be converted by sawing into scantlings, sizes for, if the log is left to dry or season, it is liable on shrinking to split. The usual method is to saw a log into planks or boards by cutting it into slices longitudinally as shown in fig. 1; this is called bastard sawing, and is the most economical method, but, as will be seen in the diagram, the quality of the boards will vary very much, some consisting almost entirely of sap-wood cut at a tangent to the annual rings such as a, b, c, whilst the centre boards contain the heart-wood cut in the best way at right angles across the annual rings as d, e, f. For oak and other hard woods another method of conversion is often adopted, called quarter sawing. The log is first cut into quarters and then sawn diagonally (fig. 2). In oak this develops the beautiful silver grain by cutting longitudinally through the medullary rays. Timber is now generally sawn into marketable sizes in the country of its growth, and shipped as scantling timber.

Definitions and sizes are given below of the most usual forms of sawn timber:

A log is the trunk of a tree with the bark removed and branches lopped.

A balk is a log hewn or sawn to a square section, and varying in size from 11 to 18 in. square.

Planks are parallel-sided pieces of timber from 2 to 6 in. thick, 11 or more ins. wide, and from 8 to 21 ft. long.

Deats are similar pieces 9 in. wide, and 2 to 4 in. thick.

Battens are similar pieces, but not more than 7 in. wide. Pieces of planks, deals and battens under 8 ft. long are called ends. Many of the soft woods, such as pine and fir, are sold by the standard. The standard of measurement most in use is the St Petersburg standard, which contains 145-cubic ft. or 720 lineal ft. of 11 in. by 3 in.

A load of sawn or hewn timber contains 50 cub. ft., and a load of unhewn timber 40 cubic ft.

A square is a superficial measurement, used chiefly for boarding, and contains 100 sq. ft.
TIMBER

Norwegian timber is stencilled with the shipper's initials in blue letters painted on the ends. Swedish timber is stencilled with red letters on the devices, the inferior qualities in blue. Russian timber is stencilled on the sides near the middle. By stencilling is meant that the distinguishing letters are roughly cut in with a gouge. Russian timber is dry-stamped or hammer-branded on the ends. American (Canadian) timber is stencilled in black and white. United States timber is marked with red chalk on the sides.

To fit timber for use in building construction the superfluous sap and moisture contained in the green wood must be evaporated, either by natural or artificial means. During this process the wood shrinks considerably, and unless much care and attention are given to the drying wood it will warp and shake sufficiently to unfit it for practical uses. After the log is converted into scantlings, or 'lumber,' as it is termed in America, it is stacked in the timber yard under covered sheds with open sides to enable it to 'season.' The wood is carefully piled in tiers or courses, with strips of wood about an inch thick between each layer, so as to allow of the free circulation of air all round each piece. This is the natural and best method of seasoning, and timber treated in this way is more durable than that seasoned by artificial methods; the time taken, however, is much longer. For joiners' work the drying of the wood is often hastened by stacking the timber in well-ventilated rooms kept at a temperature of from 80° to 100° F. The time taken in seasoning wood by this desiccating process is not more than that required in a natural method. Where it is convenient, timber is sometimes treated with a water seasoning process which enables it to be more easily dried. The wood is placed in a running stream and so tied or chained down as to be entirely submerged. The water enters the pores of the wood (which should be placed with the butt end pointing up stream) and dissolves and forces out the sap. After about two weeks in this position it is taken out and stacked in open sheds to be dried in the natural way, or treated by warm air in special chambers. Steaming and boiling are sometimes resorted to, but even these methods, while they may be expedient, are not to the same extent, as the timber deteriorates under such treatment, and the cost of the process is in many cases prohibitive. When wood is required to be bent, however, this is often the method that is adopted, to soften the material, so as to allow it to be bent easily. The time allowed in the English government dockyards for the natural process of seasoning for hard woods such as oak is, for pieces 24 in. sq. and upwards, 26 months; from 16 in. to 20 in. sq., 18 months; from 8 in. to 12 in. sq., 10 months; from 4 in. to 8 in. sq., 6 months. Soft woods are allowed half these periods. When the wood is in such a state as to "dry season," it is allowed for the length of time is given. Planks are allowed from a half to two-thirds of the above time, according to their thickness.

Deals with coarse annual rings (i.e. coarse grain) should be rejected for good work, as also those with wane or naturally bevelled edges. The wide annual rings show that the tree was grown too quickly, probably in marshy ground. Timber with wane edges has a large proportion of sapwood, and is cut either from a small tree or from the outer portion of a large one, the wane edge being obviously due to irregularities in the surface of the tree. "Cup shake" is a natural splitting in the wood, and is found in Swedish and American timber. Scandinavian timber is supposed to be caused in severe weather by the freezing of the ascending sap. "Heart shake" is often found in old trees and extends from the pith or heart of the tree towards the circumference. When there are fissures radiating in several directions it is called "star shake." "Upsets" are the result of some crushing force or violent shock to the bark or log. Foxeye timber is tinged with a brownish or blackish discoloration and is similar to that found in the walnut. "Downdecay," similarly, is a spotted or speckled stain denoting decay in certain varieties of timber, such as beech and some kinds of oak.

The primary causes of decay in timber are the presence of sap, exposure to conditions alternately wet and dry, and want of efficient ventilation, especially if accompanied by a warm air. The moist atmosphere of damp timber is conducive when in black and dry ventilated, but some varieties last an indefinite period when kept continually under water. When, on the other hand, the wood becomes alternately wet and dry, "wet rot" results. The wood affected shrivels up and becomes reduced after a time to a fine brown powder. It is only by actual contact that wet rot affects the surrounding good timber. If the decayed portion be cut out the remainder of the wood will be unaffected.

"Dry rot," which usually attacks the sap-wood, generally starts in a warm damp unventilated place, and if the conditions are favorable, will readily spread and attack other parts of the ground. The spores are visible to the naked eye, some microscopic. The spores from the fungi on the decayed wood float in the air and alight on any adjacent timber, infecting this with the same condition. In damp or wet weather the fungus will find a way through brickwork, concrete and similar material, in order to reach woodwork that may be on the other side. Damp-ness in buildings is the greatest predisposing cause of dry rot, and it is under these conditions that it spreads most quickly, the fungus soon drying when exposed to the fresh air.

There will be little danger of the decay of timber used in the construction of ordinary buildings if care has been taken, in the first place, to have it well seasoned, and, in the second, to ensure its being well ventilated when fixed in position. There are, however, several preservative processes to which timber may be subjected when it is to be fixed in positions which favour its decay (see also DRY ROT). In creosoting, which was invented by J. B. Bouchier and patented by him in 1832, the timber is treated by soaking it in creosote by boiling the wood in the hot oil for several hours, but the better way is to place the seasoned timber in an iron chamber in which a partial vacuum is created by exhausting the air. The creosote is then forced into the wood by a pressure of from 200 lb. to the sq. in., according to the size of the timber. In warm weather the pressure need not be so great as in winter. The whole process only occupies from two to three hours. Soft woods take up from 10 to 20 lb. of the fluid. Hard woods are not usually treated by this process. Kyan's process, patented in 1832, consists in impregnating the timber with corrosive sublimate which, acting on the albumen in the wood, converts it into an insoluble substance. Boucherie, a Frenchman, originated a system in which the sap is expelled from the timber under pressure, and a strong solution of copper sulphate is then injected at the end of the wood. In Boucherie's process the timber is dried, and made carbonate of copper is injected. In Burnett's process a solution of zinc chloride is forced into the pores of the wood. A new process of preserving timber by means of steam heat has been tried and seems to be effectual. The timber is placed in a chamber which is then heated to a high pressure (200 lb. to the sq. in.). The heat and pressure together exert a chemical action upon the sap, which becomes insoluble and itself preserves the wood from decay.

Posts that are to be fixed in the ground should have their buried ends either charred or else well tarred. External woodwork may be protected by painting or oiling.

The timber used in building is obtained from trees which may be classed under two heads: (1) Coniferous or needle-leaved trees; (2) the non-coniferous or broad-leaved trees. Varieties. Coniferous Trees.—This class includes most of the soft woods which furnish timber for the framing and constructional portions of nearly all building work. They are also used for the finishing joinery of the ordinary class of building. The numerous varieties of pine which are used more extensively than any other kind of wood are included in this class.

The northern pine (Pinus sylvestris) has a number of other names and may be referred to under any of the following: Scotch fir, red deal, red fir, yellow deal, yellow fir, Baltic pine, Baltic fir, Norway pine, Scotch pine, white pine, North American pine, and often gets a name from the port of shipment, such as Memel fir, Danzig fir, Riga fir, and so on. The colour of the wood of the different growths of northern pine varies considerably, the general characteristics being a light reddish yellow colour. The annual rings are well defined, each ring consisting of a hard and a soft portion, respectively dark and light in colour. No medullary rays are present. The wood is rather heavy, soft, and flexible, elastic, easy to work, and is used by the carpenter for internal and external constructional work, and by the joiner for his fittings. Tar, pitch and turpentine are obtained from the wood of this tree, the yields being nearly one in twenty per cent.

The white fir, or Norway spruce (Abies excelsa), is exported from Russia, Sweden and Norway, where it grows in enormous quantity. The wood is obtained from the trunk of the tree, which has a slender trunk to a height of from 80 to 100 ft. Like the northern pine, it is called by several names, such as "spruce," "white deal," "white wood," "Norwegian fir." The colour of the cut wood is a very light yellowish or brownish white, the hard parts of the
annual rings being of a darker shade. A characteristic feature is the large number of annual rings; knots are almost absent, and the wood is easy to work, but rather inferior in all respects to the northern pine. Its weight per cubic foot averages about 33 lb.

The red pine (Pinus resinosa or P. rubra) is also known as "Canadian pine," is a native of the northern parts of North America, where the tree attains a height of 60 or 70 ft. with a diameter of from 12 to 30 in. It weighs about 36 lb to the cubic foot. In Canada it is called Norway pine and "red pine," and in the United States it is known as "black pine." It is distinguished by yellow or red, of fine grain, and works to a smooth lustrous surface remarkably free from knots.

For joiners' work, however, it is well adapted, and glue adheres strongly to it, though nails do not hold well. It cuts about 30 lb per cu. ft.

The Kauri pine (Dacrydium australis) is a native of New Zealand. It grows to a height of from 80 to 140 ft., with a straight stem 4 to 8 ft. in diameter. The wood is a light yellowish brown in colour, fine grained, and very hard, the annual rings are marked by a dark line. It is strong, elastic and resinous. A cubic foot weighs about 35 to 40 lb.

The pitch pine (Pinus rigida) is a native of Canada and is common throughout the eastern United States and the Pacific States of America. It is remarkable for the large quantity of resin it contains, the weight of the wood, which is about 48 lb per cu. ft., and the strong red markings of the surface. It attains a height of about 100 ft., but the average height is about 80 ft.

The larch is the most beautiful variety known in Great Britain. Its diameter attains about 6 ft., and it weighs about 56 lb per cu. ft. or less.

Of the elm (Ulmus) there are five common varieties, the two most extensively used being the tough-leaved elm (Ulmus campestris), which is grown in large quantities in England and North America, and the smooth-leaved yew elm (Ulmus glabra). The colour of the wood is brown; it is hard, heavy, strong and very tough, and when wet is easily bored. It is not very liable to warp and shake, and is porous and usually cross-grained.

The pines of old London Bridge were of elm, and after six centuries of immersion were little decayed. The wood is not much used in building operations. It weighs about 40 lb per cu. ft.

The common ash (Fraxinus excelsior) is a native of Europe and Northern Asia, and is grown extensively in Great Britain. Its ornamental light brown, sometimes with a greenish tint, with the annual rings of darker colour. The wood is very tough and strong, and superior to most wood in elasticity; and it weighs about 45 to 55 lb per cu. ft.

Birch (Fagus sylvatica) grows in the temperate districts of Europe. The wood is heavy, strong and hard; white to light reddish-brown in colour; and durable if kept either dry or wet; is porous and works easily; it weighs about 40 to 50 lb per cu. ft. The red beech (Fagus purpurea) is found in China and in North America.

Sycamore (Acer pseudo-platanus), sometimes mistakenly called the plane tree, is common in Germany and Britain and in the eastern states of America. The wood is very tough and strong, and is used for ornamental joinery. Itattains a height of about 60 ft., and weights less than 40 lb per cu. ft.

Teak (Tectona grandis) is a native of southern India and Burma. It grows rapidly to a great height, often exceeding 150 ft., with a straight trunk and spreading branches. Teak wood is straight in the grain, and is not readily split, and it has the nature of being able to resist the attacks of insects and to preserve iron, nails and fastenings. It weighs from 45 to 56 lb per cu. ft.

Mahogany (Swietenia mahogani) is a native of the West Indies and Central America, the best-known varieties being Cuban or Spanish and Honduras. The Spanish wood has a darker colour and richer figure than the Honduras, and is therefore preferred for ornamental joinery. The colour of mahogany is reddish brown, and in the Cuban wood the pores are often filled with a white chalky substance which is usually absent in the Honduras variety; the latter, however, may be obtained in larger sizes, and is straighter in the grain, and easily worked. It weighs about 45 to 56 lb per cu. ft.

Greenheart (Neobalanus radicans) is a very heavy, hard and durable wood, used in ornamental joinery, being more used by the cabinet and joiner than the carpenter. It weighs about 56 lb to the cubic ft., and the Honduras variety about 36 lb.

Basswood (Tilia americana) is common to Canada and in the United States. It is soft and easy to work, and of even texture and straight grain. It may be obtained in wide boards, and this is fitted for use in large panels. It weighs about 30 lb per cu. ft.

There are several varieties of maple growing in Canada and the United States, but the one in most common use is the sugar maple, also called rock maple, which grows freely in the districts around the Great Lakes. The wood is fine-grained, frequently with a beautiful wavy figure, yellowish white to light brown in colour; it is light and easy to work, and is used in ornamental joinery, particularly for curved work.

The numerous tests of the strength of timber which have been made by various authorities from time to time vary so much, both as regards the conditions under which they were carried out and the results obtained, that no general rule can be given as to the strength of different kinds of wood. The American strength tests are not comparable with those of European counties, and the results of the American strength tests are not comparable with those of the older European strength tests.

Recently, the American Society of Civil Engineers has been conducting tests of the strength of timber. These tests have been conducted in a manner that is comparable with the European strength tests.

in America, Professor J. B. Johnson made a large number of tests for the Forest Department of the Board of Agriculture of the United States between 1891 and 1895. More than 300 trees were cut down and experimented with, the species under test embracing ten different kinds of pine and five different varieties of hard-wood trees. Records were made as to the nature of the soil and climate where the trees were grown; their conditions of growth, their age and size, and the season of felling. As in the tests made by Bauschinger, the percentage of moisture contained in the wood was very carefully observed, and it was found that this wood species has a very great influence upon the resisting power of the wood, the strength increasing with the dryness of the material up to 3 or 4% of moisture, at which point the greatest strength of the wood is reached. Wood in such a dry condition, however, is never found in actual practice, timber in an ordinary well-warmed and well-ventilated situation probably containing at least 10%.

One general conclusion arrived at both by Bauschinger and Johnson was that the strength is much affected by the specific gravity of the timber. In all cases the strength increases proportionately with the density of the wood. A more substantial and physical characteristic of the hard woods of Western Australia was completed for the government of Western Australia by G. A. Julius in 1907. This work was carried out in a most thorough manner, and as many as 16,000 tests were made, the conditions of test being based upon those laid down by Johnson. The results serve to show the great value of Australian timbers, and the comparisons made with the typical timbers of many other countries emphasize the fact that the Australian woods are equal to any in the world for hardness, strength and durability. For use under special conditions a wood suitable to the particular requirements must be selected. The following is a list of the best timbers for different situations: for general construction, spruce and pine of the different varieties; for heavy constructions, pitch pine, oak (preferably of English growth), teak, jarrah; for constructions immersed in water, Baltic pine, elm, oak, teak, jarrah; for very dry situations, spruce, pines, mahogany, teak, birch, sycamore.

There are no regulations in England limiting the working stresses that may safely be placed upon timber, although in some districts the least sizes that may be used for timbers in roofs and floors are specified. In some European and other countries, however, the safe working stresses of timber used for constructional purposes are defined. The building by-laws of the municipality of Johannesburg and the Acts of the Legislative Assembly contain the following table:

<table>
<thead>
<tr>
<th>Safe Working Stresses for Timber. In tons per square inch.</th>
</tr>
</thead>
<tbody>
<tr>
<td>Hardwood.</td>
</tr>
<tr>
<td>Fir and Pine.</td>
</tr>
</tbody>
</table>

Note.—The compressive stress are for short struts and columns where the length does not exceed for timber 15 times the least transverse dimension, and where the ends are fixed. Where the ratio of the length to the least transverse dimension is higher, the load per square inch shall be proportionately reduced. No part of timber shall exceed in length 30 times its least transverse dimension.

**Timber-Line — Timbuktu**

In physical geography, the line of elevation above sea-level above which trees do not grow. In any hilly locality, which is not of too high latitude to allow of trees growing near the sea-level, this line is generally clearly marked. It varies not only with general but also with local conditions of climate, just as does the snow-line.

**Timber-Wolf (Canis occidentalis), or grey wolf, an American species, or, perhaps, a geographical race of the European C. lupus (see Wolf).** The length of good specimens is about 64 in., of which the tail forms nearly a quarter, and the range of colour is from black to white. Cattle ranchers and shepherds have established a war of extermination against this wolf and their efforts have been several times interrupted by a bounty fixed by the government. The reward was at one time $10 on wolf-scallips. In Montana in 1901 during a month in the saddle an observer saw no wolves, which have become so scarce that the occupation of the professional wolf-hunter is almost gone. These animals are, however, far from being exterminated, the "bad lands" forming an absolutely secure refuge.

**Timbrel or Tarret (the taf of the ancient Hebrews, the deff of Islam, the adufe of the Moors of Spain), the principal musical instrument of percussion of the Israelites, identical with the tambourine.** The word timbal is used in the Old Testament in both its plural and singular forms; it was the name of a vessel containing a set of bells or small gongs fixed at intervals in hoops. The Israelites learnt to use the timbrel during their sojourn in Egypt, and it has been suggested that as the Egyptians used it to scare away their evil spirit Typhon, the word taf is derived from the latter. The tabret or timbrel was a favourite instrument of the women, and was used with dances, as by Miriam, to accompany songs of victory, or with the harp at banquets and processions; it was one of the instruments used by King David and his musicians when he danced before the Ark. It was also used in the valley of Hinnom at the sacrificial rites, when human victims were "passed through the fire" to Moloch.

(K. S.)

**Timbs, John (1801-1875), English antiquary, was born in Clerkenwell, London, on the 17th of August 1801. He was educated at a private school at Hemel Hempstead, and in his sixteenth year apprenticed to a druggist and printer at Dorking. He had early shown literary capacity, and when nineteen began to write for the Monthly Magazine. A year later he became secretary to Sir Richard Phillips, its proprietor, and permanently adopted literature as a profession. He was successively editor of the Mirror of Literature, the Harlequin, the Literary World, and sub-editor of the Illustrated London News. He was also founder and first editor of Year-Book of Science and Art. His published works amounted to more than one hundred and fifty volumes. In 1834 he was elected a fellow of the Society of Antiquaries. He died in London on the 6th of March 1875.**

**Timbuktu (French spelling Tombouctou), chief town of the territory of Timbuktu, French West Africa, 9 m. N. of the main stream of the Niger in 16° N. and 5° W.**

Timbuktu lies on a terrace formed by the southern scarps of the Sahara, about 800 ft. above sea-level, and overlooking a chain of dunes or marshy hollows, fringed here and there with a few mimosas and palm trees, and surrounded sandy wastes. These dunes, which are flooded every three or four years, convert the lowland tracts between the terrace and the main stream into a labyrinth of channels and backwaters, mark the bed of a navigable creek which formerly branched from the Niger northwards to the foot of the scarps, and which in 1640 inundated a low-lying quarter of the city. It is conjectured that the main stream followed this course before it took its present easterly curve to Burrum, where it divides southwards to the coasts, and finally joins the foregoing remote period of Wadi Messuara from the Tuat oases south of Algeria, although the rough levels taken by the topographer Less and other maps are uncertain whether the flow of waters to this delta is from the north or north-west. In any case Timbuktu has been left, so to say, high and dry by the general process of desiccation going on throughout the Saharan region.

Timbuktu has been described as "the meeting point of the camel and the canoe," "the port of the Sahara in the Sudan," and (more correctly) "the port of the Sudan in the Sahara." It is a great "exchange" for the produce of North Africa and
that of the rich countries south and west of the Niger. It was
formerly a much larger place than it was found to be at the time
of its occupation by the French in 1893–1894. Extensive ruins
exist north and west of the present town. The great mosque
which at one time stood in the centre of the town now lies near
the well, an outbuilding, where its high but slightly east tower
forms a striking landmark. The mosque of Sidi Yaia (in
the centre of the town) and that of Sankoré in the north-east also
possess prominent towers. Two forts, built by the French
and placed, one on the northern the other (Fort Bonnier) on
the southern side of the town, protect the roads to the desert and
the river respectively. Whereas in 1893 the town was little more
than a vast ruin, under French protection the inhabitants,
relieved from the fear of Tuareg oppression, set about repairing
and rebuilding their houses; trade revived; new streets were
broadened; European schools, churches and other establishments
were opened.

The industries of Timbuktu—cotton-weaving, earthenware,
leather-work and embroidery—are of subordinate importance,
and the great bulk of the people are occupied exclusively with
trade. The whole traffic of the surrounding lands converges on
Timbuktu, which has a transit trade estimated at over £500,000
per annum. Considerable quantities of British and German
fabrics, hardware, beads, &c., are conveyed across the Sahara
from Mogador (Morocco), while two great caravans of 3000 or
4000 camels are yearly charged with salt from the Taduni
district, salt being an important item in the Niger caravan trade.
The imports via the Sahara average about £50,000 annually,
and by way of Senegal goods of equal value are received.
From the south come cereals, gold, wax, ivory and coarse native
cotton goods, now brought to Kabara (the port of Timbuktu)
by steamers plying on the upper Niger. Cowries, the former
currency (2500 = 5 francs), have been generally replaced by
French money. It is proposed to connect the city with the
Niger by a canal.

Timbuktu, which possesses some valuable Arabic manuscripts
—notably the Tarik es-Sudan, a 17th-century history of the
Sudan written by Abderrahman Sadi of Timbuktu—and is
a centre of Moslem teaching, is a converging point of the chief
west Sudanese and Saharan races—Arabs or Arabized Berbers
to the west; Songhio in the immediate vicinity, and thence
south-eastwards along the Niger; Ireghenaten or "mixed"
Tuareg southwards across the Niger as far as the Hombori Hills
and in the fertile Llibbako plains beyond them; Fula, Mandingo,
and Bambara in and about the city; and Imoshagh (Tuareg)
belonging to the Aweilmedien confederacy mainly to the north
and west.

The local administration—preserved under French rule—
is in the hands of an hereditary kahia, a kind of mayor, descended
from one of the Runa families (see below). The kahia, during
the greater part of the 19th century, was more or less under
the control of the powerful Bakhai (Bacay) family, who, as
"sheriffs" and marabouts, were revered throughout the western
Sahara.

History.—The history of Timbuktu is intimately connected
with that of the city of Jenne and the Songhoi Empire. The
Songhio (q.v.) are a negro race reported to have come to the Niger
country from the Nile valley. In the 8th century they made
themselves masters of a considerable tract of country within
the bend of the Niger, and built the city of Gao (q.v.) 200 m.
in a direct line S.S.E. of Timbuktu, making it their capital. In
the 11th century they were converted to Islam. Besides Gao,
the Songhio founded Jenne (q.v.), which early attained consider-
able commercial importance. Meantime (11th century) a
settlement had been made at Timbuktu by Tuareg. Perceiving
the advantages for trade with the north offered by this desert
rendezvous, the merchants of Jenne sent agents thither (12th
century), and Timbuktu shortly afterwards became known to
the inhabitants of the Sahara and Barbary as the best market
in which to dispose of their salt and other goods, and also for
the purchase of the many commodities of the western Sudan.
In the 12th or 13th century Timbuktu fell under the power
of the Mandingo kings of Melle or Mali, a country lying west and
south of Jenne. Its fame as a mart for gold and salt spread to
Europe; "Timboutch" being marked on a Catalan map dated
1523, and in 1525 had been visited by the famous traveller Ibn
Batuta. In 1434 the Tuareg made themselves masters of the
city, which in 1460 was captured by the Songhoi king Sunni Ali.
In the days of Sunni's successor Askia (1494–1529), who com-
pleted the conquest of Melle begun by Sunni Ali, the Songhoi
empire reached its highest development, and Timbuktu rose
to great splendour. The "university" of Sankoré became a chief
centre of Mahomedan culture for the peoples of the western
Sudan. One of the sheiks of Sankoré, Ahmad Baba, was among
the most learned of Moslems. Some of his writings are still
existed. The riches of Timbuktu. The eminence of El
Mansur, sultan of Morocco, who, in 1590, sent an army across
the Sahara under an "Andalusian" Moor (that is, a Moor
descended from those expelled from Spain), which captured
Timbuktu (1591) and completely broke up the Songhoi empire.
The Moors made Timbuktu their capital city. For about twenty
years after the conquest the pasha who ruled at Timbuktu was
nominated from Morocco, but the distance of the Niger countries
from Marrakesh enabled this vast viceroyalty to throw off all
allegiance to the sultan of Morocco.

The Tuareg Moors, known as Rumas after El Mansur's musketeers,
who maintained a tradition of their own, and provided by
them, the negro tribes. By the end of the 18th century two hundred years
of oppression had reduced Timbuktu to comparative desolation and
poverty. By this time the whole country was in a state of
anarchy, and in 1800 the Tuareg swooped down from the desert
and captured the place. They were in turn (1813) dispossessed
by the Fula, who in 1840 gave place to the Tukulor, led by El
Haj Omar, the first great opponent of the extension of French
influence in the Niger bend. When the French reached Tim-
buktu in December 1893 they found that the town had again
fallen beneath the rule of the Tuareg. The townsmen, instead
of the time from the decay of the Ruma power being at the
mercy of all comers, were content to pay tribute to each in turn
and sometimes to more than one simultaneously, for which they
indemnified themselves by peaceful intervals of trade
whenever the land routes were open and the upper and lower
reaches of the Niger clear of pirates. But at times even the short
tract separating the town from Kabara was so beset with
marauders that it bore the ominous name of "Ur-immaness," that is,
"The (God) hears not." Little wonder then that the townsmen,
weary of the constant and internecine strife of their Fula and Tuareg
masters, freely opened their gates to the French as soon as Liet. Boiteux reached Kabara in command of a small flotilla.

The occupation of the town, against orders, was a daring
exploit of a handful of marines. The force which "garrisoned"
Timbuktu consisted of but seven Europeans and twelve Sene-
galese, a somewhat larger body being left with the gunboats at
Kabara. On the 28th of December the Tuareg attacked the
boat party, killing Naval Ensign Aube, another officer, and
eighteen black sailors. Colonel T. P. E. Bonnier, who was at
the time a prisoner in the town, marched to the relief of Boiteux
and entered Timbuktu without opposition on the 10th of January
1894. Leaving part of his force in the town the colonel set out
with about 100 men to chastise the nomads. In the night of the
14th–15th January his camp was surprised and the colonel
and nearly all his men perished. The enemy did not follow
up their victory, and within a short period French rule was
firmly established in Timbuktu.

Apart from some Christian captives, the place was reached
during the 19th century, previous to its capture by the French,
by four Europeans—Major Gordon Laing from Tippoli (1820),
who was murdered by order of the Fula; René Caillée from
the south (1828), Heinrich Barth from Central Sudan (1855) and
Oskar Lenz from Morocco (1880). (In 1893 the French authori-
ties placed commemoratve tablets on the houses occupied by

1Tim-Buktu in Arabic may stand for "the well of Buktu," in
the Songhio tongue the word means a hollow.
the four men during their stay in Timbuktu. The tablets bear simply the name of the explore and the date of his visit.) In 1895
Felix Dubois made a stay of some duration in the town, investi-
gating its history and that of the surrounding country. In 1904
Timbuktu became part of the colony of Upper Senegal and Niger.

The British connexion with Timbuktu may be briefly stated.
British explorer, Dr. E. J. P. du Chaillu, visited the town in 1868

and the inclination of its orbit to the equator, so that it becomes
necessary to introduce an imaginary mean sun moving in the
equator with uniform velocity. The equation of time is the
difference between apparent (or true) solar time and mean
solar time. The latter is that shown by clocks and watches used
for ordinary purposes. Mean time is converted into apparent
time by applying the equation of time with its proper sign, as
given in the Annual Almanac, during a universal day for every
day at noon. As the equation varies from day to day, it is
necessary to take this into account, if the apparent time is
required for any moment different from noon. The ephemerides
also give the sidereal time at mean noon, from which it is easy
to find the sidereal time at any moment, as 24 hours of mean
solar time are equal to 24° 36' 56.55' of sidereal time. About
the 21st of March each year a sidereal clock agrees with a mean
time clock, but it gains on the latter 3° 56.5' every day, so that
in the course of a year it has gained a whole day. For a place
not on the meridian of Greenwich, the sidereal time at noon
must be corrected by the addition or subtraction of 9° 8.5'6"
for each hour of longitude, according as the place is west or
east of Greenwich.

While it has for obvious reasons become customary in all
civilized countries to commence the ordinary or civil day at
midnight, astronomers count the day from noon, being
the transit of the mean sun across the meridian, in strict conformity
with the rule as to the beginning of the sidereal day. The hours
of the astronomical day are also counted from 0 to 24.

Determination of Time.—The problem of determining the
exact time at any moment is practically identical with that of
determining the apparent position of any known point on the
celestial sphere with regard to one of the fixed (imaginary) great
circles appertaining to the observer's station, the meridian or the
horizon. The point selected is either the sidereal or one of the
standard stars, the places of which are accurately determined
and given for every tenth day in the modern ephemerides.
The time thus determined furnishes the error of the clock, chronon-
\_meter or watch employed, and a second determination of time after
an interval gives a new value of the error and thereby the
rate of the timekeeper.

The ancient astronomers, although they have left us very
ample information about their dials, water or sand clocks (\_clespydrae),
and similar timekeepers, are very reticent as to the means they
employed in applying this method. Ptolemy, states nothing whatever as to how the time was found when the numer-
ous astronomical phenomena which he records took place;
but Hipparchus, in the only book we possess from his hand,
gives a list of 44 stars scattered over the sky at intervals of
right ascension equal to exactly one hour, so that one or more
of them would be on the meridian at the commencement of
every sidereal hour. H. C. F. C. Schjellerup \(^1\) has shown that
the right ascensions assumed by Hipparchus agree within about
15' or one minute of time with those calculated back to the year
140 B.C. from modern star-places and proper motions. The
accuracy which, it thus appears, could be stated by Hipparchus
in their determinations of time was far beyond what they seem
to have considered necessary, as they only record astronomical
phenomena (e.g. eclipses, occultations) as having occurred
"towards the middle of the third hour," or "about 8½ hours of
the night," without ever giving minutes. \(^2\) The Arabians had a

\(^{2}\) For astronomical purposes the ancients made use of mean-
time horai, \_epotai, horai ephemeridales—which into which
they translated all indications expressed in civil hours of varying length—
\_pse kaupakal, horai temporales. Ptolemy counts the mean day from
noon.
clearer perception of the importance of knowing the accurate
time of phenomena, and in the year 829 we find it stated that at
the commencement of the solar eclipse on the 30th of November
the Tycho's fan of an instrument was observed at the mid 21°, as
observed at Bagdad by Ahmed ibn Abdullah, called Habash. 1 This
seems to be the earliest determination of time by an altitude; and this
method then came into general use among the Arabians, who,
on observing lunar eclipses, never failed to measure the altitude
of some bright star at the beginning and end of the eclipse. In
Europe this method was adopted by Purbach and Regiomontanus
apparently for the first time in 1457 Bernhard Walther, a pupil
of the latter, seems to have been the first to use for scientific
purposes clocks driven by weights: he states that on the 16th of
September he observed the longitude of the planets Mercury,
and immediately attached the weight to a clock having an hour-
wheel with fifty-six teeth; at sunrise one hour and thirty-five
teeth had passed, so that the interval was an hour and thirty-
seven minutes. For nearly two hundred years, until the applica-
tion of the pendulum to clocks became general, astronomers
could place little or no reliance on their clocks, and conse-
quently it was always necessary to fix the moment of an observa-
tion by a simultaneous time determination. For this purpose
Tycho Brahe employed altitudes observed with quadrants; but he
remarks that if the star is too near the meridian the altitude
may be too low, and if too near the horizon the refrac-
tion (which at that time was very imperfectly known) introduces
an element of uncertainty. He sometimes used azimuths, or with
the large "armillary spheres" which played so important a part
among his instruments, he measured hour-angles or distances
from the meridian along the equator. 2 Transits of stars across
the meridian were also observed with the meridian quadrant,
an instrument which is alluded to by Ptolemy and was certainly
in use at the Marâgha (Persia) observatory in the 13th century,
but of which Tycho was the first to make extensive use. But he
very aptly employs the star-planet to determine, after obtaining
the clock error by the methods already described.

In addition to these methods, that of "equal altitudes" was
much in use during the 17th century. That equal distances east
and west of the meridian correspond to equal altitudes had of
course been known as long as sundials had been used; but, now
that quadrants, cross-staves and parallactic rules were commonly
employed for measuring altitudes more accurately, the idea
naturally suggested itself to determine the time of a star's or
the sun's meridian passage by noting the moments when it
reached any particular altitude on both sides of the meridian.
But this plan of an instrument in the same line of thought
was not forgotten, and from the end of the 17th century, when
Römer invented the transit instrument, the observation of
transits across the meridian became the principal means of
determining time at fixed observatories, while the observation
of altitudes, first by portable quadrants, afterwards by reflecting
sextants, and during the 19th century by portable alt-azimuths
or theodolites, has been used on journeys. Since about 1830
the small transit instrument, with what is known as a "broken
teleScope," has been much employed on scientific expeditions,
but dry gemination is necessary in using it, as the difficulty of
getting a perfectly rigid mounting for the prism or mirror
which reflects the rays from the object glass through the axis
to the eyepiece appear to be very great, for strange discrepan-
cies in the results have often been noticed. The gradual develop-
mend of astronomical instruments has been accompanied by
a corresponding development in timekeepers. From being very
untrustworthy, astronomical clocks are now made to great
perfection by the application of the pendulum and by its com-
pliance, while the invention of chronometers has placed a
portable and equally trustworthy timekeeper in the hands of
travellers.

We shall now give a sketch of the principal methods of
determining time.

1 Causin, Le Livre de la grande table Hâkème, p. 100 (Paris, 1804).
2 See his Epistolas astronomicae, p. 73.
circle) is generally found on observation of four or five "clock stars," these being standard stars not near the pole, of which the altitudes may be determined with considerable accuracy, besides observation of a close circumpolar star for finding the error of azimuth and determination of level and collimation error.  

Observing the field, the instruments often find it inconvenient to wait for the meridian transits of one of the few close circumpolar stars given in the ephemerides. In that case they have recourse to what is known as the method of time determination. When the alt-azimuth of a pole star is directed to one of the standard stars near the pole, such as α or δ Ursae Minoris, using whichever is nearest to the meridian at the time. The instrument is set so that the star in a few minutes will cross the middle vertical wire in the field. The spirit-level is in the meantime put on the axis and the inclination of the latter measured. The time of the transit of the star is then observed, after which the instrument is tilted in the south, is turned to a cock wire and the transit of this over all the wires is observed. The level is applied again, and the mean of the two results is used in the reductions. In case the collimation error of the instrument is not accurately known, the instrument should be reversed and another observation of the same kind taken. The observations made in each position of the instrument are separately reduced with an assumed approximate value of the error of collimation, and two equations are thus derived from which the clock error and correction to the assumed collimation error are found. This use of the transit or alt-azimuth out of the meridian throws considerably more work on the observer, but for the meridian alone it does not seem ever never resorted to except when an observer during field operations is pressed for time. The formulae of reduction as developed by Hansen in the Astronomische Nachrichten (xxviii, 113 seq.) are given by Czerny in his Spherical and Practical Astronomy ii. 216 seq. (4th ed., Philadelphia, 1873). The subject has also been treated at great length by Döll in two memoirs: Die Zeitbestimmung mit Hilfe der Durchmusterung im Verticale des Polardreieck (ato, St. Petersburg, 1863 and 1874).

Longitude.—Hitherto we have only spoken of the determination of local time. But in order to compare observations made at different places on the surface of the earth a knowledge of their difference of longitude becomes necessary, as the local time varies proportionally with the longitude, one hour corresponding to 15°. Longitude can be determined either geodetically or astronomically. The first method supposes the earth to be a sphere of known dimensions. Starting from a point of departure of which the latitude has been determined, the azimuth from the meridian (as determined astronomically) and the distance of some other station are measured. This second station then serves as a point of departure to a third, and by repeating this process the longitude and latitude of places at a considerable distance from the original starting-point may be found. Referring for this method to the articles EARTH, FIGURE OF THE, and GEODESY, we shall here only deal with astronomical methods of determining longitude.

The earliest astronomer who determined longitude by astronomic means is said to have been Hipparchus, who chose for the first meridian that of Rhodes, where he observed; but Ptolemy adopted a meridian laid through the "Insulae Fortunatae" as being the farthest known place towards the west. When the voyages of discovery began the peak of Teneriffe was frequently used as a first meridian, until a scientific congress, assembled by Richelieu at Paris in 1630, selected the island of Ferro for this purpose. Although various other meridians (e.g. that of Uarburg and that of San Miguel, one of the Azores, 29° 25' W. of Paris) continued to be used for a long time, that of Ferro received the most recognition. The first meridian of the Xth. Observ., in the field, portable instruments of 1830, was the Greenwich meridian, adopted with the recommendation of a conference held in 1851, and found by Captain Tyndall, in the course of his voyage to the doubtful and tropical regions of the world. Meteorological observations are commenced, with the recommendation of a conference of the British Association of 1852. The Greenwich meridian was adopted by the United States, in 1854, with the recommendation of a conference of 1854. In 1853 four standard meridians were defined to the United States, 76°, 90°, 105°, 120° west of Greenwich, so that clocks showing "Eastern, Central, Mountain, or Pacific time" are exactly five, six, seven or eight hours slower than a Greenwich mean time clock. In Europe Norway, Sweden, Germany, Austro-Hungary, Switzerland and Italy use mid-European time, one hour fast on Greenwich. In South Africa the legal time is two hours fast on Greenwich, &c.

The simplest method for determining difference of longitude consists in observing at the two stations some celestial phenomenon which occurs at the same absolute moment for the whole earth. Hipparchus pointed out how observations of lunar eclipses could be used in this way, and for about fifteen hundred years this was the only method available. When Regiomontanus began to publish his ephemerides towards the end of the 15th century, they furnished other means of determining the longitude. Thus Amerigo Vespucci observed on the 23rd of August 1499, somewhere on the coast of Venezuela, that the moon at 7° 30' p.m. was 17°, at midnight 35° east of Mars; from this he concluded that they must have been in conjunction at 6° 30', whereas the ephemeris announced this to take place at midnight. This gave the longitude of his station as roughly equal to 53 hours west of the prime meridian. This instrumen could, of course, be very imperfect, the longitudes determined were very erroneous. The invention of the telescope early in the 17th century made it possible to observe eclipses of Jupiter's satellites; but there is to a great extent the same drawback attached to these as to lunar eclipses: that it is impossible to observe with sufficient accuracy the moments at which they occur.

Eclipses of the sun and occultations of stars by the moon were also much used for determining longitude before the invention of chronometers and the electric telegraph offered better means for fixing the longitude of observatories. These methods are now hardly ever used except by travellers, as they are very inferior as regards accuracy. For the necessary formulae see Chauvenet's Spherical and Practical Astronomy, i. 518-542 and 550-557.

We now proceed to consider the four methods for finding the longitudes of fixed observatories, viz. by (1) moon calculations, (2) rockets or other signals, (3) transport of chronometers and (4) transmission of time by the electric telegraph.

1. Moon Calculations.—Owing to the rapid orbital motion of the moon, its sidereal proportional motion is different for different meridians. If, therefore, the rate of the moon's change of right ascension is known, it is easy from the observed time of culmination on the meridian to find the sidereal times to be as much as possible independent of instrumental errors, some standard stars nearly or at the parallel of the moon are observed at the two stations; these "moon-culminating stars" are given in the ephemerides in order to secure that both observers take the same stars. As either the preceding or the following limb, not the centre, of the moon is observed, allowance must be made for the time the semi-diameter takes to pass the meridian and for the change of right ascension during this time. This method was proposed by Pigot towards the end of the 18th century, and has been much used; but, though it may be very serviceable on journeys and expeditions to theœ, its use is not recommended in cases where observations cannot be employed, it is not accurate enough for fixed observatories. Errors of four to six seconds of time have frequently been noticed in longitudes obtained by this method from a limited number of observations: e.g. 4-47' in the case of the London observatory.

2 For fixed stations the photographic method first proposed and carried out by Captain Tyndall, at the Cape of Good Hope, was advantageous. A camera of rigid form is set up and some instantaneous moon-exposures are made, after which the camera is left untouched until a few exposures can be made of a couple of bright stars, which are allowed to impress their trails on the plate for 15 or 30 seconds. If the exact local time of each exposure be known, such a plate gives the data necessary for computing the moon's position at the time of each exposure, and hence the Greenwich time and longitude (Mem. Roy. Astr. Soc., 1899, iii. 117).
2. Signals.—In 1671 Picard determined the difference of longitude between Copenhagen and the site of Tycho Brahe's observatory at Helsingør by observing the transit of a star across the meridian from both stations. He placed a telescope on the roof of his observatory in Copenhagen. The stars were observed with an instrument of 9 inches in diameter, which was later increased to 12 inches. The observations were made from the beginning of May to the middle of July. On the first day of May, a star was observed to cross the meridian at 3 p.m. at Copenhagen and at 3:06 a.m. at Helsingør. The difference in time was 100 minutes, so that the longitude of Copenhagen was determined to be 9 degrees west of Helsingør.

3. Use of Rocket Signals.—In 1848, a rocket was launched from the top of the tower of the observatory at Copenhagen. The rocket was equipped with a small灯笼, which was set on fire by a spark produced by a battery. The flame was visible for a distance of 20 miles, and was observed at several observatories in England and France. The rocket signals were used to determine the difference of longitude between Copenhagen and London.

4. Determination of Longitude by Signals.—In 1849, a signal was sent from the western station A at the local time T1, and received at the eastern station B at the local time T2. The difference in time T2 - T1 is the longitude of station A, and is determined by this method. The signal was transmitted by a chronograph, which was a device for measuring time accurately. The chronograph was placed on a platform which could be moved horizontally. The platform was driven by a spring, and the motion of the platform was transmitted to a lever which operated a register. The register was a device for recording the time on a card. The chronograph was operated by a clock, which was set by a signal from the western station. The clock was set by a signal from the eastern station, and the difference in time was taken either by eye or by ear or by the chronograph, but as the observations made with the chronograph were somewhat more accurate than those made by eye and ear, the chronograph should be used in preference to the other methods.

The method of simultaneous registration at both stations of transits of the same star has one advantage. Each transit observed at both stations furnishes a value of the difference of longitude, and the final result is the mean of the two values. In the first method, which necessitates the combination of a series of clock errors determined during the night to form a value of the difference of longitude, the errors are cumulative.

When using this method it is advisable to select the stars in such a manner that only one station at a time is at work, so that the intensity of the current can be readjusted (by means of a rheostat) for the intensity of the current for the other station. When a single station is in use, the intensity of the current is necessary whatever method is employed, as the constancy of the transmission time (z in the above equations) chiefly depends on the constancy of the current. The probable error of a difference of longitude deduced from one star appears to be 3 degrees for eye and ear transit and 0.008 degree for chronograph transit.

Wireless telegraphy was first used in 1869 to determine the longitude of the western station of Altona-Greenwich in England. The signals were sent from Nauen, 32 km from the station, and from 183 km from the latter station. The clock-differences were found to be quite independent of the energy of the electric current in the wireless telegraph. The results made it possible for the first time to determine the longitudes of ships in places where it may be desirable to determine the longitudes of a number of stations at the same time.

The results of a determination of longitude depend to a very great extent on the accuracy of time of the two stations, and great care must therefore be taken to determine the instrumental errors repeatedly during a night's work. But in addition to the uncertainty which enters into the results from the ordinary errors of observation, there is another source of error which becomes of special importance in longitude work, viz., the range of the observer. It is sometimes possible to conceive that one person may hear and then see, while another these sensations take place in the reverse order; and to this possible source of error may be added the sensible time required by observers to analyse and then start to act on the third signal, and this time is referred to the latter for its exact determination. As the chronographic method of observing dispenses with one sense (that of hearing) and merely requires the watching of the star's motion and the pressing of an electric button, it is possible to compensate for the subjective element in the personal errors should in this case be much smaller than when the eye and ear method is employed. And it is a fact that in the former method there have been or occurred errors of between half and a whole second such as have not infrequently appeared in the latter method.

In transit observations generally this personal error does not cause any inconvenience, so long as only one observer is employed at a time, and unless the amount of the error varies with the magnitude of the star (which is often the case); but when absolute time has to be determined, as in longitude work, the full amount of the personal error is received between the times T1 and T2, and the latter is referred to the former for its exact determination. It may be conceived that one observer may hear and then see, while another these sensations take place in the reverse order; and to this possible source of error may be added the sensible time required by observers to analyse and then start to act on the third signal, and this time is referred to the latter for its exact determination. As the chronographic method of observing dispenses with one sense (that of hearing) and merely requires the watching of the star's motion and the pressing of an electric button, it is possible to compensate for the subjective element in the personal errors should in this case be much smaller than when the eye and ear method is employed.

1 Albrecht, Bestimmung von Längendifferenzen mit Hilfe des elektrischen Telegraphen, p. 80 (Leipzig, 1869).

2 Maskelyne had in 1795 noticed that one of his assistants observed transit signals which he considered too slow, and that it was supposed to arise from some wrong method of observing adopted by the assistant, and the matter was not further looked into.
caused by a shifting of the reflector inside the telescope, by means of a rack and pinion, which produced an apparent shifting of the image of the spider lines, unless the eye-piece was very accurately focused for the observer's sight. The simplest and best way to find the equation between two observers is to let one observer work at the completion of a certain number of and the other observe the transits over the remainder, each taking care to refocus the eye-piece for himself in order to avoid the above-mentioned effect. Repsold's equation was reduced to have immediately the equation; and, in order to eliminate errors in the assumed wire-intervals, each observer uses alternately the first and the second half of the wires. In longitude work, the two wires are taken as the basis of a certain number of nights' work exchange stations and commence a new set of observations; the mean of the two results thus obtained should be free from the effect of personal error, provided that the errors of both observers happen to be equal in respect to the same wire. Whichever of the two observers happens to let the observers compare themselves at the beginning, middle and end of the operations, and, if possible, at both the instruments employed. A user—General results are afforded by simultaneous experiments with one of the instruments contrived by C. Wolf, Kaiser and others, by which the absolute personal error of an observer can be determined. Though differing much in detail, these instruments are all constructed on the same artificial star (a lamp shining through a minute hole in a screen mounted on a small carriage moved by clockwork) passes in succession across a number of lines drawn on oiled paper, while an electric contact with the instrument is made at each transit by means of conductors on each line by the carriage passing a number of adjustable contact makers. The currents thus made register the transits automatically on a chronograph, while the operator observes and apprises the carriage by his eye and ear or by chronograph, thus immediately finding his personal error. These contrivances have sometimes been used to educate pupils, there being good examples of them. It is shown that the possible personal error can be generally somewhat diminished through practice. By using Repsold's self-registering micrometer, which enables the observer to follow the motions of the star with a movable vertical wire which automatically registers its passage over coter fixed points in the eyepiece, the effect of personal error is almost completely eliminated. In the determination of the difference of longitude between Fortsdaan and Dresden, the longitude of the station 3° 0', the relative error on the appearances through the eyepiece, and the sum of their personal and instrumental equation was 0.0006 with a probable error of 0.0005.

LITERATURE—Great treatises on spherical astronomy, such as Brünnow's Lehrbuch der sphärischen Astronomie (3rd ed., Berlin, 1871; trans. into English and several other languages) and Chauvenet's Manual, treat very fully of the numerous methods of determining time by combination of altitudes or azimuths of several stars. For telegraphic longitude work see the Publications des kön. preussischen geodätischen Instituts; the Reports of the United States Coast and Geodetic Survey; the A Ccounts of the Great Trigonometrical Survey of India; and Report of the Chief Astronomer, 1905 (Ottawa, 1906), which gives a useful review of recent longitude work in the Pacific and adjacent countries. On personal errors see the Memoire, of the Acad. des Sciences, and "Recherches sur l'équation personelle par M. F. Connessat" in the Trav. de l'observ. de Lyon (1892), vol. ii. (J. L. E. D.)

TIME, STANDARD. Local time is determined by the relation of the meridian of a place to the sun. Noon at any place is defined as the moment when either the true or mean sun passes the meridian of that place, according as apparent or mean time is used. Practically, the use of mean time is now universal, so that we may regard the mean sun as that by which noon is determined. As the earth revolves, all its meridians are brought under the sun in succession. At any instant the earth, rotation time, revolves about the earth, making the circuit in twenty-four hours. It follows that noon, and therefore any other hour of the day, is later by four minutes for every degree of longitude towards the west, so that a watch carried east or west will be found to deviate from local time by an amount proportional to the change of longitude. Before the time of railways this deviation was not productive of inconvenience. But when railway travelling became common, train schedules had to be more exact than those of a mail coach, and the traveller was rapidly carried to places where the local time continually deviated from that shown by his watch. The invention of railways had thus produced a situation in which communication with others of a different longitude was frequent. Thus arose a practice on the part of railways of using the time of some central or important city on its line for all places not too distant, which time would naturally be adopted by the inhabitants of the region through which it passed. For a similar reason, in countries which did not extend through a large fraction of an hour of longitude, it was natural to use the time of the capital throughout all or a large part of its extent. Thus Greenwich time has long been in use throughout England, and all the railways of France are run by Paris time. But inconvenience was still unavoidable in passing from one country to another, or in travelling through long stretches in the same country. The inconvenience was especially felt in the United States, where every railway, and even every long stretch of several great railways, had its own time system. Thus it happened not infrequently that in a single station clocks would be found set to the time of three different meridians, one for the road toward the east, another for the road toward the west, and a third for the meridian of the place, or local use. A device now being generally adopted to do away with this confusion was planned in 1878-1879 by Mr (afterwards Sir) Sandford Fleming, and published in the Journal of the Canadian Institute of Toronto for 1879. On the initiative of this organization, Mr Fleming's proposals were officially communicated to the leading governments of the world with a view of securing an international unification of the method of designating the hour of the day for common use. Naturally connected with the proposal was that of a prime meridian, from which all longitudes should be reckoned. United States invited an international conference, which was held in Washington in 1884, for the purpose of adopting a standard meridian to which longitudes and times should be referred.

Before this conference was called the railway managers of the United States, after long discussion, adopted the system. Its fundamental idea was that twenty-four standard meridians should be established 15° apart in longitude, starting from the meridian of Greenwich and extending round the globe. Then on each meridian the local time would differ from Greenwich time by some entire number of hours. At every point of the globe the time to be adopted for common use was that of the nearest standard meridian. These twenty-four standard meridians would then divide the earth into lines of twenty-four zones, within each of which the time to be adopted would be uniform, but which would change by an hour on passing from one zone into another. The inhabitants of each zone naturally take the time of the zone instead of their local time, the maximum difference between the two being half an hour.

When the system was first established in the United States a delicate legal question arose as to whether the business of banks and courts should be legally adjusted to the new time. This was soon settled by law making the standard time legal within the limits of each zone. A similar system is being adopted in Europe, the standard meridians being those of 15°, 30°, &c., east of Greenwich. France, however, still adheres to Paris time, but Belgium and Holland use Greenwich time, and Switzerland, Italy and central Germany use the time of 15° E., and therefore one hour in advance of that of Greenwich. This is termed mid-European time.

The system we have described is that adopted for the purposes of the railways and of daily life. For scientific and for some international purposes yet other modifications are desirable. An important distinction must be made between the cases in which no inconvenience results that the time be 4 hours behind the hour of the day, and those where no such relation is required. The former is the case in designating acts or occurrences which depend upon our daily routine of rest and wakefulness. But if nothing is necessary except the designation of some moment of absolute time, irrespective of our daily routine of life, then only a single measure for the whole world is necessary. At the Washington Meridian Conference of 1884 it was proposed that Greenwich time should be adopted as a standard for the whole world in all matters of this class, especially in astronomical practice and in cable despatches. But this system does not seem to have been extensively adopted outside of astronomy, the
cultivators of which are most accustomed to the conversion of local into standard or Greenwich time. An unavoidable inconvenience associated with the system is the uncertainty in many cases whether local or Greenwich time is understood. This must be especially the case with magnetic and seismic phenomena, the designation of which should be uniform for the whole earth; at present, however, we cannot invariably expect local observers to convert their observations from local into Greenwich mean time.

Associated with this question is that of the moment when the day should begin, or from which the hours should be counted. This civil day begins at midnight (the beginning of the day at midnight and p.m. (post meridiem, after mid-day), now practically universal in household and ordinary civil life, is impracticable for scientific purposes, where a count of the hours from 0 up to 24 is necessary. In railway schedules the necessity of distinguishing a.m. from p.m. when our civil time is used is found so troublesome that in some countries, especially Italy and Canada, the 24-hour system is used. Hours after noon are there designated as 13, 14, &c., up to midnight, at which moment a new day begins. On the other hand, with some few exceptions, astronomers have always from the immemorial begun their day at noon, and navigators have very generally adopted the same practice, but for a quite different reason. In astronomy the day begins at noon for two reasons of convenience. One is that as the day is fixed by the transit of the sun over the meridian, it is more natural to start the count of the hours from this moment than from that when the sun is on the invisible meridian at midnight. This practice also coincides with that of counting the hours of sidereal time from the transit of the vernal equinox, and leads to the simple rule that the local mean time is equal to the hour angle of the mean sun. The other reason is that, as the astronomer makes most of his observations at night, and often after midnight, it is inconvenient to begin a new day at the latter hour. This consideration is however reversed in day observations, especially those on the sun, but these are few in number.

Navigators began the day at noon because their latitude is determined by observations of the sun, while the longitude is also generally determined during the daytime. Thus, in doing the "day's work" in the log, the position of the ship was always computed for noon. Such being the case, it was found more convenient to begin the count of a new day at this hour, to be continued through the night until the following noon. But the navigator's count of days was one day in advance of that of the astronomers; for example, March the 10th, astronomical time, begins on the 10th day of March at noon, and this count continues until noon of the day following, so that the forenoon of March the 11th, civil time, is still March the 10th, astronomical time. But the navigator begins March the 11th at noon on March the 10th. This difference is worthy of mention because a widespread misapprehension exists that the navigator was forced to count his days from noon owing to the adoption of the same system in the Nautical Almanac. The fact is that the practice of the navigator, like that of the astronomer, was adopted purely for his own convenience, and for the reasons just set forth. It is, however, being changed so as to conform to civil time, but as yet no general law prescribes the change.

At the Meridian Conference of 1884, it was proposed that the practice of beginning the day at midnight should be adopted universally in astronomy and navigation, and that the hours should be counted from that moment in all the nautical and astronomical ephemerides. The question of adopting this system became a subject of international correspondence. The views of the directors of the astronomical ephemerides, so far as elicited, were strongly against the change. The considerations which determined them were the confusion which the change would introduce into the tables and the count of time in the ephemerides, including the relation of sidereal and solar time; the unavoidable doubt as to whether the one or the other system was used in astronomical publications; and the danger of placing in the hands of the navigator an ephemeris in which the hours should have a different meaning from that to which he was accustomed. On the other hand, the reasons of convenience which led to the practice of beginning the day at noon still continued, so that nothing could be shown to counterbalance these drawbacks. Still, in works to be used by the public, especially almanacs and other astronomical annuals, it is necessary to convert astronomical into civil time. This must continue to be done, but offers no difficulty to the authors of such works, who are acquainted with the difference, nor to the public, which has no interest in the ephemerides and measures of time used by the profession of the mathematician.

TIME BARGAINS, a financial or commercial term, is the transfer of ephemerides in securities or commodities which are to be completed at a future date, as opposed to bargains which are settled immediately. (See Market.)

TIMGAD, a ruined city 23 m. S.E. of Batna in the department of Constantine, Algeria. Timgad, the Thamugas of the Romans, was built on the lower slopes of the northern side of the Aures Mountains, and was situated at the intersection of six roads. It was traversed by two main streets, the Cardo Maximus running north and south, and the Decumanus Maximus east and west. The residential part of the town was on a lower level than the capitol and most of the other public buildings. The ruins of the capitol occupy a prominent position in the southwest of the city. Some of the columns of the façade (which are of the Corinthian order and 45 ft. high) have been re-erected. The dimensions of the capitol correspond with those of the Pantheon at Rome. Immediately north of the capitol are the remains of a large market; to the east are the ruins of the forum, basilica and theatre. The auditorium of the theatre, which held nearly 4000 persons, is complete. A little west of the theatre are baths, containing paved and mosaic floors in perfect preservation. Ruins of other and larger thermae are found in all four quarters of the city, those on the north being very extensive. Across the Decumanus Maximus just north-east of the market is the arch of Trajan—still erect, and restored in 1900. The arch is of the Corinthian order, and has three openings, the central one being 11 ft. wide. Each façade has four fluted columns 15 ft. high. The chief material used in building the arch was sandstone. The fluted columns are of fine white limestone and smaller columns are of coloured marble. At the other (eastern) end of the street are the remains of another triumphal arch. West of the capitol are the ruins of a large theatre, which was circular at the circumference, built in the 1st century. There are also remains of six other churches. About 400 yds. south of the city, the walls nearly entire, is a ruined citadel, a quadrangular building 360 ft. by 295 ft., with eight towers. It was built (or rebuilt) by the Byzantine army in the 6th century. Near the northernthermae is the house of the director of the excavations and a museum containing small objects found in the ruins.

 Numerous inscriptions have been found on the ruins, and from them many events in the history of Thamugas have been learnt. In the year A.D. 100 the emperor Trajan gave orders to build a city on the site of a fortified post on the road between Thamugas and Lambaesis. This city, called Colonia Marciana Trajana Thamugas (Marciana in honour of Trajan's sister) appears from the inscriptions to have been completed, as far as the principal buildings were concerned, in seventeen years. A legion of Parthian veterans was stationed in the newly founded city. From the time of its foundation to the 4th century Thamugas seems to have enjoyed a peaceful and prosperous existence. Numerous inscriptions testify to the manner of life of the citizens. In the 3rd century Thamugas became a centre of Christian activity, and in the next century espoused the cause of the Donatists. The city declined in importance after the Vandal invasion in the 5th century, and was found in a ruinous condition by the Byzantine general Solomon, who occupied it A.D. 535. It is believed that the Berbers from the neighbouring mountains destroyed the city, hoping thus to prevent it being used as a stronghold from which to harry them. Thamugas was, however, repeopled, and in the 7th century was a Christian
TIMOCREON-TIMOR

city. After the defeat of Gregory, governor of Africa, by the Arabs in 647, Thamugas passes from history. After centuries of neglect James Bruce, the African traveller, visited the spot (1765), made careful drawings of the monuments and deciphered some of the inscriptions. Bruce was followed, more than a century later (1873), by Sir R. Lambert Playfair, British consul-general at Algiers, and soon afterwards (1875-1876) Professor Masquerey published a report on the state of the ruins. Since 1881 Thamugas has been systematically explored, and the ruins excavated under the direction of the Service des monuments historiques. Among the objects discovered are a series of standard measures—five cavities hollowed out of a stone slab.

Seventeen miles west of Timгад, on the site of the Roman city Lambes (q.v.).

See G. Boeswillwald, R. Cagnat and A. Ballu, Timгад, une cite africaine sous l'epoque romain; and A. Ballu, Guide illustre de Timгад (Paris, 1903).

TIMOCREON, of Ialysus in Rhodes, Greek lyric poet, flourished about 480 B.C. During the Persian wars he had been banished on suspicion of "medism." Themistocles had promised to procure his recall, but was unable to resist the bribes of Timocreon's adversaries and allowed him to remain in exile. Timocreon thereupon attacked him most bitterly (see Plutarch, Thémistocle, 321) and Themistocles, the friend of Thucydides, retorted in an epigram (Anth. Pal. vii. 348). Timocreon was also known as a composer of scolia (drinking-songs) and, according to Suidas, wrote plays in the style of the old comedy. His gluttony and drunkenness were notorious, and he was an athlete of great prowess.

TIMOLEON (c. 411-337 B.C.), of Corinth, Greek statesman and general. As the champion of Greece against Carthage he is closely connected with the history of Sicily, especially Syracuse (q.v.). When his brother Timophanes, whose life he had saved in battle, took possession of the acropolis of Corinth and made himself master of the city, Timoleon, after an ineffectual protest, tacitly acquiesced while the friends who accompanied him put Timophanes to death. Public opinion approved his conduct as patriotic; but the curses of his mother and the indignation of some of his kinsfolk drove him into retirement for twenty years. In 344 envoys came from Syracuse to Corinth, to appeal to the mother-city for relief from the intestine feuds from which the Syracusans and all the Greeks of Sicily were suffering. Carthage too, their old and bitter foe, was intriguing with the local despots. Corinth could not refuse help, though her chief citizens declined the responsibility of attempting to subdue a settled government with a land army. The tumultuous reply of Syracuse, Timoleon, being named by an unknown voice in the popular assembly, was chosen by a unanimous vote to undertake the mission, and set sail for Sicily with a few of the leading citizens of Corinth and a small troop of Greek mercenaries. He eluded a Carthaginian squadron and landed at Tauromenium (Taormina), where he met with a friendly reception. At this time Hicetas, tyrant of Leontini, was master of Syracuse, with the exception of the island of Ortigia, which was occupied by Dionysius, still nominally tyrant. Hicetas was defeated at Adranos, an inland town, and driven back to Syracuse. In 343 Dionysius surrendered Ortigia on condition of being granted a safe conduct to Corinth. Hicetas now received help from Carthage (60,000 men), but ill-success roused mutual suspicion; the Carthaginians abandoned Hicetas, who was besieged in Leontini, and compelled to surrender. Timoleon was thus master of Syracuse. He at once began the work of restoration, bringing new settlers from the mother-city and from Greece generally, and establishing a popular government on the basis of the democratic laws of Diocles. The citadel was razed to the ground, and a court of justice erected on its site. The amphipolos, or priest of Olympian Zeus, who was annually chosen by lot out of three clans, was invested with the chief magistracy. The impress of Timoleon's reforms seems to have lasted to the days of Augustus. Hicetas again induced Carthage to send (340-339) a great army (70,000), which landed at Lilybaeum (Marsala). With a miscellaneous levy of about 12,000 men, most of them mercenaries, Timoleon marched westwards across the island into the neighbourhood of Selinus and won a great and decisive victory on the Crimissus. The general himself led his infantry, and the enemy's discomfiture was completed by a blinding storm of stone which hit the barbarians. The victory gave the Greeks of Sicily many years of peace and safety from Carthage. Carthage made, however, one more effort and despatched some mercenaries to prolong the conflict between Timoleon and the tyrants. But it ended (338) in the defeat of Hicetas, who was taken prisoner and put to death; by a treaty the dominion of Carthage in Sicily was confined to the west of the Halycus (Platani). Timoleon then retired into private life without assuming any title or office, though he remained practically dictator not only at Syracuse, but throughout the island. Notwithstanding the many elements of discord Sicily seems to have been during Timoleon's lifetime tranquil and contented. He became blind some time before his death, but persisted in attending the assembly and giving his opinion, which was usually accepted as a unanimous vote. He was buried at the cost of the citizens of Syracuse, who erected a monument to his memory in their market-place, afterwards surrounded with porticoes, and a gymnasium called Timoleontium.

Lives by Plutarch and Cornelius Nepos; see also Diod, Sic. xvi. 64-65; G. Wachsmuth, Photographic Reconstructions (1860) which contains an exhaustive examination of the authorities; also SICILY: History; and SYRACUSE, with works quoted.

TIMOMACHUS, a Greek painter of the 1st century B.C. He was noted especially for two pictures, one of which represented Ajax during his madness, the other Medea meditating the slaying of her children. Both of these works were remarkable for their power of expression, especially in the face, and so belong to the late phase of Greek art. Of the Medea we may form some idea from paintings at Piantani, in the neighbourhood of Naples, standing with a sheathed sword in her hand, and watching the children at play (Helbig, Wandgemälde Campaniens, Nos. 1262-1265).

TIMON, of Athens, the noted misanthrope, celebrated in Shakespeare's play, lived during the Peloponnesian War. He is more than once alluded to by Aristophanes and other comedians. Plutarch introduces a short account of his life in his biography of Mark Antony (ch. 70), who built a retreat called Timonium (Strabo xvii. 794) at Alexandria. Timon also gave his name to one of Lycias's dialogues. Shakespeare probably derived his knowledge of Timon mainly from Plutarch; but the Timon of Shakespeare so resembles the Timon of Lucian that Shakespeare (or whoever wrote the first sketch of the play) may have had access to the dialogue.

TIMON (c. 320-230), of Phlius, Greek sceptic philosopher and satirical poet, a pupil of Stilpo the Megarian and Pyrrho of Elis. Having made a fortune by teaching and lecturing in Chaldexon he spent the rest of his life chiefly at Athens, where he died. His writings (Diogenes Laërtius, ix. ch. 12) were numerous both in prose and verse: besides the ΣΑΛΟΣ, he is said to have written epic poems, tragedies, comedies and satyr dramas. But he is best known as the author of the ΣΑΛΟΣ, three books of sarcastic hexameter verses, written against the Greek philosophers.

The fragments that remain (about 140 lines or parts of lines, printed in F. W. A. Mullach, Frag. phil. graec. i. 84-98) show that Timon possessed some of the qualities of a great satirist, together with a command of the hexameter; but he had no loftier aim than to awaken laughter. Philosophers are "excessively cunning murderers of many wise saws" (p. 96); the only two whom he spares are Xenophon, "the modest censor of Homer's lies" (p. 97), and Pyrrho, against whom "no other mortal dare contend" (p. 126). Besides the ΣΑΛΟΣ we have some lines preserved from the Ιθέλοιαν, a poem in elegiac verse, which appears to have inculcated the tenets of scepticism, and one or two fragments which cannot be with certainty assigned to either poem. There is a reference to Timon in Aus. Praep. Ex. xiv. (Eng. trans. by E. H. Gifford, 1903, p. 761). Fragments of his poems have been collected by Wilke, De graecor. Philocontro (Wiesbaden, 1882), and by Pape, Aprodile (Berlin, 1877), and Wachsmuth, Sillographorum graec. reliquiae (Leipzig, 1885).

TIMOR, an island of the Malay Archipelago, the easternmost and largest of the Lesser Sunda Islands, stretching S.W. and N.E.
for 300 m. between 8° 40' and 10° 40' S., and between 123° 30' and 129° E. It has a mean breadth of 60 m., and an area of about 12,500 sq. m. Politically its north-eastern half is Portuguese, as are two small enclaves in the south-western half, the remaining being Dutch. Timor lies in deep water a little to the west of the hundred fathom line, which marks in this direction the proper limit of the shallow Arafura Sea, extending between it and northern Australia. It differs considerably from the other members of the Sundanese group both in the direction of its main axis and in the prevalence of old rocks and slighter charcoaliferous circumstances. southwestward. The region stretching from the north of Sumatra, through Java and the other Sundanese islands, round to Ambon, Tidore, Ternate, Halmahera and the Philippines. There appear to be volcanic centres in both the east and the west of the island, and the surface is everywhere extremely rugged, with ridges from 4000 to 8000 ft. high, forming a confused orographic system, which is by no means fully understood. Mount Kabalaki in the north rises above 10,000 ft.; the culminating point appears to be Mt Alas (over 12,000 ft.) near the coast. Owing to the prevalent dry easterly winds from the arid plains of north Australia and New Guinea, the islands, and the islands beyond, have a much drier climate, and a poorer vegetation, than islands further west, and has few perennial streams and no considerable rivers. Hence, apart from almost untouched mineral wealth, such as iron, copper and gold, the island is poor in natural resources. Coal and petroleum have been found. At Kupang, on the south coast, the number of rainy days per month in the six months May to October dwindles from 4 to 0, while the monthly rainfall gradually sinks from a little less than 2 in. to nil; the northern districts are better watered. Though the mineral pit deposits are varied, the supply of ores of copper has proved scanty; besides which their exploitation is rendered difficult by the lack of labourers, water and wood. The uplands yield fairly under cultivation, while the woodlands, which nowhere form true forests, contain much excellent sandalwood.

This and a noted breed of hardy ponies form the chief articles of export. Owing to the deep water between Timor and the Arafura Sea, the fauna of Timor presents scarcely any Australian types beyond a marsupial cuscus. The few mammals; such as deer, civet, pigs, shrews and monkeys, as well as the birds and insects, resemble ordinary Malayan forms.

The name Timor is of uncertain origin. The Timor Islands consist of a core of Jurassic rocks (Archean?) upon which rest Permian and later deposits of sedimentary origin. Volcanic rocks are also present but they are not so extensively developed as in the islands of the Javan arc. The Permian beds consist chiefly of sandstone and limestone similar to those of eastern Java. The middle and upper divisions of the Proterozoic limestone of northern India and the Artinsk stage of the Urals. The best-known locality is the bed of the Ayer Mati near Kupang. These rocks were originally referred to the Carboniferous system, and similar limestones have been recorded in many parts of the island. Triassic beds with *Halobia* and *Monotis* are well-developed in Rotti and appear also to occur in Timor. The fauna is similar to that of the Mediterranean Trias. Fragments of Jurassic rock have been found amongst the volcanic material on the island of Rotti, but they have not yet been discovered in situ. The Tertiary deposits form a fringe around the older rocks, and in some places this fringe extends far up into the interior of the island.

The bulk of the population is certainly Papuan, but intermingled with Malay, Polynesian and other elements; hence it presents an extraordinary diversity of physical characteristics. There is a great number of portrait and caricature heads in the portraits figured in H. O. Forbes's *Naturalist's Wanderings in the Eastern Archipelago*. The natives, still mainly independent of their nominal Dutch and Portuguese rulers, are divided into hostile tribes, speaking as many as forty distinct Papuan and Malay languages or dialects. Some are addicted to head-hunting, at least during war, and to other barbarous practices. In the primitive churches and other traditional arts, rites are performed resembling those of the Polynesian islanders.

**PORTUGUESE TIMOR** includes the neighbouring isle of Pulo Kambing, and has an area of about 7450 sq. m. Estimates of the population vary from 300,000 to over half a million. Dili, on the north coast, the administrative headquarters and chief settlement, is a poor little place of some 3000 inhabitants, containing hardly any European or Europeanised persons. Official statistics allow 3,000 Portuguese residents unites to Portuguese Timor till 1896, and still pays a contribution to the revenue. The estimated revenue for 1901–1902 was £25,196 (£7200 from Macao), and in 1905–1906 it was £26,968; the estimated expenditure was £35,532 in the earlier and £43,320 in the later period. Few ships visit the colony, except Dutch vessels trading in the archipelago, which call regularly at Dili. Exports (principally copra) are estimated at about £55,000 annually, and imports at about the same amount.

**Dutch Timor** has an area of a little over 5000 sq. m. Kupang, the chief town of the residency, contains some 8000 inhabitants, of whom 1000 are Europeans and about 43 Arabs. In agriculture, European plants have not been successful, and of native products the supply is only sufficient for the home consumption. The export of sandalwood, ponies, rhinoceros horns and nuts of *Hedyosmum* is a slight but growing trade. Dutch Timor gives its name to a residency comprising, besides its own territory, the small adjacent islands, Rotti, Pemam, &c., the Samboja Islands, Sumbawa, Lombok, all islands of eastern Sumatra, and the eastern half of Flores, all lying between 8° 5' and 12° 5' S. and 125° 3' and 125° 15' E., the total area being 17,698 sq. m. It is divided into four administrative districts—Timor, Rana, Rana, Ambon, Larantuka (eastern Flores) and Sumba. Pop. of the residency (1905), 308,500.

It is possible that the Portuguese visited Timor before the Spanish did so in 1521. They were followed by the Dutch, who established on the island when the Dutch expelled them from Kupang in 1613. During the 18th century the two powers came frequently into conflict; and in 1895 their boundaries were settled by treaty. This treaty was replacing the deep seas area of the 18th century, and the Dutch had proved irksome in many ways, especially as it left portions of the territory belonging to protected chiefdoms of each power as enclaves within the boundaries of the other. This led to frequent difficulties, and a mixed boundary commission was therefore appointed under the new treaty and determined more satisfactory boundaries. The new treaty, moreover, stipulates that all future disputes shall be referred to arbitration. The declaration, signed at the same time, that either power would favour the interests of the other in granting concessions, &c., to the exclusion of all others. Thus Portugal and Holland secured the exclusive possession of Timor to themselves.

See P. A. van der Lith, *Nederlands-Indië* (Leiden, 1893–1894). H. O. Forbes, *A Naturalist's Wanderings in the Eastern Archipelago* (London, 1889); and other general works (cf. MALAY ARCHIPELAGO). Some of the problems connected with the physical characteristics of Timor are discussed in H. Zondervan's "Timor en de Timorezen," *Tijdsschr. Aard. Gen.* (1888), vol. v. (with bibliography); K. Martin and A. Wichert, "†Roteck,* Arch. Naturkund. Berlin, *Aussagen* (Leiden, 1887–1884); and A. Wichert, *Infor, über die Reise nach der Timoreischen Inseln, Archipel," *Tijdsschr. Aard. Gen.* (1889–1892), with sketches of Timor, map, &c.; A. Rothpletz, *Die Perm-, Trias- und Jura-Formation auf Timor und Rotti im Timorischen Archipel, Palaeonoeigraphica* (1892) pp. 57–106. There is a summary of Rothpletz's results in *American Naturalist* (1891), xxv. 959–962. For the remarkable flying survey of the south coast by the commandant of the Siboga expedition, replacing the deep seas area of the 18th century, and the Dutch had proved irksome in many ways, especially as it left portions of the territory belonging to protected chiefdoms of each power as enclaves within the boundaries of the other. This led to frequent difficulties, and a mixed boundary commission was therefore appointed under the new treaty and determined more satisfactory boundaries. The new treaty, moreover, stipulates that all future disputes shall be referred to arbitration. The declaration, signed at the same time, that either power would favour the interests of the other in granting concessions, &c., to the exclusion of all others. Thus Portugal and Holland secured the exclusive possession of Timor to themselves.

**TIME LAUT** ("Seaweed Timor"; Dutch, *Timor Laeot*), Teninber of Tenimbar, a group of islands in the Malay Archipelago, S.W. of the Aru Islands, between 6° 20' and 8° 30' S., and 130° 40' and 132° 5' E. By the Dutch, in whose residency of Ambon they are included, they are politically divided into two districts; Larat, including the inhabited islands of Larat, Vord, Molu, and Maro, together with many uninhabited islands; and Sera, including the Sera Islands, Selaru, and the southern part of Yamdena, all inhabited. Only Yamdena and Selaru are by the natives called Timor Laeot; all the others they call Tenimbar. The group is in the main coralline. Vordate, Molu and south-eastern Yamdena have a maximum height of 820 ft.; the rest are low and flat, except Labobor, apparently a volcanic islet on the west, which has an extinct crater 2000 ft. high. Yamdena, the largest island, has an area of about 1100 sq. m.; the rest together about 1000. Rtalbel in Larat is the only safe roadstead during the east and west monsoons. The vegetation includes many species of *Hedysomum*, cuscus, some bats, the beautiful scarlet lory, rare varieties of the ground-thrush, honey-eater and oriole. The population is estimated at about 19,000. The aborigines are Papuans, but mixed much with Malay and perhaps Polynesian elements. They are a fine race, often over 6 ft. tall, noted for their artistic sense. In other respects they are pagans in a low state of culture, mostly divided into hostile communities and addicted to piracy. The only means of subsistence is primitive agriculture.
TIMOTHEUS—TIMOTHY, FIRST EPISTLE TO

on a poor soil, turtle and trepang fishery and cattle-rearing. The yearly export (trepang, turtle and kamuong wood) is valued at only £60 to £160.

TIMOTHEUS, Athenian statesman and general, son of Conon, the restorer of the walls of Athens. From 378-356 B.C. he frequently held command in the war between Athens (in alliance with Thessalia), and Sparta. The object of Athens was to revive the old confederacy (see Delian League, § 2), and to regain command of the sea, and in 375 Timothues was sent with a fleet to sail round the Athenians by way of demonstration against Sparta. He gained over Cephallenia, secured the friendship of the Acazarians and Molossians, and took Corcyra, but used his victory with moderation. Want of funds and jealousy of the Thebans led to a short peace. In 373 Timothues was appointed to the command of a fleet for the relief of Corcyra, then beleaguered by the Spartans. But his ships were not fully manned, and to recruit their strength he cruised in the Aegean. The delay excited the indignation of the Athenians, who brought him to trial; but, thanks to the exertions of his friends—Jason, tyrant of Phocis, and Alcetas, king of the Molossians, both of whom were dear to Athens and expelled the Athenians in three days. He had previously been superseded in his command by Iphicrates. Being reduced to great poverty—for he had pledged his private property in order to put the fleet in an efficient state—he left Athens and took service with the king of Persia. We next hear of him about 366, when, having returned to Athens, he was sent to support Arbobarzanes, satrap of Phrygia. But, finding that the satrap was in open revolt against Persia, Timothues, in conformity with his instructions, abstained from helping him and turned his arms against Samos, then occupied by a Persian fleet. He hurried to Athens to plead his cause—he was acquitted.

He had previously been superseded in his command by Iphicrates. Being reduced to great poverty—for he had pledged his private property in order to put the fleet in an efficient state—he left Athens and took service with the king of Persia. We next hear of him about 366, when, having returned to Athens, he was sent to support Arbobarzanes, satrap of Phrygia. But, finding that the satrap was in open revolt against Persia, Timothues, in conformity with his instructions, abstained from helping him and turned his arms against Samos, then occupied by a Persian fleet. He hurried to Athens to plead his cause—he was acquitted.

He then took Sestus, Crithote, Torone, Potidaea, Methone, Pydna and many other cities; but two attempts upon Amphipolis failed. An action was brought against him by Apollodorus, the son of the banker Pasion, for the return of money lent by the father. The speech for the plaintiff is still extant, and is attributed (though not unanimously) to Demosthenes. It is interesting as showing the manner in which Timothues had exhausted the large fortune inherited from his father and the straits to which he was reduced by his sacrifices in the public cause. In 358 or 357, the Athenians, in response to a spirited appeal of Timothues, crossed over to Samos and expelled the Persians. In the course of the Social War Timothues was despatched with Iphicrates, Menestheus, son of Iphicrates, and Chares to put down the revolt. The hostile fleets sighted each other in the Hellespont; but a gale was blowing, and Iphicrates and Timothues decided not to engage. Chares, regarding their opposition, lost many ships, and in his despatches he complained so bitterly of his colleagues that the Athenians put them on their trial. The accusers were Chares and Aristophon, both men of notoriously bad character. Iphicrates, who had fewer enemies than Timothues and was acquitted; but Timothues, who had always been disliked for his reserve, was condemned to pay a very heavy fine. Being unable to pay, he withdrew to Chales, where he died soon afterwards. The Athenians showed their regret by remitting the greater part of the fine to his son Conon. His remains were buried in the Ceramicus and statues erected to his memory in the agora and the acropolis.

See Life by Cornelius Nepos; Diodorus Siculus xiv., xvii., Isocrates, De permutacione: Pseudo-Demostenes, Adversus Timothemum; C. K. Wood, Life of Iphicrates, Charioteer, Timol. (1845); and especially Holm, Hist. of Greece (Eng. trans., vol. iii).

TIMOTHEUS, an Athenian sculptor of the 4th century B.C., and one of the artists employed on the Mausoleum of Halikarnassus. An inscription at Epidauros shows that he was employed to furnish models for the pedimental sculptures of the temple of Aesculapius on that site, and to execute marble the external decorations (acroteria) for one of the gables. Considerable remains of the acroteria and the pedimental figures have been discovered (see Gerasen Arct, fig. 44; and Euphaurus). TIMOTHEUS, of Miletus (c. 465-437 B.C.), Hesych. Hist. of Greece, bk. v. ch. 2. He composed musical works of a mythological and historical character. Fragments in T. Bergk, Poetae lyrici graeci. A papyrus-fragment of his Persians (the oldest papyrus in existence), discovered at Aburaz has been edited by Usher and published in J. R. Riedel (1903), with discussion of the name, metre, the number of strings of the lyre, date of the poet and fragment. See V. Strazzulla, J. Persiani di Eschilo ed il nome di Timoteo (1904); S. Sudaus in Rhein. Mus., xviii. (1903). See also J. R. Riedel and M. Croiset in Revue des études grecques, xvi. (1903), pp. 62, 332.

TIMOTHY, in the Bible (Acts xvi. 17, xvi. 14, &c.), a Lycaonian, the son of a Gentile father and a Jewish mother, Eunice (2 Tim. i. 5), was born at Lystra, and was already a member of the Christian Church there at the time of Paul's second visit. He took the place formerly occupied by John Mark in Paul's company, and in deference to Jewish feeling was circumcised. He accompanied the apostle on many of his journeys, and was employed by him on important missions (Acts xvi. 4). See also (2 Cor. iv. 17, xvi. 10). Paul speaks of him as his "son," and the fact (see Acts xvi. 22) that he was brought up a Jew rather than to spiritual parentage. He was especially interested in the Macedonian churches, which he helped to found. His name is associated with that of Paul in the opening salutations of both epistles to the Thessalonians, the second epistle to the Corinthians, and those to the Philippians and Colossians. He was, therefore, with Paul at Rome. At a later date he is mentioned in Heb. xiii. 23 as having undergone imprisonment, but as having been released. On the basis of the epistles of Paul to Timothy, Timothy is traditionally represented as bishop of Ephesus and traduced to the charge that he suffered under Domitian. His martyrdom is celebrated on the 24th of January in the Latin Church, on the 22nd in the Greek.

The apocryphal Acta Timothei (Greek and Latin) have been edited by Usener (Bonn, 1877) as Lipsius, Apokr. Apostelgeschichten (1884), ii. 2.

TIMOTHY, FIRST EPISTLE TO. This book of the New Testament is really a pastoral letter upon church order, addressed by the apostle Paul to the Asiatic Christian communities in and round Ephesus (i. 3). The object of the writing is stated in i. 5: "τὸ πάσαν ἐκ σοῦ ἀκοὴν ἀκοῦσα ἰδοὺ." It is thrown into the hands of Timothy, and covered with superlatives. The writer, Timothy, but, as the closing salutation indicates (vi. 21, "τῇ ἤγειρεν εἰς σε ἀγάπην " σεῖν τῇ ἐξουσίᾳ ταύτῃ συνήθεια"), the writer really has the Church in his mind all through. The Pauline standard of discipline is set up (i. 3-20) as the norm of thought and practice. This trust and tradition is to be maintained throughout the church. It involves, the writer proceeds to argue, the proper conduct of public worship (i. 1 seq., 8 seq.), and the proper qualification for episcopi (ii. 2 seq.) and diacontes (iii. 8 seq.). The finale of this section (iii. 15-16) leads, by way of contrast, to a sharp prophetic warning against contemporary errorists (iv. 1 seq.), with advice upon the proper manner of judging of offending brethren, and upon the church (v. 1 seq.). Special attention is given to the ecclesiastical "widows" (3 seq.) and to presbyters (17 seq.). After a word on slaves and masters (vi. 1-2), the epistle recurs to the errorists (vi. 3 seq.), passing into a warning against wealth (6 seq.) and an impressive closing charge (11 seq.). The writing closes with the ἐν ἡμνίῳ μεθ ὑμῶν of verse 21. The context and contents of vi. 17-21 suggest that it is a later interpolation, such as writings on church discipline were.

1 The same motive occurs in the Preface to Irenaeus's treatise, Adv. haer.

2 The opposite view, which insists upon the definite character of the pastoral, is ably stated by A. Ruegg in Aus Schriften und Geschichte (1898), pp. 53-108. Otto and Kölling attempt to refute the view (i. 3) to Timothy, not to Paul, and in this way to refer the subject to Acts xii. 22; but this is exegetically untenable.
particularly exposed to (Harnack). Their inorganic character naturally permitted later generations to bring them up to date, and accretions of this kind may be suspected in 1 Tim. iii. 1-13, v. 17-20 (22a), vi. 17-21, as well as in Tit. i. 7-9.

Other verses, like iii. 11 and v. 23, have all the appearance of misplaced glosses, perhaps from the margin. When vi. 20-21 is thus taken as a later addition, it becomes possible to see in the reference to ἀπότομα τῆς γενεσεως γνῶσις an allusion to Marcion's well-known volume.

It has been made by some critics, particularly Hesse (Die Entstehung der neuesten. Hiirtenbriefe, 1859: i. 1-10, 18-20, iv. 1-16, vi. 3-16, 26 seq.) and Knoke (Probt. theolog. Kommentar, 1862, 1889: a-i. 3 seq., 18-20, ii. 1-10, iv. 1, v. 1, 13-6, 11-15, 19-23, 24 seq., written to Timothy from Corinth; b-i. 12-17, iii. 14-16, iv. 11-13, 16-20, iv. 12-15, v. 7 seq., vi. 17-19, i. 5-11, vi. 2c-16, 20 seq., written from Caesarea), to disentangle one or more original notes from Paul of subsequent additions, but the comparative evenness of the style does not favour such analyses. They have more relevance and point in 2 Tim. than in 1 Tim. P. Ewald, in his Probilias betr. d. Test. des 1 Tim. (1903) has, for instance, upon the occasion of the papyrus leaves or sheets having been displaced, and conjectures that i. 12-17 originally lay between i. 2 and 3, while iii. 14-10 has been misplaced from after vi. 2. But his keen criticism of Hesse and Knoke is more successful than his positive explanation of the textual phenomena, and a more thorough-going process of literary criticism is necessary in order to solve the problems of the epistle.

Its irregular character, abrupt connexions and loose transitions are due to the nature of the subject rather than to any material disarrangement of its paragraphs.

The phenomena of style have to be viewed in a broad light. Allowance must be made for the difference of vocabulary produced by change of subject. The evidence of Plutarch (Bella Buc. 180) is always to be received with caution and strict scrutiny; no hard and fast rule must be set up to judge the language of a man like Paul. Yet such considerations apart, the argument that all the arrangements of the pastoral chapters did not come from Paul's pen.

The words and phrases which are common to the pastorals and the rest of the Pauline epistles are neither so characteristic nor so numerous as those peculiar to the former, and the data of style may be summed up in the verdict that they point to a writer who, naturally reproducing Paul's standpoint as far as possible, and acquainted with his epistles, yet betrays the characteristics of his later milieu in expressions as well as ideas. Thus, of 1143 used in the occurrence of the papyri (of all the New Testament writings), 97 are foreign to the Septuagint and 116 to the rest of the Pauline letters. This proportion of 49.7 per cent. is large. If the size of the vocabulary is not taken into account, and its significance is heightened by the further fact that several of Paul's characteristic expressions tend to be replaced by others (e.g. πραπαταν and στοιχεία by ανωτάτητα, καθαρατος, ἀκριβος, ef.), the result is not a mere scrambling of vocabulary, but a genuine change in the nature of the number of Pauline words are entirely absent (e.g. δίωκος, ἀδελφος, καθαρατος, μεταφυσικα, πολλαπλασιασμος, θεωρητης, σωφρονισμος, διαλογισμος, διαλογισμος, διαλογισμος, διαλογισμος, διαλογισμος, διαλογισμος, διαλογισμος, διαλογισμος, διαλογισμος, διαλογισμος, διαλογισμος, διαλογισμος, διαλογισμος, διαλογισμος, διαλογισμος, διαλογισμος, διαλογισμος, διαλογισμος, διαλογισμος, διαλογισμος, διαλογισμος, διαλογισμος, διαλογισμος, διαλογισμος, διαλογισμος, διαλογισμος, διαλογισμος, διαλογισμος, διαλογισμος, διαλογισμος, διαλογισμος, διαλογισμος, διαλογισμος, διαλογισμος, διαλογισμος, διαλογισμος, διαλογισμος, διαλογισμος, διαλογισμος, διαλογισμος, διαλογισμος, διαλογισμος, διαλογισμος, διαλογισμος, διαλογισμος, διαλογισμος, διαλοɡισ}
TIMOTHY, SECOND EPISTLE TO

In this book of the New Testament, after a brief thanksgiving for the faith of Timothy (1. 1–5), Paul is represented as warning him against false shame (6 seq.), adducing his own example and that of Onesiphorus. The need and the reward of endurance are then urged (ii. 1–13), and Timothy is bidden to adhere in his work to the Pauline gospel against the seductions of controversial and immoral heretics (ii. 14 seq.). The practices of the latter are pungently depicted6 (iii. 1–9); Paul reiterates his opening counsels (10 seq.) and then closes with a solemn appeal to personal faithfulness. A note of personal matters concludes the epistle (iv. 6–22).

The last verse, with its two-fold greeting (6 καὶ γεροντὶς ἐκαθόρισεν σε ὧδε ἔκτενεν, ἄλογον), shows unconsciously but plainly that, while the epistle professes to be a private letter to Timothy, it is in reality addressed to a wider circle, like 1 Tim. and Titus. But its composite origin is also clear. Thus iv. 6–22a, which is certainly authentic, is not homogeneous in itself, the situation of verses 6–8 hardly agreeing with that of 9 seq., while verse 11 (6 Luke alone is with me) cannot have been written at the same time as verse 21. Various schemes of arrangement are needed to this and other passages of the same nature in the epistle, e.g. i. 15–18; iv. 1–18. But the general result of such reconstructions is tentative. All that criticism has succeeded in establishing is the fact that the author had some reliquiae Paulinae at his disposal, notes written either before or during his last imprisonment in Rome, and that these have been worked up into the present letter by one who rightly believed that his master would stoutly oppose the current errors of the age.

2 Timothy, like 1 Timothy, is written with fair precision the period and aim of the writer of the pastoral. Evidently (cf. Acts chs. 20 seq.) the Pauline literature of Ephesus was imperilled seriously during the last quarter of the 1st century. Its very growth invited attacks to weave ascetic, theosophic, semi-Jewish fancies round the faith, not unlike the attempts often made in modern India to assimilate Christian and local philosophies of religion. Against such the writer argues in Paul’s name, as Luke had already done. From the composition of a speech in Paul’s name (for, though the farewell in Acts goes back to first-hand tradition, it represents the author’s standpoint as well as Paul’s), it was but a step to compose letters in his name, some of whose contents are ascribable to local circumstances of the time.5 The general concern for local Christianity is the writer’s justification for his work, and any idea of fraudulent aims must be dismissed at once.6 “To a writer of this period, it would seem as legitimate an artifice to compose a letter as to compose a speech in the

1 Bahnson gives an ingenious analysis of this section of the epistle. In ii. 8–13, 16 it is developed; in ii. 14–26, ii. 4; and in iii. 1–4 (8), ii. 5. But this is as artificial as Otto’s attempt to classify the contents of the epistle under the three notes of the σὺμπαθεία in i. 7.
2 Rev. 2 and 3, the fragment from Paris quoted by Engb. Prac. Evang. viii. 11.
3 Cf. the epistle was an integral as we have it, its genuineness can only be maintained (L. Haag in Paulus: Leben, Lehre, Wirkung, 275). Imschenetzky, “Paulus und die chrysostomatischen Briefe,” Z. f. Theol. Wiss. 21, 245 seq., notes the same passage as a whole, and “Paul’s teaching as a whole may be denoted as the Didache.”
4 Bacon (Story of St. Paul, 198) and Clemen both assign part of the epistle to the Caesarean imprisonment, the former disentangling iv. 9, 11–18, against 20–21a, 22b, the latter iv. 9–18. Hitzig had already found a Caesarean letter in i. 15, iv. 13–16, 20–22a. One great point in favour of such theories is that they give a natural sense to iv. 16, Paul’s first defence being that before the Jews or before Felix.
5 Cf. the present writer’s Historical New Testament (2nd ed., 1907), for intimations of the same sort. See chs. 15, 16, 19. “It is beyond doubt that the Pauline society at Corinth was more or less a veritable centre of paganism” (E. L. Young, Biblical Essays, 146). A thorough knowledge of ancient pseudo-pseudo-Jewish literature is required to be written; meantime, further reference may be made to the older essays of Mosheim (Uebers. der christl. Staatsrecht des rom. Kaiserreichs, 2 vols., 1776), and Bentley’s Dissertation on Plutarus, pp. 80 seq.; K. R. Köstlin’s article in Theol. Jahrbücher (1851), p. 199–221, on “Deus puer, Litteratur der ältesten Kirche”; and A. Gudemann, in Classical Studies in Honour of H. Drissler, pp. 52–74 (New York, 1894).

XXVI. 32

993

name of a great man whose sentiments it was desired to reproduce and record; the question which seems so important to us, whether the words and even the sentiments are the great man’s own or only his historian’s, seems then hardly to have occurred either to writer or reader” (W. H. Simcox, Writers of the New Testament, 61). The second letter to Ephesus, warning them against heresies (Acts xx. 29 seq.) and solemnly bidding them exercise their disciplinary duties. The Second Epistle to Timothy carries on this line of advice. Here Paul, being dead, yet speaks through Timothy to the local Christians who are exposed to such mischievous tendencies in their environment.

Where the writer has hardly succeeded in representing Paul is in ascribing advice to Timothy. May we admit that, strictly speaking, the latter at the age of about thirty-five-five years is a very young man, and that Paul might conceivably have termed him still his visor. But the counsels addressed to him seem rather out of place when one recollects the position which he occupied. To a writer who desired a situation for such advice on church life and doctrine from the lips of Paul to his lieutenant, it was natural to think of a temporary absence. But many of the directions are much too serious and fundamental to have been given in this form; one can hardly imagine that Paul considered Timothy (or Titus) still in need of elementary advice and warning upon such matters. It is especially true that Paul’s letter is not grouped as typical figures of the later episcopi of the Church, the point of this emphasis upon elementary principles and duties is at once clear: they outline graphically the qualifications for the church office of bishop.

The pressing need of the Church, as the writer conceives it, is to maintain the true Pauline tradition (2 Tim. i. 13, 14, &c.) against every heretical and speculative notion. This maintenance takes the twofold classical form of (1) an argument against the false teaching of the “sound teaching” and (6) insistence on a succession of church officials (2 Tim. ii. 1–2) who are not merely to preside but to teach. The last point is significant in view of Didache iv. 1. The standpoint of the author is practically that of Clement Romans (xii. seq.), who asserts that the apostles preached “everywhere in country and town, appointing their first-fruits, when they had proved them by their works, to be bishops and deacons.” But the interests of discipline and doctrine were thus to be preserved. Paul’s lieutenants possess the central deposit of the apostolic faith, to carry it out as well as the right of exercising the authority with which they are invested.

The occasional coincidences between the pastorals and Barnabas or Clemens Romano do not prove anything more than a common milieu of thought, but the epistles were plainly familiar to Polycarp, who alludes to 1 Tim. i. 1, vi. 7, 10, and 2 Tim. ii. 11, 25, iv. 10 (for this and the other passages from Polycarp, see The New Testament in the Apostolic Fathers, 1905, pp. 95 seq.). This indubitable use of the pastorals in Polycarp throws the terminus ad quem of their composition back into the first decade of the 2nd century, and additional confirmation of this would be forthcoming were the evidence for their use in Ignatius more secure. The drawback was that, if Paul was soon to see his colleagues after his death (1 Tim. i. 3), such delayed advice was hardly necessary; but this imperfection was inevitable. The post-Pauline atmosphere of the ecclesiastical regulations is felt most plainly in the references to such sub-apostolic features as the organized register of “wibes.” The ἱστορία, the ἱστορία, and the χρονάρια are also forbidden to contract a second marriage.

Such, at any rate, seems the fairest interpretation of 1 Tim. iii. 2 (ἦσανον) in the light of early Christian tradition, for although the “husband” in the one passage may be a designation as a prohibition of polygamy or vice (=holy husband, or sober, married man), the antipathy to second marriages (cf. Jacoby, New Testament, 75, pp. 310, 311) is clearly based on the idea that the same state of life might be a test of Christian practice. It is almost as un-Pauline as the assumption that every ἱστορία must be married. Cf. on this whole subject Hilgenfeld (Zeitschrift für wiss. Theologie, 1886, pp. 456 seq.) and Schmiedel (Gotth. Zeitschr. 1891, pp. 1311, 1312). "The New Testament Church by Hort (Christian Ecclesia, 1898, 189 seq.) and Dr T. M. Lindsay (Hibbert Journal, i. 166 seq., and in The Church and the Ministry in the Early Christians, 1903, pp. 139 seq.)

secure. The occasional similarities of thought and expression between them and the Lucan writings suggest that the period of their origin lies within a quarter of a century after Paul's death, and, when one or two later accretions are admitted, the internal evidence, either upon the organization of the church or upon the errors controverted, tallies with this hypothesis.

LITERATURE.—Special monographs on this epistle by Leo (1859) and Bahnsen (Die sogenannte Pastoralebriefe, I., der 2 Tim., 1876) are to be noted. For a textual discussion of ii. 19, cf. Resch's Paulinismus, pp. 258-259. The allusion to the βασιλιάς, βασιλέως Ρώμης (iv. 13) has produced a wealth of discussion; the latter were probably pigulileris membranes, sheets for private memoranda. The books may have included the Logia or Evangelic Scriptures from which 1 Tim. x. 18 is quoted (so Resch), but this is a mere conjecture. Cf. on the whole question, Birt's Das antike Buchwesen, pp. 50 seq., 65, 88 seq., and Nestle's Einführung in das griechische N. T. (1899), pp. 39 seq. (J. MT.)

TIMUR (Timur i Leng, the lame Timur), commonly known as Tamerlane, the renowned Oriental conqueror, was born in 1336 at Kesh, better known as Shahr-i-Sabz, "the green city," situated some 50 m. south of Samarkand in Transoxiana. His father Teregai was head of the tribe of Berias. Great-grandson of Karachar Nevian (minister of Jagaati, son of Jenghiz Khan, and commander-in-chief of his forces), and distinguished among his contemporaries by his personal valor, Timur might have assumed the high military rank which fell to him by right of inheritance; but like his father Burkul he preferred a life of retirement and study. Under the paternal eye the education of young Timur was such that at the age of twenty he had not only become an adept in manly outdoor exercises but had earned the reputation of being an attentive reader of the Koran. At this period, if we may credit the Memoirs (Malijafrad), he exhibited proofs of a tender and sympathetic nature.

About 1358, however, he came before the world as a leader of men with the capture of the city of Tabaristan. The next ten years of his career may be thus briefly summarized from the Memoirs. Allying himself both in cause and by family connexion with Kurgan, the dethroner and destroyer of Kazan, chief of the western Jagaati, he was despatched to invade Khorasan at the head of a thousand horse. This was the second warlike expedition in which he was the chief actor, and the accomplishment of its objects led to further operations, among them the subjection of Khwarizam and Urgan. After the murder of Kurgan the contentions which arose among the many claimants to sovereign power were arrested by the invasion of Toqiluk Timur of Kashgar, a descendant of Jenghiz. Timur was appointed as the successor of the chief of Urgan, and it is recorded that he might have been appointed to the government of Mawarān- Inhār (Transoxiana). By the death of his father he was also left hereditary head of the Berias. The exigencies of his quasi-sovereign position compelled him to have recourse to his formidable patron, whose reappearance on the banks of the Sihon created a consternation not easily allayed. Mawarān- Inhār was taken from Timur and entrusted to a son of Toqiluk; but he was defeated in battle by the bold warrior he had replaced at the head of a numerically far inferior force. Toqiluk's death facilitated the work of reconquest, and a few years of perseverance and energy sufficed for its accomplishment, as well as for the addition of a vast extent of territory. During this period Timur and his brother-in-law, Hosain—at first fellow-fugitives and wanderers in joint adventures full of interest and romance—became rivals and antagonists. At the close of 1369 Hosain was assassinated and Timur, having been formally proclaimed sovereign at Balkh, mounted the throne at Samarkand, the capital of his dominions.

The next thirty years or so were spent in various wars and expeditions. Timur, not only consolidated his rule at home by the subjection of intestine foes, but sought extension of territory by encroachments upon the lands of foreign potentates. His conquests to the west and north-west led him among the Mongols of the Caspian and to the banks of the Ural and the Volga; those to the south and south-west comprehended almost every province in Persia, including Bagdad, Kerbela and Kurdistan. One of the most formidable of his opponents was Toqtamish, who after having been a refugee at the court of Timur became ruler both of the eastern Kipchak and the Golden Horde, and quarrelled with Timur over the possession of Khwarizam. It was not until 1395 that the power of Toqtamish was finally broken (see MONGOLS; GOLDEN HORDE).

In 1398, when Timur was more than sixty years of age, Farishta tells us that, "informed of the commotions and civil wars of India," he "began his expedition into that country," and on the 12th of September "arrived on the banks of the Indus." His passage of the river and upward march along the valley of the Indus to the north bank the same year, is indicated by the Tartaric conqueror to erect a mosque at Samarkand. The war with the Turks and Egyptians which succeeded the return from India was rendered notable by the capture of Aleppo and Damascus, and especially by the defeat and imprisonment of Sultan Bayzid I. (see TURKEY: HISTORY, AND EGYPT: HISTORY, Mahomedan period). This was Timur's last campaign. Another was projected against China, but the old warrior was attacked by fever and ague when encamped on the farther side of the Sihon (Syr-Daria) and died at Attrār (Otrar) on the 17th of February 1405. Marked as the "earliest known history of Timur, and the only one written in his lifetime"; and vol. i. of the Malātā'is- Sa'dīn—a choice Persian MS. work of 1495—in­troduced to Orientalists in Europe by Hammer, Jahrbücher, Dern and (notably) Quatremère. There are also the Memoirs (Malijafrad) and Institutes (Tuṣūkāt), of which an important section is styled Designs and Enterprises (Tedbīrāt wa Kangāshāhā). Upon the genuineness of this doubt has been thrown. The circumstance that this discovery and presentation to Shah Jahan in 1637 was of itself open to suspicion, the Alhazen, quoted by Purchas in his quaint notice of Timur and referred to by Sir John Malcolm, can hardly be accepted as a proof of the originality of the work. The fact that the same book is to be found in the History of Tamerlane, by De Sainctyson, published at Amsterdam in 1678. But, although the existence of this Alhazen of Jean de Bec has been believed by many, the more trustworthy critics consider the history and historian to be equally fictitious of Timur's grandson, Jahan.

Reference may be made to two more sources of information.

1 The pastors in this aspect are closer to Clemens Romanus than to Ignatius.
TIN

(1) Supposed likenesses of Timur are to be found in books and in the splendid collection of Oriental manuscripts and drawings in the Bibliothèque Nationale. Shah Tahmasp II described him as “a great specimen of illuminated Persian manuscript and exquisite calligraphy—represents a most ordinary, middle-aged Oriental Man.” Another portrait is included in a set of sketches by native artists, some of which, taken probably from life, show great care and cleverness. Timur is here displayed as a stout, long-bodied man, beardless, with a beard that unite not unlike the first portrait, but with thicker and more straggling hair, and distinetly, though not more agreeable character in the facial expression, yet with a sterner and grander expression of mind and more celebrity. The uncomfortable figure in the Bodleian Library does not give much help. Sir John Malcolm has been at some pains to invest his portrait of Timur with individuality. But an analysis of his results leaves the reader in more perplexity than satisfaction at the kind of information imparted, and he reverts insensibly to the sources from which his instructor has himself been instructed. (2) As regards plays, in Macbeth’s Tamberlane Timur is described as tall of stature, straightly fashioned, large of limb, having joints strongly knotted, long and sinewy arms, a breadth of shoulders to bear old Atlas’s burden; pale of complexion, and “broadly built” and “broad-chested” and “broadshouldered, well-built but lame, of a fierce countenance and with receding eyes, which express cruelty and strike terror into the lookers-on.” But Jean du Bec’s account of Timur’s appearances is quite different. Now Tamberlane was written in 1586. The first English translation of Jean du Bec is dated in 1595, the Life by Peroninus in 1600, and Petis de la Croix did not introduce Shahriu ‘d-Din or Ab’l Yazid to European readers till 1722. The dramatist must have heard of Timur in other quarters, equally or may be with those available in the present stage of Oriental research. At the beginning of the 18th century Timur was represented in the Tamberlane as a model of valour and virtue. The plot, however, has little to do with history, and is improbable and void of interest. By Matthew Gregory Lewis again Timour” is depicted as the conventional tyrant of a prosperous Persian, slaying, burning, slaughtering and committing every possible atrocity until checked by a violent death and a poetical climax.

Apart from modern European savants and historians, and the more strictly Oriental chroniclers who have written in Persian, Turkish or Arabic, the following authorities may be cited—Laoniuc Alchonqyds, Joannes Leuchndaviu, Joachim Camerarius, Petrus Lactantius, Franciscus Spinellus and other savants.

A score or so of other names are given by Samuel Purchas. See also Sir Clements Markham’s Clavijo, in the Hakluyt Society’s publications; White’s edition of Davy’s translation of the Inslent (1789); Tommasi’s History of Persia; and Trans. Roy. Soc. (1885): Horn, “Gesch. Iran. in Islam. Zeit,” in Geiger and Kuhn, Grundr. der iranisch. Philol. (1902); works quoted, e.g. Mongols. (F. J. G.)

TIN (Lat. stannum, whence the chemical symbol “Sn”; atomic weight=117.6, 0=16), a metallic chemical element. Being a component of bronze, it was used as a metal thousands of years prior to the dawn of history; but it does not follow that prehistoric bronzes were made from metallic tin. When the unalloyed metal was first introduced cannot be ascertained with certainty. The tin of the Bible (cauæripse in the Septuagint) corresponds to the Hebrew bedil, which is really a compound. It is not known exactly when the word tin was introduced into Europa. It is not known whether the word tin was introduced into Europa. It is not known whether the word tin was imported from Cornwall into Italy after, if not before, the invasion of Britain by Julius Caesar. From Pliny’s writings it appears that the Romans in his time did not realize the distinction between tin and lead: the former was called plumbum album or candidum to distinguish it from plumbum nigrum (lead proper). The word stannum definitely assumed its present meaning in the 4th century (J. Kopp).

By the early Greek alchemists the metal was named Hermes but at the beginning of the 6th century it was termed Zephor Jupiter, and the symbol Z assigned to it; it was also referred to as diabolus metalorum, on account of the brittle alloys which it formed.

Occurrence.—Grains of metallic tin occur intermingled with the gold ores of Siberia, Guiana and Bolivia, and in a few other localities. Of minerals containing this element mention may be made of cassiterite (q.v.) or tinstone, SnO₂, tin pyrites, Cu₂SnS₄+(Fe,Sn)SnS₄; the metal also occurs in some epidotes, and in company with columbium, tantalum and other metals. Of these tinstones is that of the greatest commercial importance. It occurs in its matrix, either in or closely associated with fissure veins or disseminated through rock masses. It is also found in the form of rolled lumps and grains, “stream tin,” in alluvial gravels; the latter are secondary deposits, the products of the disintegration of the first-named primary deposits. Throughout the world, primary deposits of tinstone are in or closely connected with granite or acid erupitive rocks of the same type, its mineral associates being tourmaline, fluor spar, topaz, wolfram and arsenical pyrites, and the invariable gangue being quartz: the only exception to this mode of occurrence is in Bolivia, where the tin ore occurs intimately associated with silver ores, bismuth ores and various sulphides, whilst the gangue includes barytes and certain carbonates. Over five-sixths of the world’s total production is derived from secondary alluvial deposits, but all the tin obtained in Cornwall (the alluvial deposits having been worked out) and Bolivia is from vein mining, while a small portion of that yielded by Australasia comes from veins and from granitic rocks carrying disseminated tinstone.

Production.—During the 16th century the world’s supply of tin was mainly drawn from the deposits of England, Saxony and Bohemia; but the fall of both these sources was then rapid, while the supplies of Saxony and Bohemia had been greatly diminished. The English supply increased, with some oscillations, to between six and seven thousand tons annually in the period 1840-1860, when it suddenly rose to about 10,000 tons, and this figure was fairly well sustained until about 1890, when a period of depression set in; the yield for 1900 was 4335 tons, and for 1905 about 4200 tons. In the opening decades of the 19th century supplies began to be drawn from Banks; in 1820 this island contributed 1200 tons; the production was increased to 17,000 tons in 1900, and the diminution set in, 1906 being the year of the largest production. Billinton became of note in 1853 with a production of 40 tons, which increased to 6000 in 1900 and has since declined to about 3000 tons in 1905. The Straths Settlements ranked as an important producer in 1870 with 2337 tons; it now supplies the greater part of the world’s supply, contributing 46,705 tons in 1900, and over 60,000 tons in 1905. Australian deposits were worked in 1872, and in the following year the production was 3000 tons; the maximum outputs were in 1851-1853, averaging 10,000 tons annually, but the supply declined to 2.40 tons in 1868 and has since increased to about 5000 tons in 1905. Bolivia produced 501 tons in 1883, 10,245 in 1900 and 19,150 in 1905.

The world’s supply in 1900 was 72,911 long tons; this increased in 1904 to 97,750 tons, but in 1905, principally owing to a shortage in the supplies from the Straths and Banks, the yield fell to 94,089 tons.

Metallurgy.—The operations in the metallurgy of tin may be enumerated; as: (1) mining and dressing; (2) smelting; (3) refining. The first stage has for its purpose the production of a fairly pure tinstone; the second the conversion of the oxide into metallic tin; and the third preparing a tin pure enough for commercial purposes.

Mining and Dressing.—The alluvial deposits are almost invariably worked openly, those of the Malay Peninsula and Archipelago chiefly by Chinese labour: in a few instances hydraulic mining has been resorted to, and in other cases true underground mining is carried on; but the latter is both exceptional and difficult. The alluvium extracted, which in the Malay Peninsula and Archipelago carries from 5 to 60 lb of tinstone (or “black tin,” as it is termed by Cornish miners) to the cubic yard of gravel, is washed in various simple sluicing appliances, by which the lighter clay, sand and stones are removed; the tinstone is then treated with water containing usually 65 to 75% of metallic tin (purely commercial tinstone contains 78.7%).

Lode tin, as tinstone derived from primary deposits is often termed in the ordinary method, the very hard gangue in
Tin

which occurs necessitating a liberal use of explosives. The vein-stuff is broken small either by hand or in rock-breakers, and stamped to fine powder in stamp mills, which are practically large mechanically-worked pestles and mortars, the stamp proper weighing from 3000 to 4000 lb. The resulting powder is of such size that the coarsest particles are removed by washing with perforations 1/16 in. in diameter, leaves the stamps in suspension in water, and passes through a series of troughs in which the heavier mineral is collected; this then passes through a series of washing operations, either in a mixture of water and pyrites or a mixture of water and arsenical pyrites, which is calcined and washed again, until finally black tin containing about 60 to 65% of metal is left. The calcination is preferably effected in mechanical roasters, it being especially necessary to produce pure tin ore containing as little antimony as possible; crude tin stuff raised in Cornwall carries on an average a little over 2% of black tin. The Bolivian tin ore is treated by first extracting the sodium and potassium oxides, &c., by roasting the ore, and then concentrating the residues; 

therefore, however, considerable difficulty is experienced in treating the poorer of these very complex ores, and several chemical processes for extracting their metallic contents have been worked out. Of the impurities of the ore the wolframite (tungstate of iron and manganese) is the most troublesome, because on account of its high specific gravity it cannot be washed away as gangue. To remove it, Oxyld fuses the ore with a certain proportion of carbonate of lime which suffices to convert the tungsten into soluble alkaline tungstate, without producing noteworthy quantities of soluble stannate from the oxide of tin; the tungstate is easily removed by treatment with hydrogen sulphide.

Smelting.—The dressed ore is smelted with carbon by one of two main methods, viz., either in the shaft furnace or the reverberatory; the former is the better suited to stream tin, the latter to lode tin. A shaft furnace is a cylindrical reverberatory with a taphole; 

tin-smelting practice yields a pure metal. Shaft furnace smelting is confined to those parts of the world where charcoal can still be obtained in large quantities at moderate prices. The furnace consists of a cylindrical furnace-chamber into which alternate layers of fuel and ore are charged, an air blast being generally injected near to the bottom of the furnace by one or more tuyeres. This was the primitive process all over the world; in the East, South America and similar regions it still holds its own. In Europe, Australasia and one large works at Singapore it has been practically replaced by the reverberatory furnace process, 

finally, at least as a whole about 24%. The first time the purified ore is mixed with about one-fifth of its weight of a non-caking coal or anthracite smalls, the mixture being moistened to prevent it from being blown off by the draught, and is then fused out. The tin is dissolved in the molten flux and the metal and produced are then run off and the latter is cast into bars; these are in general contaminated with iron, arsenic, copper and other impurities.

Drossing.—All tin, except a small quantity produced by the shaft furnace process from exceptionally pure stream tin ore, requires refining by leaching and "boiling" before it is ready for the market. In the process by which the tin is consolidated into buttons and finally cast, when relatively pure tin runs off, while a skeleton of impure metal remains. The metal run off is further purified by "poling, i.e. by stirring it with the branch of a tree—the apple-tree being preferred. The operation is double; it is necessary to remove the oxygen diffused throughout the metal as oxide, part of it perhaps chemically by reduction of the oxide to metal, the rest by conveying the finely diffused oxide to the surface and causing it to be reduced to metallic tin. To this end it is necessary to rest for a time in the pot at a temperature above its freezing point and is then ladled out into ingot forms, care being taken at each stage to ladle off the top stratum. The original top stratum is the purest, and each succeeding lower stratum has a greater proportion of impurities; the lowest consists largely of a solid or semi-solid alloy of tin and iron.

The purity of the metal the tin-smelter heats the bars to a certain temperature just below the fusing point, and then strikes them with a hammer or lets them fall on a stone floor from a given height. If the tin is pure it splits into a mass of granular strings. This is known as "powder." The operation is very difficult. Is there any doubt the oxyd as mentioned above be very pure is sold as grain tin. A lower quality goes by the name of block tin. Of the several commercial varieties Banka tin is the purest; it is indeed almost chemically pure. Next comes English granular.

For the preparation of chemically pure tin two methods are employed. (1) Commercially pure tin is treated with nitric acid, which dissolves the iron, copper, and other impurities present, while the copper, iron, &c., become nitrites; the metatannic acid is washed first with dilute nitric acid, then with water, and is lastly dried and reduced by fusion with black flux or potassium cyanide. (2) At Stoblas, beautiful crystals of pure tin can be obtained as follows: A platinum basin, coated over with wax or paraffin outside, except a small circle at the bottom where the metal is placed, is placed on the upper end of a beaker, and is filled with a solution of pure stannous chloride. The beaker also is cautiously filled with acid-water up to a point below the edge of the platinum basin.

The whole is then left to itself, when crystals of tin gradually separate out on the bottom of the basin.

Properties.—An ingot of tin is pure white (except for a slight tinge of blue); the colour depends, however, upon the temperature at which it is poured. When a plate of tin is dead white and feel, it is high, iridescent. It has a considerable lustre and is susceptible of being polished on exposure to normal air. The metal is very soft and easily flattened out under the hammer, but almost devoid of tenacity. That it is very brittle is shown by the fact that a nail driven into a metal shaft filled with tin, will easily be driven out with a hammer. Tin is also peculiar in possessing a sort of elasticity, by which it is enabled to be stretched into sheets with a hard body in circumstances permitting of free vibration. The specific gravity of cast tin is 7.09, of rolled tin 7.99, and of electrolytically deposited tin 7.143 to 7.178. A tin ingot is distinctly crystalline; hence the melting point rhombohedral forms are produced, when exposed for a sufficient time to very low temperatures (to −39°C. for 14 hours), tin becomes so brittle that it falls into a grey powder, termed the "grey modification," under a pestle; it is sometimes employed merely as a protecting coating for utensils made essentially of copper or iron. At ordinary temperature tin proves fairly ductile under the hammer, and its ductility seems to increase as the temperature rises up to about 100°C. At some temperature near its fusing point it becomes brittle, and still more so above about 14°C. The specific gravity of tin is 13.17—14.6. Some alloys of tin are more brittle; arsenic, antimony and bismuth (up to 0.5%) reduce its tenacity; copper and lead (to 10%) make it harder and stronger. Tin melts at 230°C. Tin fuses at about 230°C.; at a red heat it begins to volatilize slowly; at 1600°C. it boils. The hot vapour-produced combines with the oxygen of the air into white oxide, SnO2. Its coefficient of expansion is 0.000062; its thermal and electrical conductivities are 145 in 152 and 1191 to 1410 respectively compared to silver as 1000.

Industrial Applications.—Commercially pure tin is used for making small articles of tinplating, particularly plating, brass pots, stills, &c. It is also employed for making various kinds of tin-foil—one for the silverying of mirrors (see MIRRORS), the other for wrapping up chocolates, &c. The latter is made by taking sheets of tin of the proper quality, heating it until its specific heat 0.0652, its thermal and electrical conductivities are 145 1521 and 114.5—1410, and it is used in culinary and domestic vessels. But it is expensive, and tin vessels have to be made very heavy to give them sufficient stability of form; hence it is generally employed merely as a protecting coating for utensils made essentially of copper or iron. The tinning of a copper basin is an easy operation. The tin, made scrupulously clean, is heated to beyond the fusing point of tin, and is then poured into a metal mould. To this the articles are put at a boiling heat. In the absence of metallic tin there is no visible change; but, as soon as the metal is introduced, an electrolytic action sets in and the articles get coated over with tin.

Tinning wrought iron is effected by immersion. The most important form of the operation is making tin from ordinary sheet iron (making what is called "sheet tin"). This process was mentioned by Agricola; it was practised in Bohemia in 1620, and in England a century later. The iron plates, having been carefully cleaned with sand and hydrochloric or sulphuric acid, and hastily with water, are plunged into heated tallow to drive off the moisture. The plates are then run into cold water, and steeped in a bath, first of molten ferruginous, then of pure tin. They are then taken out and kept suspended in hot tallow to enable the surplus tin to run off. The tin of the second bath dissolves itself, and is ready for the third. To this the tin are annealed to a blue or to a bright deep blue, and then the surplus tin articles must be decarburised superficially by ignition within a bath of ferric oxide (powdered haematite or similar material), then annealed, and subjected to further treatment.

Compounds of Tin.

Tin forms two well-marked series of salts, in one of which it is divalent, these salts being derived from stannous oxide, SnO, in the other it is tetravalent, this series being derived from stannic oxide, SnO2.

Stannous Oxide, SnO, is obtained in the hydrated form SnO(OH); from a solution of stannous chloride by addition of sodium carbonate; it forms a white precipitate, which can be washed with
air-free water and dried at 80 °C. without much change by oxidation; if it be heated in carbon dioxide the white SnO remains. Precipitated stannous hydrate dissolves readily in caustic potash; if the solution is cooled slowly it crystallizes, with formation of stannic acid, 2SnO + 2H₂O = K₂SnO₃ + Sn + H₂O. If it is evaporated slowly, anhydrous stannous oxide crystallizes out in forms which are combinations of the cube and dodecahedron. Distilled stannous acid is decomposed with hydrochloric acid and burns to stannic oxide, SnO₂. Stannous oxide when heated by itself in a tube leaves stannous oxide.

Stannic Oxide, SnO₂.—This, if the term is taken to include the hydroxides, exists in two forms. (1) Tinstone (see above and also Cassiterite) is proof against all acids. Its disintegration for analytical purposes can be effected by fusion with caustic alkali in small proportion with sodium carbonate or potash carbonate, or by fusing with sulphur and sodium carbonate, with the formation of a soluble stannostannate. (2) A similar oxide (flores joviis) is produced by burning tin in air at high temperatures or exposing any of the hydrates to a strong heat. Such tin oxide, as it is called, is used for the polishing of optical glasses. Flores stannis is a finely divided mixture of the metal and oxide obtained by fusing the metal in the presence of air for some time. (3) Metastannic acid (generally written H₂SnO₄) to account for the complexion of metastannates, e.g. the sodium salt, Na₂SnO₄, is the white compound produced from the metal by means of nitric acid. It is insoluble in water, but if mixed with alkali hydroxide dissolves, but if heated with this last for some time it passes into a compound, which, after the acid mother liquor has been decanted off, dissolves in water. The solution when subjected to distillation behaves very much as the stannous oxide. The white compound is nearly insoluble in water, while a solution of orthostannic acid in hydrochloric acid behaves like a solution of SnCl₂ in water, i.e. gives off no hydrochloric acid, and no precipitate of hydrated SnO. Metastannic acid is distinguished from the stannic acid by its affinity for phosphoric and sulphuric acids. The salts are obtained by the action of alkalis on the acid. (4) Orthostannic acid is obtained as a white precipitate on adding stannous chloride to potassium stannate or potassium carbonate. A precipitated calcium carbonate to a solution of the chloride. This acid, H₂SnO₄, is readily soluble in acids forming stannic salts, and in caustic potash and soda, with the formation of orthostannates. Of these salts, SnO₂, SnO₂K, SnO₂Na, SnO₂Ca, SnO₂Mg, and SnO₂Zn, are the most important. They are used in calico-printing. Alkaline and other nates when treated with aqueous hydrofluoric acid are converted into fluostannates (e.g. K₂SnO₂ from K₂SnO₂), which are closely analogous to, and isomorphous with, fluosilicates. A colloidal or soluble stannic acid is obtained by dialysing a mixture of tin tetrachloride and alkali, or of sodium stannate and hydrochloric acid. On heating it is converted into colloidal metastannic acid. A hydrated tin trioxide, SnO₂, was obtained by Spring by adding barium dioxide to a solution of stannous chloride and hydrochloric acid. The resulting mixture, when cooled, and the colloidal solution is evaporated to form a white mass of 2SnO₂·H₂O. Stannous Chloride, SnCl₂, can only be obtained pure by heating pure tin, in a current of hydrogen, yields stannous chloride and white solid, fusing at 250 °C. to an oily liquid which boils at 600 °C., and volatilizing at a red heat in nitrogen, a vacuum or hydrochloric acid, without decomposition. The vapour density below 700 °C. corresponds to SnCl₂ above 800 °C. nearly Sn₂ as the chloride readily combines with water to form a crystallizable hydrate SnCl₂·2H₂O, known as "tin salt" or "tin crystals." This salt is also formed by dissolving tin in strong hydrochloric acid and allowing it to crystallize, and is industrially prepared by passing sulphuric acid gas over granulated tin contained in stone ware bottles and evaporating the concentrated solution produced in a closed system. Stannous chloride is basic and forms at.

The crystals are very soluble in cold water, and if the salt is really pure a small proportion of water forms a clear solution; but on adding much water most of the salt is decomposed, with the formation of tin, the gas of oxidechloride, 2Sn(OH)Cl·H₂O. According to Michel and Kraft, one litre of cold saturated solution of tin crystals weighs 1827 grammes and contains 1333 grammes of SnCl₂. The same oxidechloride is produced when the moist crystals, or their solution, are exposed to the air. The crystals, kept in the laboratory give with water a turbid solution, which contains stannic in addition to stannous chloride. The complete conversion of stannous into stannic chloride may be effected by a gaseous stream of chlorine or hydrogen chloride, readily; by mercuric chloride in the heat, with precipitation of calomel or metallic mercury; by ferric chloride in the heat, with formation of ferric chloride; by the addition of hydrochloric solutions, with precipitation of chocolate-brown metallic arsenic. All these reactions are available as tests for "stannous" or the respective agents. In opposition to stannous chloride, stannic chloride is produced by various agents. A strip of metallic zinc when placed in a solution of stannous chloride precipitates the tin in crystals and takes its place in the solution. Stannous chloride is largely used in the chemical industry as a basis for the preparation of stannic chloride, in cases where the latter is not conveniently obtainable. A granulated tin contained in a retort; the tetrachloride distils over as a heavy liquid, from which the excess of chlorine is easily removed by shaking with a small quantity of tin filings and re-distilling. It is also a valuable fuming agent for crystallizing, forming solutions at -33 °C., and boils at 113.9 °C. The chloride unites energetically with water to form crystalline hydrates (e.g. SnCl₂·3H₂O), easily obtained industrially. The tin hydrate, Sn₂Cl₄·H₂O, is a so-called "button of tin." It combines readily with alkali and other chlorides to form double salts, e.g. M₂SnCl₄, analogous to the chloroplatinate; the salt (NH₄)₂SnCl₄ is known industrially as "pink salt," on account of its use in the production of starch colour. The oxysmuret of tin used by dyers is SnCl₂·SH₂O. The plain chloride solution is similarly used. It is usually prepared by dissolving the metal in aqua regia. Stannous Fluoride, SnF₂, is obtained as small, white monoclinic tables by evaporating a solution of stannous oxide in hydrofluoric acid in a vacuum. Stannic Fluoride, SnF₄, is obtained in solution with hydrofluoric acid. It shows a decided affinity for the free element, forming a characteristic series of salts, the stannofluorides, M₂SnF₄, isomorphous with the silico-, titanio-, germano- and zirconofluorides. Stannous bromide, SnBr₂, is a light yellow substance formed from tin and hydrobromic acid. Sn₂Br₄ is a yellow compound, the tin mass, melting at 33 °C and boiling at 201 °C., obtained by the combination of tin and bromine, preferably in carbon bisulphide solution. Stannous iodide, SnI₂, forms yellow red needles, and is obtained from tin and hydroiodic acid. The yellow salt of the orange-red Sn₂I₃, forms red octahedra and is prepared similarly to stannic bromide. Both iodides combine with ammonia.

Stannous Sulphate, SnSO₄, is also known as a lead-grey mass by heating tin with sulphur, and as a brown precipitate by adding sulphurated hydrogen to a stannous solution; this is soluble in ammonium polysulphide, and dries to a black powder. Stannous sulphate, SnSO₄, is soluble in water, and when heated in air oxidizes, giving stannic sulphur and sal-ammoniac in proper proportions in the beautiful form of aurum mutuum (mosaic gold)—a solid consisting of yellow, metallic lustreous scales, and used chiefly as a yellow or "bronze" pigment. Stannous sulphate can be prepared from stannic sulphide obtained by adding sulphurated hydrogen to a stannic solution readily dissolves in solutions of the alkaline sulphides to form stanniotannates of the formula M₂SnO; the free acid, H₂SnO₄, may be obtained as an almost black powder by drying the yellow precipitate formed when hydrochloric acid is added to a solution of a stannostannate.

Tin compounds when heated on charcoal with sodium carbonate or potassium cyanide in the reducing blowpipe flame yield the metal and a scantly ring of white SnO₂. Stannous salt solutions yield a brown precipitate of SnS₂ with sulphurised hydrogen, which is converted into stannic oxide by heating, while stannic salts with hydrogen chloride yield SnCl₂ and sal-ammoniac. Stannous salt solutions give a yellow precipitate of SnS₂ with sulphurised hydrogen, which is insoluble in cold dilute acids but readily soluble in sulphide of ammonium, and is re-precipitated therefrom as SnS₂ on acidification. Only stannous salts (not stannic) give a precipitate of calomel in mercuric chloride solution. A mixture of stannous and stannic chloride, when added to a sufficient quantity of solution of chloride of gold, gives an intensely purple precipitate of gold purple (purple of Cusani). The test is very delicate, although the colour is not in all cases a pure purple. Tin is generally quantitatively estimated as the dioxide. The solutions are oxidized, precipitated and re-dissolved in hydrochloric acid, and re-thrown down by boiling with sodium sulphate. The precipitate is filtered, washed, dried and ignited.

Bibliography.—For the history of tin and its products, see: Bernard Neumann, Die Metalle (1901); A. R. Rowan and J. H. Robinson, "The Chemistry and Metallurgy of Tin", 1911. For its chemistry see Roscoe and Schorlemmer, Traite de chimie minérale; O. Dammer, Handbuch der Erdenmetalle (1891). For its production and metallurgy see Svedberg, "Flavina"; T. H. Dinsmore, "Tin Mining"; Henry Louis, The Production of Tin, and C. Schabel, Handbook of Metallurgy (English trans. by Louis, 1907). General sources of Sn are: tin bars and rats from the metal; the metallurgy, etc., are recorded annually in The Mineral Industry.

TINAMOU, the name given in Guiana to a certain bird, as stated in 1741 by P. Barrère (France equinose, p. 138), from whom it was taken and used in a more general sense by Buffon (Hist. nat. oiseux, iv. 502). In 1783 J. Latham ( Synopsis, II. 724) adopted it as English, and in 1790 (Index, ii. 633) Latinized. 

TINAMOU
it *Tinamus*, as the name of a new and distinct genus. The "Tinamou" of Barrère has been identified with the "Macucaga" described and figured by Margrav in 1648, and is the *Tinamus* major of modern authors.\(^1\)

Buffon and his successors saw that the Tinamous, though passing among the European colonists of South America as "Partridges," could not be associated with those birds, and Latham's step, above mentioned, was generally approved. The genus he had founded was usually placed among the Gallinae, and by many writers was held to be allied to the bustards, which, it must be remembered, were then thought to be "struthions." Indeed the likeness of the Tinamous' bill to that of the Rhea (q.v.) was remarked in 1811 by Illiger. On the other hand L'Hérimier in 1827 saw features in the Tinamous' sternum that in his judgment linked the bird to the Railidae. In 1830 J. Wagler (Nat. Syst. Amphilith., &c., p. 127) placed the Tinamous in the same order as the ostrich and its allies; and, though he did this on very insufficient grounds, his assignment has turned out to be not far from the mark, as in 1862 the great affinity of these groups was shown by W. K. Parker's researches, which were afterwards printed in the Zoological Transactions (v. pp. 205-232, 236-238, pls. xxxix.-xli.), and was further substantiated by him in the Philosophical Transactions (1866, pp. 172-178, pl. xv.). Shortly after this T. H. Huxley in his often-quoted paper in the Zoological Proceedings (1867, pp. 425, 426) was enabled to place the whole matter in a clear light, urging that the Tinamous formed a very distinct group of birds which, though not to be removed from the Carinatae, presented so much resemblance to the Ratitae as to indicate them to be the bond of union between those two great divisions. The group from the resemblance of its palatal characters to those of the Eme (q.v.), Dromaeus, he called Dromaeognathae, but it is now more usual to place them in a separate order, the Tinamiformes.

The Tinamous are comparatively insignificant in numbers. They are peculiar to the neotropical region—a few species finding their way into southern Mexico and none beyond. Some of them inhabit forests and others the more open country; but setting aside size (which in this group varies from that of a quail to that of a large common fowl) there is an unmistakable uniformity among them as a whole, so that almost anybody having seen one species of the group would always recognize another. Yet in minor characters there is considerable difference among them; and about sixty-four species are recognized, divided into the genera *Tinamus*, *Nothoherus*, *Crypturus*, *Rhynchosus*, *Nothoprocta*, *Noturu*, *Tearumrhus*, and *Tinamomax*.

To the ordinary spectator Tinamous have much the look of partridges, but the more attentive observer will notice that their plumage is generally inconspicuous: some tint of brown, ranging from rufous to slaty, and often more or less closely barred with a darker shade or black, is the usual style of coloration; but some species are characterized by a white throat or a bay breast. The wings are short and rounded, and in some forms the feathers of the tail, which in all are hidden by their covert, are soft. In bearing and gait the birds show some resemblance to their distant relatives the Ratitae, and A. D. Bartlett showed (Proc. Zool. Soc., 1868, p. 115, pl. xil.) that this is especially seen in the newly hatched young. He also noticed the still stronger Ratitæ character, that the male, in taking on himself the duty of incubation. The eggs are very remarkable objects, curiously unlike those of other birds; and their shell looks as if it were of highly-burnished metal or glazed porcelain, presenting also various colours, which seem to be constant in the particular species, from pale primrose to sage-green or light indigo, or from chocolate brown to pinkish orange. All who have eaten it declare the flesh of the Tinamou to have a most delicate taste, as it has a most inviting appearance, the pectoral muscles being semi-opaque. Of their habits not much has been told. Darwin (Journ. ch. iii.) has remarked upon the silliness they show in allowing themselves to be taken, and this is wholly in accordance with what W. K. Parker observes of their brain capacity and is an additional testimony to their low morphological rank. At least one species of Tinamou has bred not infrequently in confinement, and partly successful attempts to naturalize the species *Rhynchosus rufescens* have been made in England.

(A. N.)

**Tincture** (Fr. teinture, Lat. tinctura, tingere, to dye, stain), the colour with which a substance is dyed; hence, metaphorically, distinctive character or quality. The term is used in heraldry of the, metals, argent, or, of the colours, sable, azure, &c., or of the furn, ermine, tair, &c. Since the 16th century a conventional arrangement of lines and dots gives the equivalents of these tinctures in black and white (see Heraldry). In medicine, a tincture is a fluid solution of the essential properties of some substance, animal, vegetable or mineral; the menstruum being either alcohol, ether or ammonia; the various kinds are accordingly distinguished as alcoholic, ethereal or ammoniated tinctures.

**Tindal, Matthew** (d. 1733), English deist, the son of a clergyman, was born at Beer Potters (Farrs), Devonshire, on 4 Jan. 1657. He studied law at Lincoln College, Oxford, under the high churchman George Hickes, dean of Worcester; in 1678 he was elected fellow of All Souls College. About 1685 he saw "that upon his High Church notions a separation from the Church of Rome could not be justified," and accordingly he joined the latter. But discerning the "absurdities of popery," he returned to the Church of England at Easter 1688. His early works were an Essay of Obedience to the Supreme Powers (1694); an Essay on the Power of the Magistrate and the Rights of Mankind in Matters of Religion (1697); and The Liberty of the Press (1698). The first of his two larger works, The Rights of Church associated against the Roman Church and all other priests who claim an independent power over it, pt. i., appeared anonymously in 1706 (2nd ed., 1706; 3rd, 1707; 4th, 1709). The book was regarded in its day as a forcible defence of the Erastian theory of the supremacy of the state over the Church, and at once provoked criticism and abuse. After several attempts to proscribe the work had failed, a case against the author, publisher and printer succeeded on the 12th of December 1707, and another against a bookseller for selling a copy the next day. The prosecution did not prevent the issue of a fourth edition and gave the author the opportunity of issuing A Defence of the Rights of the Christian Church in two parts (2nd ed., 1709). The book was, by order of the House of Commons, burned, along with Sacheverel's sermon, by the common hangman (1710). It continued to be the subject of denunciation for years, and Tindal believed he was charged by Dr. Gibbon, bishop of London, in a Pastoral Letter, with having undermined religion and promoted atheism and infidelity—a charge to which he replied in the anonymous tract, An Address to the Inhabitants of London and Westminster, a second and larger edition of which appeared in 1730. In this tract\(^2\) he makes a valiant defence of the deists, and anticipates

\(^1\) Brisson and after him Linnaeus confounded this bird, which they had never seen, with the Trumpeter (q.v.).

\(^2\) A Second Address to the Inhabitants, &c., with replies to some of the critics of that book, bears the same date (1730), though some of the works it refers to appeared in 1731.
TINDER—TINNEVELLY

here and there his Christianity as Old as the Creation; or, the Gospel a Reproduction of the Religion of Nature (London, 1730, 2nd ed., 1731; 3rd, 1732; 4th, 1733), which was regarded as the "Bible" of deism. It was really only the first part of the whole work, and the second, though written and entrusted in manuscript to a friend, never saw the light. The work evoked many replies, of which the ablest were by James Foster (1730), John Clarke (1732), John Leland (1733) and Bishop Butler (1736).

It was translated into German by J. Lorenz Schmidt (1741), and from it dates the influence of English deism on German theology. Tindal had probably adopted the principles it expounds before he wrote his essay of 1697. He claimed the name of "Christian deist," holding that true Christianity is identical with the eternal religion of nature. He died at Oxford on the 16th of August 1733.

The religious system expounded in Christianity as Old as the Creation, unlike the earlier system of Lord Herbert of Cherbury, was based on the empirical principles of Locke. It assumed the traditional deistic antitheses of external and internal, positive and natural, revelations and religions, and perpetuated at the same time the prevalent misconceptions as to the nature of religion and revelation. The system was worked out by the a priori method, with an all but total disregard of the facts of religious history. It starts from the assumptions that true religion must, from the nature of God and his method of working, be universal, simple and perfect; that this religion can consist of nothing but the simple and universal duties towards God and man, the first consisting in the fulfillment of the second—in other words, the practice of morality. The author's method is to expound his presuppositions, and then to show, utilitarian. True revealed religion is simply a reproduction of the religion of nature or reason, and Christianity, if it is the perfect religion, can only be that reproduction, and must be as old as creation. The special mission of Christianity, therefore, is simply to deliver men from the superstition which had perverted the religion of nature. True Christianity must be a perfectly "reasonable service," reason must be supreme, and the structures of the different religious doctrines must submit; only those writings can be regarded as divine Scripture which tend to the honour of God and the good of man. The strength of Tindal's position was the conviction of the essential harmony between man's religious and rational nature. Its weakness was a consequence of the standpoint of modern theology was that, like the whole religious philosophy of the time, it was founded on a misconception of religion and revelation, and on a disregard of the contrast between man's religious development.

See works quoted under Deism.

TINDER (O. Engl. tyndre, from tindan, tendan, to kindle, cf. Dan. tonder, Ger. anwinden), a term applied to any dry substance that will readily take light from a spark and so be used for kindling a fire. Before the invention of matches (see MATCH) fire or light was procured by the ignition of tinder through sparks obtained by the striking of flint against steel, the whole apparatus of tinder, flint and steel being contained in a metal box, which was an essential utensil of all households and was also carried on the person of everyone who might require a light in an emergency.

The usual material of "tinder" was a mass of charred linen, but the term was also applied to "touchwood," or wood converted into an easily ignitable consistency by the action of certain fungi. Another form of "tinder" was "touchpaper," paper dipped in nitre and used as a slow-match for igniting gunpowder.

In both these words "touch" stands for an earlier tach, tache or tasche, tinder, of which the origin is unknown. It may be related to Du. tak, bough, twig, and would thus mean dried twigs used as tinder.

TINEO, a town of northern Spain, in the province of Oviedo; on a small tributary of the river Narcea, among the northern outliers of the Cantabrian Mountains, and on the high road from Cangas de Tineo to the Biscayan port of Cadilero. Pop. (1900), 21,865. Mining, agriculture and stock-rearing are the principal industries.

TINKER, an itinerant mender of kettles, pots, pans, &c. The name means simply one who makes a tinkling sound as he mends the vessels, and the word is found as "tinkler" in the 16th century. From early times "tinkers" were looked on as vagabonds, and were so classed in the act of Elizabeth against vagrancy.

TINNE, ALEXANDRINE PETERONELLA FRANCINA (1830—1860), Dutch traveller in Africa, born at the Hague on the 17th of October 1839, was the daughter of Philip F. Tinné, a Dutch merchant who settled in England during the Napoleonic wars, but afterwards returned to his native land, and of his wife, Baroness Van Steengracht-Capellen. Her father died when she was five years old, leaving her the richest heiress in the Netherlands. After travelling in Norway, Italy and the East, and visiting Egypt, when she ascended the Nile to Gondokoro, Miss Tinné left Europe again in 1860 for the Nile regions. Accompanied by her mother and her aunt, she set out from Cairo on the 9th of January 1862. After a short stay at Khartum the party ascended the White Nile to a point above Gondokoro, and explored a part of the Sobat, returning to Khartum in November.

Baron Theodor von Heuglin (q.v.) and Dr H. Steudner having meantime joined the ladies at Khartum, the whole party set out in February 1863 for the Bahr-el-Ghazal. The intention was to explore that region and ascertain how far westward the Nile basin extended; also to investigate the reports of a vast lake in Central Africa eastwards of those already known—reports referring in all probability to the lake-like expanses of the middle Congo.

Ascending the Bahr-el-Ghazal the limit of navigation was reached on the 10th of March. From Meshira-er-Rek a journey was made overland, across the Bahr Jur and south-west by the Bahr Kosango, to Jebel Kosango, on the borders of the Niam-Niam country. During the journey all the travellers suffered severely from fever. Steudner died in April and Madame Tinné in June, and after many fatigue and dangers the remainder of the party reached Khartum in July 1864, where Miss Tinné's health wavered, and Miss Oudebrand left the expedition. The geographical and scientific results of the expedition were highly important, as will be seen in Heuglin's Die Tinnésche Expedition im westlichen Nilgebiet (1863—1864 (Gotha, 1865, and Reise in das Gebiet des Weissen Nils Leipzig, 1866). A description, by T. Kotschy and J. Peyritsch, of some of the plants discovered by the expedition was published at English in 1867 under the title of Plantes Tinneennes. At Cairo Miss Tinné lived in Oriental style during the next four years, visiting Algeria, Tunisia and other parts of the Mediterranean. In January 1869 she started from Tripoli with a caravan, intending to proceed to Lake Chad, and thence by Wadai, Darfur and Kordofan to the upper Nile. On the 1st of August, however, on the route from Murzuk to Ghat, she was murdered, together with two Dutch sailors, by Tuareg in league with her escort, who believed that her iron water tanks were filled with gold.

TINNEVELLY, a town and district of British India, in the Madras presidency. The town is on the left bank of the Tambraparni river, on the other side of which is Palamcottah, the administrative headquarters of the district. Pop. (1901), 40,460. It is the terminus of a branch of the South Indian railway, 444 m. S.W. of Madras. Its most noteworthy building is a beautifully sculptured temple of Siva.

The DISTRICT of TINNEVELLY has an area of 5380 sq. m. It is for the most part a plain with an average elevation of 200 ft., sloping to the east with slight undulations. It is watered by numerous short streams, the principal being the Tambraparni with a length of 80 m. The chief irrigation work is the Sreevankutam anicut or dam on this river. In the north the scenery is unattractive and the soil poor; in the south the sandy soil prevails in which little save the Palmyra palm will grow. This palm yields toddy as well as a coarse sugar. Along the banks of the rivers are rice-fields and a variety of trees and crops; and coffee is grown on the slopes of the Travancore hills. The district contains many ancient and magnificent buildings. But the most interesting antiquities are the large sepulchral earthen urns of prehistoric races, which have been found at several places, especially along the course of the Tambraparni; they contain bones, pottery, beads and bronze ornaments, iron weapons, implements, &c. The South Indian railway has its maritime terminus at Tuticorin, the chief seaport. The
principal exports are rice to Ceylon and cotton to Japan and Europe. In 1901 the population was 2,059,607, showing an increase of 8% in the decade. The number of native Christians was 159,213, Tinnevelly being the most Christian district in India. The Society for the Propagation of the Gospel and the Church Missionary Society have important and flourishing stations at Tinnevelly town and Palamcottah, as also have the Jesuits. It was here that St Francis Xavier began his preaching in India. The Shans, or caste of toddy-drawers, have supplied many converts to Christianity. In 1899 their treatment by the Vellalars, or cultivating caste, led to serious riots and bloodshed.

The early history of Tinnevelly is mixed up with that of Madura and Travancore. Down to 1781 it is a confused tale of anarchy and bloodshed. In that year the nawab of Arcot assigned the revenues to the East India Company, which then undertook the [internal] administration. So the road of subjection took place, and in 1801 the whole Carnatic, including Tinnevelly, was ceded to the British.

**TIN-PLATE and TERNE-PLATE.** Tin-plate consists of sheets of iron or steel which have been thinly coated with tin by being dipped in a molten bath of that metal. Terne-plate is a similar product, but the bath is not of tin, but of tin and lead mixed, the latter metal constituting from 75-90% of the whole; it has not the bright lustre of tin-plate, whence its name, from *terne*, dull, tarnished. The sheets employed in the manufacture are known as "terne plates," or "black plates," by which the quality of tin-plate is still designated, although iron is no longer used. Tin-plate is consumed in enormous quantities for the manufacture of the tin cans in which preserved meat, fish, fruit, biscuits, cigarettes and numerous other products are packed, and also for the household utensils of various kinds made by the tinsmith or silversmith; terne-plates, which began to be produced in England in the 18th century, are widely employed in America for roofing purposes.

The manufacture of tin-plate was long a monopoly of Bohemia, but tin-plate "he-imported spread to Saxony in 1665. From Yarranton (1616-1684), an English engineer and agriculturist, was commissioned to go to Saxony and if possible discover the methods employed. According to his own account ("England's Improvement," ii. 39), he was "very well treated and was allowed to see the whole process. On his return to England his friends undertook the manufacture on an experimental scale, but though they were successful they had to abandon it, because the smelting of the metal was a "patent up" by a rival, who, however, from lack of technical skill was unable to work it. Half a century later the manufacture was revived by Major John Kay of Penrith, who "made use of the iron plates by means of cylinders," said to have been devised by him, enabled more uniform black plates to be produced than was possible with the old plan of hammering, and in consequence the English tin-plate became recognized as superior to the German. During the next hundred years or so the industry spread steadily in England and Wales, and after 1834 its expansion was rapid, especially in Wales, Great Britain becoming the chief producer. The world's known production in 1870 was 180,000 boxes of 108 lb each (in America a box is 100 lb), in 1848 it was 429,000 boxes, in 1860 it reached 1,700,000 boxes, in 1870 nearly 3,400,000 M. and in 1890 it eranged 6,500,000 boxes. In the United States the manufacture of tin- and terne-plates did not make much way until about 1890, and up to 1892 the bulk of the supply was imported from Great Britain. But subsequently the advance was swift and steady, with the American production, and in 1907 only 20% of the American tin-plate mills were at work, while the British production reached 14 million boxes.

Terne-plates are used for the tinning of the black plates. In the "palm-oil" process, which is the older, the plates, after being properly annealed, are scoured with sand and water and pickled in dilute sulphuric acid alternately until they are perfectly clean and bright. They are then washed in water, and after being boiled in palm oil to remove all traces of acid and water are dipped into a bath of molten tin, covered with oil to prevent oxidation. They are then removed to a second bath containing a little copper and molten tin, and finally to a third bath containing a little zinc and molten tin. After this they are scoured with a hempen rubber and dipped in a third bath containing the purest tin of all; then they are passed through rolls to finish the surface and regulate the thickness of the coating. As the tin in the third bath becomes alloyed with iron from the operation, it is removed into the second, pure fresh tin being substituted; and similarly the metal of the second, as the tin in it is alloyed with iron in the third, is removed. In the "acid process" only a single bath of tin is required. The molten metal is covered with a layer of muriate of zinc, which acts as the flux, and the plates are passed through rolls that are passed through this down into the tin, to be brought out at another point in the bath where there is a layer of oil on the surface.

**TINTAGEL,** or Trevena, a village in the Launceston parliamentary division of Cornwall, England, on the north coast, 43 m. from Camelford. Pop. (1901), 868. It stands on a bare upland, close to the sea; and below it is Tintagel Haven, or Porth, a small cave surrounded by cliffs of almost black slate. The scanty ruins of a castle are built partly on the mainland, partly on a rugged promontory spoken of as the Island, but united by a narrow peninsula to the shore. They have been celebrated as the birthplace of King Arthur, or as the stronghold of King Mark, in a host of medieval romances, and in the poems of Tennyson and Swinburne. The Norman walls are so darkened and weathered that, from a little distance, they seem a part of the rock itself. Portions of a chapel remain, dating from the 13th century, and including a porch and a stone altar; while beside it is the trace of a track to the bower of the slate, and some domestic building which was afterwards turned into a temple and church door. The cruciform parish church of St Marcelliana stands on a high clifl, west of the castle. Although it has been restored, there remain traces of Saxon workmanship in the chancel, besides two Norman doorways, a font of the same period, a stone altar bearing five crosses and a fine 15th-century brass. In the churchyard the graves are buttressed, storms being frequent and violent on this unprotected coast. For a time the church belonged to Fontevrault Abbey in Normandy; but it was made over by Edward IV. to the collegiate church of Wimborne Minster. The walls have always been defaced by the "mem-" of the various occupants. Portions of the vicarage date from the 14th century, and in its garden there is a stone dovecote of great age. A little slate is quarried, being taken from the rocks below the church, and exported in the small vessels which can visit Tintagel Haven in calm weather. The magnificence of the coast has inspired more than one famous painting.

Tintagel (Tintol, Dudnegal) is a parish a portion of which appears in the Domesday Survey as Bosinney (Botcinou). The latter was held in the time of the Confessor by a thegn of St Petrock and at the time of the survey by Robert, count of Mortain, and the whole belonged to the capital. The first grant of land and the next place of greatest distinction is there is the pre-Saxon times. Under the Norman earls of Cornwall this was rebuilt, embattled and furnished with munitions of war. Its officers included a constable and a chaplain. It was in a ruinous condition in Leland's time (c. 1540). Queen Elizabeth abolished the office of constable. In the parish of Tintagel is the hamlet of Bosinney which under the name of Tintagel received a charter (undated) from Richard king of the Romans, granting freedom to the borough and to the burgesses freedom from portage and stallage throughout Cornwall, a market on Wednesdays and a three days' fair at Michaelmas. This charter was confirmed in 1386. In 1335 the burgesses, those who held tenements within the borough, numbered 100. The borough, which apparently owed its existence to the castle, shared its fortunes. Leland calls attention to the decay of a great number of houses. Its charter was surrendered to Charles II. and a new one obtained from his brother in 1685. Under the latter a mayor, recorder, six common councillors, a coroner, six freemen and a common clerk were to constitute the corporation. For supplying vacancies in it the votes of those only who were members of it were required. Provision was made for the administration of the borough. Bossiney acceded to the privileges of Tintagel in 1553, the franchise being originally vested in the freeholders within the borough. By the middle of the
TINTERN ABBEY—TINTORETTO

18th century the franchise had become restricted to the freemen or burgesses. In 1784 the vicar of Tintagel, as mayor and only qualified elector, enjoyed the probably unique privilege of returning two members to the House of Commons. In 1832 there were ten resident legal voters within the borough and nine out-voters. The Reform Act transferred their votes to the county. There is now no market, and the only fair is held on the 21st of October.

TINTERN ABBEY, in Monmouthshire, one of the most famous ecclesiastical ruins in England. It is beautifully situated on the right bank of the river Wye. The abbey was founded by Walter de Clare in 1131 for Cistercian monks. The existing church, however, dates from the later part of the 13th century; it is unroofed, and the nave is imperfect, but many of the finest details of a style transitional from Early English to Decorated are preserved. The church is cruciform. Cloisters and other monastic buildings, of which there are considerable remains, lay to the north of the church. The foundation was dissolved by Henry VIII. At the time, Tintern Abbey was a station on a branch of the Great Western railway.

TINTORETTO, JACOPO ROBUSTI (1577–1649), one of the greatest painters of the Venetian school, was born in Venice in 1577, though most accounts say in 1572. His father, Battista Robusti, was a dyer, or “tintore”; hence the son got the nickname of “Tintoretto,” little dyer, or dyer’s boy, which is Englished as Tintoret. In childhood Jacopo, a born painter, began daubing on the dyer’s wails; his father, noticing his bent, took him round, still in boyhood, to the studio of Titian, to see how far he could be trained as an artist. We may suppose this to have been towards 1533, when Titian was already (according to the ordinary accounts) fifty-six years of age. Ridolfi is our authority for saying that Tintoret had only been ten days in the studio when Titian sent him home once and for all. The reason, according to the same writer, is that the great master observed some very spirited drawings, which he learned to be the production of Tintoret; and it is inferred that he became at once jealous of so promising a scholar. This, however, is mere conjecture; and perhaps it may be fairer to suppose that the drawings exhibited so much independence of manner that Titian judged that young Robusti, although he might become a painter, would never be properly a pupil. From this time forward the two always remained upon distant terms—Robusti being indeed a professed and ardent admirer of Titian, but never a friend, and Titian and his adherents turning the cold shoulder to Robusti. Active disparagement also was not wanting, but it passed unnoticed by Tintoret. The latter sought for no further teaching, but studied on his own account with laborious zeal; he lived poorly, collecting casts, bas-reliefs, &c., and practising by their aid. His noble conception of art and his high personal ambition were evidenced in the inscription which he placed over his studio—“Il disegno di Michelangelo ed il colorito di Tiziano” (Michelangelo’s design and Titian’s colour). He studied more especially from models of Michelangelo’s “Dawn,” “Noon,” “Twilight” and “Night,” and became expert in modelling in wax and clay—a method (practised likewise by Titian) which afterwards stood him in good stead in working out the arrangement of his pictures. The models were sometimes taken from dead subjects dissected or studied in anatomy schools; some were draped, others nude, and Robusti was wont to suspend them in a wooden or cardboard box, with an aperture for the entrance of air. He would frequently paint round the night as well as by day. The young painter Schiavone, four years Robusti’s junior, was much in his company. Tintoret helped Schiavone gratis in wall-paintings; and in many subsequent instances he worked also for nothing, and thus succeeded in obtaining commissions. The two earliest mural paintings of Robusti—done, like others, for next to no pay—were said to have been “Bedshazzer’s Feast” and a “Cavalry Fight,” both long since perished. Such, indeed, may be said to have been the fate of all his frescoes, earlier or later. The first work of his which attracted some considerable notice was a portrait-group of himself and his brother—the latter playing a guitar—with a nocturnal effect; this also is lost. It was followed by some historical subject, which Titian was candid enough to praise. One of Tintoret’s early pictures still extant is in the church of the Carmine in Venice, the “Presentation of Jesus in the Temple”; also in S. Benedetto are the “Annunciation” and “Christ with the Woman of Samaria.” For the Scuola della Trinità (the school or schools of Venice were more in the nature of educational institutions than of educational institutions) he painted four subjects from Genesis. Two of these, now in the Venetian Academy, are “Adam and Eve” and the “Death of Abel,” both noble works of high mastery, which leave us in no doubt that Robusti was by this time a consummate painter—one of the few who have attained to the highest eminence by dire study of their own, unseconed by any training from some senior proficient.

Towards 1546 Robusti painted for the church of the Madonna dell’Orto three of his leading works—the “Worship of the Golden Calf,” the “Presentation of the Virgin in the Temple,” and the “Last Judgment”—now shamefully repainted, and he settled down in a house hard by the church. It is a Gothic edifice, looking over the lagoon of Murano to the Alps, built in the Fondamenta de’ Mori, still standing, but let out cheap to artisans. In 1548 he was commissioned for four pictures in the Scuola di S. Marco—the “Finding of the body of St Mark in Alexandria” (now in the church of the Angeli, Murano), the “Saint’s Body brought to Venice,” a “Votary of the Saint delivered by invoking him from an Unclean Spirit” (these two are in the library of the royal palace, Venice), and the highly lusty celebrated “Miracle of the Slave.” This last, which forms at present one of the chief glories of the Venetian Academy, represents the legend of a Christian slave or captive who was to be tortured as a punishment for some acts of devotion to the evangelist, but was saved by the miraculous intervention of the latter, who shattered the bone-breaking and blinding implements which were about to be applied. These four works were greeted with signal and general applause, including that of Titian’s intimate, the too potent Pietro Aretino, with whom Tintoret, one of the few men who scorned to curry favour with him, was merely in disrepute. It is said, however, that “Tintoret at one time painted a ceiling in Pietro’s house; at another time, being invited to do his portrait, he attended, and at once proceeded to take his sitter’s measure with a pistol (or a stiletto), as a significant hint that he was not exactly the man to be trifled with. The painter having now executed the four works in the Scuola di S. Marco, his straits and obscure endurances were over. He married Faustina de’ Vescovi, daughter of a Venetian nobleman. She appears to have been a careful housewife, and one who both would and could have her way with her not too tractable husband. Faustina bore him several children, probably two sons and five daughters.

The next conspicuous event in the professional life of Tintoret is his enormous labour and profuse self-development on the walls and ceilings of the Scuola di S. Marco, a building which may now almost be regarded as a shrine reared by Robusti to his own genius. The building had been begun in 1525 by the Lombardi, and was very deficient in light, so as to be particularly ill-suited for any great scheme of pictorial adornment. The painting of its interior was commenced in 1560. In that year five principal painters, including Tintoret and Paul Veronese, were invited to send in trial-designs for the centre-piece in the smaller hall, only to be overruled by the Scuola, who fixed on Sala dell’Albergo, on the subject of which the painter had been recommended into Heaven. Tintoret produced not a sketch but a picture, and got it inserted into its oval. The competitors remonstrated, not unnaturally; but the artist, who knew how to play his own game, made a free gift of the picture to the saint, and, as a by-law of the foundation prohibited the rejection of any gift, it was retained in situ—Tintoret furnishing gratis the other decorations of the same ceiling. (This is one version of the anecdote: there is another version, which, though differing in incident, has the like general bearing.) In 1565 he resumed his work at the scuola, painting the magnificent “Crucifixion,” for which a sum of
250 ducats was paid. In 1576 he presented gratis another centre-piece—that for the ceiling of the great hall, representing the "Plague of Serpents"; and in the following year he completed this ceiling with pictures of the "Paschal Feast," and "Moses striking the Rock."—accepting whatever pitance the confraternity chose to pay. Robusti next launched out into the painting of the entire scuola and of the adjacent church of S. Rocco. He offered in November 1577 to execute the works at the rate of 100 ducats per annum, three pictures being due in each year. This proposal was accepted and was punctually fulfilled, the painter's death alone preventing the execution of some of the ceiling-subjects. The whole sum paid for the scuola throughout was 2447 ducats. Disregarding some minor performances, the scuola and church contain fifty-two memorable paintings, which may be described as vast suggestive sketches, with the mastery, but not the deliberate precision, of finished pictures, and adapted for being looked at in a hasty half-light. "Adam and Eve," the "Visitatio," the "Adoration of the Magi," the "Massacre of the Innocents," the "Agony in the Garden," "Christ before Pilate," "Christ carrying His Cross," and (this alone having been marred by restoration) the "Assumption of the Virgin" are leading examples in the scuola; in the church, "Christ curing the Paralytic." It was probably in 1560, the year in which he began working in the Scuola di S. Rocco, that Tintoretto commenced his numerous paintings in the ducal palace; he then executed there a portrait of the doge, Girolamo Priuli. Other works which were destroyed in the great fire of 1577 succeeded—the "Excommunication of Frederick Barbarossa," and "Venus and Adonis," and "Venus of Lepanto." After the fire Tintoret started afresh, Paul Veronese being his colleague; their works have for the most part been disastrously and disgracefully retouched of late years, and some of the finest monuments of pictorial power ever produced are thus degraded to comparative unimportance. In the Sala dello Scrinio Robusti painted the "Capture of Zara from the Hungarians in 1446 amid a Hurricane of Missiles"; in the hall of the senate, "Venice, Queen of the Sea"; in the hall of the college, the "Espousal of St Catherine to Jesus"; in the Sala dell'Anticollegio extra ordinary masterpieces—"Bacchus, with Ariadne crowned by Venus," the "Three Graces and Mercury," "Minerva discarding Mars," and the "Forge of Vulcan"—which were painted for fifty ducats each, besides materials, towards 1578; in the Antichiesetta, "St George and St Nicholas, with St Margaret" (the female figure is sometimes termed the princess whom St George rescued from the dragon), and "St Jerome and St Andrew"; in the hall of the great council, nine large compositions, chiefly battle-pieces. We here reach the crowning production of Robusti's life, the last picture of any considerable importance which he executed, the vast "Paradise," in size 74 ft. by 30, Alpoge, to be the latest painting ever done upon canvas. It is a work so stupendous in scale, so colossal in the sweep of its power, so reckless of ordinary standards of conception or method, so pure an inspiration of a soul burning with passionate visual imagining and a hand magical to work in shape and colour, that it has defied the connoisseurship of three centuries, and has generally (though not with its first Venetian contemporaries) passed for an eccentric failure; while to a few eyes (including those of the present writer) it seems to be so transcendent a monument of human faculty applied to the art pictorial as not to be viewed without awe, nor thought of without admiration. While the commission for this huge work was yet pending and unassigned Robusti was wont to tell the senators that he had prayed to God that he might be commissioned for it, so that paradise itself might perchance be his recompense after death. Upon eventually receiving the commission in 1588 he set up his canvas in the Scuola della Misericordia and worked indefatigably at the task, making many alterations and doing various heads and costumes direct from nature. When the picture had been brought well forward he took it to its proper place and there finished it, assisted by his son Domenico for details of drapery, &c. All Venice applauded the superb achievement, which has in more recent times suffered from neglect, but fortunately hardly at all from restoration. Robusti was asked to name his own price, but this he left to the authorities. They tendered a handsome amount; Robusti is said to have abated something from it, which is even a more curious instance of ungenerosity for pelf than earlier cases which we have cited where he worked for nothing at all.

After the completion of the "Paradise" Robusti rested for a while. He never undertook any other work of importance, though there is no reason to suppose that his energies were exhausted had his days been a little prolonged. He was seized with an attack in the stomach, complicated with fever, which prevented him from sleeping and almost from eating for a fortnight, and on the 31st of May 1594 he died. A contemporary record states his age to have been seventy-five years and fifteen days. If this is accurate, the 16th of May 1595 must have been the day of his birth; but we prefer the authority of the register of deaths in S. Marciliano, which states that Tintoret died of fever, aged seventy-five years, eight months and fifteen days—thus bringing us to the 16th of September 1518 as the true date of his birth. He was buried in the church of the Madonna dell'Orto by the side of his favourite daughter Marietta, who had died in 1590, aged thirty; there is a well-known tradition that as she lay dead the heart-stricken father painted her portrait. Marietta had herself been a portrait-painter of considerable skill, as well as a musician, vocal and instrumental; but few of her works are now traceable. It is said that up to the age of fifteen she used to accompany and assist her father at his work, dressed as a boy; eventually she married a jeweller, Mario Augusta. In 1566 the grave of the Vezovio and Robusti was opened, and the remains of nine members of the joint families were found in it; a different locality, the chapel on the right of the choir, was then assigned to the grave.

Tintoret painted his own portrait at least twice, one of the heads being in the Uffi zi Gallery of Florence and the other, done when his age was advanced, in the Louvre. It is a very serious face, somewhat blunt and rugged, but yet refined without the varnish of elegance—concentrated and resolute, its native ardour of frankness and energy welded down into lifelong laboriousness, with a pent look as of smouldering fire. The eyes are large, dark and round; the grizzled hair close and compact. The face has been held to bear some resemblance to that of Michelangelo, but this does not go very far. Robusti appears also as one of the figures in the two vast pictures by Paul Veronese—the "Marriage in Cana" and the "Feast in the House of Levi." Audacious and intrepid, though not constantly correct, as a draughtsman, majestically great as a colourist, prodigious as an executant, Tintoret was as absolute a type of the born painter as the history of art registers or enables us to conceive. Whatever the melancholy and tragic pictures which his imagination suggested (he was eminently capable of painting a lovely female countenance or an heroic man), often imposing and Romantic, fully as often turbulent and reckless, sometimes trivial, never unpainter-like or prosaic. When he chose—which was not always—he painted his entire personages characteristically; but, like the other highest masters of Venice, he conceded and attended little to the expression of his faces as evincing incidental emotion. In several of his works—as especially the great "Crucifixion" in S. Rocco—there is powerful central thought, as well as inventive detail; but his imagination is always concrete: it is essentially that of a painter to whom the principle of life—itching to make visible—asserts itself above all else, distribution—are the typical and necessitated realities. What he imagines is always a visual integer, a picture—never a treatise, theoretical—his whole art is strictly visual; he supposes that one could see—that is his ideal, not something that one could narrate, still less that one could deduce and demonstrate. In his treatment of action or gesture the most constant peculiarity is the immense relative size of figures; he deliberately increased every forest-boughs in a gale; stiffness or immobility was entirely foreign to his style, which has therefore little of the monumental or severe character. Perhaps he felt that there was no other way for combinations of Titan with the design of Michelangelo. The whole strength and the transcendent fervour of energy of the supreme Florentine might to some extent be emulated; but, if they were united with the weakness of the Venetian, this could only be attained by a process of relaxing the excessive tension and modifying muscular into elastic force. In this respect he was a decided innovator; but he had many imitators, comparatively feebly if we except Paul Veronese.
Tintoretto scarcely ever travelled out of Venice. He loved all the art of the Florentines and Venetians, as well as that of all of his own invention, and designed theatrical costumes and properties, was versed in mechanics and mechanical devices, and was a very agreeable companion. For the sake of his work he lived in a manner not requiring a large amount of money. When not painting he would remain in his working room surrounded by casts. Here he hardly admitted any, even intimate friends, and he kept his modes of work secret and away from his assistants. He abounded in pleasant witty sayings whether to guest or peer. He would also have the house wrap up money for him in a handkerchief, and on his return expected an account of it; Tintoretto's accustomed reply was that he had spent it in alms for the poor or to prisoners. In 1574 he was awakened by the sudden breaking of a window in the fondaico, with power to bequeath it—an advantage granted from time to time to pre-eminent painters. For his phenomenal energy in painting he was termed "Il Porfido." An agreement is extant showing that he undertook to finish in two months two historical pictures each containing twenty figures, seven being portraits. The number of his portraits is enormous; their merit is unequal, but the really fine ones cannot be surpassed. Sebastiano del Piombo remarked that Robusti could paint in two days as much as himself in two years; Annibale Caracci that Tintoretto was in many pictures equal to Titian, in others inferior to Tintoretto. This was the general opinion. The one who said that he had three pentimenti, the second of gold, the second of silver and the third of iron. The only pictures (if we except his own portraits) on which his signature is the church of St. Mark, of Venice (painted originally, for the brotherhood of the Crociferi), the "Miracle of the Virgin," in the Gallery, and the "Crucifixion" in the Scuola di S. Rocco; the last was engraved in 1889 by Agostino Caracci. Generally he painted at once on the canvas, without any underdrawing; and on art have been recorded as follows by Ridolfi: "the art of painting remains increasingly difficult;" "painters in youth should adhere to the best masters, these being Michelangelo and Titian, and should be strict in representing the natural forms," "the first glance at a picture is the crucial one;" "black and white, as developing form, are the best of colours;" "drawing is the foundation of a painter's work;" and "the snows, masses, etc., in the paintings by well-practised men, as the real is often wanting in beauty." Of pupils Robusti had very few; his two sons and Martin de Vos of Antwerp were among them. Domenico Robusti (1562–1637), whose work has already had occasion to mention, frequently assisted his father in the groundwork of great pictures. He himself painted a multitude of works, many of them on a very large scale; they would at best be mediocre, and, coming from the son of Tintoretto, are exasperating; still, he must be regarded as a considerable sort of pictorial practitioner in his way.

We conclude by naming a few of the more striking works of Tintoretto's works that have been left to us: Among them are:

In Venice (S. Giorgio Maggiore), a series of his later works, the "Gathering of the Manna," the "Last Supper," "Descent from the Cross," "Resurrection," "Martyrdom of St. Stephen," "Coronation of the Virgin," "Miracle of St. Ignatius," (the painted originally, for the Brotherhood of the Cross of the Bishops); (S. Francesco, Vigna) the "Entombment;" (the Frari) the "Massacre of the Innocents;" (S. Cassano) a "Crucifixion," the figures seen from behind along the hill slope; (St. Mark's) a mosaic of the "Baptism of Christ," the "Lamentation over the Dead Christ;" (Venetian Theatre, Milan) "St. Helena and other saints." In Florence (Pitti Gallery), "Venus," "Vulcan," and "Cupid." In Cologne (Wallraf-Richartz Museum), "Ovid and Cyma." In Augsburg (the town-hall), some historical pictures, which biographers and tourists alike have unaccountably neglected—one of the siege of a fortified town is astonishingly fine. In England (Hampton Court), "Esther and Ahasuerus," and the "Nine Muses;" (the National Gallery), "The Origin of the Milky Way," a memorable tour de force, "Christ washing Peter's Feet," a grand piece of colour and execution, not greatly interesting in other respects, also a spirited smallish version of "The Annunciation." In Dragoon Street, the writer who has done by far the most to establish the fame of Tintoretto at the height which it ought to occupy in Ruskin in his Stones of Venice and other books; the depth and scope of the master's power had never before been adequately brought out, although his extraordinarily and somewhat arbitrarily used executive gift was acknowledged. Ridolfi (Mervaglie dell' Arte) gives interesting personal anecdotes. Dr. Kane (On Art; a Handbook for Students) (1876) is a solid account. For an English reader the most handy narrative is that of W. R. Oliver (Tintoretto, 1879), in the series entitled "The Great Artists." Here the biographical facts are clearly presented, and a flattering account of the man but not of his work. Other works deserving of mention are: L. Menard, Études sur Tintoret (1881); T. P. Stevens, Four Great Venetians (1901); H. Thode, Tintoretto (1901); Stoughton Holborn, Jacobo Robusti (1903).

TIPASA—TIPPERA

of the commune (1906), 2725. The modern town, founded in 1857, is remarkable chiefly for its pleasant situation and sandy beach. The roadstead is exposed to the N.E. and N.W. There is a mole about 90 ft. long and anchorage in six fathoms. A considerable trade is done. The Roman city of Tipasa was built on three small hills which overlooked the sea. Of the houses, most of which stood on the cliffs, no traces remain; but there are ruins of three churches—Great Basilica and the Basilica Alexander on the western hill, and the Basilica of St Salsa on the eastern hill—two cemeteries, the baths, theatre, amphitheatre and nymphaeum. The line of the ramparts can be distinctly traced and at the foot of the eastern hill the remains of the ancient harbour. The basilicas are surrounded by cemeteries, which are full of coffins, all of stone and covered with mosaics. The basilica of St Salsa, which has been excavated by S. Gsell, consists of a nave and two aisles, and still contains a mosaic. The Great Basilica served for centuries as a quarry, but it is still possible to make out the plan of the building, which was divided into seven aisles. Under the foundations of the church are tombs hewn out of the solid rock. Of these one is circular, with a diameter of 60 ft. and space for 24 coffins.

Tipasa was founded by the Phoenicians, was made a Roman military colony by the emperor Claudius, and afterwards became a municipium. Commercially it was of considerable importance, but it was not distinguished in art or learning. Christianised early, and in the third century Tipasa was a bishopric. The see's existence has been rarely attested until, according to the legend, Salsa, a Christian maiden, threw the head of their serpent idol into the sea, whereupon the enraged populace stoned her to death. The body, miraculously recovered from the sea, was buried, on the hill above the harbour, in a small chapel which gave place subsequently to the stately basilica. Salsa's martyrdom took place in the 4th century. In 484 the Vandal king Huneric (477–484) sent an Arian bishop to Tipasa; whereupon a large number of the inhabitants fled to Spain, while many of the remainder were cruelly persecuted. After this time the city disappeared from history; and, whether or not its ruin was caused by the Arabs, they seem to have made no settlement there.

(2) Another town which in Roman times was called Tipasa is in the department of Constantine, Algeria, 55 m. due south of Bona, 3140 ft. above the sea; it is now called Tiféf. The chief ruin is that of an extensive fortress, the walls of which are 9 ft. thick.

TIP-CAT (also called Cat and Cat and Dog), a pastime which consists in tapping with a stick a short billet of wood with sharpened ends upon one of these ends, so that it jumps in the air, and the hitting of it with another stick continued heathens for many varieties of the game, but in the most common the batter, having placed the billet, or cat, in a small circle on the ground, tips it into the air and hits it to a distance. His opponent then offers him a certain number of points, based upon his estimate of the number of hops or jumps necessary to cover the distance. If the batter thinks the distance underestimated he is at liberty to decline the offer and measure the distance in jumps, and score the number made. The game is one or more hundred.

TIPPERA (Tripora), a native state and also a British district of India, in Eastern Bengal and Assam. The state, which is held as Hill Tippera (q.v.), represents that portion of the raja's territory that was never conquered by the Mahommedans. The dynasty, which is of great antiquity, was converted to Hinduism many centuries ago; but the people still profess an aboriginal religion, similar to that of the neighbouring hill tribes. The raja owns an estate of 570 sq. m., yielding an income of more than £40,000, in the British district, where he ranks as an ordinary zamindar. His residence is at Agartala, just within the boundary of Hill Tippera.

The British district of Tippera, with administrative headquarters at Comilla, has an area of 2499 sq. m. It has a flat and open surface, with the exception of the isolated Lālmāi range.
TIPPERARY

(100 feet), and is for the most part laid out in well-cultivated fields, intersected by rivers and _kahls_ (creeks) partially affected by the tides. In the lowlands the soil is light and sandy; but in the higher parts a deep alluvial soil alternates with bands of clay and sand. The principal rivers are the Meghana, or estuary of the Brahmaputra; and the Gunti, Dakkattait, and Tittas, which are also navigable for a considerable portion of their course. There are many marshes or _blys_. The wild animals include tigers, leopards, wild boars and buffaloes. The climate is mild and healthy. In 1901 the population was 2,117,991, showing an increase of 19% in the decade, being the highest rate in the province. The northern parts of Tipperary are fully one-third as densely populated as the southern. Rice is the staple crop, followed by peas, varieties of betel-nut and betel leaves, and chillies are also grown. The chief exports are rice, jute and betel-nuts; and the principal imports cotton goods, salt, and kerosene oil.

The eastern border of the district is traversed by the Assam-Bengal railway, with branches from Laksham to Chandpur and Noakhali; but waterways remain the chief means of communication.

Tippera came under the East India Company in 1755; but more than a fifth of its present area was under the immediate ruler of the hill rajahs till 1748, when Tippera was divided into six subdivisions: it produces elephants. At that time Tippera with Noakhali formed part of Jalpur, one of Shuja-ud-Din's divisions of the province of Bengal; but in 1822 it was separated, and since then great changes have been made in its boundaries. With the exception of a serious raid in 1860 by the Kukis or Lushais, nothing has disturbed the peace of the district.

_TIPPERARY_, a county of Ireland in the province of Munster, bounded N.W. by Galway, N.E. by King's County, E. by Queen's County and Kilkenny, S. by Waterford, and W. by Cork, Limerick, Clare and Galway. The county is the second in size of the Irish counties, having an area of 1,062,963 acres, or about 1,661 sq. m. The surface is varied and picturesque. The Knockmealdown Mountains on the southern border reach an elevation of 2,500 ft. To the north of this range are the picturesque Galty or Galtee Mountains (Galtymore 3,015 ft.).

To the east, bordering Kilkenny, are the Slieveardagh Hills, and near Templemore the Devil's Bit Mountains (1,583 ft.) with a curious gap on the summit. In the north-west is Keeper Hill, 2,278 ft. The greater part of the county, however, is a gently undulating plain. From the rich level country the Rock of Cashel, the ancient earl's seat, is the most prominent feature on the horizon. The Suir, which has its source in the Devil's Bit Mountains, and flows southward and eastward by Templemore, Thurles, Caher, and Clonmel. The Nore, which also rises in the Devil's Bit Mountains, soon passes into Queen's County, and the Shannon forms part of the western border. The Mitchelstown stalactite caverns, discovered accidentally in 1833, attract a large number of visitors.

There are two round towers within the county—one at Roscrea and another near Cashel. The Rock of Cashel, on an outcrop of sandstone, is known as a centre of remains of several ecclesiastical foundations of the highest interest. Of these the following are described under the names of the respective towns: the remarkable collection of buildings and adjacent to the Rock of Cashel; the Cistercian abbey of Holy Cross near Thurles, one of the finest monastic ruins in Ireland; and the abbey and Franciscan friary at Roscrea. The stronghold of Caher, occupied as a barracks, is in good preservation. At Roscrea one of the towers of the castle built by King John remains, and the stronghold of the Ormondes, erected in the reign of Henry VIII., forms the dépot attached to the barracks. The other principal ecclesiastical remains are the priory of Athassel, founded for Augustinian monks about 1200; and Fethard Abbey, founded in the 12th century, now used as a chapel.

**TIPPERARY, a market town of Co. Tipperary, Ireland. Pop. (1901), 6281. It is beautifully situated near the base of the Slievenamon hill, a branch of the Galty**

_crops. The centre of the county is occupied by the Golden Vale, the most fertile district in Ireland, which stretches from Cashel to the town of Limerick. On the higher districts the soil is light and thin, ppartaking much of the character of the clay slate and sandstone on the extreme north-east. But the Bog of Allen encroaches on the north-eastern part of the county. The proportion of tillage to pasture is roughly as 1 to 24, and the area under the standard crops of oats and potatoes has decreased, but the proportion of wheat has been more than doubled. As an agricultural region, Tipperary is well maintained, as distillation causes a steady demand for this grain. Turnips are also an important and steady crop. The numbers of cattle, sheep, pigs, goats and poultry also increase generally; and potatoes, being occupied by the county, are much employed in mining, but the occupation of the inhabitants is chiefly agricultural. There is a considerable number of meal and flour mills._

Communications are supplied by the Great Southern & Western railway, the main line of which crosses the county from north-east to south-west by Templemore and Thurles. The Ballybrophy ( upt.o. El., Clonmel) railway, whose line is joined near the south of the county at Clonmel (junction for Birr) and Ennagh. The Waterford & Limerick line passes through the south of the county by way of Clonmel and Tipperary, crossing the main line at Limerick junction. The two lines are also connected by the Thurles, Fethard and Clonmel branch.

**Population and Administration.—The population (175,217 in 1801; 160,232 in 1901) shows a serious decrease (though much less so than formerly), and emigration is very heavy. Of the total about 94% are Roman Catholics, and about 76% constitute the rural population. The principal towns are Clonmel (the county town, pop. 10,167), Tipperary (6381), Carrick-on-Suir (5400), Ennagh (4704), Thurles (4411), Cashel (a cathedral city, 2938), Roscrea (2935), Caher (2058), Templemore (2934), and Cahir (1492). Tipperary is divided into two districts, north and south, each consisting of six baronies. For parliamentary purposes it is separated into four divisions—East, Mid, North and South—each returning one member. Before the Union in 1800 the county returned two members to the Irish parliament, and the boroughs of Cashel, Clonmel and Fethard each two; afterwards, until the Redistribution Act of 1885, the county returned two members and Cashel and Clonmel each one. Assizes for the north riding are held in Ennagh and for the south riding in Clonmel. Quarter-sessions are held at Cashel, Clonmel, Ennagh, Roscrea, Thurles and Tipperary. Ecclesiastically the county belongs to the Protestant dioceses of Cashel and Killaloe, and the Roman Catholic dioceses of Cashel, Killaloe, Waterford and Lismore._

**History and Antiquities.—Tipperary is one of the counties generally considered to have been formed by King John in 1210; in 1328 Edward III. made it a county palatine in favour of the earl of Ormond; and, though the king shortly afterwards resumed his regal prerogative, the county was regranted in 1337. In 1372 the grant was confirmed to James Butler, 1st earl of Ormond, the lands belonging to the Church remaining, a small area on the south border forming the county of Cross Tipperary, or the Cross of Tipperary. In 1621 James I. took the county palatine into his own hands. It was, however, restored in 1664 to James, 12th earl and 1st duke, whose regalities were further made to include the county of the Cross. On the attainder of James, 2nd duke, in 1715, the jurisdiction reverted to the Crown, and the last of the Irish palatines thus ceased to exist._

There are two round towers within the county—one at Roscrea and another near Cashel. The Rock of Cashel, on an outcrop of sandstone, is known as a centre of ecclesiastical remains of several ecclesiastical foundations of the highest interest. Of these the following are described under the names of the respective towns: the remarkable collection of buildings and adjacent to the Rock of Cashel; the Cistercian abbey of Holy Cross near Thurles, one of the finest monastic ruins in Ireland; and the abbey and Franciscan friary at Roscrea. The stronghold of Caher, occupied as a barracks, is in good preservation. At Roscrea one of the towers of the castle built by King John remains, and the stronghold of the Ormondes, erected in the reign of Henry VIII., forms the “depot” attached to the barracks. The other principal ecclesiastical remains are the priory of Athassel, founded for Augustinian monks about 1200; and Fethard Abbey, founded in the 12th century, now used as a chapel._

TIJJO SAHIB—TIRAH CAMPAIGN

1005

range, on the Waterford & Limerick line of the Great Southern & Western railway, 3 m. S.E. of Limerick Junction and 1104 S.W. of Cork. It is governed by an urban district council. It is situated in the centre of a fine agricultural district, and its butter market ranks next to that of Cork. Condensed milk is manufactured. The town is of great antiquity, but first acquired importance by the erection of a castle by King John, of which there are no remains. A monastery founded for Augustinians by Henry III. gave a second impulse to its growth. The gatehouse, all that remains of this foundation, is the only building of antiquity in the town. Formerly Tipperary was a corporation from a grant made in 1310 by Edward II. New Tipperary was founded outside the town by Mr William O'Brien in 1890 during the "Plan of Campaign" inaugurated to boycott the Smith-Barry estate, in order to accommodate the tenants who vacated their holdings, but the scheme was a failure, and the place was abandoned and sold. TIJJO SAHIB (1753—1799), sultan of Mysore, son of Hyder Ali (q.v.), was born in 1753. He was instructed in military tactics by French officers in the employment of his father. In 1767 in the invasion of the Carnatic he commanded a corps of cavalry, and he distinguished himself in the Mahrrat War of 1775—79. On the outbreak of the first Mysore War in 1780 he was put at the head of a large body of troops, and defeated Brathwaite on the banks of the Coleroon in February 1782. He succeeded his father in December 1782, and in 1784 concluded peace with the British, and assumed the title of sultan. In 1786 he had Van Noort and Nairn invaded and provoked British invasion by ravaging the territories of the raja of Travancore. When the British entered Mysore in 1790, he retaliated by a counter-invasion, but was compelled by Cornwallis' victory near Seripagapatam to cede half his dominions (March 16, 1792). The British having deemed it necessary to renew hostilities in March 1799, he was shut up in Seripagapatam and finally killed during the storm (May 4, 1799). Tippero was of cruel disposition, and inferior in military talents to his father.

TIJSTAFF (Mid. Eng. tipped staf), a staff of officer mounted with a tip or cap of metal, or with a crown, carried by a constable or sheriff's officer, the term being hence applied to such an officer. Tipstaffs are attached to the king's bench and chancery divisions of the High Court of Justice in England; their duty is to arrest or take into custody any person on an order of committal, if within the precincts of the court, and convey him to the king's prison at Holloway. The tipstaff for the common law courts was originally appointed by the marshal of the king's bench, and the constable of the lord-chancellor's library reported to the Fleet prison. Since the abolition of these prisons the tipstaffs have been appointed by the lord chancellor and lord chief justice respectively.

TIPTON, an urban district of Staffordshire, England, in the parliamentary borough of Wednesbury, adjacent to Dudley (1½ m. S.), served by the London & North Western and Great Western railways. Pop. (1901), 30,543. Its streets are interspersed with coal-mines and iron works. Heavy iron goods are the principal products, anchors and cables being a speciality; there are numerous furnaces and rolling mills; also cement works, brick-works and maltings. The village round which the modern town sprang up is mentioned in Domesday as Tibbington; its ancient church was undermined and collapsed in 1797.

TIROBOSCHI, GIROLAMO (1731—1794), the first historian of Italian literature, was born at Bergamo on the 18th of December 1731. He studied at the Jesuit college at Monza, entered the order, and was appointed in 1755 professor of eloquence in the university of Milan. Here he produced (1766—1768) Vetra humilitatirum monumentis (3 vols.), a history of the extinct order of the Humilitati, which made his literary reputation. Nominated in 1770 librarian to Francis III., duke of Modena, he turned to the acquiring of the materials there accumulated for the composition of his Storia della letteratura italiana. This vast work, in which Italian literature from the time of the Etruscans to the end of the 17th century is traced in detail, occupied eleven years, 1771—1782, and the thirteen quarto volumes embodying it appeared successively at Modena during that period. A second enlarged edition (16 vols.) was issued from 1808 to 1812, and a third in 1840. Of late years, abridgments in German, French and English. Tiroboschi died at Modena on the 3rd of June 1794, leaving a high reputation for virtue, learning and piety.

Tiroboschi wrote besides Biblioteca moderna (6 vols., 1781—1786); Notizie de' pittoa, scultori, incisori, ed architetti moderni (1786); Memorie storiche moderni (5 vols., 1793—1794), and many minor historical works, including a valuable edition of Petrarch (1799), and left materials for a work of great research entitled Dizionario topografico-storico degli stati estensi (2 vols. 4tos, Modena, 1824—1825).

TIRAH, a mountainous tract of country on the Peshawar border of the North-west Province of India. It lies between the Khyber Pass and the Khanki Valley, and is inhabited by the Afridi and Orakzai tribes. It is chiefly notable as the scene of the Khyber Campaign and the war waged by the British in the mountains, off all the roads to India, from the difficulty of its passes and the fierceness of its inhabitants had hitherto preserved it inviolable from all invaders. Tirah comprises an area of some six to seven hundred square miles and includes under this general name all the valleys lying round the source of the Bara river. The five valleys are Maldan, Raigul, Waran, Bara and Mastura.

Maidan, the summer home of the Afridis, lies close under the snow-bound ridges of the Safed Koh at an elevation of about 6400 ft. It is oval plain about seven miles in length, and three miles wide, and slopes inwards towards the centre of its northern side, where all the drainage gathered from the four corners of the plain is shot into a narrow corkscrew outlet leading to the Bara Valley. The flat summit is studded with small tented encampments, and rich alluvial soil and made it one of the most fertile valleys on the frontier. All its alluvial slopes are terraced and revetted and irrigated till every yard is made productive. Here and there ditches in clusters all over the plain are square-built two-storied mud and timber houses, standing in the shade of gigantic walnut and mulberry trees. Up on the hillsides surrounding the Maldan basin are wild olives in wide-grown clumps, almost amounting to forest, and occasional pomegranates. Higher still are the blue pines; but below on the shelving plains are nothing but fruit trees. Raigul Valley lies north of Maidan, from which it is separated by a steep range of cold-well wooded mountains, and separated from the west of the Bara Valley, which it joins at Dwatoi. It is ten miles long, four to five miles at its widest, and has an elevation of 5000 ft. It is inhabited by the Afridis, and is known to be another valley about the same size as Maidan, lying east of it, and separated from it by the Tseri-Kandao Pass. It was the home of the Afridi mullah Sayad Akbar, and is the country of the Aka Khels. The Raigul collection is in the hands of Mr. A. F. North. Drainage at Dwatoi, the united stream receives the name of Baran, and the valley through which it flows down to its exit in the Peshawar Valley is also known by this name. The elevation of the valley is from 5000 ft. at Dwatoi to 2000 at Kajuri; on the north side it is hemmed in by the Surghar range, which divides it from the Bazar Valley; on the south lies another range dividing it from Maidan and the Waran Valley. The heat of the Bara Valley in summer is said to be excessive, malaria prevalent, and mosquitoes very troublesome, so the hamlets are deserted and the Afridis migrate to the pleasant heights of Maidan. The Mastura Valley occupies the southern half of Tirah, and is inhabited by the Orakzai and the Afridi. It is the southern valley on the frontier, lying at an elevation of 6000 ft. The Orakzais live, for the most part, in the Miranzai Valley, in the winter, and retreat to Mastura, like the Afridis, during the summer months. The chief passes in this valley are the Tseri-Kandao Pass (5695 ft.), separating Maldan Valley from Maidan; Saran Sar (8650 ft.), leading from the Zacka Khel portion of Maidan into the Bara valley; the Tseri-Kandao Pass (6565 ft.), separating Maidan from the Waran Valley, and the Sapi Pass (5150 ft.), leading from the east of the Mastura Valley into the Bara Valley in the direction of Maldan. The whole region is thoroughly explored and mapped at the time of the Tirah Expedition.

TIRAH CAMPAIGN, an Indian frontier war in 1897—98. The Afrids had for sixteen years received a subsidy from the Indian government for the safeguarding of the Khyber Pass, in addition to which the government had maintained a detachment.
purpose a local regiment entirely composed of Afridis, who were stationed in the pass. Suddenly, however, the tribesmen rose, captured all the posts in the Khyber held by their own countrymen, and attacked the forts on the Samana Ridge near Peshawar. It was estimated that the Afridis and Orakzaiz could, if united, bring from 40,000 to 50,000 men into the field. The preparations for the expedition occupied some time, and meanwhile the Mohmand rising north-west of the Khyber Pass was first dealt with (see Mohmand).

The general commanding was General Sir William Lockhart (g.v.) commanding the Punjab Army Corps; he had under him 34,582 men, British and native, in addition to 20,000 followers. The frontier post of Kohat was selected as the base of the campaign, and on 1st October the expedition was headquartered there. The traversing of the 18th of October the operations commenced, fighting ensuing immediately. The Dargai heights, which commanded the line of advance, were captured without difficulty, but abandoned owing to the want of water. On the 20th the same positions were gallantly stormed, with a loss of 190 killed and wounded. The progress of the expedition, along a wretched track through the mountains, was obstinately contested on the 20th of October at the Samgapeh Pass leading to the Mastara valley, and on the 31st at the Aryanah Pass from the Mastara to the Tirah valley. The force, consisting of a dozen brigades, now proceeded to traverse the Tirah district in all its length and breadth, and fortified hamlets of the Afridis. The two divisions available for this duty numbered about 20,000 men. A force about 3200 strong commanded by Brigadier-General (afterwards Major-General Sir Richard) Westmacott was first employed to attack Saran Sar, which was easily carried, but during the retirement the troops were hard pressed by the enemy and the casualties numbered sixty-four. On the 11th of November Saran Sar was again attacked by the brigade of Brigadier-General (afterwards Sir Alfred) Gaselee. Experience enabled better dispositions to be made, and the casualties were only three. The traversing of the valley continued, and on the 13th of November Brigadier-General Kempster's brigade visited the Waran valley via the Tseri Kandao Pass. Little difficulty was experienced during the advance, and several villages were destroyed; but on the 16th, during the return march, the rearguard was hotly engaged all day, and had to be relieved by fresh troops next morning. The casualties numbered seventy-two. Almost daily the Afridis, too wise to risk general engagements, waged a perpetual guerrilla warfare, and the various bodies of troops engaged in foraging or survey duties were constantly attacked. On the 21st of November a brigade under Brigadier-General Westmacott was detached to visit the Rajgil valley. The road was exceedingly difficult and steady opposition was encountered. The objects were accomplished, and the casualties during the retirement alone numbered twenty-three. The last important work undertaken was the punishment of the Chamkanis, Mamuzais and Massozais. This was carried out by Brigadier-General Gaselee, who joined hands with the Kurram movable column ordered up for the purpose. The Mamuzais and Massozais submitted immediately, but the Chamkanis offered resistance on the 1st and 2nd of December, the British casualties numbering about thirty. The 1st division under Brigadier-General Yeatman Biggs (d. 1898), and accompanied by Sir W. Lockhart, to move along the Bara valley. The base was thus to be transferred from Kohat to Peshawar. The return march began on the 9th of December. The cold was intense, 21 degrees of frost being registered before leaving Tirah. The movement of the 1st division though arduous was practically unsupported, but the 40 miles to be covered by the 2nd division was contested almost throughout. The actual march down the Bara valley (34 miles) commenced on the 10th, and involved four days of the hardest fighting and marching of the campaign. The road crossed and recrossed the icy stream, while snow, sleet and rain fell constantly. On the 10th the casualties numbered about twenty. On the 11th some fifty or sixty casualties were recorded among the troops, but many followers were killed or died of exposure, and quantities of stores were lost. On the 12th the column halted for rest. On the 13th the march was resumed in improved weather, though the cold was still severe. The rearguard was heavily engaged, and the casualties numbered about sixty. On the 14th, after further fighting, a junction with the Peshawar column was effected. The 1st division, asked by the Peshawar column, now took possession of the Khyber forts without opposition. Negotiations for peace were then begun with the Afridis, who under the threat of another campaign in favour of the Afridis, who under the threat of another campaign in favour of the Afridis, who under the threat of another campaign in favour of the Afridis, who under the threat of another campaign in favour of the Afridis, who under the threat of another campaign, was immediately opened.

TIRANA, a town of Albania, European Turkey, in the vilayet of Scutari; 20 m. E. by N. of Durazzo, at the southern extremity of the plain of Kroa. Pop. (1903) about 12,000. Tirana is beautifully situated on the border of the richly wooded highlands inhabited by the Albanians. It is a picturesque town with a large bazaar and many mosques, gardens and olive groves. It was founded early in the 17th century and was long the see of a Greek bishop, although the majority of its inhabitants have always been Moslems. Kroa, the ancient stronghold of Scanderbeg (g.v.), is 14 m. north.

TIRARD, PIERRE EMMANUEL (1827-1893), French politician, was born of French parents at Geneva on the 27th of September 1827, and, after studying in his native town, became a civil engineer. After five years of government service he resigned to become a jeweler merchant. His determined opposition to the empire, and his conviction in 1870 that the candidate opposed to Ollivier, was rewarded by his election as mayor of the 11th arrondissement of Paris and as deputy for the Seine. Nominated a member of the Commune, he protested against the tyranny of the central committee, and escaped from Paris to resume his place among the extreme Left in the National Assembly at Versailles. In 1876 he was returned for the 1st arrondissement of Paris to the Chamber of Deputies, and was re-elected next year. He specially devoted himself to finance, being for a short time president of the customs commission before the Albanians. It is a picturesque town with a large bazaar and many mosques, gardens and olive groves.

TIRE, an homonymous word, of which the meanings are (1) to wear away, (2) to adorn, or, as a substantive, a head-dress, (3) the quotient of a division. "Tire" in sense (1) is from the Old English teorian, to weary, transitory and intransitive. Ultimately this word is connected with "tear," to rend, the stages of meaning being to rend apart, to wear out, to be made exhausted.
In sense (2) the word is a shortened form of "attire," dress, equipment; this is from the Old French attier, to put in order, to dress, from a root that is now scarcely recognizable. Its meaning has been etymologically altered. It may be connected with "attire," especially with reference to a similarity to the band of a woman's head-dress, or it may be a corruption of "tie," "tie" meaning that which "ties" or fastens together, though this is rejected by Skeat. The spelling "tyre" is not now accepted by the best English authorities, and is unrecognized in America.

The tire of a wheel is the outer circumferential portion that rolls on the ground or the track prepared for it. When the track is smooth and level, as in a railway, the principal functions of the tire are to provide a hard, durable surface for the wheel, and to reduce to a minimum the resistance to rolling. Railway vehicle wheels usually have hard steel tires, this combination with the hard steel rail giving the maximum endurance and the minimum rolling resistance. For road vehicles also, in which durability is the prime consideration, the tires are usually rings of iron or steel or shrunk on the wooden wheels.

In bicycles, motor-cars, and other road vehicles in which freedom from vibration and shock from uneven road surface is desired, rubber or pneumatic tires are employed. These elastic tires are capable of absorbing small irregularities in the road surface without transmitting much vibration to the frame of the vehicle. Their range of yield is, however, too limited to absorb the larger irregularities met with on rough roads, so that their use does not obviate the necessity of spring support of the carriage body on the wheel axes. The pneumatic tire has a very much smaller rolling resistance than a solid rubber tire. Where the driving power is limited, as in bicycles, this consideration is by far the most important. A pneumatic tired bicycle requires less power to drive it at a given speed than does one with solid rubber tires—in popular language, it is much faster; hence pneumatic tires are now almost universally used on bicycles.

Rolling Resistance.—Professor Osborne Reynolds, in his investigations on the nature of rolling resistance, found that it is due to actual sliding of the surfaces in contact. Fig. 1 shows an iron roller resting on a flat, thick sheet of India-rubber. A series of equidistant parallel lines drawn on the India-rubber are distorted by the pressure, as shown in the figure. The distance between the marks on the periphery of the roller corresponds to that between the lines on the undisturbed sheet of rubber. The motion of the roller being from left to right, actual contact takes place between C and D. The surface of the rubber is depressed at P, is bulged up in front at D, and behind at C. The vertical compression of the rubber at P causes it to bulge laterally, this causing a lateral contraction of the sheet which in turn changes the area of contact. Of course, the frictional force is proportional to the area of contact. From this picture, the reader will readily see that the contact area is responsible for the sliding resistance of the roller and the associated work of deformation of the rubber.

FIG. 1.

The area of contact varies as the normal pressure and is inversely proportional to the coefficient of friction. The area is not constant, but varies with the load, the radius, and the length of the roller, so that although the coefficient of friction is a constant, the area of contact is not constant. This is a fundamental property of the area of contact, and it is the basis of the study of the area of contact.
TIRE

Outer Cover.—The outer cover has to be strong enough to withstand the air-pressure inside the tire and to transmit the driving or the braking effort from the wheel to the road surface. For the latter purpose, the threads of the fabric (the best disposed spirally, as shown in fig. 6) while driving in the direction of the arrow the tension on the fibres cc will be slightly increased, that on fibres dd decreased. The distortion of space to driving is thus reduced to a minimum. A woven fabric is sometimes used, but one made up of two or more layers of parallel threads embedded in rubber is better. This construction makes the outer cover more flexible, and consequently less energy is wasted in the distortion of the tire, when the tire rolls on and off the ground, while greater durability is also secured. Fig. 7 shows a plain woven fabric, from which it is seen that each thread takes the form of a sinus line. As the air-pressure inside the tire is increased the threads tend to become straighter and to press together with a cutting action. The total tension on a layer is greater than that of two layers of parallel threads, while on the latter the threads can be faced closer together. The woven fabric is therefore stiffer, weaker and less durable than that built up of parallel layers. The average tensile stress per inch width on the longitudinal section of the cover is given by the formula $pd = 4d$; that on the transverse section, $b$ by $pd = 4b$, $d$ being the diameter of an air-tight. In most tires for cycles and motor-cars an inner tube of india-rubber, made separate from the outer cover. In these double tubes the outer cover is more or less easily detachable from the rim.

The air-pressure is partly confined inside the inner cover. In accordance with the spiral disposition of the threads, as shown in fig. 6, this inequality of stress in the two principal directions is due to the transverse size of the tire, while at the same time tending to contract the tire on the rim.

Single tube, Double tube and Tubular Tires.—A tire, beside being strong enough to resist the stresses to which it is subjected under air-tight. In most tires for cycles and motor-cars an inner tube of india-rubber, made separate from the outer cover. In these double tubes the outer cover is more or less easily detachable from the rim. The air-pressure is partly confined inside the inner cover. In accordance with the spiral disposition of the threads, as shown in fig. 6, this inequality of stress in the two principal directions is due to the transverse size of the tire, while at the same time tending to contract the tire on the rim.

Attachment of Tires to Rims.—A tire can be cemented directly to the rim. For detachable double-tube tires on bicycles, two methods, the Dunlop-Welch endless wire (fig. 9), and the "beaded edge" (fig. 11), are employed for the attachment of the inner cover. In the Dunlop-Welch tire the endless wires are embedded in the two edges of the outer cover respectively, the transverse tension of the fabric being transmitted to them. Each endless wire is formed of three coils, so as to give flexibility to the edge of the cover. Each embedded endless wire is smaller in diameter than the edge of the rim. The middle portion of the rim is deepened, its diameter being less than that of the ring of endless wire. To detach the tire after deflation, one part of the cover is bent over, and the tire is forced on the rim by means of a pulling tool. For a slow speed vehicle an ordinary steel tire, shrunken or hydraulically pressed on a wooden wheel, is cheap and durable. At higher speeds over uneven roads the rubber is less satisfactory; the wheel, forming with the tire one rigid body, receives violent accelerations vertically as well as laterally, and tends to fly apart, and the tire is thenceforth useless for any further use. For passenger cars an elastic tire is a necessity. The solid rubber tire, not being able to puncture, is trustworthy if made of sufficient sectional area, but it is expensive and lacks the comfort and easy running of the pneumatic. The motor car pneumatic tire is made up of three layers of canvas. The Palmer cord tire is built up of two layers of cord (fig. 12) arranged spirally, each cord being composed of four strands of six threads. The cords are flattened between $T$ and $Q$. Then for each inch length of tire $T = pd/3$, $Q = T\cos \theta$; while $P = OQ/2$. Combining these results we get

$P = pdD/3 \cos \theta$. If $\theta = 90^\circ$, $P = 0.29pdD$,

which is a formula for the section of wire for any size can be calculated.

The "beaded edge" forming, thickened edges on the outer cover take into corresponding edges formed on the rim, and are securely held therein when the tire is inflated.

Prevention of Punctures.—The outside of the tire is covered with a thick layer of rubber, which protects the fabric from injury by contact with the rough road surfaces. In full roadster tires this outer layer of rubber is thinner at the sides than at the tread (the part which actually rolls on the ground), but still completely covers the fabric. In light roadster and racing tires the sides are not covered, and an appreciable gain in speed or ease of driving is due to the greater flexibility of the cover thus obtained. Numerous puncture proof banca and other devices have been tried with the object of absolutely preventing punctures, or making the tire self-sealing after puncture; but they increase the rolling resistance, and therefore the effort necessary to drive the bicycle at a given speed.

All Value for Pneumatic Tire.—A non-return valve is permanently attached to the inner tube of the tire, which allows the air forced from the inflater to pass inside the inner cover. The most commonly used, the Dunlop-Woods valve, consists of a short piece of rubber tubing mounted on a brass stem, which has a small hole communicating from its outer end to the inner surface of the rubber tube. Normally, the tubing closes the mouth of this hole, preventing the escape of air from the tire, but lifts freely when air is being forced from the inflater. The arrangement of the parts for deflating and for getting access to the rubber tubing is very simple and effective. The cyclist should be careful that the small piece of valve tubing, and the two flaps covering the ends of the flexible connector which serve to make air-tight the two joints between the latter and the pump and valve stem respectively, are always in good condition. If either of these seemingly small details is out of order it may be impossible to pump the tire hard enough; the bicycle being ridden, the tires may be nipped in many places between the rim and sharp edges on the road surface, and practically ruined.

Tires for Motor Cars.—In the cost of upkeep of a motor car the tires are the most expensive item. For a slow speed vehicle an ordinary steel tire, shrunken or hydraulically pressed on a wooden wheel, is cheap and durable. At higher speeds over uneven roads the rubber is less satisfactory; the wheel, forming with the tire one rigid body, receives violent accelerations vertically as well as laterally, and the tire is thenceforth useless for any further use. For passenger cars an elastic tire is a necessity. The solid rubber tire, not being able to puncture, is trustworthy if made of sufficient sectional area, but it is expensive and lacks the comfort and easy running of the pneumatic. The motor car pneumatic tire is made up of three layers of canvas. The Palmer cord tire is built up of two layers of cord (fig. 12) arranged spirally, each cord being composed of four strands of six threads. The cords are flattened
somewhat, their narrow surfaces being together at the tread of the tire, and their wide ones at the beaded edge. The anchorage of the cord to the beaded edge is obtained by steel pins passing through the fabric of the cord and into the canvas beads (fig. 13). The cords, tread and beads being all vulcanized together, the tire is practically impervious to moisture, and therefore less tendency to rot than a canvas tire. Further, the threads, by the process of manufacture, are insulated each from the other by a layer of rubber, and there is thus less tendency for them to fray or saw each other as the tire yields during contact.

These features of construction tend to greater durability.

**Pneumatic Tires for Heavy Loads.**—As each portion of the tread comes in contact with the ground it is flattened, while the rest of the transverse section has its radius of curvature slightly decreased (fig. 3). Thus the transverse section is repeatedly undergoing curvature through a range extending from flatness (radius of curvature infinity) to a radius of curvature slightly less than that of the normal section. On the longitudinal section the range of flexure is from flat to a radius of curvature equal to that of the normal section. The latter range is therefore much less than the former. The necessary thickness of the fabric and rubber to resist the air pressure and punctures involves a certain amount of stiffness; consequently the energy expended in the flexure of the tire is much greater than in a thin cycle tire. This energy appears as heat; the temperature of the cover rises until the heat carried away by the air is equal to that generated by flexure. At very high speeds this heating becomes so great as to have the injurious action on the rubber and fabric. Unfortunately, the solid rubber tire is worse off in this respect, its elastic hysteresis, and therefore the heating effect, being greater than that of a pneumatic tire. It is evident that increase of the diameter of the tire-section lessens the heating action, while reduction of diameter of the wheel has no effect, so long as the range of longitudinal flexure is less than the transverse. Nearly all tire fabrics are equally stiff longitudinally and transversely; but probably greater durability would be obtained from a fabric more flexible transversely, even if somewhat stiffer longitudinally.

**Non-Skid Devices.**—As a pneumatic tire flattens where it is in contact with the road, under certain conditions of road surface a semi-liquid film of mud gets interposed, and the frictional contact is reduced to a minimum. The vehicle has then no lateral constraint, and side-slipping or skidding may occur. On a bicycle this means a dismount, probably a severe fall; on a three or four-wheeled vehicle the steering control is temporarily lost. Cycle tires are usually provided with longitudinal ridges at the tread (figs. 8, 9, 11); the narrow surfaces of the ridges penetrate the mud and get a better grip on the solid road surface. Motor car tires are sometimes left with a smooth tread (fig. 14); fig. 13 shows a non-slippering tread with longitudinal ridges. The Dunlop non-slippering tread is formed by a series of lateral grooves about 2 in. apart all round the tire. Fig. 16 shows a tire fitted with a non-skid leather band, to which hard steel studs are fastened.

This type of non-skid band can be either vulcanized to the tire or independently fastened to the rim at the beaded edges. The Parnone "non-skid" device consists of a chain crossing the tire at right angles and fitting loosely over its surface; they are fastened at intervals to two chain rings one on each side of the wheel, and can be easily adapted to any tire.

**TIREH (anc. Tetra),** a town of Asia Minor, situated in the valley of the Kichik Menders (Casystrus) at the foot of Mt Messogis. It was the capital of the amirate of Aidin in the 14th century, and is described by Ibn Batuta as a fine city with streams and gardens. Pop. over 14,000, the latter half Moslems. It is connected with Smyrna by a branch of the Aidin railway, and has trade in raisins, wheat, rice, tobacco and cotton.

**TIRGOVISHTEA** (Rumanian Targoviste, or Târgovişte, sometimes incorrectly written Targoviste or Targoist), the capital of the department of Dimbovita, Rumania; situated at the foot of the Carpathians, on the right bank of the river Jalomiita, 48 m. N.N.W. of Bucharest. Pop. (1900), 3568. A branch line connects Targoviste with the main Walachian system, and is prolonged northwards into the hills, where there are rich deposits of petroleum, salt and lignite. Coal is also found but not worked. Apart from the splendid ruins of a 14th-century palace, the most interesting building in the town is the Metropolitan church, still one of the finest in the country, with its nine towers and monuments of the princely house of Cantacuzino. It was founded in 1515 by Neagoe Basarab, builder of the famous cathedral of Curtea de Argesh. Targoviste is a garrison town, with a cavalry training school and an artillery depot and repairing arsenal.
Under Mircea the Old (1383–1410) Targoviste was the third capital of Walachia. In the 15th century it was sacked by the Szeklers. Michael the Brave defeated the Turks under its walls in 1597. In the 16th century it had a population of 60,000 and contained 70 churches and 40 convents. After Constantine Brancovan moved the seat of government to Bucharest in 1608, Targoviste lost its importance and the population decreased.

TIRGU JIU (often incorrectly written TIRGJIU), the capital of the department of Gorj, Rumania; situated among the lower slopes of the Carpathians, on the left bank of the river Jiu, and at the terminus of a branch railway which joins the main Rumanian line between Turnu Severin and Craiova. Pop. (1900), 6,634. The town has a small trade in timber, petroleum and farm produce. Anthracite coal is found in the neighbourhood.

TIRGU OCNA (Rumanian also Targul Ocna), a town of Rumania, on the left bank of the river Trotosh, an affluent of the Sereth, and on a branch railway which crosses the Ghimesh Pass into Transylvania. Pop. (1900), 8,503. Tirgu Ocna is built among the Carpathian Mountains, on bare hills formed of rock salt. Outside the town stands the largest prison in Rumania, and in this are the mines, worked, since 1876, by convicts, who receive a small wage. The thickness of the salt is unknown; the mines yield about 11,000 tons annually.

TIRHUT, or TIRHOUT, the historic name of a tract in northern India, being that portion of Behar which lies north of the Ganges. It corresponds roughly with the ancient Hindu kingdom of Mitila (q.v.). Down to 1873 it formed a single district, which was then divided into the two districts of Darbhanga and Muzaffarpur. In 1908, when, the division of Patna was abandoned, the name of Tirhut was again officially given to a new division, containing the four districts of Darbhanga, Muzaffarpur, Saran and Champaran: total area, 12,588 sq. m.; total pop. (1901), 9,867,373. It is a continuous alluvial plain, traversed by many winding rivers, and it supports the densest population in all India. It is the main centre of the indigo industry, conducted by European planters, which is now in a declining condition. Other crops are rice, millets, wheat, maize, oilseeds, sugar-cane and tobacco. Apart from indigo there are no large industries. Since the famine of 1874 the whole country has been saved from its former isolation by the construction of the Bengal & North-Western railway, with numerous branches; but the Ganges is nowhere bridged.

TIRIDATES, or TIRIDATOS, a Persian name, given by Arrian in his Parthica (preserved by Photius, cod. 58, and Syncellus, p. 539 seq.) to the brother of Arsaces I., the founder of the Parthian kingdom, whom he is said to have succeeded. But Arrian’s account seems to be quite unhistorical (cf. PARTHIA).

The king commonly called Tiridates II. was set up by the Parthians against Phraates IV. in 32 B.C., but expelled when Phraates returned with the help of the Scythians (Dio Cass. li. 18; Justin xiii. 5 seq.; cf. Horace, Od. i. 26). Tiridates fled to Syria, where Augustus allowed him to stay, but refused to support him. During the next years Tiridates invaded Parthia again; some coins dated from March and May, 26 B.C., with the name of a king "Arsaces Philoromaios," belong to him; on the reverse they show the king seated on the throne, with Tyche stretching out a palm branch towards him. He was expelled again, and brought a son of Phraates into Spain to Augustus. Augustus gave the boy back to his father, but declined to surrender "the fugitive slave Tiridates" (Justin xiii. 5; Dio liii. 33; cf. Mom. Ancyr. 5, 54; in li. 18 Dio has wrongly placed the death of the son, 20 B.C).

Tiridates III., grandson of Phraates IV., lived as a hostage in Rome and was educated there. When the Parthians rebelled against Artabanus II. in a.d. 35 they applied for a king to Tiberius, who sent Tiridates. With the assistance of L. Vitellius Tiridates entered Seleucia, but could not maintain himself long (Tacitus, Ann. vi. 32 sqq.; Dio Cass. lixiv. 26).

The name Tiridates is also borne by some local kings of Persis, and by some Arsacid kings of Armenia and Georgia. The best known of the Armenian kings is the Tiridates (a.d. 238–314) who was baptized by Gregory the Illuminator (see ARMENIAN CHURCH).

TIRLEMONT (Flemish Thiienen), a town of Belgium in the province of Brabant, 11 m. S.E. of Louvain. Pop. (1904), 15,340. It still preserves its enceinte, 6 m. in circumference. The principal church, Notre Dame du Lac, begun in the 12th and enlarged in the 15th centuries, is still unfinished. The church of St Germain also dates from the 12th century, and contains a fine altar-piece by Wappers. John Boltand, the Jesuit who began the collection of the Acta sanctorum, was born here in 1596. The principal industries are brewing, soap manufacture and tanning.

TIRMIDHĪ [Abā Ṣāḥib Mohammed ibn Ṣāh ut-Tirmidhī] (d. 852), Arabian traditionalist, was born at Tirmidh in the Jihān. He was a scholar of the traditionalist Bukhārī, and in his search for traditions travelled through Khurasan, Irak and Hejaz. His al-Jāmi’ us-Saḥḥāḥ is one of the six canonical collections of traditions. In it he admitted every tradition that had ever been used to support a legal decision, indicating the doctrine it supported and mentioning the doctrines opposed to it. It was published at Bulaq in 1875. He also wrote the Kishād us-Samā‘, a study of the character and life of Mahommed (see Mahommed, N. 951, Calcutta, 1846). (G. W. T.)

TIROL (or Tyrol), the most southerly province of the Austrian Empire. It makes a great bend southwards towards Italy, by which it is bounded on the S.E., S. and S.W., while on the W. it adjoins part of present Switzerland (till 1652 the Lower Engadine was Tyrolean, and not Swiss) and also the Austrian province of Vorarlberg; to the N. it borders on Bavaria and to the E. the province of Upper Austria. It is traversed from west to east by the main chain of the Alps, which rises in many snow-covered summits; the most important being the Ortler (12,802 ft., the loftiest peak in Tirol and in the Eastern Alps generally), the Wildspitze (12,882 ft., Oetzthual group), the Zuckerhütt (11,550 ft., Stubai group), the Hochfeiler (11,550 ft., Zillerthual group), the Gross Venediger (12,000 ft.) and the Gross Glockner (12,461 ft., both in the Tauern range), while more to the south are the Dolomites, which culminate in the Marmolata (10,972 ft.). It is divided into two very distinct portions by the Brenner Pass (4495 ft.), connecting the Stubai and the Zillerthual groups; over this pass a splendid railway was built in 1864–1867 from Innsbruck to Tarvis on the Drave (east). The river is navigable from the earliest times been of immense importance from every point of view. The Brenner, too, being on the main watershed of the Alps, separates the two main river systems of which Tirol is composed. To the north this province comprises the middle portion of the Inn Valley, with its tributaries, as well as the upper portion of the Lech valley, all flowing towards the Danube and so to the Black Sea, while south of the pass is the great upper valley of the Adige or Etsch, with many tributaries, as well as since 1500 a portion of the upper Drave valley, which physically belongs to Carinthia—all these (save the Drave) flow to the Adriatic Sea. The area of Tyrol is 10,204 sq. m. In 1900 its population was 859,712 (but wholly Romanist), of whom more than half were German-speaking, and many in the south Italian-speaking, while in certain side valleys of the Adige system the quaint old Ladin dialect, still surviving also in the Swiss Engadine, is the prevailing tongue; in the southern half of the region there are a few German-speaking among the Italian-speaking folk. The capital is Innsbruck, while other important towns are Trent, Botzen and Rovereto.

The present very irregular shape of the district is due to historical causes. The eastern part represented part of the middle Inn valley and of the uppermost portion (the Vintschagau) of the Adige valley. In 1350, by inheritance from the counts of Götz, the Pusterthal and upper Drave valley (east) were added; in 1503 the lower portion of the Zillerthual, with the Inn (1) To speak, as is commonly done, of the "Tyrol" is as absurd as speaking of the "England." As regards the English spelling of the name adopted throughout the Ency. Brit., it should, however, be stated that the writer of this article regards "Tyrol" as more correct.—(Ed.)
TIROL

Valley from its entrance to Kufstein, and the Kitzbühel region (north-east) were all won from Bavaria; in 1517 Rovereto and several other places on the present south-eastern frontier were acquired from Venice; in 1803 many fiefs in the bishoprics of Trent and Trieste were lost to the French, here again, as in the case of the bishoprics; while finally the rest of the Zillerthal, with Windisch Matrei, was obtained in 1816 from the archbishopric of Salzburg. Besides the great railway line over the Brenner, there are other lines from Botzen past Meran to Mals, from Franzensfeste up the Pustertal to Lienz in the Drave valley, and from Innsbruck, by a tunnel beneath the Arlberg Pass to the Vorarlberg and the Rhine valley.

The majority of the population is devoted to pastoral, and in some cases to alpine, pursuits as a whole, as in the same lands, being the mainstay of the peasants. In summer they are driven up to the mountain pastures (called here Almen, but Alpen in Switzerland), which are, however, less carefully looked after than in Switzerland, partly because in many cases they have been alienated by the neighbouring hamlets to far distant places. Forestry also employs a certain proportion of the population, but the felling of trees is carried on wastefully, though less so than in former times. A few minerals are found in the district, but in this department the saltworks of Hall, near Innsbruck, take the first place. In southern Tirol, silk-spinning is still one of the principal industries, which is accompanied by the production of wine and tobacco. There are also some factories of preserved fruits and tobacco. But, save in the towns, Tirol is above all a pastoral land.

The peasants are famous for their devotion to the Roman Catholic religion, devotedness to their pastor, their duchy, their excellent marksmanship, and their love of singing and music, the zither being the national instrument. There is a university at Innsbruck, but primarily, and usually, to the ordinary peasant, knowledge not attainable at a high degree of excellence, as in summer the schools are closed, for all hands are then required in the fields or on the mountain pastures. The picturesque local costumes have nearly altogether disappeared, save in the Passeierthal, near Meran, while the increasing crowds of summer visitors have largely spoilt the simplicity of the natives. Ecclesiastically, Tirol is ruled by the archbishop of Salzburg and his two suffragans, the bishops of Trent and of Brixen. The country is divided into 21 administrative districts (Bezirke), each composed of a number of communes or civil parishes. Tirol sends 25 representatives to the Austrian parliament at Vienna. Locally it is ruled by an Imperial governor (the Statthalter) who resides at Innsbruck, where, too, meets annually the local legislature or Diet (the Landtag), composed (according to the constitution of 1861) of 68 members; the archbishop of Salzburg, the bishops of Trent and Brixen, and the rector of the university of Innsbruck sit in person, while the great ecclesiastical corporations send four deputies, the chambers of commerce of Innsbruck, Trent and Rovereto each one, the nobles ten, the towns 13, and the peasants 34.

History.—By far the greater portion of the region later called Tirol was inhabited, when it makes its appearance in history, by the Raetians (perhaps the Bagaudae, who were conquered by the Etruscans), who were conquered (14 B.C.) by Drusus and Tiberius, and were later organized into the Roman province of Raetia. In the 5th and following centuries the north portion was Teutonized, first by the Ostrogoths, mainly by the Baiouarii, but the Teutonic Langobardi who pressed up from the south became Romanized themselves, so that the double character of the inhabitants of the land appears quite early. In 774 the Carolingians conquered the Langobardi or Lombards, and in 788 the Baiouarii. But the officials charged with the rule of these parts gradually became Austrianized, and in 1667 Austria took over the region north of Trent. Some time after the break-up of that duchy in 976, the emperor Conrad II entrusted all temporal powers in the northern region to the bishop of Brixen, and in the southern portion to the bishop of Trent, detaching these southern districts from Italy (to which they had always belonged, save from 951 to 962, when the march of Verona was annexed to the duchy of Carninthia) and incorporating them with Germany. The bishops, in their turn, had to exercise their temporal rights through lay vassals, of whom the most powerful in the 12th century were the lords of Andechs, near Munich. On the extinction of this family in 1248, most of their fiefs were given by the two bishops to the father-in-law of the last lord of Andechs, Albert, count of Tirol. This new family took its name from the still existing castle of Tirol (later Roman, Teriolis), above Meran, in the upper Adige valley, and is mentioned for the first time in 1140. Albert's elder daughter, Adelaide, married Meinhard, count of Götz (north of Trieste); their elder son Meinhard (d. 1205) took Tirol, and the younger Götz; but in 1500 the latter's line became extinct, and the elder line thereby gained the possession of the duchy of Tyrol. Long before that time the senior branch of the elder line had ended in Margaret, nicknamed die Maultasche (the Pocket-mouth), who, in 1342, married Louis of Brandenburg (d. 1361), and whose only child Meinhard died in her lifetime in 1363; Tirol accordingly passed by agreement in the latter year of the junior branch of the elder line, the Habsburgs, dukes of Austria since 1282. In this way Tirol came to the dynasty which has ever since held it (save 1805–1814). From that time onwards till 1665 Tirol was generally entrusted to a cadet of the Austrian house, who ruled first at Meran, and then from 1674 to 1705 at Innsbruck, as a nearly independent principality, but since 1665 the province has been governed from Vienna. We have noted above the manner in which the limits of Tirol were gradually extended. Several of these additions were due to the archduke Maximilian, who ruled Tirol from 1490 onwards, becoming emperor in 1493 and dying in 1519. His memory is still cherished in the district, for he conferred on it the title of Gefürthte Grafenschaft, spent much time in it, and erected in the chief church of Innsbruck a sumptuous monument as his tomb.

As Tirol stands to its position astride of the Alps, and so commanding the road across them, Tirol has often been the scene of sharp fighting. In 1499 the Swiss won a victory in the Calven gorge (near the head of the Adige valley) against Maximilian, which resulted in the Swiss gaining their practical independence of the empire. In 1703 the Bavarians and French, during the War of the Spanish Succession, took Innsbruck, but were then driven back. In 1805, by the peace of Pressburg, Napoleon forced Austria to hand over Tirol to his ally, Bavaria, which held it till 1814. On the outbreak of war (1809) between France and Bavaria, the people, still adhering to the old faith, refused to acknowledge Hofer (b. 1757), a small innkeeper of the Passerental, and under him the peasants repeatedly defeated the Bavarian, French and Saxon troops. Three times (April 13, May 29 and Aug. 13) did they drive the foe out of Innsbruck. On the 15th of August, Hofer, yielding to the popular wish, assumed the government of Tirol. But in October the ill-success of the Austrians against the French elsewhere forced them to conclude the peace of Vienna, by which Tirol was definitely secured to Bavaria. The peasants refused to believe in the bad news, and continued to resist the French, but without success, though their leader was Andreas Hofer (b. 1757), a small innkeeper of the Passerental, and under him the peasants repeatedly defeated the Bavarian, French and Saxon troops. Here he was betrayed by a neighbour to the French (Jan. 27, 1810), who took him captive to Mantua, where, by express order of Napoleon, he was shot (Feb. 20, 1810) for the sole offence of being loyal to his emperor and his native land. His bones now lie in the great church at Innsbruck, side by side with those of his two chief supporters, the Capuchin friar and army chaplain, Joachim Haspinger (d. 1858), and the peasant, Joseph Speckbacher.

The pseudonym Tirso is that of the Spanish dramatist Pedro de Cervantes y Silva (1571-1648), Spanish dramatist. Born at Madrid in October 1571, he studied at the Alcáalá de Henares, joined the Order of Mercy on the 4th of November 1600, and made his religious profession in the Monastery of San Antolín at Guadalajara on the 21st of January 1601. He was a dramatist of ten years' standing when he was sent by his superiors on a mission to the West Indies in 1615; returning to Europe in 1617, he resided at the Mercenarian monastery in Madrid, took part in the proceedings of the Academia poética de Madrid, founded by Sancho de Molina Aldehues in 1614, and wrote no more tournements then in vogue, and wrote copiously for the stage. His first publication, the incomplete Cigarrales de Toledo (licensed in 1621, but apparently not published till 1624), is a miscellany, containing short tales, novels, verses and three plays; one of the novels, Los Tres maridos burlados, probably derived from Il Cioco da Ferrara's Mambriano, and the play entitled El Vergonzoso en palacio are admirable examples of witty contrivance. The preface to the Cigarrales de Toledo (the second part of which was never printed) states that Tirso de Molina had already written three hundred plays, and at this period of his career he was second only to his friend Love de Vega in popularity. He avowed himself hostile to culturismo in the Cigarrales de Toledo, and made numerous enemies by his attacks on the new school in such pieces as Amar por arte mayor and La Celosa de sí misma. The realistic character of some of his productions provided his unsuccessful rivals with an excuse for denouncing him as a corrupter of public morals to the council of Castile in 1625, and, though no legal action was taken against him, he appears to have been reprimanded privately. In 1626 it was deemed advisable to transfer him to Salamanca, and Tirso de Molina left Madrid determined to write no more for the stage. Though one of his plays, La Huerta de San Juan, is dated 1626, there is no proof that it was begun after his departure from Madrid, and it seems to have kept to his resolution for eight years. But he had not lost his interest in the theatre, and felt justified in publishing twelve representative pieces as the first part of his dramatic works (1626). This may be taken as a formal protest against the weakness of those who had sacrificed him to hypocritical clamour. In other respects he was submissive, and worked zealously on behalf of his order in which he rose to important positions; he became superior of the monastery at Trajillo in 1626, was elected later to the posts of reader in theology and defensor general, and in May 1632 was appointed chronicler of the Order of Mercy. His Deleitar aprovechado (1635) is a devout counterpart of the Cigarrales de Toledo, much inferior to its predecessor in interest; a sequel was promised to this collection of pious tales, pious lyrics, and autos, but, as in the case of the Cigarrales de Toledo, the continuation never appeared. Twelve plays constitute the third part of his dramatic works which was published (before the second) in 1634 under the nominal editorship of the writer's nephew Francisco Lucas de Ávila, but the existence of this nephew is doubtful. The second part (1635), the printing of which was paid for by the confraternity of St Jerome, contains four plays by Tirso de Molina, and eight written by him in collaboration with other dramatists; one of these collaborators was Ruiz de Alarcon (q.v.), but the internal evidence goes to show that Tirso de Molina was the predominant spirit in these literary partnerships. The fourth part of Tirso's dramatic works (1635) and the fifth (1636) each contain twelve plays; the haste with which these five volumes were issued indicates the natural desire of a great author to save some part of his work from destruction. It is the appearance of a supposititious nephew's name on the title-pages of the last four volumes indicates the equally natural desire of a prominent monk to avoid conflict with the authorities. A sixth volume of dramatic pieces, consisting of light comedies, was announced; but the project was abandoned. That dramatic composition still entertained the scanty leisure of Tirso's old age is shown by the fact that the fragmentary autograph copy of Las Quinas de Portugal is dated the 8th of March 1638; but his active career as a dramatist ended two years earlier. He was probably the last of the dramatists of this so-called classical age, for in 1639 he compiled the elaborate Historia de la merced, which occupied him till the 24th of December 1639, and still survives in manuscript. As a tribute to the count of Sástago, who had accepted the dedication of the fourth part of the plays, and who had probably helped to defray the publishing expenses, Tirso de Molina is said to have compiled the Genealogia de la casa de Sástago (1640), but the ascription of this genealogical work is disputed. On the 29th of September 1645 Tirso de Molina became superior of the monastery at Soria, and died there on the 12th of October 1648.

It is only within the last few years that it has become possible to give an outline of his life; it will always be impossible for posterity to do justice to his genius, for but a fraction of his plays have been preserved. The earliest of his extant pieces is dated 1605 and bears no sign of immaturity; in 1624 he had written three hundred plays, and in 1634 he stated that he had composed four hundred within the previous twenty years; of this immense production not more than eighty plays are in existence. Tirso de Molina is universally known as the author of El Burlador de Sevilla y convidado de pie (1627), an extant and fragmentary piece, in which Don Juan is first presented on the stage; but El Burlador de Sevilla represents only one aspect of his genius. No less remarkable than his representation of perversive depravity in El Burlador de Sevilla is his dramatic treatment of a philosophical enigma in El Condenado por desconfiado. Though manifestly attracted by exceptional cases, by every kind of moral aberration, by the infamous and the terrible, his range is virtually unlimited. He reveals himself as a master of historical interpretation in La Prudencia de la mujer and of tragic paths in La Venganza de Tamar; his sympathies incline more towards the feminine in El Condenado por desconfiado, and the story is based on the most famous Spanish love affair, with the exultant clef of El Aficionado en palacio and Don Gil de las calzas verdes, and the fine divination of feminine character in Avergutelo Vargas and La Villana de Vallecas is incomparable. Tirso de Molina has neither Lope de Vega's inventive resource, nor his infinite seduction; he has neither Calderón's idealistic visions, nor his golden music; but he exceeds Lope in massive intellectual power and in artistic self-restraint, and he exceeds Calderón in humour, in creative faculty, and in dramatic intuition. That his reputation extended beyond the Pyrenees in his own lifetime may be gathered from the fact that J. Shirley's Opportunity is derived from El Castigo del pensador; but he was neglected in Spain itself during the long period of Calderón's supremacy, and his name was almost forgotten till the end of the 18th century, when some of his pieces were timidly recast by Dionisio Solá and later by Juan Carretero. The renaissance of his fame, however, dates from 1839-1842, when an incomplete but serviceable edition of his plays was published by Hartzenbusch; and he is now accepted as among the greatest dramatists of Spain.

TIRUPATI, or Tripetty, a town of British India, in the North Arcot district of Madras, with a station on the Madras railway, 84 m. N.E. of Madras city. Pop. (1901), 15,485. It is famous for a temple on the neighbouring hill of Tirumala, 2,500 ft. above the sea, which is one of the most frequented places of pilgrimage in southern India. The town contains numerous temples connected with the shrine of Tirumala, and is noted for its brass-work and wood-carving.

TIRYNOS, the Τίρυνος τευκριδεσος of Homer (II. ii. 550), a small Peloponnesian city, in the prehistoric period of the Achaean race, long before the Dorian immigration. It stood on a small rock in the marshy plain of Argolis, about 3 m. from the sea, and was fabled to have been founded by King Proetus, the brother of Acrisius, who was succeeded by the hero Perseus. It was the scene of the early life of Hercules, who is hence called Tirynthius. The massive walls, which appear to be of earlier type than those of Mycenae, were said to have been the work of Cyclopean masons. Its period of greatest splendour was probably between the 14th and 12th centuries B.C., in Homeric and subsequent times it was usually subject to Argos. The temple existed at the time of the Dorian conquest. After the Spartan defeat of Argos in 404 B.C., Tiryns regained temporary independence, and the Tirynthians fought on the Greek side at Plataea, while the Argives held aloof. Soon after, in 468 B.C., Tiryns was finally destroyed through the jealousy of the Argives, and the site has been deserted ever since, but for a brief occupation in Byzantine times.

Excavations made in 1884-1885 by Schliemann and Dörpfeld over the rock on which Tiryns stood have exposed one of the most interesting buildings, which offers the most complete example of a palace of the Mycenean age in Greece. The rock on which Tiryns is built is of an irregular oval shape, about 330 yds. long by 112 at the widest part, and is surrounded by a very massive wall, varying from 30 to 40 ft. in thickness and averaging when complete about 50 ft. in height, measuring from its base outside. Inside, the wall was never built; nor was it not more than 10 or 12 ft. high above the ground, so the masonry acts as a retaining wall to a considerable depth of earth which covers the rock (see fig. 2 below). The wall is built of very large hammer-dressed blocks, some as much as 10 ft. long by 3 ft. 3 in. wide, which were smaller ones to fill up the interstices. The whole was bedded, not in mortar, but in clay, which has mostly been washed out of the joints; originally the surface was probably protected with a coating of stucco. The only important gateway, which was on the east side, away from the sea, probably resembled the "lion gate" at Mycenae. The other entrances are mere slits in the wall. One of these and the chief gate are shown in fig. 1. Internally the area of the city was divided by cross walls into three parts at successive levels. The lowest and middle divisions have not yet been excavated; the upper part at the south end of the rock was completely exposed in 1884-1885 by Schliemann and Dörpfeld, and the almost complete plan of the various structures clearly made out. This division contains the palace of the ruler of Tiryns, a building which shows careful and skilful construction, elaborate decoration, and a well-arranged plan, suitable to the wants of a wealthy autocratic chief, who lived in a manner which partly recalls the luxury of an Oriental king, and also resembled the feudal state of a medieval baron, surrounded by a crowd of vassals. From the main gate, which was defended by a tower, a strong passage led between the outer wall and an inner one to an inner gate, thence to a propylaeum or double porch, with two wooden columns on each side, adjoining which were chambers for guards. Then came another similar but smaller propylaeum, and opposite to that was the entrance to the great court (ἀθέα), nearly 53 by 70 ft., in which stands an altar or pit of sacrifice, in a position similar to that occupied by the altar of Zeus Hercius in the later Greek house. This court was surrounded by wooden columns supporting a roof, like a medieval cloister; on the south side are chambers for attendants (θήλαμα). On the north side is the great hall (μεγαρόν), with an outer portico supported by two columns (ἀθέα) and an inner vestibule (εὔθεα) with three doors. The hall is about 40 by 30 ft., with a circular hearth in the centre (τίριλις or κρήπον). Four columns supported the roof, the central part of which probably rose above the rest like a medieval "lantern." On the west side of the hall are a

A. Inner base of wall.
B. Inside level of city.
C. Chambers in the thickness of the wall opening out of the gallery.
D. Gallery, with roof formed of projecting courses of stone in blocks.
E. Top of main wall, paved with clay, supported by the inside.
F. Wooden columns on existing stone bases, forming a portico or bowered walk along the top of the wall.
G. Outer wall of the colonnade built of large, new masonry, of an older design.
H. Probable roof of the colonnade of wood, covered with beaten clay.

Fig. 1.—Plan of the Palace in the Upper Part of Tiryns.

1. Main gate in the outer wall.
2. Inner gate, approached between massive walls.
3. Main propylaeum.
4. Inner propylaeum.
5. Court (αὖδα) surrounded by a colonnade on three sides: the altar to Zeus Hecucus is by the entrance.
6. Αἰθέα, portico of the megaron.
7. Πρόθεα, inner porch.
8. Megaron, with roof supported on four columns, and the circular hearth in the middle.
10, 10. Chambers round the great court.
11. 11. Guard chambers by the main propylaeum.
12. Passage (λαδύ) from the main propylaeum to the second house.
15. Chambers (θήλαμα).
16. Passage to the rock-cut stairs.
17. Small postern door in the semicircular bastion, approached by flight of rock-cut steps.
18, 18. Massive outer wall of city.
19. Inner wall to guard the entrance passage.
20. Part of outer wall, with intermediate passage and rows of chambers, as shown in fig. 2.
upper floor. The circuit wall round the palace is more strongly constructed than the rest. On the south is a gallery built in the thickness of the wall, and roofed by projecting courses of stone; and chambers or storehouses open out of this gallery. The wall on the south side of the building (see fig.) at the top level was covered by a colonnade of wooden pillars resting on circular stone blocks. This supported a flat roof and constituted the parapet of the palace. The colonnade was built of brick, and is now missing, as are all the brick parts of the palace, owing to the bricks having been only sun-dried.

The methods of construction employed in the Tiryns palace are of the highest interest. The foundations and about 3 ft. of the walls above the ground are made of large blocks of stone bedded in clay; above this the wall was of brick, sun-dried, and covered with stucco. The walls were protected by a glacis, or sloping parapet. The thresholds of the doors were massive blocks of stone (Δαίμων οίδεα); others were of wood (δρυῖον οίδεα). Wood was also used for all the columns, doorposts, and stumps (στυλάδες), and in some cases the walls of the rooms were lined with wood, carefully fixed by dowels, the holes for which still exist. The doors had pivots of bronze revolving in well-fitted bronze cup-like sockets let into the thickness of the wall. In the megaron and other rooms the floors are of good concrete decorated with a simple series of incised lines, coloured red and blue. The stucco of the internal wall is decorated with bold and very effective patterns—birds and scrollos and other decorative designs. The best preserved paintings show a scene from a bull-fight. Both subjects and style show close analogy to the paintings in the palace at Crossus in Crete. One example of rich and costly decoration is the representation of a female figure, seated in a chariot, in relief with rosettes and interfacing patterns, and studded with jewel-like pieces of blue glass or enamel, the θηρίδων κόλποι of Od. viii. 87. Further excavations in the lower parts of the city will probably bring to light other well-preserved dwelling houses of the palace. The great bulk of the Tirynthians must have lived in houses outside the citadel, but under the shelter of its protection, just as in medieval Italy villages grew up round the castles of any powerful lord. The relation of the palace at Tiryns to those described in the Homeric poems has given rise to much discussion. The case is somewhat altered by the discovery of other high parts of Tiryns, behind that at Mycenae, but not at Mycenae, and where in Greece; these do not, for example, show the duplication of the essential parts of the house found at Tiryns. It is now generally recognized that, while the general character of the palace at Tiryns is the same as that of other palaces described by the Homeric poet, it is a mistake to appeal to it for the explanation of details of arrangement such as probably varied considerably according to the conditions and requirements in different cases.

Tischendorf, Lobegott Friedrich Konstantin Von (1815-1874). German biblical critic, the son of a physician, was born on the 18th of January 1815 at Lengenfeld, near Plauen, in the Saxon Vogtland. From the gymnasia at Plauen he passed in 1834 to the university of Leipzig, where he was mainly influenced by J. G. B. Winer (1789-1858), and began to take special interest in New Testament criticism. In 1838 he took the degree of doctor of philosophy, and then became master at a school near Leipzig. After a journey through southern Germany and Switzerland, and a visit to Strassburg, he returned to Leipzig, and set to work upon a critical study of the New Testament text, following the guidance of Karl Lachmann. In 1840 he qualified as university lecturer in theology with a dissertation on the recensions of the New Testament text, the main part of which appeared in the following year in the prolegomena to his first edition of the New Testament. These early textual studies convinced him of the absolute necessity of new and exacter collations of MSS. From October 1840 till January 1843 he was in Paris, busy with the treasures of the great library, seeking his materials by making collations for other scholars, and producing for them his Tischendorf's Ephemerides of the Greek New Testament, one of them exhibiting the form of the text corresponding most closely to the Vulgate. The great triumph of these laborious months was the decipherment of the palimpsest Codex Ephraemi Syri Rescriptus, of which the New Testament part was printed before he left Paris and the Old Testament in 1845. His success in dealing with a MS. much of which, owing to the fact that it had been rewritten with the works of Euphemius Syrus, had been illegible to earlier collators, brought him into note and gained support for more extended critical examination of the text. Paris, he had paid short visits to Holland (1841) and England (1842). In 1843 he visited Italy, and after a stay of thirteen months went on to Egypt, Sinai, Palestine and the Levant, returning by Vienna and Munich. From Sinai he brought a great treasure, forty-three leaves of what is now known as the Codex Sinaiticus. He kept the place of discovery a secret, and the fragments were published in 1846 as the Codex Frederico-Augustinus, a name given in honour of the king of Saxony. He now became professor extraordinarius in Leipzig, and married (1845). In the same year, with his own fees, he published his first edition of the four gospels (2 vols. 1845-1846). In 1850 appeared his edition of the Codex Amiatinus and of the Septuagint version of the Old Testament (7th ed., 1857); in 1852, amongst other works, his edition of the Codex Claromontanus. In 1853 and 1859 he made a second and a third voyage to the East. In the last of these, in which he had the active aid of the Russian government, he at length got access to the remainder of the precious Sinaitic codex, and persuaded the monks to present it to the tsar, at whose cost it was published in 1862 (in four folio volumes). After a visit to Athens, he returned to Leipzig, where Tischendorf as a Russian noble. Meanwhile, in 1859, he had been made professor extraordinarius of theology and of biblical palaeography, this latter professorship being specially created for him; and another book of travel, Aus dem heiligen Lande, appeared in 1862. Tischendorf's Eastern journeys were rich enough in other discoveries to deserve the highest praise. Side by side with his industry in collecting and collating MSS., Tischendorf pursued a constant course of editorial labours, mainly on the New Testament, until he was broken down by overwork in 1873. He died on the 7th of December 1874 at Leipzig.

The great edition, of which the text and apparatus appeared in 1869 and 1872, was called by himself edition viii., but this number is usually extended if not exaggerated; in fact, and had been extended by the editor had also the advantage of using the published labours of S. P. Tregelles. No one is more important was Tischendorf's work on the Greek Old Testament. His edition of the Roman text, with the variants of the Alexandrian MS., the Codex Ephraemi and the Frederico-Augustinus, was of service when it appeared in 1850, but, being stereotyped, was not greatly improved in subsequent issues. Its imperfections, even within the limited field it covers, may be judged by the aid of C. E. Nestle's appendix to the 6th issue (1880). Besides this may be mentioned editions of the New Testament Apocrypha [De Evangelis pace apocrpyphae origine et usu (1851); Acta Apostolicae apoecrpyphae (1853); Evangelia apocrypha (1853 ed., 1876); Apocryphae apocryphae (1866)] and various minor parts of the New Testament, and apocryphal characters, such as Wann waren unsere Evangelien verfasst ? (1855; 4th ed., 1866), Haben wir den echten Schrifttext der Evangelisten und Apostel ? (1873), and Synopsis evangelica (7th ed., 1868).

See also Tischendorf's handbooks on New Testament criticism, Carl Bertheau's article on Tischendorf in Herzog-Hauck, Realencyklopadie (3rd ed., 1907).

Tisio or Tisi, Benvenuto (1481-1559), commonly called Il Garofalo, Italian painter of the Ferrarese school, was born in

1 See his Reise in den Orient (Leipzig, 1845-1846).

2 The MSS., brought to Europe on the first two journeys are catalogued in the Anecdota sacra et profana (Leipzig, 1855, enlarged in 1861). See also the Monumenta sacra et profana (2 vols. 1845, 1846), and Nova collectio of the same (1855-1869). The preface of the last volume of the New collective gives the results of his last Eastern journey.

3 The prolegomena remained unfinished at his death, and have been supplied by C. G. Gregory (cf. his Textkritik des Neuen Testaments, vol. i., 1900).
TISSAPHERNES—TISSOT, J. J. J. 1015

1481 at Garofolo, in the Ferrarese territory, and constantly used the gillyflower (garofalo) as a symbol with which to sign his pictures. He took to drawing in childhood, and was put to study under Domenico Panetti (or Laneto), and afterwards at Cremona under his maternal uncle Niccolò Soriani, a painter who died in 1528, left him to the care of his brother Boccaccino. He stayed fifteen months with Giovanni Baldini in Rome, acquiring a solid style of draughtsmanship, and was two years with Lorenzo Costa at Mantua. He then entered the service of the marquis Francesco Gonzaga. Afterwards he went to Ferrara, and worked there four years. Attracted by Raphael’s fame, and invited by a Ferrarese gentleman, Geronimo Sauro, he again removed to Rome, and found the great painter very amicable; here he stayed two years, rendering some assistance in the Vatican frescoes. From Rome family affairs recalled him to Ferrara; there Duke Alfonso I. commissioned him to execute paintings, along with the Dossi, in the Villa di Belriguardo and in other palaces. Thus the style of Tisio partakes of the Lombard, the Roman and the Venetian modes. He painted extensively in Ferrara, both in oil and in fresco, two of his principal works being the “Massacre of the Innocents” (1519), in the church of S. Francesco, and the “Betrayal of Christ” (1524), accounted his masterpiece. For the former he made clay models for study and a lay figure, and executed everything from nature. He continued, according to De’ Rossi, to frequent meetings of artists, painting on all feast-days in monasteries for the love of God. He had married at the age of forty-eight, and died at Ferrara on the 6th (or 16th) of September 1559, leaving two children.

Garofalo combined sacred inventions with some very familiar details. A certain archaism of style, with a strong glow of colour, sufficed to distinguish from the true Raphael even those pictures in which he most closely resembles the great master—this sometimes very closely; but the work of Garofalo is seldom free from a certain trim pettiness of feeling and manner. He was a friend of Giacinto Brandi, Giorgio Tiarriti and Arcisio; in a picture of “Paradise” he painted Aristoco between St Catherine and St Sebastian. In youth he was fond of lute-playing and also of fencing. He ranks among the best of the Ferrarese painters; his leading pupil was Girolomo Carpi. The “Adoration of the Magi,” in the church of San Giorgio near Ferrara, and a “Peter Martyr,” in the Dominican church, Ferrara (sometimes assumed to have been done in rivalry of Tician), are among his principal works not already mentioned. The National Gallery, London, contains four, one of them being a Madonna and Christ enthroned, with St Francis and three other saints.

TISSAPHERNES (Pers. Çihrâfarname), Persian soldier and statesman, son of Hydarnes. In 413 he was satrap of Lydia and Caria, and commander-in-chief of the Persian forces against Asia Minor (413-406). When Darius II. ordered the collection of the outstanding tribute of the Greek cities, he entered into an alliance with Sparta against Athens, which in 412 led to the conquest of the greatest part of Ionia. But Tissaphernes was unwilling to take action and tried to achieve his aim by astute and often perfidious negotiations; Alcibiades persuaded him that Persia’s best policy was to keep the balance between Athens and Sparta, and rivalry with his neighbour Pharnabazus of Hellepontic Phrygia still further lessened his energy. When, therefore, in 408 the king decided to support Sparta against Tissaphernes was removed from the generalship, and limited to the satrapy of Caria, whereas Lydia and the conduct of the war were entrusted to Cyrus the Younger. On the downfall of Athens, Cyrus and Tissaphernes both claimed jurisdiction over the Ionian cities, most of which acknowledged Cyrus as their ruler; but Tissaphernes took possession of Miletus, where he was attacked by Cyrus, who gathered an army under this pretence with the purpose of using it against his brother Artaxerxes II. The king was warned by Tissaphernes, who took part in the battle of Cunaxa, and afterwards tried to destroy the Greek mercenaries of Cyrus by the same method of Raphides. He was then sent back to Lydia and Caria, which he managed to keep in his possession as general in chief and satrap of Lydia and Caria. He now attacked the Greek cities, to punish them for their allegiance to Cyrus. This led to the war with Sparta in 399. Tissaphernes, who once again had recourse to subtle diplomacy, was beaten by Agesilaus on the Pactolus near Sardis (193); and at last the king yielded to the representations of Pharnabazus, strongly supported by the chiliburn (vizier) Tithraustes and by the queen-mother Parysatis, who hated Tissaphernes on the principal cause of the death of her favourite son Cyrus. Tithraustes was sent to execute Tissaphernes, who was lured to Colossae and slain in 395.

(Ed. M.)

TISSERAND, FRANÇOIS FÉLIX (1845-1896), French astronomer, was born at Nuits-Saint-Georges, Côte-d’Or, on the 13th of January 1845. In 1863 he entered the École Normale Supérieure, and on leaving went for a month as professor at the lycée at Metz. Le Verrier offered him a post in the Paris Observatory, which he accordingly entered as astronome adjoint in September 1866. In 1869 he took his doctor’s degree with a brilliant thesis on Delaunay’s Method, which he showed to be of much wider scope than had been contemplated by its inventor. Shortly afterwards he went out to Malacca to observe the famous solar eclipse of the 38th of August 1868. In 1873 he was appointed director of the observatory at Toulouse, whence he published his Recueil d’exercices sur le calcul infinitésimal, and in 1874 became corresponding member of the Académie des Sciences. He took part in the French expeditions of 1874 to Japan, and in 1882 to Martinique to observe the transit of Venus. In 1876 he was elected a member of the Académie des Sciences, and in 1883 he was one of the number of assistants of the Bureau of the Longitudes. In the same year he was appointed professeur suppléant to Liouville, and in 1883 he succeeded Puiseux in the chair of celestial mechanics at the Sorbonne. Tisserand always found time to continue his important researches in mathematical astronomy, and the pages of the Comptes rendus bear witness to his surprising activity. His writings relate to almost every branch of celestial mechanics, and are always distinguished by rigour and simplicity in the solution of the most difficult problems. He treated in a masterly manner (Breviario di Astronomia, 1882) the problem of Jupiter’s satellites and the disturbances of the outer planets, and was, by the larger planets, and in this connexion published his valuable Critérion for establishing the identity of a periodic comet, whatever may have been the perturbations brought about in its orbit, between successive appearances, by the action of a planet. His principal work, Traité de mécanique céleste, is the noblest and most lasting monument to his memory, and is worthy to stand beside the Mécanique céleste of his fellow-countryman, Laplace. In this treatise, published in four quarto volumes, the last of which appeared only a few months before his death, he fused into one harmonious whole the works of Laplace and those of other workers in the same field since his time. It furnishes a faithful and complete résumé of the state of knowledge in that department of astronomy at the end, as Laplace’s great work did for the beginning, of the 19th century. In 1892 he succeeded Mouchet as director of the Paris Observatory, and was president of the committee of the photographic chart of the heavens he contributed largely to the success of that great project. Under his direction the revision of Lalande’s catalogue was brought to a completion, and four volumes of the Annales de l’Observatoire de Paris were prepared; two others were projected. He was also editor of the Bulletin astronomique from the beginning, and contributed many important articles to its pages. He died suddenly, in the fullness of his power, of congestion of the brain, on the 20th of October 1896.

(A. A. R.)

TISSOT, JAMES JOSEPH JACQUES (1836-1902), French painter, was born at Nantes on the 15th of October 1836. He studied at the École des Beaux Arts in Paris under Ingres, Flandrin and Lamothe, and exhibited in the Salon for the first time at the age of twenty-three. In 1861 he showed "The Meeting of Faust and Marguerite,,” which was purchased by the state for the Luxembourg Gallery. His first characteristic period made him a painter of the charms of women. Demimonde would be more accurate as a description of the series of studies which he called La Femme à Paris. He fought
in the Franco-German War, and, falling under suspicion as a Communist, left Paris for London. Here he studied etching with Sir Seymour Haden, drew caricatures for Vanity Fair, and painted portraits as well as genre subjects. It was many years before he turned to the chief labour of his career—the production of a series of 700 water-colour drawings to illustrate the life of Christ and the Old Testament. Some sudden shock or bereavement was said to have turned his thoughts from ideals of the café and the boulevard into a more serious channel. He disappeared from Paris, where he had still more after studying at the École des Beaux-Arts, and went to Palestine. In 1895 the series of 350 drawings of incidents in the life of Christ was exhibited in Paris, and the following year found them on show in London. They were then published by the firm of Lemercier in Paris, where he had paid him 1,000,000 francs for them. After this he turned to the scenes of the Old Testament, upon which he was still engaged at the abbey of Buillon, in the department of Doubs, France, where he died on the 8th of August 1902. The merits of Tissot's Bible illustrations lay rather in the care with which he studied the details of scenery than in any quality of religious emotion. He seemed to aim at all, at accuracy, and, in his figures, at a vivid realism, which was far removed from the conventional treatment of sacred types.

TISZOT, PIERRE FRANÇOIS (1768–1854), French man of letters, was born at Versailles on the 10th of March 1768. His father, a native of Savoy, was a perfumer appointed by royal warrant to the court. At the age of eighteen he entered the office of a procureur of the Châtelle, in order to learn the practice of the law; but he cultivated the Muses rather than the study of procedure, and, being a handsome youth, was occasionally invited to the fêtes of the Trianon. He devoted himself ardently to the cause of the Revolution, in spite of the fact that it had ruined his family. While with the procureur he had made the acquaintance of Alexandre Goujon, and they soon became inseparable; he married Goujon's sister, Sophie (March 5, 1793), and when his brother-in-law was elected deputy to the Convention and sent on a mission to the armies of the Moselle and Rhine, Tissot went with him as his secretary; he then returned to Paris and resumed his more modest position of secrétaire général des substances. On the 1st of Prairial he tried in vain to save his brother-in-law, who had been involved in the proscription. He set out to Salvagny, all he could do was to draw Goujon the knife with which he killed himself in order to escape the guillotine, and he afterwards avenged his memory in the Souvenirs de Prairial. He also took under his care Goujon's widow and children. His connexion with the Jacobin party caused him to be condemned to deportation after the attempt of the 3rd Nivose in the year IX., but Bonaparte, having been persuaded to read his translation of the Bucoliques, struck his name off the list. Though still a friend of the Republic, Tissot was henceforth an admirer of the First Consul; he celebrated in verse several of the emperor's victories, and the arrival in France of Marie-Louise (1810). So far he had lived on the income derived from a factory of horn lanterns in the Faubourg St Antoine; and, being at last in fairly comfortable circumstances he now devoted himself to literature. The abbé Dellile took him as his assistant at the Collège de France; and Tissot succeeded him as head of it (1813); the emperor signed the appointment as a reward for a poem composed by Tissot on his victory at Lützen. He was removed from this post, however, in 1821, in consequence of the publication of a Préci sur les guerres de la révolution, in which rather colourless work he had dared to say that the Convention had saved France and vanquished the Coalition. Deprived of his post, he was left free to attack the government in the press. He was one of the founders of the newspaper Le Constitutionnel, and of the review, the Minerve. Without laying stress on his literary works (Traité de la poésie latine, 1821; translation of the Bucoliques, 3rd ed., 1833; Études sur Virgile, 1825) we should mention the Mémoires historiques et militaires sur Carnot, which he based on the papers left by the “Organizer of Victory” (1824), the Discours du Général Foy (1826) and a Histoire de la guerre de la Péninsule also inspired by Général Foy (1827). On the overthrow of Charles X., Tissot made a successful effort to regain his position at the Collège de France; he was also elected as a member of the French Academy on the death of Dacier (1833). It was then that he published his chief works: Histoire de Napoléon (2 vols., 1833), and Histoire complète de la révolution française de 1789 à 1806 (6 vols., 1833–1836), full of inconsistencies and omissions, but containing a number of the author's reminiscences; in some places they become practically memoirs, and are consequently of real value. In 1840 a carriage accident almost cost him his sight; he had to find a new occupation, and passed the last years of his life in circumstances of increasing suffering, amid which, however, he preserved his cheerfulness and goodness of heart. He died at Paris on the 7th of April 1854.

See an excellent essay on Tissot by P. Fromageot in the Revue de Versailles et de Soissons, in 1901.

Tissot, P. F.—TISZA

TISZUB (Fr. tissu, tissue, participe of tisser, Lat. texere, to weave), properly the name of a fine textile fabric interwoven with gold and silver threads, hence used of any delicate or gauzy fabric (see Gold and Silver Thread). It was also early applied, as in French, to a ribbon, fillet or various forms of woven ligaments. In biology the word is of general use for an aggregate of cells forming a texture or fabric; in animal anatomy it is thus applied to the primary layers of which the parts are composed, and named by some qualifying word denoting its substance or its use (see Connective Tissue and Epithelial, Endothelial and Glandular Tissue).

TISTA, a river of northern India, which rises on the edge of the Tibetan plateau, and flows through the mountain gorges of Sikkim and Darjeeling, till it spills itself over the plain of Eastern Bengal. In the 18th century its course was due south to join the Ganges; but in 1787 great floods diverted the stream towards the south-east, and it now enters the Brahmaputra, the whole district of Rangpur being scored by various interlacing channels. Its total length in British territory is about 170 m.
TITANIUM

1017

royal decree (Dec. 10, 1855), Tisza once more represented Debreczen and formed, with Kálmán Ghyczy (1808–1888), the Left-centre party. From 1867 onwards his influence continued to increase, to the rupture of his party, which he reconstructed at the conference of Nagyvárad (March 17, 1868), when the famous Bikari pontok, or articles of Bikar, were subscribed. The Bikari pontok started from the assumption that Hungary was a free and independent state. They bound the party to repeal all laws or instalments contrary to, and to promote all measures necessary for, the national independence. Thus the delegation system and the common ministries were marked out for attack, while every effort was to be made to procure for Hungary a separate army, a separate diplomacy and a separate financial system. It was chiefly owing to the efforts of Tisza and his party that Austria remained neutral during the Franco-German War. His speech on the 3rd of March 1875 led to the resignation of Istvan Bittó's administration and the welding of Déké's followers and the Left-centre into a new party, the Szabadlevéért or Free Principles Party, which took office under Bela Wenckheim (1811–1879), whom (Oct. 2) Tisza succeeded as prime minister, a post he held, with a few interruptions, for the next fifteen years (1875–1890). In 1877 he resigned on the discussion of the question of the Composition (Ausgleich), but he returned to office on his own terms. The same thing happened the following year, when his brief resignation compelled the Magyar Diet to agree to the occupation of Bosnia. In 1879 he materially contributed to the formation of the Austro-German alliance. Not till 1888, when the national army bill was introduced, did he encounter any serious opposition, but all laws or instalments contrary to, and to promote all measures necessary for, the national independence. On the 13th of March 1890, on the occasion of the revision of the Indigenat Act, he resigned office, but continued, as deputy for Nagyvárad to place his vast political experience at the disposal of the house. It is no exaggeration to say that Hungary owes to Kálmán Tisza a consolidated government, the formation of a parliamentary majority, a healthy public spirit, public credit, the reform of the Upper House, an admirable educational system, economical, and particularly railway, development, and administrative and judicial reconstruction on modern lines. His opponents have accused him of unscrupulous lowness and party spirit, but not one of them can deny that he reshaped Hungary and made her the leading partner of the dual monarchy. As to his personal integrity and disinterestedness there has never been the slightest doubt. It is an open secret that, on the retirement of Andrassy, he was offered the chancellorship. He refused it because, to use his own expression, "I am as wholly and solely Hungarian as the river (Theiss, Hung. Tisza) whose name I bear."

See Inre Visi, Kálmán Tisza, a political appreciation (Hung.: Budapest, 1885); Kornél Abrányi, Kálmán Tisza Life and Political Career (Hung.; Budapest, 1876); G. Gratz, Kálmán Tisza (Modern Magyar Statesmen, 1) (Hung.; Budapest, 1902); P. Busbach, The Last Five Years (Hung.; Budapest, 1895).

His youngest son, Count Stephen Tisza (1861–), was born on the 22nd of April 1861. After being educated at Berlin, Heidelberg and Budapest, he entered the ministry of the interior for the purpose of studying technical and economical questions at the fountain-head, and soon became a specialist in agrarian matters. His Magyar agrárpolitik (Budapest, 1897), authoritative on its subject, was translated into German the same year (Leipzig). In 1886 Tisza began his parliamentary career, speedily becoming a large member of the principal committees and of economical and educational questions. On the resignation of Kálmán Szell (June 17, 1903) he was entrusted with the formation of a ministry of pacification, but abandoned the attempt on finding it impossible to secure a majority. On the 27th of October, however, with the assistance of the Free Principles Party, he succeeded in composing a cabinet, in which he was minister of the interior as well as premier. From the first the ministry was exposed to the most unscrupulous opposition, exacerbated by the new and stringent rules of procedure which Tisza felt it his duty to introduce if any business were to be done. The motion for their introduction was made by the deputy Gábor Daniel, supported by the premier, and after scenes of unheard-of obstruction and violence (Nov. 16–18) the speaker, in the midst of an ear-splitting tumult, declared that the new regulations had been adopted by the house, and produced a royal message suspending the session. But the Andrássy group, immediately afterwards, separated from the Free Principles Party, and during the rest of the year the opposition made legislative impossibility. By January the situation had become ex leso or anarchical. Tisza stoutly stood by his rules, on the ground that this was a case in which the form must be sacrificed to the substance of parliamentary government. But his appeal to the country at the beginning of 1905 was unsuccessful, and his opponents triumphed by a large majority. Tisza thereupon resigned and retired from public life.

The discovery of an element as was due to William Gregor in 1789 who found in the mineral ilmenite and magnetohemite a new earth, which was regarded as the oxide of a new metal, manechin. Independently of him Klaproth in 1793 discovered a new metal in rutille, and called it titanium; he subsequently found that it was identical with Gregor's element. Klaproth, however, was unable to prepare the pure oxide, which was first accomplished in 1821 by Rose. The isolation of the pure metal is of much later date. Titanium, although pretty widely diffused throughout the mineral kingdom, is not found in abundance. The commonest titanium mineral is rutile or titanium dioxide, TiO₂; anatase and brookite are crystalline allotropic modifications. Titanium is most frequently found associated with iron; ilmenite (Ger. Titan-eelzen) is FeTiO₃, peroskite (Ca,Fe)TiO₃, and the metal occurs in most magnetic iron ores. The titanates are well marked in the mineral kingdom. Ilmenite is isomorphous with gelikelite, MgTiO₃, and pyrophanite, MnTiO₃; many of the "rare minerals"—aeschynite, euxenite, polyacryse, &c.—contain titanates (and also niobates). Silicates also occur; sphene or titanite, CaTiSiO₄, is the commonest; keilhauite is rarer.

The isolation of metallic titanium is very difficult since it readily combines with nitrogen (thus resembling boron and magnesium) and carbon. In 1822 Wollaston examined a specimen of those beautiful copper-like crystals which are occasionally met with in iron-furnace slags, and declared them to be metallic titanium. This view had currency until 1849, when Wöhler showed that the crystals are a compound, Ti(CN)₂·3TiN₄, of a cyanide and a nitride of the metal. An impure titanium was made by Wöhler and Sainte-Claire Deville in 1857 by heating to redness fluoritumate of potassium (see below) in the vapour of sodium in an atmosphere of dry hydrogen, and extracting the alkaline fluoride formed by water. The metal thus produced formed a dark brown amorphous powder resembling iron as obtained by the reduction of its oxide in hydrogen. In 1887 Nilson and Peterson (Zeit. phys. Chem. 1, p. 25) obtained a purer product by heating the chloride with sodium in a steel cylinder; it then formed yellow scales with a bluish surface colour. H. Moissan (Compt. rend., 1895, 120, p. 290) obtained a still purer metal by heating the oxide with carbon in the electric furnace. The product has a brilliant white fracture, a specific gravity of 4·87, very friable, but harder than quartz or steel. Moissan (ibid., 1906, 142, p. 673) has distilled this metal in a very intense electric furnace. When heated in air it burns with the formation of the oxide. It combines directly with the halogens, and dissolves in cold dilute sulphuric acid, in hot strong hydrochloric acid and in aqua regia, but less readily in nitric acid. Its most curious property is the readiness with which it unites with nitrogen. Several nitrides have been described. Ti₃N₅ is a copper-coloured powder obtained by heating the ammonio-chloride TiCl₄·4NH₃ in ammonia. Ti₅N₆ is a dark blue powder obtained when the oxide is ignited in an atmosphere of ammonia; while Ti₇N₈ is obtained as a bronze yellow mass as hard as the diamond by heating the oxide in an atmosphere of nitrogen in the electric furnace.
In its chemical relations, titanium is generally tetravalent, and occurs in the same sub-group of the peridote classification as zirconium, cerium and thorium. It forms several compounds, TiO, TiO₂ and TiO₃ being the best known; others (some of doubtful existence) have been described from time to time.

**Titanium dioxide, TiO₂**, occurs in nature as the three distinct mineral species rutile, brookite, and anatase. Rutile, brookite and anatase are tetravalent forms isomorphous with cassiterite, SnO₂ and also zircon, ZrSiO₄; anatase is also tetravalent, and brookite or thorbomibic. Rutile is the most stable and anatase the least, a character reflected in their decreasing stability, from rutile (474°) down to anatase (39°). The minerals are generally found together—a feature rarely met with in the case of polymorphs. They have been obtained artificially by electrolysis or by the action of fluorine and steam. At a red heat rutile is produced, at the bottom of the crucible, of zinc brookite, and of cadmium anatase. It is apparent that these minerals all result in nature from pneumatolytic action. Amorphous titanium oxide may be obtained in a pure form by fusing the material very finely powdered, with six times its weight of potassium bisulphate in a platinum crucible, then extracting the melt with cold water and boiling the filtered solution for a long time. Titanium oxide separates out as a white hydrate, which, however, is fumed. Contaminated with ferric hydrate and often with tin oxide. A better method is Wöhrle's, in which the finely powdered mineral is fused with sodium carbonate and fused again in a platinum crucible, the melted powder and treated in a platinum basin with hydrofluoric acid. The alkaline titanate first produced is converted into crystalline fluotitanate, K₂TiF₆, which is with difficulty soluble and changes into a yellow, or red, or purple mass which may be collected in glass vessels if an excess of hydrofluoric acid has been avoided, deposits the greater part of the salt on cooling. The solution is then precipitated, washed, pressed and recrystallized, whereby the impurities are removed. The precipitate is dissolved in hot water and decomposed with ammonia to produce a slightly ammoniacal hydrated oxide; this, when ignited in platinum, leaves a white mass, containing a small amount of brookite, of specific gravity of which varies from 3.9 to 4.25, according to the manner in which it was kept in igniting. The more intense the heat the denser the product. The oxide is fusible only in the oxy-hydrogen flame. It is not fused by the usual crucible oxides, and melts at 2000° with a distinct blue flame, when finely powdered. If the sulphuric acid solution be evaporated to dryness the residue, after cooling, dissolves in cold water. The solution, on being evaporated and dried, turns a yellowish brown in colour, and on heating its loss in weight increases beyond the usual proportion of water. This salt is obtained by the action of hydrofluoric acid on the hydroxide, which is decomposed by the action of hydrochloric acid, the chloro-titanate, TiCl₄, obtained by decomposing a solution of the chloroxide in cold water with alkalis. The ortho-body dissolved in cold dilute acids, the meta-body does not. If titanium oxide be fused with excess of alkali carbonate a titanate, K₂TiO₃, is obtained. This salt is decomposed by water with the formation of a solution of alkali free of titanium, and a residue of an acid titanate, which yields the free metal on fusing with charcoal in the presence of an excess of carbonic acid. The titanates are very similar to the silicates in their tendency to assume complex forms, e.g. the potassium salts are K₂TiO₃·4H₂O, K₂TiO₃·3H₂O, K₂TiO₃·2H₂O, K₂TiO₃·H₂O.

**Titanium monoxide, TiO**, is obtained as black prismatic crystals by heating the dioxide in the electric furnace, or with magnesium powder. Titanium sesquioxide, TiO₂, is formed by heating the dioxide with concentrated nitric acid. When a solution of titanium in hydrochloric acid is digested with concentrated nitric acid the trichloride is precipitated with alkalis. Titanium trioxide, TiO₃, is obtained as a yellow precipitate by dropping the chloride into alcohol, adding hydrogen peroxide, and finally ammonium carbonate or potash. When shaken with potash and air it undergoes autooxidation, hydrogen peroxide being formed first, which converts the trioxide into the dioxide and possibly perititanic acid; this acid may contain oxovanadium titanium, see W. Manchot and Richter, *Ber.*, 1906, 39, pp. 320, 488, and also Faber, *Aust. Journ. Chem. Soc.*, 1907, ii, 557.

**Titanium fluoride, TiF₄**, is a fuming colourless liquid boiling at 284°, obtained by distilling a mixture of titanium oxide, fluorine and sulphuric acid; by heating barium titanofluoride, BaTiF₄ (Emrich, *Monats.*, 1904, 25, p. 907); and by the action of dry hydrofluoric acid on the chloride (Ruff and Plato, *Ber.*, 1904, 34, p. 672). By dissolving the dioxide in hydrofluoric acid a syrupy solution is obtained which probably contains titanofluoride, H₂TiF₄. The name of this acid is well known; they are isomorphous with the silico-fluorides, see C. A. Manchot and Richter, *Ber.*, 1906, 39, pp. 320, 488, and also Faber, *Aust. Journ. Chem. Soc.*, 1907, ii, 557.

**Titanium chloride, TiCl₃**, is obtained as a colourless fuming liquid of boiling point 753° and specific gravity 1.775 on freezing 3° c. (T. E. Thorpe), by heating to dull redness an intimate dry mixture of the oxide and ignited lamp-black in dry chlorine. In the method of A. Stähler and H. Wirthwein, the titanium mineral is fused with carbon in the electric furnace, the carbides treated with chlorine, and the titanium chloride condensed. The distillate is freed from vanadium by digestion with sodium amalgam. Other methods are due to E. Vigouroux and G. Arrivaut (*Aust. Journ. Chem. Soc.*, 1907, ii, 557). In the latter, Penfield and Effinger, *J. Phys. Chem.*, 1907, 11, 124, use the chlorofluor hydrocarbon over the heated dioxide the tetra-di- and tri-chlorides of titanium, with the free metal and a gaseous hydride, TiH₃ (Renz, *Ber.*, 1906, 39, p. 249). When dropped very cautiously into cold water, the white powder forms a compound which is decomposed by ammonia to form titanium chloride, TiCl₃, or titanum acid; it forms addition compounds similar to those formed by stannic chloride, and combines with ammonia to form titanum, 8NH₃, both of which with liquid ammonia give titanamide, Ti(NH₃)₂. Titanium dichloride, TiCl₂, obtained from the chlorofluor hydrocarbon over the heated dioxide, is a very hygroscopic brown powder which inflames when exposed to air, and energetically decomposes water. Titanium tetrachloride, TiCl₄, forms involatile, dark violet, scales, and is obtained by passing the vapour of the tetrachloride mixed with hydrogen through a lead tube, or by heating the tetrachloride with molecular nitrogen to 200°.

It is a powerful reducing agent.

Titanium sesquisulphate, Ti₂(SO₄)₃·H₂O, obtained by concentrating the hot solution formed when the metal is dissolved in sulphuric acid, is interesting since it forms a caesium alun, Cs₂Ti(SO₄)·12H₂O. It gives the normal sulphate as a yellow, deliquescent, amorphous mass when treated with water. According to the amount of water present.

Acid solutions of titanates are not precipitated by sulphuric hydrogen; but ammonium sulphide acts on them as if it were ammonia, the sulphurated hydrogen being liberated. Titanium oxide when fused with microscopic salt in the oxidising flame yields a black which is yellowish in the heat but colourless after cooling. In the reducing flame the black becomes violet, more readily on the addition of tin; in the presence of iron it becomes blood-red. Titanium oxides when fused on charcoal yield a white, almost colourless, metallic mass. Determined in 1885 by T. E. Thorpe gave the value 47·7 (see Journ. Chem. Soc., 1885, p. 108).

**TITANOTHERIDAE** (also known as Menodontidae and Brontotheriidae), a family of large rhinoceros-like perissodactyl ungulate mammals from the Oligocene and Eocene strata of North America. The cheek-teeth are low-crowned, with the external cones of the upper molars fused into a W-like outer cusp, and the inner cusp and the paraconid and paracristid form; while in the lower teeth the crown is formed of crescentic ridges of which there are three in the last and two each in the other teeth. There is generally little gap between the canines and the premolars.

**Titanotherium**, of the Oligocene of the Dakotas and neighbouring districts, was a huge beast, with the hinder upper premolars similar in character to the molars, a pair of horn-cores, arising from the maxilla, overhanging the nose-cavity, four front and three hind toes, only twenty dorso-lumbar vertebrae, and an almost continuous and unbroken series of teeth, in which the canines are short; the dental formula being 4, 1, c. 1, p. 4, m. 3. The muzzle probably formed a snout in life, and there is presumptive evidence that these animals were very long-lived. *Brontops* seem scarcely separated from the type genus; but the name *Brontotherium* is applied to species with two pairs of incisor teeth in both jaws. The length of the largest species was about 14 ft., and the height about 8 ft. The alleged occurrence of remains of members of the group in the Balkans apparently rests on insufficient evidence.

A second group is typified by *Palaeochoepus*, of the Bridger Epoch of Wyoming; and obtained from *P. pachyodus* being an animal about the size of a tapir. The skull is smaller, the larger face than in *Titanotherium*, lacks horn-cores, while all the upper premolars are smaller than the molars, and the full series of 44 teeth was present. The limbs were relatively slender, and the brain was small. In the lower, or Wassatch, Eocene the group was represented by the still more primitive *Lambdotherium*. On the other hand, *Palaeochoepus* is connected with *Titanotherium* by means of *Telmatherium* of the upper...
TITANS—TITHES

Bridger and Washakia Eocene, a larger animal, with a longer and flatter skull, showing rudiments of horn-cores, only two pairs of lower incisors, and a general approximation in dental character to Titanotherium. Another of these titanotherid forms is Diplocoelium, from the Upper or Uinta Eocene; an animal the size of a rhinoceros, with the thick and sharp upper premolars molar-like. It was probably off the direct ancestral line of Titanotherium. These intermediate forms render the reference of the group to a distinct family—Palaeochoeridae—unnecessary.

Professor H. F. Osborn, who recognises four genera, Titanotherium, Megacerops, Symborodon and Brontotherium, in the typical section of the family, considers that each of these represents a distinct line of descent from the Palaeochoerops-like group. The whole assemblage forms one of the four main seneages taken by Parkyns-Patry, namely the Titanotherioidea.

TITANS (Gr. ῶταρεῖς), in Greek mythology, the children of Uranus and Gaea. According to Hesiod (Theog. 133), the male Titans were Oceanus, Coeus, Crius, Hyperion, Iapetus and Cronus; the female, Thea, Rheia, Themis, Mnemosyne, Phoebe and Mnemosyne. years (Deut. xiv. 28, xxvi. 12), which the legislator directs to be stored at home, and spent in feeding the poor. Amos iv. 4, "Bring your sacrifices every morning and your tithes every three days" (not "years" as E.V.), hardly implies more than that occasions of sacrifice were three times as frequent as titheday, and so alludes to the fact that there were by old usage three annual feasts and one annual tithe. A triennial sacrificial tithe is inconceivable when it is remembered that the tithe is only an extension of the firstfruits. The triennial tithe in Deuteronomy seems to be rather an innovation necessary in the interests of the poor, when sacrificial feasts were transferred to the central sanctuary, and ceased to benefit the neighbours of the offerer, who, as stated above, had a prescriptive claim to be considered on such occasions (cf. 1 Sam. xxv. 8 sqq.; Neh. viii. 10; Luke i. 69). The priests of the sanctuaries had of old a share in the sacrificial feasts, 1 and among those who are to share in the triennial tithe Deuteronomy includes the Levites, i.e. the priests of the local sanctuaries who had lost their old perquisites by the centralization of worship. In Ezekiel as in the Law of Holiness there is no mention of tithes; he proposes to support all public worship from the proceeds of a general tax (xlv. 13) levied by the prince, the old firstfruits being allotted to the priests. In the Persian period the tithe was converted to the use of the Temple (Mal. iii. 8-10). As in Deuteronomy the phrase of the "whole tithe," the payment to the Levites (now subordinate ministers of the Temple) was perhaps still only triennial; and if even this was difficult to collect, we may be sure that the minor sacrificial tithe had very nearly disappeared. The indifference complained of in Mal. i. was in great part due to the fundamental changes in the religion of Israel, which made private altar gifts and feasts almost meaningless. On the other hand, the provision of regular support for the priests and Levites, the ministers of the public ritual, was now all important, and received special attention from Ezra and Nehemiah (Neh. x. 37 Ex. xxvii. 34, xiii. 10 sqq.). They effected it by enforcing the new law of the priestly code (Num. xviii. 21 sqq.), in which it is formally laid down that the tithe is a tribute paid to the Levites, who in turn pay a tithe of it to the priests. It is doubtful whether the system ever worked. The plain intention of the priestly code is to allow the old tithe of Deuteronomy to drop; but the harmonistic interpretation of the later scribes was to the effect that two tithes were to be paid every year, and a third tithe, for the poor, on every third year (Tob. i. 7 sqq.; Jos. Ant. iv. 8, § 22). The last change in the system was the appropriation of the Levitical tithe by the king, as was proposed in Deuteronomy "for the priest's use," and it is clear that the tradition, glaringly inconsistent with Nehemiah, ascribes it to Ezra, alleging that he deprived the Levites because so few of them were willing to return to Palestine (Mishnah, "Ma'aser Sh." v. 15; "Sota," ix. 10, and Wagensel's note). 2

**Tithes in Law.**

Tithes were generally regarded up to the 17th century as existing merely as a share in the support of the Church ever since the earliest days of Christianity. 1 The tithe offered to Yahweh may have originally been consumed—in worship or in representative part—on the altar, but in the rituals preserved to us the offering is symbolical, the deity ceding his tithe to the priest, so that from quite early times the tithe helped to support the priesthood who like the poor had a customary share guaranteed him. 2 A cattle tithe is demanded in Lev. xxvii. 32, and spoken of in 2 Chron. xxxi. 6. It is doubtful if this was ever acknowledged in practice. See Kuenen, Godsdiens, ii. 269 sqq., and Wellhausen, Prophezeiung, v. 1, § 2 (Eng. trans., p. 155 sqq.), who argue that the passage in Leviticus is a later addition. The tendency of the Pharisees was to pay tithe on everything, and to make a self-righteous boast of this (Matt. xxiii. 23; Luke xviii. 12). The Mishna (Ma'aser, p. 1) says "everything that is eaten and is watched over and grows out of the ground is liable to tithe." 3

History, as Selden showed in his learned and exhaustive treatise (History of Tithes 1618), does not bear out this view. 4 In the words of Hallam, "the slow and gradual manner in which parochial churches became independent appears to be of itself a sufficient answer to those who ascribe a great antiquity to the universal payment of tithes." 5

Long before the 8th century payment of tithes was enjoined by ecclesiastical writers and by councils of the Church; but the earliest authentic example of anything like a law of the state enforcing payment appears to occur in the Capitularies of Charlemagne at the end of the 8th or the beginning of the 9th century. Tithes were by that enactment to be applied to the maintenance of the bishop and clergy, the poor, 6 and the fabric of the Church. In course of time the principle of payment of tithes was extended far beyond its original intention. Thus they became transferable to laymen and salable like ordinary property, in spite of the injunctions of the third Lateran Council, and they became payable out of sources of income which were not originally titheable. The canon law contains numerous and minute provisions on the subject of tithes. The Decretum forbade their alienation to lay proprietors, denounced excommunication against those who refused to pay, and based the right of the Church upon scriptural precedents. 7 The decretals contained provisions as to what was and what was not tithable property, as to those privileged from payment as to sale or hypothecation to laymen, as to priority over state taxes, &c. 8 Various questions which arose later were settled by Boniface VIII. 9 The Council of Trent enjoined due payment of tithes, and exhorted those who withheld them. 10

In England the earliest example of legal recognition of tithes is, according to Selden, a decree of a synod in 786. 11 Other examples before the conquest occur in the Poedus Alfredi et Guthrunti and the laws of Athelstan, Edgar and Canute. 12

A full discussion of their origin and history is to be found in Lord Selby's Ancient Poets and Folklore. Among more recent works on Tithes (1888); the History of the Law of Tithes in England, by G. Edwardes Jones; and the Sacred Tenet, Ancient and Modern, by H. Lansdell (1906). (J. W.)

Tithes in England may be best dealt with in two chronological divisions—tithes under the system existing previously to the Commutation Acts and tithes under the system then introduced.

1. Whether or not, as it is said, before the Council of Lateran in 1150, a man could have given his tithes to any church or monastery that he pleased, at any rate since that time, with the division of dioceses into parishes, they were a common right belonging to the church within whose parish they arise, although by prescription they may belong elsewhere. The general rule was said to be that all lands within a parish are subject to tithes, and a layman was not allowed to prescribe generally that his lands were exempt; but he had to show a special exemption, and no length of possession was regarded in law in view of the maxim nullum tempus occurrat ecclesiæ, although equity did take account of it. The tithes in places extra-parochial, e.g. forest lands, belong to the Crown, although by canon law they were to be disposed of by the bishop; but by custom a parson or vicar might be entitled to them. The tithes of titheable cattle pasturing in any waste or common ground, wherever the parish is not certainly known, were made payable to the parish of the place where the cattle dwell by a statute of Edward VI. Tithes were classified according to their nature as praelical, or

7 C. viii. § 2; Tithes had to be made by Æthelwulf in 855, to which the general payment of tithes in England has been commonly traced, appears not to rest on satisfactory evidence.
arising immediately from the ground, e.g. grain of all sorts, hay, wood and the like; mixed, or arising from things immediately nourished by the ground, e.g. colts, lambs, eggs and the like; or personal, namely, of profits arising from the honest labour and industry of men, had existed, given part against another gain, e.g. fishing, mills and the like; or according to value, as great, e.g. corn, hay and wood; or little, which embraced all others. Of common right tithes were only payable of such things as yield a yearly increase by the act of God, and generally only once a year. They were not payable of the following, except by custom: things of the substance of the earth, such as coals, minerals, turf and the like; things ferae naturae, such as fish, deer and the like; things tame, such as fowls, hounds or fish kept for pleasure or curiosity; barren land, until it is converted into arable or meadow land, and, has been so for seven years; forest land, if in the hands of the king or his lessee, unless disafforested; a park which is dispaarked; or glebe land in the hands of the parson or vicar, which was mutually exempted from payment by the one to the other, but not if in the hands of the vicar's lessee. Another exception to the incidence of tithes were abbey lands. These were exempted generally by Pope Pascal II. while in the hands of their owners, but the privilege was restricted by Pope Adrian IV. in the time of Henry II. to the three religious orders of Cistercians, Templars and Hospitalers (to whom, as leading on the profession of the religious order, they might have been actually so or not, were presumed to be exempt; and a further exemption was created by parsonages coming into the same hands as tithable lands, which lasted so as such union continued.

A further exemption from tithes was given by an act of 1832 (2 & 3 Will. IV. c. 100), which fixed a period of prescription against claims of tithes by laymen or corporations aggregate, of thirty years during which there had been no payment of tithes or a mode of apportionment of the ground, in the absence of contrary evidence, and in any case of sixty years against exceptions sole, of sixty years or the tenures of two successive incumbents and three years after the entry of a third. The tithes which came into lay hands by the dissolution of the religious houses and the previous suppression of alien priories by Henry V. became in all respects incorporeal freehold property. Under the Limitation Act of 1832 twenty years of adverse possession of an estate in tithes gave a good title, except as against spiritual or ecclesiastical corporations sole whose right to recover tithes was limited, if at all, to a period of two incumbencies and sixty years after their ordination.

Tithes were generally recovered by a writ against the owner of the tithable property usually brought in the ecclesiastical courts (questions of title to tithes being reserved to the temporal courts), the jurisdiction of which in this respect was confirmed by the statutes Circumspecte agatis (13 Edw. I.), Articuli cleri (6 Edw. II.), and others of Henry VIII. and Edward VI., and was enforced by ecclesiastical censures and the writ De excommunica capiendo; and an act 2 & 3 Edw. VI. made any person refusing to set out tithes liable to pay double the value in the ecclesiastical court or treble in a common law court. Tithes of small amount or due from Quakers could be recovered by summary proceedings before justices under statutes ranging from William III. to Victoria. Tithes could also be sued for in equity, especially the equity side of the exchequer. A custom also sprang up, and was common at the time of the Commutation Acts, for a tithe-owner to accept a fixed sum of money or fixed quantity of the goods tithable in place of the actual tithes, known as a modus de capitatione, whether in respect of a whole parish or only of particular lands within it; and this modus was fixed for in the negotiable condition of the land, and could also file bills of sale to establish a modus against a tithe-owner. In the City of London there were customary tithes; in other towns and places there were compositions for tithes which were confirmed by local acts of parliament; and according to a return presented to the House of Commons in 1831, there were passed between 1757 and 1830 no less than 2000 local acts containing clauses for the commutation of tithes. Enclosure Acts often gave a portion of the lands enclosed to the spiritual or lay rector and exempted the rest from tithes; and in other local acts a similar arrangement was made. Exception, however, where made under parliamentary authority, no composition for tithes, although made between the landowner and the parson or vicar with the consent of the patron and ordinary, bound a succeeding incumbent, the statute 15 Eliz. c. 10 prohibiting any parson or vicar from making any conveyance of (inter alia) tithes, being parcel of the possessions of their churches, to any persons, except leases for twenty-one years or three lives.

2. The principle of the Tithes Commutation Acts 1836-1839 was to make the tax upon ground the tithes which had been only partial or temporary (in most cases), After the and to "substitute a corn rent (known as a tithe rent charge), permanent in quantity and payable in money, but fluctuating for all, whether payable under a modus or composition or not, which may have heretofore belonged either to ecclesiastical or lay persons" (Phillimore, Eccles. Law, li. 1161).

Commissioners (now the board of agriculture) are appointed to execute the acts; a rent charge on all lands liable to tithes at the time of the passing of the first act is substituted for those tithes, the extent of which is fixed either by the respective parishes, or by a parochial agreement, or, failing that, by compulsory award confirmed by the commissioners; and the value of the tithes is fixed in the latter case by their average value in the particular parish during the seven years preceding Christmas 1835, without deduction for parochial or county and other rates, charges and assessments falling on tithes, the rent charge being liable to all the charges to which tithes were liable. The rent charge is apportioned on all the lands liable in the parish, and such apportionment may be altered or a new one made; and the value of the rent charge is fixed at the value at the time of confirmation of the apportionment, or as a greater number of the tithe owners agreed, the average price of a bushel of wheat, barley and oats as the same would have purchased at the prices so ascertained by the advertisement (of prices of corn) to be published immediately after the passing of the act 6 & 7 Will. IV. for the years one before the passing of the act, the average price of wheat, one-third part in the purchase of barley, and the remaining third part in the purchase of oats; and the respective quantities of wheat, barley and oats so ascertained shall be stated in the draft of every apportionment. The price at which the conversion from money into corn is to be made at the time of confirmation of such apportionment, according to the provisions of the said act, are 7s. 6d. for a barrel of wheat, 3s. 11d. for a bushel of barley and 2s. 9d. for a bushel of oats (7 Will. IV. and 1 Vict. c. 69); the average price of the bushel of each grain is now computed by substituting for the "advertisement" above the statement of the average price of a bushel of each grain at the average price of the imperial bushel of British corn fixed under the Corn Returns Act 1882; and thus the value of the statutory amount of corn is now fixed for each year at the beginning thereof at the average price of the three components of corn for the previous year in the United Kingdom. The exact apportionment in value may be gathered from the fact that for 1902 the price of the wheat bushel is thus fixed at 35s. 10½d., that of the barley bushel at 35s. 0½d. and that of the oats bushel at 25s. 10½d.

As already indicated above, certain lands are exempt from payment of tithes while in the occupation of their owners, either by reason of their having been parcel of the possessions of any privileged ecclesiastical corporation or by reason of the tenure of ancient demesne and exempt whilst in the tenure, occupation or manorship of the Crown, its tenants, farmers and lessees or under-tenants, although they are subject to tithes when alienated or occupied by subjects of another realm; and in all cases in which the tenure of such owners, a fixed rent charge may be substituted for any contingent rent charge imposed on them (2 & 3 Vict. c. 62; 3 & 4 Vict. c. 15; now repealed except as to tithes not commuted). In certain cases where commutation of tithes for rent charge is, the ordinary
way was impracticable, e.g. in the case of Llanmas lands or in the case of common lands, power was given to charge a fixed sum or rate per head of the cattle there pasturing, with an exception in the case of Llanmas lands which for seven years before Christmas 1835 had paid a fixed rate. As a result of this, a common landlord, respecting a common appurtenant on the allotment made in respect of the lands to which such right of common attached (2 & 3 Vic. c. 62; 3 & 4 Vict. c. 151; 9 & 10 Vict. c. 73). By an act of 1860 (25 & 26 Vict. c. 93) a gross rate was levied upon the landholders; certain rights were charged for at a fixed sum per head; a gross rent charge made payable in respect of the tithes of a gated or stinted pasture rated to the undivided hereditament, and certain other charges, &c., were imposed in the method prescribed by the other Tithe Acts; a rent charge on commons may be commuted for part of the land or redeemed, if the landowners and persons liable for tithe so agree; and upon expiry of the commutation period, the occupier may be paid out of any tithe fund from the lands allotted. These rent charges are not subject to the Tithe Act of 1891. This act of 1860 also gave power to convert the corn rents established under local acts into rent charges.

In the case of hop-gounds, orchards, fruit-plantations and gardens power was given to the commissioners to value them separately, according to the average rate of composition for the particular land, and to fix an extraordinary charge for tithes thereof, the former for such lands going out of cultivation, the latter for such as were there afterwards cultivated: lands subject to the latter were exempted during the first three years of cultivation; and such lands were only subject to it if situated in a parish in which an extraordinary charge had been distinguished at the time of commutation (6 & 7 Will. IV. c. 71; 2 & 3 Vic. c. 62; & 4 Vict. c. 151; 24 & 25 Vict. c. 93; 36 & 37 Vict. c. 73). Such an extraordinary charge shall be levied on any such grounds so newly cultivated in future; the capital value of the existing charges was assessed, and the interest of the landowners was payable in advance in addition to all the other charges until its redemption, and in recoverable in the same way as ordinary rent charge and exempt from all rates, charges and assessments; the charge was redeemable at any time after the expiration of twenty years, and not recoverable by order of the county court, whatever its amount may be: if the land is occupied by the owner, the order is executed by the same means as those prescribed in the Tithe Acts; but if it is not, then by a receiver being appointed for the rents and profits of the land: neither landlord nor occupier is personally liable for payment; and appeal lies to the High Court on points of law; and a remission of rent charge may be claimed when its amount exceeds two-thirds of the annual value of the land. The act does not apply to the particular kinds of rent charges mentioned above.

The Tithe Acts do not apply to the city of London, which has always had its own peculiar customary payment regulated by episcopal constitutions of 1 Hen. III. and 13 Ric. II. and statutes of Henry VIII., confirming a decree of the privy council, under which the rate of tithes was fixed at 16d. for every 10s. rent, and at 2s. 9d. for every 20s. rent of houses, shops and the like by the year. Provision was made by statute after the fire of London for certain annual tithes to be paid in parishes whose churches had been destroyed, and there have been local acts from time to time with regard to particular parishes therein.

### Tithing

**Tithing** (for tithe, tenth; Lat. decima), formerly a unit of local administration in England. In some districts the men who were bound to be in frankpledge (q.v.) were grouped in associations of ten, twelve or more individuals called tithings. When a person who was accused of any crime was not forthcoming, inquiry was made whether he was in frankpledge; if he were not, and had no right of exemption, the township was amerced, but if he were in a tithing, then it was upon the tithing that the amercement fell. Each tithing was divided into ten districts normally identical with the township which discharged the duties of the frankpledge. Some townships, however, contained more than one tithing. There are also indications that in the ancient kingdom of Mercia the tithing was originally a district and not a mere association of persons; but in Northumbria it is doubtful whether the system of frankpledge and tithing, either personal or territorial, was ever established. If, as seems likely, the territorial tithing is older than the personal, each territorial hundred (q.v.) was probably divided into ten tithings.

**Tithonus,** in Greek legend, according to Homer son of Laomedon, king of Troy and husband of Eos (the morning). In the Homeric Hymn to Aphrodite, Eos is said to have carried him off because of his great beauty. She entreated Zeus that he might live for ever; this was granted, but she forgot to ask
for immortal youth for him. He became a hideous old man; Eos then shut him up in a chamber; his voice "flowed on unceasingly, but his limbs were helpless. A later development is the change of Tithonus into a grasshopper, after Eos had been obliged to wrap him like a child in swaddling-clothes and to put him to sleep in a kind of cradle. He was probably associated with the Trojan royal house, since the inhabitants of the original home of the legend (probably central or northern Greece) looked upon the East, the land of the morning, as the home of Eos. In some versions she is said to have carried him away still farther East, to the land of Ethiopia near the ocean streams; this is euhemeristically referred by Diodorus Siculus to an expedition undertaken against Ethiopia by Titonus, son of Laomedon.

It is probable that Tithonus was originally a sun-god; the scholar on Itiad, xi. 5, who calls him Titon, identifies him with Apollo, and there are many points of resemblance between him and the sun-god Helios. The story is generally regarded as an allegorical representation of the fresh morning sun dried up by the heat of the advancing day. Possibly it is merely intended as a warning to mortals not to unite with immortals, lest they incur the jealousy and wrath of the gods.

See Homer, Itiad, xi, x. 237; Hymn in Venerem, 219 sqq., with Allen and Silva's notes; Apollodorus ii. 13. 4; Diod. Siculus iv. 75.; Horace, Odes, i. 16. 30; Propertius iii. 18; O. Gruppe, Griechische Mythologie, l. 374, n. 16, who attributes a Miletian origin to the story.

In the 15th century "La Divina." The country of Cadore, in the Friuli, barren and poor, is watered by the Piave torrent poured forth from the Carnic Alps, and is at no great distance from Tirol. Titian, therefore, was not in any sense a Venetian of the lagoons and Adriatic, but was native to a country, and a range of association, perception and observation, of a directly different kind. Venice and the Alpine Friuli are as remote from the birth of Titian; and Cadore, having to choose between Venetian and imperial allegiance, declared for the former. Approaching the castle of Cadore from the village of Sotto Castello, one passes on the right a cottage of humble pretensions, inscribed as Titian's birthplace; the precise locality is named Arsenale. The near mountain—all this range of hills being of dolomite formation—is called Marmarolo. At the neighbouring village of Vallo was fought in Titian's lifetime the battle of Cadore, a Venetian victory which he recorded in a painting. In the 15th century this was the haunt of turkeys' feather-courts, and the court also of Cadore. He was called Guecello; and this name descended in 1321 to the podestà (or mayor) of Cadore, of the same stock to which the painter belonged. Titian, one of a family of four, and son of Gregorio Vecelli, a distinguished councillor and soldier, and of his wife Lucia, was born in 1477. So it has very generally been stated; but of late years a subsequent date, 1485–1490, has been suggested, so as to make Titian, at the time of his death, not so singularly long-lived a man. As to this interesting point one should remember that Vasari in one passage (at variance with some others) says that Titian was born in 1469; but according to this dating to Philip II. in 1571, he is to be counted a fifty-five-year-old man. It is to be said that Titian, when a child, painted upon the wall of the Casa Sampieri, with flower-juice, a Madonna and Infant with a boy-angel; but modern connoisseurs say that the picture is a common work, of a date later than Titian's decease. He was still a child when sent by his parents to Venice, to an uncle's house. There he was placed under an art teacher, who may perhaps have been Sebastiano Zuccato, a mosaicist and painter now forgotten. He next became a pupil of Gentile Bellini, whom he left after a while, because the master considered him too offhand in work. Here he had the opportunity of studying many fine antiques. His last instructor was Giovanni Bellini; but Titian was not altogether satisfied with his tutoring. The youth was a contemporary of Giorgione and Palma Vecchio; when his period of pupilage expired, he is surmised to have entered into a sort of partnership with Giorgione. A fresco of "Hercules" on the Morosini Palace is said to have been one of his earliest works; others were the "Virgin and Child," in the Vienna Belvedere, and the "Visitation of Mary and Elizabeth" (from the convent of S. Maria dell' Orto and in the Venetian Academy. In 1507–1508 Giorgione was commissioned by the state to execute frescoes on the re-erected Fondaco de' Tedeschi. Titian and Morto da Feltre worked along with him, and some fragments of Titian's paintings, which are reputed to have surpassed Giorgione's, are still discernible. According to one account, Giorgione was nettled at this superiority, and denied Titian admittance to his house thenceforth. Stories of jealousies between painters are rife in all regions, and in none more than in the Venetian—various statements of this kind applying to Titian himself. One should not accept nor reject them uncritically; counter-evidence of some weight can be cited for Vecelli's vindication in relation to Moreni, Correggio, Lotto and Coello. Towards 1511, after the cessation of the League of Cambridge—which had endeavoured to shatter the power of the Venetian republic, and had at any rate succeeded in clipping the wings of the lion of St. Mark—Vecelli went to Padua, and painted in the Scuola di S. Antonio a series of frescoes, which continue to be an object of high curiosity to the students of his genius, although they cannot be matched against his finest achievements in oil-painting. Another fresco, dated 1523, is "St Christopher carrying the Infant Christ," at the foot of the steps in the ducal palace of Venice. From Padua Titian in 1523 returned to Venice; and in 1553 he obtained a brother's patent in the Fondaco de' Tedeschi (state-warehouse for the German merchants), termed "La Sanseria" or "Senseria" (a privilege much coveted by rising or rising artists), and became superintendent of the government works, being especially charged to complete the paintings left unfinished by Giovanni Bellini in the hall of the great council in the ducal palace. He set up an atelier on the Grand Canal, at S. Samuele—the precise site is unknown—and many of the finest works of Titian were executed by his pupils, of Bellini, that he came into actual enjoyment of his patent, at the same date an arrangement for painting was entered into with Titian alone, to the exclusion of other artists who had heretofore been associated with him. The patent yielded him a good annuity—120 crowns—and exempted him from certain taxes—he being bound in return to paint likenesses of the successive doges of his time at the fixed price of eight crowns each. The actual number which he executed was five. Titian, it may be well to note as a landmark in this all but centenarian life of painting. Another fresco, dated 1531, is "The Assumption of the Madonna," on the wall of the church of the Frari, one of his most world-renowned masterpieces, the "Assumption of the Madonna," now in the Venetian Academy. It excited a vast sensation, being indeed the most extraordinary piece of colourist execution on a great scale which Italy had yet seen. The signoria took note of the facts and did not fail to observe that Titian was neglecting his work in the hall of the great council. The doge now at the height of his fame; and towards 1521, following the production of a figure of "St Sebastian" for the papal legate in Brescia (a work of which there are numerous replicas), purchasers became extremely urgent for his productions. In 1525, after some irregular living and a consequent fever, he married a lady of whom only the Christian name, Cecilia, has come down to us; he hereby legitimized their first child, Pomponio, and two (or perhaps three) others followed. Towards 1526 he became acquainted, and soon exceedingly intimate, with Pietro Aretino, the literary brave, of influence and audacity hitherto unexampled, who figures so strangely in the chronicles of the time. Titian sent a portrait of him to Gonzaga, duke of Mantua. A great affliction befell him in August 1530 in the death of his wife. He then, with his three children—one of them being the infant Lavinia, whose birth had been fatal to the mother—removed to a new home and got his son Orsa to
come from Cadore and take charge of the household. The pension, difficult now to find, is in the Birli Grande, then a fashionable suburb, being in the extreme end of Venice, on the sea, with beautiful gardens and a look-out towards Murano. In 1552 he painted in Bologna a portrait of the emperor Charles V., and was created a count palatine and knight of the Golden Spur, his children also being made nobles of the empire—for a painter, honours of an unexampled kind.

The Venetian government, dissatisfied at Titian's neglect of the work for the ducal palace, ordered him in 1558 to refund the money which he had received for time unoccupied; and Foppone, his formidable rival of recent years, was installed in his studio. This was a year or two after the death of Titian, who had meanwhile applied himself diligently to painting in the hall the battle of Cadore, was reinstated. This great picture, which was burned with several others in 1577, represented in life-size the moment at which the Venetian captain, D'Alviano, fought the enemy, with horses and men crashing down into the stream. Fontana's engraving, and a sketch by Titian himself in the gallery of the Uffizi in Florence, record the energetic composition. As a matter of professional and worldly success, his position from about this time may be regarded as his. That he was more than a painter is more than evident in his relations with Raphael, Michelangelo, and at a later date Rubens. In 1540 he received a pension from D'Alvino, marquis del Vasto, and an annuity of 200 crowns (which was afterwards doubled) from Charles V. on the treasury of Milan. Another source of profit—for he was always sufficiently keen after money—was a contract, obtained in 1542, for supplying grain to Cadore, which he visited with regularity almost every year, and where he was both generous and influential. This reminds us of Shakespeare and his relations to his birthplace, Stratford-on-Avon; and indeed the great Venetian and the still greater Englishman had something of the same inspiration and performance, and in the personal tendency of each to look after practical success and "the main chance" rather than to work out aspirations and pursue ideals. Titian had a favourite villa on the neighbouring Manza Hill, from which (it may be inferred) he made his chief observations of landscape form and effect. The so-called "Titian's mill," constantly discernible in his studies, is at Collolonto, near Belluno (see R. F. Heath's Life of Titian, p. 3). A visit was paid to Rome in 1546, when he obtained the freedom of the city, his immediate predecessor in that honour having been Michelangelo in 1537. He could at the same time have succeeded the painter Fra Sebastiano in his lucrative office of the plombo, and he made no scruple of becoming a friar for the purpose; but this project lapsed through his being summoned away from Venice in 1547 to paint Charles V. and others, in Augsburg. He was there again in 1559, and executed the portrait of Philip II., which was sent to England and proved a potent auxiliary in the suit of the prince for the hand of Queen Mary. In the preceding year Vecelli had advanced his daughter Lavinia, the beautiful girl whom he loved deeply and painted various times, to Cenello Sarcinelli of Serravalle; she had succeeded her aunt Ora, now deceased, as the manager of the household, which, with the lordly income that Titian made by this time, was placed on a corresponding footing. The marriage took place in 1554. She died in childbirth in 1560. The years 1551 and 1552 were among those in which Titian worked least assiduously—a circumstance which need excite no surprise in the case of a man aged about seventy-five. He was at the Council of Trent towards 1555, of which his admirable picture or finished sketch in the Louvre bears record. He was never in Spain, notwithstanding the many statements which have been made in the affirmative. Titian's friend Arcinio died suddenly in 1556, and another close intimate, the sculptor and architect Jacopo Sansovino, in 1570. With his European fame, and many sources of wealth, Vecelli is the last man one would suppose to have been under the necessity of writing querulous and dunning letters for payment, especially when the defaulter addressed was lord of Spain and of the American Indies; yet he had constantly to complain that his pictures remained unpaid for and his pensions in arrear, and in the very year of his death (February) he recites the many pictures which he has within the preceding twenty years without receiving their price. In fact, the ground for thinking that all his pensions and privileges, large as they were nominally, brought in but precarious returns. It has been pointed out that in the summer of 1566 (when he was elected into the Florentine Academy) he made an official declaration of his income, and put down the various items apparently below their value, not naming at all his salary or pensions. Possibly there was but too much reason for the omission.

In September 1565 Titian went to Cadore and designed the decorations for the church at Pieve, partly executed by his pupil, the former in the palace of the prince of the ancient family Morosini. In 1568 the Franciscans of the church of Santa Maria del Rosario (now in S. Salvatore, Venice), inscribed "Titianus fecit," by way of protest (it is said) against the disparagement of some persons who cavilled at the veteran's failing handicraft. He continued to accept commissions to the last. He had selected as the place for his burial the chapel of the Crucifix in the church of the Frari; and, in return for a grave, he offered the Franciscans a picture of the "Pieta," representing himself and his son Orazio before the Saviour, another figure in the composition being a sibyl. This work he nearly finished; but some part of it was subsequently (and by himself) added, so that the young Titian is involved in his native Pieve. Titian was ninety-nine years of age (more or less) when the plague, 1 which was then raging in Venice, seized him, and carried him off on the 27th of August 1576. He was buried in the church of the Frari, as at first intended, and his "Pieta" was finished by Palma Giovane. He lies near his own famous painting, the "Madonna di Casa Pesaro." No memorial marked his grave, until by Austrian command Canova executed the monument so well known to sightseers. Immediately after Titian's own death, his son and pictorial assistant Orazio died of the same epidemic. His sumptuous mansion was plundered by the plague, thieves, who prowled about, scarce controlled.

Titian was a man of correct features and handsome person, with aristocratic gifts of penetrating observation and self-possessed composure—a Venetian presence worthy to pair with any of those "most potent, grave and reverend signors" whom his pencil has transmitted to posterity. He was highly distinguished, courteous and winning in society, personally unassuming, and a fine speaker, enjoying (as is said by Vasari, who saw him in the spring of 1566) health and prosperity unequalled. The numerous heads currently named Titian's Mistress might dispose us to regard the painter as a man of love and pleasure; but all this is not only refuted in every statement of his life, but that these titles are mere fancy-names, and no inference one way or the other can be drawn from them. He gave splendid entertainments at his palace; and for the coming of Henry III. of France passed through Venice on his way from Paris to his imperial chair, he called on Titian with a train of nobles, and the painter presented him as a gift with all the pictures of which he inquired. He was a man of much learning and accomplishment, like Leonardo da Vinci and Michelangelo; his one great and supreme endowment was that of painting.

Ever since Titian rose into celebrity the general verdict has been that he is the greatest of painters, considered technically. In the first place neither the method of fresco painting nor work of the colossal scale to which fresco painting ministers is here in question; Titian, as province is that of oil painting, and of painting in a scale which, though often large and grand, is not colossal either in dimension or in inspiration. Titian may properly be regarded as the greatest manipulator of paint in relation to colour, tone, nuance, richness, texture, surface and harmony, and with a view to the production of a pictorial whole conveying to the eye a true, dignified and beautiful impression of its general subject-matter and of the objects of sense which form its constituent parts. Titian, as province is that of the essentially natural scheme of composition, another and essentially in painting, nor can one forecast the time in which he will be deposed. For the complex of qualities which we sum up in the words colour, handling and general force and harmony of effect, he stands unapproached. Though items in Titian's work may be superseded—indeed, not to speak of creative invention—some painters, one in one respect and another in another, may indisputably be preferred to him. It is impossible to point to that one work of the Venetian school of which the first masterpieces are due to the two Bellini, to Carpaccio; and, with more fully developed suavity of manner, to Giorgione. Pre-eminent inventive power or subtlety

1 Out of a total population of 190,000 there perished at this time 50,000.
of intellect he never evinced. Even in energy of action and more especially in majesty or influence of composition the palm is not his; it is (so far as concerns the Venetian school) assignable to Tintoretto. Titian is a painter who by wondrous magic of genius and feeling, he puts in touch with the eye, and through the eye the feelings—sometimes the mind.

Titian's pictures abound with memories of his home-country and of the region which led from the hill-summits of Cadore to the quiet vale of the Po. His palette is that of the poet. All his painting is fresh, he exhibits an appreciation of mountains, mainly those of a turreted type, exemplified in the Dolomites. Indeed he gave to landscape great form and character. Titian's early landscapes exhibit the objects of nature and their control over the sentiments and imagination with a force that had never before been approached. The earliest Italian picture expressly designated as "landscape" was one of the "Vestali" which he painted in 1565, and his fame was immense, even when we allow for the abnormal length of his professional career. In Italy, England and elsewhere more than a thousand pictures figure as Titian's; of these about 250 may be regarded as dubious or spurious. There are, for instance, the portraits in the National Gallery, London, 18 in the Louvre, 16 in the Piti, 18 in the Uffizi, 7 in the Naples Museum, 8 in the Venetian Academy (besides the series in the private meeting-hall) and 41 in the Museum. In the National Gallery, other works used to be assigned to Titian, but are now regarded rather as examples of his school.

Naturally a good deal of attention has been given by artists, critics and collectors to the study of Titian's landscapes to obtain such astonishing results in colour and surface. The idiosyncrasy of this research is but meagre; the secret seems to be not so much in these qualities as in the skill with which he worked with the brush dipped in a brown solution, and then altered and worked up as his intention developed. The later paintings were touched off rapidly, telling well from a distant view. He himself avowed that "he knew no better art in the world than to paint in art; and in his very last days he said—certainly with the modesty of genius, perhaps also with some of the tenacity of age—that he was then beginning to understand what painting meant. In his old age he entered the garment of colour rests mainly upon red and green, in the later ones upon deep yellow and blue. The pigments which he used were nothing unusual; indeed they were both fresh and cheap. Palladium. He was to possess them as well as the reds; and the copper, he was to use them in his final operations he had often more with finger than with brush. It has been said, and probably with truth, that he tried to emulate Palma Vecchio in softness as well as Giorgione in richness. Michelangelo's verdict after inspecting the picture of "Christ in the Main of Gold," executed in 1546, has often been quoted. He said, "That man would have had no equal if art had done as much for him as nature." He was thinking principally of severity and majesty of thoughtfulness, for he added, "Pity that in Venice they don't learn how to draw well." As a draughtsman of the human figure Titian was not only competent but good and fine, and he is reported to have said that he could draw a human figure in any position that he felt not a little short of the standard of Michelangelo, and even of other leading Florentines. He was wont to paint in a nude figure with Venetian red, supplemented by a little lake in the contour and sometimes augmented by. some artificial contour. His other works bear evidence to manipulate white, black and red, and that the carnations cannot be done in a first painting, but by replicating various tints and mingling the colours. He invented a "method of succession in the stroke of colour as applied to draperies—working on the principle (in which Giorgione may perhaps have forestalled him) that red comes forward to the eye, yellow retains the rays of light, and blue assimilates to shadow. In his subject-pictures the figures are not very numerous, and the attitudes are mostly reserved; even in bacchanals, or battles the athletic display has more of facility than of fury. His architectural scenes were sometimes executed by other persons, especially of the celebrated family of Giambono; and the passionate ardour of early sundown, was much affected by Titian in the lighting of his pictures. Generally it may be said that he took great pains in completing his works, although the temper of his using the brush, a hard-harsh hand he had little liking for teaching, partly from distaste of the trouble, and partly (if we are to believe biographers) from jealousy. He was quite willing, however, to take to a workshop when the work was going out of doors he would leave his studio open, so that the pupils had a clandestine opportunity of copying his works, and if the copies proved of salable quality he would buy them cheap, touch them up.

Titian's family relations appear to have been happy, except as regards his eldest son, Pomponio. This youth, at the age of six, was launched upon the ecclesiastical career; but he proved wasteful and prodigal, was turned off by the church, and at last obtained the transfer to a nephew of a benefice destined for Pomponio. The fortune which he left was, after his decease, squandered by the tissued prodigal. The other son, Orazio, born towards 1528, who (as we have seen) assisted Titian professionally, became a portrait-painter of mark—some of his likenesses, almost comparable with Titian's own, being often confounded with his by owners and connoisseurs. He executed an important picture in the year 1605, the "Entombment of Christ," which, if not of the same time which might have been bestowed upon painting. Several other artists of the Vecelli family followed, in the wake of Titian. Francesco Vecelli, his elder brother, was initiated into the art of painting probably by his father (but chronology will hardly admit of this), and painted in the church of S. Vito in Cadore a picture of the titular saint armed. This was a mark of dedication, and a very profane and carnal practice; so Francesco was diverted from painting to soldiering, and afterwards to mercantile life. Marco Vecelli, called Marco di Tiziano, Titian's nephew, born in 1545, was constantly with him in his old age. The celebrated painter died in a hospital in 1620, and in 1621 his brother Francesco. Marco called Tiziano (or Tizellino) painted early in the 17th century. From a different branch of the family came Fabrizio di Fettore, a painter who died in 1586. His brother Cesare, who also left some pictures, is well known by his book of engraved costumes "Arbini antichi e moderni." Tommaso Vecelli, also a painter, died in 1620. There was another relative, Girolamo Dante, who, being a scholar and assistant of Titian, was called Girolamo di Tiziano. Vincenzo Correr was probably his pupil. He was found it difficult to distinguish from originals. Apart from members of his family, the scholars of Titian were not numerous; Paris Bordone and Giovanni Battista Tintoretto were counted the most important. Francesco Torelli (Theotocopuli) was employed by the master to engrave from his works. It is said that Titian himself engraved on copper and on wood, but this may well be questioned.

We have seen that Titian was a prodigal in his expenditure of his individual works, taking them in approximate order of time, and merely dividing portraits from other pictures. Details already given indicate that he did not exhibit any extreme precocity; the earliest works which we proceed to mention may date towards 1505. In the chapel of S. Rocco, Venice, is his "Christ Carrying the Cross," now greatly dilapidated; it was an object of so much popular devotion as to produce offerings with which it is now enveloped. The first exhibition of his works in the scuolo is his "Man of Sorrows." The nobly beautiful picture in the Villa Borghese in Rome, commonly named "Divine and Human Love" (by some, "Artless and Sated Love"), bears some resemblance to the "Christ and the Pharisais," but the sitter that goes that Titian was enamoured of Palma's daughter; but nothing distinct on this point is forthcoming. The "Triste Money" ("Christ and the Pharies"), now in the Dresden Gallery, dated towards 1508; Titian is said to have painted this highly finished yet not yet "niggling" picture in order to prove to some Germans that the effect of detail could be produced without those extreme minutiae which mark the style of Albert Dürer. The St. Mark in the church of the Salute—the evangelist enthroned, along with SS. Sebastian, Roch, Cosmo and Damian—a picture much in the style of Giorgione, belongs to 1512. Towards 1518 was painted, also in the same class of work, the "St. George and the Dragon," now in Turin. The picture of Christ, holding the guides of a shepherd on a reed-pipe, two sleeping children, a cupid, an old man with two skulls, and a second shepherd in the distance—one of the most poetically impressive among all Titian's works—was painted in 1512. For another figure of "St. John the Baptist" in the Moldor Museum, showing a statue of Venus, two nymphs, numerous cupids hunting a hare, and other figures. Two of the pictures in the National Gallery, London—the "Holy Family and St Catherine" and the "Noli me tangere"—were going on at much the same time as the great "Assumption of the Madonna." In 1521 Vecelli finished a painting which had long been due to Duke Alphonso of Ferrara, probably the "Bacchanal," with Ariadne doing over her wine-cup, which is now in Madrid. The famous "Bacchus and Ariadne," in the National Gallery was produced for the same patron in 1523. The "Flora of the Uffizi," the "Venus of Parnassus," the "Christ in the Cornfield," and the "Manner of Water Gallery may date a year or so earlier. Another work of 1533 is the stupendous "Entombment of Christ" in the Louvre, whose depth of colour and of shadow stands as the pictorial equivalent of individual facial expression: the same composition, a less admirable work, appears in the Manfrini Gallery. The Louvre picture comes from the Gonzaga collection and from the gallery of Charles I. It is said to have been purchased for the church of SS. Giovanni e Paolo; for this work he bore off the prize in competition with Palma Vecchio and Pordenone. Of all his pictures this was the most dear to him from the action, while it 18 the style of his in the same year. It showed the influence of Michelangelo, who was in Venice while Vecelli was engaged upon it. A calamitous fire destroyed it in 1807; the copy of it which was taken to Naples was sold, and another one to the National Gallery in London. To 1531 belongs also the "Madonna del Coniglio" (Louvre), painted for Gonzaga; and 1536 the "Venus of Florence"; to 1538 the portraits of the "Twelve Caesars" for Gonzaga; and to 1539 the "Presentation of the Virgin in the Temple"—one of the

TITIAN

XCVI. 33

1025
conspicuous examples in the Venetian Academy, yet not of the first interest or importance. About 1540 were done the forcible but rather unsupervised paintings for S. Spirito, Venice, now in the church of the same name. Among them are the "Abraham and the Two Sacrifices," and "David and Goliath"; in 1543 the "Ecce Homo" of the Vienna Gallery, where Aretho figures as Pilate. The "Venus and Cupid," of Florence, the "Venus" of Madrid and the "Supper of Emmaus" in London are among the most important works of this period. In 1544 Titian was summoned to Augsburg in 1547. In 1554 he sent to Philip II. in England a second "Danac" and a "Venus and Adonis." About the same year he painted "St. Charles," at Brussels, in which he himself termed it, "Last Judgment," which represented the emperor, with his family and others, all in shrouds, praying to the Godhead; Moses and various other personages are also portrayed. This painting, which was continued and not fixed until the film of death closed on them. Later pictures, from 1558 onwards, are the "Martyrdom of St. Lawrence," "Christ Crowned with Thorns" (Louvre), Diana and Actaeon, "Diana and Actaeon" (1561), "The Magdalen" (also "The Magdalen of St. Jerome") in the Brera Palace, the "Venus of Medici" in the Uffizi, "Diana in the Garden," and "Europa"—the last six for Philip II.; of the two Diana subjects there are duplicates in London and in Vienna. Philip, it will be observed, was equally a master of nudes and titans with sanctities. The "Jupiter and Antiope," now much restored, is commonly called "La Vénus d’Hano," having at first been in the Pardo Palace. The "Magdalen" here spoken of (1561) seems to have been the first picture to turn the work of Titian, and it is a dulae letters, said that it was the most popular picture he had ever painted. In 1563 Vecelli offered to Philip II. his "Last Supper," which had been in hand for six years; it was cut down in the Escorial to suit a smaller space. A later preparatory work was more noticeable in carefully grouping. The "St Jerome" of the Brera Gallery in Milan, a work of wonderful energy, spirit and force, especially for a more than occasion; it is impossible to say whether the laurel that marked it as a replica of the in Escorial. One of the master’s latest pictures (1574-1575) is in Madrid, and commemorates the "Battle of Lepanto"; it is a work of failing power—but still the power of a Titian. The "Death of Seneca" (Louvre) was bought by the king of France, and is in the Louvre. In Berlin, has a head of the Empress Marie Theresa, and a portrait of her daughter. In the Dresden Gallery, with a jewelled casket in Lord Cowper’s collection; the Cornelio Family (Alnwick Castle); "L’Homme au Gant" (Louvre), an unknown personage, youthful and handsome, the now in the National Gallery, London. Antiope duchess of Urbino, Francesco duke of Urbino, Caterina Cornaro queen of Cyprus (these four are in the Uffizi); Charles V. on horseback (Madrid); Cardinal Bebomo (Naples), discovered in an uncovered—condition in 1878, very unlike the portrait in the Barberini Gallery. The female portraits done by Titian are few, and are almost invariably of women of exalted rank. Of Ariosto, with whom Titian was intimate, there are probably only "having been nothing approaching to a romantic friendship between them, the painter is said to have done three portraits. Much uncertainty, however, besets this matter. One of the three appears as a woodcut in an edited version of Ariosto’s work. Formerly in the Hall, corresponds with the woodcut likeness, and is signed "Titianus F."—a work of admirable beauty; it is now in the National Gallery of London. It is difficult, however, to reconcile the features here with those of the portrait in the Hall (1637). "Ariosto" at the National Gallery is also in the gallery another and singularly beautiful portrait which used to be called "Ariosto" by Titian, then was assumed to be "Ennomus" by Van Noort. Titian, but not as representing a poet. Authorities.—For English readers, the Life and Times of Titian by Crowe and Cavalcaselle (1877) superseded all previous works, such as the earlier work of Sir Hubert in London History, 1859. There is now also the translation (1904) of the monumental German work (1900) by George Gronau, which may be regarded as taking the first place of all. Claude Phillips has brought out two valuable books on Titian. "Titian in the Early Period" and "Titian in the Late," which should be consulted on controversial details. Josiah Gilbert’s book, Cadore, or Titian’s Country (1865), supplies many interesting sides. R. W. Symonds’ monograph (1885) is founded mainly on Crowe and Cavalcaselle and comes of course to form a very convenient compendium.

(W. M. R.)

TITLE (O. Fr. title, mod. titre, from Lat. titulus), an inscription prefixed to a book or other writing, designating the name by which it is to be known, and in many cases indicating the scope of the book or some idea of the nature of its contents. Further, the term is extended to the descriptive heading or caption to a document, such as a deed or other instrument, or to a bill or act of parliament. Another general meaning is that of an appellation of rank (see Titles of Honour, and the articles Emperor, King, Prince, Majesty, Highness, Duke, &c.). In law title is equivalent to the right of ownership. The instruments in writing forming the evidence of title to land are the title-deeds (see Conveyancing; Land Registration). In ecclesiastical usage, the word "title" (titulus) are used of certain churches in Rome to which districts were attached their history being of importance in the evolution of the Roman cardinalate (see Cardinal). It was also used, as now, for a condition precedent to ordination; in the early Roman Church an appointment to officiate in a particular church; this was extended gradually from the idea of locality to that of evidence of means of support. In the Church of England the candidate must have "supernumeraries," or other canons have by their function"; for deacon’s orders he must have a nomination to a curacy, and for priest’s orders either that or a presentation to a living. A fellowship or chaplaincy at the University of Oxford or Cambridge is also a sufficient "title."
companies of the United States; but the pamphlet seems to have been forgotten. The first company actually to undertake the guarantee of real estate titles was formed in Philadelphia, Pennsylvania, in 1876. It differed from the Prussian Mortgage Insurance Company (whence the word "title") in that its business is run by a dealer in, and custodian and guarantor of, mortgages) in which its main business was the issue of a policy of guarantee on a transfer of title to land. The advantages of its method were immediately recognized. Corporations of this kind were established in Washington, Baltimore, Boston and New York, in the order named, and subsequently in nearly every considerable city in the United States.

In order to be independent of the inaccurate and clumsy methods of the public record offices, title guarantee companies generally compile in their own office a copy or digest of all the real estate records of the locality in which they have established a branch for this purpose a staff of skilled clerks. To make the necessary examination of a title prior to the issuing of a guarantee, they require copious documentation and must be experienced real estate lawyers. By these means a title can be examined and guaranteed in a week, whereas thirty or forty days was formerly required. This has done much to make real estate available capital, for individual and corporate lenders on mortgage accept the guarantee of the companies as the best evidence of title, and loans can be had without the delay that once prevailed.

The expense of maintaining the staff of clerks and lawyers is greatly offset by the saving on the gross charges on titles guaranteed. Strictly speaking, the risks outstanding are also large, running up to $100,000,000 a year for a single company in New York City; but in practice the instances in which the losses are very small, not exceeding 2% of the gross charges on titles guaranteed, in that the obligations should scarcely be called risks. In spite of the office expenses, the charges for first bringing a piece of land under the guarantee, and for renewals, are usually very moderate, amounting each time of examination and opinion by counsel, amounting to about one-half of 1% on the value of the property or on the amount of the mortgage; and when once the guarantee has been issued, it is re-issued on a subsequent sale or mortgage on short notice for a small fee.

(T. H. K.)

**TITLES OF HONOUR.** "Those various names of greatness or eminency, which are the most distinguishing titles of civil dignity" (John Selden, *Titles of Honer*, 3rd ed., 1672). This definition covers, if we understand "civil" in its proper and widest sense, all titles, whether official or honorary, civil or military, temporal or ecclesiastical, of which men have been invested with the powers and attributes which are possessed by those who hold titles of honour. In this use of the word, we now understand by titles of honour what Selden calls "honorary titles," i.e. distinctive designations implying rank and dignity, not office or vocation. The broader definition would cover all titles, including those of military and ecclesiastical rank, of municipal office and of university degrees. The narrower definition, which it is proposed to adopt for the purposes of this article, would cover only what in the United Kingdom are known as the "titled classes," which embraces only those whose titles are meaningless save as a mark of rank. In this category it is, however, necessary to include, somewhat illogically, the highest titles of all—those of "kings," which are no more than others were in the habit of paying to the office expenses,

Throughout the eighteenth century various subtile hypotheses were advanced alleging that the titles of all the sovereigns of Europe were derived from certain Roman dignitaries, or from the Roman and the Frankish Emperors. In the French Revolution, the abolition of all aristocratic titles has been proposed as a means of abolishing all distinction of titles, and the restoration of a commonality of all the persons in the society. This was the object of the *pamphlet* of 1792, "Les titres de noblesse," which gave rise to the *Dictionnaire de la Noblesse* (1793). In the French Revolution, the abolition of all aristocratic titles has been proposed as a means of abolishing all distinction of titles, and the restoration of a commonality of all the persons in the society. This was the object of the *pamphlet* of 1792, "Les titres de noblesse," which gave rise to the *Dictionnaire de la Noblesse* (1793).

1 Many proper names are but primitive titles in disguise: e.g. Henry (q.v.) = "ruler of the home," or Walter = "lord of power."
devising new forms. It was not until the 17th century that they became fixed, under the influence mainly of the newly organized international diplomatic service (see DIPLOMACY). But meanwhile they had developed from the simplicity of the early feudal age into a Byzantine pomposity, the exuberance of which bored even the ceremonious court of Spain into a free use of the pruning knife. Honorary styles are, for the rest, now mere stereotyped formulas; the words that compose them have— to use Emerson's phrase—" polarized " and deprived of meaning. Not otherwise could a German journalist, late in the 19th century, have recorded, without exciting surprise, that " to-day their All-highest majesties went to church to confirm the baptism of their highest blood. "

The title "sir" is the English equivalent of the Latin term "sirius," a rare form of the word "sire," now more common in the form "sheriff." Other noble titles are generally of Latin origin, like earls, viscounts, and barons, though "knight," also of Latin origin, has developed somewhat in the English language to mean "man of honor." Titles are also used to denote the rank of officers in the army, navy, or air force. The word "major," for example, comes from the Latin "marius," meaning "soldier," and "general" comes from the Latin "generalis," meaning "leading." Titles are also used to denote the rank of officers in the army, navy, or air force. The word "major," for example, comes from the Latin "marius," meaning "soldier," and "general" comes from the Latin "generalis," meaning "leading." Titles are also used to denote the rank of officers in the army, navy, or air force. pequely aristocratic virtue ascribed by Lord Palmerston to the most Noble Order of the Garter: "There is no damned merit about it;" it has the crowning quality that it must needs be the monopoly of the few. Hereditary titles sink in value, indeed, just in proportion as they become common. In the United Kingdom their value has been kept up by the rule of primogeniture: there can be only one hearer of such a title in a single generation. In France custom distributes the various titles of a family among all the sons, the eldest son, for instance, of a duke inheriting his dukedom, the second son his marquisate, the third son his barony, and so on, until the title pass to all the sons in each successive generation, though in Prussia the rule of primogeniture has been introduced in the case of certain new creations (e.g. Fürst, prince). The result is that equivalent titles vary enormously in social significance in different countries. An attempt has been made to estimate the extent of this variation in the case of individual titles in articles devoted to them. Here we need only illustrate the argument by one striking example. The Russian title of "prince" (knyaz) implies undoubted descent from the great regal houses of Russia, Poland and Lithuania; but the title descends to all male children, none of whom is entitled to represent it par excellence. There may be three or four hundred princes bearing the same distinguished name; of these some may be great nobles, but others are not seldom found in quite humble capacities—waiters or dressykh drivers. The title in itself has little social value.

In the countries east of the marches of the old Empire, i.e. Hungary and the Slav lands, existing titles are partly developed from the native tradition (feudal in Hungary, Bohemia and Poland; autocratic and Oriental in Russia and the lands of the Balkan peninsula), partly borrowed from the West, like that of graf (count) in Hungary and graaf in Russia. Just as in autocratic Russia the sole indigenous title of honour (knyaz) is associated with royal descent, so in the Mahomedan East there are, outside the reigning families, no hereditary titles, except that of sheriff, already mentioned. In India the hereditary styles of certain great Mahomedan nobles are exceptions that prove the rule; they represent reigning families whose raj has been absorbed in the imperial government, and they are still reigning princes in the sense in which the heads of German mediatised principalities and of the Austro-Hungarian Empire are styled "Hereditary Monarch," but the titles of Oriental princes follow much the same gradation as those of the West. As caliph (g.v.), or vicar of the Prophet, the Ottoman sultan is in Islam the equivalent of the pope in Roman Catholic Christendom; his imperial dignity is signified by the Persian title of padishah (lord king), his function as leader of a militant religion by the style of "commander of the faithful" (see AMIR). Shah is in Persia the equivalent of king; the style of shah-in-shah, king of kings, recalls the days of the Persian "great king" familiar in the Old Testament. Khan (prince) and amir (commander, lord) are other Eastern sovereign titles. Pasha and bey, originally exclusively military titles, are now used also as civilian titles of honour, but they are not hereditary. When the pashalik of Egypt was made hereditary the situation was ultimately regularized by bestowing on the pasha the Persian title of khedive (g.v.). In the Far East, Japan has adopted a system of titles, based on her ancient feudal hierarchy, which closely corresponds to that of Europe (see JAPAN). China, on the other hand, stands apart in the curious custom of bestowing titles on the ancestors of persons to be honoured, and in making them hereditary only for a limited number of generations (see CHINA: Social Customs). In Europe such ennuminous titles are rendered only in the case of knighthood (see CANNONIZATION).

Of ecclesiastical titles of honour it can only be said that they tend to an even greater exaggeration than those bestowed on secular dignities. The swelling styles of the Eastern patriarchs are relics of the days when Rome, Constantinople, Antioch, Alexandria and Jerusalem were vying with each other for precedence (see CHURCH HISTORY and PATRIARCH). The style

The designation barin (boyarin, boyar) is not, properly speaking, a title, but the equivalent of "gentleman."
of the bishop of Rome, who alone in the Western Church retains the name of pope, includes the old Roman titles of pontificis maximus and pater patriae, and always in his signatures the proudly humble phrase "slave of the slaves of God" (serves servorum Dei), based on Matt. xx. 27 (see PONTIFEX). Of ecclesiastical titles those expressing orders and no more—priest, deacon, sub-deacon—and the rest—are never honorary (Prior[p] John, q.v., is a shadowy medieval exception). Those expressing office, whether in the Church at large (patriarch, archbishop, &c.) or in the papal court (e.g. protonotary), are often merely honorary. That of bishop even became for a time, after the Reformation, a title borne by certain secular princes (see Bishop). "Cardinal," which with the predicate Eminence (q.v.) is now reserved for the princes of the Roman Church, was at one time the honorary style of the chief clergy of great cathedrals generally (see CARDINAL). "Abbot," the official title of the head of the monastery, has also in several languages (e.g. Icelandic), besides this secular title, an ecclesiastical one (see ARCHDEACON). For the honorary styles of the clergy in the English-speaking countries, see the articles REVEREND, VICAR, RECTOR, CANON, DEAN. As for the archdeacon, it is only in the Church of England that he can be still defined as "one who performs archi-deaconal functions"; elsewhere, if he exists at all, he is purely titular (see ARCHDEACON).

Among titles of honour, finally, may be reckoned honorary degrees bestowed by universities, the pope, and in England by the archbishop of Canterbury. Any degree may be bestowed hono-re causa. The University of Oxford and Cambridge thus regularly below the degree of D.D. (doctor of divinity) on those of their alumni who become bishops. It is also the custom to bestow honorary degrees at the yearly "Commemora-tion" (generally D.C.L., doctor of civil law, at Oxford; L.L.D., doctor of laws, at Cambridge) on a selected list of eminent personages. The right of the archbishop of Canterbury to confer degrees honoris causa, known as "Lambeth degrees," is supposed to be derived from one of his powers as legatus natus of the pope, which survived the Reformation. An attempt was made by some of the Swiss reformers of the 16th century to abolish degrees. They were certainly "popish" in origin, and others besides Herbert Spencer have objected to them as misleading, since they are by no means necessarily a hallmark of learning. They tend, however, to multiply rather than to decrease in number, and in England some criticism has been aroused by the growing custom in certain quarters of assuming degrees (notably that of D.D.) granted corruptly, or for wholly insufficient reasons, by certain so-called "universities," notably in the United States. For a list of the degrees of the principal universities and their hoods, see UNIVERSITIES, ad fin.

The history of many peerage and other titles is outlined in the articles on historic families in this work. For British peerage titles the standard work is G. E. C. (okayne)'s Complete Peerage (1st ed., 8 vols., 1887; new ed., vol. i., 1910). For baronets and others see the manuals of Burke's and Debrett. The standard authority for the royal houses and "high nobility" of Europe is the Almanach de Gotha, published yearly. See also the article NOBILITY, and for further references the authorities attached to those on individual titles, e.g. COUNCIL.

TITMOUSE (O. Eng. missa and passa, Ger. Maus, Sweed. med, Du. mees, Fr. mésange), the name long in use for several species of small European birds, which are further distinguished from one another by some characteristic appellation. These go to make up the genus Parus of Linnaeus, and with a large number of other genera form the Passerine family Paridae. Titmice are usually non-migratory, and the genus Parus occupies most of the globe except South America and the Australian region east of Lombok and Flores.

1 The prefix "fit" by heedless writers often used alone, though equally proper to the titlark (see PRTT), is perhaps cognate with the Greek titos, which originally meant a small chirping bird (Ann. Nat. Hist., ser. i. p. 237). The term is still in use in Iceland Titling—"the English or at least Scottish titling. It is by false analogy that the plural of titmouse is made titmice; it should be titmouses. A nickname is very often added, as with many other familiar English birds, and in this case it is "tom."

Among the more common European and English forms the first to be mentioned is that called, from its comparatively large size, the coal-titmouse, T. ater. The coal-titmouse, but not the oxyee, conspicuous by its black head, white cheeks and yellow breast, down which runs a black line, while in spring the cock makes himself heard by a loud voice that resembles the noise of a brass instrument. It is widely distributed over the British Islands and over nearly the whole of Europe and northern Asia. The next is the blue titmouse, bluecap or nun, P. coeruleus, so called because of the last of the series of changes it undergoes. It is widely distributed over Europe and Asia Minor. It is not very strictly to make any description needless. A third common species, but not so numerous as either of the foregoing, is the coal-titmouse, P. ater, distinguished by its black cap, white cheeks and white nape. The last species treated is a species of the后者, in which the difference observable between the races inhabiting the scanty remnants of the ancient Scottish forests and that which occurs throughout the rest of Great Britain is too insignificant to warrant the formation of a new species, or even a distinct race; the bird, in other words, being either only, or at least the western portion of the pack, hardly either of which colours are to be seen in the same parts of more southern examples, which last have been described as forming a distinct species, P. brunnicaucus. But it is to be feared that the denizens of the old Scot shrub-woods are nearly midway in coloration between the dingy southern birds and those which prevail over the greater part of the continent of Europe. It would therefore seem unreasonable to speak of two species only; there should be either three or one, and the latter alternative is to be preferred, provided the existence of the local races be duly recognized. Much the same thing may be said of the blue titmouse, in which the differences are much more noticeable, especially in the "Norridkarls," P. bicalensis, P. camchatkanus and others, whose names denote its local variations in northern Asia, while no great violence is exer-cised if these be tacked on T. ater, with several geographical races which inhabit North America. A fifth British species, the rare crested titmouse, P. cristatus, only found in limited districts in Scotland, though common enough, especially in pine-woods, in the interior of Europe.

In addition to species of Parus, North America possesses two peculiar genera of tits—Psaltriparus and Auroiparus. During the greater part of the year the various species of the genus Parus associate in the same family parties, the leader regularly being the breeding pair. The nearest always placed in a hollow stump, and consist of a mass of moss, feathers and hair, the last being worked almost into a kind of felt. Thereon the eggs, often to the number of eight or nine, are laid, and these have a translucent white shell, freckled or spotted with rust-colour. The first plumage of the young closely resembles that of the parents; but, so far as is known, it has always a yellower tinge, very apparent on the parts, if there be such, which in the adult are white. Few birds are more restless in disposition. Most of the European species and some of the North Americans become familiar, haunting the gardens, and serving as useful agents by getting themselves of such scraps of food, about the nature of which they are not particular, as they can get.2 By gardeners every titmouse is generally regarded as an enemy, for it is supposed to do infinite damage; but, as the bird lives chiefly on insects, this impression is wholly false, for the birds destroyed are always found to be those to which a grub—the bird's real object—has got access, so that there is no doubt that the titmouse is a great benefactor to the horticulturist.

Akin to the genus Parus, but in many respects differing from it, is Acrisius, containing that curious-looking bird the long-tailed or bottle titmouse, with many local races or species. The bird itself, having its tail longer than its body, is unlike any other found in the northern hemisphere, while its nest is a perfect marvel of construction, being in shape nearly oval, with a small hole in one side. The exterior is sided with piece of kitchen, worked into a thin piece of moss, wool and spiders' nests, and the inside is profusely lined with soft feathers—2379 having been, says Macgillivray, counted in one. Not a single grain is left in it. It is built by the penduline titmouse, Aegithalos pendulinus, of the south of Europe, which differs, however, not merely in composition, but in being suspended to a bough, while the former is nearly always placed between two or more branches.

The so-called bearded titmouse, Parus brunnicus, has habits wholly unlike those of any of the foregoing, and is now placed in a

2 The signification of this name is obscure. It may perhaps be correlated with a Swedish name for the bird—Talgse, the name generally given to the whole genus, there being little trouble providing a pleasing spectacle by adopting the plan, practised by the late A. E. Knox, of hanging a lump of suet or tallow by a short string to the end of a flexible rod stuck aslant into the ground close to the nest, and then observing the results. From the abundance of some kind finds the dainty, and once found visits are made to it until every morsel is picked off. The attitudes of the birds as they cling to the swinging lure are very diverting, and none but a titmouse can succeed in keeping a foothold upon it.
a separate Passerine family—Panuridae. It was formerly found in many parts of England, especially in the eastern counties, where it bore the name of reed-pleasant; but through the draining of many of the reed-beds and the capacity of collectors, it now exists in few localities. It is a beautiful little bird, of a bright tawny colour, variegated with black and white, while the cock is further distinguished by a bluish grey head and a black tuft of feathers on the back. It lives in reed beds and samphire beds, and is said to reed seeds and the smaller kinds of fresh-water mollusces, which it finds among the reed-beds it seldom quits.

The general affinities of the Passeridae seem to lie rather with the Sittidae (see Nuthatch) and the tree-creepers. (A. N.)

TITUS, one of the companions of St Paul, was of Greek origin (Gal. ii. 3), and was perhaps a native of Asia Minor. He appears to have been among the apostle's earliest converts, being first mentioned (Gal. ii. 1) as having accompanied Paul and Barnabas to Jerusalem (cf. Acts xv. 2) "to represent the success of the Pauline gospel outside Judaism." Here the conservative section demanded that he should be circumcised; but Paul successfully opposed this (see PAUL). Subsequently he came into close connexion with the Achaean churches and especially with Corinth, bearing letters from Paul and being charged with promoting the proposed collection for poor Christians in Judea. In these matters he proved himself a trusty lieutenant, winning the esteem of the Corinthians by his zeal and disinterestedness. The liberality which a generation later was recognized by Clement of Rome as a traditional virtue of the Corinthian Church owed its inception to Titus. In the epistle with which his name is associated he is represented (Titus i. 5) as having been left by Paul in Crete to "set in order the things that are wanting, and ordain elders in every city." He is expected afterwards to join Paul at Nicopolis (iii. 12). In 2 Tim. iv. 10 he is spoken of as having gone (perhaps on a mission) to Dalmatia. Tradition, obviously resting on the Epistle to Titus, has it that he died in Crete as bishop at an advanced age; another line connects him with Venice. Attempts to make him the author of the "We" sections in Acts and to include him in the seventy disciples are futile. There is more to be said for the suggestion that he was the brother of St Luke.

See A. Souter and E. P. Boys-Smith in The Expository Times, xviii. 285, 335, 386.

TITUS, THE EPISTLE TO, in the New Testament, an epistle which purports to have been written by Paul to Titus (1:1-4), while the former is absent, perhaps on a mission to Dalmatia. Tradition, obviously resting on the Epistle to Titus, has it that he died in Crete as bishop at an advanced age; another line connects him with Venice. Attempts to make him the author of the "We" sections in Acts and to include him in the seventy disciples are futile. There is more to be said for the suggestion that he was the brother of St Luke.

The origin of Christian missions in Crete is obscure. A strong Jewish element existed among the population (cf. i. 13 seq., iii. 9), which explains the particular hue of the local heresies as well as, perhaps, the initial efforts of a Christian propaganda (cf. Acts xi. 11). The geographical situation of the island also favoured an early introduction of the new faith. "Crete was a great wintering place" for vessels (cf. Acts xxvii. 12 seq.) working their slow way to Rome along the southern coast of the Mediterranean, so that the possibility of Jewish Christian evangelists having reached it before long is to be granted freely.

1 The common names given to this bird are very inapplicable that it is a pity that 'silerea' (from silere, an oster) bestowed upon it by the French is the only descriptive term.

2 On the somewhat harsh estimate of the Cretans in i. 12 see Dr J. Rendel Harris in Expositor (7th series, vol. ii. p. 305 seq.). The other features noted in the epistle, their turbulence, drunkenness and debauchery, happen to be verified in the pages of ancient writers like Polybius.

It is more difficult to determine when Paul can have visited the island and left Titus behind him. Attempts have been made to find a setting for the epistle within the apostle's life previous to his Roman imprisonment (as recorded in Acts), but by common consent it is now held that the epistle (if written by the apostle) must be later, during the period of missionary enterprise which is supposed to have followed his release from the first captivity. Like the epistles to Timothy, the Epistle to Titus thus belongs to a phase of the apostle's life for which we possess no other contemporary evidence. The second imprisonment of Paul, during which he did not enjoy freedom from Roman control, was the occasion of the second application of his hypothesis (cf. the statement in Steinmetz's Die zweiteirn. Gefaengschaft des Paulus, p. 46 seq.), which is absolutely essential to the Pauline authorship of the pastorals. It is indeed supported by several critics who reject the latter, just as it is occasionally rejected by advocates of their authenticity. But, upon the whole, such evidence from early tradition as can be adduced from the 2nd century seems no more than an expansion of Paul's language in Rom. xvi. 24, 28. The pastoral themselves never mention any mission in Spain. Spanish tradition is silent on the fact, and, in the Clementine Recognitions (i. 7, 2; ii. 22, 6) rather events it is supposed at least as fairly of Rome as of Spain. The whole problem is not without its difficulties still, after all the research lavished upon it, but the probabilities seem to converge upon the conclusion that Paul was never released from his imprisonment, and consequently that he never revisited the East.

The internal criticism of the epistle starts from i. 7-9, which is plainly an interpolation, perhaps from the margin, upon the qualifications of episcopoi. On the other hand a passage like iii. 12-13 is indubitably a Pauline fragment, and the problem for the critic is to determine whether in the epistle as a whole we have a reduced and interpolated edition of what was originally a note from the hand of Paul, or whether the epistle drew upon some Pauline tradition (connecting Titus with Crete) and material, and was afterwards rendered into a form more suitable for a pastorally homiletic or practical use. It is perhaps more and less successful upon the whole, although there is little to choose between the two. The substantially Pauline character of the epistle, for all practical purposes, is to be granted upon either hypothesis, for the author or the editor strove not unsuccessfully, upon the whole, to reproduce the Pauline spirit and tradition. The older notion that the personal data in Titus, or in the rest of the pastorals, were invented to lend verisimilitude to the writing must be given up. They are too circumstantial and artless to be the work of a writer idealizing or creating a situation. Thus, in the present epistle, a passage like iii. 12-13 is palpably genuine. But it is another question whether we can be absolutely certain that the writer is Paul (cf. iii. 1-7, 15, by Hesse; i. 1, 4, iii. 15, by von Soeden; i. 1-6?, iii. 1-7, by McGregor), in order to reconstruct a more or less independent note that Paul's own words might have been used.

It seems improbable that Titus or any of the pastorals is directed against any one phase of contemporary heresy. The prohibition of marriage (1 Tim. iv. 3) was common to Marcion and Apelles, while the rule against the eating of food offered to idols (1 Tim. v. 21) was one of the most insistent of the Clementine Banished (Clement i. 24, 3, by Haer. i. 28, 1) and to Saturninus of Antioch in Syria (ibid. i. 24, 3), the latter being also credited with having been the first to introduce a dualism into humanity, which made God send his Saviour to destroy the evil and redeem the good, both classes having been formed by the angels (cf. Titus ii. 11; 1 Tim. iv. 10). The exhaustive discussions on this point (cf. Bourquin, pp. 55 seq.) have led most scholars to the conclusion that no one system of 2nd-century gnosticicism is before the writer's mind. He is maintaining Paul's role. He makes the apostle prophesy, vaguely of course, the evil tendencies which were to come upon the church; but the internal evidence,

W. E. Bowser, Professor Bartlet (Apostolic Age, pp. 178 seq.; cf. also article on PAUL), Lisco (Vinea sanctuarum, 1900) and Laughlin are the only recent exceptions, and their conjectural schemes are more or less largely of a destructive character. The ostracism of Titus (cf. Luke xiv. 26) is an historical fact, and any dispersion of them over a term of years. They stand or fall together, as critics of all schools are practically agreed. The impossibility of placing them within the period of Acts is best known by the works of Bretschneider (Martyrium) and Petzinger (Geschichte der christlichen Missionen, 1884). The historical site for iii. 12-13, as well as for the tradition which forms the setting of the epistle, is probably to be sought in the neighborhood of Acts xx. 3 (so Krenkel). Clement gives the scene near Miletus after 2 Cor. xii. 15 and iv. 19 of Romans (in A.D. 59).

6 Essenism, blended with Ebionitism, is the plausible conjecture of Schleiermacher, Neander and Mangold, but the Essenae do not seem to have been professed by the earliest Christians.

7 Asocism was bound up with the gnostic depreciation of the body. By a natural recoil it produced licentiousness of conduct which the pastorals hotly denounce.
Titus (Roman Emperor)—Titus Tituri

The Epp. of Paul written after he became a Prisoner (New York, 1887); Plummer, Epistles (1893); Bourquin, Étude critique sur les Paul (Paris, 1890); Harnack, Die Chronologie, 30 seq., 710-712; Moffatt, Encyc. Bib., 5059-5056, and W. Lock (Hastings’s Dict. Bible, vol. iv.).

Tituri, Flavius Sabinus Vespasianus, Roman emperor from a.d. 79-81, son of the emperor Vespasian, was born on the 20th of December a.d. 40 (or 41). He was educated in the Jewish colony and thoroughly instructed in all the Jewish lore; he could speak Greek fluently and composed verses; he was a proficient in music; he could write shorthand, and imitate handwriting so skillfully that he used to say that he might have been a most successful forger. He was handsome and commanding, and had a vigorous frame, well trained in all the exercises of a soldier. As a young man he served with credit in Germany and in Britain. Soon he had the command of a legion, and joined his father in Syria, where he took an active part in the Jewish War. In 68 he was sent by his father to congratulate the newly proclaimed emperor, Galba; but, hearing of Galba’s death and of the general confusion in Rome, he had the revelation of the apotheosis of his father, and, in the meantime consulted the oracle of the Paphian Venus and received a favourable answer. In the following year Vespasian, having been proclaimed emperor, returned to Italy, and left Tituri to carry on the siege of Jerusalem, which was captured on the 8th of September 70. On his return to Rome, Tituri and his father celebrated a magnificent triumph, which has been immortalized by the so-called Arch of Tituri. He was now formally associated with his father in the government, with the title of Caesar, and during the nine remaining years of Vespasian’s reign he was in fact emperor. He was anything but popular; he had the character of a Germanic statesman, a humane and benevolent ruler, and a wise and just judge. His connexion with Berenice, the sister of the Agrippa of the Acts of the Apostles, also created a scandal; both brother and sister followed Tituri to Rome, and were allowed to reside in the imperial palace. Public opinion was outraged, and Tituri, though he had promised Berenice marriage, felt obliged to send her back to the East. Vespasian died in 79, leaving his son a safe throne and a well-filled treasury. The forebodings of the people were agreeably disappointed, for Tituri put an end to prosecutions for high treason, and the delatores (informers) were scourged and expelled from the city. He, however, did not follow the path of absolutism, in order that he might keep his hands free from blood. He refused his brother Domitian, who more than once plotted against his life, and having let a day pass without bestowing a present, he exclaimed, “I have lost a day.”

Tituri, like his father, spent money in adding to the magnificence of Rome. The Flavian amphitheatre (latter called the Colosseum) was completed and dedicated in his reign, with combatants of gladiators, shows of wild beasts, and representations of some of the great Greek naval battles. He gave the city splendid baths, which surpassed those of Agrippa and of Nero, and supplied the mob with every kind of luxury.

During his reign, in 79, occurred the eruption of Vesuvius which destroyed Herculanum and Pompeii. The emperor visited the scenes and contributed liberally to the relief of the distressed inhabitants. During his absence a fire raged for three days at Rome, in which the new temple of Jupiter Capitolinus, the library of Augustus, and other public buildings were burnt; then followed a pestilence, and Tituri again assisted freely with his purse. Italy and the Roman world were peaceful during his reign. The only fighting was in Britain under Agricola, who died the year 80 carried the Roman arms as far as the Tay. This general was, according to Schenkel’s Biblia-Lexicon, iv. 393-402; Sabatier’s article in Encyc. des sciences religieuses, x. 250-259; J. R. Boiss.

1 Clemen (Paulus i. 148) distinguishes broadly between the errors of 2 Tim. and those controverted in the other two epistles. The former, he argues, are in the last resort libertinism and anti-Semitism. They are of the age of the Jewish church. (Tituri 1. 10; 2 Tim. iii. 16; 1 Tim. i. 7, &c.) The errors developed speculative and practical theories on the basis of the Old Testament law, which proved extremely seductive to many Churchmen. The general resurrection was purely spiritual (Lightfoot); this, however, is probably no more than an interesting coincidence, and all attempts to identify the deceased with the ressurrector are abandoned by Ellicott.

2 Tim. ii. 18. Paul’s teaching about the believer being already risen with Christ gave a welcome handle to the later Gnostics. The passage in John v. 25-29 seems a correction of the possible inferences which might be drawn from such teaching in Paul and in the Fourth Gospel itself. 

3 Cf. Von Dobschütz, Christian Life in the Primitive Church (pp. 261 seq.).
the latter, who had become Roman matrons, intervened and prevailed upon the combatants to cease fighting. A formal treaty was then arranged between the Romans and Sabines, whereby Romulus and Tatius were to be joint and equal rulers of the Roman people. Rome was to retain its name and each citizen was to be called a Roman, but as a community they were to be called Quirites (q.v.); the Sabines were to be incorporated in the state and admitted into the tribes and curies. After this arrangement had lasted for five years it came to an end by the death of Tatius, who was killed out of revenge by the inhabitants of Lavinium. According to Mommsen, the story of his death, (for which see Plutarch) look: like an historical version of the abolition of blood-revenge. Tatius, who in some respects resembles Remus, is not an historical personage, but the eponymous hero of the religious college called Sodales Tittii. As to this body Tacitus expresses two different opinions, representing two different traditions: that it was introduced either by Tatius himself to preserve the Sabine cult in Rome; or by Romulus in honour of Tatius, at whose grave its members were bound to offer a yearly sacrifice. The sodales fell into abeyance at the end of the republic, but were revived by Augustus at the beginning of the 2nd century A.D. Augustus himself and the emperor Claudius belonged to the college, and all its members were of senatorial rank. Varro derives the name from the Titaniuves which were used by the priests in certain auguries.

See Livy i. 10-14; Tacitus, Annals, i. 54, Hist. ii. 95; Dion. Halic. ii. 36-52; Plutarch, Romulus, 19-24; Marquardt, Römische Staatsverwaltung (1855) iii. 446; Schweger, Römische Geschichte, Okt. ii. 544-55.

TITUSVILLE, a city of Crawford county, Pennsylvania, U.S.A., on the Oil Creek, about 42 m. S. by E. of Erie. Pop. (1900), 82,344, of whom 1573 were foreign-born; (1910 census) 82,953. Titusville is served by the Dunkirk, Allegheny Valley & Pittsburg, and the Pennsylvania railways. It has the Benson Memorial library (1904), and in Woodlawn Cemetery there is a monument (erected by Henry H. Rogers in 1902) to Colonel Edwin L. Drake (1819-1860), who here sank the first oil well (69 ft. deep) in America in August 1859 and who is buried here. Titusville was the principal centre in Pennsylvania of the opposition to the Standard Oil Company; but after 1875, when John D. archbold (b. 1828), a leader of the independents, became a director of the Standard, few of the Titusville opera took independent action. It was in the Titusville district that the natural gas industry of Pennsylvania was first established about 1872. There are various manufactures, and in 1905 the value of the factory products was $3,740,800. The first settlement was made here in 1766 by Samuel Kerr and Jonathan Titus (in whose honour the place was named). Titusville was incorporated as a borough in 1847 and was chartered as a city in 1866. On the 5th of June 1892 Oil Creek rose suddenly, overflowed its banks and wrecked many oil mills along the bottom-lands. A large part of the water was covered with oil, which soon caught fire. About 60 persons were drowned or burned to death, and about a quarter of the city was destroyed.

TIVERTON, a market town and municipal borough in the Tiverton parliamentary division of Devonshire, England, situated amid beautiful scenery at the confluence of the Loman and Exe, 187 m. W. by S. of London by the Great Western railway. Pop. (1901), 10,352. The upper town is built on high ground along the left bank of the Exe, and a bridge leads to the lower town, named West Exe. St Peter's church, originally consecrated to a chapel by Leozic, bishop of Exeter, in 1071, is a beautiful Perpendicular building. Its high tower has four stages, each adorned with grotesques; and Greenway's chapel, built in 1517 by John Greenway, a wool merchant of Tiverton, is ornamented with figures minutely carved in stone. Of the original Norman fabric only a doorway remains. Within are some fine carvings, brasses and monuments. Of the castle, founded about 1105 by Richard de Redvers, the banqueting-hall, a tower, the chapel and a 14th-century gateway remain. After serving as the home of the Redvers and Courtenay families, earls of Devon, until the 16th century, the castle was dismantled by Fairfax. Partly rebuilt, it is used as a dwelling-house; while in its gardens an annual race-meeting is held in August. Blundell's grammar school, founded under the will of Peter Blundell, a rich cloth merchant, in 1604, has modern buildings outside the town in Tudor style; and, among others, scholarships at Balliol College, Oxford, and Sidney Sussex College, Cambridge. The number of boys is about 320. The Chilcott Free School was established in 1611, and the Bluecoat Charity School, dating from 1714, was reorganized in 1876 to give secondary education to boys and girls. After the decline of its woollen trade Tiverton became noted for the lace manufacture introduced by John Heathcoat (1783-1861), inventor of the bobbin net frame. There are also breweries, flour-mills, and a large trade in farm produce and livestock. Amicia, countess of Devon, brought a stream of water from Norwood, 5 m. distant. This system was improved in the 19th century. Hannah Cowley, the dramatist (1743-1809), Richard Cosway, the miniature painter (b. 1742) and John Cross, an artist of some celebrity (b. 1819), were natives of Tiverton. The town is governed by a mayor, 6 aldermen and 18 councillors. Area, 17,650 acres.

Tiverton (Tuverton, Totivert) exhibits traces of very early settlement, and is mentioned under the name of Tuyford in the will of King Alfred. In the Domesday survey it appears as a royal manor containing two mills, but it was bestowed by Henry I. on Richard de Redvers, and in 1245 appears as a mesne borough under Baldwin de Redvers, who in that year obtained a grant of a Monday market and a three days' fair at the feast of St James. In 1275 Amicia, countess of Devon, claimed to hold fairs at Tiverton in the festas of St Andrew and St Giles, and at the translation of St Thomas the Martyr. In 1618 the borough received its first charter of incorporation from James I., instituting a governing body of a mayor, 12 chief burgesses, and 12 assistant burgesses, with a recorder, deputy-recorder, town-clerk and two serjeants-at-mace; a court of record every fortnight on Tuesday; and fairs at Michaelmas and on the second Tuesday after Trinity Sunday, which were kept up until within the last fifty years. The borough also sent two representatives to parliament until disfranchised by the Reform Act of 1885. Cromwell in 1655 changed the market day from Monday to Tuesday. Fresh barriers to incorporation from James I., in 1689 and from George I. in 1724 left the style and constitution of the governing body unchanged. Tiverton was an important centre of the woollen trade in the 16th century, and Risdon, writing in 1608, describes it as thronged with rich clothiers, and the Monday market famous for its kersels, known as "Tiverton kersels," while as late as the reign of George II. the town had 50 fulling-mills; but about this time the industry began to decay, and is now extinct.

See Victoria County History: Devonshire; M. Dunsford, Historical Memoirs of the Town and Parish of Tiverton (Exeter, 1790); W. Harding, History of Tiverton (1845-1847).

TIVOLI (anc. Titus, q.v.), a town and episcopal see of the province of Rome, Italy, 18 m. E.N.E. of Rome by road and tramway, 243 m. by rail, 760 ft. above sea-level. Pop. (1901), 11,610 (town), 12,881 (commune). Tivoli lies on the west of the Sabine Mountains, where the river Anio issues from them, upon a limestone rock above the river. The town on one side overlooks the Campagna di Roma and Rome itself, on the other the deep gorge of the Anio, with its lofty falls, and the environs are very beautiful. The location of the town and its buildings are described under the heading of Tivoli. The Villa d'Estate, begun in 1540 by F. Ligorio for Cardinal Ippolito d'Este the younger (the cardinal of Ferrara), has the finest example of a Renaissance garden in Italy; it was erected on a steep slope, with many terraces, and embellished with numerous fountains, fantastically decorated in stucco, which once formed the background to the splendid collection of ancient statuary formed by the cardinal, but now dispersed (see F. S. Sieni, La Villa d'Este in Tivoli, Rome, 1902; T. Ashby, in Archaeologia, vol. lvi.). The villa contains damaged frescoes by the brothers Zuccari. The register of the see of
TLAXCALA—TLEMÇEN

Tivoli has documents dating from the 10th century relating to the landed property of the see (L. Brusca, Regesto della chiesa di Tivoli, Rome, 1883), and the municipal archives date from 1450. The castle was erected in 1460 by Pius II. on the site of the amphitheatre, which is now a prison. In November 1826 the flood of the Aniene led to a change in its course, and threatened to carry away the town. A new channel, consisting of two parallel tunnels (the Traverco Gregoriano) 290 and 330 yds. long, was therefore made to the north-east in 1826-1835 by Folchi, and on emerging from these the river has a fall of 35 ft. Farther north-west are smaller falls (the cascatelle) of that portion of the river which is carried through the town and serves for industrial purposes. Five miles west are the sulphur baths of Acque Albule, which were known to the ancients, and are now frequented by over 40,000 persons annually. The temperature of the water is 75°F. The falls in the river afford electric power for lighting Rome and driving its trams, as well as for driving several factories in Tivoli itself. Tivoli is also the centre of an agricultural district, and its olive trees are especially fine.

TLAXCALA, an inland state of Mexico, bounded N.E. and S. by Puebla, and W. by the state of Mexico. Area 1905 sq. m. Pop. (1900), 172,315. TLAXCALA lies on the great central plateau of Mexico and has a mean altitude of about 7000 ft. Several mountains rise in the west and south, culminating in the volcanic peak of Malinalco or Malinatin (14,036 ft). The state has three railway lines crossing its territory. The capital is TLAXCALA and the principal towns are Chiautempan (about 9000), Calpulapan, San Antonio, TLAXCALO, Huamantla and Barron-Escandon (Apizaco). The state nearly coincides with the ancient Indian republic founded in the 13th century by a branch of the Nahua Indian race, who migrated from the western shores of Lake Texcoco. Though surrounded on all sides by the great Aztec Empire, the tiny republic maintained its independence until the arrival of the Spaniards. The TLAXCALO, or Tarascans, after a bitter resistance to Cortés in 1519, acknowledged the authority of the Spaniards and contributed largely to their final success. The present inhabitants are chiefly of this original stock, and retain their language and many ancient customs.

TLEMÇEN, a town of Algeria, the capital of an arrondissement in the department of Oran, near the frontier of Morocco, 68 m. by road and 102 by rail S.W. of Oran. It stands 2500 ft. above the sea, on the north slope of the Lella Setta hills, which rise to a height of over 4000 ft. It is the chief town of a wide district comprising 12,500 square miles, composed of flat, woody and Algerian oynx; and has a population of (1900) 24,060. From Tlemçen the railway is continued westward to the Moroccan frontier at Lalla Maghnia, a distance of 44 m. Among the cities famous in the annals of Arab-Berber, or Moorish, art and civilization, Tlemçen takes high rank. In architectural merits its monuments, though not so extensive, are worthy of comparison with those of Granada. The older walls and towers—there were three ancient lines of fortifications—are in great part destroyed, but a wall built by the French encircles the town.

The various quarters are grouped around the principal mosque—

the Jewish to the south-west, the Moorish to the south-east, that of the merchants to the north-west, while the new town with the civic buildings lies to the north-west. Of the sixty-four mosques which existed at the period of the French conquest, several have disappeared. The great mosque (Jamaa-el-Kebir) has a brick minaret 122 ft. high, with a colonnade on three sides and a central pavilion with mosaic of the various colored design; a fountain of alabaster, and a fountain known as Algerian oynx—stands in the alabaster-paved inner court; and 72 columns support the arches of the interior. This mosque was built by Sultan Ali 14th century, and is finely ornamented with arabesques. The mosque of Sidi Ahmed, however, is more magnificent. B. A. 1298, now transformed into a museum of antiquities, has two series of arches, which encircle the central dome of the former palace; the arches are either of marble or of black marble, and are ornamented with figures of great beauty and richness; the delicately-carved cedar ceiling bears traces of polychromatic painting. The exterior has been much altered by the French. The principal arch of the former palace is the epigraph of Boabdil, the last king of Granada, who died at Tlemcen in 1494, and the standard cubit-measure—in marble—used in the Ksaria, beaing date A.D. 728 (1328). The mosque of the Sacred Jami (the mosque of the French) encircles the walls outside the walls of the town. It has eight magnificent columns of Algerian oynx, with richly sculptured capitals. The ceiling of cedar is richly carved, and there is a fine colonnade on each side of the court. The minaret is decorated with mosaics. The military authorities occupy the Meshuur or citadel, built in 1145, which separates the Jewish and Moorish quarters and was formerly the palace and commonly called the Black Sultan. The ruins of a small building, dating from the 14th century, and the battlemented wall, flanked by two towers, remain of its former magnificence. The vast basin (zabri) under the old walls, now dry (720 ft. in length, 490 in width and 10 in depth) was formerly for water. It was fortified in the 13th century, and period barracks of the spahis occupied all that remains of the Ksaria, the place of residence of European merchants from Pisa, Genoa, Catalonia and Provence. The barracks have been cleared away, but the ground is covered with the remains of the fortifications. The ancient college (medressa) where many learned Arabs taught—of whom Ibn Khaldun, author of a History of the Berbers, may be reckoned among the most distinguished—has been turned into a French is a fine building in the Byzantine style. Besides the large trade carried on there are native manufactories of cloth, carpets and leather goods. A special manufacture is that of red shawls, woven throughout the department of Oran by Jewish women when in mourning.

In the immediate neighbourhood of the modern Tlemçen are numerous remains of the fortifications of Agadir (vide infra), and the ruins of the palace of the former Sultan Ali. The palace was built in the 14th century, and is one of the finest in the town. From the 14th century, the lower part of which is built of large hewn stones from the Roman Pomparia. More noteworthy, however, are the ruins of Sidi Bu Medin and of Mansura. Sidi Bu Medin (more properly El Eubbad) is a little over a mile south-east of Tlemçen. It was founded A.D. 1337 by Ali V., the first of the Beni-Marin (Marinide) sultans who ruled Tlemçen, and was called the Black Sultan. The ruins of a small building, conjectured to be a palace of Sultan Ali, which commands a beautiful view, were excavated in 1881. The zoubba or tomb of Sidi Bu Medin, near the palace, is held in great veneration by the Arabs. In the palace are covered arabesques, and the famous Mekteb El-Mulk Lillah, "the kingdom is God's," is repeated again and again. The saint himself was born at Seville A.D. 1126, and died near Tlemçen in 1192; his tomb is near the palace, and the place is called El Medjir, from him. The adjacent mosque is a beautiful specimen of Moorish art. The large double doors of cedar wood, covered with bronze showing a geometric interlaced pattern, have been compared with those of the Alhambra and the Baths of Caracalla in Rome. They are columns into five aisles. Delicate lacework extends from the spring of the arches to the roof. The tile mosaics are believed to have come from Morocco. The medressa is a building resembling the mosque.

Mansura, which is about 11 m. west of Tlemçen, owes its founda-

tion to the attempts of the Beni-Marin rulers of Morocco to extend their sovereignty. The Amir Abu Yakub Yusuf besieged Tlemçen in the early years of the 14th century. The siege lasted eight years, and Yusuf turned his camp into a walled city. The siege being raised, El Mansura (the victorious), as the new city was called, was abandoned. It was reoccupied when El Mansura had been taken. On the revolt of the Marinides in 1359 Mansura was finally deserted. Besides the walls and towers, and the minaret of the mosque, little remains of Mansura, of which Ibn Khaldun has left a graphic and eloquent description. It is said that one side and parts of two other sides have perished, is one of the finest mosques in existence. It is 125 ft. high, and is divided into three stories. The grounds are encircled by columns into thirteen aisles. Excavations made by the French brought to light some of these columns, which are now in the museums of modern Algiers.

History.—A Roman town, Pomaria, occupied a site east of the present town. It derived its name from the abundance and
luxuriance of the apple, pear and other fruit trees in the neighbourhood. The Roman town was ruined in the period following the Vandal invasion, and at the time of the Arab conquest appears to have been deserted. Many inscriptions of the Christian era have been found, some as late even as the 7th century. The site was purchased from the Zenata Berbers, in the 9th century, by Idris-ibn-Abdallah, who began the building of a new city named Agadir (Berber, the fortress). Idris, founder of the Idrisite dynasty of Fez, left his brother Sulaiman in possession of Agadir, and the city was ruled by the Beni-Suleiman until 931, when it fell into the hands of the Fatimites. From the Fatimites it passed into the possession of the Beni-Yala, of the Beni-Irfen branch of the Zenata Berbers, who held it as vassals of the Omayyad rulers of Spain. In 1050 the Almoravide sovereign Yusuf ibn Tashfin, after besieging and sacking Agadir, built a new town on the site of his camp. The new town, called Tagrart, became the commercial quarter, whilst Agadir remained the royal residence. The two towns when united received the name of Tlemcen. The Almoravides reigned sixty-five years when, after holding Agadir four years against the enemy, they were overcome by the Almohades, who massacred the inhabitants, rebuilt, enlarged and repeopled the ruined town, and built a wall (1161) surrounding the double town. In 1248 Tlemcen was captured by Abu Yahia Yarmorasen (Ghamarasen) who was the Sultan of the Sultanate of Tlemcen.

The Sultanate of Tlemcen.

It was during the 13th century that the Sultanate of Tlemcen began to play a part of importance among the principal powers of the time. In 1282, founded the dynasty of the Abd-el-Wahid, who ruled the greater part of what now constitutes Algeria. Under their sway Tlemcen flourished exceedingly. The presence of Jews and Christians was encouraged and the Christians possessed a church. The bazaar of the Franks (kissaria) was a large walled enclosure, the gates of which were closed at sunset. As many as 5000 Christians lived peacefully in Tlemcen, and the Sultan included in his army a Christian bodyguard. In 1337 the power of the Abd-el-Wahid was temporarily extinguished by Sultan Abu Bakr of Morocco. They left some remembrances of the period of their ascendancy, which lasted twenty-two years. Once more, under the Abd-el-Wahid, now known as the Beni-Zeiyun, from 1359 to 1553, Tlemcen enjoyed prosperity. It had a population reputed to number 125,000, an extensive trade, a brilliant court and a powerful army. The Spanish occupation of Oran (1509) struck a fatal blow at the European commerce of the town. The Beni-Zeiyun, after the capture of Algiers in 1516 by the corsair Barbarossa (q.v.) gradually lost their territory to the Turks, while Tlemcen itself for forty years became tributary to the Spanish governor of Oran. In 1528 the town was held for a short time by Arouj Barbarossa, but Arouj was killed in a fight with the Spaniards. It is said that, while master of the town, Arouj caused twenty-two of the Zeiyun princes to be drowned in the sabri. In 1553 the Turks under Salah Rais, pasha of Algiers, captured Tlemcen and the Sultanate of Tagrart, as it was still frequently called, came to an end. Under the Turks the town ceased to be of any importance. When the French entered Algeria the sultans of Morocco were disputing the possession of Tlemcen with the Kulagis, who fought first for themselves and afterward for Fez, but in 1548 the latter drove them out. In 1578 the Moors retired, sought to re-establish the ancient empire of Tlemcen, but he retreated before General Clausel in 1836. The treaty of the Tafna (1837) gave Tlemcen to Abd-el-Kader, but, while being renewed in 1842, Tlemcen was definitely occupied by the French, under whom it has prospered.

The commune of Tlemcen, which includes a number of villages near the city, had a population (1906) of 39,757, and the arrondissement, which includes nine communes, 149,467.

See Les Monuments arabes de Tlemcen, by William Marçais and Georges Marçais (Paris, 1903). This accurate and finely-illustrated work, one of the publications of the Service des monuments historiques de l'Afrique, cites the principal works dealing with Tlemcen and gives a critical estimate of their value.

TOAD—TOBACCO

TOAD, a name commonly applied, in contradistinction to "frog," to tailless batrachians of stout build, with more or less wartly skin. Thus, of the two closely related discoglossid genera Bombinator and Discoglossus, the former is called a toad and the latter a frog. But the true toads are the Bufonidae, arcerous batrachians with dilated processes to the sacral vertebra and without any teeth in the jaws. The type of the family is our common toad, Bufo vulgaris, and round it cluster a large number of species of the same genus, and the smaller genera Europemphi, Pseudophryne, Nectophryne, Nectes, Notaden, Myobatrachus, Rhinophrynus and Cophophryne. That the shape of the body is not a safe guide in judging of the batrachians is shown by certain species, such as Bufo saurinus, which in its slender form and extremely long limbs surpasses the typical frogs, whilst on the other hand, some true frogs (Rana), adapted to burrowing habits, are absolutely toad-like. The Bufonidae include terrestrial, burrowing, thoroughly aquatic and arboreal types; Rhinophrynus, of Mexico, may be described as an ant-eater.

The genus Bufo embraces about 100 species, and is represented in nearly every part of the world except the Australian region and Madagascar. Two species are found in the British Isles: the common toad, Bufo vulgaris, and the natterjack, Bufo calamita. The former is found almost everywhere; the second, which differs in its shorter limbs with nearly free toes (which are so short that the toad never hops but proceeds in a flutter), is limited to a strip along the middle of the back, in localities there, in the south-west of England, and the west of Ireland; it is further remarkable for the very loud croak of the males, produced by a large vocal bladder on the throat which, when inflated, is larger than the head. Toads lay their eggs in long strings, forming double lines in straight, jelly-like tubes.

A small toad, Pseudophryne vivipara, recently discovered in German East Africa, has proved to be viviparous, this being the only such instance known among tailless batrachians.

TOAST, the popular name for fungi which more or less resemble mushrooms, but are either poisonous or worthless as food.

TOAST, a slice of bread scorched brown on the two surfaces by the heat of a fire. The word was borrowed from the O. Fr. toste, Lat. torrere, tostum, to scorch, burn. It was formerly the custom to have pieces of toast floating in many kinds of liquor, especially when drunk hot. It is said to be from this custom that the word is used of the calling upon a company to drink the health of some person, institution or cause (see Health). TOAST, the name (see below) for the leaves of several species of Nicotiana (nat. ord. Solanaceae), variously prepared for use as a narcotic. While it is principally manufactured for smoking, a large amount is also prepared for chewing, and, to a more limited extent, it is taken in the form of snuff. Under one or other of these forms the use of tobacco is more widely spread than in that of any other narcotic or stimulant.

History.—Although the fact has been controverted, there cannot be a doubt that the knowledge of tobacco and its uses came to the rest of the world from America. In November 1492 a party sent out by Columbus from the vessels of his first voyage, a Spanish expedition in the service of the King of Spain, returned to Spain after a voyage which they said that they had seen people who carried a lighted firebrand to kindle fire, and perfumed themselves with certain herbs which they carried along with them. The habit of snuff-taking was observed and described by Ramon Pané, a Franciscan who accompanied Columbus on his second voyage (1494-1496), and the practice of tobacco-chewing was first seen by the Spaniards on the coast of South America in 1502. As the continent of America was opened up and explored, it became evident that the consumption of tobacco, especially by smoking, was a universal and immediate usage, in many cases bound up with the most significant and solemn tribal ceremonies.

The term tobacco appears not to have been a commonly used original name for the plant, and it has come to us from a peculiar instrument used for inhaling its smoke by the inhabitants of
Hispaniola (San Domingo). The instrument, described by Oviedo (Historia de las Indias Occidentales, Salamanca, 1535), consisted of a small hollow wooden tube, shaped like a Y, the two points of which being inserted in the nose of the smoker, the other end was held into the smoke of burning tobacco, and thus the fumes were inhaled. This apparatus the natives called "tabaco"; but it must be said that the smoking pipe of the continental tribes was entirely different from the imperfect tabaco of the Caribbees. Benzonzi, on the other hand, whose Travels in America (1542-1556) were published in 1565, says that the Mexican name of the herb was "tabaco.

The tobacco plant itself was first brought to Europe in 1565 by Francisco Fernandes, a physician who had been sent by Philip II. of Spain to investigate the products of Mexico. By the French ambassador to Portugal, Jean Nicot, seeds were sent from the Peninsula to the queen, Catherine de' Medici. The services rendered by Nicot in spreading a knowledge of the plant have been commemorated in the scientific name of the genus Nicotiana. At first the plant was supposed to possess almost miraculous healing powers, and was designated "herba panacea," "herba santa," "sana sancta Indorum"; "divine tobacco" it is called by Spenser, and our holy herb nicotian by William Lilly. While the plant came to Europe through Spain, the habit of smoking was initiated and spread through English example. Ralph Lane, the first governor of Virginia, and Sir Francis Drake brought with them in 1586, from that first American possession of the English crown, the implements and materials of tobacco smoking, which they handed over to Sir Walter Raleigh. Lane is credited with having been the first English smoker, and through the influence and example of the illustrious Raleigh, who "took a pipe of tobacco a little before he went to the scaffold," the habit became rooted among Elizabethan courtiers. During the 17th century the indulgence in tobacco spread with marvellous rapidity throughout all nations, and that in the face of the most resolute opposition of statesmen and priests, the "counterblaste" of a great monarch, penal enactments of the most severe description, the knout, excommunication and capital punishment.

Botany.—There are about fifty species of Nicotiana, nearly all of which are natives of America. Few, however, are of economic importance. The great bulk of the tobacco supply is derived from

in length, while the upper are semi-amplexical and of variable outline. The seeds are brown in colour, with a rough surface, of minute size, and exceedingly numerous; as many as 1,000,000 may be produced by a single plant. The whole of the green parts of the plant are covered with long soft hairs which exude a viscid juice, giving the surface a moist glutinous feeling. The hairs are multicellular, and of two kinds, one branching and ending in a fine point, while the other, unbranched, terminates in a clump of small cells. Stomata occur on both surfaces of the leaves and, with a peculiar hair structure render the microscopic appearance of the plant highly characteristic.

From this species the tobaccos of Cuba, the United States, the Philippine Islands and the Latao of Turkey are derived, and it is also largely cultivated in India; the variety macrophylla is the source of the Maryland tobaccos. N. peracca, Persian tobacco, the source of the famous Shiraz tobacco, is regarded as only a variety of N. tabacum, and an introduction from America. East Indian, or Green, tobacco is the product of another species, N. rustica, a smaller plant with a much-branched stem and greenish-yellow flowers with a short, broad tube. It is a native of Mexico, and now widely cultivated in southern Germany, Hungary and the East Indies.

Cultivation.—Tobacco is cultivated in localities scattered over almost the whole world, ranging as far north as Quebec, Stockholm and the southern shores of Lake Baikal in one hemisphere, and as far south as Chile, the Cape of Good Hope and Victoria in the other. Whilst, however, the plant adapts itself to a great variety of climatic conditions and will grow on almost all kinds of soil, the quality and quality of the produce are profoundly affected by variations in these two factors. Very slight differences in climate appear to cause very great differences in the quality of the tobacco, and ordinary meteorological records are of little use in determining the suitability or not of a region for a particular kind of leaf; this essential point must be determined by experiment. In general, tropical and semi-tropical conditions as to temperature, with a comparatively dry climate, give the best results.

Given suitable climatic conditions, the type of tobacco produced is determined mainly by the soil, and particularly by its mechanical or physical condition. Speaking generally, clay soils retentive of moisture produce heavy-cropping tobaccos which cure to a dark red-brown colour. Sandy soils produce tobacco with a thin leaf, curing to a yellow or bright red colour. In the same locality, i.e., under the same climatic conditions, quite different kinds of tobacco may be produced in direct relation to the character of the soil. Thus the bright yellow tobacco used for cigarettes, &c., is largely produced in Virginia and North Carolina on a loose porous sand, which must be at least a foot deep, and contains usually about 8% of clay; this sand is underlain by a clay subsoil, and, as Mr Milton Whitney points out in Tobacco Soils (U.S.A. Dept of Agriculture, Farmers' Bulletin, No. 83), this clay is the same as that on which the heavy manufacturing and export tobacco is grown. Where the clay is exposed on the surface the heavy type of tobacco is produced, and bright tobacco where the clay is covered from 2 to 8 inches by a clump of sand. Tobacco soils should be well drained and contain a large percentage of humus.

Tobacco being cultivated over such a large area of the world, under very varying climatic conditions, and by many different races of mankind, the methods employed in its production naturally differ very considerably. As the United States of America produce more tobacco than any other country it will be best to deal generally with conditions there and to refer to marked differences in dealing with production in other countries.

The seed is sown in nursery beds, and the plants set out in the field later. Tobacco seeds are very small, and it is estimated that about 300,000 to 400,000 seeds go to the ounce. Allowing for those which fail to germinate (perhaps 25%), loss in transplanting, weak and back-enderd plants, &c., one ounce of seed should yield about 40,000 plants.

The greatest possible care is bestowed on the preparation of the
seed bed—it must have good, very rich soil in fine tilth, be protected from winds, and yet well exposed to sunlight; the southern or southern-westerly exposition is open in the passage. Tobacco is planted in rows six inches apart. Hot beds are made when necessary. A bed with an area of about 50 sq. yds. is advisable for 1 oz. of seed. To destroy the seeds, exc., of weeds, and the larve of insect pests, a fire is often lighted, kept from the bed by a little reticule of earth, and then allowed to burn thoroughly steamed. After this treatment the upper 2 or 3 in. of soil are well pulverized, and fertilizers added, usually, to prevent reinfesting. Tobacco seed is sown in rows, 6 in. apart, in a breadth of 1 ft. minimum, leaving about 1 ft. open. The seed is sown so that the furrow is not visible when the seed is sown. The seed is set so; it is usually thinned with a relatively large quantity of fine ashes, sand or meal, to facilitate thin and even sowing, and the surface of the bed is afterwards lighted, which makes a broad and considerate bed. The seed is usually sown at 4 in. interval. The seed is sown at the depth of 1 in. A light covering of cloth or muslin, raised on short sticks, is often stretched over the bed. Great care is necessary in handling the seed, for the handling of the young and delicate seedlings, which are ready for transplanting in about 3 weeks from the time after sowing. They must be well hardened off before being set out in the open.

The land for their reception must be thoroughly well tilled and manured. If moist, ridges are formed about 3 to 4 ft. apart; the distance apart in the rows varies greatly with various types of tobacco: 6 ft. is the normal for ordinary manufacturing and smoking tobaccos, 1 to 1½ ft. for Cuba and Sumatra types. Cigar tobaccos become coarse if planted too widely. An acre of tobacco planted 3 ft. by 15 in. will contain 11,000 plants and 3 ft. by 6 in. by 15 in., 10,000 plants. During hot, dry weather or during light rains, the plants must be handled very carefully; machines are now available which can set out and water plants over from two to six acres in a working day.

The crop reaches about another sixty days to mature, i.e. about 120 days in all from the date the seed was sown. During this period, until the plants begin to ripen, the tillth is maintained and weeds checked first by horse cultivators or horsecars, and, as the plants increase in size, by hand labour. When the plants show signs of flowering they are "topped" to prevent seed formation, the terminal buds being removed, and only a certain number of leaves at the base of each plant are left to ripen. This operation is and been an experienced judgment to decide when it should be done; the number of leaves to be left varies with the variety and vigour of the plant, the nature of the soil, climate, seasons and particular use for which the tobacco is intended. In the product which is called "topped" is of little value. In the U.S.A., in the cigar tobacco district, fifteen to twenty leaves are often left on each plant, and of manufacturing tobacco no less than twelve leaves. As one result of the "topping," the suckers are usually formed; these also must be removed, although, e.g. in Florida, vigorous suckers are sometimes allowed to remain when the plant is cut, and produce a "sucker crop." Inferior in character to the first or principal crop, but still serviceable.

The leaves now ripen, indicated by a change from a dark to lighter green, and by the appearance of yellow spots. Ripening is complete in about 35 days after topping or about 155 days after sowing. A light frost, if it is well borne, does not injure the leaves. A heavy frost, if it is allowed to happen, may destroy the foliage of the tobacco. The next step is to remove the harvested crop to the drying-shed. Primed leaves are placed at once in shallow baskets or boxes, and when under cover are strung on string or on wire and hung up on laths in the barn. Cut plants are allowed to wilt, or become leafy, before removal from the field, to prevent injury to the turgid leaves. These cut plants may be laid in rows on the ground to wilt, or spitted on long rods or laths supported on trefoils, or placed on spears or drying racks. When sufficiently wilted they are hauled to the barn and hung up there on the same laths on which they were placed in the field.

Artificial shading under development of quite recent years is that of growing some valuable cigar tobaccos under artificial shade. Sumatra produced the best cigar wrappers of the world, and efforts to cultivate Sumatra tobacco in Florida under artificial shade failed so not successful. It was noticed, however, that if the tobacco was grown under the shade of trees the character of the leaf was improved, its size increased, and yield was greater. Both supported on posts, was then retorted to with eminently satisfactory results. The U.S.A. Department of Agriculture, in cooperation with local growers, devoted a great deal of attention and the results were encouraging. Tobacco is now produced in Florida and Connecticut. The yield of leaf is much increased, the plants are protected from the weather, and the enhanced value of the crop much more than repays the very slight additional cost involved. Tobacco is produced in many other fields. So successful have the results been that American-grown tobacco of the Sumatra type is now exported even to Cuba.

Important changes take place in the tobacco leaf from the time it is cut until the finished product is ready for consumption. These may be all placed under curing, but it is usual to measure 1. Curing: (1) Curing proper; (2) fermentation; and (3) ageing.

Sun-curing, now but little practised in the United States, is the simplest method. The wilted tobacco is suspended on racks in the open air, and the air is allowed to dry the leaves without the leaves being in contact with earth. This method is only used in a portion of Virginia and Kentucky, where the tobacco is light and of a particular quality and cured in the open air. The sun preferable, if necessary cured in a barn in which fires may be required during wet weather. This method is employed in a portion of Virginia and Kentucky, where the tobacco is light and of a particular quality and cured in the open air. The sun preferable, if necessary.

In air curing the tobacco is hung in a barn in which there is a free circulation of air during dry weather. Artificial heat may be resorted to in bad weather; in the manufacture of cigarettes and cigars, the tobacco is sometimes cured in this way. The process takes about six weeks.

In flue curing the tobacco is hung in the barn, and, after it has become of a rich yellow colour, slow fires, producing a gradual increase in temperature, are allowed to warm the room, and the leaves are turned, and kept warm for four or five days. The firing must be repeated at intervals as the leaves become soft again. A considerable portion of the tobacco exported to England and Africa is fire-cured.

Flue curing, also known as the Virginian cure, is a set outside the barn, and the heat led in iron pipes or flues, into the building are under the suspended tobacco, which is placed there quite fresh from the field. The temperature is raised, during three to five days, from about 90° F. to 140° F. for primed leaves, or 160° to 175° F. for tobacco on the stalk. The process, which requires great judgment, is then allowed to cool down; a light yellow leaf so largely used for pipe tobacco, cigarettes and chewing tobacco. The name of this method, known as the Kentucky cure, large barns are used, the temperature is not raised above 150° F., and the process occupies from forty to sixty days. As the leaf after curing is brittle and cannot be handled without crumbling to powder. The contents of the barn are therefore left till moist weather occurs, and then by the admission of atmospheric air the leaf blades absorb moisture and become soft and pliant. In this condition the leaves are stripped from the stems and sorted into qualities, such as "hogs," or lower leaves, "firsts" and "seconds."

The leaves are piled up on the barn floor, or hung from six to twelve leaves. Each bundle is tied round with twine, and in this condition the tobacco is ready for bulking for fermentation.

Fermentation, whether in bundles, hands or separate leaves, is piled up or bulked on the floor in a barn into a solid stack to the height of 5 or 6 ft. Within this stack a process of fermentation is quickly set up, and the temperature of the mass rises steeply. Great care is now taken to prevent overheating and to secure the uniform fermentation of all the tobacco. The pile is from time to time taken down and rebuilt, the tobacco from the top going to the bottom and that exposed at the edges being turned in to the centre. From in three to five weeks the fermentation should be sufficiently carried out, and the leaves then have a nice uniform brownish colour, but if the temperature is allowed to mount higher than when light leaves are required. Fermentation is essentially a chemical process due apparently to the presence of enzymes, developed in the leaf, and the exact causes are not understood as far as to forward that fermentation is due to the activity of bacteria, distinct types occurring in various tobaccos, but the balance of evidence seems to point to the assumption that it is possible to inoculate a poor tobacco with, say, the special bacteria present in Cuban tobacco, and so give the product the aroma and other good qualities of the more valuable tobacco. When fermentation is completed the tobacco is graded, an operation carried out very carefully in the case of the better cigar tobaccos, and packed for export, cigar tobacco in bales, and other kinds in hogheads. It is then kept at a moderate and fairly uniform temperature in a warehouse. When, however, there is no marked outward change, the tobacco becomes more mellow. Two years are usually required for ageing, but some tobaccos are kept for four or five years before being used.

An artificial aroma is sometimes given to tobaccos, especially for the "fillers" of cigars, by saucing or treating the leaves with a solution containing an infusion of fine quality tobacco stems, raw, sun-dried and various herbs, essential oils, and essential oils, essence of valerian, powdered cloves, cinnamon and liqueur.

Pests and Diseases.—Tobacco, like other cultivated plants, is not free from attack by various pests and diseases, but fortunately those less destructive than the "wilt" have removed. Of the comparatively trivial incidents do more harm to a relatively delicate plant like the tobacco than to more robust plants.

1. Botrytis allii (firsts or "butter".) is a small active beetle, the larvae of which attack the roots, while the adult beetles cut holes in the leaves. The latter is the more serious, as in addition to the actual damage done by the beetle the holes afford entrance to fungal parasites, such as Alternaria and Stemphylium, and the larva or caterpillars of species of Protopiura. These comparatively large and voracious animals, when abundant, do great damage by eating the leaves. Other caterpillars, "badworms"(Heliolohis spp.),
TOBACCO

1038

attack the buds or burrow into the seed-pods. Seedling plants of tobacco, when young, are prone to be attacked by thrips and the caterpillars of species of Peridroma and Agrotis. " Plant bugs," which suck the juice of the leaves, have been recorded as serious enemies in some parts of the world. Recently, shade-grown tobacco in the northern part of Syria, on one of the best tobacco soils, was attacked by sucking insects known as thrips, which produce " white veins " in the leaf. White vein may also be induced by other causes besides the attack of thrips.

Dried tobacco is liable to be attacked and ruined by the " cigarette beetle," a cosmopolitan insect of very varied tastes, feeding not only on dried tobacco of all kinds, including snuff, but also on rice, wheat, oat, and corn. It is only as a pest attacking tobacco specimens. Other beetles, such as the rice weevil (Calandra oryzae), also attack dried tobacco.

The fungoid diseases of tobacco are comparatively important; the principal ones are caused by the relatively common white rust and mildew, and the cause is known, for example, " Mosaic disease " is the name given to a condition in which the leaves are more or less sharply differenti- ated in light and dark green patches. This matter has been fully investigated by Mr. A. F. Woods (Bureau Bulletin No. 18, Bureau of Plant Industry, U.S. Department of Agriculture), who attributes it to no specific parasite but to a disturbance of the normal physiological activity in the cells.

"Frog's eye," or " leaf spot," denotes the occurrence of small white specks on the leaf. This disease is probably bacterial in origin. Wind and hail may break plants or damage leaves, especially if reduction for purposes. The provision of wind breaks is the only effective remedy.

Diseases which occur in curing are important. Excessive heating causes the spots to become dry and the leaf may become dark and decay. Various names are given, such as " pole burn," " sole sweat," " house burn. " The disease is caused by raising the temperature above 110° F., and results in the leaf becoming yellow and dead. The leaf blight (Botrytis sp.), occurs in wet weather. Too rapid drying of the outer tissue of the leaf leads to the formation of " white veins," which injure leaves required for wrapper purposes, otherwise it is not important. Another defect arising during curing and fermentation is the efflorescence of salts on the surface, a phenomenon known as " saltpetre; " light brushing and spraying with a weak solution of acid will remove this condition.

Improvement by Selection. — Careful examination of a large number of individuals of one variety growing under similar conditions reveals differences in such characters as number of leaves per plant, the size and shape of leaves, leaf size, colour, degree of maturity, mildness, durability, and resistance to disease. Other tests show variability in burning quality, elasticity of leaf, texture, taste, &c. The United States Department of Agriculture has closely investigated this important question and the results obtained are brought together by Messrs. H. D. Shamel and W. W. Cobey in Tobacco Breeding (Bulletin 96, Bureau of Plant Industry, 1907). No crop, it is pointed out, respects selection or breeding too badly. A leaf is valuable if it becomes mature rapidly, as regards both yield and quality, if neglected. The variations are classified as: (1) Variation in type due to crossing, change of soil and climate, especially, for example, when seed from the Virginian produces tobacco resembling Sumatran tobacco. (2) Variation within the type, due to natural tendency to vary, local conditions and maturity of seed. When Cuban tobaccos were first introduced into Florida, the type broke up, but by carefully selecting the best plants, and allowing only those to perpetate which were of the type wanted, the type was obtained. The tobacco flower is fortunately perfectly self-fertile, and by enclosing the flowers of selected plants in paper bags, so as to exclude all possibility of hybridization, progeny true to the type of the mother plant can be obtained.

No attempt should ever be made to raise large crops of tobacco from imported seed, but only a small crop, and the seed of the selected plants should be used for future propagation. In selection work the grower must keep definitely in view the special market requirements for the kinds of tobacco he is producing. Thus for wrapper tobaccos, amongst other points a broad, rounded leaf, with a long middle rib is essential; a narrow pointed leaf is much more desirable than a narrow pointed leaf which yields perhaps only four. Plants may be found growing side by side, the one with broad leaves, the other with narrow, but by selection the broad type can be perpetuated and gradually improved.

Hybridization can also be readily controlled in the case of tobaccos, and in this connexion it is useful to note that, if pollen is desired of a certain type, a small artificial flower is made up and placed in the plant for several weeks if kept perfectly dry, and so can readily be sent by post from one place to another. Another favourable feature is the fact that a single capsule contains from 4000 to 8000 seeds, and one tobacco plant may easily produce from 500,000 to 1,000,000 seeds, &c.

Production.

United States. — Tobacco cultivation dates in the States from the very early years of the 17th century, when it was taken up in Virginia. A general description has already been given of the methods of cultivation and preparation. In 1906 the total area under tobacco in twenty-five states was 796,999 acres, and the production 682,428,530 lb., valued at about $13,500,000. The States producing over 100,000 acres and valued over $1,000,000 are: Kentucky, $4,885,400; Ohio, $1,706,600; North Carolina, $1,396,153; Wisconsin, $1,342,600; Virginia, $1,206,309; Pennsylvania, $1,079,550; Connecticut, $838,184; Tennessee, $511,035; Maryland, $466,393; and Missouri, $317,051. The average yield per acre in the States as a whole in 1906 was 857-2 lb. New Hampshire had the highest average, 1785 lb per acre, and New Mexico the lowest, 208 lb. acre.

The successful production of cigarette tobaccos from Cuban and Sumatran seed was a development of the late 19th century. Perique tobacco is worthy of special notice. This famous tobacco is produced only at Grand Points in Louisiana. Great care is given to the cultivation, and damp atmospheric conditions are desirable during the ripening stages. The leaves, when stripped from the stalk, are made into rolls and subjected to great pressure, which is known to have a choking effect to all loose dry pressed juice. To the chemical changes, mainly oxidation, which go on in this juice while it is exposed to the air, the characteristic aroma and flavour of Perique tobacco are mainly due.

Cuba. — Tobacco is the second industry of the country, the value of the crop being surpassed only by that of sugar. The cultivation is formerly a monopoly of the Spanish crown, but from 1817 onward no tax, usually heavy, has been the only restriction. The superiority of Cuban tobaccos in flavour and aroma, especially for cigar fillers, has long been recognized, but exactly to what conditions these qualities are due is not fully known. The "Vuelta Abajo" from Pinar del Rio, is perhaps the best cigar leaf of the world. The other tobacco-producing provinces in order of importance are Cuba, Puerto Rico, and the island of Hispaniola (called " Granada " by the Spaniards) and Jamaica.

Mexico is an important tobacco-producing country, and Mexican leaf is extensively used in the manufacture of coarse Havana cigars. Mexican tobacco approximates more or less closely to that of Cuba, and is cultivated and prepared in very similar ways.

France. — Tobacco cultivation is an important industry, and the home-grown is used extensively for smoking purposes. In 1905, 33,750 planters cultivated 39,439 acres, and the total crop amounted to 61,614,900 lb., of the approximate value of $2,000,000. The variety grown is usually of the Virginia type, and the leaf is coarse, dark and heavy, and suited to the manufacture of plug and snuff.

Germany. — The chief tobacco-producing divisions are Baden and Austria, the former producing medium size, heavy, and is mainly used in the manufacture of cigars.

Hungary produces tobacco of a rich, dark brown colour, useful for cigars, and also a small, bright yellow leaf, of value as a cigarette and pipe tobacco.

Russia. — In northern Russia the produce is mainly a large, coarse, heavy, dark leaf, of use only for the manufacture of plug and snuff. In southern and Asiatic Russia good tobacco of the Turkish type is produced.

Italy produces two principal types, a dark, heavy Virginia tobacco on the heavy soils of northern Italy, and a Turkish type tobacco on the sandy soils of the southern part of that country.

Syria. — The distinctive Latakia tobacco is produced in the province of Saida in northern Syria. The leaf is subjected to the smoke produced by burning in the green condition leafy branches of species of evergreen oaks (Quercus spp.). The process of fumigation lasts from seven to nine months, and during it the tobacco acquires its black colour and peculiar flavour.

Greece.—Greek tobacco from Turkish seed and closely resembles Turkish tobacco in character and uses. Egyptian cigarettes are to a great extent made from Grecian tobacco. Paper is a monopoly in Greece, and Grecian cigarette manufacturers, to escape the monopoly, have transferred their business to Egypt, where they make cigarettes from Grecian tobaccos by the aid of Greek workmen.

Turkey.—Tobacco is an important crop in Turkey, where its cultivation and cigarette trade is controlled by the Regie Compagnie interessée des tabacs de l'Empire Ottoman, and Narquileh tobacco (called "tunuki" by the Turks) is the most valuable. The leaf is grown up in various parts of the world, e.g. South Africa, and to maintain the standard of the produce fresh supplies of seed were obtained annually from Turkey. To guard against this competition, the export of tobacco seed from Turkey was prohibited in 1907. The
method of cultivation in Turkey is simple, and the plants are set out close together. For the best qualities the leaves are pruned, air-cured, or exposed to the sun, subjected to a lengthy fermentation, and then put in piles to mild fermentation. High prices are obtained for the best Turkish tobaccos. Thus in 1906 from Cavalla and Xanthi 11,000 tons were turned over for a value of about £1,010,000, the range of the various qualities per kilo ranging from 20 to 60 l. being-

The exports mainly to Austria-Hungary, Rumania, Italy, Egypt, the United Kingdom and the United States. In 1906 the production of tobacco amounted to 56,072,000 lb, yielding a profit to the government of some £3,500,000. The produce is usually leaf of considerable size, of medium colour and suited only for cigarette and pipe smoking.

China.—The cultivation is widespread throughout Southern China. The picked leaves are usually either prepared for market by simple exposure to sun for a few days, or in addition are sprinkled with groundnut oil and sometimes other materials also, which result in an increase of strength.

Sumatra.—The tobaccos of Sumatra are especially valued for cutters or wrappers, being of light texture, light brown colour, thin and elastic. They do not, however, possess the aroma essential for cigar-fillers. The industry is of quite recent origin, dating only from 1882. The famous tobacco region, about 15 miles from Buitenzorg, the eastern coast of the island, extends nearly on the equator, and has a very uniform and high temperature and a very high rainfall. The soil is mainly of volcanic origin. Delicate, strong, mild and smooth tobaccos at Sumatra.

The estates are usually very large, and are divided up into fields which are cultivated in rotation, each field being given several years' rest after producing one crop. The tobacco is air-cured, fires being applied during curing, and the process of curing occupies four or five weeks. The fermentation is very carefully controlled, and to obtain the desired light colour the temperature is kept comparatively low. The leaves are graded with the most careful care and attention. The output is about 176 lb each. The high quality of Sumatra tobacco is due in part to the local conditions of soil and climate, and perhaps to an even greater degree to the thoroughness of its stage in its cultivation and curing. The work is done by Chinese coolies under European—chiefly Dutch—supervision. The commercial success of some of the companies has been very striking, dividends as high as 111% having been paid.

Java and Borneo tobacco is very similar to that of Sumatra.

The Philippine Islands.—Tobacco is extensively cultivated in the plains and on the rich alluvial deposits along the sides of rivers. During recent years a considerable amount of tobacco has been grown in the Philippine Islands. The quantities are small, but they are apparently to deterioration in quality. The exports of manufactured tobacco, such as Manila cheroots, find their principal market in India, British India, Australia and the United Kingdom, whilst the principal tobacco used in the home market is Spanish.

British Empire.—Tobacco is grown for local use in many parts of India, but the principal centres of its cultivation on a commercial scale are Madras, Mysore and Assam, where it is extensively cultivated and processed and is grown on a large scale.

Tobacco is produced in Queensland, New South Wales and Victoria. Efforts are being made to develop the industry. New Zealand has attempted to produce tobacco as a commercial crop, but the effort was abandoned several years ago.

In the West Indies tobacco is grown on a limited scale on most of the British islands, but only in Jamaica is there a definite industry. An expert, Mr. W. Chambers, recently reported on Jamaica tobacco as quite of good quality and flavour but often of a heavy nature. The industry there was, however, really for making wrappers to be excelled by any tobacco in the world.

In the British African possessions the outlook for tobacco cultivation is in several instances favourable. Rhodesian-grown Turkish tobaccos have been eagerly accepted by English smokers, and the yield of tobacco from the Transvaal, Natal and Cape Colony have also industries of considerable local importance. Tobacco cultivation has made considerable progress in Nyasaland (British Central Africa). In 1909 there were 69 acres under this crop, the yield being

4480 lb of the value of £13. In 1907 the acreage had increased to 2330, the yield to 413,316 lb, and the value to £6889. Flue-cured bright tobacco is principally produced, but sun-cured is also exported, and in 1906-1907 experiments with Turkish tobacco gave encouraging results.

Canada produces in Ontario and Quebec coarse Virginia type tobacco.

Chemistry.

The constituents of tobacco, as of all other vegetable matter, can be grouped under three heads: water, mineral acids and bases (which pass into the ash on combustion) and organic substances.

The following analyses of upper leaves made at the Connecticut station, New York, and reported in Report No. 54, Office of Experiment Stations, U.S. Department of Agriculture, indicate the more important constituents and also the changes which take place during fermentation.

Nicotine (C₄H₄N₂) is a volatile alkaloid which appears to be present only in the plants of the genus Nicotiana (see Nicotine).

Manufacture.

In the manufacture of tobacco for smoking, we have to do with the leaf, which has been fermented by air-drying in pipes, embracing cut smoking mixtures, cakes, or plug, or roll or spun tobacco. Under this heading come also the cigar and cigarette manufacture.

The raw material in the warehouses is of various qualities: some are strong and tough and are packed in bales of about 176 lb each. Other samples are mild and fine, with aromatic and pleasant flavour, but devoid of strength. By a proper mixing and blending the manufacturer is enabled to prepare the smoking mixture which is desirable for his purpose; but certain of the rough, bitter qualities cannot be manufactured without a preliminary treatment by which their intense disagreeable taste is modified. The storing of such tobacco for a lengthened period matures and improves its quality, and the same result may be artificially hastened by macerating the leaves in water acidulated with hydrochloric acid, and washing them out with pure water. The most efficient means, however, of improving the quality of the leaf is by renewed fermentation artificially induced by moisture and heat.

The manufacturer having prepared his mixture of leaves, proceeds to damp them, pure water alone being used in the United Kingdom, occasionally with the addition of a little spirit of vitriol in Spain.

The "sauces" are employed, which consist of mixtures of aromatic substances, sugar, liqueur, common salt and sulphate of soda, &c., dissolved in water. The primary object is to render the leaves soft and pliant; the use of the sauces is to improve the flavour and burning qualities of the leaves used. When uniformly dampened, the leaves are separately opened out and smoothed, the midrib, if not already removed, is torn out, except when "bird's-eye" cut is to be made, in which mixture the midrib gives the peculiar "bird's-eye" appearance. The prepared tobacco, while still moist and pliant, is pressed between cylinders into a light cake, and cut into fine uniform shreds by a machine analogous to the chaff-cutter. The cut tobacco is now roasted, partly with the view of driving off moisture and bringing the material into a condition for keeping, but also partly to improve its smoking quality. The roasting is most simply effected by spreading it on heated slabs, on which it is constantly turned, or a roasting machine is used, consisting of a revolving drum in which the tobacco is rotated, gradually passing from one end to the other, and all the time under the influence of a current of heated air. The increase in favour of packet tobaccos has brought about the invention of elaborate packing machines.

Roll Tobacco.

Rolls are made by taking a small bundle of the dampened tobacco, each bundle being called a "cover." The material is supplied to the twisting machine by an attendant, and formed into a cord of uniform thickness, twisted and wound on a drum by mechanism which is very similar to that used in rope-making. The drum is turned by means of a foot pedal, and is divided into a number of compartments, each containing tobacco leaves being called "covers." The leaves are placed on the drum, and by being cooked or stoved in moist heat for about
twenty-four hours, are piled between plates in an hydraulic press, and subjected to great pressure for a month or six weeks, during which period the tobacco is dried. This is done to extract an aqueous exudation of juice results from the severe pressure. The juice is collected for use as a shee-dip.

During the process of manufacture, snuff is made by enveloping the desired amount of fillers within covering leaves of a fine bright colour. The packages are placed in moulds, and submitted to powerful pressure in an hydraulic press, by which they are moulded into a particular shape. Tobacco is pressed in to fill each pack. This is done to add a large quantity of vegetable matter to the tobacco used for smoking and chewing; for the latter purpose the cake is frequently sweetened with liqueur, and sold as honey-dew or sweet cavendish.

Cigar-making is the finest and most delicately flavoured qualities of tobacco are generally selected. A cigar consists of a core of central mass of fillers enveloped in an inner and an outer covering; this latter is made from the leaves of the cigar plant. The fillers or inner contents of the cigar must be of uniform quality, and so packed and distributed in a longitudinal direction that the tobacco may burn uniformly and the smoke can be freely drawn from end to end. For the binder whole leaf of the same quality as the fillers is used, but for the wrapper only selected leaves of the finest quality and colour, free from all injury, are employed. The covers are carefully cut to the proper size and shape with a sharp knife, and, after being cramped and smoothed out, are placed together in a pile. In making cigars by the hand, the operator rolls together a sufficient quantity of material to form the filling of one cigar, and envelopes it in her thumb and forefinger of the right hand. This quantity is wrapped in the inner cover, an oblong piece of leaf the length of the cigar to be made, and of width sufficient to enclose the whole material. The cigar is then rolled in the hand to consolidate the tobacco and fix it into proper shape, after which it is wrapped in the outer cover, a shaped piece made to enclose the whole in a spiral manner, beginning at the thick end of the cigar and working down to the pointed end, where it is dexterously finished by twisting to a close formation. The finished cigars are either spread out in the sunlight to be dried, or exposed to a gentle heat. They are then sorted into qualities according to their colour, price, and weight, in boxes, in which they are stored before sale. Machinery is now employed for forming and moulding the fillings of the cheaper grades of cigars.

Havana cigars are, as regards form, classification, method of production and known by the names carried by the wrapper of all classes of the goods. Genuine ("legitimas") Havana cigars are such only as are made in the island; and the cigars made in Europe and elsewhere from genuine Cuban tobacco are classed as "havana." Other brands of home manufacture contain a proportion of Cuban tobacco; and very good cigars may be made in which the name only of that highly-prized leaf is employed. When we come to the inferior classes of cigars, it can only be said that they may be made from any kind of leaf, the more ambitious imitations being treated with various spices designed to give them a Havana flavour. The highest class of Cuban-made cigars, called "havana," are purely of Vuelta Abajo tobacco. Being rolled when it is just half dry, and consequently never dashed with water at all. Next comes the "regalas," similarly made of the best Vuelta Abajo tobacco; and it is only the lower qualities, "ordinary," "select," "candados," and some others, that are made from Vuelta Abajo tobacco, but also with very inferior tobacco, the so-called "veguitas," being exceedingly high-priced. The cigars, when dry, are carefully sorted according to strength, which is estimated by the appearance of a scale. A strong cigar has reddish colorado claro, maduro or oscuro. They are pressed into the cigar boxes for sale, and branded with the name or trade mark of their makers. Cheroots differ from ordinary cigars only in shape, being either in the form of a truncated cone, or of uniform thickness throughout, but always having both ends open and sharply cut across. Cheroots come principally from Manilla, but there are now large quantities imported into the United Kingdom from the East Indie Islands and Burmah.

Cigarettes consist of small rolls of fine cut tobacco wrapped in a covering of thin tough paper specially made for such use. Originally the paper was formed by hand, but now they are very largely made by automatic machinery. The machines cut the paper, gum its edge, measure out the proper quantity of tobacco, wrap it up, make the gummed edge adhere, and roll the ends. In other machines a roll of narrow paper, the size in width equal to the circumference of the cigarette, is converted into a long tube, filled with tobacco, and automatically cut off into proper lengths. Such machines can make several hundred cigarettes per minute. Cigarettes made by hand are of inferior quality, but those made by machine are of high quality. The tobacco leaves are selected and hand-cut, and the paper tubes are filled by hand.

The manufacture of snuff is the most complex, tedious and difficult undertaking of the tobacco manufacture, but it is now of but little importance. The tobacco best suited for snuff-making is thick flaky leaf of a dark colour, but scraps and waste pieces are used. Special preparation is made of the material used for snuff, and the midrifs of leaves are largely used. The material is moistened with a solution of common salt and placed in very high fermentation for some weeks. Various flavouring materials, such as liquorice, tonka beans (Dipterix odorata) and other ingredients are added, the natures of which are often trade secrets.

Fiscal Restrictions.

In nearly all civilized countries the cultivation of tobacco and its manufactures are conducted under state supervision, and are an important source of public revenue. In some, for instance, France, Austria-Hungary and Italy, the cultivation is a state monopoly, and in other countries the crop is subject to heavy excise duties. Since the advent of Charles II. the growth of tobacco in Great Britain has been practically prohibited, the original enactment to that effect having been passed to encourage trade with the young colony of Virginia. In 1885 experiments were conducted, under certain restrictions, and the plant was grown in Norfolk, King's Lynn, and other counties with sufficient success to prove the entire practicability of raising tobacco as a commercial crop in England. In more recent years tobacco has been grown in Ireland, but up to 1910 it had been found impracticable to obtain from the government sufficient relaxation from fiscal restrictions to encourage the home cultivation, though in 1907 the prospect of licences being issued was held out.

Statistics.

The following table, taken from the Year Book of the U.S. Department of Agriculture, 1906, indicates the crops of tobacco in 1905 in the regions mentioned, so far as figures are available.

Total 2,175,193,000

The estimated value of the world's annual crop is approximately 1,400,000,000.

Consumption of Tobacco.—The comparative consumption of tobacco in various countries is best appreciated by expressing it in pounds per head of the population. The following table gives the Atlas of the World's Commerce: Belgium 6-21 lb, United States 5-40 lb, Germany 3-44 lb, Austria 3-02 lb, Australasia 2-20 lb, Canada 1-54 lb, Hungary 2-42 lb, France 2-16 lb, United Kingdom 1-05 lb, Russia 1-10 lb.

The literature of tobacco is very extensive. William Bragg of Birmingham published in 1880 a revised index of the subject, Bibliotheca tabaciana, extending to 248 quarto pages. From such a mass of authorities it would be vain here to make selections, but mention may be made of Fairholt's capital gossiping work, Tobacco, its History and Associations (2nd ed., 1876). As modern investigators work their way upon the lines of their predecessors, there is a valuable and interesting work, Geschichte des Tabaks (1856) and Wagner's Tabakultur, Tabak- und Zigaretten-Fabrikation (1884). In the foregoing account various passages from the article by J. Paxton and W. Dittmar, in the 9th ed. of the Encyc. Brit., have been utilized.

TOBAGO, an island in the British West Indies, 20 m. N.E. of Trinidad, in 11° 15' N. and 60° 40' W. Pop. 18,751. It is 26 m. long and 73 m. broad, and has an area of 114 sq. m. or 73,113 acres, of which about 10,000 are under cultivation. It consists of a single mountain mass (volcanic in origin), 18 m. in length, and rising in the centre to a height of 1800 ft. A great part of the island is clothed with dense forest, in which many valuable hardwood trees are found. The higher lands form part of what is known as the "Rain Preserve," where, in order to attract and preserve the rainfall, the trees are never allowed to be felled. The average temperature is 81° F. and the yearly rainfall is 66 in. The rainy season lasts from June to December, with a short interval in September. The valleys and rivers are not much utilized for horticulture and sheep-farming, which are growing industries. The soil is fine sandy loam, suited to sugar, cotton, sugar, coffee, cocoa, tobacco and nutmegs, all of which are exported; pimento (allspice) grows wild in the greatest profusion. The schools are conducted by various denominations, assisted by government grants. The island is divided into seven parishes. Scarborough (pop. 756), the capital, is on the south coast, 8 m. from its south-western point. It stands at the foot of a hill 425 ft. high, on which is situated Fort King George, now without a garrison. There is a lighthouse at Baedlet Point. Tobago, properly Tobacco, was discovered in 1498 by Columbus, who.
TOBIN—TOBIT, THE BOOK OF

1041

named it Assumption, and the British flag was first planted in
1580. It afterwards passed into the hands of the Dutch and
then of the French, and was finally ceded to the British in 1814.
Until 1889 it formed part of the colony of the Windward Islands,
but in that year it was joined to Trinidad, its legal and fiscal
arrangements, however, being kept distinct. Ten years later
it became one of the wards of Trinidad, under a warden and
magistrate; its revenue, expenditure and debt were merged
into those of the united colony, and Trinidadian law, with very
few exceptions, was made binding in Tobago.

TOBIN, JOHN (1770-1804), English dramatist, was born at
Salisbury on the 28th of January 1770, the son of a merchant.
He was educated at Bristol Grammar School, and practised
in London as a solicitor. From 1789 he devoted all his spare
time to writing for the stage. He submitted no fewer
than thirteen plays before, in 1803, he got an unimportant farce
staged. In 1804, having just submitted his fourteenth play,
romantic blank verse drama entitled The Honey Moon, to
the Drury Lane management, he came to the conclusion that it was
useless to continue playwriting and left London to recruit his
health. The news that his play had been accepted came too
late. He had long had a tendency to consumption, and was
ordered to winter in the West Indies. He left England on the
7th of December 1804, but died on the first day of the voyage.
In the following year The Honey Moon was produced at Drury
Lane, and proved a great success. Several of Tobin's earlier
plays were subsequently produced, of which The School for
Arts, a comedy, was probably the most successful.

See also The Memoirs of John Tobin, with a selection from his
unpublished writings, by Miss Benger (London, 1820).

TOBIT, THE BOOK OF, one of the books of the Old Testa-
ment Apocrypha. It is a good specimen of the religious novel, a
form of literature invented by the Jews. The romance may be
read in a beautiful dress in the Revised Version of the English
Apocrypha. It was never admitted into the Jewish canon, but
it was admitted into the Christian Canon at the Council of
Carthage (A.D. 397). In the Roman Church it still forms a part
of the Bible, but by the Church of England it is relegated to
the position of those other books which "the Church doth read
for example of life and instruction of manners, but yet doth it not
apply them to establish any doctrine" (art. vi.). Some verses
(Tob. iv. 7-9), however, are read in the oratory; and Tobias and
Sarah once occupied the position now held by Abraham and
Sarah in the marriage service.

The Book of Tobit has reached us in Greek, Latin, Syriac,
Aramaic and Hebrew versions; of these the Hebrew are the
latest, and need not be considered. Of the Greek there are
three forms. One is in the Vatican and Alexandrian MSS.; another
in the Sinaitic. Both these texts and both the Vatican and
Sinaitic Scribes' Segments, of the former denoted by B, and the latter
by Ν. B is the common text, which is followed in the English
Apocrypha. Nevertheless Ν is fuller, except in ch. iv., and
more intelligible; it is also more Semitic than B. The two
must have behind them a common original, for they throw light
upon one another, and the full meaning of a passage is sometimes
only to be got from a combination of both. The fullness of Ν
often runs into superfluities, which are retrenched in B. The
third Greek text is only a partial one (vi. 9—xii. 8). It may
derive from a study of Codices 44, 106, 107 in Holmes and
Parsons, which survive from the 3rd Century, and which was
probably used by St. Jerome in the Vulgate. The Itala was
published by Pierre Sabatier at Paris in 1751, and is reproduced in the
Book of Tobit by Neu-
bauer (Clarendon Press, 1878). It agrees very fairly with Ν,
except in the matter of proper names. Jerome's version is
from the Aramaic, or, as it used to be called, the Chaldee. It
cost the saint one day's work. He describes in his preface the
method of its production. He procured the services of a man
who was familiar with Chaldee and Hebrew. This man trans-
lated to him out of Chaldee into Hebrew, while Jerome dictated
to a shorthand writer his own translation into Latin. The work
was done at the request of two Christian bishops, Chromatius
and Heliodorus. Jerome does not mention the Itala, but it is
plain that he was indebted to it. The Syriac text is said to be
based on a Greek version. It was only in 1878 that the Aramaic
version was brought to light, being published by Adolph Neu-
bauer from a unique MS. in the Bodleian Library. It agrees
with Ν and the Itala, but resembles the Vulgate in having
nothing in the first person. According to Neubauer, it is the
very text which was used by Jerome, after allowance has been
made for the arbitrary methods of the Rabbis and of Jerome
himself. But the Aramaic version has Greek birthmarks (see
especially p. 7, line 18), which other scholars than its editor
have thought decisive against its originality. It was held by
Robertson Smith (after Nöldeke) to be "in the highest degree
probable that the Greek text is original." But the Greek text
appears to be itself a translation from some Semitic source.
Was this source Hebrew or Aramaic? The forms Νυδμ and
'Almugelies in xiv. 4, 15 of Ν show that, at least, that chapter is
drawn from Aramaic, not from Hebrew. But that chapter does
not appear in all the versions, and so may be later than the
rest.

With regard to the date of composition there is the widest
difference of opinion. Ewald refers it to the end of the Persian
period, about 320 B.C. (an opinion which Westcott declared to be
"almost certainly correct"); Kohut thinks that the book was
composed in Persia under the Sassanid Dynasty, about a.d. 250.
But Tobit is already quoted as "scripture" by Clement of
Alexandria (Strom. vii. 33), and it is probably later. The

The date of this document is uncertain; but in Irenæus (i. 28, § 5) in his refutation of the Kaballistic
heresy of the Ophites, we find Tobias figuring as a prophet, on
the same level as Haggai. Earlier still the Book of Tobit is
quoted, though not by name, in the Epistle of Polycarp to the
Philippianas (x. 2; Tob. iv. 10. Cf. Prov. xii. 5; Ecclus. xix. 12).
Now the martyrdom of Polycarp is assigned by C. H. Turner
to the year a.d. 156. We seem to have even a quotation by St.
Paul from the Book of Tobit (1 Tim. vi. 7; Tob. iv. 9), in
which the identity amid difference seems to show that the
Apostle is drawing, not from the Greek, but from the Semitic
original. Josephus displays no knowledge of the work, but he
may have been annotated by the same prejudice as the Pharisees
of St Jerome's day, whose displeasure, that father tells us, he
told in face to giving to Latin readers a book which was against
their canon. (Preface to Tobit.) Internal evidence shows that
the writer of the 14th chapter lived after the building of the
Second Temple, which was "not as the first." In iv. 5 and 6 of
that chapter Tobit is made to predict a glorious building of
the Temple, and this is ascribed to the Pharisees. This is the
conversion of all the Gentiles. Such a passage might well
have been penned when the idea of Herod's Temple was already
in the air. If so, this chapter may be supposed to have been
written a little before 10 B.C., while the bulk of the work may
have been indefinitely earlier.

As to the place of composition Persia, Egypt and Palestine
have each had advocates. One thing only appears fairly certain,
namely, that the Greek versions were composed in Egypt. This
conclusion could, we think, be established by an examination
of the language, especially of some technical terms, final
conclusion. But the tale itself conveys us back to Persia. It has
what Moultlen called an "Iranian background." The evil
demon Asmodeus (q.v.) is the Persian Atshima Daeva. Raphael,
"one of the seven holy angels, which present the prayers of
the saints, and go in before the glory of the Holy One," resembles
the protecting spirit Saroash. And the dog, the companion of
Srosha, is there too. For Tobit differs from all other books of
the Bible in containing the only polite reference to the dog.
Tobias's dog indeed does nothing but accompany his young
master on his journey to Ecbatana and back. But he is there
as the companion and guide of man, which is Aram, Tobit's
totally different one; and which is Aram, Tobit's
allegorical guide, not to be set up for the light of the world. It
is what Moultlen called an "Iranian background." The evil
demon Asmodeus (q.v.) is the Persian Atshima Daeva. Raphael,
"one of the seven holy angels, which present the prayers of
the saints, and go in before the glory of the Holy One," resembles
the protecting spirit Saroash. And the dog, the companion of
Srosha, is there too. For Tobit differs from all other books of
the Bible in containing the only polite reference to the dog.
Tobias's dog indeed does nothing but accompany his young
master on his journey to Ecbatana and back. But he is there
as the companion and guide of man, which is Aram, Tobit's
Even in the more Semitic of the two Greek versions, the dog has evidently been found an offence. Mention of it is suggested only in tablets in 4. ὅ Κύριος is made to go behind Tobias, instead of ὅ κατοι.

The motive of the story has been variously regarded as a desire to insist upon the duty of tithe-paying, upon that of almsgiving, and upon that of burying the dead. The Midrash given by Neubauer has no doubts on this point, as the story is immediately followed by the remark—"Behold we learn how greatly is the power of alms and tithes!" But the third motive is equally apparent. Accordingly some have insisted that the story must have been composed at some period when Jewish dead were left unburied, either by the plague of Antiochus Epiphanes (a Macc. 1, 59), or in that of Hadrian, in the turmoil of Bar-Cochbehaz.

If our choice were limited to these two periods, we should certainly prefer the former. For the book carries within itself signs of early date. It contains no Messianic expectation nor any reference to a future life. The last fact is obscured by the Vulgate. Even in the Itala the word "uterum" is added in xix. after "soluturavi vita."

A new interest has been added recently to the study of Tobit by the publication of the Wisdom of Job (in the "Bible".) In the Book of Tobit Ahiqar is represented as the prime minister of Seneca. The name, however, is nowhere claimed by Tobit as his nephew. There is a desire manifested in the book to bring Tobit and Ahiqar together.

TOBOGGANING—TOBOLSK

TOBOGGANING, the sport of sliding down snow-covered hills and artificial ice-shutes on the toboggan, a sled from 3 ft. to 8 ft. long and 2 ft. to 3 ft. wide, formed of strips of wood from ½ in. to ½ in. in width, fitted together and curved up at the front. The toboggan is not so well fitted for use on roads that are not steep or very smooth as is the sled provided with runners, but is generally used on open hills, or upon artificial courses (chutes), which are very popular in Canada. For "Tobogganing," as known in the Engadine winter resorts, see TOBOLLING.

TOBOLSK, a government of western Siberia, having the Arctic Ocean on the N., the governments of Archangels, Vologda, Perm and Orenburg on the W., the provinces of Akkumol and Semipalatinsk on the S., and the governments of Tomsk and Yeniseisk on the E. It is one of the largest provinces of the Russian Empire, occupying 530,820 sq. m. The northern coast is formed by the Yalmal or Yenamal peninsula, separating the Bay of Kara (on the west) from the double bays of the Ob and Taz (on the east). The Pal-ho coast-ridge touches Tobolsk only at its south-eastern extremity. The Urals proper, which run south-west from the Kara Sea as far as the Töll-pads (544 ft.), and thence take a south-easterly direction, form the boundary between Tobolsk and Vologda.

The remainder of the government is lowland, but varies greatly in its different parts. In the south it assumes the character of grassy steppes or prairies, in the north of immense marshes sparsely overgrown with some small trees. A line west of the Lena and north of the Ocean are approached. The steppes, in their turn, may be subdivided into two distinct portions, the Tobol and Ishim steppe in the west and the Baranai in the east. The former, nearly 43,000 sq. m. in area, is one of the most fertile parts of the empire. One-third is under forest, and the remainder has a soil of very productive black earth, which enjoys the further advantage of being sufficiently drained. The climate is continental, with a minimum temperature of 30° to 34° F., being that of the north of Sweden and of Archangel, but the warm summer (65° to 68° in July) and the amount of light received from a bright sky combine to make vegetable development possible. Livestock, especially cattle, are of great importance. The wheat fields extends to about 55,000 sq. m. and is covered with recent deposits; but, as there is no definite slope, the surface waters accumulate in a large number of lakes and marshes. The climate is moist and the summer shorter and less hot than in the Tobol and Ishim steppes. Forests, consisting chiefly of birch, occur sporadically over its surface. The soil of this region is also very productive, being drained of rainwater by the many shallow streams. The dense woods of mosquitoes in summer are a plague to both the horse and the beast.

To the north of the regions just indicated lie the administrative districts of Tura, Tobolosk and Tura, with an area of about 110,000 sq. m.; this may be described as the Russian settlers Mal. It contains throughout of impenetrable forests and quaking quagmires—the dreadful arman, which are altogether impenetrable 50 m. from the scattered settlements. Gigantic cedar-trees, larches, firs, pines, birches and maples grow very close together, and the underwood is so dense that a passage can be forced only with the hatchet, the difficulties being further increased by the abundance of decayed trees. The marsh lands, which are treacherously concealed under a swaying carpet of grassy vegetation, a kind of snow-shoe has to be used even in summer, and many can be crossed only in winter. Indeed vast areas have never been explored. Navigation lasts for nearly six months in the south. The first steamer on the Ob system was launched in 1845 and the second in 1850; since then the steam navigation has steadily developed.

The estimated population in 1905 was 1,656,700, and is practically all Russian, except for some 42,000 Tatars in the south, 16,000 Ostyaks, 4,500 Samoyedes, and 4,500 Voguls. There are, moreover, about 5,000 Germans and Finns, some Jews in the towns, and about 1,500 gipsies.

The government is divided into ten districts, the chief towns of which are Tobolsk, Berezov, Ishim, Kurgan, Sugut, Taru, Turinsk, Tyulinsk, Tyumen and Yakutsk. The standard of education is very low. The Ostyaks are in a very miserable condition, having come under heavy obligations to the Russian merchants and being compelled to hand over to them nearly all the produce of their hunting and fishing. The Tatar settlements are prosperous in character, but not so in the Tobolosk district, where their lands have been appropriated by the government. Malt, oil, butter, Samoyedes, Ostyaks and Voguls are nominally Christians. The Russians and the Tatars live mostly by agriculture. Of the total area of land regarded as suitable for cultivation (28,400,000 acres), 15,600,000 or 55% are owned by the peasant communities.

Agriculture is generally the chief occupation, and Tobolsk is fast becoming a grainary from which corn is exported to the northern regions of European Russia. The total amount of cereals produced in 1907 was 1,800,000 acres, and the principal crops are rye, wheat, oats, barley and potatoes. Flax, hemp and tobacco are cultivated in the north. Livestock breeding is carried on on a large scale. Dairy-farming is not yet the Russian farming is not yet the Russian, but it has made remarkable progress since the trans-Siberian Railway was built.

The industries are insignificant (chiefly tanning, distilling and tallow-melting). In 1900 there were 1,714,000 acres of forested land. The export of cattle, hides, tallow, corn, flour, fish and furs to Russia, both from Tobolsk and from the Kirghiz steppe, is of some importance. Spirits are sent farther east to Tomsk; while all kinds of foodstuffs, such as salted wares, flour, cereals, fruits, and fruit wines, and Ishim and Ishim are the chief centres for trade.

TOBOLSK, a town of Asiatic Russia, capital of the government of the same name, on the right bank of the Iriysh, near its confluence with the Tobol. Pop. (1900), 21,401. It is 305 m. E.N.E. from Ekaterinburg, and is no longer the capital of West
Siberia nor even an administrative centre for exiles. The kremel, or citadel, built in the reign of Peter the Great, by Swedish prisoners, in imitation of the kremel of Moscow, contains the cathedral, erected towards the end of the 17th century. Some 12 m. south-east are the ruins of the “fort of Kuchum,” the site of the capital of Siberia, Isker, before the Russian conquest. Tobolsk was founded in 1587 by Cossacks, and forms the see of the bishop of Tobolsk and Siberia.

TOBRUK (anc. Antipyrus), a settlement with small Turkish garrison on a fine natural harbour situated on the N. coast of Africa at the intersection of 32° N. Lat., with 24° E. Long. The harbour, which is small but deep, and sheltered by high ground, opens to the east. It is about 24 m. long by ½ m. wide; the depth in the centre is over 40 ft. and soundings of over 30 ft. extend to within a very short distance of the shores. It is the only safe port easily accessible to large vessels for over 1000 m., between Sfax in Tunisia and Alexandria, for, although there is safe and deep anchorage in the recess of the Gulf of Bomba, the entrance is rocky and difficult. Tobruk has long been the outlet for the trade of the oases which extend from Jarabub to Siyah, and are a stronghold of the Scussi order (see Cynecaica), and it is also the headquarters of the Libyan sponge fishery, prosecuted by Greeks. In the spring it is visited by a great number of boats, to protect which a small Hellenic warship has sometimes been despatched. But it is as a future man-of-war harbour that Tobruk is likely to be important. It has been visited both by British and Italian squadrons and has become an object of considerable solicitude to the government of Italy. By running into Tobruk and the neighbouring Gulf of Bomba the French fleet eluded British vigilance on its way to Egypt in 1798.

(D. G. H.)

TOCHI VALLEY, or Dawar, one of the chief routes into Afghanistan in the North-West Frontier Province of India. It leads from the Bannu through tribal country, and is inhabited by the Dawari (q.v.). The valley is divided into two parts, known as Upper and Lower Dawar, by a narrow pass called the Taghrai Tangi, some three m. long. Between Dawar and British territory is the low range of uninhabited hills, which skirt the Bannu district. It was by this route that Mahmud of Ghazni effected his raids into India and the remains of a road flanking the valley and of defensive positions are still to be traced. After the Waziristan Expedition of 1864 the Tochi was garrisoned by British troops; but when Lord Curzon reorganized the frontier in 1901, the British troops were withdrawn, and their place supplied by tribal militia. The chief posts are Saidig, Idak, Miranshah, Datta Khel and Sherani. The valley was the scene of action for the Tochi or Dawar Expedition under Brigadier-General Keyes in 1872, and the Tochi Expedition under General Corrie Bird in 1897.

TOCQUEVILLE, ALEXIS HENRI CHARLES MAURICE CLEREL, COMTE DE (1805-1859), was born at Verneuil on the 29th of July 1805. His family on the father's side were of good descent, and distinguished both in the law and in arms, while his mother was the granddaughter of Malesheres. Alexis de Tocqueville was brought up for the bar, or rather for the bench, and became an assistant magistrate in 1830. A year later he obtained from the government of a mission to examine prisons and penitentiaries in America, and proceeded thither with his life-long friend Gustave de Beaumont. He returned in less than two years, and published a report, but the real start of his tour was the famous De la Démocratie en Amérique, which appeared in 1835, and very soon made his reputation (3rd ed. 1840). It was thus once caught up by influential members of the Liberal party in England, which country Tocqueville soon after visited, and where he married an Englishwoman. Returning to France, he was elected a member of the Académie des sciences morales et politiques (Jan. 6, 1838), and beginning life as a country gentleman at Tocqueville, he thought to carry out the English ideal completely by standing for the chamber of deputies. But, with a scruple which illustrated his character, he refused government nomination from Molé, and was defeated. Later he was successful, and sat for several years both before and after the revolution of February, becoming in 1849 vice-president of the assembly, and for a few months minister of foreign affairs. He was a warm supporter of the Roman expeditions, but an equally warm opponent of Louis Napoleon, and after being one of the deputies who were arrested at the coup d'état he retired from public life. Twenty years after his first, he produced another book, De l'Ancien régime, which almost, if not quite, equaled its success. His health was never very strong, and in 1858 he broke a blood-vessel. He was ordered to the south, and, taking up his residence at Cannes, died there on the 16th of April 1859. He had published some minor pieces during his lifetime, and his complete works, including much unpublished correspondence, were produced after his death in uniform shape by H. G. de Beaumont (Œuvres complètes de Tocqueville, 9 vols., 1860-1865).

During the last twenty years of his life, and for perhaps half that time after his death, Tocqueville had an increasing European fame. His manner, which is partly imitated from Montesquieu, was infectious enough; and he was the first and has remained the chief writer to put the orthodox liberal ideas which governed European politics during the first half or two-thirds of the 19th century into an orderly and attractive shape. He was, moreover, as has been said, much taken up by influential persons in England—N. W. Senior, John Stuart Mill and others—and he had the great advantage of writing absolutely the first book of reasoned politics on democratic government in America. Besides, he was, if not an entirely impartial writer, neither a devotee nor an opponent of democracy. All this gave him a very great advantage which he has not yet wholly lost. At the same time he had defects which were certain to make themselves felt as time went on, even without the alteration of the centre of liberal opinion which has taken place of late years. The chief of these was a certain weakness which can hardly be described by any word more dignified than "priggishness." His correspondence with Molé, above alluded to, is an instance of this, and it was also reflected on in various epigrams by countrymen and contemporaries; one of these accuses him of having "began to think before he had begun to learn," and another declares that he avait l'air de savoir de toute hirondelle ce qu'il ne savait d'apprêter. He appears both in reading history and in conducting actual political business to have been constantly surprised and disgusted that men and nations did not behave as he expected them to behave. This excess of the deductive spirit explains at once both the merits and the defects of his two great works, which will probably remain political classics, though they are less and less likely to be used as practical guides.

See Heinrich Jacques, Alexis de Tocqueville; ein Lebens- und Geistesbild (Vienna, 1870); James Bryce, The Predictions of Tocqueville (London, 1887); and, from the French, Louis Belmont, Les Souvenirs d'Alexis de Tocqueville (1893); and Correspondance entre Alexis de Tocqueville et Arthur de Gobineau (1908).

TOCSIN, a signal of alarm given by the ringing of a bell, hence any warning or danger signal. The earliest form in English is tocksin, which was borrowed from the O. Fr. toquesin (toquer, to strike, cf. tocher and sin, mod. signe, a signal, Lat. signum). The use of "touch" and its cognate forms with the idea of giving a sound is seen in "tucket," Ital. toccato, which probably originally meant a signal given by tap of drum, but is always applied to a flourish or fanfare on a trumpet.

TOD, JAMES (1782-1835), British officer and Oriental scholar, was born on the 20th of March 1782, and went to India as a cadet in the Bengal army in 1799. He commanded the escort attached to the resident with Sindia from 1812 to 1817. In the latter year he was in charge of the Intelligence Department which largely contributed to break up the confederacy of Maratha chiefs in the Pindari War, and was of great assistance in the campaign in Rajputana. In 1818 he was appointed political agent for the states of western Rajputana, where he consolidated the chieftains, settled their mutual feudals and collected materials for "The Monuments and Antiquities of Rajasthan" (2 vols., 1829-1832). Another book of value, Travels in Western India (1830), was published posthumously. He returned from India in 1825,
was promoted lieutenant-colonel in 1826, and died in London on the 27th November 1835.

TODAS—A small pastoral tribe of Southern India, found only on the Niligiri hills. They are distinguished by their tall, well-proportioned figures, aquiline noses, long, black, wavy hair and full beards. Their colour is a light brown. Their dress consists of a single cloth, which they wear like the plaid of a Scotch highlander. The women cover the whole body with this mantle. Their sole occupation is cattle-herding and dairy-work. They practise polyandry, a woman marrying all the brothers of a family. The proportion of females to males is about three to five. Their language is a mixture of Tamil and Kanarese, and is claimed by Bishop Caldwell as a separate language of the Dravidian family. The Todas worship their dairy-buffaloes, but they have a whole pantheon of other gods. The only purely religious ceremony they have is Kona Shastra, the annual sacrifice of a male buffalo calf. Toda villages, called mands, usually consist of five buildings or huts, three of which are used as dwellings, one as a dairy and the other for sheltering the calves at night. These huts are of an oval, pent-shaped construction usually 10 ft. high, 18 ft. long and 9 ft. broad. They are built of bamboo fastened with rattan and thatched. Each hut is enclosed with various species of loose stones. The inmates of a mand are generally related and consider themselves one family.

The Todas numbered 807 in 1901.

TODHUNTER, ISAAC (1820-1884), English mathematician, son of George Todhunter, a Nonconformist minister, was born at Rye on the 23rd of November 1820. He was educated at Hastings, at which town his mother had opened a school after the death of his father in 1826. He became an assistant master at a school at Ruckham, attending the same time evening classes at the University College, London. In 1842 he obtained a mathematical scholarship and graduated as B.A. at London University, and was awarded the gold medal on the M.A. examination. About this time he became mathematical master at a school at Wimbledon. In 1844 he entered St John's College, Cambridge, where he was senior wrangler in 1845, and gained the first Smith's prize and the Burney prize; and in 1849 he was elected to a fellowship, and began his life of college lecturer and private tutor. In 1852 he was made a fellow of the Royal Society, and in 1855 a member of the Mathematical Society of London. In 1871 he gained the Adams prize and was elected to the council of the Royal Society. He was elected honorary fellow of St John's in 1874, having resigned his fellowship on his marriage in 1864. In 1880 his eyesight began to fail, and shortly afterwards he was attacked with paralysis. He died at Cambridge on the 1st of March 1884.

Works.—Treatise on the Differential Calculus and the Elements of the Calculus of Variations (1854); Treatise on Fluid Dynamics (1854); Treatise on Statics (1853, 4th ed., 1874); Treatise on the Integral Calculus (1857, 4th ed., 1874); Treatise on Plane Geometry (1858, 6th ed., 1871); Treatise on Plane Coordinate Geometry (1858, 3rd ed., 1861); Plane Trigonometry (1859, 4th ed., 1866); Spherical Trigonometry (1859); History of the Calculus of Variations (1861); Theory of Equations (1861, 2nd ed., 1875); Examples of Analytical Geometry of Three Dimensions (1868, 3rd ed., 1873); Mechanics (1867); History of the Mathematical Theory of Probability from the Time of Pascal to that of Laplace (1865); Researches in the Calculus of Variations (1871); History of the Mathematical Theories of Attraction and Figure of the Earth from Newton to Laplace (1873); Elements of the Calculus of Variations on Lagrange's and Bessel's Functions (1875); Natural Philosophy for Beginners (1877). An unfinished work, The History of the Theory of Elasticity, was edited and published posthumously in 1886 by Karl Pearson. Todhunter also published keys to the problems in his textbooks on algebra and trigonometry; and a biographical work, William Whewell, account of his writings and correspondence (1876), in addition to many original papers in scientific journals.

TODI (anc. Tuder), a town and episcopal see of the province of Perugia, Italy, 28 m. S. of Perugia by road, on a steep hill above the east bank of the Tiber, 1348 ft. above sea-level, and 866 ft. above the river. Pop. (1901), 3599 (town), 16,528 (commune). Some portions of the ancient town walls—of two enclosures, an inner and an outer, the former attributed to the original Umbrian inhabitants, the latter to the Romans—were preserved, and also remains of baths, amphitheatre, theatre, and a subterranean cell of massive masonry, with four niches. Here was found the bronze statue of Mars, now in the course of the sieges which successively surrounded the city, the temple of Mars at Rome was destroyed in the B.C. 270. The Todini were a Roman colony, with a small church and a collegiate-chapel. In 1863 the church and convent were given to the Congregation of the Sisters of Mercy.
tsar. When he recovered he was employed in strengthening the fortifications at the mouth of the Dnieper, and also those of Cronstadt. In 1836 he visited England, where his merits were well understood. In 1860 he was appointed assistant to the grand-duke Nicholas, and he became subsequently chief of the department of engineers with the full rank of general. He was given no command when war with Turkey began in 1877. It was not until after the early reverses before Plevna (56) that the soldier of Sevastopol was called to the front.

Todleben saw that it would be necessary to draw works round Osman Pasha, and cut him off from communication with the other Turkish commanders. In due time Plevna fell. Todleben then undertook the siege of the Bulgarian fortresses. After the conclusion of preliminaries of peace, he was placed in command of the whole Russian army. When the war was over he became governor of Odessa and hereditary count. But his health was broken, though for some time after 1880 he held the post of governor of Vilna, and after much suffering he died at Bad Soden near Frankfort-on-Main, on the 1st of July 1884.

His great work on the defence of Sevastopol appeared in Russian, French and German (5 vols. 1863-1872). Besides this, he wrote a letter to General Brialmont on the operations around Plevna; this was printed in the Russian engineer journal, and in German in the Archiv für gesammte Artillerie-Offiziere (1875).

See Brialmont, Le Général comte Todleben (Brussels, 1883); Rieger, "Todleben u. seines Wirkens Bedeutung für die Kriegskunst der Kolonialzeit als Quellenwerk von Geschichte des Artillerie- und Genieswesens, Vienna, 1881;" Witzel, in Internationale Revue über die gesamten Armeen und Flotten (1879); Schröder, in Archiv für Artillerie- und Ingenieur-Offiziere (Berlin, 1888); Life by Schilder (in Russian, St Petersburg, 1885-1887); Kraemer, General-Adjutant Graf Todleben (Berlin, 1885).

**TODMORDEN**, a market town and municipal borough in the Sowerby parliamentary division of the West Riding of Yorkshire, England, extending into the Middleton parliamentary division of Lancashire; 19 m. N.N.E. of Manchester, on the Lancashire & Yorkshire railway. Pop. (1901), 25,418. It lies on both sides of the river Calder, and the scenery of the valley is beautiful in spite of the numerous factories. Todmorden Hall, a picturesque old mansion of various dates, was the seat of the Radelflites, but they sold the manorial rights about the close of the 17th century. The town hall is a handsomely classical building erected in 1875; it bridges the county boundary, the Calder, enabling the magistrates to exercise jurisdiction in both counties. There is a bronze statue to John Fielden (1784-1849), to whose energy in developing the cotton manufacture the town owes much of its prosperity. The staple industry is the spinning and weaving of cotton, and there are also foundries and machine works. The municipal borough, incorporated in 1856, is under a mayor, 6 aldermen and 18 councillors. Area, 12,773 acres.

**TODDY**, T. Pennant's rendering (Gen. Birds, pp. 35, 61) through the French Todier of M. J. Brisson (Ornithologie, iv. 538) of the somewhat obscure Latin word Todus, not unhappily applied in 1756 by Patrick Browne (Cit. and Nat. Hist. Jamaica, p. 476) to a little bird remarkable for its slender legs and small feet, the "green sparrow" or "green humming-bird" of Sir H. Sloane (Voyage, ii. 306). The name, having been taken up by Brisson (loc. cit.) in 1760, was adopted by Linnaeus, and has since been recognized by ornithologists as that of a valid genus, though many species have been referred to it which are now known to have no affinity to the type, the Todus viridis of Jamaica, and accordingly have since been removed from it. The genus Todus was at one time placed among the Muscicapidae (cf. Flycatchers); but J. Murie's investigations (Proc. Zool. Society, 1872, pp. 663-686, pl. lv.) have conclusively proved that it is not passerine, and is nearly allied to the Monotisidae (cf. Motmot) and Alcedinidae (cf. Kingfisher). It being regarded as forming a distinct sub-family T odorinae of the Monotisidae peculiar to the Greater Antilles, each of which islands has its own species, all of small size, the largest, not exceeding four inches and a half in length.

Of the species already named, T. viridis, P. H. Gosse (B. Jamaica, pp. 72-80) gives an interesting account. "Always conspicuous from its bright grass-green coat and crimson-velvet gorget, it is a very tame bird; yet this seems rather the tameness of indifference than of confidence; it will allow a person to approach very near, and, if disturbed, alights on another twig a few yards distant... commonly it is seen sitting patiently on a twig, with the head drawn in, the beak peering upwards, the loose plumage puffed out, when it appears much larger than it is. It certainly has an air of stupidity when thus seen. But this abstraction is more apparent than real; if we watch it, we shall see that the odd-looking grey eyes are glancing either this way and that, and that ever and anon the bird sallies out upon a short feeble flight, snaps at something in the air, and returns to his twig to swallow it. The birds of the family also show their affinity to the kingfishers, motmots and bee-eaters by burrowing holes in the ground in which to make their nest, and therein laying eggs with a white translucent shell. The sexes differ little in plumage.

All the four species of Todus, as now restricted, present a general similarity of appearance, and possess very similar habits; and even these, by some ornithologists, might be regarded as geographical races. The Cuban form is T. multicolor; that of Haiti in T. subulatus or dominicensis; and that of Porto Rico, originally named in error T. mexicanus, has since been called hypochondriacus.

(A. N.)

**TOGGENBURG, THE**, a special name given to the upper valley of the river Thur, in the Swiss Canton of St Gall. It descends in a N.W. direction from the watershed between the Rhine and the Thur, and is enclosed N.E. by the chain of the Säntis (8216 ft.) and S.W. by that of the Kurfürsten (7576 ft.) and of the Speer (6411 ft.). It is a fertile valley of about 30 m. in length from the source of the river to Wil on the railway line between Winterthur and St Gall. The upper half is traversed by an excellent carriage road, while from Kappel there is a railway to Wil (15 m.). Its industrious population numbered 34,594 in 1900, nearly equally divided between Romanists and Protestants, mostly German-speaking. Those of the upper half are devoted to pastoral pursuits while those of the lower half are engaged in the manufacture of muslin and cotton. This valley is as yet frequented only by Swiss visitors, and retains many characteristics of sub-alpine Switzerland before the arrival of...
of the horde of tourists. At Wildhaus, the highest village (3632 ft.), the house wherein Huldreich Zwingli, the Swiss Reformer, was born in 1484, is still shown. The chief village is Lichtensteig (1387 inhab.), but those of Kirkberg (3025 inhab.) and of Wattwil (4971 inhab.) are the most populous. On the extinction of the main line of the local counts (1430), the possession of their dominions passed to the Lords of Raron (in the Wald), who sold it in 1468 to the abbot of St Gall. (W.A.B.C.)

TOGO, HEIHaICHO, Count (1847—__), Japanese admiral, was born in Kagoshima. He studied naval science and navigation in England from 1871 to 1878, and first became a prominent figure when, in 1894, as captain of the cruiser "Naniwa," he sunk the Chinese troopship "Kowshing" en route for Korea, thus precipitating war with China. When the Russo-Japanese conflict broke out in 1904, he was appointed to the command-in-chief of the Japanese fleet, and under his direction various brilliant operations took place, culminating in the battle of the battle of the Sea of Japan when the Russian fleet was annihilated. For these services he received (1907) the title of count. In 1906 he was made a member of the British Order of Merit.

TOGOLAND, a German colony on the Gulf of Guinea, West Africa. It forms part of the territory formerly distinguished as the Slave Coast and was annexed by Germany in 1884. It is bounded S. by the Atlantic, W. by the British possessions on the Gold Coast, N. by the French colony of Upper Senegal and Niger, E. by Dahomey, also a French colony. (For map see French.) Population (1902), 262,649; and in 1910 in m. in length (1° 14' E. to 5° 38' E.) but inland Togoland widens to three or four times that breadth. It contracts again at its northern boundary to about 30 m. From the coast northward the extreme breadth is 590 m. The area of the colony is some 33,700 sq. m. Pop. about 1,500,000. The white inhabitants numbered (1909) 330 of whom 300 were German. The boundary between Togo and Dahomey, by Franco-German agreement of 1897, follows the coast lagoon from Little Popo to the Mono river, ascends the middle of that river as far as 7° N., thence goes in a direct line to 9° N. and from that point in a north-westerly direction to 13° 30' W. The western boundary was settled by Anglo-German agreements of 1890 and 1899; it leaves the coast west of the town of Lome and proceeds in a zigzag line to where the Deine river joins the Volta; thence follows the Volta to its junction with the Daka and then the Daka up to the point where 9° N. cuts the river. From this point the frontier follows a north-easterly course to 11° 8' N., leaving the town of Yendi and the Chakossi territory on the German side of the boundary line. The agreement of 1899 defined the western boundary from 8° N. northward, and partitioned between the two powers a large block of territory, which by an agreement of 1899 has been annexed by the French. The northern frontier is a line drawn between the termini of the eastern and western frontiers.

Physical Features.—The coast is low and sandy and is formed by the detritus deposited by the sea current called Calena. It is perfectly straight, without harbours, and approached only through a dangerous bar. This coast strip is nowhere more than 2 m. broad. It masked a series of lagoons, of which the largest, occupying a central position, is called the Togo, Avon or Haho lagoon. It is connected by a channel running eastward parallel with the sea, with the Wolo and Libin lagoons, and with the chief lagoon in the south. Between the latter and the chief lagoon an undulating plain stretches some 50 m. The Sio and Haho, the two largest rivers of the coast region, both flow into the Togo lagoon. These rivers rise on the eastern versant of a chain of mountains which traverse the country in a south-westerly to north-easterly direction. Beginning in the south-east corner of the Gold Coast colony this range, composed of quartzites and schists, extends beyond the borders of Togoland into upper Dahomey. It has no general name in the local dialects. Called by the people the "offensive range," it presents a fairly continuous escarpment. It is most elevated in its southern portion, Mt Dabo having a height of 3133 ft., and Mt Koppo, 2950 ft. The direction of the range from 2000 and 2500 ft.; on the north-west side of the range the country is table-land some 600 to 1000 ft. high. Baumann Spitze (3215 ft.) is an isolated peak in 6° 50' N., 0° 46' E., east of the main range. The coast of the western part of the range is washed by the coast streams, drains to the Mono river. The greater part of the colony lies west and north of the chain and belongs to the basin of the Volta. The chief river traversing it is the Oti, which rises in about 12° N., enters Togoland at its north-east corner, and runs with a very sinuous course south-south-west to the coast. The river has one of the longest courses in the world, and in the distance the left bank of the Volta itself is in German territory, but its lower course wholly is in the Gold Coast colony.

The climate of Togoland is hot, humid and unhealthy. There are two wet seasons, the first lasting from March to June, the second from September to November. Apart from the coast region, seasons of drought are not uncommon. The dry wind from the south is the harmad, chiefly from March and April, and causes a red sand, causes a fall of temperature in the (European) summer.

Flora and Fauna.—Coco-nut palms, introduced about the beginning of the 19th century by the Portuguese, grow along the coast banks of the lagoons and the larger rivers. There are belts of reeds, and the coast-land is covered with low, impenetrable bush. There are considerable forests of oil palms, rubber trees and various hardwoods. The swamps and lagoons are rich in fish. The river valleys are densely wooded. On the hills the baobab and hibiscus are characteristic; on the plateau are stretches of open savanna, and park-like country with clumps of silk cotton and shea-butter trees. The fauna resembles that of other parts of West Africa; it is poor on the coast. Elephants and lions are found in the interior.

Inhabitants.—The inhabitants are negroes and negroids. In the north the people are mostly Hausa, in the west they belong to the Tahi-speaking clans, while on the coast they are members of the Ewe (Dahomey) tribes. Among the coast people there is a distinct infusion of Portuguese blood, and in all the ports are descendants of Brazilian negroes who returned to Africa after slavery. In the 19th century there were Spanish and Portuguese traders and agriculturists, in the interior they are largely pastoralists. The Hausa are often traders, travelling the country in large caravans. The inhabitants are partly Mahomedans, partly believers in fetish; comparatively few profess Christianity. As a rule the tribes are peaceful. Slave raiding has ceased, but domestic slavery in a mild form continues.

The capital of the colony is Lome (pop. about 5000) near the western frontier. It is a creation of the Germans, the site, in 1884, being occupied by a small fishing village. It is provided with a jetty; it is the terminus of the railway systems, the residence of the governor, and has churches, schools, hospitals and large business houses. The chief African traders are Hausa immigrants. Togo, which has given its name to the country, is a town on the south-eastern shores of the Togo lagoon. On the narrow spit of land between the lagoons and the sea are Bagida and Porto-Seguro—the last named one of the oldest towns on the Slave Coast and the port of Togo town—and, close to the eastern frontier, Little Lome, Aneho and a station on the German coast. About 15 m. south-west of Porto Seguro, the Anes are reported to have come from the Gold Coast by sea and to have been wrecked at this place. Little Lome dates from the 17th century or earlier. At the time of the recent epidemic of smallpox in 1903, it was in the New French colony. The streets joining these towns are named after the river Kete-Krachi; on an affluent of the Mono in 7° N. is Sagada. In the north are the large native towns of Yendi and Sannsane Mangu, both on caravan routes between Ashanti and the Niger countries.

Agriculture and Trade.—The country is rich in natural products, and its resources have been largely developed by the Germans. It was the first German colony to dispense (1903-1904) with an imperial subsidy towards its upkeep. Several firms have acquired plantations in which coffee, cocoa, cotton, kola and other tropical products are cultivated. Coco-nut palms thrive; maize, yams, bananas, tapioca and ginger are cultivated by the clergymen. Among the rare wild plants of the province are the palm oil and kernels, rubber, cotton, maize, groundnuts (Arachis), shea-butter from the Bassia pubicki (Sapotaceae), fibres of the Raphia vinifera, and the Santheveria guineensis, indigo, and kola nuts. The animals plentiful, on the plateaux and in the wild woods. The natives have several industries, including pottery, straw plaiting, smithwork and woodworking. Some of them are waling in the wood, the wood is of good quality, and dye it with indigo or other pigments; they also manufacture very handsome shawls. Cotton growing under native ownership is not extensive but small quantities were grown in 1901-1902 over 100,000 lb. of cotton grown from native, American and Egyptian seed were shipped to Bremen. In subsequent years the industry attained considerable proportions. Tobacco is grown for domestic and foreign market, and rubber is rapidly coming into importance, though little quantity is grown. Imports are mainly from Germany, exports to Germany and to other West African colonies. In 1908 the value of the imports was £425,000, of the exports £389,000.
Communications.—Good roads have been built connecting the coast towns with the principal places in the interior. A railway about 20 m. long connects Lome with Little Popo. From Lome another railway 76 m. long runs north-west to Agomé on line near Missahô. There are telegraph and telephone lines between Lome and Little Popo, and both places are in telegraphic communication with the Gold Coast and Dahomey, and thus with the international cable system. The German postal and telegraphic offices are maintained at Togoland and Hamburg, and the steamers of three French and two English lines call at Togoland ports.

Government. — The colony is administered by a governor who is advised by a nominated council of unofficial members. Revenue is derived principally from customs duties, direct taxation being slight. In 1907-1908 revenue and expenditure balanced at £103,000.

The table upside down, and the apparatus are so arranged as to which the natives are amenable. The government maintains schools at all the coast towns. Various missionary societies have also established schools. In 1909 some 10,000 native children were receiving instruction.

History.—Before its annexation by Germany the lagoons were a favourite resort of slavers, and stations were established there by Portuguese, British, French and German traders. The coast natives were dependent on the rulers of Dahomey or Porto Novo. Little Popo and Togo were capitals of small independent kingdoms. Little Popo is said to have been founded in the 17th century by refugees from Accra, who were driven out by the Akwamu. At the time that " the scramble for Africa " began, the narrow strip of coast over which the kingdom of Togo ruled was the sole district between the Gambia and the Niger inhabited by a people which the Europeans term native. At Togo Bremen merchants had trading stations, and taking advantage of this fact Dr Gustav Nachtigal, German imperial commissioner, induced the king of Togo (July 5, 1884) to place his country under German suzerainty. The claims made by Germany to large areas of the hinterland gave rise to considerable negotiation with France and Great Britain, and it was not until 1899 that the frontiers were fixed on all sides (see AFRICA, § 3). Meantime the development of the coast region had been taken in hand. On the whole the history of the colony has been one of peaceful progress, interrupted now and again, as in 1903, by severe droughts. At stated intervals the native chiefs are summoned to Lome to discuss administrative matters with the government.

See H. Klose, Togo unter deutscher Flagge (Berlin, 1899), a comprehensive survey, with bibliography; N. Seidel, Die Kiste und das Vorland der Togolosan (Berlin, 1905), and Die Einkaufsreise an der Goldküste; N. Seidel (1906): Schönhart, Volksstämme aus Togo (Dresden, 1909); R. Bütter, Die Forschungstation Bismarckburg und Adèk (1894); Das deutsche Schutzgebiet Togo (Bremen, 1894); L. Kiesow, The Geology and Geographical Vegetation, in Mittell., der geol. Gesell. in München (1905); L. Klose, "Religiöse Anschauungen und Menschentypen in Togo" in Globus 1902; P. Sprigade, Karte von Togo, scale 1:200,000, 12 sheets, also in 2 sheets of the Togoland map, 1905.

TOILET, the process or operation of dressing, also dress and its appurtenances, also applied, especially in the French form "toilette," to a particular costume worn by a lady. The word is adapted from French toilettte, a diminutive of toile, cloth, Latin tela, web, woven cloth, from root of texere, to weave; this word survives in the English "toils," net, snare.1 The earliest use of "toilet" and toilettie is for a cloth, usually of linen or other fine material spread over a table when used to hold the sewing-glass and all the other articles used in dressing, or for a small sheet or cloth thrown over the shoulders of a person while being shaved or having or his hair dressed. It was thus applied especially to the various articles collectively which form the apparatus of a toilet-table or dressing-table. Dressing-tables or toiletties were articles of domestic furniture on which the 18th century cabinet makers and ébenistes of France lavished their decorative art. The escritoire and toilettie combined which belonged to Marie Antoinette is in the Victoria and Albert Museum, South Kensington (see Furniture, Plate IV., fig. 4).

1 "Toil," labour, fatigue, weariness, must of course be distinguished from its French appellation.

TOKAJ (or Tokay), a town of Hungary, in the county of Zemplén, 148 m. E.N.E. of Budapest by rail. Pop. (1900), 5104. It is situated at the confluence of the Bodrog with the Theiss, and gives its name to the famous Tokay wine. Tokaj lies at the foot of the Hegyalja Mountains, which stretch to the north and north-west of the town, between the rivers Hernad and Bodrog, for a distance of about 60 m. as far north as Eperjes. The northern part of the range is also called Sóvar Mountains. These mountains, which have in the northern part an altitude of 2700 ft., slope down towards the south-east near Tokaj in a hilly plateau, about 1500 ft. altitude, where the vineyard region is situated. This vineyard region covers an area of about 135 sq. m., and belongs to 21 adjoining communities. The soil is of volcanic origin (trachyte). The principal places where the wine is produced are Tarczal, Tálya, Mád, Liszka, Tokaj, Tolcsva, Sárspatak, Keresztur, and Zsadány. The yearly production averages 5,000,000 gallons. It is believed that the vine was introduced into this region by colonists from Italy and Morca in 1241.

TOKAT (Armenian Estagnia, anc. Dasimon) the chief town of a sanjak of the same name in the Sivas vilayet of Asia Minor. It is situated in the Sivas-Samsun chausée, altitude 2280 ft., at the mouth of a rocky glen which opens out to the broad valley of the Tozanni Su, a tributary of the Yeshil Irmak. It rose to importance under the Seljuks. Pop. about 30,000, two-thirds Musulman. The industries are the manufacture of copper utensils and yellow leather, and the stamping of colours on white Manchester cloth. Near Tokat copper pyrites, with iron and manganese, kaolin and coal are found; but most of the copper worked here comes from the mines of Keban Maden and Arghana Maden, on the upper Euphrates and Tigris.

(T. G. H.)

TOKELAU (or Union Islands), a group of three atolls in the Pacific Ocean, about 350 m. N.E. of Samoa, belonging to Britain. Atafu consists of 63 islets, Nukunau of 93 and Fakaofo of 62. They produce little but copra. The natives are all Christians, and in type and speech are akin to the Samoans. They number about 500.

TOKEI MONEY, the term employed originally to describe the counters or "tokens" issued by traders to meet the lack of small change. It has now been appropriated by economists and officials to denote the smaller currency that circulates at a nominal value higher than its cost. It is contrasted with "standard" money, and is limited in its amount by state authority. Its power of discharging debts is also limited: in England, e.g., silver is legal tender only up to 40s., copper to 12 pence. Various substances have been utilized for the manufacture of token coinage—silver at a lower degree of fineness, copper in different alloys, and nickel. The French term monnaie artisanale has much the same meaning; so has the German Schädelmünze. A currency, restricted in amount, but with full legal tender power—such as the Indian rupees and the French 5-franc pieces—is midway between token and standard money. Representative money also bears some analogy to token coinage. (See MONEY and SEIGNORAGE.) (C. F. B.)

TOKUGAWA, the name of a Japanese family which provided the ruling dynasty of shōguns from 1603 until the revolution which restored the power of the mikado in 1867. The founder of this dynasty was leyasu Tokugawa (1542-1616), a great general and consummate politician, who was connected by descent with the Minamoto clan. The most famous of the subsequent shōguns was his grandson Ieyemitsu (from 1623 to 1650). (See JAPAN: History.)

TÓKYO (or Tōkiō, formerly called Yedo), the capital of the empire of Japan, situated in 35° 41' N. and 139° 45' E., at the head of the bay of the same name on the south-east coast of the main island. The city stands on the banks of the river Sumida, which, although pretty wide, is navigable by vessels of large tonnage owing to its shallowness. Yokohama, with which Tókyo is connected by 18 m. of railway, is practically the port of the capital. Tókyo is the centre from which several railways radiate. The trains of the Tókai-do line, starting from
the Shimabashi station, run westwards to Kobe, thence to Shimonsoski, at the western end of the main island, a distance of 700 m. The Uyeno station is the starting-point for trains to Aomori, a town 460 m. away, at the northern extremity of the island. In 1907 a central station was designed to be built south of the foreign party in 1860.

The climate is mild and healthy, and for the greater part of the year very pleasant, the seasons of spring and autumn being more especially delightful.

The area of Tókyó is about 30 sq. m. Topographically it may be divided into two parts, upland and lowland (Yamamoto and Shitamachi). There are hills varying in height from 50 to 130 ft. in the upland district; that is to say, the outskirts of the city from north to west. Lowland Tókyó, that part of the city covering the flats on both sides of the river Sumida, is intersected place to new streets and houses. Nearby Sumida, and those which span the canals, have always been distinctive features of Tókyó. The Nihon-bashi (Bridge of Japan), in the district of the same name, is by far the most famous. It is the point from which all distances in Japan are measured. The largest bridges are those named Azuma, Umay, Ryogoku, Shin-o and Eitai over the Sumida.

The streets were formerly narrow and irregular, but the principal thoroughfares have been widened under the Street Improvement Act of 1888. Electric tramcars run throughout the city carrying passengers at a uniform rate of 4 sen, which means that it is possible to travel some 10 miles for one penny. The jinrikisha, drawn by one man or sometimes two men, which were formerly the chief means of passenger conveyance, have notably decreased in number since the introduction of the tram. Tókyó has often experienced earthquakes, and more than once has suffered from severe shocks, which have hitherto prevented the erection of very large buildings. The numerous residences of the daimyōs were the chief characteristics of the old town, especially in the Kojimachi-ku. Many of these have been demodeled and government offices erected on their sites; others have given place to new streets and houses. Nearby Sumida, the centre of Kojimachi-ku, on an eminence, surrounded by moats, stood the castle of Yedo, formerly the residence of the shōguns, which was burnt down in 1873. The imperial palace was subsequently erected on this site. The palace is half European and half Japanese in its style of architecture. The Nijū-bashi is the main entrance. To the east and south of the palace the nearbourhood has undergone great changes in modern times. It was here, at the Sakurada Gate, that I Kamon-no-Kami, prime minister of the shōgun's government, was assassinated by the anti-Imperialists in 1868. Several of the old buildings stand, the offices of the royal family and the offices of the general staff. In another street, leading from the gate, are the foreign office, the supreme court, the local court and the departments of justice and the navy. The temporary buildings of the Imperial Diet, which first met in 1890, are also in this part of the capital. Adjoining the above-named buildings is the Hibiya Park, modelled on the European style, while retaining the special features of the Japanese gardeners' art. The parks have always afforded to the people their chief means of recreation. The largest and most beautiful are those in Shiba and Uyeno. Of the two, the park of the old castle of Yedo, also, are the Imperial Museum, the Imperial Library and the Zoological Gardens. The famous temple of Kwanon, the goddess of mercy, is in the Asakusa Park, in which a permanent fair is held; it is a great holiday resort of the citizens. In Kudanaka Park is the Yasukuni Temple, popularly known by the name of Shokonsa, and consecrated to the spirits of departed soldiers who fell in war. In another ground is a museum of arms, containing trophies of the wars with China and Russia.

Administration.—For administrative purposes Tókyó is divided into fifteen districts or ku, of which Kojimachi, Hongo, Koishikawa, Ushigome, Yotsuya, Akasaka, Azabu and Shiba are situated in the upland portion, while Kanda, Kiyosumishita, Shinjuku, Asakusa, Hongo and Fukuoka are in the lowland. Tókyó is divided into eight districts or gun, which, with the city proper, collectively form the Tókyó-Fu (prefecture), under the general control of one governor called Fu-Chiji. Questions affecting the interests of the whole Fu come before the Ku-kwai, or prefectural council, which is elected by a body made up of the prefect, his secretaries, and the representatives of the municipal council, of which the governor is president; while matters concerning the city alone are discussed by a Shi-kwai, or municipal assembly, and administered by a municipal council, of which the Shōchō or mayor is president. The water supply worked by the municipality. The reservoir at Yodobashi is capable of supplying water (from the river Tama) to all parts of the city; a pressure varying from 80 to 100 ft. The hydrants are fixed in all the streets for the use of the fire brigade, which has a well-disciplined and efficient personnel, and does not lack opportunities for the exhibition of its skill in a town built largely of wood. The police force is another well-trained and successful service. Both police and fire brigade are under the command of a single Keishi-sokan (inspector-general). The postal arrangements are very satisfactory, frequent deliveries being made with the utmost dispatch. The telephone system is extensive, including long-distance wires to Yokohama, Osaka and other large towns. A complete and successful system of education exists. There are many schools and for advanced students devoted to the various branches of science, mechanics and art. The imperial university of Tókyó, which consists of the colleges of law, medicine, literature, science, engineering and agriculture, is the principal institution of learning in the empire. There are several daily newspapers as well as weekly and monthly publications of all kinds. In the lowland part of the city and in the suburbs there are many factories, their number having so greatly increased in recent years that Tókyó may now be described as an industrial town.

Population.—There are no reliable data as to the population of Yedo during the shōgunate. Owing to the influx caused by the periodic visits of the daimyōs (feudal lords) with their numerous attendants, it probably exceeded 1½ million during the early part of the 19th century. The population was 845,780 in 1850; 1,207,341 in 1850; 1,339,726 in 1895; 1,497,565 in 1900, and 1,960,833 in 1905.

History.—No mention is made of Tókyó in Japanese history before the end of the 12th century. It appears to have assumed its present shape till 1457, when Ota Dokwan, a general in the service of Yuesugi Sadaoki, governor of Echigo, built a castle here. About thirty years later the town fell into the hands of Hōjō of Odawara, and on his overthrow by Hidetoshi and Ieyasu, the castle was granted to the latter, who was the founder of the shōgun house of Tokugawa. In 1590 Ieyasu made his formal entry into the castle of Yedo, the extent of which he greatly enlarged. From this date the real importance of Yedo began. The family of the Tokugawas furnished the shōguns (or tycoons) of Japan for nearly three hundred years, and these residing during that period at Yedo. At the restoration in 1868 the population of the city had increased, and the population of Yedo speedily decreased. A fresh vitality was imparted by the transfer of the court from Kiotō, and the town then received its present name Tókyó (eastern capital).

TOLAND, JOHN [christened JANUS JUNIUS] (1670-1722), English delst, was born on the 30th of November 1670, near Londonderry, Ireland. Brought up a Roman Catholic, in his sixteenth year he became a zealous Protestant. In 1687 he entered Glasgow University, and in 1690 was created M.A. by the university of Edinburgh. He then spent a short time in some Protestant families in England, and with their assistance went to Leiden University, to qualify for the B.D. degree. He spent about two years studying ecclesiastical history, chiefly under the famous scholar Friedrich Spanheim. He then went to Oxford (1694), where he acquired a reputation for great learning and "little religion," although at the time he professed to be a decided Christian. While at Oxford he began the book which made him famous—his Christianity not Mysterious (1696, anonymous; 2nd ed. in the same year, with his name; 3rd ed., 1702, including an Apology for Mr. Toland.) It gave great offence, and several replies were immediately published. The author was prosecuted by the grand jury of Middlesex, and, when he attempted to settle in Dublin at the beginning of 1697, he was denounced from the pulpit and elsewhere. His book having been condemned by the Irish parliament (Sept. 9, 1697) and an order issued for his arrest, Toland fled to England. The resemblance, both in title and in principles, of his book to Locke's Reasonableness of Christianity, led to a prompt disavowal on Locke's part of the supposed identity of opinions, and subsequently
TOLEDO, a province of central Spain, formed in 1833 from part of New Castle; bounded on the N. by Ávila and Madrid, E. by Cuenca, S. by Ciudad Real and W. by Cáceres. Pop. (1900), 376,814; area 5910 sq. m. The surface is throughout lofty, and in a great part of its extent mountainous. Towards the centre there are extensive plains or tablelands, but the whole of the south and southwestern part of the province is mountainous, with hills which separate the waters of the Tago and Duero from those of the Guadiana on the south. These mountains are of no great height; until late in the 19th century they were densely covered with forests. Toledo is well watered by the Tago (q.v.) and its numerous affluents, including the Guadarrama and Alberche on the north and the Algodor, Torcon, Pusa and Sangera on the south. The Giguela waters the eastern districts. Gold, silver, lead, iron, quicksilver, copper, tin and other minerals have been discovered, but the mining industry does not prosper and there is little export trade in agricultural products. The number of sheep, goats, asses and mules is large; dairy-farming and the breeding of draught oxen and fighting bulls are also practised. Bees and silkworms are kept in considerable number. Manufactures once numerous, but now silk and woolen cloth, earthenware, soap, oil, chocolate, wine, rough spirit (aguardiente), guitar strings and arms are almost the only articles made. There is also a small trade in charcoal and timber. The province is traversed by three lines of railway—that of Madrid-Seville-Cadiz in the south, Madrid-Toledo-Ciudad Real in the centre, and Madrid-Cáceres-Lisbon in the north.

TOLEDO, the capital of the Spanish province of Toledo and formerly of the whole kingdom, 47 m. by rail S.S.W. of Madrid, on the river Tago, 2400 ft. above sea-level. Pop. (1900), 25,317. Toledo occupies a rugged promontory of granite, washed on all sides except the north by the Tagus, which here flows swiftly through a deep and precipitous gorge. Towards the north the city overlooks the desolate Castilian plateau; beyond the river it is confronted by an amphitheatre of bare mountains, the Montes de Toledo, and in the vast form of a curl of granite, defended by the river and by a double wall on the north, and dominated by the towers of its cathedral and alcázar. The absence of traffic in its maze of dark and winding alleys creates a silence uncommon in so large a city. There are few plazas, the principal open spaces being the arcaded Zocodover, described by Cervantes in the Novelas ejemplares; and some of the finest monuments of antiquity are hemmed in by meaner structures. The houses, tall, massive and sombre, are entered by huge iron-studded doors, and, owing to the extremes of heat and cold characteristic of the Castilian plateau, most of their windows open on an sheltered inner court (patio), the walls facing the street being often blank, though their monotony is sometimes relieved by carved Gothic or Moorish stonework. Nowhere, even in Spain, have the appearance and atmosphere of a Gothic city been

service made up of passages from heathen authors, in imitation of the Church of England liturgy. The title-page still embodies the mystery which the author threw round the question how far such societies of pantheists actually existed.

Mosheim's Vindiciae antiquae christianorum disciplinae (1722), containing the most exhaustive account of Toland's life and writings; A Life of Toland (1722), by "one of his most intimate friends"; Memoirs of the Life and Writings of Mr John Toland, by John Abernethi, published posthumously in London, 1747; John Leiden's View of the Principal Deistical Writers (last ed. 1837); G. V. Lechler's Geschichte des englischen Deismus (1841); Isaac Disraeli's Calomisites of Authors (new ed., 1881); article on "The English Freethinkers" in Theological Review, No. 5 (November, 1864); J. Hunt, in Contemporary Review, No. 6, June 1868, and his Religious Thought in England (1870-1875); Leiden's History of English Thought in the Eighteenth Century, vol. i. (1881), and article in Dictionary of National Biography; J. Cairns' Unbelief in the Eighteenth Century (1881). On Toland's relation to the subsequent Tübingen school, as presented in his Nazeremus, see D. Patrick in Theological Review, No. 59 (October, 1877); and on his relation to materialism, F. A. Lange's Geschichte der Materialismus (Eng. trans. by E. C. Thomas, 1877), and also G. Berthold, John Toland und der Materialismus der Gegenwart (1876).
preserved with so little change. Though the Moslems have left their imprint upon its architecture, and though many ancient buildings have been destroyed after the Christian reconquest to make room for churches, convents and seminaries, Toledo as a whole remains as distinctively Gothic and medieval as Granada is Moorish, Madrid Castilian or Barcelona modern. It has also been from the earliest times the centre of Spanish Christianity, and its archbishop is styled ex officio "primate of all the Spains."

Principal Buildings.—The Taqos is spanned by two fortified Moorish bridges, the Puente de Alcántara, on the north-east, which was built between the 11th and 17th centuries, and the Puente del Alcántar, on the north-west, founded in 1212 and rebuilt in 1390. The inner wall of the city is said to have been founded in the 7th century by the Visigothic King Wamba; much of the present Moslem wall dates from the 11th century.

The Puerta de la Calahorra, the outer wall in 1109. To the same period belongs the Mudéjar Puerta del Sol, the finest of several ancient gateways, among which the Puerta Visgra (1550, restored 1757), and the Puerta del Cambron (1102, restored 1576) are also interesting. The Puerta Visgra Antigua, a Moorish gateway of the 9th century, has been walled up, but its original form is preserved. The Alcázar, a huge square building with a tower at each corner, was transformed into a palace by Ferdinand and Isabella, a gateway by Alonso de Covarrubias and a staircase by Herrera and Francisco de Villalpando. The Ayuntamiento, or City Hall, is a 15th-century building with 17th-century alterations. Some fine Moorish work is preserved in the Salón de Mesa (c. 1450); in the Taller del Moro, which dates in part from the 14th century and was long the workshop (taller) of masons employed in repairing the cathedral; and in the palace of the counts of Fuen-

More important architecturally than any of these secular buildings are the churches of Toledo, and especially its magnificent Gothic cathedral (for illustration see Architecture). The cathedral occupies the site of a Visigothic church, which an inscription preserved in the cloister shows to have been dedicated to the Virgin by King Recared, on the 12th of April 586. If the event thus commemorated were a reconsecration, and it was in 586 that Recared was converted from Arianism to orthodoxy—the church may well have been the cathedral of Eugenius, Elidamo and Pistion, the bishops of which city, which coin in the name of the first of whom is said to have been a disciple of St Paul. From 712 until 1227 the Visigothic church was used by the Moors as their principal mosque. It was then razed by St Ferdinand, who founded the present cathedral. In August 1523, shortly after it was completed, the main fabric was delayed until 1493, while many of the churches and other subordinate buildings were added even later; thus Renaissance and baroque features have been introduced into a design originally Gothic of the 13th century. Though sacked by the Comuneros in 1521 and by the French in 1808, the cathedral is still one of the richest and most splendid foundations in the Peninsula. The exterior is marked by adjacent buildings, its most impressive part being the western façade, flanked by two towers, of which one is unfinished while the other rises to a height of 295 ft. The interior is somewhat dwarfish in appearance by its immense width. It is 295 ft. long by 172 ft. wide, and 84 ft. high. Five naves, with central lantern and choir, and a complete series of side chapels. Most of the chapels date from the 15th and 16th centuries, and are very magnificently adorned with stonework of the Flemish school. Much of the altar work, belong to the same period and number 750. The choir-stalls, placed in alabaster recesses divided by columns of red jasper and white marble, are among the finest extant examples of late medieval and Renaissance work, though rivalled by the retablo, which rises behind the high altar to the roof. The treasury, reliquaries and library, notwithstanding their repeated despoilings, contain many priceless MSS. and works of art. The cathedral also possesses a library of about 400,000 books, which is nearly 10 ft. high and is adorned with 260 silver-gilt statuettes. In it is a monstrance, said to have been wrought from the first gold brought home by Columbus, to which there are said to have been attached the spoils of the Moors ("monstrance of the Mozarab.") Within the precincts of the cathedral are interred the archbishops and cardinals Tenorio, Fonseca, Mendoza, Ximenez, the great constable Alvaro de Luna and a long array of kings and heroes. In the principal tower is hung the campana gorda, a bell weighing nearly two tons and said to be audible as far as Madrid. Among the treasures are said to be some original Goya, El Greco, Titian and Rubens. In the Mozarabic chapel mass and other offices are still performed daily according to the Mozarabic liturgy, which was also used in those days by the majority of the inhabitants ("Mozarab.")

History.—Toledo is of immemorial antiquity; Spanish legend variously ascribes its foundation to Hercules, to Tubic, the grand-son of Noah, to "Iberia, daughter of Hispans," and to Jews who, having been exiled by Nebuchadrezzar, settled here, naming their city Toledota, "the city of generation." It was a stronghold of the Carpetanias and may have been a Cathaginian trading-station. Livy (xxv. 7) mentions Toledo as a Roman municipium, and Livy (xvi. 41) says it was founded by Lucius Pompilius Nigidius, the Roman in 86 B.C. Under Roman rule it became a colony and the capital of Carolania. Various fragmentary remains have been preserved, including parts of an aqueduct, of a circus, which seems never to have been completed, and of a temple (the so-called Cave of Hercules). Toletum was never captured by the Vandals. Its ecclesiastical importance is coeval with the introduction of Christianity into Spain; numerous church councils (see below) were held here, notably in 396, 400 and 589, and here was the chief battle-ground in the long political and religious struggle which ended (586) in the triumph of Spanish Catholicism over Arianism. From the 8th to the 10th century the Moorish Caliph of Cordova, Abd al-Rahman III (756-96), occupied the city. In 1147 Alphonso VI. of Leon and Castile captured Toledo, aided by the Cid, and in 1087 made it his Capital.
a time the Castilians emulated the tolerance of the Moors, but the Jews were expelled in 1492 and the Arabic language was forbidden (except in church services) in 1580. Before this the archbishops of Toledo had become almost independent of any secular authority: they possessed enormous wealth and some of them, such as the Cardinal Jiménez de Cisneros, directed the policy and even led the armies of all Spain. In 1521 Toledo was the centre of the revolt of the Comuneros (see Spain: History); its commercial and political decline dates from 1560, when Philip II. chose Madrid as his capital. The city was the home of Lope de Vega (1562-1535) and forms the scene of several of his dramas. It suffered severely during the Peninsular War, being several times occupied by the French in 1808-1812.

TOLEDO, a city and port of entry, the county-seat of Lucas county, Ohio, U.S.A., on both banks of the Maumee river, about 4 m. from Maumee Bay, Lake Erie, and about 95 m. W. of Cleveland. Pop. (1900), 131,822, of whom 1710 were negroes, and 27,822 were foreign-born, including 12,373 Germans, 2449 English Canadians, and 1636 English; (1910 census) 168,407. Area, 28-57 sq. m. Toledo is served by the Ann Arbor, the Cincinnati, Hamilton & Dayton, the Cleveland, Cincinnati, Chicago & St. Louis, the Detroit, Toledo & Milwaukee, the Detroit, Toledo & Buffalo, the Philadelphia & Northern, the New York, Chicago & St. Louis, and the Michigan Southern. The Michigan Central, the Pennsylvania, the Pere Marquette, the Toledo, St. Louis & Western, the Wabash, and the Wheeling & Lake Erie railroads, by a "belt line" (30 m. long), the Toledo Railway & Terminal Company, by ten interurban electric railways (about 385 m.), and by the Wabash & Erie and the Miami & Erie canals. A channel 400 ft. wide and 21 ft. deep admits the largest vessels from Lake Erie to the city. Six passenger and freight steamship lines communicate with Cleveland, Buffalo, Sandusky, Detroit, Port Huron, Alpena, Mackinac, Georgian Bay and other points on the Great Lakes, and the city has 25 m. of docks. The city park system includes Ottawa Park (280 acres), Bay View Park (102 acres), Riverside Park (118 acres), Central Grove Park (100 acres), Collins Park (90 acres), Walbridge Park (67 acres), with a zoological collection, Navarre Park (53 acres), several smaller parks and triangles, and a boulevard, 18 m. long (incomplete in 1910), connecting the parks. Noteworthy public buildings are the County Court-house, the Public Library (about 65,000 volumes in 1910), the Soldiers' Memorial Building, the Toledo Club and the Toledo Museum of Art (1901). The city is the seat of the Catholic University, including Toledo Medical College (1880), which is affiliated, for clinical purposes, with the Toledo Hospital (1876).

There are numerous hospitals and charities.

Toledo is the port of entry for the Miami customs district and is an important shipping point for the iron and copper ores and lumber from the Lake Superior and Michigan regions, for petroleum, coal, fruit, and grain and clover-seed. In 1909 the imports of the port were valued at $642,286 and the exports at $600,794. The capital invested in manufacturing under the factory system in 1905 was $38,634,590 (62-4% more than that of 1900). The value of the factory products in 1905 was $44,925,004 (40-2% more than in 1900). Foundry and machine-shop products ($4,847,457) were the most valuable manufactures in 1905. In flour and gist mill products (value in 1905, $3,676,290) Toledo is the most important city of the state. Other important manufactures in 1905 were: iron, steel and other metal products ($2,066,484); lumber and planing mill products ($1,604,274); women's clothing ($1,477,648); children's carriages and sleds ($1,465,599); car-shop construction and repairs, by steam railway companies ($1,066,506); carriages and wagons ($1,245,397); structural iron work ($1,102,033); agricultural implements, bicycles, automobiles (a recent and growing industry), plate and cut-glass (made largely from a fine quality of sand found near the city), cobalt, manganese, and other ores. The building of boats, and large vessels is also an important industry. At Rossford (pop. about 400), a suburb, is the large factory of the Ford plate-glass works. The water supply is derived from the Maumee river and is filtered by a muddy suspension of filtered.

The administration of the city became famous after 1897 when Samuel Milton Jones (1846-1903), a manufacturer of oil machinery, was elected mayor by the Republican party; he was re-elected on a non-partisan ticket in 1899, 1901 and 1903, and introduced business methods into the city government. His honesty and sincerity in business and politics gained him the nickname "Golden Rule" man. When the independent movement was led by the Republican party, it was carried on under Brand Whitlock (b. 1869), a lawyer and writer who was mayor of Toledo in 1906-1911. The city council has 16 members, three elected at large and the others by wards, and there are boards of public service, public safety, public health and recreation.

The site of Toledo lies within an immense tract of land, constituting sixteen reservations, acquired by the United States government from several Indian tribes in 1795, and a stockade fort, called Fort Industry, was built here about 1800. In 1817 two companies bought from the government a portion of the tract, at the mouth of Swan Creek, including most of the land now occupied by Toledo. Upon the tract farthest up-stream the town of Port Lawrence was laid out (in 1817). In 1832 a rival company laid out the town of Vistula on the tract immediately below Port Lawrence, in the following year these towns were united and were named Toledo, and in 1837 the city was incorporated. The "Toledo War" was a dispute over the boundary between Ohio and Michigan. When Ohio Territory was organized in 1800 its northern boundary was described as a line drawn from the southern extremity of Lake Michigan due east to the Pennsylvania line, and the official map of the time placed the southern end of Lake Michigan at 43°20' N. lat. The state constitution adopted in 1802 followed the enabling act in accepting this line, but made the proviso that if it should be agreed that Lake Erie east of the mouth of the Miami river, then the northern boundary should be a line from the southern end of Lake Michigan to the most northerly cape of Maumee Bay and thence to the Territorial line, and to the Pennsylvania line. In 1805 the Territory of Michigan was organized with a southern boundary in accordance with the line extending due east from the southern end of Lake Michigan; and therefore there was in dispute a strip of land, about 5 m. wide at its western end and about 8 m. wide at its eastern end, a rich agricultural region, stretching across portions of four counties, and including all of what are now Ashtabula and Lake counties, and portions of Geauga and Cuyahoga counties, in Ohio. Within the belt lay what is now Toledo, and its great importance as a lake port was even then clearly recognized. On the 20th of January 1818 the Ohio legislature accepted the "Harris line" (surveyed in 1817 in accordance with the proviso of the state constitution) as the northern boundary of the state.

Acting on the recommendation of Governor Robert Lucas (1781-1853), on the 23rd of February 1835 the Ohio legislature passed a law creating the new county of Lucas. The new territory was then Wood, Henry and Williams counties (lying partly within the disputed strip) north to the Harris line, and providing for the organization of new townships within this added territory, and for the appointment of three commissioners to re-mark the line. Upon the appointment (March 9, 1835) by Governor Lucas of the three commissioners to re-mark the Harris line, Governor Stevens T. Mason of Michigan ordered a division of Michigan Militia, which near the end of March entered and took possession of Toledo. A division of Ohio Militia marched to Ferryburg, on the Maumee river, about 10 m. south of Toledo; but both Militias disband when Richard Rush, of Philadelphia, and Benjamin C. Howard, of Baltimore, appeared at Toledo as peace emissaries, appointed by President Jackson. In April several members of the party accompanying the Ohio commissioners were arrested by Michigan Militia. In June the Ohio legislature created Lucas county, mostly from the disputed territory, and made Toledo its county-seat. President Jackson now urged Michigan to discontinue interfering with the re-marking of the Harris line, and requested Ohio to postpone putting into effect the Act of Feb. 23, 1835; when throughout the summer an Ohio judge and court officers at Toledo were arrested in September, he peremptorily removed Governor Mason from office. In June 1836 Congress decided the dispute in favour of Ohio, and in 1837 Michigan was admitted to the Union as a state upon condition of relinquishing all claim to the disputed territory, but received what is now known as the Upper Peninsula (the land between Lakes Superior, Huron and Michigan).
TOLEDO, COUNCILS OF, OF TOLL, J. K.

TOLEDO, COUNCILS OF (Concilia toletana). From the 5th to the 16th century about thirty synods, variously counted, were held at Toledo in Spain. The earliest, directed against Priscillianism, assembled in 400. The "third" synod of 589 marked the epoch-making conversion of King Reccared from Arianism to Roman Catholicism. The "fourth," in 633, probably under the presidency of the noted Isidore of Seville, regulated many matters of discipline, decreed uniformity of liturgy throughout the kingdom and took stringent measures against baptized Jews who had relapsed into their former faith. The "twelfth" council in 681 assured to the archbishop of Toledo the primacy of Spain. As nearly one hundred early canons of Toledo found a place in the Decretum Gratiani, they exerted an important influence on the development of ecclesiastical law. The synod of 1565 and 1566 concerned itself with the execution of the decrees of Trent; and the last council of Toledo, that of 1582 and 1583, was so guided in detail by Philip II. that the pope ordered the name of the royal commissioner to be expunged from the acts.

See Canones epistolae et conciliorum saecularium, vi., vii., vii., viii., etc., by T. Bruns, pars prior (Berlin, 1839), critical text of seventeen councils of Toledo (Acta et Pelagiana, 1841-64); E. C. F. Tischendorf, Die Kirchenlteratur von Spanien (Regensburg, 1862-1879); E. H. Landon, A Manual of the Councils of the Holy Catholic Church, revised ed. (London, 1893), vol. i., 151-169. These two summarize the chief canons. See also W. W. R.*

TOLENTINO (anc. Tolentum Picenum), a town of the Marches, Italy, in the province of Macerata, 11 m. by rail W. by S. of that town. Pop. (1901), 5111 (town), 13,197 (commune). It is situated on the Chienti, 735 ft. above sea-level, and was once a fortified town of great strength. The cathedral has a fine portal by the Florentine Giovanni Rosso (1435), and contains the remains of S. Nicholas of Tolentino (d. 1309), whose Renaissance tomb and frescoes illustrating the life of the saint is preserved in a room adjoining the chapel north of the high altar. The church of San Caterino contains the early Christian sarcophagus of that saint, which is embellished with curious reliefs. The Museo Civico contains antiquities discovered during excavations near the town (in 1880-1884) in the Picene necropolis, dating from the 8th-4th centuries B.C. The town is the birthplace of the condottiere Niccolo Mauruzi, and of the learned Francis Philibus, one of the first disseminators of classical literature, who was born in 1598. At Tolentino the treaty was made between Bosnia and the pope in 1797, by which the pope succeeded Avignon; and here in 1815 a battle was fought in which the French under Murat were defeated by the Austrians.

TOLERATION (from Lat. tolerare, to endure), the allowance of freedom of action or judgment to other people, the patient and unprejudiced endurance of dissent from one's own or the generally received course or view.

TOLFA, a town of the province of Rome, Italy, 10 m. E.N.E. of Civitavecchia by road, 1558 ft. above sea-level. Pop. (1901), 3536. It is the chief place in the Tolfa Mountains, an extinct volcanic group between Civitavecchia and the Lake of Bracciano. Volcanic rocks, limestone and sandstone, which contain coal, are found, and some mining is carried on. The output of alum averages 4000 to 5000 tons a year, and is mostly exported from Civitavecchia.

TOLL, JOHAN KRISTOFFER. COUNT (1743-1817), Swedish statesman and soldier, was born at Mölleröd in Scania. Toll came of a very ancient family, of Dutch origin, which can be traced back to the 13th, but migrated to the Baltic provinces in the 16th century. Toll's father was one of Charles XII.'s warriors, his mother a descendant of the aristocratic Gylenstenjorns. In his youth Johan Kristoffer served in the Seven Years' War, and then, exchanging the military for the civil service, became head ranger of the county of Kristianstad. During the riksdag of 1771-1772 the dominant "Caps," deprived him of his post, and Toll, shrewdly guessing that the king was preparing a revolution, almost forced his services on the conspirators, Göran Magnus Sprengtporten (q.v.) declaring that a man who knew so much of their most secret plans must either "be killed or squared." To Toll was assigned by far the most difficult part of the enterprise. It was his business to secure the important southern fortress of Kristianstad. Two days after the coronation, on the 31st of May 1772, he set forth from Stockholm with twenty-two pounds wherewith to corrupt a garrison and revolt a province. He had no sort of credentials, and the little that was known about him locally from the official point of view was not to his credit. Finally, in the fortress itself there was but one man known to be a safe royalist, namely, Captain Abraham Hellichius. On the 21st of June Toll reached Kristianstad. By sheer bluff Toll first won over Hellichius, and, six weeks later (August 17), the whole garrison of Kristianstad, being few officers who proved recalcitrant; taking possession of the records and military chest, and closing the gates in the face of the "Cap" high commissioner who had been warned by the English minister, John Gooderich, that something was afoot in the south. Seven days later Gustavus III.'s coup d'état at Stockholm completed the revolution. Toll was liberally rewarded and more and more frequently employed as his genius as an administrator and his blameless integrity came to light. His reforms in the commissariat department were epoch-making, and the superior mobility of the Swedish forces under Gustavus is due entirely to his influence. But it was upon Toll's boundless audacity that Gustavus chiefly relied. Thus as Gustavus, under the pressure of circumstances, inclined more and more towards absolutism, it was upon Toll that he principally leant. In 1783 Toll was placed at the head of the secret "Commission of National Defence" which ruled Sweden during the king's absence abroad without the privity of the senate. It was he who persuaded the king to summon the riksdag of 1786, which, however, he failed to control, and in all Gustavus's plans for forcing on a war with Russia Toll was initiated from the first. In 1786 he had already risen to the rank of major-general and was Gustavus's principal adjutant. It was against Toll's advice, however, that the king finally decided to wage war. Toll had always insisted that, in such a contingency, Sweden should be militarily as well as diplomatically prepared, but this was far from being the case. Nevertheless, when the inevitable first disasters happened, Toll was, most unjustly, made a scapegoat, but the later successes of the war were largely due to his care and diligence as commissary-general. After the death of Gustavus III. Toll was for a short time war minister and commander-in-chief in Scania and, subsequently, was sent as ambassador to Warsaw. Unjustly involved in the so-called "Armfield conspiracy," he was again dismissed by his sovereign, but was reinstated when in 1796 Gustavus IV. attained his majority. At the riksdag of Norrköping, 1800, he was elected marshal of the Diet, and led the royalist party with consummate ability. On this occasion he forced the muttonish riddarhus to accept the detested "Act of Union and Security" by threatening to reveal the names of all the persons suspected of complicity in the murder of the late king. Subsequently he displayed great diplomatic adroitness in his negotiations with the powers concerning Sweden's participation in the war against Napoleon. In the Pomeranian campaign of 1807 Toll had taken an active part, and it was urged that he was entitled to surrender on the 20th of August by Marshal Brune, whereupon the Swedish army of 13,000 men, which had retired to Rügen, seemed irretrievably lost. It was saved by Toll, who cajoled the French marshal into a convention whereby the Swedish army, with all its munitions of war, was permitted to return un molested to Sweden (September 7). For this exploit Toll received his marshal's båton. It was in the camp of Toll, then acting commander-in-chief in Scania, that Gustavus IV. was about to take refuge when the western army rebelled against him, but he was arrested in the capital before he could do so. Toll retained his high position under Bernadotte, who, in 1814, created him a count. He died unmarried.

(R. N. B.)
TOLL—TOLSTOY, L.

TOLL (etymologically, that which is numbered or counted; from a common Teutonic form, cf. "tale," "tell"); a sum of money, charge for the use and enjoyment of a privilege or advantage. In England it is now usually a sum of money; but formerly tolls in kind were frequent. Among the sins of the Miller in Chaucer's Prologue is that he could "tollen thryes," in that he was clever enough and rogue enough to subtract thrice the legal allowance from the corn he ground. In a note to the Heart of Midlothian, Scott asserts that the name of Lockman given in Old Scots to the hangman was because he was entitled to take a lock or fixed toll out of every boll of meal exposed in the market for sale. An act of 1796 for the regulation of mills, substituting a money for all kinds of tolls of corn in kind taken by millers, makes an exception for tolls to private individuals.

The Weights and Measures Act 1828 enacts that all tolls are to be charged and collected according to imperial weights and measures.

The word "toll" in early times had various meanings, thus it is defined by Glanville as the liberty of buying and selling in one's own land: "toll, quod nos vocamus thelonesum, scilicet libertatem emendi arpentis earundem a poenis quibus incolos impedit persuasit.

This right to take and the thing so taken. It formed the most obvious source of revenue in the early English boroughs; goods coming to market or passing through turnpikes, whether paid for in toll or not, still exists in various European countries under the name of octroi (q.v.). Private lords also levied tolls, but these in no case were levied as a common charge, nor were they taken in a real or feigned grant from the Crown. Imposes by the Crown are more properly taxes, though the name was frequently used, as in malefict, an arbitrary and vexatious impost levied till Edward III.'s time, or in the toll which passed for a tax, as in toll of other exclavations. We learn from Domesday Book that the men of Dover who paid the king's dues there were quit of toll throughout all England. Many subsequent charters granted the like, or even greater immunities from toll to favoured folk. In modern English law toll is either an incident of a franchise, as of a market or fair, or is independent of franchise. In the latter case it is claimed by payment of a set rate or is charged, as an adjunct of parliament, as in the case of turnpikes, railways, harbours, navigable rivers and canals. Toll traverse is paid for passing over a private way, bridge or ferry. No consideration need be proved. Toll threshold is paid for use of a highway. In this case, if charged by a private person, some consideration, such as repair of the highway, must be shown, as such a toll is against common right. At common law a toll must be reasonable. The same principle appears in various acts of parliament. The Statutes of Westminster the First inflicts a penalty for taking excessive toll. The Railway Clauses Act 1845 provides for the equality of tolls, that is, that all people shall be charged the same amount or rate, and fixes the prerogative, by grant or prescription, or by act of parliament. The king and queen consort pay no toll, and the Crown may grant to another exemption from toll. Turnpike tolls, bridge money and causeway mail were abolished in Scotland by the Roads and Bridges Act 1878 as from the 1st of June 1885. In England tolls on roads and bridges are now only payable in a few places.

In the United States tolls are a subject for state legislation, unless they affect the whole commonwealth, when they are dealt with by acts of congress. A city may levy reasonable tolls in a market established by itself. A shuntpike, or road constructed to facilitate passage of tolls on a turnpike road, may be established by a city.

The question of tolls was at one time an important one in international law. Tolls were exacted on certain straits and tidal rivers by virtue of the sovereignty of a particular state. Notable instances were the tolls imposed by the Sicilians on the Straits of Messina. These last were justified as a return for the lights maintained on the coast and the terror to pirates inspired by the castle of Elmina. In 1606, owing to the united efforts of England, France and Holland, an unwieldy rate was arranged.

See Pollock and Maitland, History of English Law (1895); Pease and Chitty, Markets and Fairs (1899); Cunningham, Growth of English Law (2 ed., 1888).

TOLLEMACHE (or TALMASH), THOMAS (c. 1561—1604), British soldier, was the second son of Sir Lionel Tollemache, Bart. (d. 1668), of Helmingham, Suffolk, although an idle report of the time made his mother, Elizabeth Murray (d. 1608), afterwards countess of Dysart and duchess of Lauderdale, the mistress of Oliver Cromwell. In 1678 he became captain in the Guards, with which he served in Tangier, and in 1685 he was made lieutenant-colonel of a regiment of fusiliers, but almost at once he gave up his commission because he disliked the proceedings of James II., and became colonel of an Anglo-Dutch regiment, usually stationed in Holland. At the head of his men he landed in England with William of Orange in 1688 and was made governor of Portsmouth and colonel of the Coldstream Guards, while in 1689 he was chosen an English member of parliament. With the Coldstreamers he served William III. at the battle of Ramillies, and then as a major-general in Ireland, where in 1691 he gained fame at the battle of Aughrim and at the sieges of Athlone, Galway and Limerick. He then went to the Netherlands and aided to his high reputation by his conduct at the battles of Steenkirk and Nieuwpoort in 1694. Tollemache, as he was generally called, proposed an expedition against Brest, the leadership of which was given to him. The fortifications, however, were too strong, and although he led on the English troops with great gallantry they were beaten off with heavy loss.

TALMASH himself was wounded, and returning to Plymouth he died there on the 12th of June 1694. He was buried in Helmingham church, where a long inscription summarizes his life.

TOLSTOY, LEO (1828—1910), Russian novelist and social reformer, was born on the 9th of September (August 28) 1828, in the family of Nicholas Petrovitch Tolstoy, at his country house (not the present one) built in a severely formal style, with Doric pillars and architraves, standing solitarily in a typical Russian landscape. The Tolstoy family, to whom it had belonged for several generations, was originally of German extraction, and had settled in Russia in the days of Peter the Great. The first ancestor of distinction was Petr Andreevich Tolstoy (q.v.). His descendant Nicholas (the father of the great author) was born in 1797. After serving for a short time in the army he retired in 1824, and led the life of a Russian boyar. By his marriage, in 1837, to Anna Leontievna von Korsakov, Count Nicholas in a great measure rebuilt the family fortunes, which had fallen into decay during the two previous decades. Count Leo Tolstoy was the youngest but one of the five children of this marriage, and lost his mother when he was barely three years old. Six years later his father died also, at the age of forty-one. As a child, Tolstoy, though observant and thoughtful, showed no marked talent. He was plain and very sensitive on the point, suffering keenly for want of notice and affection. This sensiveness led him as he grew older to hide himself away from his playmates and spend his leisure hours in books. His early life was a lonely one—he's always been alone, and deeply so. Then, one day, it dawned suddenly upon his mind that Death was ever lying in wait, and that to be happy one must enjoy the present, unconfined with the future. Whereupon the youthful Epicurean flung aside his books and pencils, and, stretched on his bed, fell to munching sweetmeats and reading romances. But Tolstoy's childhood was not without its share of wholesome pleasure. Hunting and shooting, the delight of the Russian noble, occupied much of his father's leisure, and from his earliest years the boy was wont to accompany his parent. At other times he was quite happy sitting beside his father's coachman on an expedition to one of the neighbouring towns, or with his brothers running in and out of the stables and coach-houses. The tedium of the schoolroom and the reproofs of his tutor made a reverse side to the picture, but did not prevent this fund of early memories from being, as he writes, "ever to be treasured, and fondled again and again, serving as a well-spring from which to draw my choicest treasures." After his father's death at Moscow, in 1837, Tolstoy and his brothers were placed under the guardianship of his aunt, the countess Osten-Sacken, and in the care of Mme Georgiakaya, Countess Pertsaevsky. The former died, Mme Jushkov, who lived in Kazan, Mme Jushkov was a typical Russian lady of her class. Keeping open house, fond of gaiety and society, her ideas on moral questions were liberal in the extreme. Tolstoy was eleven years old when he became subject to her influence—an influence which he subsequently regarded as having been the reverse of beneficial. A French tutor was engaged for him and his brothers, prior
to their entrance into the university of Kazan. Outside the hours of study Tolstoy spent his days either in solitary rambles, during which he reflected on the problems of life, or in violent exercise at the gymnasium (the only form of athletics enjoyed by boys of his position in Russia). Thus the physical and philosophical impulses of his nature were developed in equal measure, and these two conflicting forces began their lifelong duel. Only in later years has the philosopher sometimes seemed to outweigh the man of action in Tolstoy's vigorous personality.

In 1843, at the age of fifteen, he entered the university of Kazan, and gained with his college cap and uniform what he At College. prized most, his independence. The lax rule of the university—which was of no high scholastic repute, giving ready admittance to the sons of the rich and noble—enabled him at the same time to enter the world of society and study its complex problems at leisure. Kazan was in those days a real paradise for such as sought happiness in social excitement, dining and dancing. No city in Russia was so given up to the pursuit of pleasure. Among these scenes of luxury and licence the students played a prominent part. Amid such influences the boy soon crept shown in the poem. Tolstoy's evil genius and once more cast him in stony places and left him to work out his own salvation. History, religion and law now claimed his attention in his final efforts to gain the university diploma. 

In religion his opinions had undergone a great change. From the child's unthinking acquiescence in a hereditary faith had sprung absolute unbelief. History he held a useless form of knowledge. "Of what avail," he said, "to know what happened a thousand years ago?" Hence he neglected the lectures on these subjects, absented himself from the examinations, was confined in the university gaol for irregular attendance, and ended by coming out but moderately well in the yearly examination. The conviction that he was wasting his time forced itself upon him. An idle, dissipated life had told upon his health, and early in 1847 Tolstoy asked permission to go down, "on account of ill health and private reasons." Thus ended his college life, which from an educational point of view he had treated as a jest. Somewhat of an enigma as he was to his companions, with his alternate fits of feverish gaiety and melancholy abstraction, aristocratic hauteur and liberal views, there was yet found a little band of students to accompany him on the first stage of his journey. With the youthfulness of the monk admiring the original bent of his mind, they little dreamed their late comrade would one day be acclaimed as Russia's greatest thinker and novelist.

Tolstoy went back to his estates with fresh hope and energy, determined to ameliorate the condition of his peasants and fulfill the duties of a landlord. Rumours had reached him at Kazan from time to time of the recurring famines, revolts and miseries of the serfs. In 1847, as often before, the crops failed to suffice for the needs of the starving people, and whole districts set forth to petition the tsar for food. Here was a vital problem requiring prompt solution. In the course of desultory reading at the university he had studied the writings of Jean Jacques Rousseau, and the Frenchman's plea for Nature, honest work and simplicity of life, had impressed him greatly. Fired with enthusiasm, he now entered heart and soul on the task of realizing this ideal. Unfortunately, he was as yet without sufficient moral stamina to withstand recurring disappointments and to combat the temptations of the world. The painful task of the young author was to find the patience necessary to deal with the deep-rooted mistrust engendered by years of oppression and neglect. After six months of struggle with this discouraging state of things he temporarily gave up the attempt, and we find him in St Petersburg taking up for a time the broken threads of his education. But with the restlessness of transition strong upon him he soon returned to country life, and in company with his brother Sergius gave himself up to hunting, gambling, carousing with Zigan dancers, and throwing all serious thoughts to the winds. The Landlord's Morning may be taken as a picture of this stage of Tolstoy's life. The inevitable complacency of youth, Enlist the Army. pressed by debts and difficulties, in the spring of 1851 he betook himself to the Caucasus, where his eldest brother Nicholas was stationed with his regiment. At Pyatigorsk, at the foot of the mountains, he rented a cottage for about twelve shillings a month, and lived there with the utmost frugality.

Finally his brother's persuasions, aided by the influence of relations in high places, led him to enter the army. He passed the necessary examination at Tiflis, and joined the artillery in the autumn of the year. At that time Russia was much disturbed by the lawlessness of the Caucasian races. Bands of Circassians were constantly on the move, plundering and looting. The punitive expeditions in which Tolstoy took part were his first taste of warfare. Neither his military duties nor his love of sport entirely absorbed him, however. The great power which had hitherto lain dormant now awoke. He began to write, and within the next few years produced some of his finest works. Nekrassov, the editor of the Russian Contemporary, accepted Childhood, the young author's maiden effort. In accordance with the common practice, he added nothing for the MS. Publication of a first attempt was considered ample payment in those days. Tolstoy was now twenty-four years of age. Childhood was followed by The Landlord's Morning, Boyhood and Youth, in quick succession. His early aspirations were revived in these pages, which reflect the doctrines of Rousseau. "You neither know what happiness is nor what life is," he writes to expostulating friends. "Once taste life in all its natural beauty, happiness will consist in being with Nature, seeing her, communing with her." His philosophy notwithstanding, Tolstoy felt a pardonable desire for promotion, which was slow in coming to him. Some verses ascribed to him (an authorship never denied) making fun of the general during the siege of Sebastopol, which appeared in print, may possibly have had something to answer for. Be that as it may, the spirit of unrest and dissatisfaction was moving Tolstoy to return home, when rumours of hostilities arose, and the Crimean War burst into flame. He promptly volunteered for active service, and asked to be allowed to join the army on the Danube, under the command of Prince Gortchakov.

In the early part of 1854 we find him encamped before the walls of Silistria, a town of Bulgaria, which Gortchakov had invested. At the very height of the bombardment, however, Austrian intervention prevailed, and the siege was raised. The din of battle was hushed and revelry took its place. At the ball which promptly celebrated the event Tolstoy felt ill at ease. The joyous music and babel of tongues jarred on his sensitive ear, fresh from the moans of the wounded and dying. He went up to the prince and asked leave to start for Sebastopol. Permission being granted, he hastened from the ballroom, and left Silistria without delay.
He now exchanged the offensive for the defensive. Shot and shell fell like hailstones on the bastions of Sebastopol. Courage, fortitude, the presence of mind were at every moment demanded, while assault followed assault, until at last the overwhelming strength of the allies compelled the Russians to retreat. Throughout that trying time Tolstoy cheered his companions, whiling away many a weary hour with jest and story. Amid this "wrackful siege of battering days" he wrote those Tales from Sebastopol which earned him instant literary celebrity, and caused the emperor Nicholas to issue special orders that he should be removed from a post of danger. An official despatch recounting the events of the siege was next written by Tolstoy at the command of his superior officer, and with the charge of this duty cheerfully afforded, he was sent to St Petersburg. He was never again on the field of battle.

Tolstoy returned home with new impressions. Sad at heart and sick of the horrors of war, he came back with a feeling of brotherly love for the common soldiery, whom he had seen day by day doing quiet deeds of courage and devotion, fighting for their country without hope of reward, without fear of death. He contrasted them with the more self-seeking nobles, and felt their superiority. The stirring scenes through which he had passed, the scenes of constant toil and suffering, all helped to deepen his belief in God. Preceded by the fame of his descriptions of Sebastopol and the Caucasus, he arrived in St Petersburg to find himself the object of a general ovation. The Sovremennik (Contemporary), in which Tolstoy's first work, Childhood, had appeared, numbered among its contributors the foremost writers of the day. To be admitted to their ranks was considered by them an honour equivalent to the award of a fauteuil in the French Academy. They welcomed Tolstoy with open arms, the veteran novelist, Turgeniev, in particular hastening to greet him on his arrival, and beggin him to make his house his home. Society was equally eager to open its doors to the young soldier-author. His vivid and dramatic pictures of the war had been widely read and had created a profound sensation. The great official world of St Petersburg proceeded to offer him a brilliant series of entertainments in which he found himself the central figure. It is not surprising that this combined adulation from literary men and society overcame for a time the growing asceticism of his character. Yet it also in a measure hastened its development. Even while borne swiftly on the current of pleasure, his strenuous nature gradually reasserted itself. In the pages of My Confession Tolstoy describes the phases of this mental unrest. The narrowness of a literary life and the torrent-like existence of a man who had met with success and had been thrust into the front rank of the Russian intelligentsia at an early period, were bound to wear him out. In his study, in his room, he began to feel the oppression of his position. He began to escape from the noise and excitement of the world. During the few weeks that he passed at the fashionable watering-places, he became so engrossed in his thoughts that all conversation was impossible. His family and friends no longer sought him out, and the prospect of meeting one of them was to him a source of sorrow and disgust.

While Tolstoy was thus wakening to a sense of distaste for his environment, a great event was pending. With the accession of Alexander II. in 1855 a wave of progressive policy swept through Russia. The new tsar, Alexander II., removed the bureaucratic circles of Russia, and while fiercely resisted by some of the nobility, met generally with cordial encouragement. The emancipation of the serfs became the burning question. "The People!" and "Progress!" were the cries quickly caught up by the press of Russia and of Germany also. It was in Germany, indeed, that the novel of humble life sprang into being, Gotthelf leading the way with his tales, Ulri the Serf and Ulri the Tenant. Auerbach followed with his village stories, which opened a new world of thought; Stifter and a host of others brought up the rear. This new impulse in literature soon spread to Russia. Turgeniev in his Sportsman's Tales, Grigorovitch in The Village and the City, were among the foremost, and only to endure their sympathy with the moujik. But above all others, Tolstoy was most deeply and lastingly affected. Awakened by this echo from without of his own inmost yearnings, he realized at last the true bent of his mind. "The People!" became his watchword. One increasing purpose henceforth ruled his life, and gradually brought into harmony the inequalities and contradictions of his character. Roused from the inertia which had been caused by nerves and hypochondria, he wrote Polikoushka, a painful story dealing with the ills of serfdom. His active brain then turned to considering the meaning and scope of the catchword "Progress!," and fully to do this he determined to go abroad and study the educational and municipal systems of other countries. He finally started for Germany in January 1857.

Tolstoy only three times crossed the Russian frontier, and these journeys were all between 1857 and 1861. On his first trip, Germany and Italy were hurriedly visited. He also made a short stay in Paris, which had attractions for him in the society of several Russian friends, among whom were Nekrassov and Turgeniev. With the latter he met Mendelssohn, whom he met in Paris he went to Lucerne. An incident which occurred there, and is reproduced in his semi-autobiographical Lucerne, shows the workings of his spirit. He tells how a wandering musician stood one day in the hotel courtyard, and after his performance asked in vain for alms from the convivial crowd assembled. Tolstoy, in the person of the hero, then indignantly came to the rescue, brought the poor minstrel into the hotel, and, moved to wrath with the Churlish waiters who were unwilling to serve him, ordered a private room where he himself supplied his guest's wants, and sent him away happy within his pockets and full of music for the coming night. Outwards, the third alone was of long duration and of corresponding importance in its results. Prior to this last visit to foreign parts, his time was spent between Yasnaya Polyana and Moscow, often in the company of his friend Fet. On a bear-hunt together, Tolstoy narrowly escaped death, an incident which he graphically describes in his Fourth Reading-book for Children (20th ed., 1900, &c.). Fet also mentions it in his Reminiscences. His departure was finally hastened by the serious illness of his brother Nicholas, who had gone to France to recruit his failing health. Tolstoy, after halting in Berlin and Dresden, joined him, but only to witness of his death. Nicholas died on the 20th of September 1866, and Tolstoy's letters of that period show how deeply he was affected by the death of his brother. It gave a yet more serious turn to his thoughts. In a letter to Fet he reverted to his old trouble, the enigma of life. "In truth," he writes, "the position in which we stand is terrible." This mental gloom probably still hung over him during his wanderings through Italy. There is no record of his impressions of Rome, Naples, Florence. Turning his footsteps northwards, however, he began to take renewed interest in social conditions, elementary and secondary education, and the general subject of his quest. From Paris (where his friend spoke of him as "singular indeed, but subdued and kindly") he went to London in 1861, no noteworthy incident marking his brief visit.

The spring of 1861 found him once more at Yasnaya Polyana, where some little time before he had forestalled the Emancipation Act by freeing all the serfs on that estate. He Educational Act now began digesting the mass of information he Educational Act had acquired abroad, eager to put his ideas into practice. The feelings with which he reviewed his experiences were largely those of disappointment. Of the educational systems of Italy, France and Germany, that of the last-named country alone earned his partial approval. While there he visited the universities, prisons and working-men's clubs. He made the acquaintance of Auerbach, and was greatly influenced by his ideas on village schools. He was also much
impressed by the novel institution of the kindergarten, to which Fröbel, the great educationist, was devoting all his energies. Determined to follow these lines, he sought and obtained permission to open a school. In his zeal he also started an educational journal called Yasnaya Poliana. This journal now only exists as a literary curiosity, but the essays published in it have all been reprinted in his collected works. The time for opening the school was well chosen. The liberal spirits of Russia had gained the day and won a great victory. Just two months previously the decree of emancipation (February 1861) had been sent to the districts. The air was rife with schemes for the betterment of the peasantry. A new era seemed to have begun. Tolstoy’s school was essentially “free.” “Everything that savours of compulsion is harmful,” he said, “and proves either that the method is indifferent or the teaching bad.” So that not only were no fees paid, but the children came and went as they pleased, learned what they pleased, and were subjected to no sort of punishment. It was the duty of the teacher to fix the pupils’ attention, and his the blame if they failed to learn. “The student,” said Tolstoy, “must have the right to refuse to perform his duties which do not satisfy his instincts. Freedom is the only criterion. We of the older generation do not and cannot know what is necessary for the younger.” On these principles the Yasnaya Poliana school was started in a house near that of Tolstoy. He himself taught drawing, singing and Bible history. The Old Testament was his handbook; he held it as indispensable in any course of instruction, a model for all. Doubts and fears sometimes assailed him, still for a year all went well. Other schools were opened and the school in the district, and success seemed assured. But the eyes of the government inspectors had long been suspiciously fixed on them, and a correspondence on the subject presently ensued between the ministry of education and the home department. The verdict passed by the former was free from overt animus. “The activity of Count Tolstoy deserves respect and should win co-operation from the educational department, although it cannot agree with all his ideas; ideas which he will in all probability abandon on due consideration” (October 1862). Yet there was a subtle threat conveyed in these last words which was probably not without effect. Sighs of disappointment were heard. His masters desert him, his pupils fall away. The plague of inquisitive visitors annoys him. At the end of the second year the schools were closed, the journal discontinued, and Tolstoy, disheartened and sick, “more,” as he writes, “in mind than body,” betook himself to the healthful quiet of the steppes, to breathe fresh air, to drink koumiss and to vegetate. This was the end of his educational experiment, the aim of which was rather to develop the character than to educate in the ordinary sense of the term. When later he asked leave from the authorities to reopen the schools, it was peremptorily refused. His socialistic theories were now fully unfolded. In his view the people were everything, the higher classes nothing. The latter had misinterpreted the meaning of “progress,” imagining it to be synonymous with education; and hence compulsory teaching had been resorted to, with harmful results. Reading and writing played but a small part in forming a man’s mind and fitting him for life. They merely rendered him more articulate. These questions should be left to the people themselves. Their demands were very clearly expressed. They declared that they wanted, and were thoroughly convinced that “in the great question of their spiritual development they would neither take a wrong step nor accept that which was false.” Such was in substance Tolstoy’s doctrine. “The people,” he affirms, “are stronger, more independent, more just, more human, and, above all, more necessary than the upper class. It is not they who should come to our schools; we should learn of them.” This desire to subvert society is akin to the philosophy of Rousseau, as expressed in Emile (livre iv).:

“C’est le peuple qui compose le genre humain; ce qui n’est pas possibile n’est pas la peine de le concerter. L’homme est le meme dans tous les etats; si cela est, les etats les plus nombreux meritent le plus de respect.” Devant celui qui pense, toutes les distinctions civiles disparaissent: il voit les memes passions, les memes sentiments dans les autres que dans l’homme illustre; il n’y a differenc entre leur bonté ou leur恶情, qu’un coloris plus ou moins appele. … Etudiez les gens de cet ordre, vous verrez que, sous un autre langage, ils ont autant d’esprit et plus de bon sens que vous. Respectez donc votre homme; lorsque cette collection des peuples, que quand tous les rois et tous les philosophes en seraient dites, il n’y paratrait guere, et que les choses n’en iraient pas plus mal.”

While Tolstoy’s theories were thus in course of practical solution, his literary powers suffered eclipse. Turgenev, who lived near him in the country, writes in disgust that he “has grown a long beard, leaves his hair to fall in curls over his ears, reads newspapers in detestation, and has no soul for anything but his property.” Indeed, his time was fully taken up, for while still occupied in supporting the school, he had allowed himself to be nominated to the position of “Arbitrator,” which he held for a year and some months (1861–1862). Relations with the Peasantry.

This was an arduous post. The arbitrators were appointed under the Law of Emancipation to supervise the distribution of land, to adjust the terms, define the conditions of purchase, and decide all matters in this connexion. He could do none of this. Every day he had difficult points to deal with, deputations of peasants coming to see him, the new law and the rights it bestowed on them having to be explained. The hardest of all Tolstoy’s tasks was to remove the suspicion and mistrust felt by the serfs towards the landlord. On the other hand, he had to contend with the nobility of the district, who were well aware of the side on which his sympathies placed him. For a year and a half he tried energetically to do his duty, but his experience led him eventually to regard the Law as a not unmixed blessing. He had come too soon, and been granted too much. The condition of the peasantry was worse than before. A noble impulse, inspired by love of the people, impelled Tolstoy to become their champion and interpreter.

A tragic incident occurring about this period (1866) forcibly illustrates Tolstoy’s character as a defender of the helpless. A regiment had recently been stationed near Yasnaya Poliana, in consequence of some five hundred convicts being at work upon the railway. In this regiment was a certain Captain N., a strict disciplinarian, who led a solitary life and was much disliked by his brother officers and his men. For trifling faults he would condemn his soldiers to unheard-of punishments. One of his orders in particular, a young man of some education—who had voluntarily taken the place of a comrade to free him from military service—was constantly getting into trouble, until, for some slight clerical error in a report, Captain N. ordered him to be degraded and flogged. This was too much for the poor volunteer. He followed the officer as he was leaving the orderly-room, and struck him a blow on the face. He was immediately placed under arrest, and the details of the occurrence quickly spread through the neighbouring villages. Two officers of the regiment brought the story to Tolstoy and begged him to underwrite the accused’s defence. He consented readily, and no opposition being made by the military authorities, at once prepared for the court-martial. A few days afterwards the court assembled. Warned by the president of the severity of military law, Tolstoy made answer that he was come to defend not a criminal but a man compelled to crime by force of circumstances outside his will. The plea he set up was that the prisoner was not in full possession of his senses; but this defence was not allowed to stand. The soldier was condemned to be shot. In spite of the utmost intercession Tolstoy could make. The motion of the court was approved by his appeal, the mute acquiescence of the soldier (persuaded that death was better than the living agony of exile), the closing tragedy—all this, added to the many scenes of war and bloodshed which he had previously witnessed, made a lasting impression and caused him to raise his voice yet louder in the cause of universal love and peace. During the preceding period of ethical experiment he published only two books, but these stand high among his works. They were Three Deaths (1859) and The Cossacks (1863)—the latter written ten years before, its leading idea being that culture is the enemy
of happiness. At the conclusion of his arbitratorship, seeing his efforts partially nullified, and feeling himself overstrained and overworked, he determined to exile himself for a time to Samara, a south-eastern province. He halted on his way in Moscow, and here one night's high play cost him the MSS. of The Cossacks, which he sold to the editor of the Russian Messenger for £100 to pay his debts of honour. A pleasant feature of this visit to Moscow lay in the renewal of his intimacy with the Behrs family, Sophia, the younger daughter of the house, being his special attraction. He finally reached Samara in the spring of 1864 and wrote "knoutmaire," revelling in what he called "the life of a beast of the field."

By the month of July he felt completely restored to health, and returned to Yasnaya Polyana, where his sister Maria and his aunt, Mme Ergolskaya, were looking after the property. The house in which he now lived was comparatively new. The one in which he was born was sold to pay some earlier gambling debts, and had been removed bodily to the Dolgoe estate some 30 m. distant. He now felt a sense of something wanting in his home—a feeling of incompleteness took possession of him. He wanted to see Sophia Behrs, and accordingly left almost quietly for Moscow, where Sophia, a fashionable Russian doctor, born and bred in Moscow, and a graduate of that university. He had three daughters, of whom Sophia was the second. The friendship between the Behrs and the Tolstoy families was of old standing, Countess Maria Tolstoy having been a school companion of Mrs Behrs. It was now the height of summer, and every one of consequence was leaving the city for their country seats. The Behrs family were going on a visit to their grandfather, whose estate lay not more than 40 m. from Yasnaya Polyana. Here they accordingly broke their journey, and during the pleasant days that followed Tolstoy's attachment deepened. Not long after their departure his impulse took shape, and mounting his horse, he set out for Twycy, where they were staying. His errand was a definite one; and he lost no time in fulfilling it. At first

Marriage. Dr Behrs demurred, unwilling to allow his second daughter to marry before her elder sister, but his objections were presently overruled. On the 23rd of September 1862 the marriage took place, and Tolstoy installed his bride at Yasnaya Polyana with the conviction that calm and contentment were his at last. Two weeks later he wrote to his father almost saying that he was the happiest man he had felt quite a new man. In his Confession some years later he writes: "The new conditions of a happy family circle led me away from my researches into the meaning of life. My whole mind became concentrated on the family—on the mother, the children, and the anxiety to provide due means of subsistence. The effort after perfection resolved itself into the effort to ensure the happiness of my offspring." Tolstoy thereupon settled down to country life, and though to the young countess this exile from her town friends and relations must have been somewhat of a trial, they remained on their estates for the following eighteen years, with very short intervals of absence. They had thirteen children, of whom the eldest was born in June 1863. In the bringing up and instruction of his family Tolstoy conformed in essentials to the requirements of his position. No experiments were attempted. English and German governesses were engaged, and their educational methods followed the usual routine. Both father and mother devoted a considerable amount of time to their children. Punishment was rare. It consisted in a strict "boycott" of the offender, which was not relaxed until a frank confession of fault was made. The penalty to a sensitive child. The theory of free option in study was dropped by Tolstoy in the case of his children, but he was for ever joining in their games, taking them on his shooting expeditions and sharing in their gymnastic exercises. Manual labour was always congenial to the great writer, and formed a natural concomitant to his pastoral existence. It was a common thing for him to mow the lawns, hoe and rake the garden beds, or when out walking to take the scythe from a labourer and wield it lustily.
TOLSTOY, L.

restored by M. and Mme. Fet. The letters which subse-
sequently passed between them often served only to fan the
flame, so that even the amiable Fet was involved in the
dispute and for a short time estranged from Tolstoy. Finally, after a lengthy
and acrimonious correspondence, the threatened resort to arms
was averted through the intervention of friends; but fourteen
years were allowed to pass before a reconciliation took place.
In 1838 Tolstoy, believing himself to be in a dying state,
at length made overtures of peace to his brother-in-law; overtures
which Turgenev met cordially in the following terms:

"Dear Leo Nikolaevitch,—I received your letter to-day
which you sent to me poste restante. I was delighted and much
moved by it. With the greatest pleasure I am ready to renew our
former friendship and to press your proffered hand. You are quite
right in that you had no formality towards me. I am certain,
that they ever did exist have long since disappeared, and no remem-
brance of you now remains save that of a man to whom I am sincerely
devoted, and of a writer whose first step it was my great privilege
to be one of the earliest to welcome; whose every new work has
always aroused in me the greatest interest. I rejoice from my heart
that our misunderstanding has come to an end. I hope to be in
the province of Orel this summer, and then we shall meet. I send
you my best wishes, and once more grasp your hand in friendship."

Meanwhile Tolstoy had pursued literary labours with relent-
less ardour and with ever-increasing fame. Prince Andrei (the
hero of War and Peace) and Anna Karenina in turn occupied
all his thoughts. Several years were given to the perfecting
of these remarkable character-paintings. When the publica-
tion (1864-1869) of War and Peace had been succeeded by that
of Anna Karenina, he set himself to write yet another great
novel, dealing with the times of Peter the Great, but after
working at it for some months he suddenly abandoned the
scheme and took up the Moscow stories. One of the few excursions made during these years
of tranquillity was undertaken in 1866 to the battlefield
of Borodino, the scene of the famous fight in 1812. For two days
Tolstoy wandered over the plain, investigating and taking
notes, and there he drew a plan of the battle, which was after-
wards published as a frontispiece to War and Peace. But
the continued pressure of severe nervous and mental strain was
bound to affect a man of his calibre; health and spirits gradu-
ally sank, so that in 1870 Countess Tolstoy induced him once
more to seek the healthful air of Samara, and subject himself
in practice there to a strange feature of this "treatment"—lay in the avoidance
of meal and vegetables, the diet being strictly confined to
meat. Tolstoy pitched his tent in the village of Karakleev,
where the primitive life among the Bashkir nomads exactly
suited his habits and disposition. He had a faculty for
making himself at home with peasant folk, and was a great
favourite among them. In this district there was a large
community of Molochans, a sect whose tenets differ consider-
ably from those of the Orthodox religion of Russia. They
acknowledge no guide save the Bible, and reject all the rites
and ceremonies of the Greek Church. Their honesty, industry
and temperance made them an example to all the country
round, and caused Tolstoy to study them with special interest.
So delighted was the count with this visit to Samara, that he
shortly afterwards purchased an estate of over 2000 acres in the
district. But his pleasure was short-lived, for not long
afterwards (1872-1873) the crops failed and a serious famine
broke out. He thereupon opened a subscription fund for the
starving population, and went from village to village taking
a quantity of grain with him, and making what provision was
possible in the circumstances.

Tolstoy was now making up for lost time, learning what he
had failed to learn at the university. Greek was his great
attraction. "Without Greek," he exclaims, "there
Studied in
Philosophy
is no culture." He also became enamoured of the
writings of Schopenhauer, and for the greater part
of a year (1869) devoted himself to the study of that
philosopher. "Never," he says, "have I experienced such
spiritual joys." Enthusiastic in everything he takes up,
he assures his friends that Schopenhauer is the greatest genius
he has met with. He sets himself to translate his works,
and tries to enrol Fet as a co-translator. Philosophy at this
stage of his life went hand in hand with sport and agricultural
interests. He contemplated buying an estate in the province
of Penza, but on the 21st of October 1869 he writes:

"The purchase of the estate in Penza has not come to anything:
I have now finished the sixth volume (War and Peace), and I hope
it will be published on the 1st of November. There are a lot of
snipe. I have shot four brace, and to-day found two brace
and killed one bird."

After a period of comparative rest and ease, the shadows of
war and death once more encompassed Tolstoy. Two of his
children died in 1873, and their loss was followed by that of
his much-loved aunt, Mme. Ergolskaya. A mental restless-
ness and uneasiness came over Tolstoy, and also a desire for
the exercise of a wider philanthropy. The Russo-Turkish War
put the crowning touch to these feelings. God and death,
and the intricacies of life were now the constant subjects of
his letters. "You will not believe what joy your last letter
has given me," he writes in 1877 to his dear friend Fet. "When
you speak of the existence of the Deity, I agree with every-
thing you say, and I would wish to write much, but time fail-
s and it is difficult in a letter. For the first time you
write to me on the Divinity of God. I have been thinking about
it for a long time. Don’t say that we must not think about
it. Not only we must, but we ought. In all ages the best
people, the true people, have thought about it."

Tolstoy now resumed the study of the Bible, and took special delight
in the books of Ecclesiastes and Proverbs. He treats them as
a new discovery, and recommends them to his friends as having
much in common with the teaching of Schopenhauer! This
revived interest in religious questions was accompanied and
perhaps deepened by a state of extreme depression. It was
then he reconciled himself with Turgenev, and in December
1878 we find the latter staying with him on a visit of three
days’ duration. Turgenev writes that he finds him "very
silent, but much developed." The count on his side feels
the same want of mutual sympathy as of old, and confesses that
no real friendship seems possible between them.

Tolstoy now entered on the third phase of his life. He
himself thus describes the stages of his mental growth. In
the first phase he lived only for his own lusts and
pleasures. This came to an end at the age of
thirty-four. Then came the interest in the wel-
fare of humanity, which married life cooled and obscured
for a while. The striving for the welfare of mankind
was mingled with the striving for personal well-being. But
the third and highest phase was reached when the service of God
became the motive power of his existence. All other aims
grew subservient to this, and interest in the merely personal
life had begun to disappear. He had passed through every
imaginable grade of religious thought. As a child he had gone
to church and confession unquestioningly. As a student and
young man he had scorned and ridiculed religion. Later in life
he became a pious and devoutly orthodox Greek Churchman,
until one day during the Russo-Turkish War he was filled with
a spirit of revolt at hearing the prayers for the destruction
of the enemy, beseeching the Almighty to help them to kill
their hundreds and thousands. His whole being recoiled from
the un-Christianity of these prayers, and he then and there
renounced the orthodox faith. For three years he had exceeded
the priests themselves in the regularity of his attendance. Now
he felt there was something vitally amiss, and he flung it all to
the winds. The novelist was rapidly being hidden in the philo-
osophical cloak, to disappear in literature. So early as
1839 Turgenev had exclaimed, "If only Tolstoy would not
philosophize, all might yet be well." His brilliant contem-
poraries, Gogol, Dostoievski and others, had all in different ways
been seized in turn by what may be called the fever of religion.
Tolstoy was to suffer from it too. Like the flickering of a
dying lamp, his imagination again shone out in The Death of
Ivan Ilyitch and The Power of Darkness. Subsequently, with rare
exceptions, his writings were overloaded with ethical reasonings.
He was now fifty. While leading a life outwardly calm and

At Samara.
peaceful, he had passed through innumerable mental struggles and vicissitudes. Of these he speaks with simple candour in My Confession, an autobiographical sketch which appeared in print at intervals between the years 1880 and 1882. In the orthodoxy of the Greek Church, with fasting, prayers and rigid observances of her rites, he vainly sought an answer to his doubts; finally he broke away from a ceremonial which had become empty and lifeless to him, and built up a religion of his own. Impressed with the conviction that the peasant’s mental case was the result of his life of physical toil, Tolstoy tried to adopt the same habits, and for some ten years (dating from about 1880) he renounced the life of his own class as completely as it was possible for him to do. He rose early and went to work in the fields, and was feeding the sheep, and orphan, and helping them to gather in the crops. He also learnt boot and shoe making, and enjoyed being praised for his skill. Thus he laboured late and early, and in these simple physical acts found the best cure for his attacks of despondency. “Simplicity! Simplicity! Simplicity!” His food and drink, his pleasures and personal indulgences, were curtailed. Meat was given up and replaced by a vegetarian diet. Field sports—equivalents for cruelty and lust of blood—were abandoned, and his gun hidden away to rot and rust. Even tobacco was renounced, and smoking pipes and underclothing were given up.

But with all his straining towards simplicity, it was in the nature of things impossible for Tolstoy absolutely to lead the life of a peasant. Labour though he might throughout the day, there was his well-appointed house to return to. He could not cut himself off from his wife and children. Friends and acquaintance could not be wholly ignored by the would-be Diogenes. Circumstances in this respect were too strong for his views and wishes. The renunciation was still only a partial one. But as the strain of a great surrender is greatest while it is still incomplete, so Tolstoy felt more and more impelled to emancipate himself from all worldly concerns. The love of the simple, long spell of country life which presently occurred only served to deepen this desire. In 1881 his eldest son went to the university, and the two next in seniority soon followed him. It became necessary for the family to be in Moscow a great deal, for the sake of the children’s education. The eldest daughter had come out into society, and friends were continually calling, obliging Tolstoy to sit and talk with them. All the elements of town life were distasteful to him. Money was an evil thing in his sight, and he gave up carrying it about with him. Even when he was able to save, he abhorred the idea of having “a man good is having but few wants,” he said, and he accordingly set himself to limit his wishes rigidly, and to detach his heart from all treasured objects. The year 1880 was the census year in Russia. The government, as usual, called for volunteers to help to carry it out. Tolstoy became one of the enumerators, whose duties afforded an excellent opportunity for seeing the conditions under which the poor lived. The misery of it made him often wish to surrender all his property and have nothing more to do with lands and money, but the government and family circumstances prevented him. In the pamphlet, What are the Forms of the Future Life, he graphically narrates his census experiences. Again and again he attempted to carry his theories into effect. At last, calling his wife into his room, he explained to her that property and many possessions had become irksome to him. Wealth he now regarded as a sin. He wished to be rid of all personal ownership. In 1888 Tolstoy renounced all claim to his estates; everything was made over to his wife and children, the countess acting as trustee. True, this renunciation made little difference in his manner of life. He lived under the same roof as before, ate at the same table, wrote and read in the same study. The change was mental rather than material, and material care no longer for the growth or improvement of his estates, but gave himself up to ethical questions, and endeavoured day by day to bind himself more closely to the people. He now began to write specially for their benefit a number of simple tales which have been widely read, tales directed mostly against crying evils—the peasant’s love of vodka, and like themes. He

found willing fellow workers in the firm of Russian publishers known under the name of Posrednik (V. Tchertkov, and a group of friends). John the Fool, which was published in 1886 in the "Posrednik Series," is generally considered the best of these tales. The Penitent (1887) also appeared in this series, and was written with the same object in view. Unfortunately, the popularity of these stories aroused the attention of the government, and led to many of them being forbidden on account of their Socialist tendencies.

The terrible famine of 1891-1892 added fresh lustre to Tolstoy’s name. He and his family worked unceasingly in soup-kitchens and barns, distributing food and clothes. No true leader lacks a following. Every oppressed sect or individual turned instinctively to Tolstoy for sympathy and support, the most important case in point being that of the sect of the Malakhovs, who in 1891 rumours began to reach headquarters of social and religious excitement fermenting among the inhabitants of the Caucasus, and especially among the Doukhobors (q.v.). This people, numbering from fifteen to sixteen thousand, shared their goods and property in common, and made laws of conduct for themselves, based on a simple form of religion unobserved by ceremonies or ritual. In these matters, and especially in refusing to serve as soldiers, they defied the governors of the Caucasus provinces, so that, as their numbers increased, the growth of the sect alarmed the governor, and severe measures were put in practice for their suppression. Several of their leaders were exiled, and in 1895 some hundred of them were condemned to be enrolled for three years in the so-called “disciplinary regiment." It was in that year that Tolstoy came in contact with them personally, and became deeply interested in them. He promptly identified himself with the agitation in their favour, and by his endeavours aroused sympathy for them in other countries, especially in England. After many rebuffs from the government, and many unavailing efforts to reach the kindly ear of the Tsar, the persecution of the Doukhobors length ceased, and they were allowed to emigrate. It was in aid of these people that Tolstoy wrote and published Resurrection. The attack on the Orthodox Church in this novel was probably the chief cause which led to his formal excommunication by decree dated the 22nd of February 1901. In later years Tolstoy maintained all his interests, but old age gradually told on his strength. He died on the 20th of November 1910 at Astapovo, where he was stricken with pneumonia when carrying out a sudden election to leave Vsnataya Polyanaya and end his days in retirement.

No account of Tolstoy can pretend to any measure of completeness which does not refer to his views on religion. Tolstoy himself attributes so much importance to them that he has written several books on that subject, of which the world what he considers truth. In My Confession he describes the various stages of religious experience through which he has passed. He begins with a graphic picture of the religious state of the society in which he was brought up. There were people who were nominally orthodox, actually they believed in nothing. Indeed so inconsistent were the ideals of that society with any real belief in the Orthodox Church that at sixteen Tolstoy practically renounced Christianity and became a sceptic. During the whole of this period he felt unhappy and dissatisfied, for he had no theory which enabled him to solve the riddle of life. He found no solution to the question he often put to himself—Who am I? or to the other which depended on the first—How ought I to live?

It seemed to him that the men he met dealt with these questions in four ways. Some ignored them and treated life as if it were a meaningless jumble of vanity and evil. Others, recognizing the difficulty of satisfactorily solving these questions, simply shut their eyes and made the best of life as they understood it without thinking of the future. A third group answered these questions by regarding life as an evil and foolish thing and by putting an end to it. Fourthly, there were those who considered it a stupid and ridiculous farce and yet continued to live on, making the best of it. Tolstoy, when he first considered these questions, was himself in this fourth group, but it failed him to meet his spiritual needs. He felt that the millions who accepted the religious theory of life had somehow a better answer to the problem, notwithstanding that their solution was based on an absurd hypothesis. Although he had rejected as a lie and an illusion the idea of life, faith being understood as the theory which linked man’s finite life with the infinite. Having arrived at this conclusion Tolstoy

The Doukhobors.

Tolstoy’s Religion.
TOLSTOY, L.

society was founded upon principles disapproved of by Christ. His prison cells, factories and houses of infamy, its state church, its culture, science, art and civilization were all based on coercion and violence. People pretended that Christ did not abolish the law, but only changed it, and that he did not condemn men such as animals lived. Only man must labour, not as the animals, each for itself, but for all. The search after God was not an act of reason but of feeling. To live after God's word we must renounce all hope of life as we know it, and in that renunciation devote ourselves to all men. This belief he found in the churches, but mixed up with other things which he could not understand and which repelled him, viz. sacraments, prayers, doctrines, bowings, and sacrifices. All human beings, as commemorating miracles or alleged facts of Christ's life, were repugnant to him. Communion he explained to himself as an action done in remembrance of Christ, with the bread and wine, as a reminder of the presence of Christ's teaching. When asked by the priest to repeat before receiving the elements that he believed that what he was about to receive were the real Body and Blood, he repeated the formula but then that no wish he believed could make him where. The attitude of the various Christian churches towards one another also alienated his sympathy; it had no resemblance to a union of love. He thought that there should be but one church, but he had not so much in common, but was told that any compromise involved an admission that the clergy had altered the primitive faith and that it was their duty to hand on the faith inviolate. He was also very much shaken by the example of the church towards the poor. Suppressing the happiness of the poor as punishment. Tracing the happiness of the peasantry to their faith, he became convinced that there were certain elements of truth in Christianity. The Christian churches and the Greek Orthodox Church were in accordance with his view combined to obscure the basis of truth in Christ's teaching.

Tolstoy therefore set himself to endeavour to eliminate what he thought false doctrine and to seek the original elements which had grown up round Christianity, and to discover the varieties contained in it. Tolstoy started with the premise that Christ's teaching was communicated to unlettered persons and that it was written and written in such a manner that it may be assumed," he says, "that the Church in accepting the three synoptic gospels had accepted much that was inaccurate.

Tolstoy argues that it should be remembered that the gospels were written to answer the questions of many people, and that they were therefore at liberty to deal with them critically. He sees in Christianity not an exclusively divine revelation, nor a mere historical phenomenon, but a teaching which gives meaning to life. The commandments have not the same authority as any of the other teachings which Christianity has. Tolstoy's, but was a strainer and contorted version of what Jesus taught. The sectarianism of Christianity had its root in the idea that the gospels are to be understood only by taking them by themselves, but by interpreting them in such a manner as to make them agree not only with the other sacred writings but with the traditions of the Church, which were themselves obscure. Tolstoy maintained that the Church's teachings for a long time alienated the best minds from Christianity. Anyone taking Christ's teaching alone will see that it has no admixture of elements that contradict common sense. It has no sympathy with superstition, and has no "darkness," but is the strictest and fullest system of ethics.

The substance of Christianity seems to Tolstoy the inculcation of a life of love, fidelity, self-sacrifice, and self-renunciation. Evil is only an element of those essential attributes which attracted him throughout his life, even when he was a skeptic. The Greek Orthodox Church treated these principles rather as accessory to the teaching of Jesus than of its essence, and the Church considered dogma of more importance.

The rule of the Orthodox Church concerning dogmas, sacraments, fasts, prayers, seemed not only unnecessary but were not based on anything in Christ's teaching. The Sermon on the Mount as reported in Saint Matthew contains, according to Tolstoy, the essence of Christ's teaching which Christians should carry out entirely. The key to the sermon is contained in the words "Resist not evil," this injunction meaning that there is no reason to resist evil, but that they should not oppose it with physical force. Any physical resistance of evil is contrary to the law of love. This command he regards as the central point of all duties. It sums up in a short form all that Christ ever taught. He quotes Christ's statement, "My yoke is easy." The whole teaching of the churches was contrary to Christ's teaching when they gave their sanction and approval to armies and the enforcement of the commandments by human beings. Tolstoy denied that society not only ignored Christ's injunction not to resist evil but was actually based on a denial of its truth. The "Judge not that ye he not judged" Tolstoy treats as an expansion or rather a modification of Christ's teaching. The possibility of human justice, demonstrating in the case of the woman taken in adultery that man could not judge his fellow man, says Tolstoy. The same idea goes through the "thou shalt not kill," saying, "You believe that your laws reform criminals; as a matter of fact they only make more criminals. There is only one way to suppress evil, that is to return good for evil without respect of persons." The whole social fabric of modern so-called "Christian"
of the body this ceases to exist, but the divine spiritual life remains. It is not the death of the body but the transmigra-
tion of the spirit, its introduction to a new and unknown state of existence, to another form of manifestation of the divine spiritual essence. The more a man endeavours to live the life of the spirit after the death of the body, the less endures the somatic aspect of death. But it is impossible for the human intellect to conceive any form of existence outside space and time. So far therefore as it is necessary to imagine the body Tolstoy denies it; so far as it implies an individual condition of life, we cannot predicate nothing of it. There are two doctrines of life. One of these doctrines, the source of all error, consists in believing that the personal life exists outside space and time, and in an essential annihilation. The other doctrine, that taught by Jesus, is that the whole purpose of our personal life lies in the fulfillment of the will of God.

Before attempting to define the powers and position of an author, it would be well to have it clearly in mind that we are dealing with the development of the thoughts than of the life of a child, with a pale background of men and events. The distinct charm lies in the simplicity of early life. The book is a square of white paper, and the child introduced by the child, Nicholas Ilrtensky, to a number of characters one after the other—father, mother, grandmother, tutor, servants and sires; and are led by him from the father's study to the morning-room, from the dinner-table to the bedroom, from the game of ball at the church to the hall of the merchant's house, as in a magic crystal, the lifelike scenes on his waking—in the schoolroom—at his mother's side. But the apparently unconscious child of this early life, which is no waking but only a restless thought, hopes, fears—form the true drama of the story. The Cossacks (1865), written round the theory that culture is an enemy to happiness, was followed by War and Peace (1864-1869), which has been justly called Tolstoy's masterpiece. In it we glimpse life, as it has marshalled a panoramic array of kings, princes and nobles as they lived and moved during the times of the great Napoleonic wars. There are so many figures in the picture, so much kaleidoscope of colour and movement, that it is possible to follow the thread of the narrative. The leading characters principally belong to the highest Russian society, whose circle—with its inflexible code of laws and customs, and its vitiated moral atmosphere affecting each member of it in a greater or less degree—links them together. The interest centres not so much in any single person as in the groups formed by four leading families of the grand manner—the Bezouchnovs, the Volkonskys and the Kouragines—all bound together by common aims and interests. The men are eager to make a name and enjoy life; the women seek pleasure in gossip and romance. Peter Bezouchnov, who with his wife and children, but united by a love of truth, are the exceptions to this rule. Peter Bezouchnov is one of Tolstoy's finest characterizations, drawn with a hand that never discovered an outline in the body. And the only sinner in the novel is an abysm. On the one side there is the striving after an ideal and a capacity for self-sacrifice, on the other an absence of firmness and balance. Like Tolstoy himself, he is always in doubt as to what is right and what is wrong, as to the meaning of life and death, and, like Tolstoy at that time, can as yet find no answer to these riddles. While Peter Bezouchnov is a typical Russian, a very Tolstoy, Prince Andrei is a type striking, is a man of personality. Upright and noble-minded he is yet unable to cast off the chains of custom which have held him from childhood. He too is constantly seeking mental rest and finding none. The loves, the hates, the struggles of Andrei and Natasha in the novel are a story of passion. Natasha is a poem in itself. Natasha is almost the only heroine Tolstoy has given us who wins our affection; but even she, after many transitions, sinks to the level of the Hausfrau, with no aim beyond the propagation of her family name. The justification of the book is that in War and Peace Tolstoy winged his shafts not at men generally but at that particular section of society to which he himself by birth and association belonged.

So much for the preface followed the publication of this novel, during which the world heard little of it. At length in 1873 he issued the first parts of Anna Karenina. It is without doubt the most important, the most interesting, the most alive, the most complete in time and space in it, as in the preceding book, is large, but it has more continuity of action, and the principal characters are kept well in the foreground. It is a study of modern Russian life, and is in itself a masterpiece. Such a large circle of relationships is sharply contrasted with the transient omnipotence of passion and deep love. The hero and heroine are Count Wronsky, a young soldier in a crack regiment, and then Kitty. The heroine Anna Karenina, of an important official in the political world of St Petersburg. The parts of secondary heroine and hero are filled by Kitty Cherbatsky, a young and does not find the happy marriage of Levin, the central figure, is of course Anna herself, an elegant and fascinating person. She is honest, frank and well endowed by nature, and has an innate striving after truth and beauty in art and in life, but her early marriage to Karenin (the best known Russian character of the turn), while socially advantageous, has dulled and stunted her ideals. Ignorant of the meaning of love, she despises it, and it is not till she meets Wronsky that she realizes to the full the empti-
ness of her existence. Tolstoy is a master of his art. The recognition of no principle but his own desires, offers her the rich wine of life at a draught. She tastes it, after scant hesitation; and then, to crown it all, her husband, terrorizing her and child, drives them to the dregs, only to find that poison lies in the cup. Anna and Wronsky have no true ideal to cling to. He, as their passion cools, finds the tie irksome and a hindrance to his work and friends. The novel ends when Anna, after all that she sees that Wronsky's devotion is waning, recognizing too late that he loved her chiefly for vanity's sake, that they are slipping daily asunder, and growing displeasing to each other. Her past life is closed to her, the future opens like an abyss. The crisis has come, and swiftly obeying the impulse of her despair she seizes on death as her only weapon for avenging Wronsky and cutting the hopeless knot of her life. This pitiful end is led up to by step by step with microscopic truth and insight into the springs of human action. In the married life of Kitty and Levin, on the other hand, Tolstoy describes a state of happiness of a material nature—domestic contentment, the happiness of two good children, and the pleasures of the country. Levin is the Tolstoy of fiction. The improvement and development of his estates, the life of the countryside with its square of white paper, its vivid pictures, its own thoughts, hopes, fears—form the true drama of the story. War and Peace, the Kreutzer Sonata, published in 1890, created a profound impression. Many who were previously unacquainted with Tolstoy work read this story of love, jealousy and revenge, and were dumbfounded by its boldness. It is a startling advance upon Family Happiness, published thirty years before. This story of the Russian people in particular, is ruthlessly condemned for its views on marriage and its attitude towards the vexed question of the relations between man and woman. Marriage, Tolstoy says, can only be condoned if spiritual sympathy exists, and then only as the means to the continuance of the race; otherwise it is a breach of true morality. The "motif" of the Sonata is that the ideal we should strive after is a life where the spiritual penetrates and pervades everything, and where all that is carnal is eliminated. But in the "Sequel" to the Sonata Tolstoy adds that great ideals are always unattainable, and affirms that no man can know, whilst yet striving, how nearly he approaches them. The novel is a work of art only on condition that such subjects as sexual love, patriotism and religious devotion should be avoided. (C. H. W.)

TOLSTOY, PETR ANDREEVICH, Count (1645-1729), Russian statesman, was the son of the okoloniuchi Andrei Vasilevich Tolstoy. He served in 1682 as chamberlain at the court of Theodor III. Miscalculating the strength of the tsarsvena Sophia (g.v.) he became one of her most energetic supporters, but contrived to join the other, and winning, side just before the final catastrophe. For a long time Peter kept his latest recruit at arm's length; but when, in 1697, Tolstoy volunteered to go to Venice to learn Italian and ship-building, Peter could not restrain himself, and put him in charge of a division of Prince Shcherbatzky.

In November 1710 Tolstoy was appointed the first regularly accredited Russian ambassador to the Porte, and more than justified the confidence of the most exacting of masters; though his
peculiar expedients (e.g. the procuring of the strangulation of a grand vizier and the removal by poison of an inconvenient private secretary) savoured more of the Italian than of the Russian Renaissance. Even before Poltava, Tolstoy had the greatest difficulty in preventing the Turks from aiding the Swedes, and when Charles XII took refuge on Turkish soil he instantly demanded his extradition. This was a diplomatic blunder, as it only irritated the already alarmed Turks; and on the 10th of October 1710 Tolstoy was thrown into the Seven Towers, a proceeding tantamount to a declaration of war against Russia. On his release from "this Turkish hell," in 1714, he returned to Russia, was created a senator, and closely associated himself with the omnipotent favourite, Menshikov. In 1717 his position during Peter's reign was secured once for all by his successful mission to Naples to bring back the unfortunate tsarevich Alexis, whom he may be said to have literally hunted to death. For this he earned the undying hatred of the majority of the Russian people; but Peter naturally regarded it as an inestimable service and loaded Tolstoy with honours and riches, appointing him, moreover, the head of the secret chancellery, or official torture chamber—a post for which Tolstoy was by nature eminently fitted. He materially assisted Menshikov to raise the imperial consort to the throne on the decease of Peter (1725), and the new sovereign made him a count and one of the six members of the newly instituted supreme privy council. Tolstoy was well aware that the elevation of the grand duke Peter, son of the tsarevich Alexis, would put an end to his own career and endanger his whole family, so that when Menshikov, during the last days of Catherine I, declined in favour of Peter II, Tolstoy endeavoured to form a party of his own whose object it was to promote the accession of Catherine's second daughter, the tsarevna Elizabeth. But Menshikov was too strong and too quick for his ancient colleague. On the very day of the empress's death (May 11, 1727), Tolstoy, now in his eighty-second year, was banished to the Solovetsky monastery in the White Sea, where he died two years later. He is the author of a sketch of the impressions made upon him by western Europe during his tour in the years 1697-1698 and also of a detailed description of the Black Sea.

See N. A. Popov, "Count P. A. Tolstoy" (Russ.) in Old and New Russia (Petersburg, 1879); and "From the Life of P. A. Tolstoy" (Russ.) in Peter the Great (London, 1897); and The First Romanovs (London, 1905). (R. N. B.)

TOLTEC (Mexican Tolteca), or dwellers in Tollan (the place of reeds), the name of a people that if partly mythical is also partly historical. Traces of this people can unquestionably be detected in historic times; and many cities, particularly those which carried on traffic with the coast, claimed to be of Toltec origin. The conception of Toltecs, like that of Chichimecs, acquired in time so general and vague a significance that in vocabularies such a word as "toltecatl" is interpreted as meaning merely an expert. So that in some cases the name "Toltec" denotes no more than some race of Nahua affinities possessed of a certain degree of culture. In others, however, there is a substantial reason for believing in the existence of a specific tribe or people called Toltecs, though the genuine historical background has been obscured by the legends which the priests embroidered upon it to glorify their hero and god Quetzalcoatl.

Our ignorance as to the distribution and movements of the native peoples before the time of the Spanish invasion forbids any positive statement as to the original home of the Toltecs. It is certain, however, that they, as well as their god and their ancient city of Tollan, were known to those who lived in the Maya countries far beyond the confines of Mexico proper. Their migration-myths point to the eastern districts known as the "tierras calientes," famous for such valuable products as feathers and cacao, with which the Mexicans from the earliest times carried on a vigorous commerce. It is possible that the legendary wanderings of Quetzalcoatl (Feathered Serpent), who was said to have committed himself to the flames in Tiltlan-Tlapallan (the land of the black and red, i.e. the land of picture-writing), the region of Tabasco and Campeche, are really a mythological description of the moort's periodic course. But even in that case there can be no doubt that the nature-myth has been embellished with details derived from an actual race movement which took place in prehistoric times.

The Historia de Colhuacan y de Mexico is a most valuable manuscript written by an anonymous author in the Mexican language. In this work it is stated that Quetzalcoatl died in A.D. 865, and was followed by four Kings in succession, after which the wise Huitzilopochtli ascended the throne in A.D. 994 under the name of Atepecacatl. In the reign of this sovereign there broke out a great famine, which occasioned the institution of the custom of human sacrifice. From the same source we learn that it was in A.D. 1064 (a date which is assigned to the beginning of a half-mythical history by various other documents and MSS.) that the Toltecs left their homes and migrated eastward to Tabasco and Soconusco. At the same time Huemac killed himself in the cave of Cincaico. Tradition ascribes to him the authorship of an encyclopaedic picture-writing called 'te amatli' dealing with the history of his people, with astronomy, the calendar system, and the Aztec gods. According to the Ancient History of Tula and Mexico, which is confirmed in spite of some slight variations of detail by Itzilxochitl, the duration of the "Toltec Empire" was not more than 318 years.

Archaeologists are justified in claiming as indubitable monuments of the Toltecs the serpent-pillars which have been found in situ at Tula, close to the City of Mexico. The historian Sahagun states that Tula was an old centre of the Toltecs and explicitly mentions these pillars as their work. It is interesting therefore to note that the only other place where such pillars occur is Chichenitz in Yucatan (see Central America: Archaeology), a site which exhibits most strikingly Mexican features, so that archaeology fully confirms the assertion of the historians that Chichenitz, though in Mayan territory, was subject to the domination of some Nahua people. Chichenitz and Mayapan are the only sites in Mayan territory at which are found those round temples, which are attributable exclusively to Quetzalcoatl, the principal god and national hero of the Toltecs.

W.L.*

TOLUCA, or TOLOCANN, a city of Mexico and capital of the state of Mexico, on the S.W. border of the Anahuac plateau, at 8.09 of the Cercue de la Hija de Colhuacan ab 8,850 ft. above sea-level. Pop. (1900), 25,940. Toluca is on the Mexican National railway, 36 m. W.S.W. of the national capital. Its situation near the high cordillera gives it a cold, changeable climate. The government has a meteorological station here and a national college. Industries include the manufacture of cotton fabric, flour and wax candles. Swine-breeding is a profitable occupation in the vicinity. The Nevado de Toluca, an extinct volcano, rises to a height of 14,950 ft. on the south-west side of the town. Its summit is frequently draped with snow, and its broken-down crater contains a lake. Traditionally Toluca was one of the earliest Toltec settlements on the Anahuac tableland, but no remains of this occupation have been preserved.

TOLUENE, or Methylenebenzene, C₆H₄CH₃, an aromatic hydrocarbon; the first homologue of benzene. Discovered by Pelletier (Ann. chim. phys., 1838, 67, p. 269) in the oil obtained in the manufacture of gas from the resin of Pinus maritima, and named retinampe, it was prepared from the same gas by Couerbe (ibid., 69, p. 184) and named heptacarbarbue quadrirhydrique, C₆H₄ (C = 6); Sainte-Claire Deville (ibid. 1841 [3] 5, p. 168) obtained it by distilling Tolu balsam, naming it benzene. Générard and Bouldaut obtained a substance by the dry distillation of dragon's blood which they called dracyle. The complete identity of these substances was established by A. W. Hofmann and Muspratt, and they adopted the name toluen (anglicized to toluene), which was proposed by Berzelius. Its derivatives and its relation to benzene had been previously studied by the above and other experimenters, its relation to benzene being first proved experimentally by Cannizzaro and its constitution
settled by Fittig and Tollens's synthesis from sodium and a mixture of methyl iodide and bromobenzene.

The hydrocarbon occurs in wood-tar and in petroleum, and is prepared commercially by fractional distillation of the light oil fraction of the coal-tar distillate (see COAL TAR). It may be obtained by Fittig's method, or by Tollens's process, devised by Friedel and Craft's process, devised in 1877, of acting with aluminum chloride on a mixture of benzene and methyl chloride; this reaction leads to benzyl chloride, which may be hydrolyzed, or broken down under the continued action of the aluminum chloride; or by heating the toluene carboxylic acids obtained by oxidizing the higher homologues of benzene. It forms a colourless mobile liquid and burns with a blue flame, and has a specific gravity of 0.868 (13:1°F). It is insoluble in water, but dissolves readily in alcohol and ether. On reduction it yields hexahydrodoleulene; oxidation with dilute nitric acid or chromic acid gives benzoic acid; whilst chromic acid, and the sodium or potassium gives benzoic acid. On nitration it gives ortho- and para-nitrotoluene—which on reduction yield the valuable toluidines, C₆H₄(CH₃)NH₂—and on sulphonation the para-sulphonic acid is formed with a little of the ortho-acid. Chlorination in the cold gives ortho- and para-chlorotoluene, but at the boiling point the side chain is substituted (see BENZALDEHYDE).

TOMAHAWK, Tompkinsville

TOMAHAWK (a native American word, probably from the Algonquian verb olo'mahuk, to knock down), the war-hatchet of the North American Indians. The earliest tomahawks were of chipped stone, usually sharpened to a point at each end something like a pickaxe, and passed through a hole bored in a stout wooden cudgel. In the more primitive types the stone head was simply tied to the handle by animal sinews, or a withe was doubled over the head and fastened below to form a handgrip. Sometimes deer antlers were used instead of stones. After the arrival of the Mohawk, and especially of the Iroquois, the stone head was sharpened only at one end the blunt end was sometimes cut out into a pipe-bowl, the handle, hollowed, serving as the stem. The weapon was at once symbolic of war and peace, and was ceremoniously buried at the termination of hostilities, to be as formally exhumed when the feuds revived. Hence the colloquialism "to bury the hatchet."  

TOMASZÓW, or Tomaszhów Fabryczny, an industrial town of Russian Poland, in the government of Piotrków, 41 m. N.E. of the town of Piotrkv. Pop. (1897), 21,041. It has woolen mills, steam flour-mills and ironworks.

TOMATO, Lycopersicon esculentum (Nat. Ord. Solanaceae), a tender annual, native of South America, probably Peru. The fruit is much esteemed in salads and as a vegetable. Efforts have been made to popularize it for dessert, with varying success. Plants intended to fruit out of doors during the summer should be raised from seed sown at the end of February or early in March, under glass, in a temperature of about 60°. Pots pans or shallow boxes are the usual vessels. The soil should be composed of a mixture from, preferably of loam, sand and leaf mould in equal proportions. As soon as the young plants appear they should be fully exposed to sunlight, as near the glass as practicable. When the second pair of leaves is formed they should be pinched off, and then the pots should be 3 in. diameter, using slightly richer compost and less sand. This operation should take place with great care to be accomplished. The first flowers will appear towards the end of April or early in May. The pollen should be gathered and applied to the stigmas of the flowers by hand. The plants should be fit for planting out early in June, and should bear at least two clusters of rapidly growing fruits. They should be planted in the sunniest and warmest position available. It is customary to confine the plants to one shoot, pinching off all lateral shoots as they appear. Owing to the fickleness of the European climate it is of the utmost importance that the setting of fruit should be secured early. Manure should be applied sparingly to tomatoes until the crops become heavy. Under glass, without artificial heat, tomatoes succeed well. In cold, sunny seasons, however, the crops are seldom remunerative. The culture is substantially as advised for out of doors. In heated structures tomatoes should be raised all the year round, as they are a small and precarious crop during winter, however. During summer the crops are usually heavier and of better flavour, even in favourable seasons, than from out of doors. It is necessary to have at least two shoots trained to each fruiting shoot, those that are being worn out by heavy cropping. Periodical sowings are therefore necessary. Some prefer to raise the plants intended for winter fruiting by cuttings inserted in August. Planting out is usually effected on sheltered ground enriched with compost. The fruit is of various varieties riches and sizes. Some are kept for the production of green and dried tomatoes. The shoots trained on wires near the glass. As more nourishment is required, new soil is added. In this way excessive luxuriance, to which the tomato is so addicted, is avoided. The plants should never be allowed to become dry—they are large consumers of water. The following varieties comprise some of the best in cultivation:

TOMPAH, Yellow Frutted.—Chiswick Peach, Golden Jubilee, Carter's Green.

Early Varieties for Outdoor Culture.—Chemin, Fromgrove Selected.

TOMB (Gr. τύμβος, τύβος, properly allied to Lat. tumulus, literally a swelling, tume, to swell), a general term for a place of burial for the dead, including the excavation or cavity in which the body is Iqid and the superstructure which marks the place. (See BURIAL and FUNERAL RITES.)

The various forms which the tomb has taken throughout the ages are treated under such heads as BARROW; CAIRN; TUMULUS; CARACAS, and TOMBSTONE.

TOMPA, MIHALY [Michael] (1817-1868), Hungarian lyric poet, was born in 1817 at Rima-Szombat, in the county of Gómér, his father being village bookmaker. He studied law and theology in Sárós-Patak, and subsequently at Budapest; and, after many vicissitudes, at the age of thirty he accepted the post of Protestant minister in Beje, a small village in his native county, whence, in two years, he removed to Kelemér, and four years later to Hanva, in the county of Borsod, where he remained till his death in 1868.

At the age of four-and-twenty Tompa published his first poems in the review, Zsíros, which subsequently became known as the Zsíros-Szó. His first volume, Néprépek és Népmondák ("Folk-Legends and Folk-Tales"), in 1846, met with great success, and the same may be said of the first volume of Poésies populaires, where he took part in the War of Independence, acting as field chaplain to the volunteers of his county and seeing several battles; but the unfortunate close of that heroic struggle silenced his poetic vein for a considerable time, and when in 1852 and 1853 he gave up to his patriotic grief in some masterly allegories on the state of oppressed Hungary, he was twice arrested by the Austrian authorities. After being released he published his Virággék ("Legends of Flowers," a collection of poems showing great imagination and love of nature. Soon after this he became oppressed with melancholy and abandoned this branch of poetry. He published three volumes of sermons, "which," says his biographer, Charles Szécs, Protestant bishop of Budapest, "are among the best in Hungarian literature, and will favourably compare with those of Robertson, Monod or Parker." His collected poetical works were published at Budapest in 1870, and again in 1885.

TOMPKINS, DANIEL D. (1774-1825), American politician, was born in Cheshire, Westchester county, New York, on the 21st of June 1774. He graduated at Columbia College in 1795, and was admitted to the bar in 1797. In 1801 he was elected to the state constitutional convention, in 1803 was a member of the state assembly, and in 1804 was elected to the national House of Representatives, but became a judge of the state supreme court, and served as such until 1807. He was governor of New York in 1807-1817; and in 1817-1825, during both terms of President James Monroe, was vice-president of the United States. In March 1812, under the authority of art. xviii. of the New York constitution of 1777, he prorogued the legislature without any reference to the exercise of this power. During the War of 1812 he was active in equipping and arming the New York militia. For this purpose he borrowed much money on his personal security, and sometimes neglected to secure proper vouchers. Later the state comptroller announced a shortage of $120,000 in the military accounts, but Tompkins claimed that the state owed him $150,000. Later investigations disclosed that the state actually owed him more than $90,000. In 1821 he was president of the state constitutional convention. He died on Staten Island, N.Y., on the 11th of June 1825.

TOMPKINS, R. (1807-1817) (3 vols., 1808-1902) were published by the state. See D. S. Alexander, Political History of New York, vol. i. (New York, 1906).

TOMPKINSVILLE, a former village of Richmond county, New York, U.S.A., since 1808 a part of the borough of Richmond, New York City. It is on the N.E. shore of Staten Island in New York Bay, about 4½ m. S. by W. of the southern extremity of Manhattan Island, and is a residential district of New York City. Tompkinsville was laid out in 1814-1815 upon a tract of about 700 acres, most of which was owned by Daniel D.
Tomsk. It was chartered as a village in 1823, but because of legal flaws the charter was revoked soon after Tompkins's death (in 1825), and thereafter the village was gradually absorbed by New Brighton and Edgewater (both incorporated in 1866), though the principality continued to be called Tompkinsville.

**TOMSK.** a government of western Siberia, extending from the Chinese frontier northwards to 6° N., and bounded by the government of Tobolsk on the N.W., by Yeniseisk on the N.E. and E., by north-western Mongolia on the S.E. and by the province of Semipalatinsk on the S. and W. Its area, 327,284 sq. m., is more than one and a half times that of France. The surface includes in the south-east the high alpine tracts of the Altai Mountains, and in the north-west and west the lowlands of the Irtysh and the marshy tracts of the Ob. The Altai Mountains or Sallughem system, which at their northern extremity join with the Sayan Mountains, run from north-east to south-west along the Russo-Chinese frontier, and are cleat by a deep gorge through which flows the Yenisei (see **Altai**). A zone, some 200 m. in width, of alpine tracts fringes the outer margin of these mountains, which have a very steep slope towards the north-west, although their south-eastern foot-hills rest on the plateau of Kobdo (4500 to 5000 ft.). A chain having a north-western direction—the Salair Mountains—shoots off from the main range of the Altai, between the Tom and the Chumysh; it is about 170 m. in length, with a width of nearly 60 m., and it contains the most productive silver-mines of the region, as also several gold-washings. Its upheaval belongs to a more recent epoch than that of the Sallughem range, and (like the mountains of Turkestan, having a north-west direction) it is composed of dioritic rocks. In the Kuznetsk depression it is deprived of the Lower and Upper Carboniferous, containing beds of coal. The Kuznetskiy Ala-tau, one of A. von Humboldt's meridional upheavals, consists of a series of ridges running south-west to north-east.

Tomsk is drained principally by the Ob and its tributaries, but the south-east corner drains into the Abakan, a tributary of the Yenisei. The Ob, formed by the union of the Biya and Katun, has within the government a course of more than 800 m., and is navigated as far as Barnaul and Biysk. Its tributaries, the Tom (450 m.), Vasyugan (550 m.), Ket (230 m.) and Tym (200 m.), are all navigable. The Chulym and the Chumysh are also large rivers. The Buhkarma, Om, Uba and Tara, tributaries of the Irtysh, are worthy of notice.

The climate is severe, and is, moreover, very wet in the north-west. The average yearly temperatures at Tomsk, Kainsk and Barnaul are 30°-2°, 31° and 32°-7° (Jan., 4°, 6°-2° and 3°-7°; July, 65°-5°, 68°-5° and 62°-2°) respectively. The Altai steppes enjoy a much drier climate than the lowlands, and are clothed with beautiful vegetation; in the sheltered valleys corn is grown up to altitudes of 3400 and 4250 ft.

The population was estimated in 1906 as 2,412,700. The bulk (90%) is Russian, the remainder being Ostyaks, Mordvinians, Tatars (mostly in the Altai), Teleuts and Teleungts (Mongol tribes, chiefly in the Altai), and nomad Samoyedes, representing a mixture between the Samoyedes and the Ostyaks, and dwelling along the Ob river and its tributaries. The prevailing religion is Greek-Orthodox, but there are also some Non-conformists, Roman Catholics, Jews, Mahomedans and pagans.

Agriculture is the predominant occupation, and excellent crops are obtained in the southern portion of the government, especially in the Altai. Livestock breeding is very important, and butter-making in model dairies, partly co-operative, has developed greatly, butter being exported from Tomsk to western Europe. Trade is actively carried on at Tomsk and Barnaul, the chief centres for the trade of Siberia with Russia. The Biysk merchants carry on a barter trade with Mongolia and China.

The government is divided into six districts, the chief towns of which are Tomsk, Barnaul, Biysk, Kainsk, Kuznetsk and Marlinsk.

**TOMSK**, a town of Western Siberia, capital of the government of the same name, on the Tom, 27 m. above its confluence with the Ob. Pop. (1900), 63,533. Tomsk is an episcopal see and the largest city of Siberia, exceeding even Irkutsk in population and commercial importance. The great Siberian highway from Tyumen to Irkutsk passes within 54 m. (by branch railway to Taiga) of Tomsk, which is the terminus of the navigation by steamer from the Urals to Siberia. It has, moreover, communication by steamer with Barnaul and Biysk in the Altai. The town is not an administrative centre, like so many Russian cities, but an entrepot of wares. Before 1824 it was a mere village; but after the discovery of gold in the district it grew rapidly. It is built on two terraces on the right bank of the Tom, and is divided into two parts by the Usshaika. The best building is the university. The industries are almost entirely confined to tanning and the manufacture of carriages. Tomsk has a university (founded in 1888, with 690 students), and archaeological, ethnological, zoological, botanical and mineralogical museums, a technological institute, a cathedral (finished in 1900), public libraries and scientific societies (naturalist, geographical, medical, musical, &c.). The city was founded in 1604.

**TOM-TOM, or TAM-TAM,** a native Indian and Asiatic word, reduplicated and onomatopoeic in form, for a drum, hence often loosely applied to the various types of primitive drum used for purposes of religious excitement, war, signalling, &c., by savage tribes throughout the world. The term is applied strictly to the metal gongs of the Far East, which are flat disks with a shallow rim.
