The Korn telephotographic apparatus is based on the principle of an apparatus devised by Shelved Bidwell in 1881 for the electrical transmission of pictures to a distance, in which he converted to electrical resistance which selenium undergoes when acted upon by light. In the Korn apparatus the light from a Nernst electric lamp is allowed to strike upon a point in the form of a pencil on a picture, which is wound on a glass cylinder in the shape of a transparent photographic film. A totally reflecting prism placed inside the glass cylinder projects the light which penetrates the film upon a selenium cell situated at the end of the cylinder. An illumination of variable intensity (according to the deeper or lighter shades of the portion of the picture on which the light falls) thus takes place on the selenium cell. As the glass cylinder, driven by a motor, revolves upon its axis while also advancing (by means of a screw thread on the axis), all portions of the picture are successively brought under the beam or pencil of light and cause a beam of varying intensity to fall on the selenium cell. The varying illumination of the selenium thus produced, the resistance of the latter, and therefore the intensity of the current sent through the line to the receiving station by the battery, will be altered accordingly. At the receiving station the film is revolved synchronously with the transmitting cylinder—is covered with a photographic film or paper, upon a point of which a pencil of light from a Nernst lamp is concentrated. Before reaching the paper the light passes through perforations in two iron plates, which are, in fact, the pole pieces of a strong electromagnet; between these is an aluminium shutter which is attached to two parallel wires or thin strips of copper. In this way no current passes through the perforations and no light passes, but when a current traverses the wires they are depressed by electromagnetic action, carrying the shutter with them, and a quantity of light proportional to the current traversing the wire is admitted through the perforation. The intensity of this "light-relay" is the intensity of the light acting at any moment upon the sensitized paper is made proportional to the illumination of the selenium cell at the transmitting station. In other words, of the selenium transmitter a selenium cell similar to that at the transmitting station is arranged at the receiving apparatus, and exposed to precisely similar variations of light, the arrangement being such that the lag of this cell counters the lag of the transmitting cell. The synchronous revolutions of the transmitting cylinders are effected by making one cylinder rotate slightly faster than the other; after each revolution the cylinder which is accelerated is arrested for a moment by means of a special relay until the difference of speed is accurately compensated for. This device was originally adopted in the Arlincourt copying telegraph.

Submarine Telegraphy. For working long submarine cables the submarine wire ordinarily employed was recently ordered to be replaced by the selenium telewriter. This instrument is so designed that signals can only be used, as the retarding effect of the electrostatic capacity of the cable is so marked that signals fail to be recorded except at a very slow speed of working. The transmitted signals or electric impulses, which on a land line are sharply defined when received, become attenuated and prolonged in the case of a long cable, and are unable to actuate the comparatively heavy moving parts of which the land line instruments are formed. Other patterns of apparatus are therefore necessary.

The arrangement of the apparatus for working some of the most recent cables is shown in Fig. 30. The cable is supposed to be worked duplex; but, if S, Cb, C, and AC are removed and the key connected directly with Cb, the arrangement for simplex working is obtained. The apparatus consists of a sending battery B, a transmitting key K, a slide of selenium C, a condenser C, an artificial cable AC, the receiving instruments I and G, and one or more resistances R for adjusting the leakage currents. The key K is positively operated by the penultimate relay, and the receiving relay and condenser Cb are shown; one only is absolutely necessary, but it is convenient to have the galvanometer ready, so that in case of accident to the sender it may be at once switched into circuit by the switch S. When one of the levers of K is depressed, the condenser C and the cable, and the condenser Cb and the artificial cable, are simultaneously charged in series; but, if the capacity of Cb bears the same ratio to the capacity of C that the capacity of the cable does to the capacity of the artificial cable, and if the other adjustments are properly made, no charge will be communicated to Cb. After a very short interval of time, the length of which depends on the inductance and capacity of the cable, the condenser Cb is charged to a potential corresponding to the capacity of Cb, and Cb at the other end begin to be charged from the cable, and since the charge of Cb passes through the receiving instrument I or G the signal is received. The charging of Cb at the receiving end will take place, no matter in which direction the current is flowing, and the condensers, consequently the incoming signals are not affected by those which are being transmitted from that end. In actual practice the receiving instrument is so sensitive that the difference of potential between the two coatings of the condenser Cb produced by the incoming signal is only a very small fraction of the potential of the battery B. When the key is released the condensers and cables at one end return to zero directly, whereas if the key is depressed and released several times in rapid succession the cable is divided into sections of varying potential, which travel rapidly towards the receiving end, and indicate their arrival there by means of the instrument I. The entire system of the apparatus is explained in Fig. 30. It will be seen that any light or dark spot on the cable is transmitted as a corresponding light or dark spot on the printed copy. All cables of any great length are worked by reverse currents. A modification (known as the code cable) of the ordinary single needle alphabet is used; that is to say, currents in one direction indicate dots and in the other direction dashes.

The general principle on which the instruments for working long submarine cables are based is that of making the moving parts very light and perfectly free to follow the comparatively slow rise and fall of the electric impulses or waves. The simplest form of receiving instrument (formerly much used) is known as the "mirror." In this instrument a small and very light mirror, about 1 inch in diameter, is carried on a small magnetic needle fixed to its back, and is arranged within a galvanometer coil so that the influence of the latter causes the mirror (through the attraction of the magnetic needle) to be turned through a small angle in one direction or the other according to the direction of the current through the coil. A ray of light from a lamp is thrown on the mirror, whence it is reflected upon a white
siphon recorder| TELEGRAPH

moving slip of paper by a wavy line of ink-marks very close together. The interpretation of the signals is according to the Morse code,—the dot and dash being represented by deflections of the line of dots to one side or other of the centre line of the paper. A very much simpler form of siphon recorder, constructed by Dr Muirhead, is now in general use. The magnet between the poles of which the rectangular signal coil moves is built up of a number of thin flat horseshoe-shaped permanent magnets of a special quality of steel, and is provided with adjustable pole pieces. The signal coil is suspended by fibres and is mounted together with a fixed soft iron core on a brass plate affixed to a rack, with which a pinion operated by a milled head screw engages. To the brass plate is attached an arm carrying the bridge piece. A wire or fibre carrying the aluminium siphon cradle is stretched across this bridge piece, and on it is also mounted the small electromagnet, forming part of the "vibrator" arrangement with its hinged armature, to which one end of the stretched wire carrying the siphon is fastened. The ink-box is made adjustable, being carried by an arm attached to a pillar provided with a rack with which a pinion operated by a milled head screw engages. The motor is usually supported on a platform at the back of the instrument, its driving-wheel being connected to the shaft of the paper roller by means of a spirally wound steel band. In what is known as the "hybrid" form of recorder the permanent magnets are provided with windings of insulated copper wire; the object of these windings is to provide a means of "refreshing" the magnets by means of a strong current temporarily sent through the coils when required, as it has been found that, owing to magnetic leakage and other causes, the magnets tend to lose their power, especially in hot climates. Instruments of the siphon recorder type have been made to work both with and without electrification of the ink. In the latter case, which is the standard practice, mechanical vibration of the siphon is substituted in the place of electrification of the ink, so as to eliminate the effect of atmospheric conditions which frequently caused discontinuity in the flow of ink.

Fig. 32.—Muirhead's Siphon Recorder.

or similar undertakings, and to obviate this it is necessary to form the "earth" for the cable a few miles out at sea and make connexion thereto by an insulated return wire, which is enclosed in the same sheathing as the core of the main cable.

The heavier cores, with the consequent advance in speed of working attainable, have necessitated the introduction of automatic sending, the instruments adopted being in general a modification of the Wheatstone transmitter adapted to the form of cable signals, while the regularity of transmission thus secured has caused its introduction even on circuits where the speed cannot exceed that of the ordinary operator's hand signalling.

**Fig. 31.—Lord Kelvin's early Siphon Recorder.**

The spark recorder in some respects foreshadowed the more perfect instrument—the siphon recorder—which was introduced some years later. Its action was as follows. To an indicator, suitably supported, a to-and-fro motion was given by the electromagnetic actions due to the electric currents constituting the signals. The indicator was connected with a Ruhmkorff coil or other equivalent apparatus, designed to cause a continual succession of sparks to pass between the indicator and a metal plate situated beneath it and having a plane surface parallel to its line of motion. Over the surface of the plate and between it and the indicator there was passed, at a regularly uniform speed, in a direction perpendicular to the line of motion, a current capable of being acted on physically by the sparks, through either their chemical action, their heat, or their perforating force. The record of the signals given by this instrument was an undulating line of fine perforations or spots, and the character and succession of the undulations were used to interpret the signals desired to be sent.

In the original form of the siphon recorder (fig. 31), for which Lord Kelvin obtained his first patent in 1867, the indicator consisted of a light rectangular signal-coil of fine wire, suspended between the poles of two powerful electromagnets M, M so as to be free to move about its longer axis, which is vertical, and so joined that the current could pass through the cable pass through it. A fine glass siphon tube is suspended with freedom to move in only one degree, and is connected with the signal-coil and moves with it. The short leg of the siphon tube dips into an insulated ink-bottle, so that the ink it contains becomes electrified, while the long leg has its open end at a very small distance from a brass table, placed with its surface parallel to the plane in which the mouth of the leg moves, and over which a slip of paper may be passed at a uniform rate, as in the spark recorder. The ink is electrified by a small induction electrical machine E placed on the top of the instrument; this causes it to fall in very minute drops from the open end of the siphon tube upon the brass table or the paper slip passing over it. When therefore the signal-coil moves in obedience to the electric signal-currents passed through it, the motion communicated to the siphon is recorded on the
The automatic curb sender was originally designed by Lord Kelvin for the purpose of reducing the effect of mechanical retardation in long cables. In ordinary hand-sending the end of the cable is put to one or the other pole of the battery and to earth alternately, the relative time of the signal is determined by the earth depending to a great extent on the operator. By the automatic curb sender the cable is put to one or the other pole of the battery and then to the reverse pole for definite proportionate times during the poles of a laminated magnet, so that the motions of the two are similar. This magnet is excited by an alternating current, and the current induced in the second coil is after rectification sent through an ordinary siphon recorder. As the direction and intensity of this induced current are a function of the position of the second coil in its field, and as this position is determined by its mechanical connexion with the recorder coil, it is evident that, by a suitable choice of the electrical elements of the second coil and its alternating field, the indications on the siphon recorder can be magnified to any reasonable extent.

By means of a "magnetic shunt" Brown succeeded in increasing the working speed of long submarine cables to the extent of 10 to 15 per cent. The magnetic shunt (which is connected across the receiving instrument) consists of a low resistance coil of some 2000 turns of insulated copper wire, enclosed in a laminated iron circuit, and connected at intervals to a heavy terminal so that equal increments of inductance may be obtained. The use of the iron core renders it possible to produce a high inductive effect with a low resistance coil, and thus obtain the necessary slow time constant which is due the success of this type of magnetic shunt on cable signals. The shunts usually employed with the drum relay (referred to above) have each a resistance of about 30 ohms and an inductance of 20, 30 and 40 henrys respectively. The explanation of the action of the shunt is that all slowly varying currents affect the coil of the receiving instrument and its shunt in inverse proportion to their respective resistances; whereas with the comparatively rapid variations of current used in signalling the coil is forced at the beginning of each element of

**FIG. 33.**—Facsimile of Siphon Recorder Message.

Each signal is thus charged first positively and then negatively, or *vice versa*, for each signal. Owing to the difficulty of maintaining perfect balance on duplicated cables, curb sending is not now used, but the signals are transmitted by means of an apparatus similar to the Wheatstone automatic transmitter used on land lines and differing from the latter only in regard to the alphabet employed; the signals from the transmitter actuate a relay having heavy armatures which in turn transmit the signals to the cable. The practice of this apparatus is exhibited in the signal sent to the receiver. By this method of transmission of signals by means of the number of letters per word is really between eight and nine; and this forms a considerable factor in lowering the earning capacity of a cable.

A relay capable of working at the end of a long cable has long been desideratum. The difficulty experienced is that of securing a good electrical contact under the very slight pressure obtainable from an instrument excited by attenuated arrival-currents. In an instrument invented by S. G. Brown (Brit. Pat. 1434 of 1869) it is sought to overcome this difficulty by causing the point of a contact-arm, representing the siphon in the ordinary form of recorder, to traverse the cylindrical surface of a rapidly rotating drum. This surface is divided into two parallel halves by a short insulating space on which the arm normally rests, so that the separate conducting surfaces are provided, with either of which the arm makes contact in its excursions in one direction or the other from the central position of the drum; and it is apparent a definite rate of speed that the combination of this relay with a special form of curb sender allows of the re-transmission of signals to a second cable at a speed not less than the speed of the siphon recorder in the usual way. The special form of curb sender mentioned, termed the "Interpolator," has been devised so as to secure the correct re-transmission of any given number of consecutive elements of a letter which are of the same sign, for when signals are received at the end of a long cable the relay arm will not return to its zero position between consecutive elements of the same sign, but will remain on the respective contact surface during the whole time of transmission of such elements. The instrument consists of two arms, the form of which regulates the components of the curved surface, the cam being for the dot elements and the other to the dash elements. The letters are so arranged that the cam is driven back by the return signal. This arrangement thus enables the signal to the relay to be such as to produce a relay current equal to the reversed current, so that the negative elements of the signal are first transmitted corresponding to the duration of contact of the relay arm with the side controlling that particular element. If the modification of the apparatus is retained of the device, however, the operations of the transmitting half of the instrument may be inserted on a paper slip, which can be inserted in the usual way into an automatic transmitter, so as to send either cable or Morse signals.

**FIG. 34.**—Taylor and Dearlove's Interpolator with Brown's Improvements.

A slip as received on recorder, using ordinary relays for translating on to second cable; B, slip as received on recorder, when interpolator is used at intermediate station, for sending on to second cable; C (four cells through a line, KR = 3-6), signals with recorder under ordinary conditions; D, all conditions the same as in C, but magnifying relay inserted between the end of the line and the recorder.

A signal to take *more*, and at the end of the element *less* of the total arrival current from the cable than would traverse it if the shunts were non-inductive.

For duplex working a "magnetic bridge" is used. This consists of a low resistance coil of copper wire enclosed in a laminated iron circuit similar to the magnetic shunt already described. The coil, however, is arranged so that the sending current enters an adjustable mid-point in the coil and passes through the two halves of the winding to the ends connected to the cable and artificial line respectively. The receiving instrument is joined up across these ends in the usual manner. The action of this bridge resembles the magnetic shunt in its effect on the received signals, as the direction of the winding is the same throughout its length, and thus the full inductive action is produced for carrying purposes. To the sending currents, however, the bridge offers only apparent ohmic resistance due to the fact that the current entering the mid-point of the winding flows through the two halves or arms in opposite direction, and, owing to the winding being on the same iron core, the mutual inductive effect of the two arms on one another neutralizes the self-induction to the sending currents. The average total inductive value of these bridges to received signals is about 40 henrys, and the coil is so arranged that the arms contain three sections or blocks of winding each, two of which are joined up to strap connections, and the
third divided into small subdivisions to any terminals of which the cross circuit connections may be affixed. By this arrangement of the coil winding, similar sections can be thrown in or out of circuit with both arms, and also so combined that any amount of inductance suitable to every class of cable may be obtained. The bridge is provided with three sets of silver points, but only one gives a true or several turns of the winding between each stud to permit of the arms being thrown slightly out of balance as a rough compensation for the differences in the coil line. An additional "fine" adjustment in one of the arms by which the small daily balance variations may be corrected. As with other duplex systems it is possible to obtain several approximately correct adjustments with the bridge and its accessories, and only one gives a true balance, and careful experiment is required to make sure that this is obtained. The advantage of using the magnetic bridge duplex method is that the maximum current is sent to line or of cable, and the receiving system benefits accordingly. (H. R. K.)

COMMERCIAL ASPECTS

TELEGRAPH

The earliest practical trial of electrical telegraphy was made in 1837 on the London and North Western Railway, and the first public line under the patent of Wheatstone and Cooke was laid from Paddington to Slough on the Great Western Railway in 1843. At first the use of the telegraph was almost entirely confined to railways. The Electric Telegraph Company, formed to undertake the business of transmitting telegrams, was incorporated in 1846. For some time it restricted its operations to constructing and maintaining railway telegraphs and was not commercially successful. Its tariff was 7s. for 20 words within a radius of 50 miles, 12s. 6d. within 100 miles, 1s. if exceeding 100 miles. After about five years great improvements were made in the working of the telegraphs and the industry began to make progress. Telegraphic money orders were established in 1850; a cable was laid between Dover and Calais, and in November 1851 the stock exchanges of London and Paris were able for the first time to compare prices during business hours of the same day; numerous companies were formed, some of which were independent of the railways, and keen competition led to considerable reductions of wires and reduction of tariffs, with the result that a large increase in the volume of business took place. In the period from 1855 to 1868 the number of messages carried annually by all the telegraph companies of the United Kingdom increased from 1,017,529 to 5,781,989, and an average annual increase of 16.36 per cent. During this period the Electric Telegraph Company's average receipts per message fell from 48.1d. to 25.0d., or just over half, while the number of messages increased nearly fourfold. The working expenses were reduced in a progressively larger ratio, e.g. in 1859 the average expenses per message were only 22d.; in the last quarter of 1868 they were 18.0d. per message or only 51 per cent. of the receipts. Much dissatisfaction was felt because the larger towns where competition had been most keen were unduly benefited to the neglect of smaller towns where the business was comparatively less profitable, but it must be remembered that the telegraph lines followed the railways and that many towns were not served owing to their opposition to the railways.

In 1856 the Edinburgh Chamber of Commerce began an agitation for the purchase by the government of the telegraphs, and a similar agitation in Great Britain joined forces with this agitation, which was strongly supported by the Press. In 1865 the Postmaster-General (Lord Stanley) commissioned Mr F. T. Scudamore, second secretary to the Post Office, to inquire and report whether the electric telegraph service could be beneficially worked on the Post Office, and whether it would entail any very large expenditure on the Post Office beyond the purchase of the rights. At that time the total number of places supplied with telegraphic communication by all the companies collectively, including railway stations, was 2,500, whereas the number of places having postal communications was over 10,000. Under the then existing telegraphic tariff the charge in Great Britain was a shilling for a twenty-word message over a distance not exceeding 100 miles; 1s. 6d. for a like message over distances from 100 to 200 miles; 2s. when exceeding 500 miles. For a message between Great Britain and Ireland the charge ranged from 3s. to 6s.; to Jersey or Guernsey it was 7s. 8d. There were also extra charges under contingent regulations of great complexity, which commonly added 50 per cent. to the primary charge, and frequently doubled it. In conclusion of the foregoing the author of the bill for the acquisition of the telegraphic systems, reported that the charges made by the telegraph companies were too high and tended to check the growth of telegraphy; that there were frequent delays of messages; that many important districts were unprovided with facilities; that in many places the telegraph office was inconveniently remote from the centre of business and was open for too small a portion of the day; that little or no improvement could be expected so long as the working of the telegraphs was conducted by commercial companies striving churlily to earn a dividend and engage in wasteful competition with each other; that the growth of telegraphy had been greatly stimulated in Belgium and Switzerland by the annexation of the telegraphs to the Post Offices of those countries and the consequent adoption of a low scale of charges; that in Great Britain like results would follow the adoption of like means, and that the association of the telegraphs with the Post Office would produce great advantage to the public and ultimately a large revenue to the state.

In support of these views he reported that in Belgium in 1863 a reduction of 50 per cent. in the charge had been followed by an increase of 50 per cent. in the number of telegrams, and that in 1856 a reduction of 50 per cent. in the charge had been followed by an increase of 85 per cent. in the traffic; and similar statistics pointing to increase of business consequent on reduction of rates were produced in regard to France, Switzerland and Prussia. The relative backwardness of telegraphy in Great Britain was attributed to high charges made by the companies and to restricted facilities. Some of the complaints against the companies, however, were exaggerated, and the estimates formed of the possibilities of reduction of tariffs and rates were optimistic. The basis for these estimates was the experience of other countries, which, however, did not justify the expectation that a large increase of business consequent on reduction of rates could be obtained without serious diminution of profit. The Belgian state telegraphs were started in 1850 and were at first very profitable, but for the years 1866–7 they yielded an average profit of only 2.5 per cent., and subsequently failed to earn operating expenses, the reasons for the steady decline of the profits being the opening of relatively unprofitable lines and offices, increases in wages, and a diminution in the value of the state patents, which had constituted the most profitable part of the whole business. The Belgian government endeavoured by reducing rates and increasing facilities to stimulate inland telegraphy in the hope of thereby increasing the profits of the department. But these expectations were not realized. Upwards of 100 telegraph offices in Belgium despatched on the average less than one telegram per day, and some offices despatched less than one a month. Similar experience was adduced by the working of the state telegraphs in Switzerland and in France. The profits when earned were derived mainly from foreign messages and the differences between foreign countries, while the receipts from inland messages did not always cover expenses. In 1868 there were in France over 300 telegraph offices whose average receipts did not exceed 8 francs per annum. In that year the Swiss government reduced the rate for inland telegrams by one-half, and the traffic immediately doubled, but the cost of carrying on the service increased in a larger ratio.

The experience of the telegraph companies in the United Kingdom, moreover, showed that a uniform rate, irrespective of distance, of 1s. 20 words, addressed free, was not remunerative in the then state of telegraphy, which made it necessary for messages to be re-transmitted at intervals of about 300 miles. In 1861 the United Kingdom Telegraph Company began a competition with the other companies on the basis of a 1s. rate, and the old-established companies were forced to adopt this rate between all points served by the United Kingdom.
Company; but after a trial of four years it was found that a uniform rate irrespective of distance had not justified itself, and that for any but very short distances the tariff was "utterly unremunerative" notwithstanding a very large increase in volume of business. Even the London District Telegraph Company, which was formed in 1859 for the purpose of transmitting telegraph messages between points in metropolitan England, found that a low uniform rate was not financially practicable. The company began with a tariff of 4d. per ro words; it soon increased the rate to 6d. for 15 words with an additional porterage charge for delivery beyond a certain distance, and in 1866 the tariff was raised to 1s. The company had 123 m. of line and 83 offices, and in 1865 conveyed over 316,000 messages, but it was not financially successful. Both the telegraph companies and the railway companies had incurred heavy commercial risks in developing the telegraph services of the country and only moderate profits were earned. It cannot justly be said that the companies made large profits while neglecting to develop the services adequately, but it is true that they were not able commercially to comply with many of the demands made upon them by the public. Until speculation took place in anticipation of government purchase, the market prices of the telegraph securities were mostly below par. The stock of the Electric and International Company, the return on which had reached 10 per cent. per annum, however, was valued at about 14 years' purchase of the annual profits. Very little new capital was invested in the telegraph companies about 1865 because of the natural reluctance of the companies to extend the system under their control so long as a proposal for their acquisition by the state was under consideration. In 1868 the length of electric telegraph lines belonging to the companies was 16,643 m., and of those belonging to the railway companies 4872 m., or a total of 21,515. With regard to the statement that the companies had installed competitive systems and had expended capital needlessly, it was found by the Post Office authorities that in 1865 less than 3000 m. of telegraph lines, and 350 offices out of a total of over 2000, were redundant. The telegraph companies proposed to effect an amalgamation so as to enable the services to be consolidated and extended, and they proposed to submit to various conditions for the protection of the public, such as maximum rates and limitation of dividends, with the provision that new issues of capital should be offered by auction, but public opinion was averse to the proposal. By 1868 both political parties in the House of Commons had committed themselves to the policy of state purchase of the telegraphs.

After much negotiation the basis finally agreed upon between the telegraph companies was 20 years' purchase of the profits of the year ended 30th June 1868. The Chancellor of the Exchequer described the terms as "very liberal but not more liberal than they should be under the circumstances," and stated that Mr Scudamore had estimated that £6,000,000 was the maximum price which the government would have to pay, and that the Postmaster-General would obtain from the telegraphs a net annual revenue of £293,000 at least. In addition to the undertakings of the telegraph companies the government had to purchase the reversionary rights of the railway companies which arose out of the circumstance that the telegraph companies for the most part had erected their poles and wires along the permanent way of the railways under leases which in 1868 had still many years to run. The price awarded to the six telegraph companies was £5,733,000. A further £1,000,000 was paid for the Jersey, Guernsey, Isle of Man and other undertakings, and about £9,500,000 was paid to the railway companies for their reversionary rights, the cost of which had been estimated at £700,000.

The government acquired the perpetual and exclusive way-leaves for telegraph lines over the railways, but the monopoly of the Postmaster-General does not apply to those parts of wires which are required for the protection of life on railways. The telegraphs were transferred to the Post Office on the 5th of February 1870. During the following three years the government spent £5,000,000 in making good the depreciation suffered by the plant in the transition years of 1868 and 1869, for which allowance had been made in the purchase price, and about £1,700,000 was expended on new plant. During that period 8000 m. of posts, 46,000 m. of wire and about 200 m. of underground pipes were added. The cost of these works had been underestimated, and the report of the Select Committee of the Post Office (Telegraph Department), 1876, states that "the committee have not received any full and satisfactory explanation of the great differences between the estimated expenditure of 1869 and the actual expenditure incurred up to 1876."

The excess expenditure caused the Post Office during two or three years to make temporary application of Savings Banks' balances to telegraph expenditure, an expedient which was disapproved of by both the Treasury and the House of Commons. Probably no more arduous task was ever thrown upon a public department than that imposed on the Post Office by the transfer. The reforms which it was to bring about were eagerly and impatiently demanded by the public. This great operation had to be effected without interrupting the public service, and the department had immediately to reduce and to simplify the charges for transmission throughout the kingdom. It had to extend the hours of business at all the offices; it had to extend the wires from railway stations lying outside of town populations to post offices in the centre of those populations and throughout the country; it had to extend the wires to towns into rural districts previously devoid of telegraphic communication; it had to effect a complete severance of commercial and domestic telegraphy from that of mere railway traffic, and in order to effect this severance it had to provide the railways with some 6000 m. of wires in substitution for those of which they had been joint users. It had further to provide at low charges for the distribution of news to the Press; it had to facilitate the transmission of money orders by telegram; finally, it had to amalgamate into one staff bodies of men who had formerly worked as rivals upon opposite plans and with different instruments, and to combine the amalgamated telegraph staff with that of the postal service. So zealously was the work of improvement pursued that within little more than six years of the transfer the aggregate extent of road wires in the United Kingdom was already 63,000 m. and that of railway wires 45,000, in all 108,000 m. The number of instruments in the telegraph offices was 12,000. At that date the superintending and managing staffs of the Post Office comprised 500 persons, the staff of the old companies with only about one-third of the traffic having been 534 persons.

The first appropriation was by 1871 for the increase of messages that would result from the reduction of rates were fully realized. The number of messages increased from about 6,500,000 in 1869 to nearly 10,000,000 in 1871 and to 20,000,000 in 1875, but the expectations as to net revenue were not justified by the results. In 1869 Mr Scudamore estimated the operating expenses at 51 to 56 per cent. of the gross revenue. In 1870-1 they were 57 per cent. and in 1871-2, 78 per cent. Since 1873 the capital account has been closed with a total expenditure of £10,867,044, and all subsequent expenditure for extensions, purchase of sites and erection of buildings has been charged against revenue.

There are several reasons for the unsatisfactory financial results apart from the high price paid for the acquisition of the telegraphs. The unprofitable extension of the telegraphs has largely contributed to the loss. Moreover, since 1861 the wages and salaries of the telegraph employees have been increased on several occasions in consequence of political pressure brought to bear on members of parliament; and notwithstanding the protest of the government the House of Commons in 1883 carried a resolution that the minimum rate for inland telegrams should be reduced to 6d. This involved a large extension of wires to cope with increased traffic. The reduced rate took effect as from the 1st of October 1883.

Another reason assigned by the committee appointed by the Treasury in 1875 to investigate the causes of the increased cost of the telegraphic service since the acquisition of the telegraphs by the state is the loss on the business of transmitting Press
messages, which has been estimated as at least £300,000 a year. A further cause has been competition offered by the telephone service, but against this the Post Office has received royalties from telephone companies and revenue from trunk telephone lines. These amounted in 1887 to £26,170 and £131,932 respectively; in 1897 to £85,289 and £113,294, and in 1897 to £240,333 and £479,639 respectively.

The following table shows the financial results of the business in the year immediately following the purchase of the telegraphs by the state, in the two years preceding and the two years following the introduction of the 6d. tariff, and in the seven financial years from 1900-1907:

\[\text{5th February 1870.—Transfer of telegraphs to the state.} \]
\[\text{\dag 1st October 1885.—Introduction of sixpenny tariff.} \]

**Submarine Telegraphs.**—The first commercially successful cable was that laid across the straits of Dover from the South Foreland to Sangatte by T. R. Crampton in 1851, and two years later, after several futile attempts, another was laid between Port Patrick in the south of Scotland and Donaghadee in Ireland. This was followed by various other cables between England and the neighbouring countries, and their success naturally revived the idea which had been suggested in 1845 of establishing telegraphic communication between England and America, though this enterprise, on account of the distance and the greater depth of water, was of a much more formidable character. On the American side Cyrus W. Field acquired a concession which had been granted to F. N. Gisborne for a land line connecting St John's, Newfoundland, and Cape Ray, in the Gulf of St Lawrence, and proceeded himself to get control of the points on the American coast most suitable as landing places for a cable. On the British side the question of constructing an Atlantic cable was engaging the attention of the Magnetic Telegraph Company and its engineer Mr (afterwards Sir) Charles Bright. Visiting England in 1856, Field entered into an agreement with Bright and with John Watkins Brett, who with his brother Jacob had proposed the constructing of an Atlantic cable eleven years previously, with the object of forming a company for establishing and working electric telegraphic communication between Newfoundland and Ireland. The Atlantic Telegraph Company was duly registered in 1856, with a capital of £530,000, the great bulk of which was subscribed in England. The manufacture of the cable, begun early in the following year, was finished in June, and before the end of July it was stowed partly in the American ship "Niagara" and partly in the British ship "Agamemnon," both being war-ships lent for the purpose by their respective governments. The shore end was landed in Valentia Harbour on the 5th of August, and next morning paying out was started by the "Niagara," to which the laying of the first half had been entrusted. For the first few days the operation proceeded satisfactorily, though slowly, but on the afternoon of the 11th, when 380 m. had been laid, the cable snapped, owing to a mistake in the manipulation of the brake, and the ships returned to Plymouth with what remained. Next year, 700 m. of new cable having been made, the attempt was renewed, with the same ships, but on this occasion it was decided to begin paying out in mid-ocean, the two vessels, after splicing together the ends of the cable they had on board, sailing away from each other in opposite directions. They left Plymouth on the 10th of June, but owing to a terrific storm it was not till the 25th that they met at the rendezvous. A splice having been made they started on the 26th, but the cable broke almost immediately. Another splice was made, to be followed, after the "Agamemnon" had paid out about 40 m., by another break. Again the ships returned to the rendezvous and made another splice, and again there was a break after the "Agamemnon" had paid out 146 m., and then the "Agamemnon," after again returning to the meeting-place in the vain hope that the "Niagara" might have returned there also, made for Queenstown, where she found her consort had arrived nearly a week previously.

Although a good deal of cable had been lost, enough remained to connect the British and American shores, and accordingly it was determined to make another attempt immediately. To this end the ships sailed from Queenstown on the 17th of July, and having spliced the cable in mid-ocean, started to pay it out on the 29th. The "Niagara" landed her end in Trinity Bay, Newfoundland, on the 5th of August, while on the same day the "Agamemnon," landed hers at Valentia. The electrical condition of the cable was then excellent, but unfortunately the electrician in charge, Wildman Whitehouse, conceived the wrong idea that it should be worked by currents of high potential. For nearly a week futile attempts were made to send messages by his methods, and then a return was made to the weak currents and the mirror galvanometers of Sir William Thomson (Lord Kelvin) which had been employed for testing purposes.
TELEGRAPH

COMMERCIAL ASPECTS

while the cable was being laid. In this way communication was established from both sides on the 16th of August, but it did not continue long, for the insulation had been ruined by Whitehouse's treatment, and after the 20th of October no signals could be got through.

The next attempt at laying an Atlantic cable was made in 1865, the necessary capital being again raised in England. It was then thought that the work should be done by a single ship, and the plan was accordingly named the "Great Eastern." It was chartered by the Telegraph Company, and the undertaking was entrusted to Captain Panne Farnham, a member of the Atlantic Telegraph Company. The cable was laid between Great Britain and the United States.

In 1866, the Atlantic Telegraph Company laid the first transatlantic cable, which was successful. The cable was laid between the United States and England, with a length of 7,700 miles. The cable was made of copper, covered with rubber, and had a thickness of 0.25 inches. The cable was laid at a speed of 10 miles per hour, and the work was completed in 63 days.

The laying of the transatlantic cable was a major engineering achievement of the time. The cable was made of copper, covered with rubber, and had a thickness of 0.25 inches. The cable was laid at a speed of 10 miles per hour, and the work was completed in 63 days.

In 1867, the Atlantic Telegraph Company was reconstituted as the Anglo-American Telegraph Company, with a capital of $600,000 and a sufficient cable was ordered. The cable was again employed, and leaving the west-coast of Ireland on the 13th of July, it reached Trinity Bay on the 9th of August, without serious mishap. It was then steamed eastwards again, and on the 13th of August made its first attempt to recover the lost cable. This, like many subsequent ones, was a failure, but finally it succeeded on the 2nd of September, and having made a splice completed the laying of the cable on the 8th of September. These two cables did not have a very long life, that of 1865 breaking down in 1877 and that of 1866 in 1872, but by the latter of these dates four other cables had been laid across the Atlantic, including one from Brest to Dublin, Messrs. Piron, Pannier, and others. The first cable of submarine cable, according to Mr. Charles Bright in 1887, that by that date 157,000 miles of submarine cable had been laid, while ten years later it was computed that 162,000 nautical miles of cable were in existence, representing a capital of $400,000,000, 75 per cent. of which had been provided by the United Kingdom. Among the men of business it was undoubtedly Sir John Pender (1815-1866) who contributed most to the development of this colossal industry, and to his unfailing faith in their ultimate realization must be ascribed the completion of the first successful Atlantic cables.

The submarine cables of the world now have a length exceeding 200,000 nautical miles, and most of them have been manufactured on the Thames.

The monopoly conferred upon the Postmaster-General by the Telegraph Act 1869 was subsequently extended to telephony and wireless telegraphy, but it does not extend to submarine telegraphy. The submarine telegraphs are mainly controlled by companies, the amount of issued capital of the existing British telegraph companies (twenty-four in number) being £30,447,101, but a certain number of lines are in government hands. On the 31st of March 1889 the undertaking of the Submarine Telegraph Company was purchased by the government. France and Great Britain jointly acquired the cables between Calais and Dover, Boulogne and Folkestone, Dieppe and Beachy Head, Havre and Beachy Head, Piron, near Coutances, and Vieux Chateaux (St. Heliers, Jersey).

Belgium and Great Britain became joint-proprietors of the cables between Ramsgate and Ostend and Dover and Die la Panne (near Furnes). The two cables to Holland and one of the cables to Germany were already the property of Great Britain, and the German Union Company's cable to Germany was purchased by the German government. The offices of the Submarine Company in London, Dover, Ramsgate, East Dean and Jersey were purchased by the Post Office, as well as the cable ship; and the staff, 370 in number, was taken over by the government. The capital amount laid out by Great Britain was £67,163, and on 1st April 1890 the new business was begun with a uniform rate to France, Germany, Holland and Belgium of 2d. a word, with a minimum of 101.

In 1890 Liverpool was placed in direct telegraphic communication with Hamburg and Havre, and London with Rome. The following year, an additional cable was laid a single strand, in Norfolk, to Borkum, in Germany, at the joint expense of the British and German governments. Direct telegraphic commu-
analogous to the action of the state in the cases referred to is the action taken by municipal authorities with the authority of the legislature in competing with or superseding private companies for the supply of electric light, gas, water, tramways and other public services. The service which the government and the colonies desire is one which neither the Eastern Telegraph Company nor any other private enterprise is prepared to undertake on terms which can be considered in comparison with the terms upon which it can be provided by the associated governments.

In November 1899 a committee was appointed by the Colonial Office for the further examination of the scheme, and towards the end of 1900 a tender was accepted for the manufacture and laying of a submarine cable between the Island of Vancouver and Queensland and New Zealand for the sum of £1,795,000, the work to be completed by the 31st of December 1901. A board was constituted to supervise the construction and working of the cable, composed of representatives of the several governments, with offices at Westminster. Under the Pacific Cable Act 1901 the capital sum of £2,000,000 was provided in the following proportions:

United Kingdom, $1,518ths with 3 representatives including the chairman.
Canada, $1,518ths with 2 representatives.
Australia, $1,618ths with 2 representatives.
New Zealand, 2,18ths with 1 representative.

In these proportions the respective contributing governments are responsible for the losses made in the working of the undertaking, and the total length of the cable was to be paid for cable repairs and reserve and a fixed payment to the National Debt Commissioners of $77,544 as sinking fund to amortise capital expenditure in fifty years. The deficiency on the working for the year ended 31st March 1907 was $54,924, and the approximate number of messages transmitted during the year was 96,783 with 1,126,940 words. There was in addition a considerable inter-colonial traffic between Australia, New Zealand and the Fiji.

Since the early days of international telegraphy, conferences of representatives of government telegraph departments and companies have been held from time to time (Paris 1865, Vienna 1868, Rome 1871 and 1878, St. Petersburg 1875, London 1879, Berlin 1885, Paris 1891, Buda Pesth 1896, London 1903). In 1898 the International Bureau of Telegraphic Administrations was constituted at Berne, and a convention was formulated by which a central office was appointed to collect and publish information and generally to promote the interests of international telegraphy. International service regulations have been drawn up which possess equal authority with the convention and constitute what may be regarded as the law relating to international telegraphy. The total lengths of the telegraphs throughout the world in 1907 were 1,015,894 m. aerial, and 11,454 m. underground, and the total lengths of submarine cables of the world were 39,072 nautical miles under government administration and 104,735 nautical miles under the administration of private companies.

(E. G.)

Part II.—Wireless Telegraphy

The early attempts to achieve electric telegraphy involved the use of a complete metallic circuit, but K. A. Steinheil of Munich, however, acting on a suggestion given by Gauss, made in 1838 the important discovery that half of the circuit might be formed of the conducting earth, and so discovered the use of the earth return, since then an essential feature of nearly every telegraphic circuit. Encouraged by this success, he even made the further suggestion that the remaining metallic portion of the circuit might perhaps some day be abolished and a system of wireless telegraphy established.

Morse showed, by experiments made in 1842 on a canal at Washington, that it was possible to interrupt the metallic electric circuit in two places and yet retain power of electric communication (see Fahie, loc. cit., p. 10). His plan, which has been imitated by numerous other experimentalists, was as follows:—On each side of the canal, at a considerable distance apart, metal plates ε and η (fig. 25) were sunk in the water; the pair on one side were connected by a battery B, and the pair on the other by a galvanometer or telegraphic receiver R. Under these circumstances a small portion of the current from the battery is shunted through the galvanometer circuit, and can be used to make electric signals. Morse and Gale, who assisted him, found, however, that the distance of the plates ε and η, as well as the length of the water between them, had to be at least three or four times the width of the canal to obtain successful results. Numerous investigators followed in Morse's footsteps. James Bowman Lindsay of Dundee, between 1845 and 1854, invented and even patented Morse's method, and practically put the plan into operation for experimental purposes across the river Tay. J. W. Wilkins in 1849, and H. Highton in experiments described in 1872, also revived the same suggestion for wireless telegraphy.

The invention of the magneto-telephone put into the hands of experimenters a new instrument of extraordinary sensitiveness for the detection of feeble interrupted, or alternating, currents, and by its aid J. Trowbridge in 1880, in the United States, made a very elaborate investigation of the propagation of electric currents through the earth, either soil or water (see "The Earth as a Conductor of Electricity," Amer. Acad. Arts and Sci., 1880). He found, as others have done, that if a battery, dynamo or induction coil has its terminals connected to the earth at two distant places, a system of electric currents flows between these points through the crust of the earth. If the current is interrupted or alternating, and if a telephone receiver has its terminals connected to a separate metallic circuit joined by earth plates at two other places to the earth, not on the same equipotential surface of the first circuit, sounds will be heard in the telephone due to a current passing through it. Hence, by inserting a break-and-make key in the circuit of the battery, coil or dynamo, the uniform noise or hum in the telephone can be cut up into periods of long and short noises, which can be made to yield the signals of the Morse alphabet. In this manner Trowbridge showed that signalling might be carried on over considerable distances by electric conduction through the earth or water between places not metallically connected. He also repeated the suggestion which Lindsay had already made that it might be possible to signal in this manner by conduction currents through the Atlantic Ocean from the United States to Europe. He and others also suggested the applicability of the method to the inter-communication of ships at sea. He proposed that one ship should be provided with the means of making an interrupted current in a circuit formed partly of an insulated metallic wire connected with the sea at both ends by plates, and partly of the unlimited ocean. Such an arrangement would distribute a...
system of flow lines of current through the sea, and these might be detected by any other ships furnished with two plates dipping into the sea at stem and stern, and connected by a wire having a telephone in its circuit, provided that the two plates were not placed on the same equipotential surface of the original current flow lines. Experiments of this kind were actually tried by Graham Bell in 1882, with boats on the Potomac river, and signals were detected at a distance of a mile and a half.

At a later date, 1891, Trowbridge discussed another method of effecting communication at a distance, viz., by means of magnetic induction between two separate and completely insulated circuits. If a primary circuit, consisting of a large coil of wire P (fig. 36), has in circuit a battery B and an interrupter or current reverser, signals can be given by breaking up the continuous hum in the telephone into long and short periods. This method of communication by magnetic induction through space establishes, therefore, a second method of wireless telegraphy which is quite independent of and different from that due to conduction through earth or water.

Sir W. H. Preece, who took up the subject about the same time as Prof. Trowbridge, obtained improved practical results by combining together methods of induction and conduction. His first publication of results was in 1882 (Brit. Assoc. Report), when he drew attention to the considerable distance over which inductive effects occurred between parallel wires forming portions of two telephonic and telegraphic circuits. Following on this he made an interesting series of experiments on telephonic and telegraphic circuits, insisting on the need of separating the primary and secondary circuits as far as possible from each other. Heaviside and Smullin devised an improved method which unites both conduction and induction as the means of affecting one circuit by a current in another. In 1892, on the Bristol Channel, he established communication between Willenborough Point and Penarth, at a point 5.5 miles apart, by placing at these positions insulated single-wire telegraphy circuits, earthed at both ends and laid as far as possible parallel to each other, the distance between them being 3-3 m. The shore wire was 1267 yds. long, and that on the island 600 yds. An interrupted current having a frequency of about 400 was used in the primary circuit, and a telephone was employed as a receiver in the secondary circuit. Other experiments in inductive telegraphy were made by Preece, aided by the officers of the British Postal Telegraph Service, in Glamorganshire in 1887; at Loch Na Keal, in the Hebrides, in 1888; and at Frodsham, on the Dee, in 1894. (See Jour. Inst. Elec. Eng., 27, p. 869.) In 1889 experiments were made at Menai Straits to put the lighthouse at the Skerries into communication with the coastguard station at Cemlyn. A wire 750 yds. in length was erected along the Skerries, and on the mainland one of 33 m. long, starting from a point opposite the Skerries, to Cemlyn. Each line terminated in an earth plate placed in the sea.

The average perpendicularly distance between the two lines, which are roughly parallel, is 2-8 m. Telephonic speech between these two circuits was found possible and good, the telephone receiving any wires in the circuits by means of mutual induction, and no doubt partly by conduction. On the question of how far the effects are due to conduction between the earth plates, and how far to true electromagnetic induction, authorities differ, some being of opinion that the two effects are in operation together. A similar installation of inductive telephony, in which telephone currents in one line were made to create others in a nearly parallel and distant line, was established in 1899 between Rathlin Island on the north coast of Ireland and the mainland. The shortest distance between the two points was 10 miles, and by various experiments in the water, it was found that conduction was the only factor. The two lines were laid between an island and the mainland parallel wire circuits earthed at each end, good telephonic communication over an average distance of 6½ m. was established between these independent circuits.

The difficulty of connecting lightships and isolated lighthouses to the mainland by submarine cables, owing to the destructive action of the tides and waves on rocky coasts on the shore ends, led many inventors to look for a way out of the difficulty by the adoption of some form of inductive or conductive telegraphy not necessitating a continuous cable. Wiloughby Smith, of the telegraphic company, explains how a submarine cable, laid with wires that are not connected to any land, can be telephonic communication. He showed an improved method which depends upon conduction through sea water. (See Jour. Inst. Elec. Eng., 27, p. 538.) It may be explained as follows:—Suppose a battery on shore to have one pole earthed and the other connected to an insulated submarine cable, the distant end of which was also earthed; if now a galvanometer is inserted anywhere in the cable, a current will be found flowing through the cable and returning by various paths through the sea. If we suppose the cable interrupted at any place, and both sides of the gap earthed by connexion to plates, then the same conditions will still hold. Communication was established by this method in the year 1895 with the lighthouse on the Fastnet. A cable is carried out from the mainland at Crookhaven for 7 m., and the outer end earthed by connexion with a copper mushroom anchor. Another earthed cable starts from a similar anchor about 100 ft. away near the shore line of the Fastnet rock, crosses the rock, and is again earthed in the sea at the distant end. If a battery on the mainland is connected through a key with the shore end of the main cable, and a speaking galvanometer is in circuit with the short cable crossing the Fastnet rock, then closing or opening the battery connexion will create a deflection of the galvanometer. A very ingenious call-bell arrangement was devised, capable of responding only to regularly reversed battery currents, but not

1See Fahie, History of Wireless Telegraphy, p. 1701 also 5th Report (1897) of the Royal Commission on Electrical Communication with Lightships and Lighthouses.
to stray "earth currents," and very good signalling was established between the mainland and the rock. Owing to the rough seas sweeping over the Fastnet, the conditions are such that any ordinary submarine cable would be broken by the wearing action of the waves at the rock boundary in a very short time. Another circuit in this department of research was arranged by C. A. Stevenson, who in 1892 advocated the use of the inductive system pure and simple for communication between the mainland and isolated lighthouses or islands. He proposed to employ two large flat coils of wire laid horizontally on the ground, that on the mainland having in circuit a battery, interrupter and key, and that on the island a telephone. His proposals had special reference to the necessity for connecting a lighthouse on Muckle Flugga, in the Shetlands, and the mainland, but were not carried into effect. Professor E. Rathenau of Berlin made many experiments in 1894 in which, by means of a conductive system of wireless telegraphy, he signalled through 3 m. of water.

Sir Oliver Lodge in 1898 theoretically examined the inductive system of space telegraphy. (See Jour. Inst. Elec. Eng., 27, p. 799.) He advocated and put in practice experimentally a system by which the primary and secondary circuits were "turned" or synchronized by including condensers in the circuits. He proved that when so synchronized the circuits are inductively respondent to each other with much less power expenditure in the primary circuit than without the syntonizing. He also considered the question of another coil and an ordinary electric bell by the accumulated effect of the properly tuned inductive impulses falling on the secondary circuit. A very ingenious call-bell or annunciator for use with inductive or conductive systems of wireless telegraphy was invented and described in 1898 by S. Evershed, and has been practically adopted at Lavernock and Flat Holme. (Id., 27, p. 532.)

In addition to the systems of wireless or space telegraphy depending upon conduction through earth or water, and the inductive system based upon the power of a magnetic field to produce this conduction, there have been certain attempts to utilize what may best be described as electrostatic induction. In 1885 Edison, in conjunction with Gilliland, Phelps, and W. Smith, worked out a system of communicating between railway stations and moving trains. At each signalling station was erected an insulated metallic surface facing and near to the ordinary telegraph wires. On one or more of the carriages of the trains were placed also insulated metallic sheets, which were in connexion through a telephone and the secondary circuit by an induction coil with the earth or rails. In the apparatus used by this arrangement it was shown that an ordinary electric bell could be actuated by the accumulation of the electric potential of the earth and the cable. At the telephone used was Edison's chalk cylinder or electromotograph type of telephone. Hence, when the coil at one fixed station was in action it generated high frequency alternating currents, which were propagated across the air gap between the ordinary telegraph wires and the metallic surfaces attached to one secondary terminal of the induction coil, and conveyed along the ordinary telegraph wires between station and moving train. Thus, in the case of one station and one moving rail circuit, when, for example, the parts of the earth, the parts of the ordinary telegraph wires at the side of the track, and partly of the circuits of the telephone receiver at one place and the secondary of the induction coil at the other, two air gaps existing in this circuit. The electromotive force of the coil is, however, great enough to create in these air gaps displacement currents which are of magnitude sufficient to be equivalent to the conduction current required to actuate a telephone. This current may be taken to be of the order of two or three micro-amperes. The signals were sent by cutting up the continuous hum in the telephone into long and short periods in accordance with the Morse code, and thus the key of the primary circuit was actuated and the key of the telegraph. This system was put into practical operation in 1887 on the Lehigh Valley railroad in the United States, and worked well, but was abandoned because it apparently fulfilled no real public want. Edison also patented (U.S.A. Pat. Spec., No. 465971, 14th May 1885) a plan for establishing at distant places two insulated elevated plates. One of these was to be connected to the earth through a telephone receiver, and the other through the secondary circuit of an induction coil in the primary circuit of which was a key. The idea was that variations of the primary current would create electromotive force in the secondary circuit which would act through the air condenser formed by the two plates. It has sometimes been claimed that Edison's proposed elevated plates anticipated the subsequent invention by Marconi of the aerial wire or antenna, but it is particularly to be noticed that Edison employed no spark gap or means for creating electrical high frequency oscillations in these wires. There is no evidence that this plan of Edison's was practically operative as a system of telegraphy.

A very similar system of wireless telegraphy was patented by Professor A. E. Dolbear in 1886 (U.S.A. Pat. Spec., No. 350290), in which he proposed to employ two batteries at two places to affect the potential of the earth at those places. At the sending station one battery was to have its positive pole connected to the earth and its negative pole to an insulated condenser. In circuit with this battery was placed the secondary circuit of an induction coil, the primary circuit of which contained a telephone transmitter or microphone interrupter. At the receiving station a telephone receiver was placed in the circuit with another insulated battery, the negative terminal of which was to be in connexion with the earth. There is no evidence, however, that the method proposed could or did effect the transmission of speech or signals between stations separated by any distance. Many other more or less imperfect devices—such as those of Mahlon Loomis, put forward in 1872 and 1877, and Kitsee in 1895—for wireless telegraphy were not within the region of practically realizable schemes.

Space or Radio-Telegraphy by Hertzian Waves.—Up to 1895 or 1896 the suggestions for wireless telegraphy which had been publicly announced or tried could thus be classified under three or four divisions, based respectively upon electrical conduction through the soil or sea, magnetic induction through space, combinations of the two foregoing, and, lastly, electrostatic induction. All these older methods have, however, been thrown into the background and rendered antiquated by inventions which have grown out of Hertz's scientific investigations on the production of electric waves. Before the classical researches of Hertz in 1886 and 1887, many observers had noticed curious effects due to electric sparks produced at a distance which were commonly ascribed to ordinary electrostatic or electro-magnetic induction. Thus Joseph Henry (Scientific Writings, vol. i. p. 203) noticed that a single electric spark about an inch long thrown on to a circuit of wire in an upper room could magnetize steel needles included in a parallel circuit of wire placed in a cellar 30 ft. below with two floors intervening. Some curious distance-phenomena connected with electric sparks were observed in 1875 by Edison (who referred them to a supposed new "aetheric force"), and confirmed by Beard, S. P. Thompson, E. J. Houston and others. D. E. Hughes made some remarkable observations and experiments in 1886 and 1887; he showed that he could transmit electric waves, not describe them till some twenty years afterwards. He discovered a fact subsequently rediscovered by others, that a tube of metallic filings, loosely packed, was sensitive to electric sparks made in its vicinity, its electrical resistance being reduced, and he was able to detect effects on such a tube connected to a battery and telephone at a distance of 500 yds. These distance effects were not understood at the time, or else were referred simply to ordinary induction. Hertz, however, made known in 1887 the experimental proofs that the discharge

of a condenser produces an electric spark which under proper conditions creates an effect propagated out into space as an electric wave. He employed as a detector of this wave a simple, nearly closed circuit of wire called a Hertz resonator, but it was subsequently discovered that the metallic microphone of D. E. Hughes was a far more sensitive detector. The peculiar action of electric sparks and waves in reducing the resistance of discontinuous conductors was rediscovered and investigated by Calzecchi Onesti,1 by Brantly,2 Dawson Turner,3 Minchin, Lodge,4 and many others. Brantly was the first to investigate and describe in 1890 the fact that an electric spark at a distance had the power of changing loose aggregations of metallic powders from poor to good electric conductors, and he also found that in some cases the reverse action was produced. Lodge particularly studied the action of electric waves in reducing the resistance of the contact between two metallic surfaces such as a plate and a point, or two balls, and named the device a 'coherer.' He constructed one form of his coherer of a glass tube a few inches long filled with iron borings or brass filings, having contact plates or pins at the end. When such a tube is inserted in series with a single voltaic cell and galvanometer it is found that the resistance of the tube is nearly infinite, provided the filings are not too tightly squeezed. On creating an electric spark or wave in the neighbourhood of the tube the resistance suddenly falls to a few ohms and the cell sends a current through it. By shaking or tapping the tube the current is extinguished. In 1894 he described a simple apparatus of this kind in which the tapping back of the tube of filings was effected automatically. He ascribed the reduction of resistance of the mass to a welding or cohering action taking place between the metallic particles, hence the name 'coherer.' But, as Brantly showed, it is not universally true that the action of an electric wave is to reduce the resistance of a tube of powdered metal or cause the particles to cohere. In some cases, such as that of peroxide of lead, an increase of resistance takes place.

Between 1894 and 1896 G. Marconi gave great attention to the improvement of devices for the detection of electric waves.

Marconi. He made his sensitive tube, or improved coherer, as follows:—A glass tube having an internal diameter of about 4 millimetres has sealed into it two silver plugs By means of platinum wires WW (fig. 37); the opposed faces of these plugs are perfectly smooth, and are placed within a millimetre of each other. The interspace is filled with a very small quantity of nickel and silver filings, about 95 per cent. nickel and 5 per cent. silver, sufficient to fill loosely about half the cavity between the plugs, which fit tightly into the tube. The tube is then exhausted of its air, and attached to a bone or glass rod as a holder. This form of electric wave detector proved itself to be far more certain in operation and sensitive made, but no one had overcome the practical difficulties or actually shown how to do it.

G. Marconi, however, made the important discovery that if his sensitive tube or coherer had one terminal attached to a metal plate lying on the earth, or buried in it, and the other to an insulated plate elevated at a height above the ground, it could detect the presence of very feeble electric waves of a certain kind originating at a great distance. In conjunction with the above receiver he employed a transmitter, which consisted of a large induction or spark coil S having its spark balls placed a few millimetres apart; one of these balls was connected to an earth plate E and the other to a plate or wire insulated at the upper end and elevated above the surface of the earth. In the primary circuit of the induction coil I he placed an ordinary signalling key K, and when this was pressed for a longer or shorter time a torrent of electric sparks passed between the balls, alternately charging and discharging the elevated conductor A1 and creating electrical oscillations (see ELECTRO-KINETICS) in the wire. This elevated conductor is now called the antenna, aerial wire, or air wire. At the receiving station Marconi connected a single voltaic cell B1 and a sensitive telegraphic relay R in series with his tube of metallic filings C, and interposed certain little coils called choking coils. The relay was employed to actuate through a local battery B2 an ordinary Morse printing telegraphic instrument M. One end of the sensitive tube was then connected to the earth and the other end to an antenna or insulated elevated conductor A2. Assuming the transmitting and receiving apparatus to be set up at distant stations (see fig. 38), the insulated wires or plates being upheld by masts, its operation is as follows:—When the key in the primary circuit of the induction coil is pressed the transmitting antenna wire is alternately charged to a high potential and discharged with the production of high frequency oscillations in it. This process creates in the space around electric waves or periodic changes in electric and magnetic force round the antenna wire. The antenna wire, connected to one spark ball of the induction coil, must be considered to form with the earth, connected to the other spark ball, a condenser. Before the spark happens lines of electrostatic force stretch from one to the other in curved lines. When the discharge takes place the ends of the lines of electric force abutting on the wire run down it and are detached in the form of semi-loops of electric force which move outwards with their ends on the surface of the earth. As they travel they are accompanied by lines of magnetic force, which expand outwards in ever-widening circles. The magnetic and electric forces are directed alternately in one direction and the other, and at distances which are called multiples of a wave length the force is in the same direction at the same time, but in the case of damped waves has not quite the same intensity. The force at any one point also varies cyclically, that is, is varying at any one point

and varying from point to point. This periodic distribution in time and space constitutes an electric wave proceeding outward in all directions from the sending antenna. If we consider the lines of magnetic force in the neighbourhood of the receiving antenna wire we shall see that they move across it, and thus create in it an electric current which acts upon the coherer or other sensitive device associated with it.

**Marconi’s System of Wireless Telegraphy.**—Marconi’s system of electrical transmission consists therefore in setting up at the transmitting station the devices just described for sending out groups of damped electric waves of the above kind in long or short trains corresponding to the dash or dot signals of the Morse code. He placed in the primary circuit of the induction coil a longer or shorter time. This produced in the antenna, by the effect of the electric waves. At the receiving station he connected, as stated, one end of the sensitive tube to earth and the other to the antenna, and improved and applied a device of Popoff for automatically tapping the tube after each electric impact had rendered it conductive. He caused the relay in series with the sensitive tube to set in action not only a telegraphic instrument but also the electromagnetic tapper, which was arranged so as to administer light blows on the under side of the sensitive tube when the latter became conductive. The effect was to print a dash or dot on a strip of telegraphic paper, according as the incident electric wave lasted a longer or shorter time. In addition there was produced a slight spark from the contacts of the relay and tapper. He thus produced in 1896 for the first time an operative apparatus of electric wave telegraphy. Its simplicity and compactness recommended it immediately for communication between ship and shore and for intermarine communication generally. Marconi’s earliest experiments with this apparatus were made in Italy. In 1896 he came to England and gave demonstrations to the British postal telegraph department and other officials. These experiments were made on Salisbury Plain and others in the Bristol Channel between Lavernock and Flat Holm and Bream Down in 1897. Early in 1898 permanent stations were established between Alum Bay and Bournemouth, a distance of 143 m., where successful results were obtained. Later the Bournemouth station was removed to Poole Harbour, and the Alum Bay station to Niton in the Isle of Wight, the distance being thus increased to 20 m. In December 1898 communication was established by the Marconi method between the East Goodwin lightship and the South Foreland lighthouse, and this installation was maintained for upwards of a year, during which it was the means of saving both life and property. In March 1899 communication was effected by his system between England (South Foreland lighthouse) and France (Wimereux, near Boulogne), a distance of 30 m. He kept up the communication for 20,000 words, in all weathers, and found that ordinary commercial messages could be transmitted at the rate of 15 to 20 words a minute. In January 1901 he established communication by his new system between Cornuta and Niton in the Isle of Wight, a distance of 200 m. A full account of the development of his system was given by him in an article published in the Fortnightly Review for June 1902; see also a paper by him in the Journal of Inst. Elec. Eng., Dec., 1901, p. 727. About this time he introduced various improvements into the receiving apparatus. Instead of inserting the sensitive tube between the receiving antenna and the earth, he inserted the primary coil of a peculiar form of oscillation transformer and connected the terminals of the tube to the secondary circuit of the transformer. Lodge had previously suggested the use of transformed oscillations for acting on the coherer (see British Patent Spec., No. 11575 of 1897), but it is not every form of oscillation transformer which is suitable for this purpose.

Marconi’s successes and the demonstrations he had given of the thoroughly practical character of his system of telegraphy led to investigations in every part of the world. In Belgium many workers were under the same field of labour, whilst theorists began to study carefully the nature of the physical phenomena involved. It was seen that the effect of the incident electric waves was to produce a certain amount of electric oscillations, or in other words, high frequency alternating electric currents, such that whilst the potential variations were a maximum at the top or insulated end of the antenna, at some other point there was zero and the potential variation was zero and the current amplitude a maximum. Hence devices for detecting the oscillations in the antenna are merely very sensitive forms of ammeter and voltmeter.

We now consider the transmitting apparatus. The first stage of the transmitting part, one essential element is the antenna, aerial, or air wire, which may take a variety of forms. It may consist of a single plain or stranded copper wire upheld at the top by an insulator from a mast, chimney or building. The wire may have at the upper end a plate called a "capacity area." electrically equivalent to an extension of the wire, or part of the wire may be bent over and carried horizontally. In many cases multiple antennae are used consisting of many wires arranged in cone or umbrella-rib fashion, or a metal roof or metallic chimney may be employed (see fig. 39). In any case the antenna serves as one surface of a condenser, the other surface of which is the earth. This condenser is charged electrically and then suddenly discharged and violent electrical oscillations are set up in it, that is to say, electricity rushes to and fro between the antenna and the earth. This creates rapid variations in electric and magnetic force round the antenna and detaches energy from it in the form of an electric wave. The antenna has at one moment a static electrical charge distributed upon it, and lines of electric force stretch from it to the surrounding earth. At the next instant it is the seat of an electric current and is surrounded by closed lines of magnetic force. These static and kinetic conditions succeed each other rapidly, and the result is to detach or throw off from the antenna semi-loops of electric force, which move outwards in all directions and are accompanied by expanding circular lines of magnetic force. The whole process is exactly analogous to the operation by which a violin string or organ pipe creates an air or sound wave. The violin string is first drawn on one side. This strain corresponds to the electrical charging of the antenna. The string is then suddenly released. This corresponds to the electrical discharge of the antenna, and the subsequent string vibrations to the electrical vibrations. These communicate their energy to the surrounding air, and this energy is conveyed away in the form of air waves.

There are three ways in which the antenna may be charged:—

(i) It may be separated from the earth by a pair of spark balls which are connected respectively to the terminals of an induction coil or transformer, or other high tension generator. If these spark balls are set at the right distance, then when the potential difference accumulates the antenna will be charged and at some stage suddenly discharged by the discharge leaping across the spark gap. This was Marconi’s original method, and the plan is still used under the name of the direct method of excitation or the plain antenna.

(ii) The antenna may have oscillations excited in it inductively. F. Braun suggested in 1898 that the oscillatory discharge of a Leyden jar should be sent through the primary coil of a transformer and the secondary coil should be interposed between the antenna and the earth connexion. Marconi’s practical utility to this idea by tuning the two circuits together, and the arrangement now employed is as follows:—A suitable condenser C, or battery of Leyden jars, has one coating connected to one spark ball and the other through a coil of one turn with the other spark ball of a discharging S. These spark balls are connected either to the secondary circuit of an induction coil 1, or to that of an alternating current transformer having a secondary voltage of 20,000 to 100,000 volts. Over the coil of one turn is wound a secondary circuit of many turns of many wires connected to the earth through a variable inductance and the other end to an antenna or radiating wire A (see fig. 40). These two circuits are so adjusted that the closed oscillation circuit, consisting of the condenser, primary coil

1 See German Patent of F. Braun, No. 111578 of 1898, or British Specification, No. 1805 of 1899.

2 See British Pat. Spec., G. Marconi, No. 7777 of 1900.
TELEGRAPH

and spark gap, has the same natural time period of oscillation as the open circuit consisting of the antenna, secondary coil, and adjustable inductance. When this is the case, if discharges are made across the spark gap oscillations are excited in the closed circuit, and these induce other syntonie oscillations in the antenna circuit. J. A. Fleming devised an arrangement in which a multiple transformation takes place, two oscillation circuits being interlinked inductively, and the last one acting inductively on the open or antenna circuit. J. S. Stone similarly devised a multiple inductive oscillation circuit with the object of forcing on the antenna circuit a single oscillation of definite frequency. In the case of the inductive mode of exciting the oscillations an important quantity is the coefficient of coupling of the two oscillation circuits. If \( L_1 \) and \( L_2 \) are the inductances of any two circuits which have a coefficient of mutual inductance \( M \), then \( M/\sqrt{(L_1L_2)} \) is called the coefficient of coupling of the circuits and is generally expressed as a percentage. Two circuits are said to be closely coupled if the coefficient of coupling is near unity and to be loosely coupled if it is very small. It can be shown that if two circuits, both having capacity \( C \) and inductance \( L \), are coupled together inductively, then, when oscillations are set up in one circuit, oscillations of two periods are excited in the other differing in frequency from each other and from the natural frequency of the circuit if the two circuits are in tune so that the numerical product of capacity and inductance of each circuit is the same or \( CL_1 = CL_2 + CL \), and if \( k \) is the coefficient of coupling then the natural frequency of each circuit is \( n = 1 + k^2 \) and \( n = n/\sqrt{(1 + k)} \). Since in all cases of

wave motion the wave-length \( \lambda \) is connected with the frequency \( n \) and the velocity of propagation \( v \) by the relation \( v = \lambda n \); it follows that from such an inductively coupled tuned antenna electric waves of two wave-lengths are sent out having lengths \( \lambda_1 \) and \( \lambda_2 \) such that \( \lambda_1 = \lambda \sqrt{(1 - k)} \) and \( \lambda_2 = \lambda \sqrt{(1 + k)} \), where \( \lambda \) is the natural wave-length. It is seen that as the coupling \( k \) becomes small these two wave-lengths coalesce into one single wave-length. Hence there are advantages in employing a very loose coupling.

(iii) The antenna may be direct-coupled to the closed oscillatory circuit in the manner suggested by F. Braun, A. Slaby and O. Lodge. In this case a closed condenser circuit is formed with a battery of Leyden jars, an inductance coil and a spark gap, and oscillations are excited in it by discharges created across the spark gap by an induction coil or transformer. One end of the inductance coil is connected to the earth, and some other point on the closed condenser circuit to an antenna of appropriate length. When oscillations are created in the closed circuit syntonie oscillations are created which are increased considerably, and are propagated from the earth. In many cases additional condensers or inductance coils are inserted in various places so that the arrangement is somewhat disguised, but by far the larger part of the electric wave wireless telegraphy in 1907 was effected by transmitters having antennae either inductively or directly coupled to a closed condenser circuit containing a spark gap.

In practical wireless telegraphy the antenna generally a collection of wires in fan shape upheld from one or more masts or wooden towers. Sometimes the prolongations of these wires are carried horizontally or dipped down so as to form an umbrella antenna (fig. 42). The lower ends of these wires are connected through the secondary coil of an oscillation transformer to an earth plate, or to a large conductor placed on or near the earth called a "balancing capacity." If the direct coupling is adopted then the lower end of the antenna is connected directly to the earth. The main capacity in this last circuit consists of a battery of Leyden jars or of Leyden plates immersed in oil or some form of air condenser, and the inductance coil or primary circuit of the oscillation transformer consists of a few turns of highly insulated wire wound on a frame and immersed in oil. The oscillations are controlled either by a key inserted in the primary circuit of the exciting induction coil or transformer, or by a key cutting in and out of the primary condensers or throwing inductance in and out of the closed oscillation circuit. In one of these ways the oscillations can be created or stopped at pleasure in the radiating antenna, and hence groups of electric waves thrown off at will.

Production of Electric Waves of Large Amplitude.—In creating powerful electric waves for communication over long distances it is necessary to employ an alternating current transformer (see Transformers) supplied with alternating currents from a low frequency alternator D driven by an engine to charge the condenser (fig. 43). The transformer \( T_1 \) has its secondary or high-pressure terminals connected to spark balls \( S_1 \), which are also connected by a circuit consisting of a large glass plate condenser \( C_1 \) and the primary circuit of an air-core transformer \( T_2 \), called an oscillation transformer. The secondary circuit of this last is either connected between an aerial \( A \) and the earth \( E \), or it may be again in turn connected to a second pair of spark balls \( S_2 \) and these again to a second condenser \( C_2 \), oscillation transformer \( T_3 \), and the aerial \( A \). In order to produce electric oscillations in the system, the first or alternating current transformer must charge the condenser connected to its secondary terminals, but must not produce a permanent electric arc between the balls. Various devices have been suggested for extinguishing the arc and yet allowing the condenser oscillatory discharge to take place. Tesla effected this purpose by placing the spark balls transversely in a powerful magnetic field. Elihu Thomson blows on the spark balls with a powerful jet of air. Marconi causes the spark balls to move rapidly past each other or causes a studded disk to move between the spark balls. J. A. Fleming devised a method which has practical advantages in both preventing the arc and permitting the oscillatory currents to be controlled so as to make electric wave signals. He inserts in the primary circuit of the alternating

1 See J. S. Stone, U.S.A. Pat. Spec., Nos. 714756 and 714831.
adjust the frequency so that it has the value of the normal time period of the circuit formed of the condenser and transformer secondary circuit, and thus it is possible to obtain complete oscillatory discharges free from any mixture with alternating current arc. In this manner the condenser discharge can be started or stopped at pleasure, and long and short discharges made in accordance with the signals of the Morse alphabet by manipulating the short-circuiting key of one of the choking coils (see British Patent Spec., Nos. 18865, 20576 and 22126 of 1900, and 3451 of 1901).

In the case of transmitters constructed as above described, in which the effective agent in producing the electric waves radiated is the sudden discharge of a condenser, it should be noticed that what is really sent out is a train of damped or decaying electric waves. When electric oscillations are set up in an open or closed electric circuit having capacity and inductance, and left to themselves, they die away in amplitude, either because they dissipate their energy as heat in overcoming the resistance of the circuit, or because they radiate it by imparting wave motion to the surrounding ether. In both cases the amplitude of the oscillations decreases more or less rapidly. Such a sequence of decreasing electric oscillations and corresponding set of waves is called a damped train. In the case of the plain or directly excited antenna the oscillations are highly damped, and each wave probably only consists of most of a dozen oscillations. The reason for this is that the capacity of a simple antenna is very small—it may be something of the order of 0-0002 of a microfarad—and hence the energy stored up in it even under a high voltage is also small. Accordingly this energy is rapidly dissipated and but few oscillations can take place. If, however, the antenna is inductively or directly coupled to a condenser circuit of large capacity then the amount of energy which can be stored up before discharge takes place is very much greater, and hence can be drawn upon to create prolonged or slightly damped trains of waves. Allusion is made below to recent work on the production of undamped trains of electric waves.

Receiving Arrangements.—Before explaining the advantages of such oscillatory trains it will be necessary to consider the usual forms of the receiving apparatus. This consists of a receiving antenna similar to the sending antenna, and in any wireless telegraph station it is usual to make the one and the same antenna do duty as a receiver or sender by switching it over from one apparatus to the other. The electric waves coming through space from the sending station strike against the receiving antenna and set up in it high frequency alternating electrromotive forces. To detect these currents some device has to be inserted in the antenna circuit or else inductively connected with it which is sensitive to high frequency currents. The devices used for this purpose may be divided into two classes: (i) potential operated detectors, and (ii) current operated detectors. The oldest of the class (i) is that generically known as a coherer, the construction of which we have already described. The ordinary forms of metallic filings coherer of the Brany type require tapping to bring them back to the high resistance or sensitive condition. Lodge arranged a mechanical taper for the purpose which continually administered the small blow to the tube sufficient to keep the filings in a sensitive condition. Popoff employed an electromagnetic taper, in fact the mechanism of an electric bell with the gong removed, for this purpose. Marconi, by giving great attention to the details, improved the electromagnetic taper and, combining it with his improved form of sensitive tube, made a telegraphic instrument as follows: the small glass tube, containing nickel and silver filings between two silver plugs, was attached to a bone holder, and under this was arranged a small electromagnet having a vibrating armature like an electric bell carrying on it a stem and hammer. This hammer is arranged so that when the armature vibrates it gives little blows to the underside of the tube and shatters the fillings. By means of several adjusting screws the force and frequency of these blows can be exactly regulated. In series with the tube is placed a single voltaic cell and a telegraphic relay, and Marconi added certain coils placed across the spark contacts of the relay to prevent the local sparks affecting the coherer. The relay itself served to actuate a Morse printing telegraph by means of a local battery. This receiving apparatus, with the exception of the Morse printer, was contained in a sheet-iron box, so as to exclude it from the action of the sparks of the neighbouring transmitter. In the course of experiments Marconi connected the sensitive tube in between the receiving antenna and the earth plate, but, as already mentioned, in subsequent forms of apparatus he introduced the primary coil of a peculiar form of oscillation transformer into the antenna circuit and connected the ends of the sensitive tube to the terminals of the secondary circuit of this "jigger" (fig. 44). In later improvements the secondary circuit of this jigger was interrupted by a small condenser, and the terminals of the relay and local cell were connected to the plates of the condenser, whilst the sensitive tube was attached to the other end of the secondary circuit. Also another condenser was added in parallel with the sensitive tube.

With this apparatus some of Marconi's earliest successes, such as telegraphing across the English Channel, were achieved, and telegraphic communication at the rate of fifteen words or so a minute established between the East Goodwin lightship and the South Foreland lighthouse, also between the Isle of Wight and the Lizard in Cornwall. It was found to be peculiarly adapted for communication between ships at sea and between ship and shore, and a system of regular supermarine communication was put into operation by two limited companies, Marconi's Wireless Telegraph Company and the Marconi International Marine Communication Company. Stations were established on various coast positions and ships supplied with the above-described apparatus to communicate with each other and with these stations. By the end of 1901 this radio-telegraphy had been established by Marconi and his associates on a secure industrial basis.

Various Forms of Wave Detectors or Receivers.—The numerous adjustments required by the taper and the inertia of the apparatus prompted inventors to seek a self-restoring coherer which should not need tapping. Castelli, a petty officer in the Italian navy, found that, if a small drop of mercury was contained in a glass tube between a plug of iron and carbon, with certain adjustments, the arrangement was non-conductive to the current from a single cell but became conductive when electric oscillations passed through it. Hence the following appliance was worked out by Lieutenant Solarj and officers in the Italian navy. The tube provided with certain screw adjustments had a glass bulb, a cell and a telephone placed in series with it, and one end of the tube was connected to the earth and the other end to a receiving antenna. It was then found that when electric waves fell on the antenna a sound was heard in the telephone as each wave train passed over it, so that if the wave trains endured for a longer or shorter time the sound in the telephone was of corresponding duration. In this manner it was possible to hear a flash of light on the horizon in the telephone. This method of receiving soon came to be known as the telephonic method. Lodge, Muirhead and Robinson also devised a self-restoring coherer as follows:—A small steel wheel with a sharp edge was kept revolving by a clockwork so that its edge continually cut through a globule of mercury covered with paraffin oil. The oil film prevented

---

A third class of electric wave detector depends upon the power of electric oscillations to annul the electrolytic polarization of a sensitive cell, and it is a very simple device. A vessel of nitric acid are placed a large platinum plate and a platinum electrode of very small surface such that produced when an electric wave passes through the electrolytic cell so that the fine wire is the anode or positive pole, then the small surface will be polarized or covered with a film of electrolytically dissolved material, which increase the resistance of the electrolytic cell. If, however, one electrode of this cell is connected to the earth and the other remains antenae, then electric waves allowed to fall on the antenna, the oscillations passing through the electric cell will remove the polarization and temporarily decrease the resistance of the cell. This may be detected by putting a telephone in series with the electrolytic cell, and then on the impact of the electric waves a sound is heard in the telephone due to the sudden increase in the current through it. Such receivers were devised by R. A. Fessenden,\(^12\) and it is known as electrolytic detectors.

Discussions have taken place as to the theory of the operations in them, in which some have advocated a thermal explanation and others a chemical explanation. To V. Lessing, Ann. der Phys., 1904, 15, p. 193, and J. E. Ives, Electrical World of New York, December 1904.

A third class of wave detector comprises the thermal detectors which operate in virtue of the fact that electric oscillations create heat in a fine wire through which they pass. One form such a detector takes is the bolometer. If a loop of very fine platinum wire, prepared by the Wollaston process, is included in an exhausted glass bulb like an incandescent lamp, then when electric oscillations are sent through it its resistance is increased. This increase may be made evident by making the loop of wire arm of a Wheatstone bridge and arranging the circuits that the oscillations pass through the fine wire. H. Rubens and Ritter in 1890 (Wied. Ann., 1890, 40, p. 56) employed an arrangement as follows: Four fine platinum or gold wires were joined in lozenge shape, and two of these sets of R and S were connected up with two resistances P and Q to form a bridge with a galvanometer G and battery B. To one of these sets of fine wires an antenna A and earth connexion E is added (fig. 47) and when electric waves fall on A they excite oscillations in the fine wire resistance R and increase the resistance, and so upset the balance of the bridge and cause the galvanometer to deflect. Such a bolometer is known as a resistance bridge. A similar instrument has been used by C. Tisson (Comptes rendus, 1904, 137, p. 846) and others as a receiver in electric wave telegraphy.

Fessenden employed a simple fine loop of Wollaston platinum wire in series with a telephone and shunted voltaic cell, so that when electric oscillations passed through the fine wire its resistance was increased and the current through the telephone suddenly diminished. A. A. Popoff, U.S.A. Pat. Spec., No. 706742 and No. 706744 of 1902. I. Klemencic devised a form of thermal receiver depending on thermo-electricity. A pair of fine wires of platinum and constantan are twisted together in the middle, and one pair of these wires are connected to a galvanometer. If then oscillations are sent through the other pair heat is produced at the junction and the galvanometer indicates a thermo-electric current (Wied. Ann., 1904, 45, p. 75). Another thermo-receiver was made vastly more sensitive by W. Duddell (Phil. Mag., 1904, 8, p. 91). He passed the oscillations to be detected through a fine wire or strip of gold leaf, and over this, but just not touching, suspended a loop of bismuth-antimony wire, and the loop was adapted to move in a very strong magnetic field, and when one junction was heated by radiation and convection from the heating wire the loop was deflected.

teled regularly traversed by a current and detected in the field. Its deflection was observed by an atherometer.

Another form of thermolectric receiver has been devised by J. A. Fleming (Phil. Mag., December 1906) as follows:—It consists of two glass vessels like test tubes one inside the other, the space between the two being exhausted and then filled with four copper strips having platinum wires at their ends sealed through the glass. In the inner space between the test tubes one pair of these platinum wires are connected to a galvanometer, and when electric oscillations are sent through the fine wire they cause a deflection of this galvanometer (fig. 48). The thermal detectors are especially useful for the purpose of giving a very sensitive indication of the number of oscillations passing through the hot wire. On the other hand, the coherer or loose contact detectors are chiefly affected by the initial value of the electromotive force acting on the junction during the train of oscillations, and the magnetic detectors by the initial value; the current. and also to a considerable extent by the number of oscillations during the train. Hence the coherer type of detectors are called integral current detectors, whilst thermal are called integral current detectors, the current detectors depending entirely or to some extent upon the magnitude of oscillations of current, and is to say, upon the number of oscillations forming a train.

The fifth type of wave detector depends upon the peculiar property of rarefied gases or vapours which under some circumstances possess a unidirectional conductivity. Thus J. A. Fleming invented in 1904 a detector which can detect an oscillating current of electricity. The apparatus was as follows: A small carbon filament incandescent lamp has a platinum plate or cylinder placed in it surrounding or close to the filament. This plate is supported by a platinum wire sealed through the glass. Fleming discovered that if the filament is made incandescent by the current from an insulated battery there is a unidirectional conductivity of the rarefied gas between the hot filament and the metal plate, such that if the negative terminal of the filament is connected outside the lamp a current flows through the vacuum space. This phenomenon is connected with the fact that incandescent bodies, especially in rarefied gases, throw off or emit electrons or gaseous negative ions.

The first use of this device was first used by Fleming as a receiver for wireless telegraph purposes in 1904 as follows:—In between the receiving antenna and the earth is placed the primary coil of an oscillation transformer; the secondary circuit of this transformer consists of a galvanometer in series with it, and the two together are joined between the external negative terminal of the carbon filament of the above-described lamp and the insulated platinum plate. When this is the case oscillations set up in the antenna will cause a continuous current to flow through the galvanometer, the lamp acting as a valve to stop all those electric oscillations in one direction and only permit the opposite one to pass (fig. 49). Weinhold discovered that the same effect could be produced by using instead of a carbon filament a platinum wire coated with the oxides of calcium or barium, which when incandescent have the property of copiously emitting negative ions. Another form of the detector depends upon the property of rarefied gases and vapours. A highly insulated tube contains a little mercury, which is used as a negative electrode, and the tube also has sealed through the glass a platinum wire carrying a hot iron plate as an anode. A current conducted from an electric battery is passed through the tube, and can be used to filter off all those oscillations in a train which pass in one direction and make them readable on an ordinary galvanometer. In addition to the above gaseous rectifiers of oscillations it has been found that some crystals, such as carboborundum (carbide of silicon), hessite, anastase and many others possess a unidirectional conductivity and enable us to rectify trains of oscillations into continuous currents which can affect a telephone.

Also several contacts, such as that of galena (sulphide of lead) and plumbago, and molybdenite and copper possess similar powers, and can be used as detectors in radio-telegraphy. See G. W. Pierce, The Physical Review, July 1907, March 1909, on crystal rectifiers for electric oscillations.

**Syntonic Electric Wave Telegraphy.**—If a simple receiving antenna as above described is set up with an oscillation-detecting device attached to it, we find that it responds to incident electric waves of almost any frequency or damping provided that the magnetic force of the wave is perpendicular to the antenna, and of sufficient intensity. This arrangement is called a non-syntonic receiver. On the other hand, if a closed oscillation circuit is constructed having capacity and considerable inductance, then oscillations can be set up in it by very small periodic electromotive forces provided these have a frequency exactly agreeing with that of the condenser circuit. This last circuit has a natural frequency of its own which is numerically measured by $\frac{1}{2\pi}\sqrt{CL}$, where $C$ is the capacity of the condenser and $L$ is the inductance of the circuit. The problem of syntonic electric wave telegraphy is then to construct a transmitter and a receiver of such kind that the receiver will be affected by the waves emitted by the corresponding or syntonic transmitter, but not by waves of any other wavelength or by irregular electric impulses due to atmospheric electricity. It was found that to achieve this result the transmitter must be so constructed as to send out prolonged trains of slightly damped waves. Electric-radiative circuits like thermal radiators are divided into two broad classes, good radiators and bad radiators. The good electric radiators may be compared with good thermal radiators, such as a vessel coated with lamp black on the outside, and the bad electric radiators to poor thermal radiators, such as a silver vessel highly polished on its exterior. When electric oscillations are set up in these two classes of electric radiators, the first class send out a highly damped wave train and the second a feeble damped wave train provided that they have sufficient capacity or energy storage and low resistance. A radiator of this last class can be constructed by connecting inductively or directly an antenna of suitable capacity and inductance to a nearly closed electric circuit consisting of a condenser of large capacity, a spark gap and an inductance of low resistance. When oscillations are excited in this last circuit they communicate to the antenna provided this last circuit is joined or sympathized to the closed circuit, and the radiating antenna has thus a large store of energy to draw upon and can therefore radiate prolonged trains of electric waves. The above statements, though correct as far as they go, are an imperfect account of the nature of the radiation from a coupled antenna, but a mathematical treatment is required for a fuller explanation.

---

wave trains; but, although other patentees have suggested the same plan, the author is not aware that any such success has attended the practice. In Marconi's practice, the principal problem of isolation in connexion with wireless telegraphy stations was given by Anders Bull (Electrician, 1901, 46, p. 573). Very briefly stated, his method consists in sending out syntonized wave trains at certain irregular but assigned intervals of time to constitute the simplest signal equivalent to a dot in the Morse code, and a sequence of such trains, say three following one another, to constitute the dash in that code. The apparatus is very complicated and can only be understood by reference to very detailed diagrams. (See Principles of Electric Wave Telegraphy, by J. A. Fleming, 1906, sect. 13, chap. VIII.) By means of the Anders Bull system several messages can be sent simultaneously from different transmitters and received independently and simultaneously upon corresponding receivers, while no ordinary non-electric or other receiver is able to obscure the messages being sent to the Anders Bull receivers or to interpret those that may be picked up. Although complicated the apparatus seems to work fairly well.

**Practical Electric Wave Telegraphy.**—At this stage it may be convenient to outline the progress of electric wave telegraphy since 1899. Marconi's success in bridging the English Channel at Easter in 1899 with electric waves and establishing practical wireless telegraphy between ships and the shore by this means drew public attention to the value of the new means of communication. Many investigators were thus attracted into this field of research and invention. In Germany A. Slaby and F. Braun were the most active. Slaby paid considerable attention to the study of the phenomena connected with the production of the oscillations in the antenna. He showed that in a simple Marconi antenna the variations of the potential are maximum at the insulated top and a minimum at the base, whereas the present methods of development we find that in 1898 Professor F. Braun showed that oscillations suitable for the purposes of electric wave creation in wireless telegraphy could be set up in a circuit consisting of a Leyden jar or jars, a spark gap and an inductive circuit, and communicated to an antenna either by inductive or direct action. The apparatus is shown in fig. 50. When the methods for effecting this had been worked out practically it finally led to the inventions of Slaby, Braun and others being united into a system called the Telefunken system, which, as regards the transmitter, consisted in forming a closed oscillation circuit comprising a condenser, spark gap and inductance which at one point was attached either directly or through a condenser to the earth or to an equivalent balancing capacity, and at some other point to a suitably tuned antenna. The receiving arrangements comprised also an open or antenna circuit connected directly with a closing out or inductance circuit, but in place of the spark gap in the transmitter an electrolytic receiver was inserted, having in connexion with it as indicator a voltaic cell and telephone. In this manner the signals are read by ear. In the same way the arrangements finally elaborated by Lodge and Muirhead consisted of a direct coupled antenna and nearly closed condenser circuit, and a similar receiving circuit containing as a detector the steel wheel revolving on oily mercury which actuated a siphon recorder writing signals on paper tape. Arrangements not very different in general principle were put into practice in the United States by Possendieck and de Forest and others.

Hence it will be seen that the difference between various forms of the so-called spark systems of wireless telegraphy is not very

---

The success so far achieved in isolating electric wave telegraphic stations has been based upon the principles of electric resonance and the fact that electric oscillations can be set up in a circuit having capacity and considerable inductance by feeble electromagnetic impulses, provided they are of exactly the natural frequency of the said circuit. We may illustrate the matter as follows: A heavy pendulum possesses inertia and the property of being displaced from a position of rest but tending to return to it. These mechanical qualities correspond to inductance and capacity in electric circuits. Such a pendulum can be set in vigorous vibration even by feeble puffs of air directed against it, provided these are administered exactly in time with the natural period of vibration of the pendulum.

Although inventors had more or less clearly grasped these principles they were first embodied in practice in 1900 by G. Marconi in an operative system of syntonic wireless telegraphy. His transmitter consists of a nearly closed oscillating circuit comprising a condenser or battery of Leyden jars, a spark gap, and the primary coil of an oscillation transformer consisting of one turn of thick wire wound on a wooden frame. Over this primary is wound a secondary circuit of five to ten turns which has one end connected to the earth through a variable inductance coil and the other end to an antenna. The two circuits are sympathized so that the closed or condenser circuit and the open or antenna circuit are adjusted to have, when separate, the same natural electrical time of vibration. The receiving arrangement consists of an antenna which is connected to earth through the primary coil of an oscillation transformer and a variable inductance. The secondary circuit of this transformer is cut in the middle and has a condenser inserted in it, and its ends are connected to the sensitive metallic filaments of a coherer as shown in fig. 50. This receiver therefore, like the transmitter, consists of an open and a closed electric oscillation circuit inductively connected together; also the two circuits of the receiver must be sympathized or tuned both to each other and to those of the transmitter. When this is done we have a syntonic system which is not easily affected by electric waves of other than the right period or approximating thereto. Marconi exhibited in October 1900 this apparatus in action, and showed that two or more receivers of different tunings could be connected to the same antenna and made to respond separately and simultaneously to the action of separate but tuned transmitters. A. Slaby in Berlin shortly afterwards made a similar exhibition of syntonic electric wave telegraphy. O. Lodge had previously described in 1897 a syntonic system of electric wave telegraphy, but it had not been publicly seen in operation prior to the exhibitions of Marconi and Slaby. Lodge was, however, fully aware that it was necessary for syntonic telegraphy to provide a radiator capable of emitting sustained trains of waves. His proposed radiator and absorber consisted of two wing-shaped plates of copper, the transmitter plates being interrupted in the centre by a spark gap, and the receiver plates by an inductive coil from the ends of which connections were made to a coherer. At a later date a syntonic system comprising, as above stated, an antenna directly coupled to a resonant closed condenser, was put into operation by Lodge and Muirhead, and much the same methods have been followed in the system known as the Telefunken system employed in Germany.

A method of telegraphic telephony proposed by A. Blondel (Comptes rendus, 1900, 130, p. 1383) consisted in creating a syntonized gap between the frequency of the oscillations in the sender and receiver circuits but between the groups of oscillations constituting the
TELEGRAPH

great. All of them make use of Marconi’s antenna in some form both at the transmitting and receiving ends and make use of an earth connexion, or its equivalent in the form of a balancing capacity or large surface having capacity with respect to the earth, which merely means that they insert a condenser of large capacity in the same way as they couple the transmitting antenna directly or inductively to a capacity-inductive circuit serving as a storage of energy, and all of them create thereby electromagnetic oscillations of the same type moving over the earth’s surface with the magnetic force of the wave parallel to it. At the receiving station the differences in these systems depend chiefly upon variation in the actual form of the oscillation detector used, whether it be a loose contact or a thermal, electrolytic or magnetic detector.

In July and August 1899 the Marconi system of wireless telegraphy was tried for the first time during British naval manœuvres, and the two cruisers, “Junio” and “Europe,” were fitted with the new means of communication. The important results obtained showed that a weapon of great power had been provided for assisting naval warfare. From and after that time the British Admiralty and the navies of other countries began to give great attention to the development of electric wave telegraphy.

Transatlantic Wireless Telegraphy.—Having found that the principles of resonance could be successfully applied so as to isolate wireless telegraph receivers, Marconi turned his attention to the accomplishment of his great ambition, viz. Transatlantic wireless telegraphy, which he was able to immediately increase the speed of transmission without difficulty by electric waves from the Isle of Wight to the Lizard, viz. 200 m., and he considered that the time had come for a serious attempt to be made to communicate across the Atlantic. A site for a first Transatlantic electric wave power station was secured at Poldhu, near Mullion in south Cornwall, by the Marconi Company, and plans arranged for an installation. Up to that time an induction coil known as a 10-inch coil had sufficed for spark production, but it was evident that much more power would be required to send electric waves across the Atlan-tic. At St. John’s in Newfoundland he erected a temporary transmitting electrode and a condenser, and at Cape Breton these high tension transmitters were used to charge condensers and set up powerful oscillations in a multiple antenna. The special electrical engineering arrangements employed at the outset for this first electric wave power station required to create the oscillations of the desired power were designed for Marconi by J. A. Fleming, but the arrangements were subsequently altered and improved by Marconi, one of the most important additions being a form of high-speed rotating disk discharger devised by Marconi, which he was able to immediately increase the speed of transmission. The first antenna employed consisted of 50 bare copper wires 200 ft. long, arranged in fan-shape and upheld between two masts. Subsequently this antenna was enlarged, and four wooden lattice towers were built, 215 ft. high and 200 ft. apart, sustaining a conical antenna comprised of 400 wires (see G. Marconi, Proc. Roy. Inst., 1902, 17, p. 208). This transmitting plant was completed in December 1901, and Marconi then crossed the Atlantic to Newfoundland and began to make experiments to ascertain if he could detect the waves emitted by it. At St. John’s in Newfoundland he erected a temporary receiving antenna consisting of a wire 400 ft. long upheld by a box kite, and, employing a sensitive coherer and telephone as a receiver, he was able, on December 12, 1901, to hear “S” signals on the Morse code, consisting of three dots, which he had arranged should be sent out from Poldhu at stated hours, according to a preconcerted programme, so as to leave no doubt they were electric wave signals sent across the Atlantic and not accidental atmospheric electric disturbances. This result created a great sensation, and proved that Transatlantic electric telegraphy was quite feasible and not inhibited by distance, or by the earth’s curvature, even over a very great circle 3000 m. in length. In a repetition of this experiment at the end of February 1902 Marconi, on board the s.s. “Philadelphia,” received wireless messages printed on the ordinary Morse tape at a distance of 1557 m. from the sending station at Poldhu, and also received the letter “S” at a distance of 2009 m. from the same place. In the course of this voyage he noticed that the signals were received better during the night than the daytime, legible messages being received on a Morse printer only 700 m. by day but 1500 by night.

The appliances in the Poldhu station were subsequently enlarged and improved by Marconi, and corresponding power stations erected at Cape Cod, Massachusetts, U.S.A., and at Cape Breton in Nova Scotia. In 1902 Marconi was able to transmit a large number of messages across the Atlantic, receiving them by means of his magnetic detector. In the same year numerous experiments were tried with the assistance of an Italian battleship, the “Carlo Alberto,” lent by the Italian government, and messages were transmitted from Poldhu to Kronstadt, to Spezia, and also to Sydney in Nova Scotia. In 1903 having been raised whether the powerful electric waves sent out from these stations would not interfere with the ordinary ship to shore communication, special demonstrations were made by Marconi before the writer, and later before British naval officers, to demonstrate that this was not the case. In 1904 a regular system of communication of press news and private messages from the Poldhu and Cape Breton stations to Atlantic liners in mid-Atlantic was inaugurated, and daily newspapers were thenceforth printed on board these vessels, news being supplied to them daily by electric wave telegraphy. By the middle of 1905 a very large number of vessels had been equipped with the Marconi short distance and long distance wireless telegraph apparatus for intercommunication and reception of messages from power stations on both sides of the Atlantic, and the chief navies of the world had adopted the apparatus. In 1904, during the Russo-Japanese war, war news was transmitted for The Times by wireless telegraphy, the enormous importance of which in naval strategy was abundantly demonstrated.

As the power station at Poldhu was then fully occupied with the transmission of a substantial number of messages, and the Marconi Company began to erect another large power station to Marconi’s designs, at Clifden in Connemara on the west coast of Ireland. This station was intended for the Transatlantic service in correspondence with a similar station at Glace Bay in Nova Scotia. It was completed in the summer of 1907, and on the 17th of October 1907 press messages and private messages were sent across the Atlantic in both directions. The station was opened shortly afterwards for public service, on the rates being greatly below that then current for the cable service.

The service was, however, interrupted in August 1909 by a fire, which destroyed part of the Glace Bay station, but was re-established in April 1910.

Meanwhile other competitors were not idle. The inventions of Slaby, Braun and others were put into practice by a German wireless telegraph company, and very much work done in erecting land stations and equipping ships. In France the scientific study of the subject was advanced by the work of Blondel, Tissot, Ducretet and others, and systems called wireless telegraphy were put into operation. In the United States the most active workers and patentees at this period were R. A. Fessenden, Lee de Forest, J. S. Stone, H. Shoemaker and a few others. In England, in addition to the Marconi Company, the Lodge-Muirhead Syndicate was formed to operate the inventions of Sir Oliver Lodge and Dr Muirhead.

Directive Telegraphy.—A problem of great importance in connexion with electric wave telegraphy is that of limiting the radiation to certain directions. A vertical transmitting antenna sends out its waves equally in all directions, and these can be equally detected by a suitable syphon or other receiver at all points on the circumference of a circle described round the transmitter. This, however, is a disadvantage. What is required is some means for localizing and directing a beam of radiation. The first attempts involved the use of mirrors. Hertz had shown that the electric radiation from an oscillator

could be reflected and converged by cylindrical parabolic mirrors. He operated with electric waves two or three feet in wave-length. Experiments precisely analogous to optical ones can be performed with somewhat shorter waves. Marconi in his first British patent (No. 12059 of 1896) brought forward the idea of focusing a beam of diverging electric waves by parabolic mirrors on a distant station by means of parabolic mirrors, and tried this method successfully on Salisbury Plain up to a distance of about a couple of miles. As, however, the wave-length necessary to cover any considerable distance must be at least 200 or 300 ft., it becomes impracticable to employ mirrors for reflection. The process of reflection in the case of a wave motion involves the condition that the wave-length shall be small compared with the dimensions of the mirror, and hence the attempt to reflect and converge electric waves 1000 ft. in length by any mirrors which can be practically constructed would be like attempting optical experiments with mirrors one-hundred-thousandth of an inch in diameter.

Another closely connected problem is that of locating or ascertaining the direction of the sending station. To deal with the latter question first, one of the earliest suggestions was that of J. S. Stone (U.S.A. Pat. Spec., Nos. 716134 and 716135, also reissue No. 12148), who proposed to place two receiving antennae at a distance of half a wave-length apart. If these were widely on to the direction of the sending station on the shorter side, phase would be produced in the wave, but if they were in line with it then the oscillations would be in opposite phases. It was then proposed to arrange a detector so that it was affected by the algebraic sum of the two oscillations, and by swivelling round the double receiving antennae to locate the direction of the sending station by finding out where the detector gave the best signal. Even if the proposal had been practicable with waves 1000 or 2000 ft. in length, which it is not, it is essentially based upon the supposition that the damping of the waves is negligible. A proposal was made by L. Poulsen (Eng. Pat. Spec., No. 771858) to employ a receiving antenna consisting of vertical wires held in a frame which could be swivelled round into various positions and used to locate the position of the sending station by ascertaining the position in which the frame must be placed to create in it the maximum oscillatory current. Other inventors had professed to find a solution of the problem by the use of looped receiving antennae or antennae inclined in various directions.

G. Marconi, however, gave in 1906 the first really practical solution of the problem by the use of bent transmitting and receiving antennae. He showed that if an antenna was constructed with a short part of its length vertical and the greater part horizontal, or if the lower end of the vertical part be earthed, and if oscillations were created in it, electric waves were sent out most powerfully in the plane of the antenna, or in any direction other than that of a perpendicular to the free end pointed. Also he showed that if such an antenna had its horizontal part swivelled round into various directions the current created in a distant receiver antenna varied with the azimuth, and when plotted out in the form of a polar curve gave a curve of a peculiar figure-of-8 shape. The mathematical theory of this antenna was given by J. A. Fleming (Proc. Roy. Soc., May 1906, also Phil. Mag., December 1906). Marconi also showed that if such a bent receiving antenna was used the greatest oscillations were created in it when its insulated end pointed directly away from the sending station. In this manner he was able to provide means for locating inaccessible sending stations. F. Braun gave an interesting solution of the problem of directive telegraphy. In his method three vertical antennae are employed, placed at equal distances, and oscillations are created in the three with a certain relative difference of phase. The radiations interfere in an optical sense of the word, and in some directions reinforce each other and in other directions neutralize each other, so making the resultant very small in some directions than others. Very valuable work in devising forms of apparatus and directive telegraphy has been done by MM. Bellini and Tochi, who have devised instruments, called radioinometers, for projecting radiation in required directions and locating the azimuth of a transmitting station.

**Improvements in the Production of Continuous Trains of Electric Waves.**—All the above-described apparatus employed in connexion with wireless telegraph transmitters, in which the oscillatory discharge of a condenser is used to create oscillations in an antenna, labours under the disadvantage that the time occupied by the oscillations is a very small fraction of the total time of actuation. Thus, for instance, when using an induction line, an induction line is not sufficiently formed for a long-time current; it is not generally convenient to make more than 50 discharges from a condenser, and each of these may create a train of oscillations consisting of, say, 20 to 50 waves. Supposing, then, that these waves are 1000 ft. in wave-length, the frequency of the oscillations would be 1,000,000 per second, and accordingly 50 of these waves would be emitted in 1/20,000th part of a second; and if there are 50 groups of waves per second, the total time occupied by the oscillations in a second would only be 1/400th part of a second. In other words, the intervals of silence are nearly 400 times as long as the intervals of activity. It very soon, therefore, becomes clear to inventors that a very great advantage would be gained if some means could be discovered of creating high frequency oscillations which were not intermittent but continuous. The condenser method of making oscillations is analogous to the production of air vibrations by twanging a harp string at short intervals. What is required, however, is something analogous to an organ pipe which produces a continuous sound.

A method of producing these oscillations devised by Valdemar Poulsen is based upon the employment of what is called a musical or telephone arc. In a telephone arc, Poulsen, it is said, had the carbon arc had its carbon electrodes connected by a condenser in series with an inductance, then under certain conditions oscillations were excited in this condenser circuit which appeared to be continuous and unaffected by the Maxwellian term. Poulsen proved that the carbon arc is in an atmosphere of hydrogen, coal-gas or some other non-oxidizing gas, and at the same time arranging it in a strong magnetic field in such a way that he was able to produce an apparatus which created continuous trains of oscillations suitable for the purposes of wireless telegraphy. The so-called musical arc of Duddell has been the subject of considerable investigation, and physicists are agreed that in the telephone arc the vibrations of the oscillations of production of the oscillations. It appears, however, to depend upon the fact that an electric arc is not like a solid conductor. Increase in the voltage acting upon a solid conductor increases the current through it, but in the case of the electric arc an increase in current is accompanied by a fall in the difference of potential of the carbons, within certain limits, and the arc has therefore been said to possess a negative resistance.

Poulsen's method of producing continuous or undamped electrical waves has been applied by him in radio-telegraphy. The electric arc is formed between cooled copper (positive) and carbon (negative) electrodes in an atmosphere of hydrogen or coal-gas. In recent apparatus, to enable it to be used on board ship, a hydrogenous spirit is used which is fed drop by drop into the chamber in which the arc is worked. Across the arc is a transverse or radial magnetic field, which produces a bending of the electric lines of force, consisting of a condenser and inductance. The antenna is connected either directly or indirectly with the circuit. At the receiving end are a similar antenna and resonant circuit, and a telephone is connected across one part of the latter through an automatic interrupting device called by Poulsen a "ticker." To send signals the continuous or nearly continuous train of waves must be cut up into Morse signals by a key, and these are then heard as audible signals in the telephone. An important modification of this method enables not only audible signals but articulated words to be transmitted, and gives thus a system of wireless telephony.

at the same time it has taken a position of the greatest importance in connexion with naval strategy and communication between ships and ships and the shore in time of peace. It is now generally recognized that Hertzian wave telegraphy, or radio-telegraphy, as it is sometimes called, has a special field of operations of its own, and that the anticipations which were at one time entertained of its great impact on the world. It would specifically annihilate all telegraphy conducted with wires which have been dispersed by experience. Nevertheless, transoceanic wireless telegraphy over long distances, such as those across the Atlantic and Pacific oceans, is a matter to be reckoned with in the future, but it remains to be seen whether the present means are sufficient to render possible communication to the antipodes. The fact that it has become necessary to introduce regulations for its control by national legislation and international conferences in the supremely important position which it has taken in the short interval of one decade as a means of communicating human intelligence from place to place over the surface of the globe. An important International Conference on radiotelegraphy was held in Berlin in 1906, and as a result of its deliberations international regulations have been adopted by the chief Powers of the world. The decisions of the Conference were ratified for Great Britain by the British government on July 1, 1908.

TELEMACHUS, in Greek legend (Odyssey i.–iv., xv.–xxiv.), Hyginus, Fab. 127), son of Odysseus and Penelope. When he reached manhood, he visited Pylos and Sparta to make inquiries about his father, who had been absent for nearly twenty years. On his return, he found that Odysseus had reached home before him. Then father and son, aided by Eumaeus and Philoetius, slew or drove out the suitors of Penelope (see Odyssey). According to later tradition, Telemachus became the husband of Circe and by her the father of Latinus and of a daughter Roma, afterwards the wife of Aeaeus. In another story, he married a daughter of Circe, named Cassipheon; having slain his mother-in-law in a quarrel, he was himself killed by his wife. This is the only notice of the death of Telemachus. The foundation of Clusium in Etruria was attributed to him.

TELEMARK, or THELEMARK, a district of southern Norway, wholly comprised in the amt (county) of Bratsberg. It covers the lake-brands and the small mountains of the country, having its highest point in the Gaustafjel (2600 ft.), and contains several large and beautiful lakes, as Nordsfjø, Bandaksvand, Tinsjø, Mjøsvand, and Toksvåg. The two
first are connected by the Bandaks canal, a fine engineering work giving access from the port of Skien to Dalen at the head of Bandaksvand. From Dalen, which may be reached by road from the railway at Kongberg (58 miles) a driving road much frequented by travellers winds north-west. It traverses a precipitous wooded gorge, its course in parts hewn out of the rock, and skirts the Bøtte and Grungedal lakes, follows the Flaathyl river, passes the Vafos and Little Rjukanfos (waterfalls), and Lake Voxtli, and culminates at Haukellidsaeter, a station grandly situated among the fields at a height of 3085 ft. It rises to the watershed (3715 ft.) and then, leaving the district, descends abruptly with a remarkable winding course to Røldal (58 miles from Dalen), and soon divides, one branch surmounting the Horrebrækleike pass and continuing to Odde, the other traversing the beautiful Bratlandsdal. On the Kongberg-Dalen road is Hitterdal, with a good specimen of the Stavekirke or medieval timber-built church. A divergence from this route may be made by way of Tinsjø to Fosso, where the Maan river forms a fine fall (Rjukanfos) of 415 ft.

**TELEOLOGY** (Gr. τέλος, end), in philosophy and theology, strictly that branch of study which considers "final causes" as real principles of explanation, i.e. which explains things as existing solely as pre-requisites of the results which they produce. More commonly the term is applied to the doctrine that everything, even the whole being has been planned on a definite design, or at least that it tends towards some end. The term has been used very loosely, and its meaning has changed considerably. The root idea arises from the analogy of the acts of human beings which are observed to have certain purposes: hence it was natural to assume that the whole sum of existence with its amazing complexity and its orderly progress can be explained only on the assumption of a similar plan devised by a conscious agent. Such a view is essential to any theistic view of the universe which postulates God as the Creator, omniscient and all-good. The modern theory of evolution, on the other hand, has reintroduced a scientific teleology, another type. This is discussed, from the biologist's point of view, in the article ZOOLOGY. Teleology, in this narrower sense, as the study of the adaptation of organic structures to the service of the organisms in which they occur, was completely revolutionized by Darwinism and the research founded on it.

**TELEOSTOMES**, members of the third sub-class of the class Fishes, being all the fishes in which the skull is invested with membrane bones, viz., the Crossopterygians, the Dipnoans, the Ganoids, and the Teleostomes. They may be further defined as fishes with an ossified or cartilaginous skull, there is much in any one jaw, gills inserted on the gill-arches, a single gill-opening on one side (exceptionally fused with its fellow on the ventral side), an opercle formed of one or several bones, the body usually covered with scales or bony plates, an air-bladder or lung, at least in the primitive forms, and without copulatory paired organs or "claspers."

The term which designates this sub-class has been adopted by Sir R. Owen, E. D. Cope, and E. Woodward in a less comprehensive sense, the Dipneusti being regarded by them as constituting a separate sub-class, and its inventor, C. L. Bonaparte (1838) had proposed it in a more restricted sense. The sturgeons, lophobanchias and plectognaths being excluded. T. Gill (1872) was the first to use it in the acceptation taken in the present article. Whether the Ostracophores should be included among the Teleostomes, as recently proposed by C. T. Regan, is still open to doubt. The sub-class is here divided into four orders, but it is difficult to decide whether, in an ascending series, the Crossopterygians or the Ganoids should be placed first. From the point of view of the evolution of the paired fins, accepting the lateral fin-fold theory as the better supported by the evidence, it is much to say in favour of regarding the Chondrosteans the Ganoids as the more primitive form. From another point of view the condition of the air-bladder in the existing Crossopterygians appears to represent the earliest form assumed by this important organ, which it seems rational to conclude was originally evolved as an accessory breathing organ and later became transformed into a hydrostatic apparatus (Ganoids and Teleostomes) on the one hand, into a true lung (Dipnoans and Batrachians) on the other. Guided by the second consideration, assuming that the air-bladder of the fossil Crossopterygians corresponded to the type known in their recent representatives, and also in deference to palaeontological chronology, whatever it be worth in the present state of our knowledge, we shall begin the series with the Crossopterygians, which pass into the Dipnoans, and then take up the Ganoids, which lead up very gradually to the Teleostees, the dominant group at the present day. But we do not deny the force of the arguments adduced by Regan in attempting to show that the paired fins of the Chondrosteans Ganoids are a nearer approach to the primitive condition than are those of the Teleostees. Not until some day we shall become acquainted with still older Teleostomes, which we may expect to establish the connexion between the two types which in Palaeozoic times have evolved on parallel lines.

**Order I.—CROSSOPTERYGII**

Paired fins, at least the pectoral, lobate, having an endo-skeletal armature, less fingers with dermal rays. Mandibular arch suspended from the upper segment of the hyoid arch (hyostylid skull), Splenial bone present. No supraopercular bone. A pair of large jugular plates, sometimes with small lateral plates and an opercle of a separate type. No or few gills. Cartilaginous membrane between the mandibular rami. Heart with a contractile, multivalvular comus arteriosus; intestine with a spiral valve; air-bladder with pneumatic duct communicating with the ventral side of the gills. Absence of the mouth.

Maxillary bone large, toothed, bordering the mouth. Bones of the upper surface of the skull mostly paired. Pectoral arch with both clavicle (so-called infra-clavicle) and clavithrum. Ventral fins inserted far back. With few exceptions (family of Coelacanthidae, dorsal and caudal fins of Polypterusidae) the dermal rays of the unpaired fins more numerous than their endo-skeletal supports, a primitive character also found in the lower Ganoids, but disappearing in the higher.

**Suborder I.—OSTEOLEPIDA**

(Including the Haplistia, Rhipidistia and Actinistia.) Pectoral fins obtusely or acutely lobate, articulating with the pectoral girdle by a single basal endo-skeletal element. Nostrils on the lower side of the snout. Two dorsal fins.

**Families:** Osteolepidae, Rhizodontidae, Holoptyridae, Coelacanthidae.

The scales may be rhombic and thickly coated with ganoine (Osteolepidae) or cycloid. The vertebral axis is strongly heteroceratal in the Osteolepidae. The arch is intermediate between the heteroceratal and the diphyceratal types in the other families; usually acerate, sometimes with ring-like rays (family of Rhizodontidae). In the Holoptyridae the pectoral fin is extremely similar to that of the Dipneusti of the family Dipteridae, which they resemble closely in form and scaling. Their teeth are remarkable for their complicated structure, resembling those of the Lower Carboniferous. The Lower Carboniferous and Permian era for the most part belong to the family Dipteridae. The Osteolepidae were mostly moderate-sized fishes, the largest (Megalechis) measuring about 4 ft. in length.

These Crossopterygians first appear in the Lower Devonian, are abundant in the Upper Devonian, Carboniferous and Permian; in later periods they are represented only by the more specialized Coelacanthidae, which appear in the Lower Carboniferous, and persist as late as the Upper Chalk.

**Suborder II.—CLADISTIA**

A single family: Polypterusidae.

The existing Crossopterygians which form this sub-order differ very considerably from the extinct Osteolepida, perhaps quite as much as these differ from the Dipneusti. The ventral fins are not lobate, the vertebral column is well ossified and its termination is of the diphyceratal type. Spiracles, covered by bony valves, are present at the upper branch of the gill-opening. The dorsal fin is among fishes, being formed of detached rays consisting of a spine-like fulcrum scale supporting the fringes of the ray; these rays have been regarded, erroneously, as representing so many distinct fins, or "fles." The scales are bony, rhombic and thickly coated with ganoine.

The Polypterusidae are confined to tropical Africa and the Nile, and represented by two genera: Polypterus and Calamichthys, the former moderately elongate and provided with ventral fins, the
latter serpentine form and devoid of ventrals. We now know ten species of Polystomus, from the Nile, Congo, the rivers of South Africa, and the Suckshel of Calico mishtis, which inhabits West Africa from the Niger delta to the Chiloango. The largest species of Polystomus reach a length of nearly 10 feet. The eyes are large, lacks a supraneurary, and the gill very similar to the gills of larval salmonids. The air-bladder acts as an accessory breathing organ, although these fishes are not known ever to leave the water. The development is stated by the late Mr. D. G. C. Haeckel, as occurring without a larval stage. Both eggs of Dipnoii, but the results of the study of the material collected by him shortly before his death have not yet been published.

ORDER II.—DINPEUSTI

Often called Dipnii, a term proposed for this order by J. Müller in 1845, but which had already been used for the Batraciihns (P. Leuckart, 1821) before the discovery of Lepidodes. The substitute Dinpeusti (E. Haeckel, 1866) is, therefore, preferable. Paired fins lobate, or reduced to a jointed endo-skeletal axis. Upper segment of the mandibular arch confluent with the skull (autostylic skull). Praemaxillary and maxillary bones absent, dentary absent or small and toothless; teeth on the palato- or ganoid bones, sometimes also on the vomers. No supraocipital bone. Heart trilocular, with a contractile, multivalvar conus arteriosus; intestine with a spiral valve; air-bladder transformed into a single or double lung, opening at the glottis opening of the gill caverns. The cranial roof-bones include median as well as paired plates, which cannot easily be homologized with those of other Teleostomi. These plates, in general, are small and, and, coated with ganoine, appear on the surface of the head, whilst in the later forms they are reduced in number as well as in the degree of ossification, and have sunk below the skin. Pectoral and pelvic fins are absent, except for an elongate pelvic bone. Vertebrae acrocentric. Dermal rays of vertical fins much more numerous than their supports, which correspond in number to the neural and haemal spines. The lower side of the mouth is armed with the pectoral within the mouth. Scales cycloid (almost quadratic in Segensodus, a genus of Ceratodontidae).

Families: Dipnteridae, Ctenodontoideae, Uronemidae, Ceratodontoideae.

The Dipnii are heterocercal and have two dorsal fins, as in the Crossopterygian Holopscidae; in the other families the dorsal fin is elongate and single, and extends to the extremity of the tail, which is heterocercal or barbourian; these features, which are entirely Palaeozoic, ranging from the Devonian to the Permian, the dental plates nearly always exhibit more or less clearly the points of the separate denticles of which, as shown by the development of Neoceratodus, they were originally composed, but vormerine teeth, such as exist in the Ceratodontoideae and Dipnii, do not appear to have existed. The Dipnii have a gill-bar, without well-defined gill compartments, which has become much reduced or disappeared entirely in the other members of this order. The two first families had well-developed gular plates.

In the Ceratodontoideae, which first appeared in the Trias and have persisted to the present day, the skull is more feebly ossified than in the earlier forms, and this may well be looked upon as a degeneration, since the horny plates in Trias species, such as Trias ichthyops, which is entirely Palaeozoic, ranging from the Devonian to the Permian, the dental plates nearly always exhibit more or less clearly the points of the separate denticles of which, as shown by the development of Neoceratodus, they were originally composed, but vormerine teeth, such as exist in the Ceratodontoideae and Dipnii, do not appear to have existed. The Dipnii have a gill-bar, without well-defined gill compartments, which has become much reduced or disappeared entirely in the other members of this order. The two first families had well-developed gular plates.

In the Ceratodontoideae, which first appeared in the Trias and have persisted to the present day, the skull is more feebly ossified than in the earlier forms, and this may well be looked upon as a degeneration, since the horny plates in Trias species, such as Trias ichthyops, which is entirely Palaeozoic, ranging from the Devonian to the Permian, the dental plates nearly always exhibit more or less clearly the points of the separate denticles of which, as shown by the development of Neoceratodus, they were originally composed, but vormerine teeth, such as exist in the Ceratodontoideae and Dipnii, do not appear to have existed. The Dipnii have a gill-bar, without well-defined gill compartments, which has become much reduced or disappeared entirely in the other members of this order. The two first families had well-developed gular plates.

The Ceratodontoideae, the body is much or less celled, the scales are thinner, the paired fins are reduced to slender styleform appendages, sometimes with a small tuft of cartilaginous rays bearing fine dermal rays, and the lung is paired. The development is even more Batrachian-like than that of Neoceratodus, and the length of the hind limb. The lung is absent, but the eggs are deposited in nests in the water and the male keeps guard over the eggs and young. The food is both animal and vegetable. As a rule, as a tuberculate bone, the teeth of Dipnoi burrows in the mud of drying marshes and, surrounded by a cocoon formed of hardened mucus secreted by glands of the skin, it spends weeks or months in a dormant condition, breathing air, until by its body burrowing out of its shell the contents of the cocoon have been often been brought over to Europe, and when soaked in water, the Protopterus is released in a most lively condition. Three species of Protopterus are known from different parts of Africa. One species being P. ammodytes, an inhabitant of West Africa, from the Senegal to the Niger, and Lake Chad. Of Lepidosiren only one species is known, L. paradoxa, living in the Amazon and Paragua bay.

Great uncertainty, and much difference of opinion among palaeichthyologists, still prevail as to the position in the system of a group of Devonian fishes, of which Coccosteus and Dinichthys are the best-known. L. Spence (1819) placed them with the Coccosteidae, but Woodward (1848) under the name of Placoderms; they were removed from their vicinity by the Woodwardian improve his paper, and Woodwardianed them to a group which he proposed to call Archordia. This view was based mainly on the assumption that the skull was autostylous and that maxillary bones were not developed, and also on the resemblance, previously noticed by T. H. Huxley and others, between the dermal mechanism of the Archordia as something quite different from the jaws and teeth of other vertebrates, and revert to the view of E. C. McCoy in placing the Archordia in a group Placodermata, which inserted Archordia as a co-ordinate in rank with such divisions as Cyromystom and Piscidae.

In the present state of our knowledge it is perhaps best to leave the Archordia with or near the Dipnoi. They are thus defined by Woodward:—"Fishes with both head and trunk armoured, in the more specialized genera the shield of the abdominal region articulating with the head-guard in ginglymoid facettes (Gr. ginglymos, a hinge) which admit of free motion, and even regard the dental mechanism of the Archordia as something quite different from the jaws and teeth of other vertebrates, and revert to the view of E. C. McCoy in placing the Archordia in a group Placodermata, which inserted Archordia as a co-ordinate in rank with such divisions as Cyromystom and Piscidae."

Some of the species of Dinichthys reached a great size, the head sometimes measuring a metre across.

ORDER III.—GANOIDI

Paired fins not lobate. Mandibular arch suspended from the upper segment of the hyoid arch (hyoscylic skull). Splenial bone present. No supraocipital bone. Unpaired fins often with fulcra. Heart with a contractile, multivalvar conus arteriosus; intestine with a spiral valve; air-bladder with pneumatic duct commencing with the dorsal side of the oesophagus.

ORDER II CHONDROSTEI

Pectoral arch with both clavicle and cleithrum. Vertical fins inserted for back support, hence developed endo-skeletal rays (baselets); dermal rays of the dorsal and anal fins more numerous than their endo-skeletal supports. Heterocercal. Vertebrae acrocentric. Most species have a barbamentum, and the system is divided as follows.

Families: Palaeoniscidae, Plagocentridae, Cetorhynchinae, Belonocentridae, Polyodontidae, Acipenseridae.

In the three first families (Devonian to Jurassic), the mouth is toothed, pectoral maxillary bones are present, and the maxillaries are large, the border of the submaxillary lobe is solid, the sub-maxillaries are present, and the body is covered with rhamphoid, typically ganoid bony scales. In the fourth family (Trias to Liassic), the snout is much elongate, and longitudinal series of scutes extend along the back, and the anterior of the vertebrae is developed posteriorly. In the fifth family (Jurassic to Recent), the sub-maxillaries are absent, but the maxillary bone was well developed, though small; the membrane bones of the skull were paired;
branchiostegal rays were present; scales were absent, except on the ventral side.

In the modern Polyodontidae and Acipenseridae, whose first representatives appear in the Eocene, praemaxillaries are absent and the mouth is edentulous (Acipenseridae) or beset with minute teeth (Polyodontidae), the membrane bones of the skull are more irregular and comprise azYGous elements, branchiostegal rays are absent, and the body is naked or covered with small ossifications and longitudinal series of bony scutes, whilst the caudal fin is scaled exactly as in the Palaeoniscidae. Barbed are absent in the Polyodontidae.

In the Polyodontidae, represented by one species, the paddle-fish (Polyodon spathula), the membrane bones of the skull are much more irregular and comprise azYGous elements, branchiostegal rays are absent, and the body is naked or covered with small ossifications and longitudinal series of bony scutes, whilst the caudal fin is scaled exactly as in the Palaeoniscidae. Barbed are absent in the Polyodontidae.

In the Polyodontidae, represented by one species, the paddle-fish (Polyodon spathula), the membrane bones of the skull are much more irregular and comprise azYGous elements, branchiostegal rays are absent, and the body is naked or covered with small ossifications and longitudinal series of bony scutes, whilst the caudal fin is scaled exactly as in the Palaeoniscidae. Barbed are absent in the Polyodontidae.

Barbed are absent in the Polyodontidae.
TELEOSTOMES

America. The Galaxiidae are mostly fresh-water fishes and have a wide distribution in the southern hemisphere (southern parts of South America, New Zealand, South Australia and Tasmania, Cape of Good Hope) and species identical in South America, the Falkland Islands, New Zealand and Tasmania. Their distribution has been regarded as affording support to the theory of an Antarctic continent in Tertiary times. However, the species spend part of their life, and even breed, in the sea, whilst others may be regarded as having become recently adapted to fresh water, so that the argument derived from their range is not so clear. The only true freshwater fishes are the Clariidae, which are exclusively fresh-water fishes. The Cyprinodontidae are partly brackish, partly fresh-water fishes, whilst the Scopelidae, which are traced back to the Chalk, are all marine, many being inhabitants of great depths.

SUB-ORDER VI.—HETEROMI

Air-bladder without duct. Opercle well developed, pectoral bones separating the frontals from the supraopercular. Pectoral arch suspended from the supraopercular or the epiotic, the post-temporal small and simple or replaced by a ligament; no mesocoracid bone. Ventral fins abdominal, if present.

Families: Dercetidae, Halosaridae, Lipogeniidae, Notacanthidae, Fierasferidae.

Closely related to the Plagiopriidae, but separated chiefly on account of the close air-bladder. Mostly deep-sea fishes, some of which appear as early as the Cretaceous period. The genus Fierasfer comprises small degraded fishes commensal of Holothurians and bivalve molluscs.

SUB-ORDER VII.—SELENICHYES

Air-bladder without duct. Opercle well developed. Pectoral arch solidly attached to the skull; no mesocoracid bone. Fins without spines. Ventral fins abdominal, with very numerous (15 to 17) rays.

A very aberrant type, of uncertain affinities. Its only representative is the opah, Lampris lupus, a large pelagic fish of wide distribution.

SUB-ORDER VIII.—THORACOSTEI

Embracing the Hemibranchii and Lophobranchii, but excluding the Hypostomoides (Pegasidae), which investigates the F. E. Jungersen show to be aberrant tail-checked Acanthopterygians.

Air-bladder without duct. Pectoral arch suspended from the skull; no mesocoracid bone. Ventral fins abdominal, if present. Branchial arches more or less reduced.

Families: Gastrosteidae, Aulorhynchidae, Protosyngnathidae, Aulosomata, Symmoriidae, Synagathidae. The two latter families constitute the division Lophobranchii, in which the gill-laneces are enlarged and form rounded lobes.

See articles SEA-HORSE, STICKLEBACK, and PIPE-FISHES.

SUB-ORDER IX.—PERSECOSES

Air-bladder, if present, without duct. Pectoral bones separated by the supraopercular, prootic and exoccipital separated by the enlarged opisthopterygian. Pectoral arch suspended from the skull; no mesocoracid bone. Ventral fins, if present, abdominal, or at least with the pelvic bones not solidly attached to the clavicular arch.

Families: Scombresocidae, Ammodytidae, Atherinidae, Mugilidae, Polynemidae, Chiasmodontidae, Sphyraenidae, Tetraonuridae, Stromateidae, Icosteididae, Ophichthidae, Anabantidae.

This series of families connects the Hoplopterygii with the Acanthop- erygi. The Percenees are mostly marine, but the last two families are exclusively fresh-water. Some are inhabitants of great depths, others are pelagic, like the flying-fish (Exocoetus).

SUB-ORDER X.—ANACANTHINI

Air-bladder without duct. Pectoral bones separated by the supraopercular; prootic and exoccipital separated by the enlarged opisthopterygian. Pectoral arch suspended from the skull; no mesocoracid bone. Ventral fins below or in front of the pectorals, the pelvic bones solidly attached to the clavicular symphyses and only loosely attached to it by ligament. Fins without spines.

Families: Macruridae, Gadidae, Muraenolepididae.

Nearly all the families are marine. The Macruridae are among the most characteristic fishes of the great depths. The Gadidae include some of the most valuable food-fishes.

SUB-ORDER XI.—ACANTHOPERYGI

Air-bladder usually without duct. Opercle well developed; supraopercular in contact with the frontals. Pectoral arch suspended from the skull; no mesocoracid bone. Ventral fins thoracic or jugular, more or less firmly attached to the clavicular arch. Gill-opening usually large, in front of the base of the pectoral fin.

The character from which this sub-order, the most comprehensive of the whole class, derives its name, viz., the presence of non-articulated, spiny rays in the dorsal and anal fins, is by no means universal, exceptions to the rule being numerous.

Division I. Beryciformes.—Families: Berycidae, Monocentridae, Polyodontidae.

The most primitive of the Acanthoperygiids, already well represented in the Chalk. A duct has been observed to be sometimes present between the body-bladder and the digestive tract. All marine, several benthic.

The Percidae, Centrarchidae, Toxodontidae, Nandidae, Osphromenidae, Embiotocidae, and Cichlidae are fresh-water fishes, the others are all or nearly all marine. Aiptopus, which is included among the Scorpidae, is one of the few Acanthoperygiid fishes known to have existed as early as the Cretaceous period. See articles CICHLIDS, MILLET, MURREY COD, PARROT-FISHES, PERCH, PIKE-PERCH, SHARKHEAD, WRASSE.

Division III. Scombriformes.—Families: Carangidae, Rachycentridae, Lophidae, Histiophoridae, Xiphiidae, Luvoridae, Coryphaenidae, Bramidae.

Marine fishes, several being pelagic and among the largest Teleostei and swiftest swimmers. See articles HALE-TAIL, MACKEREL, PEARL-FISH, SWORD-FISH, TUNA.

Division IV. Zeoformes.—Families: Zeidae, Amphistegidae, Pleuronectidae.

Division V. Kirtiformes.—A single family, Kirtidae, with a single genus and species from the Indian and Pacific oceans.

Division VI. Gobiiformes.—A single family, Gobiidae.

Division VII. Discophagidae.—A single family, Echeneididae.

The remarkable remoras attach themselves by means of a cephalic disk to boats or to sharks, turtles, ceteaceans, and other large swimming animals. They form an isolated group, and have no real affinity with the Scombridae, with which they have long been associated.

Division VIII. Scorpiformes.—Families: Scorpaenidae, Hexagrammidae, Conephoridae, Rhamphocottidae, Cottidae, Cylopotheridae, Platyccephalidae, Holphichthyidae, Agonidae, Pegasidae, Tridacnidae, Dactylopteridae.

The "Mail-check" Acanthoperygiids include a great variety of forms, mostly living in the sea, the best known being referred to the articles FLYING-FISH, GURNARD, LUMP-SUCKER, and MILLER'S-THUMB.

Division IX. Jujuridae.—Families: Trachinidae, Percophidae, Leptocephalidae, Nototontidae, Uranoscopidae, Trichodontidae, Centrarchidae, Gobioidei, Blediidae, Batrachidae, Pimelodidae, Zoarcidae, Congroaididae, Ophididae, Podatellidae.

Nearly all marine, some deep-water. Macrus americus, whichプロジェクトing to the Atlantic, measures 5 ft. and is the largest known deep-sea Teleostean. The other members of this division are mostly small, Anarrhichas being another exception. The weever (Trachinus) are dangerous stinging fishes.

Division X. Tainiosomi.—Families: Trachypteridae, Lophidiidae.

Deep-sea or pelagic fishes, some attaining a large size.

SUB-ORDER XII.—OPISHTHOMI

Air-bladder without duct. Opercle well developed, hidden under the skin; supraopercular in contact with the frontals. Pectoral arch separated from the vertebral column, far behind the skull; no mesocoracid bone. Vertical fins with spines. Ventral fins absent.

Bel-shaped fishes standing in the same relation to the Acanthoperygi as do the Apodes to the Malacopterygii. The single family, Mastacembelidae, is possibly derived from the Blenniidae.

Fresh and brackish waters of southern Asia and tropical Africa.

SUB-ORDER XIII.—PEDICULATI

Air-bladder without duct. Opercle well developed, hidden under the skin; supraopercular in contact with the frontals. Pectoral arch suspended from the vertebral column, far behind the skull; no mesocoracid bone. Gill-opening reduced to a foramen situated in or near the axil more or less posterior to the base of the pectoral fin. Body naked or covered with spines or bony tubercles.

Connected with the Acanthoperygiid Juggedaries through the Batra- chidae.

Families: Lophidae, Ceratiidae, Antennariidae, Gigantactinidae, Malthidae.

Nearly aberrant marine fishes, many benthidal. The best known are the flying-frog or angler, Lophius, and the Antennarius, which lives in coral groves or is carried about in mid-ocean among the Sargassum weeds.
TELEPATHY

Sub-order XIV.—PECTOGRAPHTHI

Air-bladder without duct. Opercular bones more or less reduced; supraoccipital in contact with the frontals; maxillary and premaxillary bones often firmly united. Pectoral arch suspended from the skull. No ribs. Ventral fins thoracic and much reduced if present; the pelvic fins, if present, more or less co-ossified. Gill-opening much reduced. Body covered with more or less ossaceous scales, bony scutes, or spines, or naked.

A highly aberrant group, closely connected with the Actoantherygii through the Actanthuridae.

Division I. Scleroderomi.—Families: Triacanthidae, Triodontidae, Balistidae, Ostraciidae, Ostracodermata.

Division II. Gymnomontes.—Families: Tetrodonidae, Diodonidae, Mollidae.

The Plectognaths are all marine; the recently discovered Triacanthidae, Himantura, remarkable for its long, tube-like snout from the Gulf of Manaos, is the only form of this sub-order which is confined to the deep sea. Although so highly specialized, several forms, such as Ostracion (the coffer-fish), Tetradon and Diodon, were already represented in the upper Eocene. See FILE-FISH, GLOBE-FISH and SUN-FISH.

For bibliographical references to the Teleostomi, see Ichthyology.

(G. A. B.)

TELEPATHY (Gr. τελεόν, far, πάθος, feelings), or Thought Transference, the conveyance of thoughts and feelings from mind to mind, usually inaudibly and unperceived by the sender or the percipient, is a mental function in the animal and human organism, which has been the subject of scientific investigation from time immemorial. Although the word "telepathy" was first suggested by F. W. H. Myers in 1882, the suggestion had long before been made that the transmission of ideas, images and sensations could be brought about by other than the normally operative motor and sensory apparatus of the body. More than one writer has explained wraiths at the moment of death, clairvoyance and the phenomena of spiritualism by the theory of "brain waves."

But it was not until the advent of the Society for Psychological Research that the hypothesis attracted much notice or was based by carefully collected evidence. Accepted by the society the term is a mere designation and implies no hypothesis as to "action at a distance" or the operation of any force not recognized by physical science.

The earliest recorded systematic experiments in thought transference were made in 1871 by the Rev. P. H. and Mrs. Newnham, and were continued for a period of some eight months with marked success; subsequent attempts showed no results of an evidential nature. A few years later the attention of the British Association was called to the subject by Prof. W. F. Barrett, and from 1881 onwards many experiments were made in which the S.P.R. of pedal opinion, in B the problem of "willing game" was at one time exceedingly popular; the successes, however, depended largely, if not entirely, upon muscle-reading, and usually ceased when there was no contact between agent (the sender of the idea) and percipient (the receiver).

The systematic investigation has followed two main lines: (A) experiments on persons, often in the hypnotic state, in which the aim was to transfer selected images, &c., and compare the guesses with the results which chance would give; (B) the collection and examination of records of phenomena such as apparitions at the moment of death and other spontaneous cases in which there is a correspondence between the psychical states of two individuals, usually remote in space from one another. The problems raised by the two cases are entirely different: (1) in A there is seldom any hallucinatory element (see HALLUCINATIONS), in B, though not essential, it is present in a high percentage of cases; (2) what is transferred is in A an image kept before the mind, in B the phantom of the dying person when that person has prima facie neither endeavoured to transfer this image nor, it may be, even thought of the percipient; (3) the desideratum in A has usually been to exclude the possibility of coincidence of certain facts, in B the problem is to show that coincidence will not account for the facts; for, whereas in A the relation of successes to failures is known, in B it is difficult to get statistics and to be sure that an abnormal number of successful cases do not figure in a census. Side by side with direct experimentation, the S.P.R. collected first-hand records of apparitions at or within twelve hours of the moment of death. These, together with a discussion of the experimental evidence, were issued in 1885 under the title of Phantasms of the Living. In order to provide a statistical basis for discussion of coincidental apparitions, a census of hallucinations was undertaken by Edmund Gurney, and replies were obtained from over 5000 persons. A defect of the collection in Phantasms is that the progressive deterioration of evidence with age is neglected. No narratives are regarded as evidential by the society unless they were reduced to writing less than three years after the event or are based on notes made at the time.

The second systematic attempt to collect material was the so-called hallucination inaugurated at the congress of experimental psychology of 1886, and entrusted to Professor Henry Sidgwick. The total number of persons who made returns was 17,000, of whom 1684 asserted that they had once or oftener experienced an hallucination. Analysis of the answers showed that in 350 cases the apparition was recognized; the probability that any person will die on a given day is roughly 1 in 19,000: if therefore chance alone operated, one apparition in 19,000 would coincide with a death; after making all allowances for error, the census committee found that 30 of the 350 recognized apparitions coincided with a death—in other words, that the coincidence would not be greater than chance coincidence would give. The committee reported that between deaths and apparitions of dying persons there exists a connexion which is not due to chance alone.

The experimental evidence for telepathy is made up partly of the results of trials where direct transference of thoughts, images or sensations was attempted, partly of successes in hypnotization at a distance; dreams (q.e.) also provide some material; and in a small but important class of cases, transitional between wraiths and ordinary experimental cases, the agent has caused his phantasm to appear to the percipient.

Among the chief experimenters may be mentioned Prof. M. Dessor, Mr Guthrie, Sir Oliver Lodge and Prof. Sidgwick. In experiments conducted by the latter and Mrs Sidgwick at Brighton with numbers as the objects to be guessed, 617 trials were made with the agent and percipients in the same room: the numbers were between ten and ninety, and ninety successes were recorded, the probable total, if chance alone had operated, being eight. In a later series, conducted by Mrs Sidgwick, a similarly high proportion of successes was recorded; but when agent and percipients were in different rooms the results were not always what chance would give. These results were criticised by Prof. Lehmann and others, but were not seriously shaken: it was pointed out that the failure of experiments at a distance might be due to psychological causes rather than to the fact that the increase of distance eliminated the possibility of communication by normal means. In subsequent experiments, however, the successes in no series of any length were so far above chance as to give substantial support to a belief in telepathy.

Experiments in hypnotization at a distance provide some of the most conclusive evidence for telepathy. In 1885 trials were made both by Dr Janet and by Prof. Richet with the same subject. Out of twenty-five experiments the former held that nineteen were complete successes; Prof. Richet secured two successes and four partial successes in nine trials. The most striking point was that the hypnotic trance always coincided with or followed at an interval the attempt to hypnotize the patient; this is a feature of much importance in considering the possibility of coincidence or of auto-suggestion.

It is usually impossible to prove that a dying person has been thinking of the percipient; much less can we show that there was any idea of causing his phantasm to appear. There are, however, a small number of cases in which apparitions, of the agent or some other person, prima facie telepathic, have been produced experimentally. A singularly interesting instance is recorded by Wesermann, who tried the experiment in the early part of the 19th century; he wished to make the phantasm of a lady appear to a lieutenant, who was residing some miles away; at the time of the experiment he was, owing to an unforeseen visit, not alone, and his visitor is said to have seen the apparition also. More recently, in cases recorded in Phantasms
and the Census, the figure of the agent himself has been seen by the percipient. The so-called, reciprocal cases are evidentially of much importance. Each of the two persons concerned appears to receive a telepathic impulse from the other, so that each receives information about the other, or sees his phantasm. Occasionally telepathic impressions from animals to human beings are reported, but the facts are usually far from well established. Telepathic communication has also been suggested as the explanation of the simultaneous movements of large flocks of birds.

Various theories have been put forward to account for telepathy, but they only agree in the total lack of an experimental basis. Broadly speaking, they are divisible into physical and psychical. Sir W. Crookes suggests that transmission is effected by means of waves of smaller magnitude and greater frequency than those which constitute X-rays. Undulations starting from nervous centres are adopted as the explanation by Prof. Flournoy and others. But Myers and others regard the case against a physical explanation as complete. The main difficulty in the way of it is that the strength of the impulse does not seem, in the spontaneous cases, to vary with the distance, as by all physical laws it should. On the other hand, a curious phenomenon has been noted in experiments; if the percipient gaze at an arrow with its head turned to the right, there is a tendency, disproportionately strong if we suppose that chance alone operates, for the arrow to be seen reversed. This fact is, however, more important in all probability for the light which it throws on the mechanism of hallucinations (q.v.) than on that of transmission. Telepathy is often invoked as an explanation of the facts of mediumship (see Medium, and Possession); but it seems insufficient to explain them unless we assume for the medium a far greater power of reading other people’s minds than experimental evidence has so far shown to exist.

TELEPHONE

(Cr. 174, far, and φως, voice), voice. Telephony is the art of reproducing sounds at a distance from their source, and a telephone is the instrument employed in sending or receiving such sounds. The term “telephony” was first used by Philipp Reis of Friedrichsdorf, in a lecture delivered before the Physical Society of Frankfort in 1851. But, although this lecture and Reis’s subsequent work received considerable notice, little progress was made until the subject was taken up between 1874 and 1876 by Alexander Graham Bell, a native of Edinburgh, then resident in Boston, Mass., U.S.A. Bell, like Reis, employed electricity for the reproduction of sounds; but he attacked the problem in a totally different manner. This will be better understood if we consider shortly on what the chief characteristics of sound depend.

The sensation of sound is produced by rapid fluctuation in the pressure of the atmosphere on the tympanum of the ear. If the fluctuations are irregular and non-periodic, the sound is called a noise; if they are cyclic and follow a regular and sufficiently rapid periodic law, the sound is a musical sound. The present subject is important to notice the three characteristics of a musical sound, namely, pitch, loudness and quality. The pitch of a musical sound depends on the number of cycles passed through by the fluctuations of the pressure per unit of time; the loudness depends on the amount or the amplitude of the fluctuation in each cycle; the quality depends on the form or the nature of the fluctuation in each cycle. The necessary condition for a successful system of telephony is the ability to reproduce these characteristics.

In 1831 Wheatstone by his “magic lyre” experiment showed that, when the sounding-boards of two musical instruments are connected together by a rod of pine wood, a tune played on one will be faithfully reproduced by the other. This only answers, however, for telephoning musical sounds to short distances. Another and somewhat similar example is furnished by what has been variously designated as the “string,” “toy,” “lovers,” and “mechanical” telephone. Two disks of thin metal, or two stretched membranes, each furnished with a mouthpiece, are connected together by a thin string or wire attached at each end to the centres of the membranes. A good example may be made with two cylindrical tin cups; the bottoms form the membranes and the cups the mouthpieces. When the connecting string is held taut and sounds, such as those of ordinary speech, are produced in front of one of the membranes, pulses corresponding to the fluctuations of the atmospheric pressure are transmitted along the string and communicated to the other membrane, which in its turn communicates them to the air, thus reproducing the sound.

In both these examples all the three characteristics—pitch, relative intensity, and quality—of sound are reproduced.

In July 1837 Dr C. G. Page of Salem, Mass., drew attention to the sound given out by an electromagnet at the instant when the electric circuit is closed or broken, and in October of the same year he discussed, in a short article entitled “Galvanic Music,” the musical note produced by rapidly revolving the armature of an electromagnet so that the poles were alternately brought close to it. These experiments were subsequently made by a great number of investigators.

Page’s discovery is of considerable importance in connexion with the theory of action of various forms of telephone, and was a very important feature in the early attempts by Reis to transmit music and speech. On the 26th of August 1854 there appeared in L’Illustration (Paris) an interesting article by Charles Bourseul on the electric transmission of speech. The writer recommended the use of a flexible plate at the source of sound, which would vibrate in response to the varying pressure of the air, and thus open and close an electric circuit, and of a similar plate at the receiving station, which would be acted on electromagnetically and thus give out as many pulsations as there are breaks in the current. These suggestions were to some extent an anticipation of the work of Reis; but the conditions to be fulfilled before the sounds given out at the receiving station can be similar in pitch, quality and relative intensity to those produced at the transmitting station are not stated, and do not seem to have been appreciated.

In Reis’s lecture an apparatus was described which has given rise to much discussion on the priority in the invention of the telephone. The instrument was described in over fifty publications in various countries, and was well known to physicists previous to Bell’s introduction of the electric telephone as a competitor with the electric telegraph. Reis caused a membrane to open and close an electric circuit...
Bell's object was to reproduce at a distance not only music but also human speech; but that he did not wholly succeed is clear from the following extract from his lecture:—"Hitherto it has not been possible to reproduce human speech with sufficient distinctness. The consonants are for the most part reproduced pretty distinctly, but not the vowels as yet in an equal degree." Considering the time at which he wrote, Reis seems to have understood very well the nature of the vibrations he had to reproduce, but he failed to comprehend how they could be reproduced by electricity. His fundamental idea—the interruption of the current—was a fatal mistake, which was not at the time properly understood. The suggestion of Bourseul and the experiments of Reis are founded on the idea that a succession of currents, corresponding in number to the successive undulations of the pressure on the membrane of the transmitting instrument, could reproduce at the receiving station sounds of the same character as those produced at the sending station. Neither of them seemed to recognize anything as important except pitch and amplitude, and Reis thought the amplitude was to some extent obtained by the varying length of contact in the transmitting instrument. This might possibly be true to a small extent; but, considering the small capacity of the circuits he used and the nature of his receiving instrument, it is hardly probable that the duration of contact sensibly influenced the result. The quality of the sounds was to some extent also reproduced; but, judging from the results of later telephone investigation, it is highly probable that this was due, not to the varying duration, but to the varying firmness of the contact.

The next worker at the telephone, and the one to whom the present great commercial importance of the instrument is due, was Bell. His aim was the production, by means of the undulations of pressure on a membrane caused by sound, of an electric current the strength of which should at every instant vary directly as the pressure varied. His first idea seems to have been to employ the vibrations of the current in an electric circuit, produced by moving the armature of an electromagnet included in the circuit nearer to or farther from the poles of the magnet. He proposed to make the armature vibrate of the vibrations of the atmosphere either by converting it into a suitable vibrator or by controlling its vibrations by a stretched membrane of parchment.

In the early trials the armature had the form of a hinged lever of iron, which was pressed against or released from a small part of a stretched membrane of parchment. Fig. 1 shows the arrangement. M was a membrane stretched by a ring R over the end of a tube T fixed at one side of the frame F. To the opposite side of the frame an electromagnet I was fixed with its axis in line with the tube T and between the end of the electromagnet and the membrane a hinged armature A was arranged in such a way that its motion could be controlled by the membrane. The instrument was joined in circuit with a battery and another similar instrument placed at a distance; and a continuous current was made to flow through the circuit, keeping the electromagnets energized. The experiment with this form was not successful, and, with the view of making the moving parts as light as possible, he substituted for the armature a small piece of clock spring, about the size of a sixpence, glued to the centre of the diaphragm. The magnet was mounted with its end carrying the coil opposite, and very close to, the centre of the piece of clock spring. This answer sufficiently well to prove the feasibility of the plan, and subsequent experiments were directed to the discovery of the best form and arrangement of the parts. An increase in the size of the iron disk attached to the membrane augmented both the loudness and the distinctness of the sounds, and this finally led to the adoption of a thin iron disk supported round its edge, acting as both membrane and armature (fig. 2). Again, the form of the opening or mouthpiece in front of the membrane exercised considerable influence on the efficiency of the instrument, and it was ultimately ascertained that a small central opening, with a thin air space extending across the face of the membrane, was best. It was also found that comparatively small magnets were sufficient, and that there was no particular virtue in the closed circuit and electromagnet, but that a small permanent magnet having one pole in contact with the end of the core of a short electromagnet, the coil of which was in circuit with the line, but which had no permanent current flowing through it, answered the purpose quite as well. The apparatus thus acted as both a transmitter and a receiver; indeed it is essentially the magneto-receiver which has come into universal use in practical telephony, though for transmission it was soon superseded by forms of microphonic transmitters. One of the latest forms of

A telephone transmitter and a receiver on a novel plan were patented in July 1877 by Edison, shortly after the introduction of Bell's instruments. The receiver was based on Edison's invention of a device for producing an electric current through the point of contact of certain substances in relative motion. In one form a drum, mounted on an axis and covered by a band of paper soaked in a solution of caustic potash, was turned under a spring the end of which was in contact through a platinum point with the paper. The spring was attached to the centre of a diaphragm in such a way that, when the drum was turned, the friction between the point of the spring and the paper deflected the diaphragm. The current from the line was made to pass through the spring and paper to the cylinder. Now it had been previously shown by Edison that, when a current was made to pass through an arrangement like that just described, the friction between the paper and the spring was greatly diminished. Hence, when the undulating telephonic currents were made to pass through the apparatus, the constant variation of the friction of the spring caused the deflexions of the diaphragm to vary in unison with the variation of the electric currents.\footnote{The extreme smallness of the magnets which might be successfully employed was first demonstrated by Professor Peirce of Brown University, Providence, R.I.}
currents, and sounds were given out corresponding in pitch, and also to some extent in quality, with the sounds produced at the transmitting station. A cylinder of chalk was used in some of Edison's later experiments with this receiver.

The transmitter (fig. 4), in an early form, consisted of a cell of immersion about 18 inches long and 9 inches in diameter, a bottom flat-headed screw G; on the top of G was a layer of carbon powder C, on the top of that a platinum disk D, and above that again, forming the cover of the cell, a disk of ivory B, held in position by a ring E. Resting on the centre of the ivory disk was a small piece of rubber tubing, and this was lightly pressed by the diaphragm A, which was held in place by the mouthpiece M. The varying pressure on A, while the operator was speaking into it, caused corresponding variations in the pressure on the carbon powder, and this produced similar variations in its electric resistance.

Experiments very similar to those of Edison were made by Elisha Gray of Boston, Mass., and described by him in papers communicated to the American Electrical Society in 1875 and 1878. In these experiments the electric current passed through the diaphragm to the electromotive forces, as in the Bell telephone. Sir W. Thomson (Lord Kelvin) observed in 1862 that when a condenser was charged or discharged, a sharp click is heard, and a similar observation was made by Croxton and F. Varley, who proposed to make use of it in a telegraphic receiving instrument. In Bell's instrument one plate of a condenser was a flexible diaphragm, connected with the telephone line in such a way that the varying electric potential produced by the action of the transmitting telephone caused an increased or diminished charge in the condenser. This alteration of charge caused a corresponding change in the mutual attraction of the plates of the condenser; hence the flexible plate was made to copy the vibrations of the diaphragm of the transmitter. It is obvious that this apparatus might be used either as a transmitter or as a receiver, but that the effects must under ordinary circumstances be in either case extremely feeble.

It was very early recognized—and, indeed, is mentioned in the first patents of Bell, and in a caveat filed by Elisha Gray in the United States patent office only some two hours after Bell's application for a patent—that sounds and spoken words might be transmitted to a distance by causing the vibrations of a diaphragm to vary the resistance in the circuit. Bell and Gray proposed to do this by introducing a column of liquid into the circuit, the length or the resistance of which could be varied by causing the vibrations of the diaphragm to vary the depth of immersion of a light rod fixed to it and dipping into the liquid.

On the 4th of April 1877 Émile Berliner filed a caveat in the United States patent office, in which he stated that, on the principle of the variation with pressure of the resistance at the contact of two conductors, he had made an instrument which could be used as a telephone transmitter, and that, in consequence of the mutual forces between the two parts of the current on the two sides of the point of contact, the instrument was capable of acting as a receiver. The caveat was illustrated by a sketch showing a diaphragm with a metal patch in the centre, against which a metal knob was lightly pressed by an adjusting screw. This seems to have been the first transmitter in which it was proposed to use the resistance at the contact of two conductors.

Almost simultaneously with Berliner, Edison conceived the idea of using a variable resistance transmitter. He proposed to introduce into the circuit a cell containing carbon powder, the pressure on which could be varied by the vibrations of a diaphragm. He sometimes held the carbon powder against the diaphragm in a small shallow cell (from a quarter of an inch in diameter and about an eighth of an inch deep), and sometimes he used what he described as a "fluff," that is, a little brush of silk fibre with plumbago rubbed into it. In another form the plumbago powder was worked into a button cemented together with syrup and other substances. In the specification of the patent applied for on the 21st of July 1877 he showed a sketch of an instrument which consisted of a diaphragm, with a small platinum patch in the centre for an electrode, against which a spring point, made of plumbago powder cemented together with india-rubber and varnish, was pressed by a long spring, the pressure of the carbon against the platinum being adjusted by a straining screw near the base of the spring. Subsequently he filed an application for a patent in which various forms of springs and weights assisted in maintaining the contacts and otherwise improved the instrument.

In the early part of 1878 Professor D. E. Hughes, while engaged in experiments upon a Bell telephone in an electric circuit, discovered that a peculiar noise was produced whenever hard electrodes, such as two wires, were drawn across each other, or were made to touch each other with a variable degree of firmness. Acting upon this discovery, he constructed an instrument which he called a "microphone," and which consisted essentially of two hard carbon electrodes placed in contact, with a current passing through the point of contact and a telephone included in the same circuit. One of the electrodes was attached to a sounding board capable of being vibrated by sound-waves and the other was held either by springs or weights in delicate contact with it. When the sounding board was spoken to or subjected to the action of sound-waves, the resistance of the hard electrode, due to its weight, or to the spring, or both, served to vary the pressure at the contact, and this gave rise to vibrations corresponding to the sound-waves, and it was therefore capable of being used as a speaking-telephone transmitter.

The next transmitter of note was that introduced by Francis Blake, which came into wide use in the United States of America and other countries. In it the electrodes were of platinum and carbon.

To a frame F (fig. 5) was attached a diaphragm D of thin sheet iron; in front of this was a cover M, provided with a suitable cavity for directing the sound-waves against the diaphragm. The microphone arrangement consisted of a spring S, about the thickness of an inch thick and the eighth of an inch broad, fixed at one end to a lever L, and carrying at its free extremity a brass block W. In one side of W a small disk C of carbon was inserted, resting on the hemispherical end of a small platinum pin K, about the twentieth of an inch in diameter, held in position by a similar diaphragm A. The pressure of the carbon on the platinum point could be adjusted by the screw N, which turned the lever about the flexible joint G. The electrical connections of the instrument as arranged for actual use are also illustrated in the figure. The current circuit went through S, W, C, K, A, and the primary circuit of the induction coil I to the battery B, and thence to S again. This formed a local circuit at the transmitting station. The line current was passed through the secondary of the induction coil I to the line, from that to the telephone T at the receiving station.

and then either to earth or back to the induction coil by a return line of wire.

Another type of microphone which was used in Europe much more than in the United States was the multiple-contact instrument. In this several microphonic joints were employed.

![Diagram of Blake's Transmitter](image)

**Fig. 5.—Blake's Transmitter.**

Thus, in the Crossley transmitter four hard carbon pencils were arranged in a lozenge-shaped figure, the ends of each pencil resting loosely in a small carbon block. These blocks were fastened to a diaphragm of wood. The circuit connections were such that two adjacent sides of the lozenge were in parallel and two in series. In the Ader transmitter as many as twelve carbon pencils were employed, arranged in a series of two groups with four pencils in parallel in each group. These were supported at their ends in parallel carbon bars, which were carried by a nearly horizontal wooden diaphragm. Such multiple-electrode transmitters give a loud although somewhat harsh sound, and will bear being spoken to very strongly without breaking the circuit.

A type of transmitter which has come to be invaluable in connexion with long-distance telephony, and which has practically superseded all other forms, is the granular carbon transmitter. The earliest instrument of this kind was the Hunnings transmitter, patented in 1875. This was constructed of a shallow box placed in a vertical position, with metallic front and back and insulating sides. The front face was of thin metal, and served as a diaphragm. The box was filled nearly, but not quite full, of granulated hard carbon. The current from the battery used passed from the diaphragm through the granulated carbon to the metallic back of the box. When spoken to the diaphragm vibrated, and thus set the carbon granules into vigorous vibration. The vast number of microphonic contacts present give rise to very strong electrical undulations, and hence to a loud sound.

The chief difficulty with this transmitter, and with various others of later date based upon it, has been the frequent packing of the carbon granules, which renders the instrument inoperative. The difficulty was first satisfactorily overcome in the long-distance transmitter, invented by A. C. White in the laboratory of the American Bell Telephone Company, and commonly known as the "solid back transmitter" (fig. 6).

The microphonic portion of the transmitter is contained in a thin cylindrical box or case of brass A, the inner curved surface of which is covered with an insulating layer of paper. The case is firmly fixed to a "bridge" B with its back or bottom in a vertical position. To the brass bottom of the case is attached a thin disk of polished hard carbon C, which is slightly less in diameter than the brass bottom, so that the carbon disk almost entirely covers this brass back, leaving only a slight annular space around its edge. The front or cover of the case is a similar button of hard polished carbon D, also slightly smaller in diameter than the cylindrical wall of the box. It is attached to a brass disk E, which is fastened to the centre of the diaphragm F by means of a rivet, and is capable of moving to and fro like a plunger when the diaphragm vibrates. A washer of thin flexible mica G concentric with the carbon button is carried by the brass disk, and projecting over the edge of this is held firmly against the rim of the cylindrical wall of the case by an annular brass collar H, which is screwed upon the outer curved surface of this wall. The box is thus entirely closed at the front, while the front carbon disk, which constitutes an electrode, is perfectly free to follow the motions of the diaphragm.

**Fig. 6.—Solid Back Transmitter.**

The space enclosed between the front and rear faces of the box is filled about three-quarters full of finely granulated hard carbon, which therefore lies in contact with the front and rear carbon disks of the apparatus, and also fills up the space lying between the lower edge of these disks and the curved surface of the case. The current from the battery passes from one of the carbon disks to the other through the particles of granulated carbon which fill the space between them.

The disks and granules constitute a very powerful microphone. The motions impressed upon the carbon granules are very vigorous, and this together with the particular arrangement of the parts of the instrument is effectual in overcoming the difficulty from packing which attended the use of earlier forms of granulated carbon transmitters. This instrument has almost entirely displaced all other forms of transmitter.

**Subscribers' Organization.**—The employment of the telephone as one of the great means of communication requires a definite organization of the subscribers. It is not practicable to connect each subscriber directly to all the others, hence a system of exchanges has been adopted. The territory in which a telephone administration operates is usually divided into a number of local areas, in each of which one or more exchanges are placed. An exchange is a central station to which wires are brought from the various subscribers in its neighbourhood, any two of whom can be put in telephonic communication with each other when the proper pairs of wires are joined together in the exchange.

When the subscribers in a local area exceed a certain number, or when for some other reason it is not convenient or economical to connect all the subscribers in the area to one exchange, it is usual to divide the area into a number of districts in each of which an exchange is placed, and to connect these district exchanges together by means of "junction circuits." In some cases the exchanges are connected together directly; but when the volume of traffic is not sufficient to warrant the adoption of such a course connections between two exchanges are made through junction centres to which both are connected.

A system of wires, similar to that which connects the district exchanges in an area, links together the various local areas in the territory, and sometimes the territory of one administration with that of another. These inter-area or long-distance lines, called trunk circuits in England, terminate at one exchange in each local area, and between that exchange and the various
district exchanges junction circuits are provided for the purpose of connecting subscribers to the trunk lines.

Circuit and Working Arrangements.—The method first employed for working a telephone line was extremely simple. A single line of wire, like an ordinary telegraph line, had a bell telephone included in it at each end, and the ends were put to earth. Words spoken to the telephone at one end could be heard by holding the telephone to the ear at the other. To obviate the inconvenience of placing the telephone to the mouth and the ear alternately, two telephones were commonly used at each end, joined either parallel to each other or in series. The contrivance most generally adopted for calling attention was a call-bell ringer either by a small magneto-electric machine (magneto-generator) or by a battery.

The telephone was switched out of circuit when not in use and the bell put in its place, a key being used for throwing the battery into circuit to make the signal. This arrangement is still employed, a hook being attached to the switch lever so that the mere hanging up of the telephone puts the bell in circuit. In some cases when a magneto-generator is employed for calling purposes the coil of the machine is automatically cut out of circuit when it is not in action, and is brought into circuit when the handle is turned by the operation of a central fugal spring.

At first it was usual to join the microphone transmitter in the direct circuit. It was soon found that it could only be used to advantage in this way when the total resistance of the circuit, exclusive of the microphone, was small compared with the resistance of the microphone—that is, on very short lines worked low resistance telephones. The transmitter on long and high-resistance lines worked better by joining, in the manner shown in fig. 7, the microphone, a battery and the primary of an induction coil in a local circuit, and putting the line in circuit with the secondary of the induction coil, which acted as the transmitter. The resistance of the microphone can thus be made a large fraction of the total resistance of the circuit in which it is placed; hence by using considerable currents, small variations in its resistance can be made to induce somewhat powerful currents in the wire line. The microphone of this arrangement is shown in fig. 7.

In the earliest telephone switchboards the lines were connected to vertical conducting strips, across which were placed a series of similar horizontal strips in such a manner that any horizontal could be connected to any line strip by the insertion of a plug into holes provided in the strips for the purpose. Any two lines could be connected together by connecting both to the same horizontal strip.

The next step of importance was the introduction of what was termed the "Standard board." This board was equipped with spring-jacks and announciators (calling-drops) for the subscribers' lines, and with flexible cords terminating in plugs for connecting purposes. The spring-jack used was a form of switch with two contact springs which pressed against each other, one being connected to the subscriber's line wire and the other to the announciator, which was also earthed. When a plug was inserted in the spring-jack the connexion between the springs was opened, disconnecting the calling-drop from the line. Each connecting-cord circuit had associated with it a clearing-out drop connected between the line and ground by means of which the subscriber's speaking and ringing apparatus could be brought into circuit. When a subscriber called (by turning the handle of his magneto-generator) the shutter of the announciator associated with his line was dropped. This attracted the attention of the attendant, who in response to the call inserted a plug into the spring-jack and connected the speaking apparatus to the circuit by means of the key. The telephone was now connected to the subscriber, and the operator connected the second plug to the spring-jack of the wanted subscriber, whom she rang up. When the conversation was finished either of the subscribers could release the shutter of the clearing-out drop by turning his generator handle, and the operator thus notified of the fact removed the plugs and discontinued the connexion.

The single-wire earthed circuits used in the early days of telephony were subject to serious disturbances from the induction of currents in the lines by magnetic fields and electric currents in the earth, and from the varying potential of the earth due to natural or artificial causes. The introduction of electric tramways caused an increase in the number of such disturbances of this class. It was early recognized that a complete separation of the telephone circuit from the earth would obviate the disturbing effects of the disturbing wires, and that if the outgoing and incoming branches of the circuits were parallel and kept, by transformers, at equal potential, the effect of the disturbing wire induction would likewise be removed.

These advantages led to the gradual supersession of the single-wire system until at the present day the all-metallic system is employed in the majority of cases. Since its introduction all switchboards have been arranged for metallic circuits.

Though many types of manually operated switchboards have been brought into use, differences from each other in respect of circuit and working arrangements, yet each of them is placed in one or other of three main classes according as the system of working is magneto, call-wire, or common battery. The fundamental principle of the magnetic system has been described in connexion with the "Standard board."

In a large exchange a number of operators are necessary to attend to the calls. Several single-switchboards like that described may be employed, each being in charge of a certain number of subscribers, and placed in care of an operator. In these circumstances, when, as frequently will be the case, the person calling desires to speak with a subscriber who is in communication with one or more others, many additional switchboard operations are required. In connexion with the introduction of the "multiple switchboard" this board is built up in sections of one or more operators' positions each. All the subscriber's lines are connected in order to the boards on the first, second or third operators' positions, and these connections are repeated or "multiplied" upon each succeeding similar group of positions. Each subscriber's circuit is further connected to another spring-jack directly associated with the calling-drop. These spring-jacks, known as answering jacks, are distributed along the switchboard, a certain number being terminated upon each position and placed in care of the operator assigned to that position. Hence this operation is much simplified, and in the ordinary way, can be put at the disposal of these subscribers in connexion with any subscriber whatever, without the necessity of calling upon another operator to make connexion.

Two methods of "multiplying" have been much used. In the arrangement first introduced the line wire is connected in series through the various spring-jacks, the circuit finally passing through the answering jack to the calling-drop. This arrangement is liable to give trouble, as disconnections may arise in the spring-jacks in consequence of the failure of the springs to make contact. Operating mistakes also cause interruptions to conversations, as it is impossible for an ordinary telephone to work without being connected in the circuit between two talking subscribers. To overcome these difficulties the "branching multiple" was introduced. In this case, all the being of being introduced in connexion with a subscriber, rather than that subscriber's circuit being treated as an independent branch from the main circuit. With the "branching multiple" the "self-restoring drop" was introduced. This apparatus has two coils, one of which, connected across the line, is provided for the purpose of projecting the shutter, while the other is intended for its restoration and is joined in a local circuit arranged to be closed when a plug is inserted in any one of the associated jacks.

It is necessary that the operators working at a multiple board shall be able to ascertain without entering a subscriber's circuit whether the circuit is disengaged. This requirement is usually met by means of a "test" button. Each test button is associated with a subscriber's line, and by making the circuit arrangements such that this wire is either disconnected or at earth potential when the line is not in use, and at some potential above or below earth when the circuit is engaged. With a proper arrangement of the operator's speaking set it is possible, by touching the socket of a jack with the tip of a pen or a special "test" thumble, to determine whether the circuit connected to the jack is in use or not.

Both the series and the branching methods of multiplying are recognized at the present time as standard methods, although the former is the more extensively employed because of the comparative disadvantage of the magneto system itself is dying out. There are still many magneto exchanges in existence, but when new exchanges are erected only the very smallest are equipped for magneto working, that system having been displaced by other systems. The "call-wire" system has been used to some extent, but it is now obsolete. The feature of the system was the provision of special service circuits, termed call-wires, for purposes of communication.
between the subscribers and the exchange operators. Each subscriber was given the exclusive use of a circuit in other systems, and shared a call-wire with a number of other subscribers. Each telephone set was equipped with a special key or switch by means of which the telephone could be transferred from one exclusive line to the call-wire at will. A subscriber desiring a connexion pressed the key and communicated his own number and that of the subscriber to the operator in attendance on the call-wire. Then, when the connexion was made, the originating subscriber rang up the other. At the close of a conversation the originating subscriber again entered the call-wire and requested the operator to take down the connexion. The call-wires were usually equipped with drops in order that the exchange might be called at night when the operators were not listening continuously.

One of the greatest advances made in the development of the art of telephony was the introduction of the "common battery relay system." This advance did not merely remove the primary batteries from the subscribers' stations; it removed also the magneto-generator, and at the same time it modified considerably the conditions governing the exchange operating. The calling-drop of the magneto system was displaced by a relay and a small electric incandescent lamp, and whereas in the older system the calling-drop and the answering jack were two apparatus separated by some distance, the calling-lamp and the answering jack of the newer system were placed in juxtaposition. This alteration improved the operating conditions in three ways. In the first place it increased the visibility of the signaling instrument; in the second place it brought that instrument into the position in which it could most readily catch the operator's eye; and finally it eliminated the effort involved in associating one piece of apparatus with another and in finding that other. Moreover the clearing-out drop of the cord circuit was replaced by an arrangement which included the provision of one signal to be controlled through the agency of a relay by the calling subscriber, and another to be controlled by the person wanted. These supervisory signals took the form of lamps and were placed on the keyboard in positions immediately adjacent to the associated cords. With the adoption of relays the signaling between the subscribers and the exchange became automatic, and, with the introduction of the principle of double and automatic supervision on the cord circuits, it became possible for the operators to tell at any instant the state of the connexion. As a result the time occupied by an operator per call was reduced from 50-77 seconds to 16-63 seconds.

Three fundamental common battery transmission systems have been devised and are shown in figs. 8, 9, and 10. In the Hayes system (fig. 8) a repeating coil is placed in the cord circuit, and when two subscribers are connected together the winding connected to the line of the subscriber who is talking for the time being acts as primary, and the other, which is in the line of the listening subscriber, as secondary.

The Stone system (fig. 9) is characterized by the use of impedance coils between the battery and the line wires. When one of two subscribers connected together by this arrangement talks, the variation in resistance of the subscriber transmitted into causes a variation of the pressure at the line terminals of the impedance coils, and since those terminals are common to the two circuits the variable E.M.F. operates in the line of the listening subscriber, causing the reproduction of the speech in the latter's receiver.

The Stone system, compared with that of Hayes, possesses the disadvantage that one of the conditions affecting the supply of current to any particular subscriber's circuit is the resistance of the other circuit to which it is connected for the time being. An improvement in this respect has been effected by the insertion of condensers in the cord circuits, coupled with the use of two sets of impedance coils, one set on each side of the condensers.

Dean's method (fig. 10) embodies the idea of supplying current to the transmitters over the line wires in parallel instead of round the loop circuit, as in the other systems referred to. An earth return is used. The transmitter is placed in multiple with the primary winding of an induction coil whose secondary operates in the loop circuit, and consequently when the transmitter is spoken into, a variable E.M.F. is impressed upon the circuit through the medium of the induction coil. The impedance coils shown connected between the battery and the lines and between the latter and the transmitters are joined up non-inductively as regards the transmitter circuits, but inductively as regards the secondary circuits. Figs. 11 and 12 indicate typical subscriber's and connecting-cord circuits as equipped by the Western Electric Company. At the subscriber's station when the receiver is on the hook, the circuit is through the call-bell and a condenser. The conditions permit of the circulation of the alternating currents of low periodicity, which are used for operating the bells, but in respect of the battery the circuit is open until the subscriber lifts the receiver, when the hook switch, thus released, joins the transmitter with one winding of an induction coil in series across the circuit. A current then flows and in passing round the circuit operates the line relay with the result that the calling-lamp is lighted. The operator, whose attention is thus attracted, inserts a peg in the jack, then throws over the speaking key of the cord circuit, and having ascertained particulars of the requirement places the other peg of the pair in the nearest multiple jack of the wanted subscriber, whom she proceeds to ring up. In the meantime the calling-lamp has darkened; and each subscriber's line being equipped with a cut-off relay whose function it is to disconnect the calling apparatus while the circuit is in use, the insertion of a peg is immediately followed by the disappearance of the calling signal. The supervisory lamp associated with the peg in the wanted subscriber's jack glows from the time that the peg is inserted until...
the subscriber responds, when it darkens, in which condition it remains until the subscriber restores the receiver to the hook and causes the lamp to light up again. The other supervisory lamp on the cord circuit is controlled in a similar manner by the subscriber who originated the call, and as that subscriber's telephone is off the hook when the peg is inserted, the lamp is not lighted at all until the subscriber replaces the receiver. When both lamps glow, the operator, who thereby knows that both subscribers have restored their instruments, discontinues the connexion.

A cord circuit, similar in many respects, including the method of operation, but equipped with condensers and impedance coils, in place of the repeating coil, is shown in fig. 13.

In fig. 11 a meter or counter is shown associated with the subscriber's line, the whole between 12 and 13 positive meters are shown connected to the cord circuits. The operation of these meters is controlled by the operators. The subscriber's meter is joined in multiple with the cut-off relay, and whenever a peg is connected to the circuit a current flows through the meter. This current is small, however, and the meter is not operated until a much larger current is passed through it. Calls are registered by pressing a key, which connects a battery through a position meter of very low resistance to the socket of the line jack, thereby furnishing the necessary energy to the meter. The position meter just mentioned is common to all the cords on one position and records all completed calls handled at the position. Some administrations, in addition to employing the ordinary position meter, use a second one for registering ineffective calls.

In large towns served by a number of exchanges the junction equipment is an important feature. In many cases from 60 to 80 per cent. of the calls originated at an exchange are for subscribers connected to other exchanges, and in these cases the junction plant forms a considerable fraction of the whole equipment. Moreover each call junctioned is dealt with by at least two operators. The junction circuits connecting two exchanges are invariably divided into two groups, one for traffic from exchange A to exchange B, the other for traffic from B to A. At the outgoing end the circuits are multiplied on the subscribers' switchboard, while at the incoming end they terminate in plugs on a special incoming junction switchboard upon which the subscribers' lines are multiplied in the usual way.

When a subscriber at exchange A asks for a connexion to a subscriber at B, the operator at A drives the signal, and instructs the receiver to essay connexion with B. He makes the connexion, and rings the subscriber. During the progress of these operations the A operator connects the originating subscriber to the junction circuit passed by the B operator. There is only one signal on the cord circuit at B, and that signal is controlled by exchange A. Each of the subscribers controls a signal at A, and when either or both of the telephones are replaced, the action is indicated by the lamps there. Control of the call is thus vested in the operator at the originating exchange, at which point the connexion must be severed before a clearing signal can appear at B.

Party Lines.—A circuit which serves more than one subscriber is termed a "party line." It was originally the practice to place the calling apparatus in series in the line circuit, but the effect of the large impedance introduced by the electromagnets of the call-

bells was such that not more than two or three persons could be connected without seriously impairing the efficiency of the circuit for speech transmission. An improvement was effected in this respect by the introduction of the "bridging" system, in which the bells possessing high inductance are placed in parallel between the two wires of the circuit, and thereby in circuit their high impedance prevents any appreciable interference with the telephonic currents. In America, on farmers' circuits, ten or more stations are frequently connected to one line; but in England ten is practically the maximum. In city districts the modern practice is to restrict the number to four stations per line, and to equip the exchanges and stations for selective ringing. In one arrangement, now in extensive use, each telephone is fitted with a relay of high inductance which is bridged across the circuit in series with a condenser. When the relay is actuated it connects a bell between one of the wires of the circuit and earth, while the bell itself is arranged to respond to current pulsations in one direction only. The four telephones on a circuit are so wired that the relays connect two of the bells between each wire and earth, and further that one of each pair of bells responds to positive and the other to negative pulsations. This system of course requires that the exchange equipment shall include machines capable of delivering a positive pulsating current and a negative pulsating current, besides the usual alternations required for the ringing of ordinary subscribers.

In another party line system a harmonic principle is employed; the ringing machines deliver alternating currents of four frequencies, while each bell is constructed to operate at a particular frequency. Of the four bells connected to a circuit each responds to a different frequency.

Trunk Line Working.—Trunk or long-distance working is complicated by the necessity for recording all calls. The system of the British Post Office is worked as follows: A subscriber desiring a long-distance connexion calls up his local exchange in the ordinary way, and the operator there, being informed that a trunk connexion is desired, extends the subscriber's line to the Post Office by means of a record circuit. At the Post Office a record operator supplies and takes particulars of the connexion, and these are entered upon a ticket. The record operator then removes her speaking apparatus from the circuit, and the local operator, receiving a disconnect signal, sever the connexion at the local exchange. Meanwhile the ticket is conveyed to the position where the lines to the town wanted are terminated. If there be a line free, or when the turn of the call is reached, particulars of the connexion wanted are passed to the distant end, and the trunk operators request the local exchanges to connect the subscribers by means of junction circuits to the trunk exchanges where the necessary connexions are made between the trunk line and the junctions. The call is controlled by the trunk operators, the junction circuits being equipped in such a manner that signals appear at the trunk exchanges, from which point disconnecting signals are sent automatically to the local exchanges, when the connexions between the trunk and the junction circuits are removed.

The large modern trunk exchanges are of the extendable-relay and lamps for signalling purposes. "Calculated graphs" are employed for stamping the time upon the tickets, and there is associated with each trunk circuit a device which lights a lamp as soon as the scheduled limit of the period of conversation is reached.

Particulars of calls are now passed between trunk centres to a great extent over telegraph circuits superposed upon the trunk
TELEPHONE

lines. This arrangement permits particulars of calls to be passed over lines while conversations are in progress.

Automatic Systems.—The idea of automatic telephony is to substitute electrical equipment for mechanical or other switching systems, which, controlled in its movement by the action of the subscriber, will automatically select, connect, and disconnect circuits of which there are many thousands, embodying this idea have been developed, and one of them has been put into extensive operation. Each subscriber's circuit on this system terminates upon the incoming portion of a selector switch, called a selector, and is multiplexed upon the outgoing portions of a number of similar switches called connector switches. Only calls originated by a subscriber pass through the selector switch (first selector) provided for his sole use; the calls incoming to him pass through one or other of the various connector switches upon which his circuit is multiplexed. Each connection involves the use of three switches, viz., a first selector, a connector switch, and a second selector which is brought into operation between the other two.

The subscribers' lines in an exchange are arranged in groups of 1000, which are divided in turn into sub-groups of 100 each. By means of his first selector the circuit of a calling subscriber is connected to the outgoing end of a junction whose other end terminates upon the incoming portion of a second selector in the thousand group to which the wanted subscriber belongs. The second selector in turn extends the connexion by means of another junction circuit to one of the selector switches in the hundred group wanted, while finally the connector switch completes the desired connexion. Conductors may be placed upon the outgoing portion of each switch, and the contacts upon which they terminate are arranged in a number of horizontal rows upon the face of a curved surface, at whose axis a vertical shaft is placed. This shaft usually consists of a number of ferrules, each ferrule supporting a number of conductors, so that the wipers may be brought, first opposite any particular horizontal row of conductors, and then opposite any particular row of conductors in the particular set in the series. The movements of the shaft are controlled by relays and electro-magnets which operate in response to the action of the subscriber whose telephone is fitted with a call-system. The circuit may be made for a certain number of times for each figure in the number of the wanted subscriber.

Wire Plant.—In suburban and rural districts subscribers are usually connected by means of wires laid upon the tops of iron poles. As subscribers’ lines are invariably short, the smallest gauge of wire possessing the mechanical strength necessary to withstand the stresses to which it may be subjected can be employed, and bronze wire weighing 40 lb per mile is commonly used. In large towns telephone distribution by means of open wires is practically impossible, and the employment of cables either laid in the ground or suspended from poles or other overhead supports is necessary.

In the types of cables that were first used, the wires, usually with a cotton insulation, were drawn into lead tubes, and the tubes filled with a strong paraffin filling which kept the wires from the injurious effects of any moisture which might penetrate the lead tube. This form of cable has been superseded by a type with paper insulation. The separate wires are surrounded only with a paper covering, or else each of such furnishing an improved insulation. In the manufacture of the cable the wires are first enclosed in the paper, which is applied sometimes longitudinally and sometimes spirally. The paper is then, with a double layer in the gauge of the paper now is, laid in the air. These pairs are laid up symmetrically into cables, each layer being protected with an additional covering of paper and all adjacent layers revolving with an opposite twist. The cable is then placed in an oven, and, after all moisture has been driven off, it is passed through a lead press whence it emerges protected by a continuous lead pipe. The electrostatic capacity of a cable of this type is low, and its direct application for the transmission of telephonic purposes is limited by the presence of a lead sheath. The direct advantages of the cable are therefore obtained by using a copper pipe either under the ground or on poles. Copper pipe is employed for communication purposes, and iron pipe for the transmission of telephonic purposes.

When a number of cables follow the same route, they are generally laid in conduits made up of earthenware or metal ducts; iron pipes are used when the number of cables is small. Manholes are placed at intervals, and accommodated for the introduction in and jointing of the cables, and surface boxes are placed in the footways for distributing purposes. Various methods of making the connexion between the large main pipes and the smaller pipes and manholes are employed. In one of them the main cables terminate in large air-tight iron boxes placed in the manholes. There, the large cables divide into a number of small cables, which are carried along the floors of the manholes in copper or earthenware conduits. Another method of distribution, largely adopted, is to run the lead cables into the interior of blocks of buildings, and to terminate them there in iron boxes from which the circuits are distributed to the surrounding buildings by means of rubber-covered wires run along the walls. Aerial distribution from distributing poles is a method frequently adopted. In this case the cables terminate upon the poles, the connexions between the cable wires and the open wires being made by means of earthing}

As no practical process of telephone relaying has been devised, it is extremely important that the character of the line should be such as to favour the rapidity of the transmission of the telephone current. In circuits possessing high resistance and capacity and low inductance per mile, telephonic currents are rapidly attenuated, and the higher the frequency the more rapid is the attenuation. Moreover, as the velocity of propagation is a function of the frequency, there is distortion of the complex waves. Oliver Heaviside showed mathematically that uniformly-distributed inductance in a telephone line would diminish both attenuation and distortion, and that if the inductance were great enough and the insulation resistance not too high the circuit would be distortionless, while currents of all frequencies would be equally attenuated. He also showed that by placing inductance coils in circuit, at distances apart of less than half the length of the shortest component wave to be transmitted, a uniform conductor might be made approximately distortionless. It was applied to submarine cables, so that by "loading" the manner proposed by Pupin during recent years, especially in underground cables, and it has been found in practice that the inductance coils inserted at regular intervals, from three to four times their value unloaded. Open aerial long-distance lines have also been loaded, but not to the same extent. The introduction of inductance coils into such circuits renders them susceptible to trouble from atmospheric electricity and more sensitive to leakage variations.

In consequence of their high capacity, the attenuation constant of submarine cables is high, and only a small number of cables, of comparatively low capacity, are employed. Attempts have been made to improve submarine cables in this respect, and in 1906 a short cable "loaded," with Pupin coils was laid across Lake Constance. The problem, however, of constructing a deep-sea cable satisfactorily, with suitable inductance coils inserted at short distances apart, is a difficult one, and one which it cannot be said has been solved (H. R. K.).

Commercial Aspects.—The records of the telephone industry in Great Britain during the thirty years from 1877 to 1907 form an instructive chapter in the industrial history of the country. The aspects which stand out most prominently in this history are: (a) The elevation of successive governments to the position of conscious custodians of the public rights of users of the telephone, and the provision of apparatus for transmitting messages or other communications with the aid of electricity, magnetism, or any other like agency.

1876. The Edison telephone Company of London was formed. Both the Bell and the Edison Companies opened negotiations with the Post Office for the sale of their patents to the government; but without success. The Edison Company proceeded to start telephone business in London, and the Postmaster-General instituted proceedings against the company
for infringement of his monopoly rights under the Telegraph Act 1869.

1880. The two companies amalgamated as the United Telephone Company Ltd. Mr Justice Stephen decided (Attorney-General v. Edison Telephone Company, 6 Q.B.D., 244) that the telephone was a patent infringing invention and that the companies could not legally be carried on except by the Postmaster-General or with his consent. The decision covered also future invention in regard to "every organized system of communica-
tion of messages by means of wires according to any precor-rected system of signals."

1881. The company's appeal against the decision was withdrawn, the Postmaster-General deciding in favour of the licence areas of about 5 m. in London and about 2 m. in the provinces. The licences merely conformed the infringement of the Telegraph Act 1869, and did not confer powers to erect poles and wires, to construct underground wires or to lay down any property. The licence was precluded from opening public call offices and from laying trunk lines from one town to another. The licences were for 31 years, expiring in 1922, without any provision for purchase or compensation, and were subject to the payment of a minimum royalty to the Post Office of 10 per cent. of the gross revenues. The United Telephone Company confined its operations to Local Com-
sidiary companies were formed to operate in the provinces. The Post Office at the same time established several telephone exchanges in provincial towns so as to enable the Postmaster-General to "exercise control over the telephone companies in a satisfactory manner for licences."

1882. The Postmaster-General (Mr Fawcett) declared that he would issue new licences unless the licensees agreed to sell telephones to the Post Office at a price fixed by the government. Eight companies out of over seventy that had applied obtained or accepted licences.

1883. The Post Office proposed to engage in active competition with the telephone companies, but the Treasury at that time opposed this policy on the ground that the state should at most be ready to supplement and not to superease private enterprise.

1884. The licences within restricted areas having proved unsatis-
factory for the growing business, public opinion appealed to the Post Office to issue new licences applicable to the whole country. All restriction was lifted, the licences being allowed to open public call offices but not to receive or deliver written messages, and they were allowed to erect trunk wires. The royalty of 10 per cent. was continued. The Post Office reserved the right to compete either directly or by granting other licences, and it was under no obligation to grant way-leaves. The new licences were to terminate in 1911 without any provision for purchase or compensation in that year, but with the option to the government to purchase the plant of the licensees in 1890, 1897, or 1904 at a price to be deter-
mined by arbitration. The United Telephone Company asked parliament for rights of way in streets, and its only right to place overhead wires was obtained by private way-leaves.

1885. The United Telephone Company again applied successfully for right to lay wires underground.

1888. The application for the company for permission to lay wires in streets was again refused.

1892. The Postmaster-General, after the removal of the restriction against the com-
pamies erecting trunk wires it became evident that the develop-
ent of the telephone service throughout the country would be facilitated by complete intercommunication and uniformity of systems, and that economies could be effected by concen-
tration of management. The various companies therefore amalgamated as the National Telephone Company.

1898. The government had the option to buy out the companies under the licences of 1884, but did not exercise it. The Bell telephone patents expired. The National Telephone Company applied to the London County Council for permission to lay wires underground, and continued efforts till 1899 to obtain this power, but without success.

1891. The duke of Marlborough, in the name of the New Tele-
phone Company, inaugurated a campaign for cheaper telephone service, because the telephone was thus far used only to make business calls at a cost that the public was much fearful of. The National Telephone Company was subsequently merged in the National Telephone Company.

1892. The National Telephone Company again applied to parlia-
ment for permission to lay underground wires under a bill dis-
cont with inadequate telephone services was expressed, and at the same time the competition of the telephone with the Post Office telegraph became more manifest. The government again changed its mind, and the combined companies, finding it more economical to use the existing trunk wires to the Post Office, leaving the local exchanges in the hands of the companies. It also expressed willingness that the companies should have rights of way in the streets. 

1893. The National Telephone Company applied to parliament for power to lay wires underground, but was refused.

1894. The draft agreement between the government and the National Telephone Company to carry out the policy of 1892 was submitted to parliament and led to much discussion. Local authorities (notably the City of London (Glasgow)) refused to permit the company to lay wires underground.

1895. A select committee of the House of Commons (with Mr Arnold Morley, Postmaster-General, as chairman) was ap-

nounced "to consider the support which has been or may be made for the telephone service in local areas is adequate, and whether it is expedient to supplement or improve this pro-

ever or licit in law, or of any other or otherwise."

The committee was unanimous and made no report, but merely submitted to the House the evidence it had received.

1896. The trunk wires were transferred to the Post Office in pursuance of the policy of 1892, but for all practical purposes the local authorities had vetoed the permission of the govern-
ment to the company to lay wires underground.

1897. The government had an option to purchase the plant of the company under the licences of 1884, but did not exercise it. The corporation of Glasgow having persisted in its efforts to obtain a licence, the Treasury appointed Sheriff Andrew Jameson (afterwards Lord Ardwall) a special commissioner to hold a local inquiry in Glasgow to report whether the tele-
phone service in that city was adequate and efficient and whether it was expedient to grant the corporation a licence. The commissioner reported that the service was adequate but not efficient; that the rates were reasonable but that the competition was not sufficiently complete to avoid withholding facilities, thus rendering the service inefficient; that it was inexpedient to grant the corporation a licence because the funds of a city ought not to be applied for the benefit of a limited number of citizens; that the trunk systems in one area would increase the difficulties of the government in 1911; and that the corporation had not proved that it would work the licence without placing a burden on the rates.

1898. The policy of the government was now changed; Mr R. W. Hanbury, Financial Secretary to the Treasury and representative in the House of Commons of the Post-
master-General, advocated the granting of licences to local author-
ities. A select committee was appointed with Mr Hanbury as chairman to consider whether the telephone service is calculated to be beneficial or is an idolatry, and whether it is being undertaken by municipal and other local authorities, and if so under what conditions. The committee reported (9th August) that the telephone service was not likely to become of general benefit "so long as the present practical monopoly in the hands of a private company shall continue."

The committee considered that the Post Office was not prevented either by legal agreement or by good faith from limiting or ending the monopoly of the company, and that competition appeared to be both expedient and necessary in order to extend and popu-
larize the service and to avoid the danger that a purchase of the company's service by the government would be forced upon the government. While considering that a really efficient Post Office service would afford the best means for service such competition between the Postmaster-General, imme-
diate and effective competition should at once be undertaken either by the Post Office or by local authorities. The Associa-
tion of Municipal Corporations passed resolutions on the 28th of August that "the telephones were to be used as an imperial and not as a local one, and that the Postmaster-
general should have the sole control of the telephone system," and that in the event of the Postmaster-General not taking over the telephone service it should be competent for municipal and other local authorities to undertake such services within areas composed of their own districts or combination of such districts."

1899. In pursuance of the report of the select committee, 1898, the Telegraph Act 1899 was passed to enable the Post Office to develop its telephone exchange business, for which a loan of £200,000 was raised, and to extend to the telephone service subject to certain conditions, to enter upon telephone business. The licence of the National Telephone Company was extended so as to be co-extensive with that of a competitive licence for any network on the Continent of Europe. The licence included intercommunication with the telephone systems of the new licensees. In short, all-round competition was authorized, and the Post Office designed to erect a telephone system in London in competition with the company.

1900. The Telegraph Act 1899, while providing for intercom-
munication between the telephone systems of the local author-
hities and the companies, gave no compulsion to demand intercommunication between its exchanges and those of the company. The Post Office co-operated with the London County Council to put difficulties in the way of the company which led to application for an injunction to restrict the consent of the local road authorities. In February the Postmaster-General applied for an injunction to restrain the
company from opening any street or public road within the county of London without a permit granted by the General and the London County Council, which injunction was granted in July.

1901. The government policy of 1899 was abandoned in London, the equal to 7½ per cent. more telephones with the consent and regard to the London business. The company consented to free intercommunication between its subscribers and those of the Post Office, and undertook to charge rates identical with those charged by the Post Office. The Postmaster-General on the other hand agreed to provide underground wires for the company on a rental, and agreed to buy in 1911 the company's plant (excluding at the cost of construction less allowance for repairs and depreciation.

1903. The government had option to purchase the company's provincial plant under the licence of 1884. Negotiations took no presentment was expected to be completed in 1907. The government contracted to buy the company's plant in 1911, thus in effect annulling the act of 1899 which had failed to accomplish its object of establishing an all-round competition.

By 1907 altogether 59 local authorities had examined the proposition of establishing telephone systems after 1899, and licences were granted to local authorities at Brighton, Belfast, Chard, Glasgow, Grantham, Huddersfield, Hull, Portsmouth, Swansea, Tunbridge Wells, Oldham, Scarborough and Hartlepool, but only six municipalities proceeded with the business. Glasgow opened its exchange in March 1901, Tunbridge Wells in May 1901, Portsmouth in March 1903, Brighton in October 1903 and Hull in October 1904. The Tunbridge Wells and Swansea municipal undertakings were subsequently sold to the National Telephone Company, and the Glasgow and Brighton undertakings to the Post Office.

These two with the other municipal telephone systems working in 1907.

The effect of the unsettled policy of the Post Office until 1903 and of the difficulties created by the local authorities was that the National Telephone Company was never able to do its best to develop the enterprise on the most efficient lines. In 1885 there were only 2,800 telephone subscribers in London and less than 10,000 in the rest of the United Kingdom, and telephonic services were available in only about 75 towns, while in the same year the American Telephone Company had over 134,000 subscribers. The removal in 1884 of the prohibition against the erection of trunk lines at once enabled considerable expansion to take place. Within six years the services had been extended to 400 towns with about 55,000 subscribers. Large as this progress was it would have been much greater if the Telephone Company had been granted adequate powers to put wires underground and thus install a complete metallic circuit in place of the single wire, earth-return, circuit which it was constrained to employ. Subsequently the progress was still greater. In 1906 there were 39,551 telephone subscribers in the United Kingdom than in the ten European countries of Austria, Hungary, Belgium, Denmark, Holland, Italy, Norway, Portugal, Russia, Sweden and Switzerland, having a combined population of 288 millions as against a population of 42 millions in the United Kingdom. Apart from France, Germany and Switzerland, there was no European country that had as many telephones working as London. That city, with a population of 6 millions, had nearly as many telephones as the whole of Sweden with about the same population, or as the whole of France, with a population of 39 millions. The only province which can be compared with the United Kingdom in telephone development is Germany. With a population of 53 millions there are 10-2 telephones per 1,000 of the population in that country compared with 10-15 in Great Britain and Ireland. The development of telephony in the United States of America is much greater than anywhere else; on the 1st of January 1907, 5 per cent. of the population were telephone subscribers.

Tariffs.—Telephone business is characterized by two features: (1) that the capital account is never closed, and (2) that the costliness of the service increases with the size of the undertaking. The original method of charging adopted in Great Britain took the telephone instrument as the unit, charging a fixed annual rental independent of the amount of use to which the instrument was put. The study of telephone economics showed that the proper basis for charging was the "message-mile," on the theory that the user should pay according to the facilities offered and the extent to which he uses them. The importance of the Post Office connected exchanges have to be built and thousands of subscribers are put into communication with each other, the service is at once more costly and more valuable than in a small town with a few hundred subscribers. The change in the way of charging in the country not only in the size of towns, but in the arrangement and characteristic of the population, make each district a telephone problem by itself, and nullify close comparisons between telephone rates and telephone efficiencies in different areas and different circumstances. But the tendency is towards a system of charging a moderate surcharge to cover the rent of the instrument and an additional fee per message or some similar basis. In the city of London, for instance, the tariff is 5s. per annum plus 1d. per call within the county and 2d. per call outside the county. Subscribers outside the county of London pay only 4d. in annual subscription and 1d. per call to subscribers within the county, and the same rate per 2d. per call to subscribers in the same county.

In each case the minimum annual amount for message fees is £1, 10s. The alternative is given of an unlimited service ("flat rate") at £17 per annum. In the provinces the unlimited service costs only £7 10s. for subscribers within half a mile of the exchange, £1, 5s. being charged for every additional quarter of a mile or fraction thereof. The toll or message rates are 3d. per call in the case of the service varies in proportion to the amount of use, the toll rate is more scientific, and it has the further advantage of discouraging the unnecessary use of the instrument, which causes congestion of traffic at busy hours. In order to encourage local subscribers to make more frequent use of the instrument, a toll is charged when serious business calls are made. The tariff for unlimited use has to be made very high to cover the cost of the additional burdens thrown upon the service, and it is only work economically that will be used in normal circumstances. There is usually a larger number of calls originating from his instrument. The message-rate system equalizes the charges according to the service rendered. Another advantage is that the charge, known as the "measured service," is designed to make the subscriber pay in proportion to the quality and quantity of the service he takes. It is widely used in America, and was introduced into Great Britain in 1907. The subscriber may make three different annual contracts with the Post Office, viz., (1) the ordinary telephones, say 500; additional calls he purchases in advance in blocks of several hundred at so much per hundred, the price being reduced as the number increases. (2) Subscribers who desire the telephone for occasional use, the party-line system has been devised, whereby several telephones are connected to one line leading to the exchange. In a telephone town party service costs 4d. per annum, the message fees being 1d. per call to subscribers within the county and 2d. per call to those outside it, with a minimum of 5s. The fee charged for the use of public telephone call offices is 2d. per message.

The trunk line service is charged at rates which vary from 3d. (for 25 m.) up to 1s. (for 100 m.) for a three minutes' conversation between 6 a.m. and 8 p.m. For every 40 m. above 100 m. an additional 6d. per conversation is charged. A telephone call placed the charges are 1d. for trunk calls at 120 miles, and calls for single periods of three minutes are allowed at half the ordinary rates between 7 p.m. and 7 a.m. A call between London and Liverpool, which ordinarily costs 2s., may be made for 1s. between 7 p.m. and 7 a.m. The growth of traffic on this basis has been considerable, and the arrangement has proved of advantage to the public, as it provides cheap facilities at times which are convenient for social conversation.

The charges for submarine and inter-island services of the Post Office may be reached through the local exchange system, or by means of the trunk wires, in order that the messages may be written down and forwarded as telegrams or express letters or ordinary letters. Subscribers to exchanges may also make arrangements to have all telegrams (except Press telegrams) addressed to them delivered by telephone instead of messenger. Telephone subscribers may also obtain the services of an express messenger by telephoning to the nearest post office connected with the exchange.

National Telephone Company.—The issued share and debenture capital in the company at the end of December 1907 was £2,251,670, consisting of 15,000 6½ per cent. first preference shares of £1 each £150,000, 15,000 6 per cent. 2nd preference shares of £1 each £150,000, 250,000 5 per cent. 3rd preference shares of £1 each £1,250,000, £2,250,000 preferred stock, 576,715 new shares of £1 each £576,715 share dividend £2,715, new shares of £1 each £2,715, debenture stock £5,700,000, debenture stock £1,716,593 £11,216,593.

The company has a reserve fund of £2,675,707, the major part of which is invested in the investments of the Post Office. The total capital and surplus of the company on 31st December 1907 amounted to £3,702,228, of which £2,557,920 was paid to the Post Office in respect of royalties. The working expenses amounted to
to £1,530,003 or 62.6 per cent. of the net income, leaving a profit for the year of £90,000.

At the time of the formation of the various telephone companies the enterprises were regarded as speculative, and much of the capital was raised at a discount. The business subsequently proved remunerative, and the companies, in the most part, commanded a premium in the market. After the consolidation of the companies in 1889-90 the profits declined, patent rights had expired, material reductions were made in the rates, and the public realized that the whole, although promising, was not necessary, the cost of which was charged to revenue.

Agreement of 1905.—By this agreement the Postmaster-General agreed to purchase all plant, land and buildings of the National Telephone Company, and that the Postmaster-General would construct after that date in accordance with the specifications and rules contained in the agreement, subject to the right of the Postmaster-General to object to take over any plant not suited to his requirements. Mr. Halliwell, the then Chairman of the Council, proposed that G. and C. Commissioners as arbitrators on the basis of the "then value," exclusive of any allowance for past or future profits or any compensation for compulsory sale or otherwise. In those cases in which the company's licence has been extended beyond 1911 (Glasgow to 1913, Swansea to 1926, Brighton to 1926 and Portsmouth to 1926) the Postmaster-General will buy the unexpired licence with allowance for goodwill. The company also agreed also to buy the private wire plant of the company at a value based upon three years' purchase of the net profits on the average of the three years ending 31st of December 1911. Postmaster-General, and the company would for the company an annual rental of £1 per mile of double wire in any local area in which the company was operating, but not in areas in which the number of subscribers had not increased. An agreement was established by the agreement between the subscribers of the company and those of the Post Office, and a scale of charges was adopted or arranged to be agreed as binding on both companies. The latest Mar. 31st 1911, the company's books showed an over £2,000,000 per annum and its net revenue of £950,000, which the company had built up. The company had had to pay for all the experiments and the full amount of the Post Office's expenses, of any new industry. It had paid the Post Office in royalties already £1,848,000, and the Post Office under the agreement would into the business in 1911 by merely paying for the plant employed. The London County Council, the London County Council, the Post Office and the London County Council, on the other hand, considered the terms of purchase to be too favourable to the company. The London County Council, according to the statement of its comptroller, was disturbed by the hope expressed by the manager of the company, that the holders of the company's ordinary shares would obtain the par value of their shares in 1911. Inasmuch as the debenture stocks and preferences of the company to be incorporated would amount to £1,700,000, of which the company may be between 3 and 5 per cent., the state would have to pay the company £353,000 in excess of the total of the outstanding securities in order to enable the ordinary shares to receive par, and in the company's opinion it would diminish the prospects of the Post Office being able to afford a substantial reduction in the telephone charges.

Post Office Telephone.—The number of trunk wire centres open on the 1st of March 1917 was 2,304, and the total number of tr. of 31st of March 1907 was 19,803,300. The gross revenue derived from the trunk services was £480,658, being an average of 5.92d. per conversation. The total number of subscribers of the Post Office provincial exchanges was 1,611,000 at the 1st of March 1907 (excluding those of Glasgow and Brighton) was 10,010, and the number of telephones rented was 12,006. The Glasgow system included 11,103 subscribers' lines with 2,900 miles, and the London system 101 miles with 1,000 subscribers' lines with 1,884 telephones. The sum received by the Post Office as rental in respect of private wires was £183,000. The years working of the whole telephone system of the Post Office shows that on an average the telephone service amounted to £2,522,000 at 3 per cent. on the total expenditure of £7,522,000 was £435,776. Of the exchanges connected with the Post Office system in the metropolitan area on the 31st of March 1907 was 41,236, and additional subscribers were being connected at the rate of about 15,000 per year. The Post Office is continually extending the London area. The length of underground pipelines which had been laid in the metropolitan area for telephone purposes was 2030 m. Cables containing 317,789 m. of wire had been laid, including 69,066 m. recorded for the purpose of constructing an exchange circuit in the metropolitan area (including the installation of telephone instruments and of exchange apparatus, but excluding the provision of spare plant) has been £33, taking into account the whole system (including the plant of all kinds) and the capital expenditure per station (i.e., per telephone connected, with an exchange) stands at less than £50.

Anglo-G. and C. Trunk Telephone Service, which was opened between London and Paris in April 1891, was extended to the principal towns in England and France on the 11th of April 1904. The service has since been extended to cities in the British provincial towns; and the Anglo-Belgian telephone service has similarly been extended. There are now four circuits between London and Paris, one between London and the Belgian capital, and several others extending to carrying an increasing amount of traffic. Experiments have been made in telephonic communication between London and Rome by way of Paris. It was found possible to exchange speech when the conditions were exceptionally favourable; but, in spite of the partial success of the experiment, a public service between the two capitals is not at present practicable.

TELESCOPE, an optical instrument employed to view distant objects. The term "photographic telescope" has been applied to instruments employed to record the appearance of celestial objects by photography. The word was coined by Democritus, a Greek scholar, at the request of Fereglio Cesii, founder of the Accademia del Lince, from the Greek τηλεος, far, and οπαποιοι, to see. It was used by Galileo as early as 1612, and came into English use much later, when it supplanted the terms hitherto used to denote the telescope.

History

The credit of the discovery of the telescope has been a fruitful subject of discussion. Thus, because Democritus announced that the Milky Way is composed of vast multitudes of stars, it has been maintained that he could only have been led to form such an opinion from actual examination of the heavens with a telescope. Other passages from the Greek and Latin authors have similarly been cited to prove that the telescope was not invented until much later. In 1895 Dr. Robert Grant (History of Physical Astronomy, p. 515), we are no more warranted in drawing so important a conclusion from casual remarks, however sagacious, than we should be justified in stating that Seneca was in possession of the discoveries of Newton because he predicted that comets would one day be found to revolve in periodic orbits. William Molyneux, in his Dioptrica Nova (1602), p. 256, declares his opinion that Roger Bacon (who died c. 1264) "did perfectly well understand all kinds of optic glasses, and knew likewise the method of combining them so as to compose some such instrument as our telescope." He cites a passage from Bacon's Opus Majus, p. 377 of Jebb's edition, 1733, translated as follows—

"Greater things than these may be performed by refracted vision. For it is easy to understand by the canons above mentioned that the greatest objects may appear exceedingly small, and the contrary, also that the most remote objects may appear just at hand, and the converse; for we can give such figures to transparent bodies, and dispose them in such order with respect to the eye and the objects, that the rays shall be refracted and bent towards any place we please, so that we shall see the object near at hand or at any distance under any angle we please. And thus from an incredible distance we may read the smallest letters, and may number the smallest particles of dust and sand, by reason of the greatness of the figures which we can give to transparent bodies. All which stars may be made to descend hither in appearance, and to be visible over the heads of our enemies, and many things of the like sort, which persons unacquainted with such things would refuse to believe." Molyneux also cites from Bacon's Epistle ad Poriiseniem, p. 1176. The objections of the Ancients to the telescope—

"Glasses or diaphanous bodies may be so formed that the most remote objects may appear just at hand, and the contrary, so that..."
TELESCOPE

physician to the king of France, published at The Hague, in 1655, a work De vero Telescopio Inventore. He was assisted in its preparation by Willem Janssen, who owned the patent, and the latter declares, as the result of patient investigation, that Jansen and his father were the real inventors of the telescope in 1610, and that Leonard had not discovered it accidentally or gratuitously.

These passages certainly prove that Bacon had very nearly, if not perfectly, arrived at theoretical proof of the possibility of constructing a telescope and a microscope; but his writings give no account of the trial of an actual telescope, nor any detailed results of the application of a telescope to an examination of the heavens. It has been pointed out by Dr Robert Smith, in his Complete System of Opticks, that Bacon imagines some effects of telescopes which cannot be performed by them, and his conclusion is that Bacon never actually looked through a telescope.

Gambattista della Porta, in his Magia Naturalis, printed in 1561, makes the following remarkable statement:—

"The concave and convex glasses, if joined together, you will see both remote and near objects larger than they otherwise appear, and withal very distinct."

Wolfsius infers from this passage that its author was the first actual constructor of a telescope, and it appears not improbable that by happy accident Porta really did make some primitive forms of a telescope which excited the wonder of his friends. Here, however, his interest in the matter appears to have ceased, and he was unable either to appreciate the importance of his discovery or to describe the means by which the object was attained. Kepler, who examined Porta’s account of his concave and convex lenses by desire of his patron the emperor Rudolph, declared that it was perfectly unintelligible. Poggendorff (Gesch. der Physik, p. 134) throws considerable doubt on the originality of Porta’s statement.

Thomas Digges, in his Stratioticus, p. 359, published in 1579, states that his father, Leonard Digges, "among other curious practices had a method of discovering by perspective glasses set at due angles all objects pretty far distant that the sun shone upon, which lay in the country round about," and that this was by the help of a manuscript book of Roger Bacon of Oxford, who he conceived was the only man besides his father who knew it. There is also the following passage in the Pantometria (bk. i., chap. 21) of Leonard Digges 1 (originally published by his son Thomas in 1571, and again in 1591):—

"Marvellous are the conclusions that may be performed by glasses concave and convex, of circular and parabolic forms, using for multiplication of beams sometime the aid of glasses transparent, which, by refraction, shall unite or dissipate the images or figures presented by the refraction of other."

He then describes the effects of magnification from a combination of lenses or mirrors, adding:—

"But of these conclusions I mind not here to intreate, having at large in a volume 2 by itselfe opened the miraculous effects of perspective glasses."

It is impossible to discredit the significance of these quotations, for the works in which they occur were published more than twenty years before the original date claimed for the discovery of the telescope in Holland.

But it is quite certain that previous to 1600 the telescope was not possessed not yet possibly to individuals who failed to see its practical importance, and was upon its use to "curious practices" or to demonstrations of "natural magic." The practical discovery of the instrument was certainly made in Holland about 1608, but the credit of the original invention has been claimed on behalf of three individuals, Hans Lipperhey and Zacharias Jansen, spectacle-makers in Middelburg, and James Metius of Alkmaar (brother of Adrian Metius the mathematician).

Descartes, in his treatise on Optics (1637), attributes the discovery to Metius "about thirty years ago," whilst Schuyraeus de Rhetta, a Capuchin friar, in his Quaest. Ench. et Eliae (Antwerp, 1645), gives the credit to Lipperhey about 1609. Peter Borel, 3

1. He died about 1570. His son alludes to his untimely death in the preface to the Pantometria.
2. There is no further trace of this volume.

no tube was employed, and they were consequently termed aerial telescopes. Huygens contrived some ingenious arrangements for directing such telescopes towards any object visible in the heavens—the focal adjustment and centring of the eye-piece being preserved by a braced rod connecting the object-glass and eye-piece. Other contrivances for the same purpose are described by Philippe de la Hire (Mém. de l'Acad., 1715) and by Nicolaus Hartsoeker (Miscel. Berol., 1710, vol. i. p. 261).

Telescopes of such great length were naturally difficult to use, and must have taxed to the utmost the skill and patience of the observers. But even if they made admiration to the men who, with such troublesome tools, achieved such results.

Reflecting Telescopes.—Until Newton's discovery of the different refrangibility of light of different colours, it was generally supposed that object-glasses of telescopes were subject to no other errors than those which arose from the spherical figure of their surfaces, and the efforts of opticians were chiefly directed to the construction of lenses of other forms of curvature. James Gregory, in his Optics Promota (1663), devised for the production of images and objects produced by lenses and mirrors, and arranged that the intermediate surfaces of the lenses or mirrors are portions of spheres the images are curves concave towards the objective, but if the curves of the surfaces are conic sections the spherical aberration is corrected. He was well aware of the failures of all attempts to perfect telescopes by employing lenses of various forms of curvature, and accordingly proposed the form of reflecting telescope which bears his name. But Gregory, according to his own confession, had no practical skill; he could find no optician capable of realizing his ideas, and after some fruitless attempts was obliged to abandon all hope of bringing his telescope into practical use. Newton was the first to construct a reflecting telescope. When in 1666 he made his discovery of the different refrangibility of light of different colours, he soon perceived that the faults of the refracting telescope were due much more to this cause than to the spherical figure of the lenses. He overhastily concluded from some rough experiments (Optics, bk. i. pt. ii. prop. 3) "that all refracting substances diverged the prismatic colours in a constant proportion to their mean refracture"; and he drew the natural conclusion "that refraction did not produce, without colour," and therefore "that no improvement could be expected from the refracting telescope" (Treatise on Optics, p. 112). But, having ascertained by experiment that for all colours of light the angle of incidence is equal to the angle of reflexion, he turned his attention to the construction of reflecting telescopes. After much experiment he selected an alloy of tin and copper as the most suitable material for his specula, and he devised means for grinding and polishing them. He did not attempt the formation of a parabolic figure on account of the probable mechanical difficulties, and he had besides satisfied himself that the chromatic and not the spherical aberration formed the chief faults of previous telescopes. Newton's first telescope so far realized his expectations that he could see with its aid the satellites of Jupiter and the horns of Venus. Encouraged by this success, he made a second telescope of 63-in. focal length, with a magnifying power of 38 diameters, which he presented to the Royal Society of London in December 1671. A third form of reflecting telescope was devised in 1672 by Cassegrain (Journal des Savants, 1672). No further practical advance appears to have been made in the design or construction of the instrument till the year 1723, when John Hadley (best known as the inventor of the sextant) presented to the Royal Society his reflecting telescope of the Newtonian construction, with a metallic speculum of 6-in. aperture and 62½-in. focal length, having eye-pieces magnifying up to 230 diameters. The instrument was examined by Pound and Bradley, the former of whom reported upon it in Phil. Trans., 1723, No. 378, p. 382. After remarking that Newton's telescope "had lain neglected these fifty years," they stated that Hadley had sufficiently shown "that this noble invention does not consist

the first, he took it to Venice, where he communicated the details of his invention to the public, and presented the instrument itself to the doge Leonardo Donato, sitting in full council. The senate, in return, settled him for his life in his lectureship at Padua and doubled his salary, which was previously 500 florins and which then became treble that which any of his predecessors had enjoyed. Galileo may thus claim to have invented the telescope independently, but not till he had heard that others had done so. In fact the time was ripe; and, as often happens in similar circumstances, only a hint was necessary to complete the latent genius in the mind of the expert. He devoted all his time to improving and perfecting the telescope. Knowing the theory of his instrument, and possessed of much practical skill, coupled with unwearied patience, he conquered the difficulties of grinding and polishing the lenses, and soon succeeded in producing telescopes of greatly increased power. His first telescope magnified three diameters; but he soon made instruments which magnified eight diameters, and finally one that magnified thirty-three diameters. With this last instrument he discovered in 1610 the satellites of Jupiter, and soon afterwards the spots on the sun. This led to his invention of the microscope and the early valleys on the moon. He demonstrated the rotation of the satellites of Jupiter round the planet, and gave rough predictions of their configurations, proved the rotation of the sun on its axis, established the general truth of the Copernican system as compared with that of Ptolemy, and fairly routed the fanciful dogmas of the philosophers. These brilliant achievements, together with the immense improvement of the instrument under the hands of Galileo, overshadowed in a great degree the credit due to the original discoverer, and led to the universal adoption of the name of the Galilean telescope for the form of the instrument invented by Lipperhey.

Kepler first explained the theory and some of the practical advantages of a telescope constructed of two convex lenses in his Cælestrics (1611). The first person who actually constructed a telescope of this form was the Jesuit Christoph Scheiner, who gives a description of it in his Rosa Ursina (1630). William Gascoigne was the first who practically appreciated the chief advantages of the form of telescope suggested by Kepler, viz., the visibility of the image of a distant object simultaneously with that of a small material object placed in the common focus of the two lenses. This led to his invention of the micrometer and his application of telescopic sights to astronomical instruments of precision (see Micrometer). But it was not till about the middle of the 17th century that Kepler's telescope came into general use, and then, not so much because of the advantages pointed out by Gascoigne, but because its field of view was much larger than in the Galilean telescope. The first powerful telescopes of this construction were made by Huygens, after much labour, in which he was assisted by his brother. With one of these, of 12-ft. focal length, he discovered the brightest of Saturn's satellites (Titan) in 1655, and in 1659 he published his Systema Saturni, in which was given for the first time a true explanation of Saturn's ring, founded on observations made with the same instrument. The sharpness of image in Kepler's telescope is very inferior to that of the Galilean instrument, so that when a high magnifying power is required it becomes essential to increase the focal length. G. D. Cassini discovered Saturn's fifth satellite (Rhea) in 1672 with a telescope of 35 ft., and the third and fourth satellites in 1684 with telescopes made by Campani of 100- and 136-ft. focal length. Huygens states that he and his brother made object-glasses of 170 and 210 ft. focal length, and he presented one of 123 ft. to the Royal Society of London. Adrien Auzout (d. 1691) and others are said to have made telescopes of from 500 to 600 ft. focus, but it does not appear that they were ever able to use them in practical observations. James Bradley, on 27th December 1722, actually measured the diameter of Venus with a telescope whose object-glass had a focal length of 212½ ft. In these very long telescopes

1 This last power could not be exceeded with advantage in this form of telescope till after the invention of the achromatic object-glass.
TELESCOPE

in bare theory." They compared its performance with that of the object-glass of 125-ft. focal length presented to the Royal Society by Huygens, and found that Hadley's reflector

"will bear such a charge as to make it magnify the object as many times as the latter with its due charge, and that it represents objects as distinct, though not altogether so clear and bright... Norwithstanding the excellence in the original glass of the object

which was made compatible with this reflecting telescope to see whatever we have hitherto discovered with the Huygenian, particularly the transit of Jupiter's satellites and their shadows over his disk, the black line, burnt ring, and the edge of his shadow cast on his ring. We have also seen with it several times the five satellites of Saturn, in viewing of which this telescope had the advantage of the Huygenian at the time when we compared them; for, being in another, and the Huygenian telescope being managed for an eye-tube, the twilight prevented us from seeing in this some of these small objects which at the same time we could discern with the reflecting telescope.""Bradley and Molyneux, having been instructed by Hadley in his methods of polishing specula, succeeded in producing some telescopes of considerable power, one of which had a focal length of 8 ft.; and, Molyneux having communicated these methods to Scarlet and Hearne, two London opticians, the manufacture of telescopes as a matter of business was commenced by them (Smith's Opticks, bk. iii. ch. 1). But it was reserved for James Short of Edinburgh to give practical effect to Gregory's original idea. Born at Edinburgh in 1710 and originally educated for the church, Short attracted the attention of Maclaurin, professor of mathematics at the university, who persuaded him about 1731 to become a prelate, and to give the college buildings for experiments in the construction of telescopes. In Short's first telescopes the specula were of glass, as suggested by Gregory, but he afterwards used metallic specula only, and succeeded in giving to them true parabolic and elliptic figures. Short then adopted telescope-making as his profession, which he practised first in Edinburgh and afterwards in London. All Short's telescopes were of the Gregorian form, and some of them retain even to the present day their original high polish and sharp definition. Short died in London in 1768, having realized a considerable fortune by the exercise of his profession. Achromatic Telescope.—The historical sequence of events now brings us to the discovery of the achromatic telescope. The first person who succeeded in making achromatic refracting telescopes seems to have been Chester Moor Hall, a gentleman of Essex. He argued that the different humours of the human eye so refract rays of light as to produce an image on the retina which is free from colour, and he reasonably argued that it might be possible to produce a like result by combining lenses composed of different refracting media. After devoting some time to the study of the subject, and combining lenses found in different kinds of glass the effect of the unequal refrangibility of light was corrected, and in 1733 he succeeded in constructing telescopes which exhibited objects free from colour. One of these instruments of only 20-in. focal length had an aperture of 2½ in. Hall was a man of independent means, and seems to have been careless of fame; at least he took no trouble to communicate his invention to the world. At a trial in Westminster Hall about the patent rights granted to John Dollond (Watkin v. Dollond),2 Hall was admitted to 1 The same argument was employed by Gregory more than fifty years previously, but had been followed by no practical result. The lens of the human eye is not achromatic.

2 At a meeting of the Royal Astronomical Society held on 9th May 1886 a legal document, signed by Chester Moor Hall, was presented by R. B. Procter of the Patent Office to the society. On the same occasion A. C. Gray made the following interesting statement respecting Hall:—

"Some years ago very little was known about Moor Hall. It was generally supposed that he was the inventor of the achromatic object-glasses. In 1733 the Copley medal had been awarded to Dollond for making achromatic object-glasses, it was claimed by the latter that Hall had invented the achromatic object-glasses at least seven years before the patent for making achromatic object-glasses was granted to Dollond, and in 1747 Lord Mansfield held in an action that John Dollond was not the real inventor, and that such telescopes had been made twenty-five years before the granting of his patent by Mr Moor Hall. John Dollond, to whom the Copley medal of the Royal Society had been the first inventor of the achromatic telescope; but it was ruled by Lord Mansfield that "it was not the person who locked his invention in his scrutatory that ought to profit for such invention, but he who brought it forth for the benefit of mankind." In 1747 Leonhard Euler communicated to the Berlin Academy of Sciences a memoir in which he endeavoured to prove the possibility of correcting both the chromatic and the spherical aberration of an object-glass. Like Bradley and Hall, he argued that, since the various humours of the human eye were so combined as to produce a perfect image, it should be possible by suitable combinations of lenses of different refracting media to construct a perfect object-glass. Adopting Euler's mathematical line of reasoning, and using the rays of light, he proved analytically the possibility of constructing an achromatic object-glass composed of lenses of glass and water. But all his efforts to produce an actual object-glass of this construction were fruitless—a failure which he attributed solely to the difficulty of procuring lenses worked precisely to the requisite curves (Mem. Acad. Berlin, 1753). Dollond admitted the accuracy of Euler's analysis, but disputed his hypothesis on the grounds that it was purely a theoretical assumption, that the theory was opposed to the results of mathematical experiments, and that he proved it impossible to determine a physical law from analytical reasoning alone (Phil. Trans., 1753, p. 286). In 1754 Euler communicated to the Berlin Academy another memoir, in which, starting from the hypothesis that light consists of vibrations excited in an elastic fluid by luminous bodies, and that the difference of colour of light is due to the greater or less frequency of these vibrations in a given time, he deduced his previous results. He did not doubt the accuracy of Newton's experiments quoted by Dollond, because he asserted that the difference between the law deduced by Newton and that which he assumed would not be rendered sensible by such an experiment. Dollond did not reply to this memoir, but soon afterwards he received an abstract of a memoir by Samuel Klingenstierna, the Swedish mathematician and astronomer, which led him to doubt the accuracy of the results deduced by Newton on the dispersion of refracted light. Klingenstierna showed from purely geometrical considerations, fully appreciated by Dollond, that the results of Newton's experiments could not be brought into harmony with other universally accepted facts of refraction. Like a practical man, Dollond at once put his theory to the test of experiment, confirmed the conclusions of Klingenstierna, disproved "a difference far beyond his experiments in the refractive qualities of different kinds of glass with respect to their divergency of colours," and was thus rapidly led to the construction of achromatic telescopes in which first the chromatic and afterwards the spherical aberration were corrected (Phil. Trans., 1758, p. 733).

We have thus followed somewhat minutely the history of the gradual process by which Dollond arrived independently at his invention of the refracting telescope, because it has been asserted that he borrowed the idea from others. Montucla, given for his invention, was the dead, and his son brought an action for infringing the patent against Champness. There is no report of the case, but the facts are referred to in the reports of the committee. It appears that the workmen who had been employed by Mr Moor Hall were examined, and proved that they had made achromatic object-glasses as early as 1733. Dollond's patent was not set aside, though the evidence with regard to the prior manufacture was accepted by Lord Mansfield, who tried the case, as having been satisfactorily proved... Mr Hall was a bencher of the Inner Temple, and was alive at the time of the action. He was a man of some profession, and some property, and (as his tombstone as an excellent lawyer and mathematician. He was not a fellow of the Royal Society, but must certainly have known of the gift of the Copley medal to Dollond, as it was given to him in the same year that Dollond's patent was granted." (Astron. Register, May 1886, p. 219.)

4 For a good account of this controversy, see Dr H. Servus, Geschichte der Fernrohrs, p. 77 seq. (Berlin, 1880).
in his *Histoire des Mathématiques* (pp. 448-449), gives the following footnote, communicated to him by Lalande:

"Ce fut Chestertonhall" (an obvious misprint for Chest Moor Hall) "qui, vers 1750, eut l'idée des lunettes achronomiques. Il s'adressait à Dollond, comme il le dit, mais Dollond, ayant eu besoin de Bass pour un verre que demandait le duc d'Yorck, se reporta à Ayscough. Ayscough, qui fut le dernier maître verrier de Londres, a donné de la construction à Bird, qui n'en tint point compte. Dollond en profitant. Dans le procès qu'il eut entre Dollond et Watkin, au banc du roi, cela fut prouvé; mais Dollond gagna, parce qu'il étoit le premier qui eut fait d'ales lunettes achronomiques."  

It is clearly established that Hall was the first inventor of the achromatic telescope; but Dollond did not borrow the invention from Hall without acknowledgment in the manner suggested by Lalande. His discovery was beyond question an independent one. The whole history of his researches proves how fully he was aware of the conditions necessary for the attainment of achromatism in refracting telescopes, and he may be well excused if he so long placed implicit reliance on the accuracy of experiments made by so illustrious a philosopher as Newton. His writings sufficiently show that but for this constant limitation he might have arrived sooner at a discovery for which his mind was fully prepared. It is, besides, impossible to read Dollond's memoir (*Phil. Trans.*, 1758, p. 733) without being impressed with the fact that it is a truthful account, not only of the successive steps by which he independently arrived at his discovery, but also of the logical processes by which these steps were successively suggested to his mind.

The triple object-glass, consisting of a combination of two convex lenses of crown glass with a concave flint lens between them, was introduced in 1765 by Peter, son of John Dollond, and many excellent telescopes of this kind were made by him.

The limits of this article do not permit a further detailed historical statement of the various steps by which the powers of the telescope were developed. Indeed, in its practical form the principle of the instrument has remained unchanged from the time of the Dollonds to the present day; and the history of its development may be summed up as consisting not in new optical discoveries but in utilizing new appliances for figuring and polishing, improved material for specula and lenses, more refined means of testing, and more perfect and convenient methods of mounting.

About the year 1786, William Herschel, then a teacher of music in Bath, began to occupy his leisure hours with the construction of specula, and finally devoted himself entirely to their construction and use. In 1778 he had selected the *chef-d'œuvre* of some 400 specula which he made for the celebrated instrument of 7-ft. focal length with which his early brilliant astronomical discoveries were made. In 1783 he completed his reflector of 18½ in. aperture and 20-ft. focus, and in 1789 his great reflector of 4-ft. aperture and 40-ft. focal length. The fame of these instruments was rapidly spread by the brilliant discoveries which their maker's genius and perseverance accomplished by their aid. The reflecting telescope became the only available tool of the astronomer when great light grasp was requisite, as the difficulty of procuring disks of glass (especially of flint glass) of suitable purity and homogeneity limited the dimensions of the achromatic telescope. It was in vain that the French Academy of Sciences offered prizes for perfect disks of optical flint glass. Some of the best chemists and most enterprising glass-manufacturers exerted their utmost efforts without succeeding in producing perfect disks of more than 33 in. in diameter. All the large disks were crossed by striae, or were otherwise deficient in the necessary homogeneity and purity. The subsequent history of the development of the art of manufacturing glass disks for telescopic objectives will be found in the article GLASS: § Optical Instruments, &c.

We proceed to give an account of the methods and principles of construction of the various kinds of telescopes, and to describe in detail special typical instruments, which, owing to the work accomplished by their aid or the practical advances exemplified in their construction, appear most worthy of record or study.

**Refracting Telescope**

In its simplest form the telescope consists of a convex objective capable of forming an image of a distant object and of an eye-lens, concave or convex, by which the image so formed is magnified. When the axis of the eye-lens coincides with that of the object-glass, and the focal point of the eye-lens is coincident with the principal focus of the object-lens, parallel rays incident upon the object-glass will emerge from the eye-piece as parallel rays. These, falling in turn on the lens of the human eye, are converged by it and form an image on the retina.

Fig. 1 shows the course of the rays when the eye-lens is convex (or positive), fig. 2 when the eye-lens is concave (or negative). The former represents Kepler's, the latter Lippershey's or the Galilean telescope. The magnifying power obviously depends on the proportion of the focal length of the object-lens to that of the eye-lens, that is,

\[ \text{magnifying power} = \frac{F_e}{F_o} \]

where \( F_e \) is the focal length of the object-lens and \( e \) that of the eye-lens, and \( F_o \) is also the diameter of the pencil or parallel rays emerging from the eye-lens, which is the focal diameter of the object-lens inversely as the magnifying power of the telescope. Hence one of the best methods of determining the magnifying power of a telescope is to measure the diameter of the emergent pencil of rays, and to focus the telescope has been adjusted to focus upon a star, and to divide the diameter of the object-glass by the diameter of the emergent pencil. If we desire to utilize all the parallel rays which fall upon an object-glass it is necessary that the full pencil of emerging rays should enter the observer's eye. Assuming with Sir William Herschel that the normal pupil of the eye extends to one-fifth of an inch in diameter when viewing faint objects, we obtain the rule that the minimum magnifying power which can be efficiently employed is five times the diameter of the object-glass expressed in inches.

The defects of the Galilean and Kepler telescopes are due to the chromatic and spherical aberration of the simple lenses of which they are composed. The substitution of a positive or negative eye-piece for the simple convex or concave eye-lens in the Galilean, or achromatic object-glass for the simple object-lens, transforms these early forms into the modern achromatic telescope. The Galilean telescope with a concave eye-lens instead of an eye-piece still suffers from the defects of the modern achromatic combination, but the object-glass and eye-lens are achromatic combinations.

(D. G.)

**Telescope Objectives.**—In spite of the improvements in the manufacture of optical glass (see GLASS) practically the same crown and flint glasses as used by John Dollond in 1738 for achromatic objectives are still used for all the largest of the modern refracting telescopes.

It has long been known that the spectra of white or solar light yielded by ordinary crown and flint glasses are different: that while two prisms of such glasses may be arranged to give exactly the same angular dispersion between two Fraunhofer lines, in the case of short-sighted persons the image for very distant objects (that is, for parallel rays) is formed in front of the retina; therefore, to enable such persons to see distinctly, the rays emerging from the eye-piece must be slightly divergent; that is, they must enter the eye as if they proceeded from a comparatively near object. For normal eyes the natural adaptation is not to focus for quite parallel rays, but on objects at a moderate distance, and practically in the same manner, more or less to adjust the focus of a telescope, for most distinct and easy vision, so that the rays emerge from the eye-piece very slightly divergent. Abnormally short-sighted persons require to push in the eye-lens nearer to the object-glass, and long-sighted persons to withdraw it from the adjacent lens, employed by those of normal sight. It is usual, however, in computations of the magnifying power of telescopes, for the rays emerging from the eye-piece when adjusted for distinct vision to be parallel.

For the methods of grinding, polishing and testing lenses, see OBJECTIVE.
lines, such as C and F, yet the flint glass prism will show a relative drawing out of the blue end and a crowding together of the red end of the spectrum, while the crown prism shows an opposite tendency. This want of proportion in the dispersion for different regions of the spectrum is called the "irrationality of dispersion"; and it is as a direct consequence of this irrationality, that there exists a secondary spectrum or residual colour dispersion, showing itself at the focus of all such telescopes, and roughly in proportion to their size. These glasses, however, still hold the field, although glasses are now produced whose irrationality of dispersion has been reduced to a very slight amount.

The primary reason for this retention is that nothing approaching the difference in dispersive power between ordinary crown glass and ordinary dense flint glass (a difference of $1$ to $1\frac{1}{2}$) has yet been obtained between any pair of the newer glasses. Consequently, for a certain focal length, much deeper curves must be resorted to if the new glasses are to be employed; this means not only greater difficulties in workmanship, but also greater thickness of glass, which mitigates against the chance of obtaining large disks quite free from strain and perfect in their state of annealing. In fact, superfine disks of over 15 in. aperture are scarcely possible in most of the newer telescope glasses. Moreover the greater depths of the curves (or "curvature powers") in itself neutralize more or less the advantages obtained from the reduced irrationality of dispersion. When all is taken into consideration it is scarcely possible to reach the secondary curve at the focus of such a double object-glass to less than a fourth part of that prevailing at the focus of a double objective of the same aperture and focus, but made of the ordinary crown and flint glasses.

The only way in which the secondary spectrum can be reduced still further is by the employment of three lenses of three different sorts of glass, by which arrangement the secondary spectrum has been reduced in the case of the Cooke photo visual objective to about 1/30th part of the usual amount, if the whole region of the visible spectrum is taken into account. It is possible to construct a triple objective of two positive lenses enclosing between them one negative lens, the two former being made of the same glass. For relatively short focal lengths a triple construction such as this is almost necessary in order to obtain an objective free from aberration of the 3rd order, and it might be thought at first that, given the closest attainable degree of rationality between the colour dispersions of the two glasses employed, which we will call crown and flint, it would be impossible to devise another form of triple objective, by retaining the same flint glass, but adopting two sorts of crown instead of only one, which would have the secondary spectrum very much further reduced. Yet such is the rather surprising fact. But it can be well illustrated in the case of the older glasses, as the following case will show.

The figures given are the partial dispersions for ordinary crown and ordinary extra dense flint glasses, styled in Messrs. Schott's catalogue of optical glasses as o-60 and o-102 respectively, having refractive indices of 1.5179 and 1.6480 for the D ray respectively, and $(\mu_{0} - 1)/(\mu_{4} - \mu_{0}) = 62:2$ and 33:8 respectively to indicate their dispersive powers (inverted), $= \frac{4}{\mu}$. The $\Delta \mu$ from C to F being taken as unity in each case, then the $\Delta \mu$s for the other regions of the spectrum are expressed in fractions $\Delta \mu$ (C to F) and are given under the asterisks. Let it be supposed that two positive lenses of equal curvature powers are made out of these two glasses, then in order to represent the combined dispersion of the two together the two $\Delta \mu$s for each spectral region may be added together to form $\Delta \mu$ as in the line below, and then, on again expressing the partial $\Delta \mu$s in terms of $\Delta \mu$ (C to F) we get the new figures in the bottom row beneath the asterisks. We find that we have now got a course of dispersion or degree of rationality which very closely corresponds to that of an ordinary light flint glass, styled o-569 in Schott's catalogue, and having $\mu_{0} 1.5738$ and $(\mu_{4} - 1)/(\mu_{4} - \mu_{0}) = 41:4 = r$, the figures of whose course of dispersion are as below:

\[
\begin{array}{|c|c|c|c|c|}
\hline
\text{C to F} & A' to D & D to F & F to G \\
\hline
0.01385 & 1.000 & 0.00583 & 615. & 0.0087 & 713 & 0.00831 & 600 \\
\hline
\end{array}
\]

Hence it is clear that if the two positive lenses of equal curvature power of o-60 and o-102 respectively are combined with a negative lens of light flint o-569, then a triple objective, having no secondary spectrum (at any rate with respect to the blue rays), may be obtained.

But while an achromatic combination of o-60 and o-102 alone will yield an objective whose focal length is only 1:28 times the focal length of the negative or extra dense flint lens, the triple combination will be found to yield an objective whose focal length is 73 times as great as the focal length of the negative light flint lens. Hence impossibly deep curvatures would be required for such a triple objective of any normal focal length. This case well illustrates the much closer approach to strict rationality of dispersion which is obtainable by using two different sorts of glass for the two positive lenses, even when one of them has a higher dispersive power than the glass used for the negative lens.

It is largely to this principle that the Cooke photo visual objective of three lenses (fig. 3) owes its high degree of achromatism. This form of objective has been successfully made up to 12½ in. clear aperture. The front lens is made of baryta light flint glass.

![Fig. 3.](image)

(0-543 of Schott's catalogue) and the back lens of a crown glass, styled o-374 in Schott's older lists.

The table gives their partial dispersions for six different regions of the spectrum also expressed (in brackets) as fractional parts of the dispersion from C to F.

\[
\begin{array}{|c|c|c|c|c|c|}
\hline
\text{C to F} & A to D & D to F & E to F & F to G' & F to H \\
\hline
0.543 & 0.1145 & 0.00374 & 0.00790 & 0.00369 & 0.00650 & 0.01322 \\
(1-000) & (1-000) & (1-000) & (1-000) & (1-000) & (1-000) & (1-000) \\
\hline
0.374 & 0.00844 & 0.00296 & 0.00893 & 0.00247 & 0.00479 & 0.00976 \\
(1-000) & (1-000) & (1-000) & (1-000) & (1-000) & (1-000) & (1-000) \\
\hline
\end{array}
\]

Since the curvature powers of the positive lenses are equal, the partial dispersions of the two glasses may be simply added together, and we then have:

\[
\begin{array}{|c|c|c|c|c|c|}
\hline
\text{C to F} & A to D & D to F & E to F & F to G' & F to H \\
\hline
0.1959 & 0.00670 & 0.01383 & 0.00643 & 0.0129 & 0.02298 \\
(1-000) & (1-000) & (1-000) & (1-000) & (1-000) & (1-000) \\
\hline
\end{array}
\]

The proportions given on the lower line may now be compared with the corresponding proportional dispersions for borosilicate flint glass o-658, closely resembling the type o-164 of Schott's list, viz.:

\[
\begin{array}{|c|c|c|c|c|c|}
\hline
\text{C to F} & A to D & D to F & E to F & F to G' & F to H \\
\hline
0.068 & 1.546 & 0.0501 & 1.748 \\
(1-000) & (1-000) & (1-000) & (1-000) & (1-000) & (1-000) \\
\hline
\end{array}
\]
A slight increase in the relative power of the first lens of 0.543 would bring about a still closer correspondence in the rationality, but with the curves required to produce an object-glass of this type of 6 in. aperture and 108 in. focal length a discrepancy of 1 unit in the third decimal place in the above proportional figures would cause a linear error in the focus for that colour of only about 0.025 in., so that the largest deviation implied by the tables would be a focus for the extreme violet H ray about 0.37 longer than the normal. It will be seen, then, that the visual and photographic foci are now merged in one, and the image is practically as achromat as that yielded by a reflector.

Other types of triple object-glasses with reduced secondary spectra have recently been introduced. The extension of the image away from the axis or size of field available for converting a photographic plate with fair definition is a function in the first place of the ratio between focal length and aperture, the longer focus having the greater relative angular covering power, and in the second a function of the curvatures of the lenses, in the sense that the objective must be free from coma at the foci of oblique pencils or must fulfil the sine condition (see ABERRATION).

Eye-pieces.—The eye-pieces or oculars through which, in case of visual observations, the primary images formed by the objective are viewed, are of quite secondary importance as regards definition in the central portion of the field of view. If an eye-piece blurs the definition in any degree in the centre of the field it must be very badly figured indeed, but the definition towards the edge of the field, say at 20° away from the centre, is, of the field of view, depends very intimately upon the construction of the eye-piece. It must be so designed as to give as flat an image as is possible consistently with freedom from astigmatism of oblique pencils. The mere size of the apparent field of view depends upon obtaining the oblique pencils of light emerging from it to cross the axis at the great possible angle, and to this end the presence of a field-lens is indispensable, which is separated from the eye-lens by a considerable interval.

The earlier arrangement of two lenses of the Huygenian eye-piece (see MICROSCOPE) having foci with ratio of 3 to 1, gives a fairly large flat field of view approximately free from distortion of tangential lines and from coma, while the Mittenzwey variety of it (fig. 4) in which the field-lens is changed into a meniscus having radii in about the ratio of +1 to -9 gives still better results, but still not quite so good as the results obtained by using the combination of two convexo-plane lenses of the focal ratio 2 to 1.

In the Ramsden eye-piece (see MICROSCOPE) the focal lengths of the two plane-convex lenses are equal, and their convexities are turned towards one another. The field-lens is thus in the principal focal plane of the eye-lens, if the separation be equal to \( \frac{1}{2}(f+\frac{2}{3}r) \). This is such a practical drawback that the separation is generally \( \frac{3}{4}r \) or \( \frac{2}{3}r \) of the theoretical, and then the principal image viewed by the eye-piece may be rather outside the field-lens, which is a great practical advantage, especially when a reticule has to be mounted in the primary focal plane, although the edge of the field is not quite achromatic under these conditions.

Kellner Eye-piece.—In order to secure the advantage of the principal focal plane of the eye-piece being well outside of the field-lens and at the same time to obtain a large flat field of view with oblique achromatism and freedom from coma and distortion, there is no better construction than the modified Kellner eye-piece (fig. 5) such as is generally used for prismatic binoculars. It consists of a plane-convex field-lens, a convex glass and an approximately achromatic eye-lens, some distance behind it, consisting of an equi-convex crown lens cemented to a concavo-convex lens, the latter being attached.

There are also other eye-pieces having the field-lens double or achromatic as well as the eye-lens, in cases where it is important to get the maximum quantity of light into the eye, the field-lens is discarded and an achromatic eye-lens alone employed. This yields a very much smaller field of view, but it is very valuable for viewing feeble telescopic objects and very delicate planetary or lunar details. Zeiss and Steinhelf's monochromatic eye-pieces and the Cooke annular achromatic eye-piece (fig. 6) are examples of this class of oculars. (H. D. T.)

Reflecting Telescopes.

The following are the various forms of reflecting telescopes:

The Gregorian telescope is represented in fig. 7. A and B B are concave mirrors having a common axis and their concavities facing each other. The focus of A for parallel rays is at F, that of B for parallel rays at \( \frac{A}{B} \) between B and F. Parallel rays falling on A converge at F, where an image is formed of the rays after they have reflected from the two concave surfaces. A and B. In the case of parabolic mirrors the aberrations tend to increase each other, and it is extremely difficult to give a true elliptic figure to the necessarily deep concavity of the small specular. Short aperture telescopes having the spherical aberration in a manner, and his Gregorian telescopes act in the present day. The magnifying power of the telescope is \( \frac{F}{f} \), where F is the focal length of the large and small mirror, f the focal length of the eye-piece, and \( x \) the distance between the two (chief) foci of the two mirrors (\( =f \)) in the diagram when the instrument is in adjustment for viewing distant objects. The images are erect.

The Cassegrain telescope differs from the Gregorian only in the substitution of a convex hyperboloidal mirror for a concave ellipsoidal mirror as the small specular. This form has the following two distinct advantages: (1) If spherical mirrors are employed their aberrations have a tendency to correct each other; (2) the instrument is shorter than the Gregorian, caeteris paribus, by twice the focal length of the small Concave mirror. Fewer telescopes have been made of this than perhaps of any other form of reflector; but in comparatively recent years the Cassegrain has acquired importance from the fact of its adoption for the great Melbourne telescope and from its employment in the 60-in. reflector of the Mount Wilson Solar Observatory (see below). For spectroscopic purposes the Cassegrain form has peculiar advantages, because in consequence of the less rapid convergence of the rays after reflection from the convex hyperboloidal mirror, the equivalent focus can be made very great in comparison with the length of the tube. This permits the employment of a spectroscope furnished with a collimation of long focus. The magnifying power is computed by the same formula as in the case of the Gregorian telescope.

The Newtonian telescope is represented in fig. 8. A A is a concave mirror whose axis is \( \infty \). Parallel rays falling on A converge to a principal focal plane, and are reflected at right angles to the axis, forming an image in the focus of the eye-piece E. The surface of the large mirror should be a paraboloid of revolution, that of the small mirror a true optical plane. The magnifying power is \( \frac{F}{f} \). This form is employed in the
construction of most modern reflecting telescopes. A glass prism of
total reflection is sometimes substituted for the plane mirror.

The Herschelian or front view reflector is represented in fig. 9. A A is a concave parabolic mirror, whose axis is perpendicular to the axis of the tube a b so that the image of an object in the focus of the mirror may be viewed by an eye-piece at E, the angle a b c being equal to the angle e c E. This form was adopted by the elder Herschel to avoid the loss of light from reflection in the small mirror of the Newtonian telescope. The view from the telescope, however, has hardly been at all employed except by the Herschels. But at the same time two instruments have swept the whole sky for the discovery of faint nebulae; and

probably no other astronomers have worked for so many hours on end for so many nights as they did, and they emphasize the easy
position of the observer in using this form of instrument.

Construction of Specula.
The composition of metallic specula in the present day differs very little from that used by Sir Isaac Newton. Many different alloys have been suggested, some including silver, nickel, zircon or arsenic; but that which has been practically found best is an alloy of four equivalents of copper to one of tin, or the following proportions by weight: copper 252, tin 117-8. Such speculum metal is exceedingly hard and brittle, takes a fine white polish, and when subjected to flame has little liability to tarnish. The process of casting and annealing, in the case of the specula of the great Melbourne telescope, was admirably described by Dr Robinson in Phil. Trans., 1869, 159, p. 135. Shaping, polishing and figuring of specula are accomplished by methods and tools very similar to those employed in the construction of lenses. The reflecting surface is first ground to a spherical form, the parabolic figure being given in the final process by regulating the size of the pitch squares and the stroke of the polishing machine.

Soon after Liebig's discovery of a process for depositing a film of pure metallic silver upon glass from a salt of silver in solution, Steinheli (Gaz. Univ. d'Augsburg, 24th March 1850), and later, independently, Foucault (Comptes Rendus, vol. xliv., February 1857), proposed to employ glass for the specula of telescopes, the reflecting surface of the glass speculum to be covered with silver by Liebig's process. Those silver-on-glass specula are now the rivals of the achromatic telescope, and it is not probable that many telescopes with metal specula will be made in the future. The best speculum metal and the greatest care are no guarantee of freedom from tarnish, and, if such a mirror is much exposed, as it must be in the hands of an active observer, frequent repolishing will probably be necessary. This involves refiguring, which is the most delicate and costly process of all. Every time, therefore, that a speculum is repolished, the future quality of the instrument is at stake; its focal length will probably be altered, and thus the value of the constants of the micrometer also have to be reetermined. Partly for these reasons the reflecting telescope with metallic mirror has never been a favourite with the professional astronomer, and has found little employment out of England. In England, in the hands of the Herschels, Rosse, Lassell and De la Rue it has done

1 There is a noteworthy exception in the case of the 18-in. speculum-metal mirror employed by Sir William Huggins at Tulse Hill, with which a large part of his remarkable and important series of astrospectroscopic results have been obtained. So far as we know, this mirror has never been repolished since its first installation in 1870, and still retains its admirable surface. One of the mirrors, made about 1760 or 1770, of 6-in. aperture, now in the possession of Sir William Huggins, has surfaces which still retain their original perfection although they have never been repolished.

2 Herschel, Phil. Trans., 1795, 85, p. 347; Rosse, Phil. Trans. 1840, p. 503; 1861, p. 581.

TELESCOPE

Mounting of Telescopes.
The proper mounting of a telescope is hardly of less importance
than its optical perfection. Freedom from tremor, ease and
delicacy of movement and facility of directing the instrument
to any desired object in the heavens are the primary qualifica-
tions. Where accurate differential observations or photographs
involving other than instantaneous exposures have to be made,
the additional condition is required that the optical axis of the
telescope shall accurately and automatically follow the object
under observation in spite of the apparent diurnal motion of
the heavens, or in some cases even of the apparent motion of
the object relative to neighbouring fixed stars.

We pass, therefore, directly to the equatorial telescope, the
instrument par excellence of the modern extra-meridian
astronomer. The article Transit Circle describes one form
of mounting in which the telescope is simply a refined sub-
stitute for the sights or pinules of the old astronomers. The
present article contains a description of the mounting of the
various forms of the so-called zenith telescope. In its simplest
form the mounting of an equatorial telescope consists of an axis
parallel to the earth's axis, called "the polar axis"; a second
axis at right angles to the polar axis called "the declination
axis"; and the telescope tube fixed at right angles to the
declination axis.

In Fig. 10 A A is the polar axis; the telescope is attached to the
declination axis; the latter rotates in bearings which are
attached to the polar axis and concealed by the telescope itself.
The telescope is counterpoised by a weight attached to the opposite
end of the declination axis. The lower pivot of the polar axis rests
in a cup-bearing at C, the upper bearing upon a strong metal casting
M M attached to stone ster piler S. A vertical plane
passing through A A is therefore in the meri-
dian, and the polar axis is inclined to the horizon at an angle equal to the
amount of the latitude of the place of
observation. Thus when the decli-
nation axis is horizontal the telescope
moves in the plane of the horizon
by rotation about the polar axis.

When the declination axis is hori-
izontal the telescope moves in the plane of the horizon by rotation about the
declination axis only. Now, if a
graduated circle B B is attached to the declination axis, together with
the necessary vernier for microscopes V V for reading it (see Transit
Circle), so arranged that when the telescope is turned on the declina-
tion axis till its optical axis is parallel to A A the vernier reads o°
and when at right angles to A A 90°, then we can employ the readings of
this circle to measure the polar distance of any star seen in the tele-
scope, and the readings will also be true (apart from the effects of
atmospheric refraction) in any position taking the meridian of the
observer as the axis A A. Thus one important attribute of an equatorially
mounted telescope that, if it is directed to any fixed star, it will
follow the diurnal motion of that star from rising to setting by
rotation of the polar axis only. If we now attach to the polar axis
a graduated circle D D, called the "hour circle," of which the
microscope or vernier K reads ° when the declination axis is
horizontal, we can obtain by this means the hour angle of the hour
of any star to which the telescope may be directed at the
instant of observation. If the local sidereal time of the observation
is known, the right ascension of the star becomes known by adding
the observed hour angle to the sidereal time if the star was on the
meridian, or subtracting it if east of the meridian. Since the
transit circle is preferable to the equatorial for such observations
wherein great accuracy is required, the declination and hour circles
of an equatorial are employed, not for the determination of the right
ascensions and declinations of celestial objects, but for directing
the telescope with ease and certainty to any object situated in an
approximately known position, and which may or may not be
visible to the naked eye, or to define approximately the position of
an unknown object. Further, by causing the hour circle, and
with it the polar axis, to rotate by clockwork or some similar
mechanical contrivance, at the same angular velocity as the earth
on its axis, but in the opposite direction, the telescope will, apart
from the effects of refraction, automatically follow a star from
rising to setting.

Types of Equatorials.—Equatorial mountings may be divided into
six types. (A) The pivots or bearings of the polar axis are placed
at its upper extremities. The declination axis rests on bearings attached
to opposite sides of the polar axis. The telescope is attached to
the end of the declination axis, and counterpoised by a weight at
the other end, as in fig. 10. (B) The polar axis is supported as in
the preceding; the telescope is mounted on the declination axis and
is mounted symmetrically with respect to the polar axis; no
counterpoise is therefore requisite. (C) The declination axis
is mounted on the prolongation of the upper pivot of the polar axis;
the telescope is placed at one end of the declination axis and counter-
poised by a weight at the other end. (D) The declination axis
is mounted on a forked piece or other similar contrivance attached
to a prolongation of the upper pivot of the polar axis; the tele-
scope is mounted between the pivots of the declination axis. (D)
The eye-piece of the telescope is placed in the pivot of the polar
axis; a portion or the whole of the axis of the telescope tube co-
incides with the polar axis. (F) The telescope is fixed and the rays
are reflected along its axis from an external mirror or mirrors.
Mountings of types A and B—that is, with a long polar axis sup-
ported at both ends—are often called the "English mounting," and
type C, in which the declination axis is placed on the extension
of the upper pivot of the polar axis, is called the "German mounting,"
from the first employment of type C by Fraunhofer. A description
of some of the best examples of each type will illustrate their relative
advantages or peculiarities.

Type A.—Fig. 10 may be taken as a practical example of the
earlier equatorials as made by Troughton in England and afterwards
by the various English and French observatories. In the Phil. Trans.
for 1824 (part 3, pp. 1-421) will be found a description by Sir John
Herschel of the Great Refractor of Sir James South, one of the
earliest equatorial telescopes which they employed in their measurements
of double stars. The polar axis was
similar in shape to that of fig. 10,
and was composed of sheets of tinned
iron. In Smyth's celebrated Bedford telescope the polar axis was
made of mahogany. Probably the best
example of this type of mounting
applied to a refractor is that made
by the late Mr. Cooke of the firm of
Dorset, of Tarnbank: the polar axis
is of cast iron and the mounting very satisfactory and convenient, but
unfortunately no detailed description has been published. In recent
years another important type of mounting has been introduced.

Type B.—The most important examples of type B are Airy's
equatorial at Greenwich (originally made to carry a telescope of
13-in. aperture, but now fitted with a telescope by Grubb of 28-in.
aperture), and the photographic equatorials of 13-in. aperture
employed at Paris and other French observatories. Some slight
alterations have been made in the design in this plan; but type B
has been chosen by Grubb for the great Melbourne reflector, of 48-in. aperture, with marked
success. The various parts of the instrument are peculiarities of the case.
Fig. 11 shows the whole instrument on
a small scale with the telescope directed to the pole, and the hour
circle set ° from the meridian.

pendently of the clock. Slow motion in declination can be com-
monicated by a screw acting on a long arm, which latter can be
cramped at pleasure to the polar axis. An oblong metallic box
fitted with pivots, whose bearings are attached to the triangular
frame, forms for the tube for two parallel telescopes: these are
separated throughout their length by a metallic diaphragm. The
chromatic aberration of the object-glass of one of these telescopes
is corrected for photographic rays, and the image formed by it is
received on a highly sensitive photographic plate. The other
telescope is corrected for visual rays and its image is formed on the
plane of the spider-threads of a micrometer. The peculiar form
of the tube is admirably suited for rigid preservation of the relative
parallelism of the axes of the two telescopes, so that, if the image
of a certain selected star is retained on the intersection of two wires
of the micrometer, by means of the driving clock, aided by small
axes in composed of hollow metal in right ascension and declination
(required on account of irregularity in the clock movement, error
in astronomical adjustment of the polar axis, or changes in the star's
apparent place produced by refraction), the image of a star will
continue on the same spot of the photographic film during the whole
time of exposure. In these telescopes the photographic object-
glass has an aperture of 15 in. and the visual object-glass of 10 in.
Both telescopes have the same focal length, viz. 112 ft., so that,
in the image produced, 1 mm. is = 1° of arc. An excellent mounting
of type B, made by T. Cooke & Sons of York, has been employed
by Franklin Adams for making his maps of the sky.

Type C.—Many more telescopes have been made of type C than
of any other, and this form of mounting is still most generally
employed for the mounting of modern reflectors. Fraunhofer's
chef-d'oeuvre, the great Dorpat reflector, made for Otto Struve
about 1820, had a mounting of this type, and was the first equatorial
of any importance to be provided with clockwork. The instrument,
shown in fig. 13, is described in detail by Struve (Beschreibung des
auf der Sternwarte zu Dorpat befindlichen grossen Refraktors von
Fraunhofer, Dorpat, 1825), and was an enormous advance upon all previous telescopes for micrometric research. In the hands of Struve results were obtained by it which in combined quality and quantity had never before been reached. Its success was such that the type of Fraunhofer's telescope became stereotyped for many years not only by Fraunhofer's successors but throughout Germany. When, twelve years afterwards, Struve ordered the 15-in. refractor for the new observatory at Pulkovo, the only important change made by Fraunhofer's successors was, at Struve's suggestion, the substitution of a stone pier for the wooden stand in the original instrument.

Both the Dorpat and the Pulkovo refractors are defective in rigidity, especially in right ascension. The declination circle is most inconvenient of access, and slow motion in declination can only be accomplished when the instrument is clamped by a long and inconvenient handle; so that, practically, clamping in declination was not employed. The slow motion in right ascension is defective, being accomplished in the Dorpat refractor by changing the rate of the clock, and in the Pulkovo refractor by a handle which, when used, affects very injuriously the rate of the clock for the time being. Struve's skill as an observer was such that he used to complete the bissection on the fixed wire of the micrometer by a pressure of the finger on the side of the tube—a method of proved efficiency in such hands, but plainly indicative of the want of rigidity in the instrument and of the imperfection of the slow motions (see Micrometer).

The driving circle is also much too small, so that a very slight mechanical freedom of the screw in the teeth invades a large angular freedom of the telescope in right ascension, while its size increases the lower end of a too weak polar axis tends to create instability from torsion of that axis. Strange to say, the wooden tube long retained its place in German telescope-mountings.

About 1840 a great advance was made by the Repsold of Hamburg in the equatorial mounting of the Oxford heliometer. The driving circle was greatly increased in diameter and placed at the upper end of the polar axis, and both the polar and declination axes were made much stronger in proportion to the mass of the instrument they were designed to carry. (A figure of the instrument is given in the Oxford Observations for 1850.) About 1850 Thomas Cooke of York began his career as a maker of equatorial telescopes. The largest example of his work is the refractor of 24-in. aperture, originally made for the private observatory of Robert Stirling Newall at Gateshead, Northumberland, and afterwards presented by him to the University Observatory, Cambridge. Cooke's mounting is admirable for its symmetry and simplicity of design, its just apportioning of strength, and a general suitability of means to ends.

It is not a little curious that the obvious improvement of trans-

![Fig. 13. Dorpat Refractor.](image)

fering the declination axis as well as the declination-clamp to the telescope end of the declination axis was so long delayed; we can only suppose that the desire to retain the declination circle as a part of the counterpoise. We believe the first important equatorials in which the declination was read from the eye-end were the 15-in. by Grubb and the 6-in. by Cooke, made for the observatory of Lord Crawford (Lord Lindsay) at Dun Echt, Aberdeenshire, about 1873. The plan is now universally adopted. Telescopes of such dimensions can be conveniently directed to any object by the circles without the observer being under the necessity to climb a special ladder. But when much larger instruments are required the hour circle becomes inaccessible from the floor, and means have to be devised for reading both circles from the eye-end. This was first accomplished by Grubb in the great refractor of 27-in. aperture which he constructed for the Vienna observatory, represented in section in fig. 14. The observer's eye is applied to the small telescope E, which (by means of prisms numbered 1, 2, 3, 4) views the vernier attached to the cross-head and the graduated arc at the upper end of the polar axis. Light to illuminate the vernier and circle is thrown from the lamp L upon prism 4 by the prisms 6 and 5. Prism 1 is in the axis of the declination circle and always reflects rays along that axis, whatever the position of the telescope may be, whilst the prisms 2, 3, 4 and 5 are attached to the cross-head and therefore preserve their relative positions to each other. Through the eyepiece of the bent telescope E another hour circle attached to the lower end of the polar axis can be seen; thus an assistant is able to direct the telescope by a handle at H to any desired hour angle. A slight rotatory motion of the telescope E on its axis enables the vernier of the declination circle to be read through prism 1. The leading features of this fine instrument represent those of all Grubb's large telescopes. The mode of relieving the friction of the declination axis is similar to that employed in the Melbourne telescope and in the account of the Vienna telescope published by Grubb. The end friction of the polar axis is relieved by a ring of conical rollers shown in section beside the principal figure. From this point we must condense farther description into a few words only.

(1) Telescopes of Moderate Size for Micrometric Research Only.—Fig. 15 shows the mounting of the 8-in. refractor, of 4-ft. focal length, at the private observatory of Dr Engelmann, Leipzig. The object-glass is by Messrs Clark of Cambridge, Mass., the mounting, by the Repsold of Hamburg. The declination circle reads from the eye-end, and four handles for clamping and slow motion in right ascension and declination are situated near the observer's hands. The tube is of sheet steel, light, stiff, and free from tremor. The eyepiece carries the micrometer with an illuminating apparatus similar to that described under Micrometer. The lamp near the eye-end illuminates the field or the wires at pleasure, as well as the position circle of the micrometer and the declination circle; a separate lamp illuminates the hour circle. An excellent feature is the short distance between the eye-piece and the declination axis, so that

![Fig. 14. Grubb's 27-in. Refractor (Vienna).](image)
TELESCOPE

The observer has to follow the eye-end in a comparatively small circle; another good point is that the flattening of the cast-iron centrepiece of the tube so that the flange of the declination axis is attached as near as to the axis of the telescope tube as is consistent with free passage of the cone of rays from the object-glass. The substitution of small incandescent electric lamps is an improvement now universally adopted.

(2) Telescopes for General Purposes.—The modern equatorial should, for general purposes, be capable of carrying spectrosopes of considerable width, so that the proportional strength of the axes and the rigidity of the instrument have to be considerably increased. The original mounting of the Washington refractor of 26-in. aperture and 324-ft. focal length (described in Washington Observations, 1874, App. 1) was in these respects very defective, the polar and declination axes being only 7 in. in diameter. The great Pulkovo refractor (fig. 16) erected in 1885 is of 30-in. aperture and 45-ft. focal length. The object-glass is by Clark, the mounting by the Repsold. The tube is cylindrical, of riveted steel plate, graduated in thickness from the centre to its extremity by very powerful flanges to a strong short cast-iron central tube, in which, as in Dr. Engelmann’s telescope (fig. 15), the attachment to the flange of the declination axis is placed as close as it can be to the axis of the tube without interfering with rays converging from the object-glass to any point in the field of view. A new feature in this instrument is the platform at the lower end of the polar axis, where an assistant can view the hour circle by one eye-piece and the declination circle by another (looking up the perforated polar axis), and where he can also set the telescope to any hour angle by one wheel, or to any declination by a second, with the greatest ease. The observer at the eye-end can also read off the hour and declination circles and communicate quick or slow motions to the telescope both in right ascension and declination by conveniently placed handles. The eye-end presents an appearance too complicated to be figured here; it has a micrometer and its illumination for the position circle, a micrometer head, and a bright or dark field, clamps in right ascension and declination and quick and slow motion in the hour circle. Microscopes for reading the hour and declination circles, an illuminated dial showing sidereal time, and driven by an electric current from the sidereal clock, and counter weights which can be removed when a spectroscope or other heavy appliance is added. All these, although making up an apparently complicated apparatus, are conveniently arranged, and are all necessary for the quick and easy working of so large an instrument. We have the authority of Otto for stating that in practice they are all that can be desired. There is in this instrument a remarkably elegant method of relieving the friction of the polar axis. Let A A (fig. 17) be a section of the polar axis; it is then easy to adjust the weight P at such a distance from its lower end so that the centre of gravity X of the whole moving part of the instrument shall be in the vertical (V V) of a line passing through the apex of the hollowed flange p q at q, which forms a part of p q. If now a wheel W is forced up against q with a pressure equal to the weight of the moving part of the instrument, the whole weight of the moving part would rest upon W in unstable equilibrium; or if a pressure R, less than W, is exerted, we have the end friction on the inclined plane of the upper pivot removed to the extent R sin φ, where φ is the latitude of the place. The wheel W is therefore mounted on a guided rod, which is pressed upwards by suitable levers and weights so that the relief is precisely proportional to the pressure on the respective bearings. The Repsold find it unnecessary to relieve the friction of the declination axis.

In such large telescopes it becomes a matter of the first importance to provide means of convenient access to the eye-end of the instrument. This the Repsold have done in the Pulkovo telescope by means of two platforms, as shown in fig. 16. These platforms are capable of easy motion so that the astronomer may be conveniently situated for observing an object at any azimuth or altitude to which the telescope may be directed. For the great refractor mounted at Potsdam, Messrs. P. & F. Repsold have a large platform mounted on a framework which is moved in azimuth by the dome, so that the observer on the platform is always opposite the dome-opening. This framework is provided with guides on which the platform, whilst preserving its uniformity, is raised and lowered nearly in an arc of a circle of which the point of intersection of the polar and declination axes is the centre of the dome, and with it the platform-framework, is accomplished by means of electric motors, as also is the raising and lowering of the platform on its framework. The current is supplied by accumulators, and the switch-board is attached to the platform in a position convenient for use by the astronomer or his assistant.

The original design supplied for the 36-in. telescope of the Lick Observatory at Mount Hamilton, California, Grubb suggested that the whole floor, 70 ft. in diameter, should be raised and lowered by water power, under control of the observer by means of electric keys which act on secondary mechanism that in turn works the valves and reversing gear of the water engines. Other water engines, particularly at key-sets at the observer’s hands, rotate the dome and perform the quick motions in right ascension and declination. (An illustration showing these arrangements appeared in The Engineer of July 9, 1886.) Grubb’s suggestion of the raising floor and mechanism, although his original plans for the mounting were not carried out; the construction of the mounting, dome, floor, etc., having been entrusted to Messrs. Warner & Swasey of Cleveland, Ohio, U.S.A. It has been contended that it is undesirable to move so great a mass as a floor when a platform alone is required to carry the observer. But a floor, however heavy, suspended by three wire ropes and properly balanced over large, well-mounted pulleys, requires an amount of energy to work it which does not exceed that required to operate a platform of moderate dimensions, and there is a freedom, a safety, and a facility of working with a complete floor that a semicircular platform can be most satisfactorily operated by hydraulic means, a platform cannot be so well worked in this way. The best floor mounting we know of is that designed by O. Chadwick for the Victoria Telescope of the Cape Observatory. An account of it will be found in the History and Description of the Cape Observatory. This floor can be raised at the rate of 1 ft. per second or as slowly as the observer desires—whilst in all the large platforms we have seen (Potsdam, Paris), the rate of shift is tedious and tiresome.

The largest refracting telescope in active use is the Yerkes telescope, with an object-glass of 40-in. diameter by Alvan Clark & Son of Cambridge, U.S.A., and with a mounting dome floor by Warner & Swasey of Cleveland, Ohio, U.S.A. The reader will gather a good general idea of the design from fig. 16. The eye-end is shown on the plate, fig. 25. The chief defect in equatorial mountings of type C is that in general they are not capable of continued observing much past the meridian without reversal. This is an unquestionable drawback when long exposures near the meridian are required. By the

use of an overhanging polar axis the difficulty can be overcome; it has been successfully adopted by Repsolds for their astrographic equatorials of 15-in. aperture and 11-25-ft. focus, and on a much smaller scale by Warner & Swasey for the Bruce telescope of 10-in. aperture and 60-in. focus, made for the Yerkes Observatory. The latter is shown in fig. 19. Stability in this method of mounting can only be secured by excessive weight and rigidity in the support of the overhanging axis. In the case of the Victoria telescope (24-in. aperture and 224-ft. focus) mounted at the Cape of Good Hope on this plan, it has been found necessary to add supporting stays where great rigidity is required, and thus to sacrifice continuous circum-meridional motion for stars between the zenith and the elevated pole.

Type D.—The first important equatorial of type D was the 4-ft. reflecting telescope of Lassell (Mem. R.A.S., xxxvi. 1-4), and later Lord Rosse’s 36-in. reflecting telescope at Birr Castle (Phil. Trans., clxxi. 153), and A. Compton’s 36-in. reflecting telescope mounted by him at Ealing (Mem. R.A.S., xlvii. 173-181). In Lassell’s instrument (a reflector of the Newtonian type) the observer is mounted in the open air on a supplementary tower capable of motion in any azimuth about the centre of motion of the telescope, whilst an observing platform can be raised and lowered on the side of the tower. In Lord Rosse’s instrument (also of the Newtonian type) the observer is suspended in a cage near the eye-piece, and the instrument is used in the open air. Compton’s telescope presents many ingenious features, especially the relief-friction by flotation of the polar axis in mercury, and in the arrangements of the observatory for giving ready access to the eye-piece of the telescope.

Type C seems indeed to be the type of mounting most suitable for reflecting telescopes, and this form has been adopted for the 60-in. reflector completed by G. W. Ritchey, under the direction of Professor G. E. Hale, for the Mount Wilson Solar Observatory. The instrument is shown in fig. 20, and its design is unquestionably the most perfect yet proposed for modern astrophysical research.

The declination axis is here represented by what are practically the trunnions or pivots of the tube, resting in bearings which are supported by the arms of a very massive cast-iron fork bolted to the upper end of the polar axis. This axis is a hollow forging of nickel steel, of which the accurately turned pivots rest on bearings attached to cast-iron uprights bolted upon a massive cast-iron base plate. The base plate rests upon levelling screws which permit the adjustment of the polar axis to be made with great precision. The combined overhanging weight of the cast-iron fork, the mirror and tube is so great, that without a very perfect relief-friction system the instrument could not be moved in right ascension with any approach to practical ease. But a hollow steel float, 10 ft. in diameter, is bolted to the upper end of the polar axis just below the fork. This float dips into a tank filled with mercury so that practically the entire instrument is floated by the mercury, leaving only sufficient pressure on the bearings to ensure that the pivots will remain in contact with them. The 60-in. silver-on-glass mirror (weighing about one ton) rests at the lower end of the tube on a support-system consisting of a large number of weighted levers which press against the back of the glass and distribute the load. Similar weighted levers around the circumference of the mirror provide the edge support. The telescope is moved in right ascension and declination by electric motors controlled from positions convenient for the observer. The driving clock moves the telescope in right ascension by means of a worm-gear wheel, 10 ft. in diameter, mounted on the polar axis.

The 60-in. mirror is of 25-ft. focus, but for certain classes of work it is desirable to have the advantage of greater focal length. For this purpose the telescope can be used in the four different ways shown in fig. 21.

1. As a Newtonian reflector, fig. 21 (a), the converging rays from the 60-in. mirror being reflected to the side of the tube where

mirror, which returns the rays towards the centre of the large mirror and causes them to converge less rapidly. They then meet a small plane mirror supported at the point of intersection of the polar and declination axes, whence they are reflected down through the hollow polar axis as shown in fig. 2, and come to focus on the slit of the powerful spectroscope that is mounted on a pier in the chamber of constant temperature as shown in fig. 20. In this case the equivalent focal length is 150 ft.

(3) As a Cassegrain reflector, for photographing the moon, planets or very bright nebulae on a large scale, as shown in fig. 21 (c), with an equivalent focal length of 100 ft.

(4) As a Cassegrain reflector, for use with a spectroscope mounted in place of the photographic plate, fig. 21 (d); in this case a convex mirror of different curvature is employed, the equivalent focus of the combination being 80 ft.

Type E.—In the Comptes Rendus for the year 1883, vol. 96, pp. 735-741, Loewy gives an account of an instrument which he calls an ‘equatorial could,’ designed (1) to attain greater stability and so to measure larger angles than is generally possible with the ordinary equatorial; (2) to enable a single astronomer to point the telescope and make observations in any part of the sky without changing his position; (3) to abolish the usual expensive dome, and to substitute a covered shed on wheels (which can be run back at pleasure), leaving the telescope in the open air, the observer alone being sheltered. These conditions are fulfilled in the manner shown in fig. 22. E P is the polar axis, rotating on bearings at E and P. The object-glass is at O, the eye-piece at E. There is a plane mirror at M, which reflects rays converging from the object-glass to the eye-piece at E. A second mirror N, placed at 45° to the optical axis of the object-glass, reflects rays from a star at the pole; but by rotating the box which contains this mirror on the axis of its supporting tube T a star of any declination can be observed, and by combining this motion with rotation of the polar axis the astronomer seated at E is able to view any object whatever in the visible heavens, except circumpolar stars near lower transit. An hour circle attached to E P and a declination circle attached to the box containing the mirror N, both of which can be read or set from E, complete the essentials of the instrument. There must be a certain loss of light from two additional reflections; but that could be tolerated for the sake of other advantages, provided that the mirrors could be made sufficiently perfect optical planes. By making the mirrors of silvered glass, one-fourth of their diameter in thickness, the Henriys have not only succeeded in mounting them with all necessary rigidity free from flexure but have given them optically true plane surfaces, notwithstanding their large diameters, viz., 11 and 15.7 in.

Sir David Gill tested the equatorial could on double stars at the Paris Observatory in 1884, and his last doubts as to the practical value of the instrument were dispelled. He has never seen more perfect optical definition in any of the many telescopes he has employed, and certainly never measured a celestial object in such favourable conditions of physical comfort. The easy position of the observer, the convenient position of the handles for quick and slow motion, and the absolute rigidity of the mounting leave little to be desired. In a much larger
instrument of the same type subsequently mounted at Paris, and in like instruments of intermediate size mounted at other French observatories, the object-glass is placed outside the mirror $N$, so that both the silvered mirrors are protected from exposure to the outside air.

A modification of Lowey's equatorial coudeé has been suggested by Lindemann (Astr. Nachr., No. 3933); it consists in placing both of the mirrors of Lowey's "equatorial coudeé" at the top of the polar axis, so that the lower end of the reflecting tube becomes unnecessary, and neither the pier nor the observer obstruct the view of objects above the horizon near lower declinations. This arrangement also avoids the necessity of having to pass down the tube from the direction of the elevated pole instead of upward towards that pole. The observer, however, is, at the bottom of the tube instead of the top and looks upward instead of downward to the eyepiece, which is large enough to be visible through the aperture of the large size of the upper pivot (viz. the diameter of the tube) and of the lower pivot (which must be perforated by a hole at least equal in diameter to the photographic field of the telescope), conditions which involve very refined arrangements for relief of friction, and (2) the less comfortable attitude of looking upward instead of downward. The plan, however, would be a very favourable one for spectroscopic work and for observation, especially of the polar ground room of constant temperature. The difficulties of relief friction could probably be best overcome by a large hollow cylinder concentric with the polar axis fixed near the centre of gravity of the tube. But this must be barred by the necessity of having to float the tube in the Mount Wilson 60-in. reflector already described, but in this case the floating cylinder would be below and not above the upper pivot.

In 1884 Sir Howard Grubb (Phil. Trans. R. Dub. Soc., vol. iii. series 2, p. 61) proposed a form of equatorial telescope of which an excellent example was erected at Cambridge (Eng.), in which the axis of rotation is always horizontal. This is the equatorial coudeé of Lowey, but instead of two mirrors there is only one. A flanged cast-iron box, strongly ribbed and open on one side, forms the centre of the tube, and the polar axis is attached to the lower end of this box, and a strong hollow metal cone, terminating in the other pivot, forms the upper part of the polar axis. The declination axis passes through the two opposite sides of the central box. Upon an axis concentric with the declination axis is carried a plane mirror, which is geared so as always to bisect the angle between the polar axis and the optical axis of the telescope. If there is a direct view, the reflected beam from the object-glass is received by the plane mirror from which it is reflected upwards along the polar axis and viewed through the hollow upper pivot. Thus, as in the equatorial coudeé, the observer remains in a fixed position looking down the polar axis from above. He is provided with quick and slow motions in right ascension and declination, which can be operated from the 60-end, and he can work in a closed and comfortably heated room. A long tube is also provided, and all the other parts of the polar axis, in order to allow the telescope to be pointed nearer to the pole than would otherwise be possible; even so, stars within $12^\circ$ of the pole may be observed. A detailed description of the instrument is given by Sir Robert Ball (Mon. Not. R.A.S., lix. 152). The instrument has a triple photo-visual Taylor object-glass of 121 in. aperture and 19-3 ft. focal length.

The previously described types of telescope mounting the axis of rotation of the object-glass directly at the object or at the pole; in the latter case the rays from the star under observation are reflected along the polar axis by a mirror or mirrors attached to or revolving with it. Equatorials of types A, B, C and D have the advantage of avoiding interposed reflecting surfaces, but they involve inconveniences from the continual motion of the eye-piece and the consequent necessity for providing elaborate observing stages or rising floors. In those of type B, the eye-piece has a fixed position and the observer may even occupy a room maintained at uniform temperature, but he must submit to a certain loss of light from one or more reflecting surfaces, and from possibly considerable air and other interferences for the position of the eye-piece and the mirror or mirrors. In all these types the longer the telescope and the greater its diameter (or weight) the more massive must be the mount, and the mechanical difficulties both in construction and management.

But if it be possible to mount a fixed telescope by which a solar or stellar image can be formed within a laboratory we give the following description of a practical design of the equatorial type, viz.:

(1) the focal length of the telescope; (2) the clockwork and other appliances to move the mirror, which reflects the starlight along the axis, are much lighter and smaller than those required to move a large telescope; (3) the position of the object-glass in any scopes of any weight can be used on piers within the laboratory; and (4) the angular value of any linear distance on a photographic plate can be determined by direct measurement of the distance of the photographic image from the plate.

The difficulty is that the automatic movement of a single mirror capable of reflecting the rays of any star continuously along the axis of a fixed horizontal telescope, requires a rather complex mechanism owing to the variation of the angle of reflexion with the diurnal motion.

Forcaut appears to have been the first to appreciate these advantages and to surmount the difficulty of designing a siderostat which, theoretically at least, fulfills this condition. A large siderostat, constructed by Eichens after Forcaut's design, was completed in 1868—the year of Forcaut's death. It remained at Paris Observatory, but this apparatus was subsequently employed by Deslandres for solar photography. The largest refracting reflecting telescope yet made, viz., that constructed by Gautier for the Paris Observatory in 1900, was arranged on this plan (type F), the stars' rays being reflected along the horizontal axis of a telescope provided with visual and with photographic object-glasses of 49-in. diameter and nearly 200-ft. focal length, in order both to secure the optical qualities of the images furnished by the object-glass and to avoid the use of the object-glass necessary in a first class reflecting telescope. However, the working of the instrument, have, so far as we know, been submitted to any severe test. It is, however, certain that the Forcaut siderostat is not capable, in practice, of maintaining the reflected image in a constant direction with perfect uniformity on account of the sliding action on the arm that regulates the motion of the for such an action must, more or less, take place by jerks. There are further inconveniences in the use of such a telescope, viz., that the image undergoes a diurnal rotation about the axis of the horizontal telescope, so that, unless the sensitive plate is provided with clockwork, it is not possible to obtain sharp photographs with any but instantaneous exposures. A sidereal rotation of a single star with a slit-spectroscope, this rotation of the image presents no inconvenience, and the irregular action of a clockwork on Forcaut's plan might be overcome by the following arrangement:

A B (fig. 23) is a polar axis, like that of an equatorial telescope, and terminates in a fork C D, on which is mounted a mirror C D, capable of turning about A on an axis at right angles to it. If A B is a fixed axis instead of being parallel to the latter axis. The mirror C D is set at such an angle as to reflect rays from the stars in the direction of the mirror R and thence to the horizontal telescope T. The mirrors are at the extremity of a line (1) the equatorial coudeé reflecting light downwards upon the mirror $R$ would furnish an ideal siderostat for stellar spectroscopy in conjunction with a fixed horizontal telescope.

Coelostat.—If a mirror is mounted on a truly adjusted polar axis, the plane of the mirror being parallel to that axis, the normal to the mirror surface will fall on the polar axis. The observer, therefore, stands at the point on the celestial equator through which whatever angle the axis is turned. Also, if the axis is made to revolve at half the apparent diurnal motion of the star, an image of the celestial sphere, viewed by reflection from such a moving mirror, will describe a circle in the direction of the apparent motion of the star, and the image thus formed is the coelostat. Any telescope may be fitted with such a coelostat, or, by rotating the polar axis independently of the clockwork, the observer can pass in review all the stars visible above the horizon whose declinations come within the limits of his original field of view. Therefore, to observe stars of a different declination it will be necessary either to shift the direction of the fixed telescope, keeping its axis still pointed to the coelostat mirror, or to employ a second mirror to reflect the rays from the coelostat mirror along the axis of a fixed telescope. In the latter case it will be necessary to provide means to move the coelostat on a carriage by which it can be moved east and west without changing the altitude or azimuth of the mirror. For a polar axis with a coelostat, it may receive all the light from the reected beam. Besides these complications there is another drawback to the use of coelostats for general astronomical work, viz., the obliquity of the angle of reflection, which can never be less than that of the declination of the star, and may be greater to any extent. For these reasons the coelostat is never likely to be largely employed in general astronomical work, but it is admirably adapted for spectroscopic and other work where a fixed point is required. For details of the coelostat applied to the Snow telescope—the most perfect installation for spectroheliography and bolometer work—see The Study of Stellar Evolution by Prof. G. E. Hale, p. 131.

The Zenith Telescope

The zenith telescope is an instrument generally employed to measure the difference between two nearly equal and opposite positions of the same object at geographical latitudes in the field work of geodetic operations; more recently it has been extensively employed for the determination of
of variation of latitude, at fixed stations, under the auspices of the International Geodetic Bureau, and for the astronomical determination of the constant of aberration. The instrument is shown in its most recent form in fig. 24. A is a sleeve that revolves very freely and without shake on a vertical steel cone. This cone is mounted on a circular base b which rests on three levelling screws, two of which are visible in the figure. The sleeve carries a cross-piece on its upper extremity to which the bearings of the horizontal axis c are attached. A reversible level d rests on the accurately turned pivots of this axis. The telescope is attached to one end of this axis and a counterpoise e to the other. The long arm f serves to clamp the telescope in zenith distance and to communicate slow motion in zenith distance when so clamped. On the side of the telescope opposite to the horizontal axis is attached a graduated circle g, and, turning concentrically with this circle, is a framework h, to which the readers and verniers of the circle are fixed. This frame carries very sensitive levels k and l, and the whole frame can be clamped to the circle g by means of the clamping screw m.

The object-glass of the telescope is, of course, attached by its cell to the upper end of the telescope tube. Within the focus of the

time. Assuming, for example, that the northern star has the ascension of the object-glass, it is necessary to place 5, placed in the meridian towards the north; the verniers of the graduated circle g are set to read the reading \( \phi = (\lambda - \phi_s) + (\alpha + \phi) \), where \( \phi \) is the approximate latitude of the place and \( \phi_s \), \( \phi \), the declination of the object of the star as observed. The level frame h is turned till the levels k and l are in the middle of their run, and then clamped by the screw m, aided in the final adjustment by the level l.

The telescope is now turned on the horizontal axis till the levels read near the centres of these scales and the telescope is clamped to the arm f. When the star enters the field of view its image is very difficultly obtained by the spider web of the micrometer, the exact bisection being completed in the immediate neighbourhood of the meridian. The readings of the levels k and l and the reading of the micrometer drum are then entered, and the observation is completed. Now the instrument is slowly turned towards the south, till the azimuth arm is gently brought into contact with the corresponding stop s, care being taken not to press on any part of it, except the south arm itself. When the southern star enters the field the same process is repeated.

Suppose now, for the moment, that the readings of the levels k and l are identical in both observations, we have then, in the difference between the micrometer readings north and south, a measure of the difference of the two zenith distances expressed in terms of the micrometer screw; and, if the "value of one revolution of the micrometer screw" is known in seconds of arc we have for the resulting latitude

\[ \phi = \frac{1(\lambda - \phi_s) + (\alpha + \phi)}{2} \]

where \( \phi_s \), \( \phi \), are the difference of the micrometer readings converted into arc—it being assumed that increased micrometer readings correspond with increased zenith distance in the star.

If between the north and south observation there is a change in the level readings of the levels k and l, this indicates a change in the zenith distance of the object, the object being directed to the telescope to a distant object, or to the intersection of the webs of a fixed collimating telescope (see TRANSIT CIRCLE), it is easy to measure the effect of a small change of zenith distance of the axis of the telescope in terms both of the level and of the reading of the micrometer. This and, thus, if the levels are perfectly sensitive and uniform in curvature and graduation, to determine the value of one division of each level in terms of the micrometer screw. The value of "one revolution of the micrometer screw" is thus determined, and to observe at transit the difference of zenith distance of two stars of known declination in terms of the micrometer screw, the instrument remaining at rest between their transits; or by measuring at known instants in terms of the screw, the mean of two levels therefore adds to the accuracy of the result.

Attempts have been made to overcome the difficulties connected with this method by adopting the method of using one micrometer and observing transit the difference of the true altitudes of the two stars, without the division of the micrometer.

S. C. Chandler in 1884 constructed an equal altitude instrument on this principle, which he called the almucantar, and he found that after disturbance the telescope recovered its original zenith distance within \( \frac{1}{5} \)° of a second of arc. R. A. Sampson at Durham (see Trans. R. A. Soc. of Durham) had a similar instrument constructed in 1872 (the A. H. Howe Bubble Level transit instrument). Dr. J. Lyon had instruments constructed on the same general principle. It is, however, obviously impossible to apply a micrometer with advantage to such instruments, because to touch such an instrument with the fingers is impossible, and to turn a micrometer screw, would obviously set it into motion. The almucantar was therefore used only to observe the vertical transits of stars in different azimuths over fixed horizontal levels, without observing transit the vertical distance of the stars.

By the use of photography, however, it is possible to photograph the trail of a star as it transits the meridian when the telescope is directed towards the north, and another trail be similarly photographed when the telescope is turned towards the south. The interval between the two trails, measured at right angles to the direction of the trails, obviously corresponds to the difference of zenith distance of the two stars. This principle has been applied with great completeness and accuracy of result by John A. Cook, and to the construction of a "photographic floating zenith telescope."
which he has erected at Cambridge (Eng.) and applied to an investigation of the change of latitude and a determination of the constant of refraction. A description of the instrument, and some preliminary results obtained by it, is given by him (Monthly Notices R.A.S., xi. 314).

TELELSIA [mod. Telesa], a town of the Samnites, 24 m. N.W. from Beneventum. It possesses remains of walls in opus reticulatum, of a total length of over a mile; two inscriptions of the Republican period record the erection of towers. The remains of baths (Thermæ Subiniani) and of an amphitheatre still exist: and the city was supplied with water by an aqueduct. There are sulphur springs in the vicinity, which may have supplied the baths.

TELESILLA, Greek poetess, a native of Argos, one of the so-called nine lyric muses. According to the traditional story, when Alexander, king of Sparta, invaded the land of the Argives in 310 B.C., and slew all the males capable of bearing arms, Telesilla, dressed in men's clothes, put herself at the head of the women and repelled an attack upon the city of Argos. To commemorate this exploit, a statue of the poetess, in the act of putting on a helmet, with books lying at her feet, was set up in the temple of Aphrodite at Argos. The festival Hybristica or Endymatia, in which men and women exchanged clothes, also celebrated the heroism of her female compatriots. Herodotus (vi. 76) does not refer to the intervention of Telesilla, but mentions an oracle which predicted that the female should conquer the male, whence the tradition itself may have been derived. Further, the statue seen by Pausanias may not have been intended for Telesilla; it would equally represent Aphrodite, in her character as wife of Ares and a warlike goddess (the books, however, seem out of place). The Hybristica, again, was most probably a religious festival connected with the worship of some androgynous divinity. Of Telesilla's poems only two lines remain, quoted by the grammarians Hephastion, apparently from a Parthenion, or song for a chorus of maidens.

See Curtius, 18, 20; Plutarch, De Virtut. Muliebris, 8; Clement of Alexandria, Stromata, iv. 19, p. 522; Bergk, Poetae Lyrici Graeci, iii.; and especially Macan, Herodotus iv.-vi., i. 336 foll. and notes.

TELESIO, BERNARDINO (1509-1588), Italian philosopher and natural scientist, was born of noble parentage at Cosenza near Naples in 1509. He was educated at Milan by his uncle, Antonio, himself a scholar and a poet of eminence, and afterwards at Rome and Padua. His studies included all the wide range of knowledge then possessed by the philosophers, which constituted the curriculum of the Renaissance scholars. Thus equipped, he began his attack upon the medieval Aristotelianism which then flourished in Padua and Bologna. Resigning to his brother the archbishopric of Cosenza, offered to him by Pope Pius IV., he began to lecture at Naples and finally founded the academy of Cosenza. In 1563, or perhaps two years later, appeared his great work De Rerum Natura, which was followed by a large number of scientific and philosophical works of subsidiary importance. The heterodox views which he maintained aroused the anger of the Church on behalf of its cherished Aristotelianism, and a short time after his death his books were placed on the Index.

Telesio was the head of the great South Italian movement which protested against the accepted authority of abstract reason, and sowed the seeds from which sprang the scientific methods of Campanella and Bruno, of Bacon and Descartes, with their widely divergent results. He, therefore, abandoned the purely intellectual sphere and proposed an inquiry into the data given by the senses, from which he held that all true knowledge really comes. Instead of postulating matter and form, he bases existence on matter and force. This force has two opposing elements: heat, which expands and cold, which contracts. These two processes account for all the diverse forms and types of existence, while the mass on which the force operates remains the same. The harmony of the whole consists in this, that each separate thing develops in and for itself in accordance with its own nature while at the same time its motion benefits the rest. The obvious defects of this theory, (1) that the simplest cases cannot be reduced to this (2) that he adduced no evidence to substantiate the existence of these two forces, were pointed out at the time by his pupil, Patrizzi (see article on Patrizzi, Francesco). Moreover, his theory of the cold earth at rest and the hot sun in motion was doomed to disproof at the hands of Copernicus. At the same time, they were sufficiently coherent to make a great impression on Italian thought. When Telesto went to Rome, his mind and matter, he was still more heterodox. Material forces are, by hypothesis, capable of feeling; matter must also have been formed by the first essential and the air, and when consciousness exists, and could not have been developed out of nothing. Again, the soul is influenced by material conditions; consequently the soul must have a material existence. He further held that all knowledge is sensation ("non ratione sed sensu"); and that intellectual evidence is, therefore, an agglomeration of isolated data, given by the senses. He does not, however, succeed in explaining how the senses allow the mind to perceive objects. His work has been generally held, but there is room for doubt, especially in the few passages where he appears to have been probably in disproof to theological prejudices, he added an element which was utterly alien, namely, a higher impulse, a soul superimposed by God, in virtue of which we strive beyond the world of sense. The whole system of Telesio shows lucidity in argument, and ignorance of essential facts, but at the same time it is a forerunner of all subsequent empiricism, scientific and philosophical, and marks clearly the period of transition from authority and reason to experiment and individual responsibility. Beside the De Rerum Natura, he wrote De Somno, De his quae in aere sunt, De Mari, De Comets e CirculoLoctete, De usi respirations, etc.

TELESPHORUS, bishop of Rome from about 126 till about 132, was a successor of Cerealus.

TELFORD, THOMAS (1757-1834), British civil engineer, was the son of a shepherd, and was born at Westerلكir in Eskdale, Dumfriesshire, on the 9th of August 1757. From early childhood he was employed as a herdsman, occasionally attending the parish school of Westerkirk, where his quickness and diligence helped to make up for his lack of opportunity. On being apprenticed, at the age of fifteen, to a stonemason at Langholm, he found leisure not only to gain an acquaintance with Latin, French and German, but to gratify his literary tastes by a wide variety of reading. In his early manhood he was much given to the writing of verses; a poem of some length on Eskdale appeared in 1784 in the Poetical Museum, published at Hawick; under the signature of "Eskdale Tam" he contributed verses to Ruddiman's Weekly Magazine; and he addressed an epistle in rhyme to Burns, which was published in James Currie's Life of the poet. In 1780 Telford went to Edinburgh, where he was employed in the erection of houses in the "new" town, and occupied much of his spare time in learning architectural drawing. Proceeding to London two years later, he found employment in the erection of Somerset House, having expanded his education and experience sufficiently for the commissioner at Portsmouth dockyard, he next repaired the castle of Sir W. Pulteney, member for Shrewsbury, who conceived such a high opinion of his talents that he got him made surveyor of public works for the county of Salop. In 1793 he was appointed engineer of the Ellesmere canal, for which he built the Chirk and Pont-Y-Cysylte aqueducts, and this work established his reputation as a canal engineer. He was consulted in 1806 by the king of Sweden regarding the construction of the Göta Canal, and, his plans having been adopted, he visited the country in 1810 to superintend some of the more important excavations. In the early years of the 19th century the question of improving the communications in the Highlands of Scotland engaged the attention of the government, and Telford was commissioned to report on the matter. In consequence of his recommendations, he was appointed engineer for the Caledonian Canal, which was begun in 1824 and forms one of the largest but by no means the most useful of his undertakings, and also for the construction of 920 miles of roads, a great part through very difficult country. Of the numerous bridges built in this line of roads mention may be specially made of that across the Tay at Dunkeld. Consequently he was employed on the improvement of the road between Carlisle and Glasgow, which was undertaken as a result of a parliamentary inquiry in 1814, and he was then entrusted with the execution of another scheme, of equal magnitude and importance with that in the Highlands of Scotland, for a system of roads through the more inaccessible parts of Wales, which involved the erection of the magnificent
TELIGNY—TELL, WILLIAM

suspension bridge across the Menai Straits, begun in 1820, and the Conwy Bridge, begun in 1824. While his fame rests chiefly on his road and canal engineering, and the erection of these and of the Grand Canal and aqueducts which this involved, he also did good work in harbour construction. The fisheries and industries of Scotland benefited by the improvements he effected at many of the harbours on the east coast; he constructed the St Katherine's Docks, London (finished in 1828); and his last piece of professional work was a plan for the improvement of Dover harbour. Other achievements of his later years were the drainage of the north level of the eastern Fen district, an area of 48,000 acres, and erection of the Dean Bridge, Edinburgh, and of the Broomielaw Bridge, Glasgow. He died at Harrow on 29th September 1854 in London, and was buried in Westminster Abbey.

Telford was never married. For twenty-one years he lived at the Salopian coffee-house, afterwards the Ship Hotel, Charing Cross, whence he removed to 24 Abingdon Street. He was a fellow of the Royal Societies of London and of Edinburgh, and was annually elected president of the Institution of Civil Engineers from its foundation. He received the Swedish order of knighthood of Gustavus Vasa.

See Telford's Memoirs, written by himself and edited by John Richardson; also Smiles's Lives of the Engineers. **TELIGNY, CHARLES DE** (c. 1535-1572), French soldier and diplomat, belonged to a respected Huguenot family of Rouerque, and received an excellent training in letters and arms at the house of Coligny. He was employed on several peace missions; he represented the Protestants before the king, and was entrusted by Condé with the presentation of his terms to the queen-mother in 1567, and in the following year he assisted at the conference at Châlons and signed the peace of Longjumeau, which was destined to be of short duration. On the outbreak of war, he took part in the siege of Poitiers, distinguishedly, while, as the war was largely a struggle between the court under Coligny at Moncontour, and participated in the negotiations ending in the treaty of Saint-Germain (8th of August 1570). In 1571 he retired to La Rochelle and married Louise de Coligny, but was speedily recalled to Paris to serve on the bi-partisan commission of adjustment. Although he won the special favour of Charles IX., he was one of the first victims in the massacre of St Bartholomew's Day (24th of August 1572). His remains were taken to the Castle of Téligny in 1627, but eight years later were thrown into the river by the hiss and hoots of the populace.**

**TELL, WILLIAM.** The story of William Tell's skill in shooting at and striking the apple which had been placed on the head of his little son by order of Gessler, the tyrannical Austrian bailiff of Uri, is so closely bound up with the legendary history of the origin of the Swiss Confederation that they must be considered together. Both appear first in the 15th century, probably as results of the war for the Toggenburg inheritance (1430-59); for the intense hatred of Austria, greatly increased by her support of the claims of Zürich, favoured the circulation of stories which assumed that Swiss freedom was of immemorial antiquity, while, as the war was largely a struggle between the civic and rural elements in the Confederation, the notion that the (rural) Schwyzers were of Scandinavian descent at once separated them from and raised them above the German inhabitants of the towns.

The Tell story is first found in a ballad the first nine stanzas of which (containing the story) were certainly written before 1474. There is no mention made of the names of the bailiff or of his master, or of the hat placed on a pole. Tell is called "the first Confederate," and his feat is treated as the real and only reason why the Confederation was formed and the tyrants driven out of the land. It is probably to this ballad that Melchior Russ of Lucerne (who began his Chronicle in 1482) refers when, in his account (from Justinger) of the evil deeds of the bailiffs in the Forest districts, he excuses himself from giving the story. He goes on to narrate how Tell, irritated by his treatment, stirred up his friends against the governor, who seized and bound him and was conveying him by boat to his castle on the lake of Lucerne, when a storm arose, and Tell, by reason of his great bodily strength, was, after being unbound, given charge of the rudder on his promise to bring the boat safely to land. He steers it towards a shelf of rock, called in Russia's time Tell's Plate, springs on shore, shoots the bailiff dead with his crossbow, and goes back to Uri, where he stirs up the great strife which ended in the battle of Morgarten. In these two accounts, which form the basis of the Uri version of the origin of the Confederation, it is Tell and Tell only who is the actor and the leader. We first hear of the cruelties of Austrian bailiffs in the Forest districts in the Bernese Chronicle of Conrad Justinger (1460). No names or details are given, and these are those which are described in Tschudi's Chronicle as "olden days before Bern was founded" (i.e. before 1191 and 1260. Several details, but only one name, are added in the De Nobilitate et Rusticitate Dialogus (cap. 33) of Felix Hemmerli, a canon of Zürich, who wrote it after 1451 and before 1454; in this last year he was imprisoned by the Schwyzers, whom he had repeatedly insulted and attacked in his books. According to him the men of Schwyz and of Unterwalden were the first to rise, those of Uri following suit much later. But neither Justinger nor Hemmerli makes any allusion to Tell or his feat.

The Tell story was later worked up into a ballad by Hans Sachs, and the first recensions of the Chronicle combined in a MS. known as the White Book of Sornen. They are contained in a short chronicle written between 1467 and 1476, probably about 1470, and based on oral tradition. Many details are given of the oppressions of the bailiffs: we hear of Gessler, of the meeting of Stoupacher of Schwyz, Fürst of Uri, and a man of Nidwalden at the Rüttli,—in fact, the usual version of the legend. To give an instance of tyranny in Uri, the author tells us the story of the refusal of "der Thall " to do reverence to the hat placed on a pole, of his feat of skill, and of his shooting the bailiff, Gessler, from behind a bush in the " hollow way," or Kantonweg. Tell is the immediate occasion of the rising who swore at the Rüttli to drive out the oppressors; but the narrative of his doings is merely one incident in the general movement which began quite independently of him. The chronology is very confused, but the events are placed after Rudolf's election to the empire in 1273. This is the only account in which Tell is called " der Thall," which name he himself explains by saying, " If I were short (wittig) I should be called something else and not der Tali," i.e. the simpleton or slow-witted man. (It is worthy of notice that the same meaning is attributed to the name Tell by the Swiss, the "der Tell") is the abridgment of the Historia Danica of Saxo Grammaticus, which may, somehow, have influenced the Swiss version.)

The only other known instance of the Uri version of the legend relating to the origin of the Confederation are the Latin hexameters of Glareanus (1513), in which Tell is compared to Brutus as " assertor patriae, vindex ulterior tyrannum," and the Urserspiel (composed in 1511-12), a play acted in Uri, in which Russ's version is followed, though the bailiff, who is unnamed, but announces that he has been sent by Albert of Austria, is slain in the " hollow way." Tell is the chief of the Rüttli leaguers, and it is his deed which is the immediate occasion of the rising against the oppressors, which is dated in 1296. Mutius (1540) is the latest writer who, in his description of the origin of the Confederation, does not mention Tell and his act. The two stories are now firmly bound together; the version contained in the White Book is the accepted one, though small additions in names and dates are often made.

The task of filling up gaps, smoothing away inconsistencies, rounding off the tale, was accomplished by Giles Tschudi (q.v.), whose recension was adopted, with a few alterations, by Johannes von Müllner in his History of the Confederation (1580). In the final recension of Tschudi's Chronicle (1734-36), which, however, differs in many particulars from the original draft still preserved at Zürich, we are told how Albert of Austria, with the view of depriving the Forest lands of their ancient freedom, sent bailiffs (among them Gessler) to Uri and Schwyz, who committed many tyrannical acts, so that finally on
TELL, WILLIAM

8th November 1307, at the Rütli, Werner von Stauffacher of Schwyz, Walter Fürst of Uri, Arnold von Melchthal in Unterwalden, each with ten companions, among whom was William Tell, resolved on a rising to expel the oppressors, which was fixed for New-Year's Day 1308. A few days later (November 15th) the Tell incident takes place (described according to the White Book version), and on the appointed date the general rising. Tschudi thus finally settled the date, which had before varied from 1260 to 1314. He utterly distorts the real historical relations of the Three Lands, though he brings in many real historical names, their owners being made to perform historically impossible acts, and introduces many small additions and corrections into the story as he had received it. In particular, while in his first draft he speaks of the ballif as Gryssler—the usual name up to his time, except in the White Book version of Stumpf's Chronicle of 1540—his final revision he calls him Gessler, knowing that this was a real name. Later writers added a few more particulars,—that Tell lived at Bürglen and fought at Morgarten (1358), that he was the son-in-law of Fürst and had two sons (early 15th century), &c. Johannes von Müller (1780) gave a vivid description of the oath at the Rütli by the three (Tell not being counted in), and threw Tschudi's version into a literary form, adding one or two names and adopting that of Hermann for Gessler, calling him of "Bruneck." Schiller's play (1804) gave the tale a world-wide renown, and Voltaire expressed the opinion that it was suspicious as regards by Guiliam in a private letter of 1607, and doubts were expressed by the brothers Iselin (1727 and 1754) and by Voltaire (1754); but it was not till 1760 that the legend was definitely attacked, on the ground of its similarity to the story of Tokko (see below), in an anonymous pamphlet by Freudenher, a Bernese pastor. This caused great stir; it was publicly burnt by order of the government of Uri, and many more or less forged proofs and documents were produced in favour of Tell. The researches of J. E. Kopp (Urkunden zur Geschichte d. eidgenössischen Bünde, 2 parts, 1835 and 1851, and Geschichte der eidgenössischen Bünde, vol. i, 1847), first cleared up the real early history of the league, and overthrew the legends of the White Book and Tschudi. Since then many writers have worked in the same direction. Vischer (1867) has carefully traced out the successive steps in the growth of the legend, and Rochholz (1877) has worked out the real history of Gessler as shown in authentic documents. The general result has been to show that a mythological markman and an impossible ballif bearing the name of a real family have been joined with confused and distorted reminiscences of the events of 1245-47, in which the names of the ground of many of evidence have been imitated and many unauthentic acts attributed to them. Th. von Liebenau has, however, shown (in an article reprinted from the Katholische Schweizerblätter in the Bulletin Storico della Svizzera Italiana for 1890) that in 1283 the Emperor Rudolf of Habsburg gave the right of receiving the tolls for escort over the St Gotthard Pass to his sons, the dukes of Austria. The levying of these tolls gave rise to various disputes between the men of Uri and the ballifs of the dukes of Austria, and by 1310 (if not already in 1300) the claim to levy them was silently given up. These facts show (what could not hitherto be proved) that at the time when legends arose these days have been imitated and many unauthentic acts attributed to them. Th. von Liebenau has, however, shown (in an article reprinted from the Katholische Schweizerblätter in the Bulletin Storico della Svizzera Italiana for 1890) that in 1283 the Emperor Rudolf of Habsburg gave the right of receiving the tolls for escort over the St Gotthard Pass to his sons, the dukes of Austria. The levying of these tolls gave rise to various disputes between the men of Uri and the ballifs of the dukes of Austria, and by 1310 (if not already in 1300) the claim to levy them was silently given up. These facts show (what could not hitherto be proved) that at the time when legends arose these days have been imitated and many unauthentic acts attributed to them.

The story of the skillful markman who succeeds in striking some small object placed on the head of a man or child is very widely spread; we find it in Denmark (Tokko), Norway (two versions), Iceland, Holstein, on the Rhine, and in England (William of Cloudesley). How it came to be localized in Uri we do not know; possibly, through the story of the Scandinavian colonization of Schwyz, the tale was fitted to some real local hero.

The alleged proofs of the existence of a real William Tell in Uri in the 14th century break down hopelessly. (a) The entries in the parish registers are forged. (b) As to the Tell chapels,—(a) that in the "hollow way" near Küsnacht was not known to Melchior Rius and is first mentioned by Tschudi (1572). (b) That on Tell's Platte is first mentioned in 1504. The document which alleges that this chapel was built by order of a "landgemeinde" held in 1538, at which 114 men were present who had been personally acquainted with Tell, was never heard of till 1759. The procession in boats to the place where the chapel stands may be very old, but is not connected with Tell till about 1582. (c) The chapel at Bürglen is known to have been founded in 1582. Other documents and statements in support of the Tell story have even less claim to credit. It has been pointed out above that with two exceptions the ballif is always called Gryssler or Grissler, and it was Tschudi who popularized the name of Gessler, though Grissler occurs as late as 1765. Now Gessler is the name of a real family, the history of which from 1250 to 1753 has been worked out by Rochholz, who shows in detail that no member ever played any part attributed to the ballif in the legend, or could have done so, and that the Gesslers could not have owned or dwelt at the castle of Küsnacht; nor could they have been called Von Bruneck.

In the Urnerispiel the name of the ballif's servant who guarded the hat on the pole is given as Heintz Vögely, and we know that Friedrich Vögeli was the name of one of the chief military officers of Peter von Hagenbach, who from 1495 to 1743 administered for Charles the Bold, duke of Burgundy, the lands of Tell. It is greatly to be regretted (and we are not走得 to see why) that Hagenbach is known to have committed many cruelties like those attributed to the ballifs in the legend, and it has been plausibly conjectured that his case has really given rise to these stories, especially when we find that the Confederates had a hand in his capture and execution, that in a document of 1358 Hagenbachs and Gesslers appear side by side as witnesses, and that the Hagenbachs had frequent transactions with the Habsburgs and their vassals.

In general see two excellent works by Franz Heinemann, Tell-Iconographie, Lucerne, 1902 (reprint, with text, of the chief documents of Tell in the Schweizerblatter, and Tell-Bibliographie (including that of Schiller's play), published in 1908 at Bern.

Among the vast number of books and pamphlets on the Tell story, the two most to be recommended are W. Vischer, Die Sage von der Befreiung der Waldstätte (Leipzig, 1867), and E. L. Rochholz, Tell und Gessler, with a volume of documents 1250-1515 (Heilbronn, 1877). Convenient summaries of the controversy will be found in any modern book on Swiss history, and more particularly in G. von Wyss, Über d. Gesch. d. drei Länder—U, Schwyz, a. Unterwalden (Bâle, 1871), and many articles in the Schweizer Monatsschrift. Of the many biographies of Habsburg, telluris, the relic of Old Norse, is preserved in the parish churches of those villages, whereas the pilgrims go to the chapels therein, he brings forward no new evidence. His book is a striking proof that the popular Tell legend cannot
claim the support of authentic history, while his attempt to find room for the atrocities of the wicked ballifs elsewhere than at Aldorf consists only in suggesting an intricate series of possibilities, none of which are supported by any positive evidence.

In his pamphlet Die Sagen v. Tell u. Slawfachser (Basel, 1896) August Bernoulli, and in his elaborate Geschichte d. Schweiz. Politik (vol. 1; Frauenfeld, 1906) J. Schollenberger, have applied the same sort of method, but without attaining any great degree of historical success.

(W. A. B. C.)

TELL EL AMARNA, the name now given to a collection of ruins and rock tombs in Upper Egypt near the east bank of the Nile, 58 m. by river below Assiut and 190 m. above Cairo. The ruins are those of Ekhaton (Akhet-Aton), a city built c. 1360 B.C. by Akhenaton (Amenophis IV.), as the new capital of his empire (in place of Thebes) when he abandoned the worship of Ammon and devoted himself to that of Aton, i.e. the sun (see Egypt: History, § Ancient). Shortly after the death of Akhenaton the court returned to Thebes, and the city, after an existence of perhaps only twenty years—of which little was abandoned. Not having been inhabited since, the lines of the streets and the ground-plans of many buildings can still be traced. The chief ruins are those of the royal palace and of the House of the Rolls; there are scanty remains of the great temple. In the palace are four pavements of painted stucco work in fair preservation. They were discovered in 1891–92 by Prof. Fliinders Petrie (see his Tell el Amarna, 1894). In the Rolls House were discovered in 1887 by the feliah some 300 clay tablets inscribed with cuneiform characters. They are letters and state documents addressed to Amenophis IV. and his father, from the kings of Babylon, Assyria, &c., and from the Egyptian governors in Syria and neighbouring districts. The greater part of them were purchased for the Berlin Museum, but a large number were secured for the British Museum. Their contents proved invaluable for the reconstruction of the history, social and political, of Egypt and Western Asia during that period.

Hewn out of the sides of the hills which close in on the east the plain on which Ekhaton stood are two groups of tombs; one group lies 1 ½ m. N.E., and the other 3 m. S. of the city. The tombs, all of which belong to the time of Akhenaton, are full of interesting scenes in the peculiar style of the period, accompanied by hymns to the sun god. The most important tomb is, perhaps, that of Meri-Ra, high priest of the sun, which has a façade nearly 100 ft. long and two large chambers. On one of the walls of the main chamber is depicted the scene, now well known, in which a blind choir of harpists and singers celebrate the arrival of the court at the temple. In the early centuries of Moslem rule in Egypt the northern tombs were inhabited by Copis, one tomb, that of Pa-Nehesi, being turned into a church. In a ravine opening into the plain between the north and south tombs, and some seven miles from the city, is a tomb supposed to be that of Akhenaton.

The tombs and the great stela sculptured on the cliffs which mark the bounds of the city of Akhet-aton have been the object of special study by N. de G. Davies on behalf of the Archaeological Survey of Egypt. The results, with numerous plates and plans, are embodied in a series of memoirs, Rock Tombs of El Amarna (six parts, 1903–8).

For the tablets see Tell el Amarna Tablets in the British Museum (1892); C. Bezold, Oriental Diplomacy; the transcribed text of the Cuneiform Despatches discovered at Tell el Amarna (1893); The Tell el Amarna Letters (English translation by M. Winckler, Berlin, 1896); E. A. Kraeling, Die El-Amarna Tafeln (Leiden, 1901); W. M. F. Petrie, Syria and Egypt from the Tell el Amarna Letters (1898).

TELLER, WILHELM ABRAHAM (1734–1804), German Protestant divine, was born at Leipzig on the 9th of January 1734. His father, Romanus Teller (1703–1750), was a pastor at Leipzig, and afterwards became professor of theology in the university. He edited the earlier volumes of a Bibelwerk (19 vols., 1749–70) which was designed as an adaptation for German readers of the exegetical works of Andrew Willet, Henry Alswes, Symon Patrick, Matthew Poole, Matthew Henry and others. Wilhelm Abraham studied philosophy and theology in the university of his native town. Amongst the men whose influence mainly determined his theological position and line of work was J. A. Ernesti. Teller’s writings present rationalism in its course of development from biblical supernaturalism to the borders of deistical naturalism. His first learned production was a Latin translation of Benjamin Kennicott’s Dissertation on the State of the Printed Hebrew Text of the Old Testament (1758), which was followed the next year by an essay in which he charged his appointed, pastor, professor of theology and general superintendent in the university of Helmstedt. Here he pursued his exegetical, theological and historical researches, the results of which appeared in his Lehrbuch des christlichen Glaubens (1764). This work caused some commotion, as much by the novelty of its method as by the heterodoxy of its matter, and more by its omissions than by its positive teaching, though everywhere the author seeks to put theological doctrines in a decidedly modern form. In 1767 Teller, whose attitude had made his position at Helmstedt intolerable, was glad to accept an invitation from the Prussian minister for ecclesiastical affairs to the post of provost of Kölln, with a seat in the supreme consistory of Berlin. Here he found himself in the company of the rationalistic theologians of Prussia—F. S. G. Sack (1738–1817), Johann Joachim Spalding (1714–1804) and others—and became one of the leaders of the rationalistic party, and one of the chief contributors to C. F. Nicolai’s Allgemeine Deutsche Bibliothek. Teller was not long in making use of his freest position in Berlin. In 1772 appeared the most popular of his books, Wörterbuch des Neuen Testamentes zur Erklärung der christlichen Lehre (4th ed., 1801), in which he reduced the language and ideas of the New Testament and gave them the form of 18th-century Illuminism. The author maintains that the Graeco-Hebraic expressions must not be interpreted literally, but explained in terms intelligible to the modern mind. By this lexicon Teller had put himself amongst the most advanced rationalists, and his opponents charged him with the design of overthrowing positive Christianity altogether. In 1786 the author became a member of the Berlin Academy of Sciences.

The "Wöllner edict" of July 9, 1788, for the enforcement of Lutheran orthodoxy, and Teller’s manly action, as member of the consistorial council, in defiance of it (cf. his Wohlgemeinte Erinnerungen, 1788), led the Prussian government to pass upon him the sentence of suspension for three months, with forfeiture of his stipend. He was not, however, to be moved by such means, and (1792) issued his work Die Religion der Völkermoneren, an exposition of his theological position, in which he advocated at length the idea, subsequently often urged, of "the perfectibility of Christianity,"—that is, of the ultimate transformation of Christianity into a scheme of simple morality, with a complete rejection of all specifically Christian ideas and methods. This book represents the culminating point of German Illuminism, and is separated by a long process of development from the author’s Lehrbuch. In the same year he published his Anleitung zur Religion überhaupt und zum Allgemeinen des christenthums besonders; für die Jugend höhere und gebildeter Stände aller Religionsparteien. Teller died on the 9th of December 1804. Besides his contributions to the Allgemeine Deutsche Bibliothek, he edited a popular and practically useful Magazin für Prediger (1792–1801).

Wolf, art. in Herzog-Hauck, Realencyklopädie (ed. 1907); Heinrich Döring, Deutsche Kanzelredner des 17ten und 18ten Jahrh., p. 506 seq.; Edward Pusey, Causes of the Late Rationalistic Character of the English Church and theology, in his Popular Lectures, p. 150; and cf. the article in the Allgemeine Deutsche Bibliographie.

TELCHELLERY, a seaport of Britain, in the Malabar district of Madras, between Cannanore and the French settlement of Mahe. Pop. (1901) 27,893. It is a healthy and picturesque town, built upon a group of wooded hills running down to the sea, and is protected by a natural breakwater of rock. The town with its suburbs occupies about 5 sq. m., and was at one time defended by a strong mud wall. The old fort
TELLURIUM—TEMESVÁR

The town stands to the north of the town. The East India Company established a factory here in 1685 for the pepper and cardamom trade. For two years (1780-82) the factory stood a siege by Hyder’s general, and in the subsequent wars with Mysore Tippoo Sultaan the castle was the base of operations for the ascent of the Ghats from the west coast. The town is a busy centre of export trade in coffee, cacao-nut produce, spices and sandal-wood. The Basel Protestant mission has a station here. The municipality manages the Brennen college founded in 1862.

TELLURIUM [Symbol Te, atomic weight 127.5 (O=16)], a chemical element, found to a certain extent in nature in the uncombined condition, but chiefly in combination with other metals in the form of tellurides, such, for example, as sylvanite, blende, galena, grey or silver telluride, and quartz telluride. It is occasionally met with in iron pyrites, and hence tellurium is found with selenium in the flue dust, or chimney deposits of sulphuric acid works. Tellurium was first recognized as a distinct element in 1798 by M. H. Klaproth. It may be obtained by heating tellurium bismuth with sodium carbonate, lixiviating the fused mass with water, filtering, and exposing the filtrate to air, when the tellurium is gradually precipitated as a grey powder (J. J. Berzelius). J. Farbaky (Zeit. angew. Chem., 1897, p. 17) extracts the element from black tellurium as follows:

Tellurium is also obtained as an insoluble grey powder, if the solution of tellurium dichloride in dilute hydrochloric acid is allowed to stand on the bench, or if dilute hydrochloric acid is added to a solution of tellurium which is somewhat decomposed, or if the solution is heated to boiling. The element is obtained by precipitating tellurium with sulphur dioxide from a solution in hydrochloric acid, or from an alcoholic solution of a mercury telluride, or from a solution of a potassium telluride; or by evaporating the solution on a water bath, or by distilling the solution into water. It is a colourless solid and behaves as a dibasic acid. The alkaline tellurides are soluble in water. It also gives rise to super-acid salts, such as KHTeO2, H2TeO4 and other acid salts, which are decomposed by water or by boiling with water, or by diluting the solution with water. Tellurium is also obtained by distilling the solution with copper oxide, or by adding a solution of potassium chloride to a solution of tellurium nitrate, and precipitating the element from the resulting solution by added copper oxide; or by boiling the solution with water, or by boiling the solution with water, or by evaporating the solution on a water bath, or by distilling the solution with copper oxide, or by adding a solution of potassium chloride to a solution of tellurium nitrate, and precipitating the element from the resulting solution by added copper oxide.
on the navigable Béga canal and on the river Béga, and consists of the inner town, formerly strongly fortified, and of four outlying suburbs. Several parks have been laid out on the site of the broad glacis which formerly separated Temesvár from its suburbs, which are now united with it by broad avenues. Temesvár is the seat of a Roman Catholic and a Greek Orthodox bishop. Amongst its principal buildings are the Roman Catholic cathedral, built (1735-57) by Maria Theresa; the Greek Orthodox cathedral; a castle built by Hunyady Janos in 1442, now used as an arsenal; the town and county hall, the museum and large barracks. In the principal square rises a Gothic column, 40 ft. high, erected by the Emperor Francis Joseph in 1851 to commemorate the successful resistance of the town to the siege of 107 days laid by the Hungarian revolutionary army in 1849. Temesvár is the most important centre of commerce and industry of south Hungary, and carries on a brisk trade in grain, flour, spirits and horses. Its industrial establishments include factories for tobacco, cloth, matches, leather, artificial manure, besides breweries and distilleries.

Temesvár is an old town, and although destroyed by the Tatars in 1242, it was a populous place at the beginning of the 14th century, and was strongly fortified by King Charles Robert of Anjou, who resided here several years. The Hunyady family held the middle of the pass. In 1514 the pestilence, Stephen Dozsa, was defeated by the Transylvanian voivod, John Zápolya, near Temesvár, captured and executed. Unsuccessfulley besieged by the Turks in 1552, it was captured by them in the following year after a heroic resistance. It remained in their hands until 1716, when it was liberated by Prince Eugene of Savoy. New strong fortifications were erected, and the town grew steadily in importance, serving as the capital of the whole Banat. It endured another siege in 1849, when it resisted successfully the attacks of a Hungarian revolutionary army.

**Tempe—Temperance**

**Tempe, Vale Of,** the ancient name (i.e. "eleft," from Gr. τέλων, to cut) of a narrow valley in N. Thessaly, through which the river Peneus (mod. Salamandra) reaches the sea. The valley, which the Greeks were accustomed to associate with rural delights, is a chasm, cleft in the rocks, the fable tells us, by the trident of Poseidon, between Olympus and Ossa; but though it possesses every element of the sublime, yet its features are soft and beautiful, from the broad winding river, the luxuriant vegetation, and the glades that at intervals open out at the foot of the cliffs. It is about four miles and a half long, and towards the middle of the pass. The precipices in the direction of Olympus fall so steeply as to bar the passage on that side; but those which descend from Ossa are the loftiest, for they rise in many places not less than 1500 ft. from the valley. Owing to the length and narrowness of the ravine, it was a position easily defended, but still it offered a practicable entrance to an invading force; a number of castles (of which the ruins still exist) were built at different times at the strongest points. Tempe was sacred to Apollo, to whom a temple was erected on the right bank. Every ninth year a sacred mission proceeded to the valley to pluck the laurel for the chaplets for the Pythian games. Owing to its widespread fame, the name Tempe was given also to the valley of the Velinus near Reate (Italy) and that of the Helorus in Sicily.

**Temper (from Lat. temperare, to mingle or compound in due proportion, to qualify, rule, regulate, to be moderate, formed from tempus, time, fit or due season), to blend, modify, or qualify by mixing, to combine in due proportions, hence to restrain, calm. A specific application of the word is to the bringing of steel or other metal to a proper hardness and elasticity (see MELT and IRON AND STEEL). The word is also used as a substantive, especially in the transferred sense of disposition or frame of mind, generally with some qualifying epithet, but when used absolutely signifying a hasty, passionate temper, or display of such.**

**Tempera (the Italian term), or Distemper, a method of painting in which solid pigments are employed, mixed with a water medium, in which some kind of gum or gelatinous substance is dissolved to prevent the colours from scaling off. Tempera is also called in Italian fresco a secco, as distinguished from fresco buono, or true fresco, painted on freshly laid patches of the Rough. Various media have been used for tempera work, such as the glutinous sap of the fig and other trees, various gums which are soluble in water, and size made by boiling down fish-bones, parchment and animals' hoofs. A mixture of egg and vinegar has also been found to make a good medium, especially when it is desirable to apply the colours in considerable body or impasto. For the nature and history of painting in tempera and fresco, see Painting.**

**Temperance.** The word "temperance," which strictly means moderation, has acquired a particular meaning in connection with intoxicating liquor, and it is here used in that limited sense. The "temperance question" is the equivalent in English of *Palcoholismus* and *Alcoholismus* in French and German-speaking countries respectively; it embraces all the problems that arise in connexion with the use or abuse of alcoholic drink. This usage has arisen from the practice of societies formed for the purpose of suppressing or reducing the consumption of such liquors, and calling themselves Temperance Societies. Their activity is often spoken of as the Temperance Movement, though that term properly covers very much wider ground.

**Hence it was also called "water-work"; see Shakespeare, Hen. IV., part ii. act ii. sc. 1.**
Temperance Organization.—In 1808 a temperance society was founded at Saratoga in the state of New York, and in 1813 the Massachusetts Society for the Suppression of Intemperance made its appearance. These have been the earliest organizations, though the device of a pledge of abstinence had been introduced in 1800. The movement made rapid progress mainly under the influence of the Churches. In 1826 the American Society for the Promotion of Temperance was founded in Boston, and by 1833 there were 6000 local societies in several states with more than a million members. The campaign was for the most part directed against the use of spirits only, and the proposal to include all alcoholic drinks in the pledge of abstinence, though adopted by a few societies, did not attract much interest in the American Society, but accepted in 1836 and retained ever since.

In Europe the earliest organizations were formed in Ireland. A temperance club is said to have been started at Skibbereen in 1818, and others followed; but it was in 1829 that the organized movement began to make effectual progress with the formation of the Ulster Temperance Society. By the end of that year there were twenty-five societies in Ireland and two or three in Scotland. In 1830 the movement spread to Yorkshire and Lancashire, and supported a newspaper called the Temperance Advocate. According to which there were then 127 societies with 23,000 paying members and 17,000 associated abstainers. In 1831 the British and Foreign Temperance Society was founded in London with the Bishop of London (Blomfield) for president and Archbishop Sumner for one of the vice-presidents. This important society, of which Queen Victoria became patron on her accession in 1837, came to an end in 1859, when the whole cause was under an eclipse.

The latter part of this quotation is particularly interesting because it proves the participation of women in public drunkenness at this period and shows that the physical ruin caused by excess and its national consequences were then for the first time recognized. It was the first step towards the inauguration of the Temperance Movement in the sense of a spontaneous and conscious effort on the part of the community as distinguished from the action of authority responsible for public decency. The need was only realized by degrees. Intemperance was one of many questions which we can now see were struggling into existence during the latter half of the 18th century, to become the subject matter of "social reform" in the 19th. Like the majority of them it was a question of bodily welfare, of health. A breach had been made in the unthinking traditional belief in the virtue of alcoholic liquor by the experiences referred to; and medical thought, as soon as it began to busy itself with health as distinguished from the treatment of diseases, took the matter up. In 1804 Dr Trotter of Edinburgh published a book on the subject, which was an expansion of his academic dissertation written in 1788; Dr Benjamin Rush of Philadelphia, a distinguished American physician and politician, who had studied in Edinburgh and London, wrote a striking paper on the same subject in the same year; and very soon after this the organized Temperance Movement was set on foot in the United States, where the habit of spirit-drinking had been transplanted from the British Islands.
in 1853 of the United Kingdom Alliance "to procure the total and immediate legislative suppression of the traffic in intoxicating liquors as beverages."

Since that time the organized movement has embraced both elements, the voluntary and the compulsory, and has combined the voluntary and the compulsory with the legislative, in the form of legislation for the reduction or suppression of the traffic. On the whole the latter has predominated, particularly in the United States, where organized agitation has for more than half a century made temperance a political question and has produced the various experiments in legislation of which an account is given in the article on Liquor Laws. In 1869 a National Prohibition Party was formed. In Great Britain the political element has been less predominant but sufficiently pronounced to form a distinguishing feature between the early and more enthusiastic stage of the movement, which after lasting twenty years suffered a reaction, and the later one, which began between 1860 and 1870 and made way more gradually. In addition to combining the moral and the political elements the modern movement is characterized by the following features:

(1) International organization, (2) organized co-operation of women, (3) juvenile temperance, (4) teaching of temperance in schools and elsewhere, (5) scientific study of alcohol and inebriety.

(1) International organization appears to have been started by the Order of Good Templars, a society of abstainers formed in 1851 and spread over the United States and Canada, and in 1858 it was introduced into Great Britain. Some years later it was extended to Scandinavia, where it is very strong, and to many other countries, especially Italy and the continent of Europe. The Good Templar organization has spread to several other European countries, to Australasia, India and South Africa, and to many American states and territories. There are also several other international societies, and international congresses have been held, the first in 1885 at Antwerp. A World's Prohibition Conference was held in London in 1909. It was attended by almost all the countries of the continent of Europe and by nearly all nations of the world, and resulted in the foundation of an International Prohibition Federation, which embraces every country in Europe with three or forty exceptions, the United States, Mexico, Argentina, the British self-governing Dominions, India, China, Japan, Palestine, Tunisia and Hawaii. The formation of this body indicates the growth of the most uncompromising form of antagonism to the liquor traffic. Its object is the total abolition of the legalized traffic throughout the world.

(2) The organization of women, which has also become international, dates from 1874, when the National Women's Christian Temperance Union was founded at Cleveland in the United States. In 1897 it had branches in every state in the Union and in about 10,000 towns and villages with an aggregate membership of 550,000. It passed 246 laws in 1890, the greatest number of any temperance organization, although it has not exercised as great influence as the women's organizations in the United States, but it has exercised great influence in promoting that drastic legislation which characterizes the United States. It has also taken up many other questions relating to women, in addition to temperance, and opened the way for the advancement of other interests. About the year 1883 Miss Frances Willard, who had been the moving spirit of the Union, carried the organization of women into other lands and formed the World's Woman's Christian Temperance Union, which now possesses branches in some fifty countries with a total membership of half a million. It has held several conventions in America and Europe and circulated a polyglot petition, said to be the largest record, on which has been presented to a large number of sovereigns and other heads of states. There are several other female organizations in the United Kingdom.

(3) The inclusion of children in temperance organization goes back to 1847, when a society was formed at Leeds, in Yorkshire, of juvenile abstainers who had taken the pledge; it took the name of Band of Hope. The practice spread, and in 1851 a Band of Hope Union was formed. There are now a number of such societies, for the temperance movement is strong in Scotland, Ireland and separate counties in England; the Bands of Hope are said to number 15,000 in all. There are also several other juvenile organizations, some of which are, however, of very recent formation. Out of the whole section of the Church of England Temperance Society, which has 485,888 members (1910). Children's societies in the United States are usually called the Loyal Temperance Legion, but there are societies in the United Kingdom in the United States and Canada. Some of these organizations exist in several countries and notably in Sweden and Belgium (sociétés scolaires).

(4) The teaching of temperance in schools, which has become a great question, began to be pressed by private effort in 1852, when the late Mr John Hope inaugurated a regular weekly visitation of day-schools in Edinburgh. In 1876, at the invitation of the Edinburgh Temperance Society, Sir Henry M. Hope-Brown wrote his Temperance Lesson Book, which was adopted by many schools as a primer. In 1889 school-teaching by travelling lecturers was taken up by the United Kingdom Band of Hope and extended to the existing schools. The Band of Hope Unions in England alone have spent over £3,000 a year for the last twenty years in itinerant lectures; object-lessons on the nature and effects of alcohol are given in some fifteen schools. The Church of England Temperance Society carries on similar work in diocesan schools, and examines the children in the subject of temperance; in 1909 it had in use 6,000 temperance and alcoholic problems, and 100,000 temperance books have been given free to schools for use in teaching the subject. The voluntary temperance teaching having grown continuously and become very extensive, has led to action by central education authorities. In 1906 the Board of Education in Ireland made it compulsory in some of the denominational schools and in 1909 the Board for England and Wales made compulsory teaching in temperance in all of the elementary schools optional. In Scotland also courses of teaching on hygiene and temperance are permissive and have been adopted by many local educational authorities. In the United States compulsory teaching is of much longer standing and more advanced. The Temperance Union (see above) in 1879; it was believed that by teaching the physiological effects of alcohol to all children the problem of in-temperance would be effectually "solved," and a systematic policy on the subject was adopted. In Europe plans have been drawn up for legislation to make temperance teaching a compulsory subject. The campaign was successful in New York in 1884, in Pennsylvania in 1885 and subsequently in other states of the American confederation. Legislation has been introduced in Canada, Japan, China, Japan, Palestine, Tunisia and Hawaii. The formation of this body indicates the growth of the most uncompromising form of antagonism to the liquor traffic. Its object is the total abolition of the legalized traffic throughout the world.

(5) The scientific study of the physiology and pathology of alcohol is a very large subject in itself. As has been shown above, the pioneers of the temperance movement were medical men; and though the Churches soon became interested, the interest was more in reform than science, and in more recent times since people learnt to bow down to the name of Science there has been a marked tendency to have recourse to scientific authority for arguments. Some of the first and most notable works in this line of science is an illustration. At the same time the increasing interest taken in all questions relating to health has directed the attention of scientific investigators to this subject, and the subject has been studied by the National Researches of physiology or hygiene is an illustration. At the same time the increasing interest taken in all questions relating to health has directed the attention of scientific investigators to this subject, and the subject has been studied by the National Researches of physiology and hygiene are one of the most important results of this activity. There is no doubt that it has had a strong influence on public opinion and on the whole in the direction of temperance. A great change of attitude has taken place not only among medical men, but among the public, who have come to look upon alcohol, especially of distilled spirits, have long been recognized, but the tendency now is to question whether any alcohol-containing drinks are of any value at all and to deny any valid distinction between intoxicating and non-intoxicating drinks. Numerous societies have been formed in England, Germany, Belgium, Holland, Norway, Sweden and Denmark.

Present State of the Movement.—No comprehensive data are available for estimating the numerical strength of the temperance organizations or the number of abstainers at the present time; but
The Alliance Year Book contains a directory of societies, which at least give some idea of the wide distribution of the movement. The following summary figures are extracted from the list; they relate to distinct organizations, exclusive of branches and sub-sections, having for their object the promotion of individual abstinence or of legislation: The United Kingdom; 62; Australasia; 11; Canada; 2; South Africa; 3; India; 2; United States; 10; Austria-Hungary; 8; Belgium; 2; Denmark; 5; France; 4; Germany; 12; Holland; 6; Sweden; 6; Switzerland; 11. The figures are no doubt very imperfect and must not be taken in any way to represent the relative strength of temperance organizations in the several countries. The list for the United Kingdom is much more complete than for the other countries. The Alliance Year Book indeed gives the names of 130 organizations in the United Kingdom connected in some way with temperance work; but these include local branches, juvenile sections, insurance companies, orphanages and so on. An attempt has been made to pick out the temperance societies as ordinarily understood; but some of those included are merely committees for promoting particular pieces of legislation, and on the other hand bodies like the Salvation Army and the Church Army, which do a great deal of temperance work but are not primarily or principally engaged in it, have been omitted. Altogether the subject is full of confusion and not susceptible of exact statement. The number of societies is no guide to the number of individuals, for many persons belong to several organizations. There can be little doubt that the organized movement is numerically strongest in the United States and next strongest in the United Kingdom, but no reliable estimates can be made.

Some of the British societies call for particular notice. The two principal ones are the Church of England Temperance Society and the United Kingdom Alliance. The latter, founded in 1853, is the chief fighting political organization, having total prohibition of the liquor traffic for its object; its income is about £12,000 a year. The Church of England Temperance Society is much the largest of the British societies. It was founded in 1862 and reconstituted in 1873 on a dual basis of total abstinence and general

</table>
anti-intemperance. Its objects are (1) the promotion of habits of temperance, (2) the reform of the intemperate; (3) the removal of the causes which lead to intemperance. Thus it embraces both the moral and the legislative spheres, but the former takes first place. In the circles of the latter, there are few better proofs of the "forward movement" in spiritual activity. On the legislative side the society supports measures of reform rather than prohibition; in the latter there is still a considerable movement directed by the temperance body. The table is marked a increase in the consumption of beer. It has occurred in some measure in the following countries—Russia, Sweden, Denmark, Belgium, Holland, Germany, Spain, and India. In each of these countries, the United Kingdom and Norway, in both of which the consumption has fallen largely and steadily since 1899. In Germany it has also fallen somewhat since 1900, but not so steadily, and over the whole period there has risen in that country. It is impossible to detect these various movements either with legislation or with temperance organization. If the fall in Norway is ascribed to them, it must be chiefly to the effects of the temperance movement among the young. The consumption of spirits shows no such movement, having risen since 1897. No one who has studied the subject in the different countries affected can doubt that the rise is due to the introduction and growing popularity of the light beers originally brewed in Germany and Austria, and commonly called "lager." This is notably the case in France, Sweden, and many of the central European states.

The temperance movement has been accompanied by a corresponding reduction of other alcoholic wine. The consumption of spirits is largely consumed only in countries where it once was grown, namely, in France, Italy, and Switzerland, out of the countries enumerated. The consumption is very irregular and dependent mainly on the abundance of the crop. But the tendency of wine has also been to rise; it has very much increased in the United States, Belgium, Germany, Italy, and Austria. With regard to spirits, the only general movement is that consumption has fallen in most European countries since 1900. But this does not appear to be compensatory to the rise of beer, which extends over the whole period and went on when spirits were rising too.

Exceptions to the downward movement of spirits since 1900 are offered by the United States and Canada, and to a less extent by Russia, Italy, and Norway. The only country in which all classes of drink have steadily fallen is the United Kingdom; this singular fact will be discussed presently, but its peculiarity should be noted here in connexion with other countries.

In the tables, an attempt has been made to express the total consumption of each country in terms of alcohol by allowing a certain percentage of spirit for wine and beer and reducing all three to a common denominator. The calculation yields a simple and uniform measure of consumption of alcohol in the order of their alcoholic consumption; but it must be regarded as a somewhat arbitrary estimate, because the strength of both wine and beer varies considerably. The Brewer's Almanac gives the following table based on the results quoted above:

Apart from the gaps in the information, which speak for themselves, allowance must be made for other defects. In no case is the nominal consumption per head a valid index to the relative temperatures of different peoples unless other conditions are by equal. That they are of the drinking has to be taken into account, and this is conditioned by the age and sex constitution of the population and by the habits of the people. A country in
TEMPERANCE

which every person except infants takes a minute quantity of drink at every meal every day will have a far larger consumption per head and yet may be far more temperate than one in which a large proportion of the population consumes nothing at all and the drinking is concentrated in regard to both time and person. The Portuguese and Spaniards, for instance, are more temperate than any of the nations below them on the list; drunkenness is never seen in Portugal and in the south of Spain (the bishop of Barcelona has in many instances bore testimony to the sobriety even of such a large seaport as Barcelona). The aggregate consumption is brought up to a comparatively high level by the national practice of drinking a little wine freely diluted with water, a beverage which contains less alcohol than many "temperance" drinks. In like manner the French and Italians, whose high place is due to wine, are more sober than the greater part of the nations ranked below them. They are the only nations of the extensive inquiries on this head in France. There is drunkenness, to which Zohn's "I'Assommoir" bears testimony, but outside Paris and the seaports it is rare. Employers of labour in all the principal industrial centres, including the mining districts of the north, agree on this point. The very high position of Belgium is mainly due to a prodigious consumption of beer, which is explained by the general practice of giving it to children. On the other hand, drunkenness is exceedingly prevalent in Russia, which is near the bottom of the list, and is due to the consumption of vodka. The comparatively small amount per head put down in the returns may, if it is correct, be explained by the very large proportion of children in the population. The opposite condition is illustrated by Western Australia, which has a consumption per head nearly three that of any other Australian province. These instances will show the conditions that must be taken into account when making comparisons and the fallacy of measuring national sobriety by consumption per head.

Consumption in United Kingdom.—Statistics of consumption for a long period of time than that covered by the table given above are available for the United Kingdom, the United States and Scandinavia, and they are of particular interest because these are the only countries in which the Temperance Movement has been most active and productive of most legislation. The United Kingdom is distinguished by being the only country in the list which shows a distinct fall in the consumption of all three kinds of liquor since 1856. To estimate the significance of this interesting fact it must be placed in historical perspective. The following table, compiled from the official returns, gives the annual average consumption per head in decennial periods from 1831 to 1890, and subsequently for each year to 1909. No continuous record of beer was kept until after 1856.

United Kingdom: Average Annual Consumption per head in Gallons.

</table>

It will be observed that the consumption has oscillated up and down during the whole period of 70 years. More spirits were drunk in 1851-60 than in the three following decades, and more wine than in the two following decades. The decennial period of greatest consumption was 1871-80; and the highest points reached were: wine, 0.36 gal. in 1876; beer, 0.34 gals. in 1874; spirits, 1.20 gals. in 1876. Since then the consumption has been always on the wane, with fluctuations. The up and down movement is always associated with the state of trade, and the connexion is well marked in the last ten years. The progressive fall is striking, particularly in regard to beer, which is the staple drink of the people; but the period is too short to warrant the inference that it represents a permanent movement which will continue. The fluctuations shown for the decennial table may be attributed to the fallibility of a subsequent rise with a revival of trade. Chronic depression and unemployment have prevailed in many industries since 1900, and these conditions always cause a diminished consumption. Nevertheless they do not fully account for the movement by any means, because the fall in consumption has been progressive, whereas the state of trade has fluctuated considerably; the curves do not coincide. Some other factor has been at work, and there is reason to think that it is a gradual change in the habits of the people.

The facts of consumption agree with much other evidence in pointing to this conclusion. The expenditure in drink is not so high as it was in the 1880s and 1890s, and in any event the country is much more prosperous than in the earlier period. The calculation of annual expenditure prepared for the United Kingdom Alliance, and commonly called the National Drink Bill, points to this conclusion. It is based on an arbitrary estimate of the cost of drink to the consumer and must not be taken to represent established facts; but it has some comparative value. The following table gives this calculation for the last 26 years:

National Drink Bill, United Kingdom.

</table>

The table begins and ends in two periods of marked depression, with one of marked prosperity in between; but it is to be noted that in the earlier term of depression, although it was very acute, the expenditure never sank so low as in the later one. During the four lowest years (1884-88) the mean expenditure was nearly 4s. a head more than in the five lowest years (1905-9). At the other end of the scale the high-water mark in the table, which is the year 1859, shows an expenditure per head of 1.8d. for the whole high-water mark comparable with it, namely 1876, shows an expenditure of £5, 1s. 9d., when calculated on the same basis. The figures, therefore, rather confirm than contradict the general belief that the population have grown more temperate in the last 40 years.

With regard to the expression "national drink bill," which tacitly suggests so much money thrown away on drink, it must be remembered that a large proportion is devoted to public purposes and would hardly be found in a bill which was balanced in the ordinary manner. In condensation which 1909 the trade paid a direct contribution of £37,494,575 to the national exchequer in excise and customs duties, in addition to income-tax and local taxation; all this comes back to the public pocket. Then it also maintains directly and indirectly a population reckoned at 2,000,000. The net amount spent on drink which might have been saved and spent on other things is not more than a third of the total sum.

The United States.—The movement in the United States has been totally different. The figures below are taken from the statistical abstract of the U.S. government as quoted in the American Prohibition Year Book. The figures for each state differ widely throughout from those given for the same years in the Board of Trade returns of international consumption quoted on p. 581. The discrepancy is too great and too constant to admit of any explanation, but that the two sets of returns are calculated from different bases. It illustrates the defects of these statistics and the need of caution in using them. The American figures show a far larger consumption in the United States than the British.

The most noticeable fact here shown is the continuous and large increase in the consumption of beer. Every year shows a rise down to 1898, when for the first time in 70 years a fall was recorded. It was continued in 1899 and 1900, and since then the consumption has always been on the rise, with fluctuations. The up and down movement is also no doubt mainly attributable to the financial state of the country. Down to 1880 beer was to a considerable extent taking the place of spirits, the consumption of which has been very large, and the fall in the consumption of beer was not accompanied by a reverse movement in spirits; and from 1896 to 1907 all three kinds of liquor rose together, though not with equal steadiness. The rising consumption of beer has been accompanied
TEMPERANCE

by an enormous increase in home production, the capital invested in breweries having risen from 4 million dollars in 1850 to 515 million dollars in 1905. The consumption of spirits is at a much higher level than in the United Kingdom, and two considerations and greatly to the significance of the fact—one is that drinking takes place more between meals and less at them, and the other that it is more confined to men. Women, other than prostitutes,

do not frequent the bar as they do in the United Kingdom, and children not at all. The expenditure in drink, so far as it can be calculated, has fluctuated somewhat, but shows a general tendency to rise. The following table has been prepared by Mr G. B. Waldron, an American statistician. It is taken from the Prohibition Year Book, with the American currency converted into English on the basis of 4s. to the dollar, omitting fractions of a penny; for purposes of comparison with the British statistics given above.

Comparison with theKitchen at a glance shows an opposite movement in the two countries. While expenditure has steadily fallen in the United Kingdom since 1890, it has as steadily risen in the United States; and whereas in 1888 the expenditure in the former was 41 per cent. higher than in the latter, the two had drawn equal in 1906 and since then have changed places. Moreover the different system of taxation brings back a much larger proportion of the whole expenditure into the exchequer in the United Kingdom (see Liquor Laws). The comparison is of much interest in view of the very different laws and regulations under which the trade is conducted in the two countries. It may be objected that the statistics are merely estimates, but both sets are put forward by the advocates of prohibition and are of equal authority, so that they hold good for comparison.

Norway and Sweden.—The statistics for these countries are imperfect, because there is no record of wine, and in recent years the use of spirits has been supplemented to a considerable extent by artificial wines heavily loaded with spirits. But, as they stand, the statistics derive special interest from the peculiar conditions under which the traffic is conducted. The Scandinavian company system was started in Sweden in 1865 and in Norway in 1871 (see Liquor Laws).

The difference between these contiguous countries is remarkable. The consumption of spirits has always been much higher in Sweden than in Norway. In the old days before any legislation the estimated consumption was in Sweden 46 litres (1829) and in Norway 16 litres (1833) a head. In recent years, under the company system, the figures for both countries are vastly less, but the Swedish consumption has hardly ever been less than the Norwegian and sometimes three times as great. The difference, observed over a long period before regulation and after, points to different conditions and national habits; but such constant differentiating factors hardly explain the strikingly dissimilar movements shown by the tabulated countries are obviously affected by the trade of state. The high-water mark of spirit-drinking in modern times for both was the same period, 1874-76, as noted above for the United Kingdom; Sweden then averaged 12.4 litres a head and Norway 6.6. Both show also the influence of the 1900 boom in trade and the subsequent decline. But in Sweden the increase of beer-drinking, which in 1871-80 was less than in Norway, has been enormous. If the two drinks are put together it cannot be said that the consumption in Sweden was appreciably less in 1866-1905 than in 1871-80, whereas in Norway it was distinctly less. This may in part be explained by the substitution of the made wine, called laddern, to which reference has already been made. The marked fall in the consumption of spirits which occurred in 1866-98 is attributed to this cause (Rowntree and Sherwell); the importation of wine alone from 2,330,300 litres in 1861-92 to 5,876,750 litres in 1898. Subsequently importation was checked by heavier duties and reduced consumption followed. In 1886-90 the quantity consumed per head in litres averaged o-88; in 1896-1900 it was increased to 2.49, with a maximum of 2.75 in 1898; in 1905 it had fallen again to o-88 (Pratt). A careful study of the foregoing statistics of consumption in the three countries—United Kingdom, United States and the Scandinavian peninsula—which have paid most attention to the problem and have for a long period applied forcible but widely different methods of control, does not permit any confident conclusion upon the comparative merits of any particular system. The United States, in whose multitudinous liquor laws prohibition plays the most prominent part, has most conspicuously failed to check consumption. Norway and Sweden, both of which combine the
TEMPERANCE

principle of disinterested management, though not in the same form, with a certain amount of prohibition, show markedly different results. British temperance systems have long been the subject of considerable study, the British legislative system has been held to be the least adequate as any of the others. The most probable conclusion to be drawn from the facts is that the movement in each country has been mainly determined by other forces; the rise of consumption in the United States by the rapid and progressive urbanization of the people and the great increase of wealth; the diminution of consumption in the United Kingdom by a change in the habits of the people due to many causes, to which further reference is made below; we may add that the introduction of temperance in Norway is due to differences of national character and habits already noted, though some influence must be attributed to the superior system and more stringent control of Norway. But if we go back to earlier periods there is no doubt at all that an incomparably worse state of things existed in the United Kingdom and in Scandinavia when the spirit traffic was under little control or none at all.

They vary according to (1) the laws relating to drunkenness; (2) the administration by police and justices; (3) the method of compounding returns. All these vary in different countries and towns and at different times, so that the statistics must not be used for minute comparisons. But properly handled they are of great value, and the discrepancies are less than might be supposed, because it is found on inquiry that the actual behaviour of the police towards drunkenness, however, does not at all differentially interfere with the liquor trade, nor is there any evidence as to the ascertainment of the number of persons who have been recently drinking; the mode of compounding returns is the most serious cause of error. Many countries have no returns, and in others they are incomplete. Those available, however, throw considerable light on the subject.

The following quinquennial table shows the movement in England and Wales since the drunken period 1874-78. The important act of 1872, which increased the number of offences, vitiates comparison with the earliest returns, which are, however, given in the article on Drunkenness.

Drunkenness, England and Wales.

</table>

When allowance is made for the act of 1902 it is seen that the movement of drunkenness corresponds broadly with that of consumption, but the decline of drunkenness is more marked; the level is lower than it was to be whether good or bad times be taken. This plainly shows a large change in the habits of the people, which is further emphasized by the fact that police procedure has become more stringent and the returns more complete. The exceptional figure for 1909 (estimated) is ascribed to the heavy increase of spirit duties in that year. The change has been accompanied by a decided diminution in the number of drunken persons arrested. Between 1870 and 1900 the number of licences was reduced from 53,3 to 26,3 per 10,000 of the population; but the corresponding number of public-houses has fallen steadily from year to year, whereas drunkenness, like consumption, has fluctuated with the state of trade. The facts, therefore, demonstrate a connexion, but it is not a direct one. The reasons why which have brought about the general decline of drunkenness are more and deeper. The standard of behaviour has gradually changed with education and the provision of alternative recreations in many forms. The habits of the people have been altered, for example, public libraries, institutes, tea shops and eating houses. At the same time great social changes have taken effect and have tended to remove class barriers and foster the aspirations of the working classes. But in some measure we conduct ourselves in a manner prevalent among the more highly educated sections of society. The old drinking habits of the latter, which were notorious at the end of the 19th century, began to give way to greater sobriety early in the 19th century; and the movement was greatly promoted, as a feature of social life, by the influence of Queen Victoria's reign. It is worthy of note that police drunkenness is higher in Wales, Scotland and Ireland than in England. The respective numbers of licences per 10,000 in the years 1899-1903 were: England, 49-8; Wales, 55-2; Scotland, 123-3; Ireland, 175-6. The figures for Wales are strictly comparable, those for Scotland and Ireland less so; but the difference is striking. The greater prevalence of spirit drinking as a national habit, particularly in Scotland and Ireland, may account in part for the discrepancy. Other points which distinguish the three countries from England are their Celtic blood and Sunday closing. No connexion can be shown between the number of licensed houses and the prevalence of drunkenness; they are fewer in Scotland than in England and Wales, but more numerous in Ireland, though there has been a diminution there since 1902, which may have something to do with the fall in drunkenness. The same lack of correspondence is shown more fully by the detailed figures for England and Wales published in the official volume of the licensing statistics. Taking the county groups according to the number of licences in proportion to the population we get the following:

Licences and Drunkenness, County Boroughs, 1905

<table>
<thead>
<tr>

</tr>
</tbody>
</table>

It is curious that the mean figures for these two groups at opposite ends of the scale exactly reverse the number of licences and convictions; but the individual discrepancies show that other factors really determine the results. The chief of these is unquestionably occupation. All the counties with the highest number of convictions are pre-eminently mining counties. Year after year Northumberland, Durham and Glamorgan occupy the same place at the head of the convictions, and other mining counties are always high. These areas are as drunken because the publicans are few, but vice versa; the licences are kept down because of the drunkenness. The influence of occupation and character is further revealed by a broader survey. The following table from the judicial statistics for 1894 brings out these elements very clearly:

<table>
<thead>
<tr>
<th>Persons Proceeded Against for Drunkenness per 10,000.</th>
</tr>
</thead>
<tbody>
<tr>
<td>Seaports</td>
</tr>
<tr>
<td>Mining counties</td>
</tr>
<tr>
<td>Metropolis</td>
</tr>
<tr>
<td>Manufacturing towns</td>
</tr>
<tr>
<td>Pleasure towns</td>
</tr>
</tbody>
</table>

In other countries the same distribution is observed; drunkenness is most prevalent in seaports and mining districts. It is further fostered by a northerly situation, and these three factors go far to explain the condition of Scotland, as of Northumberland and Durham.

The United States.—The Census Bureau at Washington issues from time to time statistics of cities, which contain a good deal of information concerning drunkenness. The last return, published in 1910, contains details of 158 cities having a population of over 30,000 in the year 1907, to which the statistics relate. It appears from these returns that drunkenness is exceedingly prevalent in American towns. The figures are not comparable with the English ones, because they relate to arrests, which are more numerous than "proceedings" and still more than convictions. The number of women included is very considerable, but the data are too imperfect to permit the calculation of a general percentage. In New York the proportion of women arrested for drunkenness and disorder was 24-3 per cent. of the whole number. The cities are divided into four groups according to population:—(1) 10,000, (2) 100,000 to 300,000, (3) 500,000 to 1,000,000, (4) 3,000,000 to 5,000,000. The average number of arrests per 10,000 inhabitants in each group and in all cities together is—(1) 191-0, (2) 193-6, (3) 249-8, (4) 248-8. The comparative small range of difference between the groups is remarkable, and indicates a general prevalence of police drunkenness. The higher figures for groups (3) and (4) are explained by the excessive number of cases in certain manufacturing, mining and Southern coloured towns of small and medium size. These figures are for drunkenness alone, so that they cannot be confused with other offences; but on examining the details of individual cities it becomes clear that the cause varies considerably in making up the returns, and that in some places nearly all the arrests of drunken persons are charged to drunkenness whereas in others a large proportion are returned under the head of disorderly conduct. In considering the relation between drunkenness and the number of licensed houses, therefore, it seems desirable to put both sets of figures, as in the following table. It will be seen that there is a correspondence between the number of licensed houses and the amount of drunkenness alone or of drunkenness and disorderly conduct together, except that the fourth group has the largest number of licences and the most disorder.

There are large discrepancies between different cities, but not greater than among British towns. The following table gives the figures corresponding to the above for each of the great cities included in group 1, with the exception of San Francisco, the population of which could not be estimated:

</tbody>
</table>

To a certain extent the same inverse relation appears here as in England; the places with the smallest proportion of licences—namely, Philadelphia, Boston, Pittsburg and Washington—are conspicuous for drunkenness and disorder, while those with the largest proportion of licences—namely, Detroit, Cincinnati, Milwaukee and New Orleans—are distinguished by the lowest amount, with the exception of New Orleans, which is a special case by reason of the large coloured and Creole population. The exceptional position of Boston is obviously due to exceptional police activity and that of Chicago to the opposite. At Boston and Cleveland, it will be noticed, the police prefer the charge of drunkenness; at Baltimore the opposite. The position of Washington is explained by the very large coloured population and the strength of the police force, which is greater in the capital than elsewhere and very strict in regard to order in the streets. Philadelphia, Pittsburg and Cleveland are great manufacturing centres with a large population of foreign workmen; the vast influx of European immigrants, consisting of men disposed to drink by age, occupation, race and habits, and receiving higher wages than they have been used to, must always be borne in mind with regard to drunkenness in the United States. It is interesting to note the condition of those cities in which there is no licensed trade. There are none such in the first two groups, but 14 in the third and fourth groups. The following are the figures:

</tbody>
</table>

The majority are prohibition cities in Massachusetts, the only state in which this measure was applied to any place of considerable size in 1907. In all of them the drunkenness is below the mean for the group and considerably below that of similar and neighbouring towns. For instance, Brockton is a boot-manufacturing town.
comparable with Lynn in the same state; the respective figures are 240-9 and 561-1. The evidence here, so far as it goes, is in favour of local prohibition. On the other hand there are a number of licensed cities with lower figures, and two of those on the list—Chelsea and Salem—are very high up. State prohibition does not make such a good showing in Boston, Cambridge, one of the most drunken places in America—a fact confirmed by many observers—and Wichita in Kansas is above the mean. Kansas City is better. This place is peculiarly situated, being continuous with Kansas City, Missouri; the boundary between the two states passes through the town. Consequently the inhabitants have only to go into the Missouri half to obtain drink. Cambridge is similarly situated in relation to Boston. Charleston, which is above the mean for the group, was under the state dispensary system. In sum, these police figures furnish some argument for prohibition and some against; but they clearly demonstrate the limits of compulsion. Altogether the statistical evidence from the United States, whether of consumption, expenditure or drunkenness, offers no inducement to the United Kingdom to adopt any of the American methods of control in place of its own system.

The principal feature of this table is the much higher level in the second 20 years than in the first, though the police procedure has been the same. In the first 15 years the figure has exceeded that of 1865, which was practically the year before the company system was introduced, as it did not begin operations until October. Once more the influence of trade oscillations is well marked, particularly in the prosperous period of 1891-1900. To convert convictions into arrests for comparison with the following tables about 3 per 1000 should be added; this difference is very evenly maintained in Gothenburg.

Temperance

**Use and Abuse of Alcohol.**

The evils caused by the abuse of alcoholic liquors have always been recognized by mankind; they are too obvious to be ignored. Intoxication produces imbecility, bestiality, violence and crime; continued excess produces incapacity, poverty, misery, disease, delirium, insanity and death. But all these effects are produced by other causes and it is very difficult to estimate the precise share of the particular agent. In modern times scientific investigation has attempted to do this and to give precision to the conclusions drawn from ordinary observation. We will briefly summarize some of the results.

Drinking is associated with crimes against the person, but not with crimes against property, which form in England nineteenth of the whole (Judicial Statistics, 1901). Dr W. C. Sullivan, medical officer in the prison service, calculates that alcoholic intoxication is as accountable for drunkenness as for other crimes. The statistics of convictions for drunkenness are higher than for any other crime, and for a rather higher proportion of minor offences of the same class; and further that "it is probably the cause of the crimes as lust," but it makes no appreciable contribution to crimes of acquisitiveness. He gives the following table:

### Annual Average per 100,000—1891-1900.

<table>
<thead>
<tr>
<th>Areas</th>
<th>Drunkenness</th>
<th>Homicides and Assaults</th>
<th>Attempted Suicide</th>
</tr>
</thead>
<tbody>
<tr>
<td>Agricultural</td>
<td>226:3</td>
<td>116:33</td>
<td>3:46</td>
</tr>
<tr>

<td>6:42</td>
</tr>
<tr>
<td>Seaports</td>
<td>990:6</td>
<td>409:73</td>
<td>10:56</td>
</tr>
</tbody>
</table>

This does not show a regular connexion. The mining areas, where the most drunkenness, are only second in violence and lowest of all in suicide. Sullivan explains this discrepancy by the theory that chronic alcoholism is less prevalent among miners, and that this form is chiefly responsible for the crimes in question. It is impossible, however, to establish any constant relation between drink and violent crime; the two do not vary together. It was pointed out in the Judicial Statistics for 1901 that whereas in the year 1899 consumption of drink was 8 per cent. higher than the previous quinquennial period, crimes of violence were 1-62 per cent. lower. These statistics apply only to England. When other countries are taken into consideration it is still clearer that other factors are more important. Mr W. D. Morrison gives the following table of homicides in proportion to population in different countries (Crime and its Causes):

### Persons Tried for Homicide per 100,000.

<table>

<td>1:10</td>
</tr>
</tbody>
</table>

Except that England, Scotland and Ireland are in the order of relative drunkenness, the table shows no correspondence between drunkenness and homicide. In Sweden the converse is evidently the case. We have therefore given the following evidence from the United States, whether of consumption, expenditure or drunkenness, offers no inducement to the United Kingdom to adopt any of the American methods of control in place of its own system.

**Poverty.—** Much poverty is undoubtedly caused by drink, but it is not easy to establish a certain connexion between the two than in the case of crime. Pauperism and drink stand to a great extent in inverse relation; in good times the first diminishes and the second increases. But poverty is taken partly for incapacitation in England, which has had a general tendency to fall for many years, rose rapidly in the period of low consumption after 1860, fell still more rapidly in the great drinking years 1870-77, and rose again when they gave place to depression. With falling consumption after 1891 (see the table above) it rose till 1894, when
the opposite movement began; and, during the steady fall of drink since 1909 pauperism has been rising again. The only exception to the 1914-18 period of alcohol and the depression of 1929-33, was the influence of work and wages. Mr Charles Booth's statistical investigation in East London resulted in the following estimates of the percentage of poverty caused by drink: "great poverty" (20 per cent., drunken or thriftless wife, 5 per cent.; "poverty" (two next classes) the figures were—drinking, 7 per cent., drunken or thriftless wife, 6 per cent. These results can hardly be said to confirm the opinion that drink is the chief cause of poverty. Mr Rowntree's investigation in York did not enable him to make any numerical estimate of the percentage of the number of poor or of pauperism due to poverty (the lowest class), but he thought it the "predominant factor" in producing "secondary" poverty. Alderman McDougall's inquiry in Manchester (1883) resulted in the following proportions of drink-pauperism to pauper drink: 24.5 per cent.; females, 4.40 per cent.; widows and children of drunks, 21.84 per cent.

An inquiry conducted in 1894-95 by the Massachusetts Bureau of Statistics of Labour found that 39-44 per cent. of paupers attributed their position to their own intemperance and about 5 per cent. to that of their parents. All these inquiries are on a very small basis, and the last is particularly deceptive. Drink is commonly confessed by those who in the presence of observers do not serve as a plausible excuse for a condition really due to dislike of work. When poverty is examined by local distribution it is found to have very little connexion with drink. In 1901 the average proportion of pauperism to pauper drink in England was 5.2 per cent. The proportion of the pauper drink in the rural districts of Northumberland and Durham were all below it, the sober eastern counties all above it (Blue-book on Public Health, Social Conditions, Col. 481).

Insanity.—Dr Robert Jones finds that 16 per cent. of all the persons (7,182 out of 43,694) admitted into the London asylums during the twelve years 1893-1905 were definitely ascertained to owe their insanity to drink or intoxication. "The proportion in Claybury Asylum during the same period was 17 per cent., being 22 per cent. of the men and 12 per cent. of the women. Dr R. H. Crowley says:—"One may safely assert that from 20 to 25 per cent. of those cases caused by indulgence under the influences of drink are directly due to intemperance." Dr T. B. Hyslop says:—"With regard to insanity there is some difference in experience as to the relative frequency of alcohol in its causation. This difference ranges from being entirely unimpaired to 30 per cent. My own experience is that alcohol is a direct cause or an indirect factor in the causation of at least 50 per cent. of the cases of insanity." Dr T. S. Clouston estimates that alcoholic excess is the cause of about 20 per cent. of all the insanities in Great Britain and Ireland. These are the opinions of experienced medical men in charge of the insane. On the other hand, those in charge of insane hospitals are inclined to assign "irregularities of the alimentary canal" and "deficiency of certain kind." Dr Branthwaite, government inspector under the Inebriates Acts, observes in his Report for 1908, published in 1910, "There is no doubt whatever in detailing and treating persons sent to us under diagnosis as pauperism that we are dealing with a large number of cases under the administration of the act...a class known as 'feebly-minded.'...It would be difficult to find many more than about a third of all persons under detention capable of passing muster under mental capacity." In this statement he gives the following classification of 30.32 cases:

<table>
<thead>
<tr>
<th>Classification</th>
<th>Number</th>
<th>Percentage</th>
</tr>
</thead>
<tbody>
<tr>
<td>Insane</td>
<td>63</td>
<td>14.51</td>
</tr>
<tr>
<td>Very defective; persons more or less completely imbecile, degenerate or epileptic</td>
<td>377</td>
<td>47.04</td>
</tr>
<tr>
<td>Defective; eccentric, silly, dull, senile, or subject to periodical paroxysms of uncontrollable temper</td>
<td>1497</td>
<td>18.22</td>
</tr>
<tr>
<td>Of management or capacity, on admission or after six months' detention</td>
<td>1105</td>
<td>13.95</td>
</tr>
</tbody>
</table>

Insanity is therefore a cause as well as a consequence of excessive drinking, and the estimates given about it must be qualified accordingly. The following are given for foreign countries. In Italy a report of 1896 gives 26 asylums among 1,000, with a total of 20.6 per cent. of the admissions given as alcoholic. Dr Castelnuovo with regard to the method of classification. In Switzerland, of the admissions in 1900-04, 21·1 per cent. among males and 4·37 per cent. among females were alcoholics. In Denmark, of the admissions in 1899-1904, 19·3 per cent. of the admissions for the same period were alcoholics. In 1903-04, 14·0 per cent. were alcoholics. In France the proportion of all persons in asylums in 1907 with an alcoholic history was 12·5 per cent.

Mortality.—The influence of drink on mortality is an unascertainable quantity, because it may be associated with other causes to an extent which varies in an infinite series of gradations. All attempts to estimate it are more or less plausible guesses. We have however some perceptive data. The Registrar-General's Reports since 1867-8 contain the heading "alcoholism, delirium tremens," as a cause of death. The following are the rates per million recorded in quarterly periods from 1867-8 to 1910-11: 47·5, 42·0, 48·5, 46·8, 47-9, 47-8, 48, 5·7, 7·8, 7-9, 8·5, 7·8. This is unsatisfactory for two reasons: the first is, that alcoholism does not nearly cover all the mortality directly caused by drink; and the second is, that being a very vague term, it is used in certifying the cause of death depends largely on the views of the practitioner and current opinion in the medical profession. The attention paid to the subject has led to a growing recognition of alcoholism, which, indeed, does not appear at all in the older text-books. This accounts for the steady increase of deaths ascribed to it, which is otherwise inexplicable, being quite at variance with the consumption of drink during the same period. The Seventy-first Annual Report of the Registrar-General states that the mortality from alcoholism in the years 1900 and 1901 was materially increased by the transference of deaths that had been originally certified as from neuritis. It is now usual to classify alcoholism and cirrhosis as "delirium tremens." The following are the death-rates for twenty years:

These figures dispose of the current belief in an enormous increase of female intemperance based on the progressive rise of the death-rates. Discussing this question some years ago the present writer pointed out the defects of the statistics and said that the returns of the next few years might upset the whole argument. They have done so.

The statistics of alcoholism and cirrhosis, however, are very far from covering all the mortuary death from drink. It is not safe to calculate by inference from the returns of Denmark and Switzerland that the deaths directly attributed to alcohol in England and Wales should be some six times higher than they appear in the returns, and that they would then amount to 5 per cent. of the total deaths of adults instead of about 0·8 per cent. He adds:—"This percentage probably greatly understates the real facts." It may be so, but the calculation is based on too many assumptions to be accepted with confidence. In addition to the direct mortality there is an unknown score against alcohol in predisposing to other diseases and in accelerating death. Consumption is one of the diseases thought to be particularly associated with alcohol and the same occurs in several others. The following table shows the comparative mortality of males aged 25 to 65 from certain classes of disease in different groups of occupations. They include those with the highest and those with the lowest mortality. The heading "diseases of the circulatory system" includes heart disease and anaemia; diseases of respiratory system include bronchitis, pneumonia and pleurisy, but not phthisis, which is separately given; diseases of urinary system include Bright's disease. The table is compiled from the Supplement to the Fifty-sixth Annual Report of the Registrar-General, published 1908. No other country has similar statistics. In 1890-91 these were 11·8 per cent. per cent. of the deaths of males over 20 years directly or indirectly to alcohol, and for Denmark, where the corresponding figure is 42 per cent.

The consumption of a high degree of alcoholic mortality with weakness of all the organs is clearly shown by the figures for unoccupied males, general labourers, dockers, costermongers, innkeepers and inn-servants. Potters and file-makers, with a comparatively low degree of alcoholic mortality, alone show a similar condition,

General labourers  2,235 40 37 491 233 324 444 96

and it is no doubt due to the inhalation or absorption of irritating or poisonous particles through the nature of their occupation. The clergy, who have the lowest alcoholic mortality, show a remarkably low level of organic disease of all kinds; railway engine-drivers, who come next, suffer more from circulatory and respiratory diseases, navvies and coal-miners still more, while civil servants are more susceptible to phthisis. Agriculturists, though with a higher alcoholic mortality, nearly equal the clergy in general healthiness, which must be attributed to the open-air life. The low alcoholic level of coal-miners and navvies is striking, because both are hard-drinking classes; their position can only be explained by the fact that they drink beer, and it goes far to prove the innocuousness of beer when combined with hard work. The enormous and absurdly disproportionate mortality from diseases of the liver among inkeepers, and in a lesser degree among unoccupied males, is obviously due to a prejudice for stating that cause in place of alcoholism. The condition of unoccupied males revealed by this table is worth a volume of sermons. The mortality among them between the ages of 25 and 65 is higher than that of any other class of the community. It is also worth noting that good health is good for health. The clergy are the poorest of the educated and professional classes; and agricultural labourers, who are the poorest of the manual working classes, are nearly as healthy all round except that they are somewhat more liable to phthisis; their comparative mortality figure from all causes is only 621.

Longevity.—A great deal of statistical information with regard to the comparative longevity or expectation of life at different ages among abstainers and non-abstainers has been collected by life-insurance companies and friendly societies. The table is given in the syllabus of temperance teaching in elementary schools issued in 1909:—

Expectancy of Life.

Similar statistics have been prepared showing the relative mortality experience among insured persons. Mr R. M. Moore gives the following proportional figures at different ages for all the societies embraced in the Institute of Actuaries tables, as compared with the abstaining section of the United Kingdom Temperance and Provident Institution, which is taken as 100:

The United Kingdom Temperance Institution has a general as well as an abstaining section. The experience of the twenty-two years 1884-1905 gives the following result: percentage of actual to expected deaths—general section, 79-53; temperance section, 54-25. Other offices having abstaining sections show similar results; thus:—

General Temperance. Sceptre Life Association (25 years) 79-67 53-05
Scottish Temperance Life Assurance Co. (25 years) 64 46

Pathology.—Dr Sims Woodhead thus summarizes the results of experimental investigation into the direct action of alcohol upon living cells and tissues.

Alcohol plays a prominent part in bringing about degeneration of nerves, muscles and epithelial cells; it determines the accumulation of waste products in the tissues by paralysing the tissue cells, interfering with oxidation, with secretion and with excretion; it induces the proliferation of the lower forms of tissue, often at the expense of the more highly developed tissues, which in its presence undergo marked degenerative changes; it interferes directly with the production of immunity against specific infective diseases, and coming from the liver it may cause the inflammation, diarrhea and equally important part in impairing the resistance of tissue to the advance of the active agents in the production of disease that may have already obtained a foothold in the body.

With regard to this aspect of the subject it must be remembered that laboratory experiments by which alcohol is placed in direct contact with cells and tissues are an entirely different thing from the dietetic use of beverages containing dilute alcohol with other things. It would be interesting to know how the tissues would behave when similarly treated with common salt, lemon juice, vinegar, theine, caffeine or other substances in general dietetic use or with ordinary tonics such as quinine, quassia and dilute acids.

Inebriety.—Much study has been devoted to inebriety as a diseased condition. The general tendency is that the continued and excessive indulgence in alcohol is characterized by dyspepsia or a craving for alcohol, which is chronic or periodical and which the subject cannot resist. It is accompanied by organic changes in the interior of the system, probably begin in the stomach, but end in disintegration of the brain cells with the development of alcoholic insanity. The only chance of cure lies in complete abstinence from liquors with, at first, suitable medical treatment.

The recognition of this fact has led to the establishment of special institutions for this purpose, both of a voluntary and a compulsory character. An account of the laws relating to the subject is given under the heading of INEBRIETY. In accordance with the law three classes of institutions have been established in the United Kingdom:— (1) Certified inebriate reformatory, to which patients are committed by the courts for various periods of detention. There are in number, not disclosed in the year report, the committals to them numbered 262 (218 women and 44 men). The total number committed since their establishment in 1897 is 3002 (2948 women and 44 men); the highest number in any one year was 453 (428 women and 65 men) in 1907. (2) State Inebriate Reformatories, more of a penal character, for persons committed but too refractory for the previous class. There are two, one for women and one for men; the average number under detention in 1908 was 74 women and 42 men; the admissions were 27 women and 10 men. (3) Licensed retreats, for voluntary patients. In 1908 they numbered 20, and had under treatment 493 patients (285 men and 208 women). In all about 800 habituees are thus treated. The results cannot be stated with any precision, but they are certainly disappointing. The Inebriates After-Cure Association gives the following analysis of 407 cases treated from reformatories and looked after in the years 1903-8:—Satisfactory result, 82 (59 women, 32 men); unsatisfactory, 114 (78 women, 36 men); not known, 221 (162 women, 49 men). One explanation of the failure of treatment and the frequency of relapses...
TEMPEST, MARIE

We know that they exist by their taste and their effect; they make the difference between port and sherry, between claret and Burgundy; between one vintage and another, between brandy and whisky, between many influences without alcohol, and alcohol, and knows very little about that—but vastly important to the human organism. Another group of experiments are equally fallacious, they are done to a different end. The effect of alcohol in mental operations is tested by the competitive or provoking action of work is done after a dose and without it. The effect has been found to be diminished speed and ease; but these experimenters do not suggest that these are a direct cause for all, nor are the people to work not just before work; after work they find them all, alcohol included, beneficial. The mortality statistics are treated in a similar one-sided way. The case of alcohol the injury done by the abuse of alcohol, but what of its moderate use? Agricultural laborers are the most typical medium drinking class, and are one of the healthiest in spite of exposure, bad housing and poverty. If the unhealthiness of the work done has anything to do with the drink, then the healthiness of those who drink moderately should be referred to it too.

The absolute condemnation of alcoholic drinks has never been endorsed by public opinion or by the medical profession because it is contradicted by their general experience. That many persons are better without any alcohol, and that many more would be better if they were less or not at all, is equally undeniable that many derive benefit from a moderate use. Sir James Paget, than whom no man was more completely master of his appetites or better qualified to judge, drank port wine himself and regarded it as the best of all preventives of tuberculosis. The latter of the medical profession as a whole and of temperate men in general. Attempts to support the case for abolishing the use of alcoholic liquors by denying them any value and by attributing to them effects which spring from many other causes, do not carry conviction or advance the cause of temperance. Much a stronger argument lies in the difficulty of drawing a definite line between use and abuse; then, too, much to men, the moderate use of alcohol is a safeguard against the evils of the latter. It may also be argued that the evils of the latter are sufficiently great to justify the restriction of the former. But the use of most things is open to the same objection, and mankind at large has never consented to forego the great advantages of their use.

Nor is there any sign of an intention to make an exception in favour of alcohol. On the other hand, moderation is attainable by every single individual. It is in fact observed by the great majority and to an increasing extent. There is a line between use and abuse, and every one really knows where it is in his own case. If he cannot draw it let him abstain, as Dr Johnson did for that reason. But society can do much to assist the individual by inculcating moderation, setting a standard, promoting its maintenance by helpful environment, discouraging excess and diminishing temptation. All the evidence points to those means as the most likely to bring about the improvement which has taken place in Great Britain.

This article should be read in conjunction with that on LIQUOR LAWS, and it will therefore be in place here to give some additional information regarding the latter. The policy of prohibition has recently gained ground in several countries. In 1910 nine American states had adopted it—namely, Maine, Kansas, N Dakota, Georgia, Oklahoma, Alabama, New Hampshire, North Carolina and Tennessee; and it was estimated that nearly half the population of the United States were living under state or local prohibition. In Canada the province of Prince Edward Island has adopted complete prohibition in 1906 Ireland by a popular vote resolved to prohibit the manufacture, importation and sale of intoxicating liquor. In Norway nearly half the towns have adopted prohibition under the law of 1906. In Belgium and Switzerland the manufacture of spirits is prohibited. In New Zealand the principle of prohibition has gained ground, and in 1910 was in force over one-seventh of the colony.

TEMPEST, MARIE (1866-1936), the stage name of the English actress, née Marie Susan Etherington, who in 1898 married Cosmo Gordon-Lennox ("Cosmo Stuart"), a grandson
of the 5th duke of Richmond, and himself an actor and playwright. She had a charming soprano voice and was educated for the operatic and concert stage, but at first appeared in light comic opera, in which she became very popular. Abandoning music, however, for the comedy stage: she made an even greater success as an actress, notably for her performances of non-exceptional characters produced in later years she produced a succession of modern comedies, in which her capacity for rivalling in London the triumphs of Réjane in Paris was conspicuously displayed.

**TEMPIO PAUSANIA**, a town of Sardinia, in the province of Sassari, from which town it is 52 m. E.N.E. by road. It is also reached by rail by a branch line (25 m.) N.W. from the main line from Terranova to Cagliari, leaving the latter at Monti, 14 m. S.W. of Terranova. Pop. (1901) 4521 (town), 14.573 (community). It lies in a mountainous district 139 ft. above sea-level, to the N.N.W. of the Monte Limbara. It is the chief town of the Gallura, and has been an episcopal see since the 9th century (with Ampurias). The cathedral is a modern building. The district is agricultural and pastoral.

The costumes are picturesque, especially those of the women. For the name Pausania see TERRANOVA PAUSANIA.

**TEMPLARS.** The Knights Templars, or Poor Knights of Christ and of the Temple of Solomon (poaerres commiliones Christi templique Salomonici), formed one of the three great military orders of the 12th, and 13th centuries. Unlike the Hospitallers and the Teutonic Knights it was a military order from its very origin. Its founders were a Burgundian knight named Hugues de Payns (Hugo de Paganis and Godefroi de St Omer, a knight from northern France, who in 1129 undertook the pious task of protecting the pilgrims who, after the first crusade, flocked to Jerusalem and the other sacred spots in the Holy Land. They were quickly joined by six other knights and soon afterwards organized themselves as a religious community, taking an oath to the patriarch of Jerusalem to guard the public roads, to forsake worldly chivalry, “of which human favour and Christ was the cause” and in chastity, obedience and poverty, according to the rule of St Benedict, “to fight with a pure mind for the supreme and true King.”

To this nascent order of warrior monks Baldwin I., king of Jerusalem, handed over a part of his royal palace lying next to the former mosque of al-Aksa, the so-called “Temple of Solomon,” whence they took their name. They had at first no distinctive habit, wearing any old clothes that might be given to them. Nor was their community exclusive. Their primitive rule seems to have enjoined them especially upon “chivalry” the mutual assistance which a knight was expected to render another after absolution by the bishop, to their order, and they thus served a useful purpose in at once disciplining and converting the unruly rabble of “rogues and impious men, robbers and committers of sacrilege, murderers, perjurers and adulterers” who streamed to the Holy Land in hope of plunder and salvation. It was this rule which led later to the most important privilege of the order, the immunity from sentences of excommunication pronounced by bishops and parish priests.

This practice, as Prutz points out, might have brought them at once under the suspicion of the Church, and it soon became expedient to obtain the highest sanction for the new order and its rules. In the autumn of 1127 accordingly Hugues de Payns, with certain companions, appeared in Europe, where he was fortunate enough to secure the enthusiastic support of the all-powerful abbot of Clairvaux. Grateful pilgrims had already elected him H.W. (De laude novae militiae, a glowing panegyric of this new holy community, was addressed by Bernard to Hugues de Payns by name, insured the success of his mission. In 1128 the council of Troyes discussed and sanctioned the rule of the order which, if not drawn up by Bernard, was undoubtedly largely inspired by him.4

**Rule of the Temple.**—No MS. of the original French Rule of the Temple (Règle du Temple) exists. Of the three extant MSS, reprinted by recent editions, one is preserved at the Accademia dei Lincei at Rome (Cod.做大一 at one at the city of Troyes (fonds français 1927), the third in the departmental archives at Dijon (H. 111). The last of these, probably intended for the use of the master of a subordinate house, is much abbreviated; it dates, however, from the early part of the 13th century, whereas the others are of the end of the century at earliest. In essentials these copies preserve the matter and spirit of the primitive Rule, and they prove that to the end the order was, in principle at least, submitted to the same strict discipline as at the beginning.

The Règle du Temple in its final form as we now possess it contains four articles for the administration of the order; the duties and privileges of the various officers; the monastic rules, regulations as to costume and as to religious services; rules for the holding of chapters, and a summary of offences and penalties. The order was governed by a titular master and at receptions into the order; a definition of the relations of the order to the pope, and to other religious orders. It must be observed however, that, although the order as described above was only gradually developed, not having its seat fixed at Troyes. At first the master of the Temple at Jerusalem was only one among many; the seneschal and marshal appear not until 1135; and the grand master and his household not till the middle of the century. It was, however, under the aegis of Pope Alexander III. (1163), the great charter of the order, that its organization was definitely centralized.

Constitution.—As finally constituted, the order consisted of (1) knights (chevaliers), (2) chaplains (curaumes), (3) sergeants or esquires (frateres servientes armigeri), (4) menials and craftsmen (frateres servientes famuli et officii). All were bound by the rules of the order and enjoyed its privileges. Women were not admitted to the order.6

1. At the head of the order was the master of the Temple at Jerusalem (in Cyprus after the fall of the Latin Kingdom), known as the grand master. His authority was very great—except in certain reserved cases his word was law—but he was not absolute. Thus in matters of special importance—alienation of the estates of the order, attack on a fortress, declaration of war, conclusion of an armistice—his consent was necessary; but he was only an envoy to the French king, and was bound by the vote of the majority; nor could he modify or abrogate a decree of the council of the order without their consent. He had to act with the consent of the chapter also to the nomination of the grand constable; and to ordain or establish anyHieratical officer. The grand master, however, was alone, and so on till the number of the twelve apostles had been reached. A chaplain, representing Jesus Christ, was then added to complete the ecclesiastical college (see Curzon, Règle du Temple, p. xxxv).7

The grand master was allowed four horses for his ordinary use. His household consisted of a frater capellanus, a cleric, a frater servientes with two horses, a Saracen secretary (écuyer saracinotis) etc.8

Bernard was not present at the council, but the “ humble emissaries of the Règle of the Temple” (un tel des envoys chargés de le commandement dou concile et dou venerable per Bernard abbes de Cleraveus.” Compare the rule also with the chapter (iii,) of the De laude: De millibus Christi.9

4. Of a secret Rule, in so far as the most diligent research, no trace has ever been found. It is now generally held that none ever existed. The legend of its existence, so fatal to the order, is probably traceable to the fact that the complete Rule was hardly known by the commonalty, and, moreover, only fragments being given to the heads of the lesser houses (e.g. the Dijon MS.) and known generally to the knights.

5. Of the origin of the compaignie de feme, que le deable ancien compaignie de feme a depluit plusieurs de droit sentier de paradis. It is interesting to compare this with the more wholesome view of the best of the contemporary chivalrous poets, e.g. Waltharius who urges the knight to win a good name in the world, to hold up true love as the highest earthly incentive to noble deeds.

6. The bull Omne datum optimum (1163) decreed that the master must be a knight of the order who had taken the vows, and vested the election exclusively in the knights.
TEMPLARS

as interpreter, a turcoplie, i.e. a soldier belonging to the light-horse attached to the order, a farrier and a cook, two footmen (gardians de pied) in the special colour of red, and ten servants, only used for horse, only used at the time. He was further attended by two knights of the order of high rank. The ensigns of his presence on campaign were the large red cross of the order, the black and white pennant, charged with the red cross of the order.

2. The second officer of the Temple was the seneschal. He had a right to attend all chapters, even the most secret. His equipage, that of a master of the order, with the great white ensign attached to his person were two squares, a knight companion, a frater servientes, a secretary in deacon’s orders to say the hours, a turcoplie, a Saracen squire, and two foot-servants.

Third in order was the marshal, who was supreme military authority, and had under his charge the horses and arms. In the absence of master and seneschal he acted as locum tenens. His equipage and suite were much the same as those of master and seneschal.

The provincial marshals were absolute in their provinces, but subordinate to the marshal of the order.

The commander of the land and realm of Jerusalem was grand treasurer of the order, administered its estates in the province of Jerusalem, and was responsible for the lodging of the brethren. If a horse had charge of the field, the commander of the part of Acre being his subordinate. His equipage and suite were much the same as those of seneschal and marshal.

The commander of the city of Jerusalem was the hospitaler of the order, and was to go together with the seneschal to the Holy Land, and with the duty of supplying them with food and horses. Ten knights were specially attached to him for this purpose, and to act as guard to the relics of the True Cross. Subordinate to the commander of the Templars for Jerusalem was the seneschal.

The commanders of Tripoli and Antioch enjoyed all the rights of the grand master within their provinces, except when he was present. The master of the chivalry of the order was the seneschal.

Besides these, the rule mentions the commanders of France, England, Poitou, Portugal, Apulia and Hungary, whose rights and privileges are analogous to those of the commanders above mentioned.

Lastly, of the great officers of the order must be mentioned the dropper, who was charged with the supervision of the clothing of the brethren. He was closely associated with the commander of the order, and was called to be a companion of the knights, but his suite included a number of tailors.

Below the great dignitaries there were in the provinces commanders of the orders, knights of the chivalry, and the commanders of the knights, who acted as lieutenants of the marshals.

Turning to the general body of the order: the knights (milites) were entitled to three horses and a squire, or by special favour to four horses and two squires. They had two tents.

Of the sergeants (servientes) five occupied an exceptional position: the deputy marshals (sous-maresschals), who looked after the arms and armour, the gendarmier, who was responsible for the discipline and morals of the brethren, the gendarme of the arms, the seneschal of the tunics, and the seneschal of the copes. These had two horses, a squire and a tent. All the others, even if commanders of houses, had but one horse. At the head of all the sergeants was the second in the order, the squire of the copes. He had four horses in his equipage and certain special prerogatives; in battle he took his orders only from the master or seneschal.

Of particular importance were the chaplains (fratres capitani). These did not originally form part of the order, which was served by priests from outside. The bull Omne datum optimum of 1193 imposed on clerics attaching themselves to the order an oath of life-long obedience to the grand master; by the middle of the 13th century the chaplains took the same oath as the other brothers and were distinguished from them only by their orders and the privileges these implied (they were spared the more humiliating punishments, shaved the face, and had a separate cup to drink out of). The order thus had its own clergy, exempt from the jurisdiction of diocesan bishops and parish priests, owing obedience to the grand master, who had a special position (non episcopus). In 1197, when the Templars were allowed to confess to any save a priest attached to the order, if one were available, and such priest was formally declared to have received from the pope more power to absolve than an archbishop, it remained undisturbed. The order admitted either for life or for a term of years. Married men were also received, but on condition of bequeathing one half of their property to the order (remise).

The chapters of the order were either secret, composed of such brothers as the master might esteem "wise and profitable for giving advice," or general assemblies of the order, at the discretion of the master, who was to listen to the counsel given and do what seemed best to him.

Habit of the Order.—The characteristic habit of the order was the white mantle, symbolic of purity, with the red cross, the ensign of the order. Their geometry was the same as those of the principality of Antioch, except that the Templars imposed their habit on all knights bound by life-long vows, however, were privileged to wear the white mantle, which was also given to chaplains in episcopal orders. The rest wore a black or brown robe with a white mantle. The order had no hooded habits. All the chaplains were distinguished by wearing the mantle closed.

Conduct and Discipline.—The brethren were to attend daily services; but the soldier on war, with his nightly duties might com; he must attend no functions of the church except at Matins and Mass. Two regular meals were allowed for each day; but to these might be added, at the master’s discretion, a light collation, and a supper, but not of other meat. Meat must be eaten twice a week; and in other days there was to be a choice of vegetable fare so as to suit the tenderest stomach. Brethren were to eat by couples, each keeping an eye on his fellow to see that he did not practise an undue austerity. Wine was served at every meal, and at those times silence was strictly enjoined that the words of Holy Writ might be heard with the closest attention. Special care was to be taken of aged and ailing members. Every brother owed the absolute obedience to the master of the order, and was to go wherever his superior bade him without delay, "as if commanded by God." All undue display in arms or harness was forbidden. Party-coloured garments were not allowed; and the rule of the order extended to All Souls a linen shirt might be substituted for one of wool. The hair was to be worn short, and a rough beard became one of the distinguishing marks of the order. Hunting and hawking were prohibited, and the possessor of the order of knighthood was forbidden to keep or carry arms. A lion, however, being the type of the evil one, was legitimate prey. Strict watch was kept by the knights in every enclosure, and their quarters were so out by night to visit the Sepulchre of our Lord. No letter, even from the nearest relative, might be opened except in the master’s presence; nor was any member to feel annoyance if he saw his relative’s gift transferred at the master’s bidding to some other brother. The brethren were to sleep in separate beds in shirts and breeches, with a light always burning in the dormitory. Those who lacked a mattress might place a piece of carpet on the floor; but no Laurier was discarded.

A term of probation was assigned to each candidate before admission; and a special clause discouraged the reception of boys below the age of three years.

For grievous offenses, such as desertion to the Saracens, heresy, losing the gonfanon, murdering a Christian, or failing to account for all the property of the order in his possession, a Templar might be expelled (perdre la maison): for minor offenses, such as disobedience, lowering the banner in battle, or killing a slave or a horse, the punishment was that of servitio, e.g. by the sale of two horses of another religious order was received by the Templars, and no Templar could leave the order without permission of the master, no Templar was to marry, but the order might refuse to grant a dispensation to a Templar’s daughter. The Templars were not to be married to anyone who was not a freeman or a free woman. By mutual agreement the Templars and Hospitaliers, despite their long and deadly feud, were bound not to receive ejected members of the rival order; and the Templar cut off in battle did not commit the sin of rejoining his own ranks which might rally to the cross of St John.

History.—Long before St Bernard’s death (1153) the new order was established in almost every kingdom of Latin Christendom. Henry I. granted them lands in Normandy. They seemed to have been settled in Castile by 1129, in Rochelle by 1131, in Languedoc by 1136, at Rome by 1138, in Brittany by 1141, and in Germany at perhaps a still earlier date. Alphonso I. of Aragon and Navarre, if we may trust the Spanish historians, bequeathed them the third of his kingdom (Mariana, x. c. 9). Raymond Berengar IV., count of Barcelona, and Alphonso’s successor in Aragon, whose father had been admitted to the order, granted them the strong castle of Monzon (1143), and established a new chivalry in imitation of their order. Louis IX. of France bequeathed to them a piece of marsh land outside Paris, which in later times became known as the Temple, and was the headquarters of the order.

The Bible was read in a French translation. A MS. of a Templar rule, existing in the old library of the Inquisition, and published by F. Prutz, is now in the Bibliothèque Nationale in Paris. See Prutz, Tempelorden, p. 116.

This rule was not observed later on, postulants being admitted without any period of novitate, and among the Templars arrested in 1307 were many young boys.

1 The titles varied. The provincial commander is “Master” or Grand Prior. In Flanders, when large territories fell into the order’s hands, they were ruled by Grand Masters, each with a core of major preceptors over large estates, and under them “preceptors” of houses. Preceptors took their name from the mandate of the master issued to them: “Preceptoribus tuis.”

2 Rule 299. Car il en est greignier pori de l’apostolé (i.e. the pope) d’esse assourdre que un arcevesque (Curzon, p. 165).
of the order in Europe. Stephen of England granted them the manors of Cressing and Witham in Essex, and his wife Matilda that of Cowley, near Oxford. Eugenius III., Louis VII., and 130 brethren were present at the Paris chapter (1147) when Louis seemed to have granted the count of Anjou, lord of land near Hitchin; and the list of English benefactors under Stephen and Henry II. includes the noble names of Ferrers, Harcourt, Hastings, Lacy, Clare, Vere and Mowbray. Spiritual privileges were granted to them by the popes as lavishly as temporal possessions by the princes and people. Pope Adrian IV. allowed them to have their own churches; Eugenius III. added to these the right to have churchyards; and churches and churchyards, as in the case of the order generally, were exempted from the operation of ordinary excommunications and interdicts. Thus a person dying excommunicated, refused burial elsewhere, sometimes—like Geoffrey de Mandeville—found a resting-place in the consecrated ground of the Templars. Eugenius III. also granted the Templars the right to have interdicted churches opened twice a year for the purpose of making their collections. They were, moreover, as defenders of the Church, exempted from the payment of tithes. Finally, they were exempted from the action even of general censures and decrees of the popes, unless mentioned in them by name. Very soon the order refused to submit in any way to the ordinary jurisdicions of the civil courts; and in the case of bishops of separate ecclesiastical organization under the pope as supreme bishop. The result was that, scarce twenty-five years after its foundation, the order was at open feud with bishops and parish priests, and the popes found it necessary to issue decree after decree to protect it from violence and spoliation. The complaints of the secular clergy, on the other hand, came to a head in 1179 at the Lateran Council, when even Pope Alexander III. had to consent to a series of decrees directed against the abuse of its privileges by the order (Prutz, p. 41).

So long, however, as the attention of the papacy and of Countess Matilda was fixed on the problem of recovering and safeguarding the Holy Land, the position of the Templars was unassailable, and all efforts to curb the growth of their power were in vain. The order as such had no European policy; the whole of its vast organization was maintained for the purpose of feeding the holy war against the infidels with recruits and with money; and its ultimate fate depended on its success or failure in the East.

(W. A. P.)

After the council of Troyes Hugues de Payns came to England and induced a number of knights to follow him to the Holy Land. Among these was Fulke de Ferrers, count of Nür al-Din, who had been a Templar before assuming the crown of Jerusalem in 1111. Hugues de Payns died about the year 1136 and was succeeded by Robert de Crons, who is said to have been Anselm's nephew. Everard de Bæres, the third master, was conspicuous in the second crusade. In the disastrous march from Lodizica to Attalica his troops alone kept up even the show of discipline; and their success prompted Louis VII. to regulate his whole army after the model of the Templar knights. In the French king's distress for money the Templars lent him large sums, ranging from 2000 silver marks to 30,000 solidi. When Conrad III. of Germany Nür al-Din in Jerusalem he was entertained at his palace (Easter 1145); and in the summer of the same year they took part in the unsuccessful siege of Damascus. The failure of this expedition was ascribed by a contemporary writer to their treachery—a charge to which Conrad would not assent. This is the first note of the accusations which from this time were of constant recurrence.

Henceforward for 140 years the history of the Templars is the history of the Crusades (q.v.). In 1149 the Templars were appointed to guard the fortress of Gaza, the last Christian stronghold on the way towards Egypt. Four years later the new master, Bernard de Tremsilai, and forty of his followers, bursting into Ascalon, were surrounded by the Saracens and cut off to a single man. William of Tyre has preserved the scandal of the day when he hints that they met a merited fate in their eagerness to possess themselves of the city treasure.

Next year the rumour went abroad that they had sold a noble half-converted Egyptian prince, who had fallen into their hands, to chains and certain death for 60,000 aurei. In 1166 Amalric, the Latin king of Jerusalem, hanged twelve Templars on a charge of betraying a fortress beyond the Jordan to an ambassador of Nür al-Din of Damascus. The military power of Nür al-Din (1145-73) was a standing menace to the Christian settlements in the East. Edessa had fallen to the prowess of his father (1144-45); Damascus was conquered by the son (1143), who four years earlier had carried his depredations almost to the walls of Antioch, and in 1157 laid siege to the Christian town of Panias near the sources of the Jordan. In the disastrous fight that followed for the safety of the fortress of the Hospitallers, Bertrand de Blanquefort, the master of the Templars, and Odo de St. Amand were taken prisoners. Bertrand was released later when Manuel was preparing to march against Nür al-Din. The Templars do not seem to have opposed Amalric's early expeditions against Egypt. It was Geoffrey Fulcher, the Templar correspondent of Louis VII., who brought back (1167) to Jerusalem the glowing accounts of the splendour of the caliph's court at Cairo with which Gibbon has enlivened his great work. Nor was the order less active at the northern limits of the Latin kingdom. Two English Templars, Gilbert de Lacy and Robert Mansel, "qui Galensibus praeceperat," starting from Canterbury, met up with the king of Lebanon and of Tripoli and put him barefooted to flight. But jealousy or honour led the Templars to oppose Amalric's Egyptian expedition of 1168; and the wisdom of their advice became apparent when the renewed discord on the Nile led to the conquest of Egypt by Asad al-Din Shirkuh, and thus indirectly to the accession of Saladin, in 1169. In 1170 he beat Saladin back from their frontier fortress of Gaza; and seven years later they shared in Baldwin IV.'s great victory at Ascalon.

Meanwhile Saladin had possessed himself of Emesa and Damascus (1174-75), and, as he was already lord of Egypt, he could afford to neglect the Latin kingdom on every side. In July 1173 Amalric was succeeded by his son Baldwin IV., a boy of twelve. Raymond III., count of Tripoli, a man suspected of being in league with the Saracens, was appointed regent, although in 1176 the masters of the Templars and the Hospitallers united in offering this office to the newly arrived Philip of Flanders. The construction of the Temple fortress at Jacob's ford on the upper Jordan led to a fresh Saracen invasion and the disastrous battle of Panas (1179), in which the young king and the Holy Cross escaped with difficulty, while Odo de St. Amand, the grand master, was carried away captive and never returned.

During Odo's mastership the Old Man of the Mountains sent to Amalric offering to accept the Christian faith if released from the tribute he had paid to the Templars since (according to the History of the Fratres of the Temple, p. 335-336.)
recounting of M. Defrémery) somewhere about 1149. The Templars murdered the envoys on their return (c. 1172). Amalric demanded that the offenders should be given up to justice. Odo refused to yield the chief culprit, though he was well known, and invoked the protection of the pope. Amalric had to vindicate his right by force of arms at Sidon and died while preparing to take stronger measures. The connexion between the Templars and the Old Man was still vital eighty years later when the two grand masters rebuked the insolence of the Assassin envoys in the presence of Louis IX. Odo de St Amanda was succeeded by Arnold de Torroge, who died at Verona on his way to implore European succour for the Holy Land. The power of Saladin was new (1184) increasing daily; Baldwin IV. was a leper, and his realm was a prey to rival factions. There were two claimants for the guardianship of the state—Raymond III. of Tripoli and Guy de Lusignan, who in 1180 had married Sibylia, sister of the young king. Baldwin inclined to the former, against the patriarch and Arnold de Torroge.

There is something Homeric in the story of the fall of the Latin kingdom as related by the historians of the next century. A French knight, Gerard de Riderfort or Bildeford, coming to the East in quest of fortune, attached himself to the service of Raymond of Tripoli, looking for the hand of some wealthy widow in reward. But on his claiming the hand of the lady of Botron he was met with a refusal. Angered at this, Gerard enrolled himself among the Templars, hid his time for revenge, and was elected grand master on the death of Arnold. Baldwin IV. died (1185), leaving the throne to his young nephew Baldwin V., the son of Sibylia, under the guardianship of Raymond, whose office was not of long duration, as the little king died in September 1186. This was Gerard's opportunity. The Templars carried the body of their dead sovereign to Jerusalem for burial; and then, unknown to the barons of the realm, Gerard and the patriarch crowned Sibylia and her husband Guy. The coronation of Guy was the triumph of Raynal of Chatillon, once prince of Antioch, and Saladin's deadlest foe. It was at the same time the downfall of Raymond, who was already, as both Latin and Arabic writers are agreed, that the Christian court and the Mahommedan sultan now entered into an alliance. To break this friendship and so save the kingdom, the two grand masters were sent north to make terms with Raymond. But the rash valour of the Templars provoked a hopeless contest with 7000 Saracens. The grand master of the Hospitalers was slain; but Gerard made his escape with three knights to Nazareth (1st May 1187). In this emergency Raymond became reconciled with Guy; and Gerard placed the Temple treasures of Henry II. at his king's disposal. Once more it was the Templars' rashness that led to the disastrous battle of Hittin (4th July). Gerard and the king fell into the hands of Saladin, but were released about a year later; Raymond of Tripoli made his escape through treachery or fortune; and 230 Templars fell in or after the battle, for the fight was scarcely over before Saladin ordered all the Templars and Hospitalers to be murdered in cold blood. One after another the Christian fortresses of Palestine fell into the hands of Saladin. Jerusalem surrendered on 2nd-3rd October 1187, and the treasures of the Temple coffer were used to purchase the restoration of the poorer Christians, part of whom the Templar warriors guarded on their sad march from the Holy City to Tripoli. Part of their wealth was expended by Conrad of Montfort in the defence of Tyre; but, when this prince refused to admit Guy to his city, both the Templars and the Hospitalers from the neighbouring parts flocked to the banner of their released king and accompanied him to the siege of Acre (22nd August 1189). In his company they bore their part in the two years' siege and the terrible famine of 1190-1; and their grand master died in the great battle of 4th October 1189, refusing to survive the slaughter of his men. On the fall of Acre Philip Augustus established himself in the palace of the Templars, who are, however, stated to have sympathized with Richard. This king sold them the island of Cyprus for 100,000 bezants; but, unable to pay the purchase money, they transferred the debt and the principality to Guy of Lusignan. The English king consulted them before deciding on any great military movement; and in June 1192 they advocated the bold plan of an advance on Egypt rather than on Jerusalem. In the disputes for the Latin kingdom of the East the Templars seem to have supported Guy, and, like Richard, were credited with having had a hand in the murder of Conrad of Montfort (April 1192). It was in the disguise of a Templar and in a Templar galley that Richard left the Holy Land. When Acre was recovered, the Templars, like the Hospitalers, received their own quarters in the town, which from this time became the centre of the order. On the death of Henry of Champagne (1197) they vetoed the election of Raoul de Taharie; after the death of his successor Amalric they refused to renew the truce with Saladin's brother, Saif al-Din, and led an expedition against the Saracens before the arrival of the new king, John de Brienne, at whose coronation in 1210 William de Chartres, the grand master, was present. Seven years later, with the aid of Walter de Avennis and of the Teutonic Knights, they commenced the building of their fortress of Castle Pilgrim, near Acre, on a rocky promontory washed by the Mediterranean on every side except the east. This wonderful structure, whose ruins are still to be seen, was fortified with a strong wall, founded on the substructure of a yet more extensive one running from sea to sea, and was flanked by lofty towers of huge squared stones, surrounded by a moat of pure water, besides fishponds, salt-mines, woods, pastures, orchards, and all things fitted to furnish an abode in which the Templars might await the day of their restoration to Jerusalem.

It was from this castle that in May 1218 the fifth crusade started for the expedition against Egypt. The Templars were the heroes of the siege of Damietta, at which William de Chartres was slain. "First to attack and last to retreat," they saved the Christian army from annihilation on 29th August 1219; and when the city surrendered (5th November) the order numbered 1161 twelve-tower tents that had begun to give way had been shaken by their engines. On the other hand, it was largely owing to their objections that John de Brienne refused the sultan's offer to restore Jerusalem and Palestine.

From the very first the Templars seem to have been opposed to Frederick II. and, when he landed at Acre (7th September 1228) they refused to march under the banners of an excommunicated man, and would only accompany his host from Acre to Joppa in a separate body. They were accused of notifying Frederick's intended pilgrimage to the Jordan to the sultan, and they were stripped of the new castle, of their all their lawful possessions, and of their former position of garrison. Their chief concern was to have peace with the Saracens, and to this end they engaged in the treaty of Jaffa, 1229. On the 3rd May 1229, and on landing in Apulia gave orders to seize the estates of the order and chase all its members from the land.

Long before the expiration of Frederick's European peace Europe was preparing for a fresh crusade against the now divided realm of the Ayyubids. The elder of Navarre and his crusaders, who reached Palestine about August 1239. The Templars shared in the great defeat near Jaffa, an engagement which their temerity had done much to provoke (13th November 1239). If the king ever accepted the overtures of Sahib of Damascus, he was supporting the policy of Hermann of Perigord, the grand master, who, towards the summer of 1244 wrote a triumphant letter to England, telling how he had engaged this sultan and Nâsir of Kerak to make an alliance against the sultan of Egypt and restore the whole of Palestine from the Jordan to the sea. Frederick, however, before leaving the Holy Land (27th September 1240), signed a ten years' truce with Sahib of Egypt. The Hospitalers seem to have been won over to his view, and
when Richard of Cornwall arrived (11th October) he had to decide between the two rival orders and their opposing policies. After some hesitation he concluded a treaty with the sultan of Egypt, much to the annoyance of the Templars, who openly mocked his efforts. On his departure the three orders came to open discord: the Templars laid siege to the Hospitaliters in Acre and drove out the Teutonic Knights "in the form of imperialists." They were successful on all sides. The negotiations with Damascus and Kerak were reopened, and in 1244 Hermann of Pergoìed wrote to the princes of the East that after a "silence of fifty-six years the divine mysteries would once more be celebrated in the Holy City."

It was in this moment of danger that the sultan of Babylon called in the barbarous Khazarins, whom the Mongol invasions had driven from their native lands. These savages, entering from the north, flowed like a tide past the newly built and impregnable Templar fortress of Safed, swept down on Jerusalem, and annihilated the Christian army near Gaza on St Luke’s day (18th October) 1244. From this blow the Latin kingdom of the East never recovered; 600 knights took part in the battle; the whole force of the Templars, 300 in number, was present, but only 18 survived, and of 200 Hospitaliters only 16. The masters of both orders were slain or taken prisoners. Despite the admirable valour of the Templars, their policy had proved the ruin of the land. Jerusalem was lost to Christendom forever; and, though the Khazarins melted away in the course of the next three years, they left the country so weak that all the acquisitions of Theobald and Richard fell an easy prey to the Turks of Babylon.

Recognizing the fact that the true way to Jerusalem lay through Egypt, Louis IX. led his host to the banks of the Nile, being accompanied by the Templars. Their master, William de Sonnac, attempted in vain to restrain the rash advance of the count of Artois at the battle of Mansura (8th February 1250), which only three Templars survived. St Louis, when captured a few weeks later, owed his speedy release to the generosity with which the order advanced his ransom-money. Shortly after his departure from Acre (April 1254) they consented to an eleven years’ truce with the sultans of Egypt and Damascus.

A new enemy was now threatening Mahommedan and Christian alike. For a time the Mongol advance may have been welcomed by the Christian cities, as one after another the Mahommedan principalities of the north fell before the new invaders. But this new danger stimulated the energies of Egypt, which under the Mameluke Bibars encroached year after year on the scantly remains of the Latin kingdom. The great Flemish shipyards, from which all was lost, made haste to sell their lands to the Templars and Hospitaliters before quitting Palestine for ever. In 1260 the former purchased Sidon and Beaufort; next year the Hospitaliters purchased Arsal. In 1267, by a skilful adaptation of the banners of both orders, Bibars nearly surprised Antioch. The Templar fortress of Safed surrendered with its garrison of 600 knights, all of whom preferred death to apostasy (June 1266). Beaufort fell in 1268, Antioch six weeks later; and, though the two orders still made occasional brilliant dashes from their Acre stronghold, such as that to Ascalon in 1264 and the three with Prince Edward of England to destroy Kâkûn in 1277, they became so enfeebled as to welcome the treaty which secured them the plains of Acre and a free road to Nazareth as the result of the English crusade of 1272.

But, though weak against external foes, the Templars were strong enough for internal warfare. In 1277 they espoused the quarrel of the bishop of Tripoli, formerly a member of the order, against his nephew Bohemond, prince of Antioch and Tripoli, and began a war which lasted three years. In 1276 their conduct drove Hugh III., king of Cyprus and Jerusalem, from Acre to Tyre. In the ensuing year, when Mary of Antioch had sold her claim to the crown to Charles of Anjou, they welcomed this prince’s lieutenant to Acre and succeeded for the moment in forcing the knights of that city to do homage to the new king. Thirteen years later (26th April 1290) Tripoli fell, and next year Acre, after a siege of six weeks, at the close of which (16th May) William de Beaujeu, the grand master, was slain. The few surviving Templars elected a new master, and, forcing their way to the seashore, sailed for Cyprus, which now became the headquarters of the order. A last attempt was made in 1300 and 1301 to hold Antioch, but the same time (1300–2) are the closing acts of their long career in the western parts of Asia.

For more than a hundred years the Templars had been one of the wealthiest and most influential factors in European politics. If we confine our attention to the East, we realize but a small part of their enormous power. Two Templars were appointed guardians of the disputed castles on the bosphoral of Prince Henry of England and had the Franks deprived in 1185. Other Templars were almoners of Henry III. of England and of Philip IV. of France. One grand master was godfather to a daughter of Louis IX.; another, despite the prohibition of the order, is said to have been godfather to a child of Philip IV. They were summoned to the great councils of the Church, such as the Lateran of 1215 and the Lyons council of 1274. Frederick II.’s persecution of their order was one of the main causes of his excommunication in 1239; and his last will enjoined the restoration of their estates. Their property was valued every century of Christendom, from Denmark to Spain, from Ireland to Cyprus, their wealth was immense and their influence unbounded. The 14th century Matthew Paris reckons their manors at 9000, Alberic of Trois-fontaines at 7050, whereas the rival order of St John had barely half the latter number. Some fifty years earlier their income from Armenia alone was 20,000 bezants. Both in Paris and in London their houses were used as strongholds for the royal treasure. In the Temple in London Hubert de Burgh and the Poitevin favourites of Henry III. stored their wealth; and the same building was used as a bank into which the debtors of the foreign usurers paid their dues. From the English Templars, and later every country of Christendom, from Denmark to Spain, from Ireland to Cyprus, the Templars made the magnetic centres of all their operations financial. Whereas the Templars were a vivid light on the banking and a magnet as a centre of treasure, while their reputation as monks guaranteed their integrity. Thus they became the predecessors, and later the rivals, of the great Italian banking companies. See L. Delisle, "Mémoire sur les opérations financières des Templiers et des hospitaliers," in "Histoire de la banque nationale de France," t. xxxii. To take interest (usury) was of course unlawful. The method of circumventing this seems to have been that the mortgages paid to the mortgagors a nominal rent which afterwards reduced the deduction of the debt. The difference between this and the real rent represented the interest. See Ancient Charters, Pt. i. (Pipe Roll Soc., London, 1888), edited by J. H. Round, p. 94.

"Abandonment of Pales-

1 The wealth of the Templars was due not so much to their territorial possessions as to the fact that they were the great international financiers and bankers of the age. The Paris Temple was the centre of the world’s money market. In it popes and kings deposited their revenues, and these vast sums were not hoarded but issued as loans on adequate security. Above all, it was the Templars who made the exchange of money with the East possible. It is easy, indeed, to see how they were the ideal bankers of the age; their strongholds were scattered from Armenia to Ireland, their rapacity was abounded and their lease-running and their method of sharing the usury was very simple and adequate. They advanced as much as they would have the bank deposit, and if the debtors paid the interest they could, at any time, demand their capital. In this way the Templars secured a very large portion of the gold and silver which passed from the East to Europe, as well as a large share of the silver and copper which passed from the West to the East. In short, the Templars were the first bankers of the world.

2 The Templars in Aragon and the other kingdoms of the Spanish peninsula were far more subordinate to the crown than elsewhere. None but natives were admitted to their ranks, and there were very few exchanges of knights with foreign commanderies. They were only allowed to become members of the order after confirmation from the king, and were consequently much more dependent on the crown than the crusader kings. In 1217 the last grand master of the Templars of Aragon, who had been attached to the crown, was impeached and deprived of his position. The pope, in 1228, annulled the confirmation of the Templars of Aragon by the king, and this act was followed by a strong declaration against the Templars in the bull "Admirant," which was directed against the Templars of Aragon. The Templars of Aragon were also deprived of the right of holding land and of fighting on the scent of the king, and were obliged to pay the service of noble seigniors. The French, of course, were not so dependent on the crown, and were able to resist the pressure of the king to a much greater extent.
Such were the power and wealth of the Templars at the time when Philip IV. of France accused them of heresy and worse offences, had them arrested (13th October 1307), and forced them to confess by tortures of the most excruciating kinds. Five years later (26th May 1312) the order was suppressed by decree of the council of Vienne and its goods transferred to the hospital of St. John of Jerusalem (T. A. A.).

Doubt had the order of the Temple been to all appearance more powerful than immediately before its ruin. Sovereign power, in the sense of that of the Teutonic Knights in Prussia or the Knights of St. John in Rhodes and later in Malta, it had never possessed; but its privileges and immunities constituted it a church within the church and—in France at least—a state within the state. Philip IV., indeed, in pursuance of his policy of centralizing power in the crown, had from 1287 onwards made tentative efforts to curtail the power and wealth of the order; in 1287 he proclaimed the sequestration of all its property acquired since the confirmation of its privileges by Louis IX. in 1258; in 1289 the ordinance of Ferrières in Gâtinais was directed against its illicit acquisitions and its interference with the jurisdiction of the king and his vassals; in 1290 the parlement decided that the privileges of the order could only be enjoyed by those who actually wore its habit. Soon, however, the king's necessities forced him to change his policy. In January 1303 the privileges of the order in and about Paris were confirmed and extended, and in 1307 Philip borrowed 5200 livres tournaises from the Paris Temple.

'Fier de grandeur et de magnificence,' the Devil of Paris, as we know, directed in 1307 that the order should be present at the reception of a new Templar. 1Yet for some two years past the king had been plotting a treacherous attack on the order. His motives are clear: he had used every expedient to raise money, had robbed and expelled the Jews and the Lombard bankers, had debased the coinage; the suppression of the Templars would at once rescue him from their unwelcome tutelage and replenish his coffers. He cherished also another ambition. The question of an amalgamation of the great military orders had often been mooted; the project had been approved by successive popes in the interests of the Holy Land; it had been formally proposed at the Lyons council of 1274, only to be rejected by the opposition of the Templars and Hospitallers themselves. To Philip this scheme commended itself as an opportunity for bringing the orders under the control of the French crown; there was to be but one order, that of the "Knights of Jerusalem," of which the grand master was always to be a prince of the royal house of France. 2Clearly, it only needed an excuse and a favourable opportunity to make him attack the Templars; and, once having attacked them, nothing short of their entire destruction would have been consistent with his safety. The excuse was found in the denunciation of the order for heresy and unseemly bound to respond to demands of the grand master for consignments of men and money, but their main duty was to assist the king in his wars against the Moors at home (cf. Urraca coronata and Amadis) against the Moors and Saracens or to defend the interests of the Church abroad (cf. the English crusades). 3

3 He himself was to be its first head, with the title of "King of Jerusalem." See the letter (No. 75) from Leget F. to Bernard F. in Finke ii. 114.

Suppression of the order.

1 The Correspondence of the Grand Masters of the Teutonic Order, p. 265.
2 Die Seele des Templerorden (Berlin, 1886), p. 35.
3 See also Prutz, Templerherrenorden, p. 61 seq. In Portugal the Templars were practically feudatories of the crown, the master taking an oath of fealty to the king and his heirs. (W. A. F. p. 9.)

able immoralities by a venal informer; the opportunity was the election of a pope, Clement V., wholly devoted to the interests of the king of France.

For perhaps half a century there had been strange stories circulating as to the secret rites practised by the order at its midnight meetings, stories which probably had their origin in the extreme precautions taken by the Templars, originally perhaps for military reasons, to secure the secrecy of their proceedings, which excited popular curiosity and suspicion. Among the Templars alone of the religious orders the ceremonies of reception were conducted in strict privacy; chapters were held at daybreak with closely guarded doors, and no one participating was allowed to reveal what had passed, even to a fellow-member of the order, under pain of expulsion. It was inevitable that, considering the temper of the age, all this should lead to stories of rites too repulsive to bear the light. It was said that on his initiation each member had to dissolve his belief in Christ, to spit upon the crucifix, to submit to indecent ceremonies. When the mass was celebrated the consecrating words Hoc est corpus were omitted; on Good Friday the holy cross was trampled under foot; and the Christian duty of alms-giving had ceased to be observed. Even the vaunted chastity of the order towards women had, it was said, been turned into the formal obligation to committing more horrible offences. These evil practices were part of the secret statute law of an order which in its nightly assemblies worshipped an idol named Baphomet or the devil in the shape of a woman, whose name signified "the assimilation to the home" (succubi), with whom the brothers had carnal intercourse.

In England the very children at their play bade one another beware of a Templar's kisses. Stranger stories yet were rife in England and gravely reported before bishops and priests—of children slain by their fathers because they cheated to witness the nightly orgies of the society; of one prior's being spirited away at every meeting of the general chapter; of the great preceptor's declaring that a single hair of a Saracen's beard was worth more than the whole body of a Christian man. In France they were said to roast their illegitimate children and smear their idols with the burning fat.

In the spring of 1304 or 1305 a certain Esquieu de Floyran of Beziers pretended to betray the "secret of the Templars" (factum Templatorum) to James II. of Aragon. The pious king, who had every reason to think well of the order, did not affect to be convinced; but the prospect of spoils was alluring, and he seems to have promised the former a share of the booty if he could make good his charges. 4Esquieu now turned to Philip of France, with more immediate success. For the purpose of collecting additional evidence the king caused twelve spies to find admission to the order, and in the meantime sought to win over the pope to his views. But Bertrand de Got, archbishop of Bordeaux, who on the 5th of June 1305 became pope as Clement V., owed the tiera to the diplomacy of Philip's agents, perhaps to their gold; but though a weak man, and moreover a martyr to ill health, he was not so immediately accommodating as the king might have wished, 4 Two of the Templars examined at Carcassonne spoke of an idol named Baphomet or a piece of wood on which was represented a figure of Baphomet. A Templar at Florence called the idol Mahomet or Magomet. Baphomet was a common mediaeval corruption of Mahomet (Mahom, Mahon, &c.), who was regarded not as a false prophet only, but as a demon, a false god to whom human sacrifices were offered. Hence any unholy or fantastic rites came to be called baphumeres, mahomeres, moheres, i.e. "exercises and stories of the forbidden." Hence the baptism of Metis i.e. the baptism of Metis (the supreme wisdom), has no trustworthy evidence to support it. See Leobserve, Doctrine secrete, p. 97 seq. 5

The Sanchez Minta, p. 85. No. 26. See also系统: en:Esquieu publishes a letter of Esquieu to the king, dated 21st January 1308, claiming his reward. Esquieu is the Squin de Florian of Villani; the other informer mentioned by him, Nofilo Del (Deghi) of Florence, had, however, nothing to do with the Templars; he was a merchant in the service of the Montforti, a branch of the Montfort, of Paris, and was hanged for swindling. Nor was Esquieu's motive to save himself from execution, but purely mercenary. The existence of an informer, doubted by Lea (Inquisition ii. 255) and others, is now proved.
expressing his disbelief in the charges against the order, and, though promising an inquiry, doing his best to procrastinate. Philip determined to force his hand. All France was at this time under the jurisdiction of the Inquisition, and the Inquisition could act without consulting the pope. The grand inquisitor of France, William of Paris, was Philip's confessor and creature. The way was thus open for the king to carry out his plan by a perfectly legal method. His informers denounced the Templars to the Inquisition, and the grand inquisitor—as was customary in the procedure in the case of persons accused of heresy—demanded their arrest by the civil power. On the 14th of September 1307, accordingly, Philip issued writs to his baillis and seneschals throughout the kingdom, directing them to arrest the members of the order on the following 13th of October.

The Templars had for some time past been aware of the charges against them. On the 6th of June 1306 Pope Clement had summoned Jacques de Molay, the grand master, from Cyprus to France, in order to consult him on the projected crusade. He had obeyed the call, and, in an interview with the pope, had taken the opportunity to demand a full inquiry. They had, however, taken no measures to defend themselves; the sudden action of the king took them wholly by surprise; and, though they were placed in a strong position, their arrest was effected without difficulty. Jacques de Molay himself with sixty of his brethren being seized in Paris. Next day they were haled before the universite of Paris, to hear the recital of their crimes; and Sunday the populace was collected in the royal gardens, where preachers inveighed against the iniquities of the order.

The Templars were caught in toils from which there was no escape. To force them to confess, they were first tortured by the royal officials, before being handed over to the inquisitors to be, if need were, tortured again. In Paris almost thirty-six died under process. The reason was, as it was, the outset, all that the king could desire. Of 136 Templars examined in Paris between the 19th of October and the 24th of November, some of them old men who had been in the order the greater part of their lives, 123 confessed to spitting on (or "near") the crucifix at their reception. Many of the prisoners, on the other hand, confessed to all the charges, however grotesque. But the most damning confession was that of the grand master himself, publicly made with tears and protestations of contrition and embodied in a letter (October 25) sent to all the Templars in France. He had been guilty, he said, of denying Christ and spitting on the cross; the greater charges he indignantly repudiated.1

To the pope, meanwhile, the proceedings in France were to the highest degree unpromising. He had, indeed, become convinced, if not of the general guilt of the order, at least of the guilt of some of its members. But the affair was one which he desired to reserve for his own judgment; Philip's action he interpreted, rightly, as an encroachment of the civil power on the privileges and property of the Church, and his fears were increased when the French king, without consulting him, sent letters to King James of Aragon, Edward II, of England, the German emperor, the king of France and other princes, calling upon them to imitate his example. On the 27th of October Clement issued letters suspending the powers of the Inquisition in France. What followed is not clear, for the documentary evidence for these months is very defective. On the 17th of November James of Aragon wrote to Philip, in answer to his letter and the report of the proceedings in Paris forwarded to him, expressing his surprise at the charges against the Templars, who had done himself and his forefathers great service against the infidel, but promising to proceed against them since required to do so by the Church.2 In Portugal no action was taken at all. Edward II. of England replied that he must first receive information as to the charges from his officials in Agen (whence the charges had originated), and on the 6th of December he wrote to the kings of Aragon, Castile, Portugal and Sicily begging them not to believe the evil reports against the order (Pruitz, p. 159). But meanwhile, on the 22nd of November, Pope Clement had issued a bull calling on all kings and princes to arrest the Templars everywhere, his motive probably being (according to Finke) to forestall the probable action of the grand inquisitors and his seneschals in his own kingdom.

Scruples and hesitations now vanished. In England the Templars were arrested on the 10th of January 1308, in Sicily on the 24th of the same month, in Cyprus on the 27th of May; in Aragon and Castile the process was less easy, for the knights, forewarned, had put their fortresses into a state of defence, notably their strong castle of Monzon, which was only taken after a long siege on the 17th of May, while the last of the Templars' strongholds, Castellat, did not fall until the 2nd of November.3 Meanwhile, on the 26th of May, Philip had made his solemn entry into Paris, and the inquisitors and cardinals had already assembled for the purpose of conferring with the king on the matter. The debates that followed were protracted and stormy; but Philip was in a position to back his argument for the suppression of the order by pressing other and more dangerous claims: the canonization of Celestine V., the condemnation of Boniface VIII. for heresy, the absolution of Guillaume de Nogaret, the executor of the outrage at Anagni, the summoning of a general council, the settlement of the papacy at Avignon. At last, on the 27th of June, an arrangement was come to. The king agreed to hand over to the papal inquisitors in France the grand master, Jacques de Molay, for his part, withdrew the sentence of suspension against the grand inquisitor of France (July 5) and ordered an inquisition into the charges against individual Templars by the diocesan bishops with assessors nominated by himself. The examination of the grand master, of the grand visitor of France, and of the grand preceptors of Cyprus, Normandy and Aquitaine he reserved to himself. Inquisition was to be made into the conduct of the order in each country by special papal commissions; and the fate of the order as a whole was to be decided by an international general council.

These decisions were at once acted on. At Poitiers Clement had already heard the confessions of seventy-two Templars, carefully selected from the royal prisons (June 29 to July 1).4 The grand master and the three preceptors were re-examined at Chion, and renewed their old confessions (20th August). Lastly, the bull Regiones in Coelo summoned a great council at Vienne for the 1st of October 1311, when the question of the guilt of the order might be considered. Meanwhile the pope and cardinals had elaborated the organization of the new inquisition. In this the actual inquisitors, though admitted, played a quite subordinate part: the commissions centered around the diocesan bishops, who had as assessors prelates, abbots, priors and canonists. These commissions were two-fold, usually—though erroneously—distinguished as papal and episcopal (both were in fact papal); the first were charged with the inquisition into the accusations against the order itself and the grand preceptors of the various countries, the second with

1 Michelet, Proces, i. 36.
2 Jacques de Molay's confession was partly due to fear of torture, partly to secure the withdrawal of a specific charge of unnatural crime brought against him by the Templar Guillaume de Gasci (Gmelin ii., Tab. i. No. 12). But he continued to demand access to the pope, declaring that he could satisfactorily explain the practices of the order.
3 Text in Finke ii. 55.
4 Finke i. 302 ff. Some of the Spanish Templars turned Moslem (Manuel of Lepanto, and joined the sack of Granada in an invasion of Aragon (Finke ii. 188, No. 105).
5 This was to be devoted to the cause of the Holy Land. In fact its administration fell into the hands of Philip's confidants and the greater part remained in his possession (Finke i. 227).
6 For a detailed account of the negotiations see Finke i. 200 ff. He holds that Clement, though now convinced of the Templars' guilt, was anxious to treat them leniently and, if possible, to save the order (p. 215).
7 See Gmelin ii., Tab. vii. and viii.
that into the accusations against individual Templars. The papal commission in Paris began its sessions on the 9th of August 1309; on the 12th, citations were issued to those Templars who "of their own free will" were prepared to come and defend the order. There was much confusion and delay, however, and the actual public trial did not begin till the 11th of April 1312. Many Templars, in the meantime, had volunteered to defend the order and withdrew their previous confessions. They were soon undeceived; the commission, presided over by the "garde des seaux" of the king, the archbishop of Narbonne, was packed with creatures of the crown. The evidence given in Paris for or against the order was, it was soon found, used against the individual Templars on their return to the provinces; the retraction of a confession, under the rules set up for the diocesan inquisition, was punished with death by fire. On Tuesday the 12th of May, fifty-four Templars who had retracted their confessions before the commission were burnt in Paris by order of the archbishop of Sens; a few days later four were burnt at Senlis, and towards the end of May nine more, by order of the archbishop of Reims. Forty-six Templars now withdrew their defence, and the commissioners in Paris decided (30th May) to adjourn till November. The second examination lasted from the 17th of December 1310 to the 16th of May 1311. Meanwhile (c. April 1311) Clement and Philip had come to terms. The pope condemned the Templars. The council of Vienne met in October 1311 to consider the charge, and on May 1, 1312, it was adopted as a whole, and the order was declared to be heretical in their own defence. Clement, it is said, broke up the session to avoid compliance; and when seven Templars offered themselves as deputies for the defence he had them cast into prison. Towards the beginning of March Philip came to Vienne, and he was seated at the pope's right hand when that pontiff delivered his sermon against the Templars (3rd April 1312), whose order had just been abolished, not at the general council, but in private consistory (22nd March). On 2nd May 1312 he published the bull Ad Providam, transferring the goods of the society, except for the king's share, to Aragon, and Majorca, to the Knights of St. John. The order was never formally pronounced guilty of the crimes laid to its charge; its abolition was distinctly, in the terms of Clement's bull Considerantes Dudum, "non per modum definitivae sententiae, cum eam super hoc secundum inquisitiones et processus super sui habitos non possemus ferre de jure sed per viam provisionis et ordinations apostolicae" (6th May 1312).

The final act of the stupendous tragedy came early in 1314. Jacques de Molay, the grand master, had not hitherto risen to the height of the king's expectations. Philip, c. April 1314, was sufficiently enraged to make him confess, and this confession had been used to extract avowals from his brethren, subject as they were to unspeakable sufferings and accustomed to yield to the military chief. Humiliation on humiliation had been heaped on the wretched man, public recantations, reiterated confessions. Before the papal commission he had flamed into anger, protested, equivocated—only in the end to repeat his confession once more. The same had happened before the commission of cardinals at Chinon; the audience with the pope, which he demanded, he had never obtained. On the 6th of May, in the pope's presence, at the time of the Templars in general; that of the five great offices of the order he reserved in his own hand. With this a silence falls over the history of the Templars; the fate of the order had been decided, that of the individuals still under trial was of little interest to contemporary chroniclers. Then the veil is suddenly lifted. Jacques de Molay has found his wonted courage at last, and with him Gautier de Charney, the preceptor of Normandy; on the 14th of March 1314 they were brought out on to a scaffolding erected by order of the archbishop of Sens, and there, in the presence of all legates and of the people to repeat their confessions and to receive their sentence of perpetual imprisonment. Instead, they seized the opportunity to withdraw their confessions and to protest to the assembled thousands the innocence of the order. King Philip the Fair did not wait to consult the church as to what he should do; he had them burnt "in the little island" of the Seine "between the Augustinians and the royal garden"; with them perished Guy (the Guido Delphini of the trials), the youthful son of the dauphin of Auvergne. After the deaths of the popular Flemings, who had contributed to the new order of Carthusian people remembered that the grand master had summoned them with his dying breath before the judgment seat of God; but the sole recorded contemporary protest is that of the Augustinians at the trespass committed by the royal officers on their land!

On the question of the guilt or innocence of the Templars in recent times, the emphasis has, in large part, been on which the order was condemned opinion has long been divided. Their innocence was maintained by the greatest of all their contemporaries, Dante, and among others by the historian Villani and by the sainted Antoninus, who, for a time, placed the charge of heresy of the order into the discussion of the question owing to its having been for centuries brought into the arena of party controversy, and finally by the inquisitors, Gardini and Guglielmo, the Swiss, who, after having published his Historia Templaria (Amsterdam, 1691, 2nd ed. 1703) to show, as a good Protestant, that the Templars had the usual vices of Roman Catholics, while, according to Louiseleur, the Great Council of Dublin (which, later published at Brussels) were Freemasons who, under false names, gambled the old material and inserted new in the interests of the suppressed origin of their own order in that of the Templars. Several Roman Catholic champions of the order now entered the field, e.g., the Benedictine historian Languedoc, Dom Dominique Joseph Vallisse, and notably the Premonstratensian canon R. P. M. Jeune, prior of Etival, who in 1790 published at Paris his Histoire critique et apologétique de l'ordre des chevaliers... des Templiers, a valuable work directed specifically against Gurtler and Dru Puy. In the 19th century a fresh impetus was given to the discussion by the publication in 1813 of Raynouard's brilliant defence of the property was nominally handed over to the Hospitals, but most of it actually remained in the hands of the sovereigns or their financial agents. The king of Portugal, for instance (in suppressing the order and torturing its members), in the Spanish peninsula the Temple castles and estates were in some cases handed to other military orders, and, in others, to the new order of Carthusian monks. In 1319 the castle to those of Ucles and Calatrava; in Aragon one frontier castle with its domain, Montasia, was given to the knights of Calatrava; the rest—so far as they had not been annexed by the king and the riones krombers—to the Hospitaliers. As to the Templars: they were granted in most cases generous pensions; some continued to live in groups, though without organization, on their old property; others joined various orders; many married, on the plea that the suppression of the order had released them from their vows; while others, again, took service with the Moors in Africa. (Finke, l. c., p. 12.)

Raggio il nuovo, Pazzo si cruderele
Che cie col nasia, ma, senza decreto,
Porta nel tempio le cupide vele.—(Purg, xx, 92.)

1 History of the order military of the templars, &c. The titles of the various editions differ.

2 There is, of course, no foundation whatever for this claim. It is examined and refuted, inter alios, by Wilcke, iii. 353 seq. A delightfully absurd attempt to assert the continuity of the "Templars" as a driving force of Protestantism in the United States, with the suppressed order, is made by Jeremy L. Cross in The Templars Chart (New York, 1845); he actually gives a list of our "Templars" under the names of Sidney Smith (1838), and asserts that "the Encampment of Baldwin which was established at Bristol by the Templars who returned with Richard I. from Palestine, still continues to exist, and that members of it have preserved the ancient costume and ceremonies of the order."

3 Finke devotes an interesting chapter to tracing what became of the property of the order and of the individual Templars. The

4 This was, of course, only one of some twenty-five separate commissions in different countries. It was, however, the most important and is the best known. It was issued at the instance of Philip of Castile, brother of Enguerrand de Marigny, the king's minister, who had already been appointed archbishop of Sens at Philip IV.'s instance in April, and was naturally full of zeal for the royal cause. The condemned Templars appealed to the papal commission which was represented by the pope's legates, but refused to accept their authority to interfere with the archbishop's ordinary jurisdiction. (Raynouard, p. 92.)
In the opinion of the present writer, the defenders of the order have proved their case. Even the late Mr Archer, who took the order up as a cause célèbre, was forced to admit of the following: "The opinion that the monstrous charges brought against the Templars were false," he wrote (Encyc. Brit., 9th ed. xii, 164), "and that the confessions were only extracted by torture is supported by the evidence already referred to, and which we have given elsewhere (outside France), as we have them collected in Raynouard, Labbe, and Du Puy. In Castile, where the king flung them into prison, they were never acquired, or at least, not pronounced the order blameless. At Treves, at Messina, and at Bologna, in Romagna and in Cyprus, they were either acquitted or not pronounced the order blameless. At the council of Ravenna the question as to whether the order was answered in the negative except by two Dominicans; all the Templars were absolved—even those who had confessed through fear of torture being pronounced innocent (15th June 1010). Six Templars were examined at Florence, and their evidence is for its length the most remarkable of all that is still extant. Roughly speaking, they confess with the most elaborate detail to every charge—even the most loathsome; and the perusal of their evidence induces a constant suspicion that their answers were practically dictated to them in the process of the examination or invented by the examiners. Evidence, however, was throughout the trials, was not used, out of eighty Templars examined only four confessed to the charge of denying Christ, and of these four two were apostate knights. But some English Templars would only guarantee the truth of their confessions and the results of their examinations, and the charges held to be not absolutely proved seems evident from the form of confession to be used before absolution, in which the Templars were thus led to abjure themselves to be defamed in the matter of certain articles that were published in England. Nearly all the worst evidence comes at second or third hand, or through the depositions of Franciscans and Dominicans," i.e. the rivals and enemies of the order. But what is the nature of the evidence "too strong to be explained away" on which Mr Archer bases his opinion that certain of the charges were proved at least in France? The modern practice of the English courts tends to eliminate the larger elements of confession in cases of heresy, and it is now freely made. What is the value of these confessions of the Templars which lie before us in the Tables published by Gmelin? The proof of the Templars is more authentic than any other to those accused on a "vehement suspicion" of heresy, by confession or death under lingering torture; to withdraw a confession meant instant death by fire. The Templars, for the most part simple and illiterate men, were suddenly arrested, cast separately into dark dungeons, loaded with chains, starved, terrorized, and tortured. They were told the charges to which their leaders had confessed, or were said to have confessed; to repeat the monotonous formula admitting their guilt, under torture, and to seal it at the cost of a comparatively mild pence. The wonder is not that so many confessed, but that so many persisted in their denial, for the charge was of heinous and monstrous crimes, new, wholly worthless, as even some contemporaries suspected it to be.

A word must be added as to the significance of the work of the Templars and of the manner of their fall in the history of the world. Two great things the order had done for European civilization: in the East and in Spain it had successfully checked the advance of Islam; it had deepened and given a religious sanction to the idea of the chivalrous man, the homo legatus, and so opened up, to a class of people who for centuries to come were to exercise enormous influence, spheres of activity which—what effects of which are still recognizable in the world in the advancing tide of Turkish conquest in the East? Or in Spain against the Moorish powers? If not, why did the Hospitalers survive? Froude's contribution is but a popular lecture, however, and, for all its beauty of style, characteristically careless (e.g. such mistakes as Hugh von Peyraud, Esquin von Florian).
TEMPLE, FREDERICK

popular belief in witchcraft and personal intercourse with the devil, sanctioned the expeditious of wringing confessions of such intercourse from the accused by unspeakable tortures, and so made possible the hideous witch-persecutions which darkened the later middle ages and, even in Protestant countries, long survived the Bible with a vengeance. If I were to name a day in the whole history of the world," said Döllinger at the conclusion of his last public lecture, "which appears to me in the truest sense as a dies nefastus, I should be able to name no other than the 13th of October 1597."

Authorities.—A great mass of original sources has now been published. Those given by Du Puy, though often valuable, were selected by the Edel with a view to point out the departure was made with the publication of Michelet’s Proces des Templiers (t. i. 1851, t. ii. 1861), an edition of the original minutes of the trial preserved at the Bibliothèque Nationale (it is especially interesting as the earliest complete and detailed record of a criminal trial in existence). This is elaborately analysed and the results tabulated in vol. ii. of Gmelin. Of documents published in other works the most important collections are those in Schottmüller (mainly from the Vatican Archives) and Finke (Aragonese Archives). The Rule of the Temple has been several times published; the most accessible edition, giving the various Rules with critical commentary, is that of H. de Curzon, La Règle du Temple (Paris, 1886); see also Maillard de Chambure, Règle et statuts secrets des Templiers, préc. de l’histoire de cette ordre (Dijon—Paris, 1840).

TEMPLE, FREDERICK (1821-1902), English divine, archbishop of Canterbury, was born in Santa Maura, one of the Ionian Islands, in 1821. He was the son of Thomas Frederick Temple, M.P. and was subsequently appointed lieutenant-governor of Sierra Leone. On his retirement he settled in Devonshire as a small landowner, and contemplated a farming life for his son Frederick, giving him a practical training to that end. But the boy was sent to Blundell’s School, Tiverton, and soon exhibited abilities which marked him out for a different career. He retained through life a warm affection for the school, where he did well both in the classes and the games, and was famous as a walker. His father’s means were narrow, and the boy knew how to make the most of his opportunities. He took an important step in that way by winning a scholarship at Balliol College, Oxford, before he was quite seventeen years old. The “Tractarian Movement” had set in five years earlier, but the memorable tract, No. 90, had not yet been written, and Temple entered a university which was vibrating with intellectual and religious excitement. After much discussion and reflection he drew closer to the camp of “the Oxford Liberal Movement.” In 1842 he took a “double-first” and was elected fellow of Balliol, and lecturer in mathematics and logic. Four years later he took orders, and with the aim of helping forward the education of churchmen the bishop of Kensington, a scholar and a generous man, in 1845, gave to Temple a living more suitable to the calling. He took as his subject “the election of bishops” and wrote a brilliant paper, which was accepted by the prime minister.” At the confirmation of his election counsel was instructed to object to it, and in the voting the chapter was divided. But Gloucester stood firm, and Temple was duly consecrated on the 21st of December 1860. There were at first murmurings among his clergy against what they deemed his harsh control, but his real kindness soon made itself felt, and, during the sixteen years of his tenure of the see, his sound and vigorous rule dissipated the prejudices against him, so that when, on the death of Dr John Jackson in 1885, he was appointed to London, the clergy accepted the appointment with satisfaction. In 1884 he was Bampton Lecturer, taking for his subject “The Relations between Religion and Science.” In 1885 he was elected honorary fellow of Exeter College, Oxford. Dr Temple’s tenancy of the bishopric of London was marked, if possible, by more strenuous labours than ever. His normal working day at this time was one of fourteen or fifteen hours, and he refused to spare himself one hour of toil, though under the strain blindness was rapidly coming on. He was still felt by many of his clergy and by candidates for ordination to be a rather terrifying person, and to entertain almost impossible standards of diligence, accuracy, and preserving efficiency, but his manifest devotion to his work and his zeal for the good of the people rooted him deeply in the general confidence. In London he was not less conspicuous as a temple of righteousness than he had been in Exeter, and the artisan classes instinctively

Whilst making the school a strong one on the classical side, he instituted scholarships in natural science, built a laboratory, and gave importance to that side of the school work. He had the courage also to reform the games, in spite of all the traditions of the playing fields. His own tremendous powers of work and his rugged masculinity was the most frightful enemy ever, but his popularity was soon undoubted, and he brought up the school to a very high level. His school sermons were deeply impressive: they rooted religion in the loyalties of the heart and the conscience, and taught that faith might dwell secure amid all the bewildlements of the intellect, if only the life remained rooted in pure affections and a loyalty to the sense of duty. It was two years after he had taken up his work at Rugby that the volume entitled Essays and Reviews gave rise to an extraordinary storm. The first essay in the book, “The Education of the World,” was by Dr Temple. It was declared in a preface to the volume that the authors were responsible only for their respective articles, but some of these were deemed so destructive that many people banned the whole book, and a noisy demand, led by Samuel Wilberforce, then bishop of Oxford, called on the headmaster of Rugby to dissociate himself from his comrades. Temple’s essay had treated of the intellectual and spiritual growth of the race, and had pointed out the contributions made respectively by the Hebrews, the Egyptians, the Greeks, the Romans, and others. It was generally declared to be a text-book of the boys at first, but it was claimed as found in bad company. Temple refused, so long as the storm lasted, to comply with the request that he would repudiate his associates, and it was only at a much later date (1870) that he saw fit quietly to withdraw his essay. In the meantime, however, he printed a volume of his Rugby sermons, to show definitely what his own religious positions were.

In politics Temple was a follower of Mr Gladstone, and he approved of the disestablishment of the Irish Church. He also refused to be a candidate for the Canterbury see in 1866, when the Act, which made him an active member of the Endowed Schools Commission. In 1869 Mr Gladstone offered him the deanship of Durham, but this he declined on the ground of his strong interest in Rugby. When later in the same year, however, Henry Phillpotts, bishop of Exeter, died, the prime minister turned again to Temple, and he accepted the bishopric of that city so dear to him from boyhood, and left Rugby for a home amongst his own people. The appointment, however, raised a fresh storm.

G. A. Denison, archdeacon of Taunton, Lord Shaftesbury, and others formed a strong committee of protest, whilst Pusey declared that “the election of bishops should be perpetrated by a prime minister.” At the confirmation of his election counsel was instructed to object to it, and in the voting the chapter was divided. But Gloucester stood firm, and Temple was duly consecrated on the 21st of December 1860. There were at first murmurings among his clergy against what they deemed his harsh control, but his real kindness soon made itself felt, and, during the sixteen years of his tenure of the see, his sound and vigorous rule dissipated the prejudices against him, so that when, on the death of Dr John Jackson in 1885, he was appointed to London, the clergy accepted the appointment with satisfaction. In 1884 he was Bampton Lecturer, taking for his subject “The Relations between Religion and Science.” In 1885 he was elected honorary fellow of Exeter College, Oxford.

Dr Temple’s tenancy of the bishopric of London was marked, if possible, by more strenuous labours than ever. His normal working day at this time was one of fourteen or fifteen hours, and he refused to spare himself one hour of toil, though under the strain blindness was rapidly coming on. He was still felt by many of his clergy and by candidates for ordination to be a rather terrifying person, and to entertain almost impossible standards of diligence, accuracy, and preserving efficiency, but his manifest devotion to his work and his zeal for the good of the people rooted him deeply in the general confidence. In London he was not less conspicuous as a temple of righteousness than he had been in Exeter, and the artisan classes instinctively

1 Döllinger, Akademische Vorträge (Munich, 1891), ix, “Der Untergang des Tempelordens.”
recognized him as their friend. When, in view of his growing blindness, he offered to resign the bishopric, he was induced to reconsider his proposal, and on the sudden death of Archbishop Benson in 1866, though now seventy-six years of age, he accepted the see of Canterbury.

As archbishop he presided in 1897 over the decennial Lambeth Conference. In the same year Dr Temple and his brother archbishop issued an able reply to an encyclical of the pope which denied the validity of Anglican orders. In 1900 the archbishops again acted together, when an appeal was addressed to them by the united episcopate, to decide the vexed questions of the use of incense in divine service and of the reservation of the elements. After full hearing of arguments they gave their decision against both the practices in question. During his archbishopric Dr Temple was deeply distressed by the divisions which were weakening the Anglican Church, and many of his most memorable sermons were calls for unity. His first charge as primate on "Disputes in the Church" was felt to be a most powerful plea for a more catholic and a more charitable temper, and again and again during the closing years of his life he came back to this same theme. He was zealous also in the cause of foreign missions, and in a sermon preached at the opening of the new century he urged that a supreme obligation rested upon Britain at this epoch in the world's history to seek to evangelize all nations. In 1900 he presided over, and later World Temple as primate was a conspicuous figure in several and on one occasion preached in the interests of women's education. In 1902 he discharged the important duties of his office at the coronation of King Edward VII., but the strain at his advanced age told upon his health. During a speech which he delivered in the House of Lords on the 2nd of December 1902 on the Education Bill of that year, he was seized with sudden illness, and, though he revived sufficiently to finish his speech, he never fully recovered, and died on the 23rd of December 1902. He was interred in Canterbury cathedral four days later. His second son, the late Lord Temple's youngest son, who had succeeded his father at Oxford, was in 1910 appointed headmaster of Repton.

TEMPLE, SIR RICHARD, BART. (1826-1902). English administrator, a descendant in the female line of the Temples of Stowe, was born on the 8th of March 1826, and after being educated at Rugby and Haileybury, joined the Bengal Civil Service. His industry and ready pen soon obtained appreciation, and in 1849 he was appointed to the Indian civil service in India, first to the India Office, then to John Lawrence in the Punjab, and gaining useful financial experience under James Wilson, he was appointed Resident at Haidarabad. In 1866 he was made K.C.S.I. In 1868 he became a member of the supreme government, first as foreign secretary and then as finance minister; and he did admirable work during the famine of 1874, in the course of which he was made lieutenant-governor of Bengal. His services were recognized by the bestowal of a baronetcy in 1876. In 1877 he was made governor of Bombay, and his activity during the Afghan war of 1878-79 was so successful that he was induced to enter on a political career in England, but it was not till 1885 that he was returned as a conservative for the Evesham division of Worcestershire. Meanwhile he produced several books on Indian subjects. In parliament he was assiduous in his attendance, and he spoke on Indian subjects with admitted authority; but he was not otherwise a parliamentary success, and to the public he was best known by the caricatures in Punch, which exaggerated his physical peculiarities and made him look like a lean and hungry tiger. In 1885 he became vice-chairman of the London School Board, and as chairman of its finance committee he did useful and congenial work. In 1892 he changed his constituency for the Kingston division, but in 1895 he retired from parliament, being in 1896 made a Privy Councillor. He had kept a careful journal of his parliamentary experiences, intended for posthumous publication; and he himself published a short volume of reminiscences. He died at Hampstead on the 15th of March 1902. He was twice married, and left a daughter and three sons, all of the latter distinguishing themselves in the public service.

TEMPLE, RICHARD GRENVILLE-TEMPLE, 1st Earl (1711-1754). English statesman, eldest son of Richard Grenville (d. 1727) of Wootton, Buckinghamshire, was born on the 9th of September 1711. His mother was Hester (c. 1692-1752), daughter, and ultimately heiress, of Sir Richard Temple, Bart. (1634-1697), of Stowe, Buckinghamshire, and sister of Richard Temple, Viscount Cobham, whose title she inherited under a special remainder in 1749; in the same year, her husband having been long dead, she was created Countess Temple. Her son, Richard Grenville, was educated at Eton, and in 1734 was returned to parliament as member for the borough of Buckingham. In 1735, on the death of his mother, he inherited her titles together with the rich estates of Stowe and Wootton, and he then took the name of Temple in addition to his own surname of Grenville. The turning point in his political fortunes was the marriage of his sister Hester in 1752 to William Pitt, afterwards earl of Chatham. Although Lord Temple was a man of little ability and indifferent character, Pitt persistently linked his own career with that of his brother-in-law. In November 1756 Temple became first lord of the admiralty in the ministry of Devonshire and Pitt. He was intensely disliked by George II., who detested both his Pitt and office in April 1757. But when the memorable coalition between the Pitts and Newcastle and Pitt was formed in June of the same year, Temple received the office of privy seal. He alone in the cabinet supported Pitt's proposal to declare war with Spain in 1761, and they resigned together on the 5th of October. From this time Temple became one of the most violent and factious of politicians, and it is difficult to account for the influence, wholly evil, which he exerted over his illustrious brother-in-law. He himself is said to have avowed that "he loved faction, and never distrusted Pitt." He was at variance with his younger brother, George Grenville, when the latter became first lord of the treasury in April 1765, and he had no place in that ministry; but the brothers were reconciled before 1765, when Temple, who probably aimed at forming a ministry mainly confined to his own family connexions, refused to join the government, and persuaded Pitt to refuse likewise. A few weeks later the king offered the most liberal terms to induce Pitt to form or join an administration; and "a ministry directed by that great statesman," says Lecky, "would have been beyond all comparison the most advantageous to the country; it had no serious difficulty to encounter, and Pitt himself was now ready to undertake the task, but the evil genius of Lord Temple again prevailed. Without his co-operation Pitt could not, or would not proceed, and Temple absolutely refused to take office even in the foremost place." Pitt's continued refusal to join the Rockingham administration was no doubt partly due to the same disastrous influence, though before the close of 1765 the old friendship between the brothers-in-law was dissolving; and when at last in July 1766 Pitt consented to form a government, Temple refused to join; being bitterly offended because, although offered the head of the treasury, he was not to be allowed an equal share with Pitt in nominating to other offices. Temple forthwith began to inspire the most virulent libels against Pitt; and in conjunction with his brother George he concentrated the whole Grenville connexion in hostility to the government. After George Grenville's death in 1770 Lord Temple retired almost completely from public life. He died on the 12th of September 1779.

1 The Temple family belonged originally to Leicestershire, where, at Temple Hall, the elder line had resided since the 14th century. Peter Temple (1600-1663), the recusant, was a member of this elder line; a younger branch had settled in Oxfordshire and passed thence to Buckinghamshire, where John Temple purchased Stowe in 1589. This John was brother of Anthony, who was great-grandfather of Sir William Temple, the famous statesman. John Temple, son Thomas, who was created a baronet in 1611, was the great-grandfather of Earl Temple.
Lord Temple was entirely without statesmanship; he possessed an insatiable appetite for intrigue, and is said to have been the author of several anonymous libels, and the inspirer of many of them. Mr. Macaulay's well-known comparison of him with a mole working below "in some foul, twinkled labyrinth, whenever a heap of dirt was flung up," which perverts the spleen of Horace Walpole, perhaps exceeds the justice of the case; but there can be no question that Temple's character as a public man was rated very low by his contemporaries. In private life he used his great wealth with generosity to his relations, friends and dependents. Pitt was under pecuniary obligation to him. He paid the costs incurred by Wilkes in litigation, and he provided the agitator with the freehold qualification which enabled him to stand for Middlesex in the famous election of 1768.

In addition to the estates he inherited, Temple gained a considerable fortune by his marriage in 1737 with Anne, daughter and co-heiress of Thomas Chambers of Hanworth, Middlesex; a volume of poems by her was printed at the Strawberry Hill press in 1764. The only issue of the marriage being a daughter who died in infancy, Temple was succeeded in the earldom by his nephew George (1753-1813), second son of George Grenville the prime minister, who then assumed in addition to the name of Grenville not only the name of Temple, but also that of Nugent, his wife being daughter and co-heiress of Robert, Viscount Clare, afterwards Earl Nagent. The 2nd Earl of Temple was lord-lieutenant of Ireland in 1783-4; in 1784 was created marquess of Buckingham; and was again lord-lieutenant of Ireland in 1787-9.

His son and successor, Richard Temple-Nugent-Brydges-Chandos-Grenville (1776-1839), was created duke of Buckingham and Chandos in 1822, his wife being only daughter of the 3rd duke of Chandos; he was in the same patent created Earl Temple of Stowe, with special remainder as regards this title, in virtue of which, on the death without male issue in 1809 of the 1st earl of Buckingham and Chandos and the consequent extinction of the original earldom of Temple, the title of Earl Temple of Stowe devolved upon William Stephen Gore-Langton (1847-1902), whose mother was granddaughter of the 1st duke of Buckingham, grantee of this earldom. In 1902 Algernon William Stephen Temple-Gore-Langton (b. 1871) became 5th Earl Temple.

(2nd Earl Temple was lord-lieutenant of Ireland in 1783-4; in 1784 was created marquess of Buckingham; and was again lord-lieutenant of Ireland in 1787-9.)

TEMPLE, SIR WILLIAM, BART. (1628-1699), English statesman, diplomatist, and author, was born in London, and came of an old English family, but of the younger branch of it, which had for some time been settled in Ireland. He was the eldest son of Sir John Temple (1600-1677), Irish master of the rolls, whose grandfather Sir William Temple (1555-1627), provost of Trinity College, Dublin. His mother was Mary Hammond. Temple received a liberal education, calculated to produce that moderation of judgment for which he was afterwards remarkable. He was first a pupil of his uncle Dr Henry Hammond, the divine, after which he went to the grammar-school at Bishop Stortford, and then to the Puritan college of Emmanuel at Cambridge, where he came under the influence of Cudworth. At the commencement of the civil troubles his father embraced the popular cause and was deprived of his office. Coming to England, he sat in the Long Parliament as member for Chichester, and was one of the recalcitrant members turned out by Colonel Pride. Before this event happened his son had left Cambridge, without taking a degree, and in 1647 started to travel abroad. In the Isle of Wight, while on his way to France, he fell in with Dorothy Osborne, and won her affections. Her father, Sir Peter Osborne, was governor of Guernsey and a Royalist. Her family were opposed to the match, and threw difficulties in the way, which hindered its consummation for seven years. During this period Temple travelled in France, Spain, Holland, and other countries, gaining knowledge of the world and keeping up a constant correspondence with his betrothed. At last, apparently in 1654, the difficulties were surmounted and the marriage took place. In 1655 Temple and his wife went to Ireland. The next five years were spent in the house of Sir John Temple, who had made his peace with Cromwell, and had resumed his official position. His son took no part in politics, but lived the life of a student and a country gentleman.

The accession of Charles II. rescued Temple, like many others, from obscurity. In 1660 he sat in the convention parliament at Dublin as member for Carlow, and he represented the same constituency along with his father in the regular 4th Saini, which followed. After a short visit to England in 1661, as commissioner from the Irish parliament, he finally removed thither in 1663. There he attached himself to Arlington, secretary of state, and two years later received his first employment abroad. It was in March 1665 that the disastrous war with the United Netherlands began. Charles II. was anxious to obtain allies, especially as Louis XIV. was taking up a hostile attitude. At this juncture Christoph Bernhard van Galen, bishop of Münster, sent an envoy to England, offering to attack the Dutch if the English government would supply him the means. Temple was sent over to negotiate a treaty, and in this business he succeeded not only of the diplomatic skill but of the peculiar candour and frankness for which he was afterwards so distinguished. He was successful in making the treaty, but it was rendered ineffectual by the declaration of war by France, the threats of Louis, and the double-dealing of the prelate, who, after receiving a great part of the subsidy, made a separate peace with the Netherlands. As a reward for his services Temple was created a baronet, and in October 1665 became the English representative at the viceregal court at Brussels. While the war continued, Temple's duties became chiefly in cultivating good relations with Spain, which was a neutral in the quarrel between England and the Dutch, but was threatened by the claims of Louis XIV. on the Spanish Netherlands. Louis's designs became apparent in the spring of 1667, when he marched an army into Flanders. This event was one of those which led to the peace of Breda, and to the subsequent negotiations, which are Temple's chief title to fame. The French conquests were made at the expense of Spain, but were almost equally dangerous to the United Netherlands, whose independence would have been forfeited had Louis succeeded in annexing Flanders. While the French were taking towns after towns, Temple made a journey into Holland, where he visited De Witt. The friendship established and the community of views discovered during this interview facilitated the subsequent negotiations. Temple had for some time pressed on his government the necessity of stopping the French advance, and had pointed out the way to do so, but it was not till December 1667 that he received instructions to act as he had suggested. He at once set out for The Hague, and in January 1668 a treaty was made between England and the United Netherlands, which, being joined shortly afterwards by Sweden, became known as the Triple Alliance, which was made against the encroachments of France. Whether we regard the skill and celerity with which the negotiations were conducted or the results of the treaty, the transaction reflects great credit on the Temple. The French king was checked in mid-career, and, without a blow being struck, was obliged to surrender almost all his conquests. Pepys records public opinion on the treaty by saying that it was "the only good public thing that hath been done since the king came into England." Unfortunately the policy thus indicated was but short-lived. In taking up a hostile attitude towards France Charles's object had apparently been only to raise his price. Louis took the hint, increased his offers, and two years later the secret treaty of Dover reversed the policy of the Triple Alliance. Meanwhile Temple had developed the good understanding with the Dutch
by contracting a commercial treaty with them (February 1668),
and had acted as English plenipotentiary at Aix-la-Chapelle,
where peace between France and Spain was made in May 1668.
Shortly afterwards he was appointed ambassador at The Hague.
Here he lived for three years. Parliament was under De Witt
and with the young prince of Orange, afterwards William III.
The treaty of Dover led to Temple's recall; but the plot was
not yet ripe, and Temple nominally held his post for another
year. He perceived, however, that his day was over and retired
to his house at Sheen. In June 1671 he received his formal
dismissal. The war with the Netherlands broke out next year,
and was almost as discreditable to England as that of 1665.
Want of success and the growing strength of the opposition in
parliament forced Charles to make peace, and Temple was
brought out of his retirement to carry through the change of
front. After a negotiation of three days, carried on through
the medium of the Spanish ambassador, the treaty of West-
minster was made (February 1674). As a recognition of his
services Temple was now offered the embassy to Spain. This
he declined, as well as the offer of a far more important post,
that of secretary of state, but accepted instead a renewal of his
embassy to The Hague, whither he went in July 1674. In the
March following he was nominated ambassador to the congress
at Nijmegen; but, owing to the tortuousness of Charles's
dealings, it was not till July 1676 that he entered that town.
The negotiations dragged on for two years longer, for Charles
still receiving money from France, and English mediation
was no more a ruse. In the summer of 1677 Temple was
summoned to England and received a second offer of the
secretaryship of state, which he again declined. In the autumn
of the same year he had the satisfaction of removing the last
difficulties which hindered the marriage of William and Mary,
an event which seemed to complete the work of 1668 and 1674.
Louis still remaining obstinate in his demands, Temple was
commissioned in July 1678 to make an alliance with the states
of the Netherlands, and to bring their military and financial
resources to bear upon the Stuart plan. This treaty was instrumen-
tal in bringing about the general pacifica-
tion which was concluded in January 1679.
This was Temple's last appearance in the field of diplomacy;
but his public life was not yet over. A third offer of the
secretaryship was made to him; but, unwilling as ever to mix
himself up with faction and intrigue, he again declined. He
did not, however, withdraw from politics; on the contrary, he
was for a short time more prominent than ever. The state
was passing through a grave crisis. Political passion was
om-
mented by religious fanaticism. The Protestant settlement was
under the royal head and was pressing on the Exclusion Bill. The
root of all the mischief lay in the irresponsibility of the cabinet
to parliament and its complete subservience to the crown. To
remedy this, Temple brought forward his plan for a reform of
the privy council. This body was to consist of thirty members,
half of whom were to be the chief officers of the crown, the other
half being persons of importance, lords and commons, chosen
without reference to party. Special care was taken to select
men of wealth, which Temple considered as the chief source of
political influence. By the advice of this council the king
promised to consult his parliaments; and the crown was sup-
posed would trust such a body, and would cease to dictate to the
king. The scheme was accepted by the king, but was a failure from
the outset. Intended to combine the advantages of a parliament
and a council, it created a board which was neither the one
nor the other. The conduct of affairs fell at once into the hands
of a junta of four, of whom Temple was at first one, and the king
violated his promise by dissolving parliament without asking
the advice of the council. Temple retired in disgust to his
villa at Sheen, and appeared only occasionally at the council,
where he soon ceased to exercise any influence. In 1680 he was
nominated ambassador to Spain, but stayed in England in
order to take his seat in parliament as member for the university
of Cambridge. He took no part in the debates on the great
question of the day, and acting on the king's advice declined
to sit in the parliament of 1681. Early in that year his name
was struck off the list of the council, and henceforward he dis-
appeared from public life. He continued to live at Sheen till
1686, when he handed over his estate there to his son, the only
survivor of seven children, and retired to Moor Park in Surrey.
Here he lived until his death. William III. came to the throne Temple was pressed to
take office, but he declined. He married a second time, but
committed suicide immediately afterwards. Sir William,
though occasionally consulted by the king, took no further part
in public affairs, but occupied himself in literature, gardening
and other pursuits. It should not be omitted that Swift lived
with him as secretary during the last ten years (with one short
interval) of his life. Temple died at Moor Park on the 27th of
January 1699.

Temple's literary works are mostly political, and are of consider-
able importance. Among them may be mentioned An Essay on the
Present State and Settlement of Ireland (1668); The Empire,
Sweden, &c., a survey of the different Governments of Europe and
their relations to England (1671); Observations upon the United
Provinces (1672); Essay upon the Original and Nature of Govern-
ment (1672); Essay upon the Advancement of Trade in Ireland
(1673). Some of these were published in the first part of his Miscel-
nanea (1679). In the same year apparently his Poems were privately
printed. In 1683 he published for the first time his famous
letters of correspondence, extending from 1665 to 1671, he destroyed unpublishd;
the second, from 1672 to 1679, was published without his authority in
1690. The third, which was completed by a new editor, was published by Swift in
1709. In 1692 he published the second part of his Miscellanea,
containing among other subjects the essay Upon the Ancient and
Modern Learning, which is remarkable only as having given rise to the
controversy about "Letters to the Contemporaries of Particular
Persons." An Introduction to the History of England, a short sketch of English history
to 1687, was published in 1695. Several collections of his letters
were published by Swift and others after his death.

His fame rests, however, far more on his diplomatic triumphs
than on his literary work. His connexion with domestic affairs
was slight and unsuccessful. He was debarred both by his virtues
and his defects—by his impartiality, his honesty, and his want of
ambition—from taking an active part in the disgraceful politics of
his time. But in the foreign relations of his country he was
intimately concerned for a period of fourteen years, and in all that
his country combined a deep interest and a zeal. It may be
called great, but he will be remembered as one of the ablest
negotiators that England has produced, and as a public servant
who, in an unprincipled age and in circumstances peculiarly open
to corruption, preserved a blameless record.

See Life and Works of Sir William Temple (2 vols., 1720; 2nd ed.,
with Life by Lady Giffard, 1731); a more complete edition, including
the Letters, was published in 4 vols. in 1814; Burnet, History of his
own Time; T. P. Courtenay, Memoirs of the Life, &c., of Sir William
Temple (2 vols., 1836); Macaulay, Essay on Sir William Temple;
A. F. Sieveking, Sir W. Temple and other Carolean Garden Essays,
(1869); H. F. E. von Moltke, Sir William Temple (Somerset his-

TEMPLE, a city of Bell county, Texas, U.S.A., about 35 m.
S.S.W. of Waco. Pop. (1890) 4047; (1900) 7065 (1423 being
negros and 360 foreign-born) (1910) 10,993. It is served by
the Gulf, Colorado & Santa Fé, and the Missouri, Kansas &
Texas railways (the former has repair shops here), and is
connected with Belton (pop. in 1910, 4164), the county seat,
about 10 m. W., by an electric railway. In the city are a Carnegie
library, a King's Daughters' Hospital, the Temple Sanitarium,
and a hospital of the Gulf, Colorado & Santa Fé railway.
T. E. is situated in a rich farming country; cotton is ginned
and baled here, and there are various manufactures. The city
owns the water supply. Temple was founded in 1881-82 by
the Gulf, Colorado & Santa Fé railway, and was chartered as
a city in 1884.

TEMPLE, a term derived from the Lat. templum (Gr. ἱερά),
which originally denoted a space marked off by the augurs
for the purpose of observing the flight of birds or other
 ceremonies; later it was applied to the dwelling-place, the
auses sacrar, of the gods. In this latter sense it is the equivalent
of the Hebrew ḫelū (Gk. ἱερός), literally "a
god's seat," and of the foreign ḥēkal, palace, temple, a loan-word
from Sumerian through the medium of the Babylonian Ṛ-kālu
(lit. great house). A temple or "god-house," however, repre-
sents a comparatively advanced stage in the development of
Semitic religion. At first the Semite recognized the abodes
of his deities in certain outstanding and impressive natural
TEMPLE

objects, a spreading tree, a bubbling spring, a conspicuous rock or stone, a lofty mountain peak and the like. Besides these he met and held converse with his gods. The native rock was the first altar.

It was a distinct step in advance when it was recognized that a deity might take up his abode, elsewhere than in such natural sactuary, as in the massēbah or stone pillar and the ashērah or sacred post of wood, reared not by nature but by the hand of man (cf. Gen. xxviii. 18, 22, the origin of the sacred pillar at Beth-el).

The further advance to a real house or temple may be traced to the influence of at least two factors in the social and religious life of a people. One such factor came into play when men began to represent the deity by means of an image, or even when some object, whether natural, like the black stone of Moza, or manufactured, like the ark of the Hebrews, came to be regarded as spiritually sacred from its association with the deity. Such objects or images required a house to shelter and guard them. Another factor is to be found in the advance in material comfort which follows the transition from the nomadic to the agricultural mode of life. Among the settled Semites there arose the feeling that the gods of the community ought also to share in this advance (cf. 2 Sam. vii. 2). Accordingly they were invited to take up their abode in a bēth 'elōhim or temple. The dignity and comfort of the god's abode pari passu with those of their worshippers.

It must be kept in mind, however, that the altar remained as before the centre of the sacrificial worship. Around it or before it, under the open sky, the worshippers assembled. To the temple the priests alone, or the head of the sacral community in his priestly capacity, had access. In this respect the worship associated with altar and temple offers a striking contrast to the more spiritual worship of the Jewish synagogue and the Christian Church.

At the date of the Hebrew invasion of Canaan its numerous city-states had reached a fairly high level of civilization. Alongside of the typical Canaanite sanctuary, as known to us from the Old Testament references and from excavations in Ugarit, with its altar of earth or stone and its stately massēbah, a temple was probably to be found in all the more important centres. In an early Hebrew document there is a reference to the temple of El-berith at Shechem, which was large enough and strong enough to serve as a place of refuge in time of war (Judges ix. 46 ff.). The Philistines also had their temples in this period: thus we hear of a "house" of Dagon at Gaza (ib. xvi. 23 ff.) and also at Ashdod (1 Sam. v. 2), while a temple of Ashhtar (Iṣhtar-Aṣstar) is mentioned in 1 Sam. xxxxi. 10, predating that of Jerusalem (ib. i. 16).

The earliest reference to a temple built by Hebrew hands is to "an house of gods" reared by Micah to shelter an ephod and other sacred images which he had made (Judges xvii. 5). Micah's images were soon transported to Dan, where doubtless another house was built for their protection (xviii. 18, 30 f.). Somewhat later we find the ark of Yahweh installed in "the house of Yahweh" at Shiloh, which house was not a mere tent but a real temple (keleton, 1 Sam. i. 9, iii. 3) with doors (iii. 15) and doorposts (i. 9), and a hall in which the worshippers partook of the sacred meal (2 Sam. vi. 18, Greek text; cf. iv. 22 the guest-chamber," Heb. lohḥāh). After the destruction of Shiloh and the hands of the Philistines, its priesthood migrated to Nob, where also the incidents recorded in 1 Sam. xxi., note especially the presence of the shew-bread and the ephod—imply the existence of a temple.

The Temple of Solomon.—The primary source of our information regarding the erection of Solomon's temple is the account contained in 1 Kings vi.—vi. i., the details of which must have been derived ultimately from the temple archives. On this earlier narrative the chronicler (2 Chron. iii.—iv.) and Josephus (Antiq., VIII. iii. 1 ff.) are alike dependent. Unfortunately these two chapters of Kings are among the most difficult in the Old Testament, partly by reason of our ignorance of the precise meaning of several of the technical terms employed, partly owing to the unsatisfactory state of the received text, which has been overlaid with later additions and glosses. As regards the foundation of the temple, most writers have adhered to the main results of Stade's epoch-making essay in his Zeitschr. f. d. alttest. Wissenschaft, iii. (1883), 129—177, reprinted in his Akademische Rede, &c., with which compare Stade and Schwally's critical edition of Kings in Hermann's Sacred Books of the Old Test. See also, in addition to the standard commentaries, Burney, Notes on the Heb. Text of ... Kings, Vincent's critical appendices, and Stade's Die Heilige Stätte (Oct. 1907), and the literature cited at the end of this article.

(a) The Site of the Temple.—On this important point our earliest authority is silent. It is now universally acknowledged, however, that the whole complex of buildings erected by Solomon stood along the crest of the eastern hill, crowned by the temple at the highest point, as Josephus expressly testifies (Bell. Jud.; V. v. 1, with which compare the letter of (Pseudo) Aristeas, sect. 84). This at once brings to the site of the temple into proximity to the world-famous sacred rock, the sakkra, over which now stands the building known as the Mosque of Omar, and, more correctly, as the Dome of the Rock. Here an other important consideration comes to our aid. From the recognized persistence of sacred sites in the East through all the changes in the dominant religion, it is well-nigh certain that the sanctity of the sakkra rock goes back to the days of David and Solomon, or even, it may be, to prehistoric times. On it, or over it, the angel was believed to have been seen by David, and there David built his altar (2 Sam. xxiv. 18—25; cf. Judges vi. 20 f., 24; xiii. 19 ff.). This is undoubtedly the site assigned to the temple by the oldest extant tradition (see Chron. xii. 1; cf. 2 Sam. xxivv.). By every token, then, Solomon's temple of the sakkra rock was no lighter idea than the sakkra (see below), at least stood upon it. Since the altar necessarily stood in front, i.e. to the east, of the temple, the site of the latter was a short distance to the west of, and in line with, the sacred rock (see Jerusalem).

The alternative view, associated in recent times with the names of Schick and Conder, which places the most holy place, or innermost shrine of the temple, over the sakkra, has now few advocates (e.g. Col. Wallis in the Quarterly Statement of the Palestine Exploration Fund for 1896 and 1910). Apart from difficulties of space towards the east, which this location involves, it cannot be accepted in face of the fact that the sakkra still bears the marks of its former use as altar (see esp. Kittel, Studien zur k. Altertumskunde, 12 ff.). Moreover the rock, measuring as it does some 55 ft. by 40, could not have been contained within the "holy of holies," which was less than 20 ft. square.

A third site, still within the present Haram area, but towards its south-west angle, favoured by Fergusson (The Temple of the Jews), Robertson Smith (Encyc. Brit., 9th ed., art. "Temple") and others, was that of a "house" of Shiloh, near by, and also in the time of Solomon (Stade, op. cit., 12 ff.).

(b) The Temple Building.—In the fourth year of his reign Solomon "began to build the house of the Lord" with the laying of a massive foundation of "great stones," as required by the rapid fall of the ground to the west of the sakkra. Architecturally the temple consisted of three distinct parts: (1) the naos or temple proper, (2) a porch or pylion in front of the naos, and (3) a lower and narrower building which surrounded the naos on its other three sides (see fig. 1).

(1) The first of these, the "house of the Lord" in the strict sense, in which alone He was worshipped, was oblong in plan, and was divided into two compartments by a partition wall 2 : 1 by a partition wall. The room next the porch was 40 cubits in length by 20 in breadth, with a height of 30 cubits, 1

1 The length of the cubit at this period cannot be determined with absolute certainty. From the fact that Herod's naos was an exact replica of Zerubbabel's as regards inside measurements, coupled with the presumption that Zerubbabel built upon Solomon's foundations, it is possible to suppose that the same standard of length was used throughout. Now the present writer has shown from an inductive study of the height of the courses in the walls of the Haram and of other existing remains of the Hebrew temples that the cubit used by Herod's builders was exactly 17.6 in. or 447 millimetres (see Expository Times, xx. [1908—09] 24 ff.). There is therefore good reason for believing that this was also the cubit of Solomon's temple, notwithstanding the statement of 2 Chron. iii. 3 that the latter was a cubit "after
 The beams forming the floors and ceilings of the several storeroys being let into the wall of the hēkāl, three successive rebates of one and a half cubits in depth were cut into it (see fig. 2), consequently the width of the chambers was 5, 6 and 7 cubits in the three storeroys respectively (vi. 6). The total height, allowing for floors and roof, of the lateral building cannot have been less than 17 cubits. Entrance to the side-chambers was provided by a single door on the south side (see ground-plan, fig. 1).

So far there is no difficulty as regards the general plan and dimensions of the temple, provided it is kept in mind that the figures given must necessarily be placed in the upper third of the side walls, as will presently be seen. Adjoining the hēkāl on the west lay the dēbir or sanctuary, later termed "the most holy place" (lit. "holy of holies"). The inside space formed a perfect cube of 20 cubits, say 30 ft., in length, breadth and height (vi. 20), symbolizing the perfection of the Deity, for whose abode this part of the naos was specially designed. The dēbir, as has been said, was separated from the hēkāl by a transverse wall, whose existence we are left to infer from the obscure description of the door between the two compartments (vi. 31, see next section).

**Fig. 2.** Section of Temple along a-b of Ground Plan.

---

1. If the view presented below as to the height of the various parts of the temple is accepted, this wall becomes a structural necessity, being required to support the back wall of the hēkāl.
it may reasonably be inferred, was the height of the porch in the first temple, from which, in that case, the figure was derived. The probable outside measurements for the porch are thus 32 cubits for the breadth across “the house,” 15 for the depth including the front wall, and 60 cubits or 88 ft. for the height. As to the later height.

Still following the Egyptian model, the hēkāl will have had its separate roof of massive cedar beams, covered probably by heavy laterite blocks forming which 11-2 cubits may be allowed, giving a total of 32 cubits (42 ft.), equal to the outside width of the temple. In the same way the roof of the δēbrō will have had to 10 cubits lower, or circa 22 ft. in all, that of the lateral building about 4 cubits lower. According to the text (see下面的section on the temple from W. to E. in fig. 2). While the measurements given are, as they must necessarily be, in part conjectural, it is claimed for them that they introduce the element of proportion between the parts to an extent not attempted hitherto.

(c) The Interior of the Temple and its Furniture.—The entrance to the temple was through a wide and lofty opening in the front wall of the porch. Crossing the vestibule one entered the hēkāl by a large folding-door of cypress wood (vi. 34)—probably to 30 cubits wide as in Ezekiel’s temple—each of its four la-\n\nIt is 105 feet high above the ground level, or 10 cubits lower, or circa 22 ft. in all, that of the lateral building about 4 cubits lower. According to the text (see above on the temple from W. to E. in fig. 2). While the measurements given are, as they must necessarily be, in part conjectural, it is claimed for them that they introduce the element of proportion between the parts to an extent not attempted hitherto.

By the way, the width of the temple was about the same as that of the porch, or 10 cubits. The hēkāl was divided into two sections: the “greater court” and the “inner court.”

While the eastern (vi. 7-26) was for the sanctuary, the western (vi. 18-27) was for the holy of holies, the “holiest of holies.” The entrance to the hēkāl was through a large, folding-door (c. 34) of cypress wood, 10 cubits wide, each of its four leaves being ornamented with carved figures of chereubim, palms and flowers, all overlaid with gold. The inner walls of the hēkāl and the δēbrō were lined with boards of cedar from floor to ceiling, while the floor was covered with planks of cypress wood. From the hēkāl, a door in the partition wall gave entrance to the δēbrō. The doorway was not rectangular but apparently pentagonal in form (see the commentary on vi. 31), the lintel consisting of a boss of stone meeting at an angle, a feature “introduced to distribute the pressure of the superincumbent wall” (W. R. Smith). The walls of the δēbrō were ornamented with “pure gold” according to our present text (vi. 20); an enhancement of the dignity of the edifice as the earthly dwelling-place of the heavenly King is not so incredible as the profuse application of gold decoration to other interior and inferior parts of the house, even, as we have seen, to its floor (on this question see the critical works cited above).

As regards the furniture of the house, it is probable that the original text of 1 Kings introduced only the altar of cedar now found in the LXX text of vi. 20, and to be identified with the table of shewbread, as the sole furniture of the holy place. The ten golden candlesticks, properly lampstands, of vi. 23 are generally believed to have been introduced at a later date (cf. Jer. lii. 18 f.). In the most holy place stood the palaudium of Israel’s religion, the sacred ark of Yahweh. On either side of this venerable relic of the past were two cherubim, sculptured from olive wood and overlaid with gold, each 12 cubits high, their outstretched wings reaching right across the δēbrō, and forming a baldachin over the ark (vi. 23-28).

Although a part of the interior furniture of the temple, the remarkable twin pillars, either side of the entrance to the porch may be mentioned here, since they belonged rather to the temple than to its court. These pillars, which in the received text bear the enigmatical names of “Jachin and Boaz,” were hollow columns—the bronze metal being about 3 in. in thickness—over 26 ft. in height and 6 ft. in diameter, surmounted by elaborate capitals about 7½ ft. high. The latter were globular in form, ornamented by a specially cast network of bronze, over which were hung festoon-\n
1 The overlying of the floor with gold (1 Kings vi. 30) is a later interpolation; the same is probably true of the statues. The sculptures on the walls, which may have been added at a later date (cf. Ezek. xli. 18).

2 This partition and altar, if it can be remembered, had to support the back wall of the hēkāl according to the view of the temple archi
tecture advocated above.

3 The two “banners” of iii. 14 will be remembered, had to support the back wall of the δēbrō according to the view of the temple archi
tecture advocated above.

4 The various forms which the latter name assumes, in the Greek text, suggest an intentional disguise of an original Baa!, applied of course to Yahweh (Barnes, Jorn. of Thoel. Studies, v. 447 ff.).
TEMPLE

contemporary art. Where, it has often been asked, shall we look for the model or prototype of the temple edifice? Whence were derived the motif's to be seen in its decoration? What influences can be detected in the elaborate apparatus above described? Now it has long since been recognized that Syria, including Phoenicia and Palestine, was from the earliest times the meeting-place of streams of influence, religious, artistic and other, issuing from the two great fountains of civilization and culture in the ancient world, Egypt and Babylonia. To these must now be added the early civilization of the Aegean as revealed by the excavations in Crete, and the later but highly developed culture of the Hittites. As a result the art of Phoenicia and Syria, originally borrowed from Egypt mainly, had by the 10th century become thoroughly eclectic. Of this synthesis of traditions three great masters of contemporary art, for which Solomon was indebted to Phoenician architects and Phoenician artists. Thus the general disposition of the temple with its walled court, porch or vestibule and naos has been shown by modern excavation, and by later representations on coins, to be characteristic of Phoenician and North Syrian temple architecture. Here, however, we have an adaptation of the earlier temple architecture of Egypt. Egyptian influence is most clearly seen in the gradual decrease in the illumination of the several parts. In the temple court, as in its Egyptian counterpart, men worshipped under the bright sunlight; in the covered porch there was still a door to exclude the light which streamed in through the lofty entrance. But in the holy place only a dim light was admitted through latticed windows high up in the side walls, while the holy of holies, like the Egyptian cella, was completely dark.1

The sculptured panels of the interior were shown by Robertson Smith (Encyc. Brit., 9th ed., art. "Temple") to reveal familiar Phoenician motives, although Babylonia is probably the ultimate home of the cherubim. Excavations at Sinjirli in Northern Syria and at Megiddo have, further, solved the problem of the "tree of life" in the cedars of Lebanon. Within the temple were two rows of delicate "false beams" which were the architectural feature of the walls of the various courts (1 Kings vii. 12).2 The use of wooden beams alternately with courses of stone was a familiar expedient in early times. The practice of building walls with recurring rebates has also been illustrated by the recent excavations. While the prototype of the temple itself is to be sought, as has been said, in Egypt, Babylonian influence is clearly traceable in the symbolical "brazen sea," the apse of contemporary Babylonian, and doubtless also Phoenician, temples. The bronze lavers, finally, have been found to be dependent, both in their construction and in the motifs and iconography, on the art of the Aegean. From Crete and Cyprus they passed through Phoenician intermediaries to Syria and Palestine. The temple of Solomon, in short, is a product of the best Syro-Phoenician art of the period, itself the product of ideas which had their source in other lands.

The Temple of Zerubbabel.—In the year 536 B.C. the temple of Solomon was committed to the flames by order of Nebuchadrezzar (2 Kings xxv. 8; Jer. lii. 12 f.). Seventy years later its successor was finished and dedicated, the foundation having been laid in the second year of the reign of Cyrus (520 B.C.) by the governorship of Zerubbabel (Hag. ii. 18). There is every reason for assuming that the massive foundation courses of the earlier temple were still in situ, and available for the new building.3 The latter's inferiority, attested by Hag. ii. 3, was rather in respect of its decoration and equipment, as compared with the magnificence of the first temple, than as regards the size of the building. The dimensions given in the royal decree (Ezra vi. 3)—60 cubits for height and the same for breadth—probably refer, as was pointed out in a previous section, to the extremes of height and breadth applicable to the porch and temple respectively. In these and most other respects it may be supposed both temples followed the lines of Solomon's temple. It is probable, however, that the walls of the naos, including both the holy and the most holy place, were now raised to a uniform height, the separate back wall of the former having been abolished and the naos covered by a single roof. This seems a legitimate inference from the absence in the second and third temples of a supporting partition wall within the naos. Its place, as separating the two compartments, was taken by a magnificent curtain or "veil," which is mentioned among the spoils carried off by Antiochus Epiphanes (1 Macc. i. 21).4

In the matter of the sacred furniture, the holy place contained from the first the table of shewbread, and one golden "candlestick" or lampstand in place of the ten which illuminated the hêkâl in the later days, at least, of the first temple (Jer. lii. 19). The golden altar of incense, which fell a prey with the rest of the furniture to Antiochus (1 Macc. i. xxii. f.) was probably introduced later than the time of Zerubbabel, since a Jewish author, writing in the 3rd century B.C. under the name of Hecataeus of Aldera, mentions only "an altar and a candlestick both of gold," and it is natural to identify the former with the gold-plated table of shewbread.5 In one important respect the glory of the second house was less than that of the first. The holy of holies was now an empty shrine, for no one had dared to construct a second ark.

The second temple also differed from the first in having two courts, an outer and an inner, as prescribed by Ezekiel for his temple of the future. The outer court formed a square, each side of which was 500 cubits in length, also as prescribed by Ezekiel, with the sâbêra rock in the centre (see Exp. Times, XI, 257). Within the temple were two courts, one for the temple outer building, and one for the temple inner temple. The former, as described by Hecataeus, was composed of white unhewn stones (cf. Exod. xx. 25), "having each side 20 cubits long, and its height 10 cubits" (Josephus, Contra Apion, i. § 198), dimensions which agree with those assigned by the chronicler to the earlier altar of bronze (2 Chron. iv. 1).

In 165 B.C., three years after the spoliation of the temple and the desecration of its altar by Antiochus IV., Judas Maccabaeus rededicated the holy house, made sacred furniture, and erected a new altar of burnt-offering (1 Macc. iv. 41 f.). But long before this date the temple had assumed a character which it retained to the end of the Jewish state. It had become a fortress as well as a place of public worship, and existing records tell of the repetitive strengthening of its defences. "At the time of Pompey's siege (63 B.C.) it constituted an almost impregnable fastness, strengthened on its weakest or northern side by great towers and a deep ditch (Annal. xiv. 4, § 2). Twenty-six years later the temple was again besieged by Herod, who, attacking like Pompey from the north, had to force three lines of defence—the city wall, and the outer and inner temple," i.e. the walls of the outer and inner courts (W. R. Smith).

The Temple of Herod.—In the 18th year of his reign (20-19 B.C.), Herod obtained the reluctant consent of his subjects to his rebuilding scheme for enlarging the temple and beautifying its courts. The former was finished in eighteen months by a thousand priests trained for this special purpose, the courts in eight years, but the complete reconstruction occupied more than eighty years, lasting almost till the final breach with Rome, which culminated in the destruction of the sacred edifice by the soldiers of Titus in A.D. 70.

1 M. Clermont-Ganneau has put forward the interesting conjecture that the veil presented by Antiochus to the temple of Zeus at Olympia (Pausanias, V. xii. 4) was that taken from the temple at Jerusalem (see "Le Dieu sacré," Rec. du Journ. asiatique, 1904, 156). But long before this date the temple had assumed a character which it retained to the end of the Jewish state. Its size, as described by Hecataeus, was composed of white unhewn stones (cf. Exod. xx. 25), "having each side 20 cubits long, and its height 10 cubits" (Josephus, Contra Apion, i. § 198), dimensions which agree with those assigned by the chronicler to the earlier altar of bronze (2 Chron. iv. 1).

2 The witness of the Pseudo-Hecataeus and of another Jewish Hellenist, the Pseudo-Aristeas, regarding the second temple has recently been examined by G. A. Smith in his volumes on Jerusalem (see esp. index to vol. ii., and cf. Vincent. "Jérusalem d'après la lettre d'Aristée," Rev. bibliographie, 1908, 520 ff. (1909), 555 ff.).
(a) The Outer Court, its Gates and Colonnades.—The outer court of Zerubbabel's temple (900×300 cubits) was doubled in area according to Josephus (Bell. Jud. I. xxi. 1). The extension was principally on the south, which involved enormous subtractions on both sides of the hill, in order to secure the necessary level surface. There can be little doubt that this part of the present Haram area with its containing walls is essentially the work of Herod. The northern boundary of this great court, termed "the mountain of the house" in the Mishnah, and now generally known as "the court of the Gentiles," remained as before, and is represented by a line of scarped rock immediately to the north of the present inner platform of the Haram. This line of scarp, when prolonged east and west for about 1000 ft. in all, meets the east wall of the Haram a little to the north of the Golden Gate, at a point 300 yds. (800 cubits) from the S.E. angle, and the west wall at the same distance from the S.W. angle.1

The principal entrance to the temple enclosure, and the only one on a level with it, was on its western side by a bridge or viaduct which spanned the Tyropoeon at the spot marked by Wilson's arch. It is first mentioned in connexion with the siege of Pompey in 63 B.C., and according to the Mishnah it bore the name of the Gate of Kiponos (probably Coponius, the first procurator of Judea). Of the other three gates which Josephus assigns to this side (Ant. XV. xi. 5), the two leading to "the suburb" necessarily lay further north; one is represented by the old entrance now named Warren's gate, the other has not been identified. Josephus' third gate which led to the other, or lower city was undoubtedly Barclay's gate, and not, as is usually maintained, an entrance from Robinson's arch. In the south wall were two gates—the Huldah or "mole" gates of the Mishnah (Midr. i. 3)—represented by the present "double" and "triple" gates. Like the three last mentioned they had to be placed at the foot of the lofty retaining wall. From either gate a double ramp, which passed under the royal porch, led into the court in the direction shown on the accompanying plan. The Mishnah also names the "Shushan gate" on the east and the "Tadi gate" on the north.

Round the four sides of the great court ran a succession of magnificent porticoes in the style of contemporary Hellenistic architecture (Ant. XV. xi. 5). Those on the E., N., and W. sides had each three rows of columns forming a double walk or aisle; the eastern colonnade bore the old name of "Solomon's Porch" (John x. 23; Acts iii. 11). The southern portico was still more imposing and magnificent.

It had three aisles formed by four rows of monolithic marble columns of the Corinthian order,2 the first row engaged in the south wall of the court. The two side aisles were 30 ft. in width, the central aisle half as wide again (45 ft.); the columns of the former may be estimated at circa 60 ft., that of the latter at 100 ft. (Exp. Times, xx. 68 f.). The roofs were formed of deeply coffered cedar beams, that of the centre aisle being supported on pillars partly engaged in an ornamental stone balustrade. The "royal porch," as it was termed, worthily represents the high-water mark of Herod's architectural achievements in connexion with the reconstruction of the temple.

(b) The Inner Courts and Gates.—To the outer court Jew and Gentile, under certain conditions, had alike access. The sanctuary proper, from which the Gentile was rigidly excluded, began when one reached the series of walls, courts and buildings which rose on successive terraces in the northern half of the great enclosure. Its limits were distinguished by an artistic stone balustrade, named the sekera, which bore at intervals notices in the Greek tongue warning all Gentiles against advancing further on pain of death. Beyond the zôrg a narrow stone terrace, approached by flights of steps, was carried round all sides of the sanctuary save the west (see Bell. Jud. i. 5 [§ 38]), and extended to the foot of the lofty fortified walls of the temple enclosure (see X Y Z on plan, fig. 3).

The walls, over 35 ft. in height (25 cubits), were pierced by nine gateways, marked HÎ to HÎ on the accompanying plan, of which four were in the north and south walls respectively, and one in the east wall. These nine gates opened into massive two-storied towers, each 30 cubits deep (Bell. Jud. v. v. 3). Eight were "covered over with gold and silver, as were also the jambs and lintels" (ibid.), while the ninth, the principal entrance to the sanctuary, in the east wall (HÎ) was composed entirely of Corinthian brass, the gift of a certain Nicoran. Hence it was variously named "the Corinthian gate," "the gate of Nicoran" and "the beautiful gate" (Acts iii. 2, 10).4

Entering the sacrosanct area by this gate one found oneself in a colonnaded court, known as the court of the women (A) since women as well as men were admitted to this court, and at that epoch were engaged in the various arts of domestic worship. The four corners of the women's court were occupied by large chambers for various ceremonial purposes, while between these and the gate-houses were smaller chambers, one set being known as "the treasury" (Mark xii. 42). The western side was bounded by a high wall, beyond which, on a higher level, lay the inner or priests' court. The entrance to the latter was by an enormous gateway, 50 cubits by 40, through which an uninterrupted view was obtained of the altar and of the temple beyond it. To this "upper gate" 5

---

1 Which see for key to the several parts.
2 The area of the "court of the Gentiles," including the walls, was thus 800 cubits in length from N. to S., with an average width of circa 650 cubits of 17-6 in.—the present south wall measures 922 ft.—i.e., circa 520,000 sq. cubits as compared with the former area of 250,000, a remarkable confirmation of Josephus' statement as to the doubling of the temple courts. For the statements and measurements in this and the following sections differing from those of previous writers, reference may be made to the series of preliminary studies entitled "Some Problems of Herod's Temple," by the present writer, which appeared in The Expository Times, vol. xx (1908-1909), pp. 24 ff., 66 ff., 181 ff., 270 ff.
3 Such one gigantic monolith was discovered a few years ago in a disused quarry (see Exp. Times, xx. 69).
4 For this triple identification see Schürer's essay, Zeits. f. neuter. Wiss. (1906), 57–89; Berto, Rev. des études juives, ix. (1910), 30 f.; also Exp. Times, xx. 270 f.
(H1) a flight of fifteen semicircular steps led up from the court of the women. On a level with the entrance and running round three sides of the inner court (so Josephus) was a narrow strip (B), about 18 ft. broad, called the "court of the men of Israel." The rest of the oblong area, however, was not open to the public, but the priests and such of the laity as might require admission for the offering of their sacrifices. As in the lower court, the spaces between the gates were occupied by chambers, as to the purpose of which details are given in the Mishnah.

With regard to the more precise location of these temple courts, the present writer in the series of essays above referred to (see esp. Exp. Times, xx. 182 ff.),1 has endeavoured to prove that the whole fortress-sanctuary within the great walls stood on what is now the inner platform of the Haram, the present extended area of which is indicated by the double dotted line on the plan. According to the Mishnah (Middoth, ii. 5, 6) the upper and lower courts together formed a rectangle measuring 322 cubits from west to east by 135 cubits from north to south. The upper court 137 by 135, the lower 135 by 135. But, on the one hand, no account is taken of the gate-towers and priests' chambers which lined the courts, and on the other, the frequent recurrence of the number 11 and its multiples in the details which make up the above totals awakens suspicion as to their accuracy. The measurements of the accompanying plan are based on a critical comparison of the data of the Mishnah and those of Josephus with the relation of the whole to the altar on the sakhra (see next section). The total area covered by the sanctuary, including the terrace or khal, is entered as 315 cubits (462 ft.) across the rock from west to east, and 280 cubits (367 ft.) from north to south (for the detailed measurements see Exp. Times, xx. 181 ff., 271 ff.). The upper court shows an area of 170 cubits by 160, the lower court has a free space between the colonnades of 135 cubits (the Mishnah figure) by an average width of 110 cubits.

(c) The Altar of Burnt-offering.—Herod's great altar (D on the plan) was formed of unhewn stones, like that which preceded it. Its size, however, was increased till it formed a square, each side of which measured 32 cubits or 47 ft. at the base, thus occupying almost the whole of the exposed surface of the sakhra. The sides of the square decreased upwards by three stages until the altar-hearth was only 24 cubits square. The priests went up by an inclined approach on the south side (cf. Exod. xx. 26). To the north was the place where the sacrificial victims were slaughtered and prepared for the altar (cf. Levit. i. 11). It was provided with rings, pillars, hooks and tables. A laver (O on the plan) for the priests' ablutions stood on the west of the altar ramp.

(d) The Temple Building.—A few yards to the west of the altar rose the temple itself, a glittering mass of white marble and gold. Twelve steps, corresponding to the height (12 cubits) of the platform, led up to the entrance to the porch. In the disposition of its parts Herod's temple was in all essential respects a replica of its two predecessors. But there were differences in details. Thus the porch was increased in width and height until its front elevation measured, according to our authorities, Josephus and the Mishnah, 100 cubits by 100. This, however, probably includes the platform, as the principles of design both in relation to the other dimensions suggest 96 cubits by 96 (over 160 ft.) for the actual building. In shape the porch may be supposed to have retained its original likeness to an Egyptian pylon, as suggested in the accompanying diagram (fig. 4).

The holy place (F) retained its former area (40×20 cubits), but was raised in height to 40 cubits. A magnificent double curtain, embroidered in colours, screened off the most holy place. A richly bound a period, a shrine was made by cutting a passage-way giving access to the side-chambers and requiring an extra outer wall. Herod increased the width of the temple building to at least 60 cubits (70 according to the Mishnah). The problem of the height of the naves remains almost as perplexing as before. Josephus, it is true, agrees with the Mishnah (Middoth, lv. 6) in giving it a height of 100 cubits. It may be that Herod, "if he was forbidden to extend the House, would at least make it soar!" (G. A. Smith.) But the details given by the Jewish doctors do not inspire confidence, for, as Fergusson long ago perceived, "one storey is merely an ill-understood duplication of the other. A more modest height of 66 cubits (88 1/2 ft.), reduced to the extreme width, gives at least an element of proportion to the edifice which is altogether wanting in the traditional figures (compare the accompanying reconstruction, fig. 4)."

The entrance to the porch now measured 40 by 20, equal to the section of the holy place. The "great door of the house," 20 cubits high and 10 wide, was covered with gold; in it was suspended a richly embroidered Babylonian veil, while above the lintel was fixed a huge golden vine.

(e) The Temple Furniture.—This remained as before. In the holy place in front of the holy of holies, still a dark and empty shrine, stood the altar of incense, against the south wall the seven-branched golden lampstand, and opposite to it the table of shewbread. The two latter, as every one knows, were carried to Rome by Titus, and representations of them may still be seen among the sculptures adorning the arch which bears his name.

When one considers the extraordinary height and strength of the outer walls of the temple area, parts of which excite the wonder of every visitor to the holy city, the wealth of art lavished upon the wide-extended cloisters, the imposing character of the temple façade, and the impression produced by the marble-paved terraces and courts rising in succession, each above and within the other, one is not surprised that the temple of Herod was reckoned among the architectural wonders of the ancient world. There is for once no exaggeration in the words of Josephus when he records that from a distance the whole resembled a snow-covered mountain, and that the light reflected from the gilded porch dazzled the spectator like "the sun's own rays" (Bell. Jud. v. 6).

LITERATURE.—In addition to the primary sources, the Bible, Josephus, and the Mishnah treatise Middoth (ed. Surenhusius with commentaries), the commentaries and notes on Kings by Benzinger, Kittel, Stade, Burney and Skinner, the articles on the temples in the recent Bible Dictionary and the "Archaeologies" of Benzinger and Nowack, the following should be consulted: Le Temple de Jérusalem (1868); J. Fergusson, The Temples of the Jews (1878); Perrot et Chipiez, Le Temple de Jérusalem (1889); C. Schick, Die Stützhauste, der Tempel, &c. (1896); W. Shaw Caldecott, Solomon's Temple (1906), and The Second Temple (1908); R. Kittel, "Tempel" and "Tempelgeräte" in Herzog-Hauck, Realencyklopädie, 3rd ed. (1907), vol. xix.; G. A. Smith, Jerusalem, 2 vols. (1906, see index to each vol.); also W. R. Smith's article "Temple" in Encyclopaedia Britannica. For Herod's temple especially see Malmonides' treatise Beth Ha-bekhem (the chosen house), trans. in Quart. Statement of Pal. Explor. Fund (1888); and the recent studies by Watson, ibid. (1906 and 1910); Waterhouse, in Sunday's Sacred Sites of the Gospels (1903); A. R. S. Kennedy, "Some Problems of Herod's Temple," Expository Times, vol. xx. (1908-1909); G. Dalman, "Der zweite Tempel zu Jerusalem," in Jerusaleminhabrbuch (1900); P. Bletterman, "Ein Tempel in Jeru- salem," Rev. des études juives, lix.-lx. (Jan.-July 1910), and the articles in the Jewish Encyclopedia. For the study of the site the works of the English surveyors (see Jerusalem), including Sir C. Wilson's large-scale map of the Haram, are indispensable.

5
Egyptian Temples.—In the architectural sense the earliest temples in Egypt probably consisted only of a small cella, or sanctuary, with a portico, such as are represented in the models of soul-houses found in 1907 by Flinders Petrie at Rifeh; in front of these various additions were made, so that eventually the temple assumed far greater importance than was at first contemplated. This custom is at variance with that which takes place in the development of other architectural styles, where the older buildings are constantly taken down and rebuilt in accordance with the increased knowledge acquired in construction and design. It follows from this that although the Egyptian temples vary in their dimensions and extent, as a rule they present the same disposition of plan. The principal exceptions to this rule are the sepulchral temples, such as those of Deir el Bahri, and the more ancient example adjoining it, discovered in 1906, in which there are no enclosed halls of columns or sanctuary, and the Mammeisi temples (Fig. 5), which in plan resemble the Greek peristylar temples and might have been suggested by them, had not the example at Elephantine (destroyed in 1852) been of much earlier date, having been built by Amenophis III. (1414-1379).

The earliest example of which remains have been found is the temple built by Cephen in front of his pyramid at Memphis, and this consisted only of a sanctuary of small size without any architectural perfections. The next in date would be the sepulchral temple built by Mentuhotep (2832-2796) adjoining Deir el Bahri at Thebes; then follows the sanctuary of Karnak, built by Senwosri (Usertesen I.) (2758-2714), which formed the nucleus of that immense temple, which covered an area of 400,000 sq. ft. This temple may be taken as an extreme type of the accumulation which is found in nearly all the Egyptian temples, owing to the additional perfections to the original structure by successive monarchs, instead of rebuilding, as was the general custom in all other styles. To a certain extent the same conservative principle seems to have governed the design of all other temples, and even the temple at Edfr, which was set out on a plan conceived from the first, has the appearance of having been added to at various periods, the fronts of the inner halls showing inside those built in front. It is not only in the plan that the close resemblance of one building to another is shown; the architectural design is repeated in the earliest and latest temples; the raking sides of the pylons and walls with the torus-moulding of the quoins and the cavetto cornice are identical, so that it is only by the inscriptions that one is able to ascribe the buildings to the kings of the 18th or following dynasties and distinguish them from those erected by the Ptolemies, or even under Roman rule. The only differences are those exhibited in the great halls of columns, which, in the earlier temples, were built in between the pylons and side walls, receiving their light through clerestory windows, as at Karnak (Fig. 6), the other temples in its vicinity and the Ramesseum; whereas in the later temples on one side of the walls a screen was built between the columns, over which the interior was lighted. The second change was that made in the capitals of the columns, which are of wonderful diversity of design, some on the same hall, including every variety of river plant, in addition to the papyrus and lily flowers; in the later temples also the columns are more slender in their proportions and not set so closely one to the other.

Although generally the temples are built symmetrically on a central axis, with walls at right angles to one another, there are some special exceptions; thus the axial line of the great entrance court of the temple at Luxor is at an angle of about 15° with that of the temple in its rear, and in the island of Philae no two buildings are on the same axis or are parallel to or at right angles to one another, thus conforming to the irregular site on which they were built.

Assyrian.—The temple in Chaldaea or Assyria (known as a zigurart) was of an entirely different class, and took the form of a many-storeyed structure, of which the typical example is the Birs Nimrud. This originally consisted of six storeys, each one set behind the other, so as to admit of a terrace round each, the upper storey being crowned by a shrine.

Access to the several storeys was obtained by flights of steps, either lying parallel with the front or in one continuous flight in centre of same, or again as at Khorsabad by a ramp winding round the tower; the architectural design consisted of sunk panels on the various storeys with battlement parapets, and, like the Birs Nimrud, the several storeys were dedicated to the seven planets, the walls being enriched with the colours sacred to each.

Greek and Roman.—In Greece the earliest example of a temple is that of the Heraeum at Olympia, ascribed by Dr Dörpfeld to the 10th century B.C. The Heraeum (fig. 7) consisted of

a central naos or sanctuary with pronaoi in front and opisthodomus in the rear, the whole enclosed by a peristyle, thus presenting the characteristics of the fully developed temple of the 5th century. As, however, the description of the several types would be rendered clearer if they were taken from the simplest plan to the more elaborate, adopting to a certain extent the definitions given by Vitruvius, they are as follows:—
**TEMPLE**

611

**DISTYLE-IN-ANTIS**, a cella or naos preceded by a portico of two columns placed between the prolongation of the cella wall. Fig. 8.

The Temple of Themis Rhamnus.

**Fig. 8.**

**Fig. 9.**

**Fig. 10.**

**Amphidistyle-in-antis**, similar to the foregoing but with a second portico in the rear. Fig. 9.

The Temple of Diana Propylaea, Eleusis.

**Tetrastyle prostyle**, with a portico of four columns in front. Fig. 10. The Temple B. Selinus, Sicily.

**Tetrastyle amphiprostyle**, with an additional portico of four columns in the rear. Fig. 11. The Temple of Nike Apteros, Athens.

**Hexastyle peripteral**, six columns in front and rear and a peristyle round the cella forming a covered passage round. Fig. 12. The Temple of Theseus, Athens.

**Octostyle peripteral**, eight columns in front and rear and a peristyle round. Fig. 13. The Parthenon, Athens.

**Octostyle dipteral**, eight columns in front and rear and a double row in the peristyle. Fig. 14. The Temple of Jupiter Olympus, Athens.

**Octostyle pseudo-dipteral**, similar to the last, except that the inner row of columns is omitted, thus giving a passage round of twice the ordinary width. Fig. 15. The Temple of Apollo (Sminthis), Troad.

**Decastyle dipteral**, ten columns in front and rear and a double row in the peristyle. Fig. 16. The Temple of Apollo Didymaeus, at Branchidae, near Miletus.

The above definitions apply to Greek temples, whether of the Doric, Ionic or Corinthian orders. The Romans in some of their temples adopted the same disposition, but with this important difference, that, instead of the temple resting on a stylobate of three steps, it was raised on a podium with a flight of steps in front. In some of their temples, requiring a larger cella wherein to store their works of art, it occupied in the rear the full width of the portico in front; they retained, however, the semblance of the peristyle, the columns of which became semi-attached to the cella wall. If the portico had four columns, the temple was known as **tetrasyle pseudo-peripteral**, of which the so-called temple of Fortuna Virilis at Rome is an example; and if six columns, **hexastyle pseudo-peripteral**, as in the Maison Carrée at Nîmes.

In front of the naos or cella of the Greek temple there was always a pronaos, viz. a vestibule with two or more columns in antis, and in the rear a similar feature known as the epistheodos or treasury; in a few cases, as in the Parthenon, this formed a separate chamber, which was entered through a similar vestibule to that in front of the naos; this same vestibule in the absence of the separate chamber was sometimes enclosed with bronze grilles and used as the epistheodos; the Latin term posticum is frequently given to this rear vestibule, for which the Germans and Americans have adopted the term epinaos when speaking of Greek temples. In Roman temples the posticum is rarely found; the portico, on the other hand, was increased in importance, being frequently the depth of three bays or columnisations. In most of the early Greek temples the cellas were comparatively narrow, owing to the difficulty of roofing them over, as the Greeks could not seem to have been acquainted with the principle of the trussed beam. When therefore more than the usual width was required it became necessary to introduce columns on each side within the cella to carry the ceiling and roof, the earliest example of which existed in the Heraeum at Olympia. There are two other temples in which some of these internal columns still exist, as in the temples at Aegina and Paestum. At Aegina there were five columns on each side, carrying an architrave with five smaller columns superposed; in the temple of Neptune at Paestum there were seven on each side; and in the Parthenon nine columns and a square pier at the end with three columns in the rear, thus constituting an aisle on three sides, round which privileged visitors, like Pausanias, were allowed to pass, there being bronze rails between the columns. In the temple of Zeus at Olympia traces of the barriers have been found, as also of an upper gallery, access to which was given by a wooden staircase. The question of the lighting of these temples has never been definitely settled; it is probable that as a rule the only direct light received was that through the open doorway (see **HYPOTECHOS**).

In the earliest temples, those of the Heraeum at Olympia, of Apollo at Thermon, and the arched temple at Argos, the columns of the peristyle were in wood and carried a wooden architrave; in the Heraeum the wooden columns were replaced by columns in stone when they showed signs of deterioration; the earliest stone columns which were introduced date from the 5th century, and in the Heraeum in the 2nd century saw one wood column still in situ in the epistheodos. From about the middle of the 7th century...
the columns were always in stone, and were generally built in several courses with drums or frusta, there being very few instances of monolithic columns in Greek temples; the Romans, on the other hand, in their principal columns considered the monolith to be more monumental, and not only employed the finest Greek marbles to that end, but used granite and porphyry.

The favourite type of Greek temple was that known as hexastyle peripteral, of which the temple of Aphaea at Aegina, of the

![Fig. 20.](image)

Doric order, is one of the best-preserved examples; on account of the width of its naos it was necessary to provide columns inside it to carry the ceiling and the roof, so that it represents the fully developed type of a Greek temple. The plan of the temple is shown in fig. 18; the elevation is given in fig. 19, representing the west front, the columns of which rest on a stylobate of three steps, and carry the entablature and pediment. Fig. 20 shows the three first columns of the flank elevation, the entablature carried by them, and the tiled roof with antefixa and crested ridge.

![Fig. 21.](image)

Fig. 21 gives the section through the stylobate, peristyle and pronaos, and half of the naos, showing the superposed columns, ceiling and roof, all based on the conjectural restoration by Cockerell. The temple of Aegina is supposed to have been erected about 500 B.C., the magnificent sculpture with which it is enriched being added c. 480 B.C. The temple was built of a fine calcareous stone from quarries close by, which was coated over with a thin layer of stucco of lime and marble dust; this enabled the masons to give finer profiles to the mouldings, and afforded a field for colour, of which the restoration is shown in Cockerell's Temple of Aegina, from which the illustrations are taken; the cymatium and the tiles covering the roof were in Parian marble.

The Greek Temples were always enclosed in a temenos, in which were other shrines, altars and treasuries; in Athens the temenos was the Acropolis, on which the temples were built; at Delphi it was in a valley on inclined ground; and in Grgenti the temples were raised on the ridge of a hill; in all these cases the Greeks accepted the inequalities of the site, and, adding art to nature,

![Fig. 22.](image)

united their work with that of the Creator, so that it seemed to form part of the same design. Some of the sites of the temples, such as those at Olympia, Epidaurus and Delos, were practically level, but even in those the temples and other structures were arranged in groups, thus producing a much more picturesque effect than in those of the Romans, which, when enclosed, were always

![Fig. 23.](image)

planned on axial lines and raised on artificial platforms or terraces, as at Baalbek, Palmyra and Aizani, with peristyles round the raised court. The best-preserved Roman temple is that known as the Maison Carrée at Nîmes in the south of France, a hexastyle pseudo-peripteral temple, of which the elevation is given in fig. 22 and the plan in fig. 23. It was of the Corinthian order, and instead of a stylobate of three steps was raised on a podium 11 ft. high with a flight of steps in front. For further descriptions of both the Greek and Roman temples see Architecture.

(R. P. S.)
TEMPLE BAR, an historic site in London, England. In more than one of the main roads converging upon the city of London a bar or chain marked the extra-mural jurisdiction of the Corporation. Temple Bar stood at the junction of the present Strand and Fleet Street, over against the Law Courts. A bar is first mentioned here in 1301, but the name is most familiar in its application to the gateway designed by Sir Christopher Wren, which replaced an older structure here in 1673. This was removed in 1878, and set up in 1888 at the entrance to Theobalds Park near Cheshunt, Hertfordshire. A pedestal surmounted by a dragon or "griffin" marks the old site. When the sovereign is about to enter the city in state, whether by Temple Bar or elsewhere, the Lord Mayor, in accordance with ancient custom, presents the sword of the city to him, and he at once returns it. Formerly the bar or gate was closed against the sovereign until this ceremony was carried out.

TEMRYUK, a seaport of Russia, in northern Caucasus, and in the government of Kuban, on the Sea of Azov, 81 m. W.N.W. of Ekaterinodar. Pop. (1897) 14,476. Here was a Turkish fortress, Abas, till 1774. The place is now a growing seaport for the export of grain, and has many flour-mills.

TENASSERIM, a division of Lower Burma, bordering on Siam. Area, 36,976 sq. m. Pop. (1901) 1,159,558, including 38,269 Christians, the great majority of whom are Karens. The headquarters of the commissioner are at Moulmein. It is divided into six districts: Tungoo, Salween, Thaton, Amherst, Tauyoy and Mergui. It formed the tract south of Pegu conquered from Burma in 1826, which for many years known as the Tenasserim province. The southern extremity of the division approaches the insular region of Malaysia, and it is fringed along its entire western boundary by a number of islands, forming in the north the Moscos and in the south the Mergui Archipelago. The eastern frontier is formed by a mountain range 7000 ft. high, which acts as a water-parting between the Tenasserim and the Siamese river systems.

TEN BRINK, BERNHARD EUGENIUS KONRAD (1841-1892), German philologist, of Dutch origin, was born at Amsterdam on the 13th of January 1841, but was sent to school at Düsseldorf, and afterwards studied at Münster, and later under Diez and Delius at Bonn. In 1866 he began to lecture at the Münster Academy on the philology of the English and Romance languages. In 1870 he became professor of modern languages at Marburg, and after the reconstitution of Strassburg University was appointed professor of English there in 1873. In 1878 he began to edit, in conjunction with W. Scherer, E. Martin and E. Schmitz, Quellen und Forschungen zur Sprache und Kulturgeschichte der germanischen Völker. He devoted himself for many years to the study of Chaucer. In 1877 he published Chaucer: Studien zur Geschichte seiner Entwicklung und zur Chronologie seiner Schriften; in 1884, Chaucers Sprache und Verskunst. He also published critical editions of the Prologue and the Complaynt of Pity. Ten Brink's work in this direction stimulated a revival of Chaucer study in the United Kingdom as well as in Germany, and to him was indirectly due the foundation of the English Chaucer Society. His Bewußt-Untersuchungen (1888) proved a hardly less valuable contribution to the study of Early English literature. His best known work is his Geschichte der englischen Literatur (1889-93), (English by H. Kennedy in Bohn's Standard Library), which was unfortunately never completed, and broke off just before the Elizabethan period. It was his intense admiration of Shakespeare that first attracted him to the study of English, and five lectures on Shakespeare delivered at Frankfurt were published after his death (1893). Ten Brink's collections and good collection of books died in 1892.

TENBURY, a market town in the Bewdley parliamentary division of Worcestershire, England, on the Kidderminster-Woofferton branch of the Great Western railway, 153 m. W.N.W. of London. Pop. (1901) 2080. It is pleasantly situated on the right bank of the Teme, here the boundary with Shropshire. The town has a spa, whose waters are efficacious in rheumatic affections and diseases of the skin. The church of St Mary the Virgin has Norman remains in the tower and chancel. The district produces hops and fruit, and there is trade in cider. The Teme abounds in trout and grayling, and Tenbury is in favour with anglers. At Old Wood, 2 m. S.W. of Tenbury, are St Michael's church and college (1858), founded and partially endowed by the Rev. Sir Frederick Gore Ouseley, in which the ordinary preparatory education of boys is combined with a school for choristers and instruction in ecclesiastical music.

TENBY, a market town, seaside resort, a municipal and contributory parliamentary borough of Pembrokeshire, Wales, finely situated on a long narrow promontory of limestone rock washed on three sides by the sea on the west shore of Carmarthen Bay. Pop. (1901) 4400. Tenby is a station on the Whitland-Pembroke Dock branch of the South Wales system of the Great Western railway. Its chief attractions as a watering-place are its picturesque appearance and surroundings, its extensive antiquarian remains, its mild climate and its two excellent beaches known as the North and South Sands. The ancient town walls survive almost intact on the north and west sides, and retain the fine St George's gateway, locally called the "Five Archers." These walls, which were largely rebuilt by Jasper Tudor, earl of Pembroke, during the Wars of the Roses, were again repaired under Elizabeth during the alarm of the Spanish invasion, as is shown by a contemporary tablet bearing the queen's cipher and the date 1588. The inconceivable ruins of the castle, presenting a portion of the keep and outer walls, occupy a rocky peninsula to the S.E. of the town known as the Castle Hill, which also contains the Welsh national monument to Albert, prince consort, an immense statue and pedestal of white marble erected in 1865. Upon the Castle Hill is a small museum, containing several antiquities of the local tribe and marine fauna, for which last Tenby has long been celebrated. Opposite the Castle Hill, about 100 yds. distant, but only accessible to foot passengers at low tide, is St Catherine's Rock with a fort constructed in 1815. Facing the Esplanade and South Sands, about 2½ m. from the shore, stretches Caldy Island, 1 m. in length and 3rd m. in breadth, with a population of seventy persons and containing a ruined priory, which was a subsidiary house to St Dogmell's Abbey. To the west, between Caldy Island and Gilar Point on the mainland, lies St Margaret's Rock. The parish church of St Mary, situated at the northern extremity of the island, where the principal open space in the town, is one of the largest churches in South Wales, and exhibits all varieties of architecture from the 12th to the 16th centuries. Its massive tower, crowned with a spire, is 152 ft. high, and forms a prominent object in all views of the town. The handsome interior is remarkably rich in early tombs and monuments, the most important of them being the elaborate altar-tomb of John and Thomas White (c. 1483), members of an opulent family of merchants long seated in Tenby. In the adjoining churchyard are some remains of the Carmelite friary founded by John de Woofferton in 1399. The harbour on the northern beach is protected by an ancient stone pier, and in 1805 an iron pier was erected below
TENCH—TENDER

the Castle Hill for the convenience of the steamboats which ply between the town and Bristol, Ilfracombe, &c. The trade of Tenby is inconsiderable, but the fisheries, for which the place was noted at an early period and which gave it its Welsh name of Dibnych y Pygdrd, are of great value.

The name of Tenby is undoubtedly a corrupted form of Daneby, recalling the Scandinavian origin of the place. The real importance of Tenby dates from the 13th century, when walls, castle and church were erected for the convenience of the Flemish colonists, who were then being planted in Dyfed. On more than one occasion the newly-founded town was captured, sacked and destroyed by marauding bands of Welshmen, notably in 1152; but on each occasion the place was rebuilt and refortified by the earls-patine of Pembroke, who greatly favoured this important settlement. The first earl of Pembroke to grant a charter of incorporation was William de Valence, 9th earl (temp. Henry III.), and these privileges were extended by his successor, Earl Aylmer. Henry IV., by a charter obtained in 1402, vested the government of the town in a mayor and two bailiffs to be elected annually. Elizabeth in 1580 confirmed all previous charters and incorporated the freeholders under the designation of "the mayor, bailiffs and burgesses of the borough of Tenby." During the 15th and under the Tudors the town grew extremely prosperous, and contained many wealthy mercantile families, of which that of White offers the most striking example. A member of this house, Thomas White, whilst mayor of Tenby, did signal service to the Lancastrian cause in 1471 by harbouring Jasper Tudor, earl of Pembroke, and his nephew Henry Tudor, earl of Richmond (afterwards King Henry VII.), prior to the conquest, to France. John Leland (c. 1540) described Tenby as being "very wealthy by merchandize," and noted its stone pier and well-built walls. The town suffered severely during the Civil Wars, undergoing two sieges, firstly in 1644 when the parliamentarian, Colonel Laughrane, took the place by storm, and secondly in 1648 when it capitulated to Colonel Horton. After the Restoration the importance and wealth of Tenby showed a constant tendency to decline, but towards the close of the 18th century it rose into great popularity as a watering-place, and it has since maintained its reputation as the most picturesque seaside resort of South Wales. Since 1536 Tenby has been a contributory borough to the Pembroke (now Pembroke and Haverfordwest) parliamentary district.

TENCH (Tinca vulgaris), a small fish of the Cyprinid family, which is one of the commonest and most widely spread fresh-water fishes of Europe. It is generally distributed in all suitable localities throughout England, but is limited to a few lakes and ponds in the south of Scotland and in Ireland. As the tench is of comparatively uncommon occurrence in unenclosed waters, its place among the indigenous fishes of Great Britain has been denied, and it has been supposed to have been introduced from the Continent; a view which, however, is not supported by any evidence, and is practically disposed of by the fact that fossil remains of the fish are found in the Pleistocene deposits of Great Britain. In central Europe it thrives best in enclosed, preserved waters, with a clayey or muddy bottom and with an abundant vegetation; it avoids clear waters with stony ground, and is altogether absent from rapid streams. The tench is distinguished by its very small scales, which are deeply imbedded in a thick skin, whose surface is as slippery as that of an eel.

All the fins have a rounded outline; the short dorsal fin is without a spine, but the males possess a very thick and flattened outer ray in the ventral fins. The mouth is rather narrow and provided at each corner with a very small barbel. Tench if kept in suitable waters are extremely prolific, and as they grow within a few years to a weight of 3 or 4 lb, and are then fit for the table, they may be profitably introduced into ponds which are already stocked with other fishes, such as carp and pike. They live on small animals or soft vegetable substances, which they dig out from the bottom. The tench or "golden tench," as it is known, is often kept in ponds or aviaries, and is recommended for ornamental waters, as its bright orange colours render it visible for some distance below the surface of the water. This variety, which seems to have been originally bred in Silesia, is not less well-flavoured than the normally coloured tench, and grows to the same size, viz., to 6 and even 8 ft.

The tench is really an excellent fish for the table, if kept in cool, clear water for a few days, as it is the custom to do in Germany, in order to rid it of the muddy flavour imparted to it by its favourite abode.

TENCIN, CLAUDINE ALEXANDRINE GUÉRIN DE (1681–1749), French courtesan and author, was born at Grenoble. Her father, Antoine Guérin, sieur de Tencin, was president of the parlement of Grenoble. Claudine was brought up at a convent near Grenoble and, at the wish of her parents, took the veil, but broke her vows and succeeded, in 1714, in gaining formal permission from the pope for her secularization. She joined her sister Mme. de Ferriol in Paris, where she soon established a salon, frequented by wits and roverseaux. Among her numerous lovers were the Chevalier Le Camus Destouches, the due de Chandos, and according to her biographer many other persons of distinction. The last of her liaisons had a tragic ending. M. de la Fresnaye committed suicide in her house, and Mme. de Tencin spent some time in the Châtelet in consequence, but was soon liberated as the result of a declaration of her innocence by the Grand Conseil. From this time she devoted herself to political intrigue, especially for the preferment of her brother the abbé Tencin, who became archbishop of Embrun and received a cardinal's hat. Eventually she formed a literary salon, which had among its habitants Fontenelle, de St. Conté, Mme. de la Condamine, and many others. Hers was the first of the Parisian literary salons to which distinguished foreigners were admitted, and among her English guests were Bolingbroke and Chesterfield. By the good sense with which she conducted what she called her "menagerie," she almost succeeded in effacing the record of her early disgrace. She was a novelist of considerable merit. Her novels have been highly praised for their simplicity and charm, the last qualities the circumstances of the writer's life would lead one to expect in her work. The best of them is Mémoires du comte de Comminges (1735), which appeared, as did the other two, under the name of her nephews, MM. d'Argentat and Pont de Veyl, the real authorship being carefully concealed. Mme. de Tencin died on the 4th of December 1749.

Her works, with those of Mme. de la Fayette, were edited by Etienne and Jay (Paris, 1825); her novels were reprinted, with introductory matter by Lescure, in 1885; and her correspondence in the Lettres de Mmes. de Villars, de La Fayette et de Tencin (Paris, 1869–1892). See P. Masson, Madame de Tencin (Paris, 1909).

TENCIN, PIERS GUÉRIN DE (1679–1758), French ecclesiastic, archbishop of Embrun and Lyons, and cardinal, was born at Grenoble on the 22nd of August 1679. He owed his quick advance to power to his sister Claudine (see above). He was a strong opponent of the Jansenists, and in 1742 was appointed a minister of state to Louis XV., though he held no portfolio. He died on the 2nd of March 1758.

TENDER. (1) An adjective meaning soft, either physically or figuratively, derived from Fr. tendre, Lat. tener, soft, allied to tensis, thin, and ultimately to be referred to the root, tan-, to stretch out, as in Lat. tendere. (2) A legal term meaning an offer for acceptance, particularly an offer in money for the satisfaction of a debt or liability or an offer to pay or deliver
according to the terms of a contract; for "legal tender," the currency which can legally be offered and must be accepted in payment, see Payment. The term is also applied specifically to an offer to do a specified piece of work or to supply certain goods for a certain sum or at a certain rate or to purchase goods at a certain rate. Contracts for large or important works or for the supply of large amounts of goods are usually put out to tender in order to secure the lowest price. In this sense the word is from 14th to 17th century, from G. tendern, to see the new edition of the dictionary.

Between Tenebrae and the modern term the Tenebrae, a form of the word *tendere* (Lat. tendere, to stretch out); (a) a "tender" is also one who "attends" (Lat. *attendere*, to stretch towards, to give heed to), and so is applied particularly to a small vessel which brings supplies, passengers, &c., to a larger vessel, or which is used to take or bring messages from or to her, and similarly to a carriage attached to a locomotive engine on a railway which carries coal or other fuel and water.

**Tenebrae** (Lat. for "shadows," "darkness"), the name for an office sung in Roman Catholic churches on the afternoon or evening of Wednesday, Thursday, and Friday of Holy Week. The name is derived, according to Durandus (Ration., lib. vi. cap. 72, n. 2), from the fact that the "light of the world" or the Messiah cultivates darkness (tenebras colit): firstly because it is in sorrow and grief on account of the Lord's Passion, and because for three days it celebrates his exequies since for three days he was dead; secondly, the office of Tenebrae symbolizes the darkness that fell on the face of the earth while the Sun of justice was hung upon the cross," &c. The falling darkness is symbolized by a peculiar and singularly impressive ceremony (see LIGHTS, CEREMONIAL).

**Tenement** (Med. Lat. *tenementum*, from *teneo*, to hold), in law, a term which, according to Coke, "includes not only all corporate inheritances which are or may be held, but also all inheritances issuing out of those inheritances, or concerning, or annexed to, or exercisable within the same" (Co. Litt. 203). In its more general legal sense it is applied to reality, as opposed to personality. In its popular sense tenement is used as meaning a house or dwelling, and, more particularly in large cities, tenement houses are buildings occupied by several families living independently of one another, but having a common right in the hall, staircases and outhouses. In the heart of great towns the problem of housing is a difficult one, and it is only of recent years that attention has been directed to the unsuitable and insanitary condition of many houses occupied on the tenement system as defined above, but in many cases never built with the conveniences necessary for joint occupation. In most of the large cities in Great Britain and the United States tenement houses are now built on the most modern plans (see HOUSING), and it is to be noted that the municipality of New York has a special Tenement-House Department, under charge of a commissioner, with wide authority to supervise the structure of tenement houses and their occupancy in the interest of health and general welfare.

**Teneriffe** [Tenerife], the largest of the Canary Islands; in the Atlantic Ocean, and belonging to Spain. Pop. (1890) 138,008; area, 782 sq. m. Tenerife lies a little west of the centre of the archipelago, between the islands of Grand Canary and Gomera. It is of irregular shape, 60 m. long, with an extreme breadth of 30 m. A chain of mountains traverses the island in the direction of its greatest length (east to west), and in the middle of the broadest part rises the celebrated peak, locally known as the Pico de Teyde (or Teide), which, with its summit and spurs, occupies nearly one-third of the whole island. It has a double top: the highest point, El Pito, is 12,200 ft. above the sea; the other, Chahorra, connected with the first by a short narrow ridge, has a height of 9880 ft. They are both oriches in the same grand dome of trachyte. Neither reaches the line of perpetual snow. There is, however, a natural cavern, 11,050 ft. above the sea, where snow is preserved all the year. Snow remains for about four months on the upper part of the peak.

For more than one-half of its circumference the base of the true peak rises from an elevated but comparatively level tract, called by the Spaniards El Llano de la Retama (retama being the name of the *Cytisus subinclusus* which abounds there), and by the English the Pumice-Stone Plains. On the south-east, south and south-west are a high curved ridge overlooking the Pumice-Stone Plains, and presenting a very steep aspect; and on the north-west the sea the slope is more gradual, and there are intervening tablelands. Peaks rise from the ridge, one of which (Guajara) attains 9000 ft., and the modern volcanic cone resembles in aspect a fortress with circular massifs and a fosse. The rapamarts are about 8 m. in diameter, and tower in some places more than 1500 ft. above the fosse. On the north-west there are particularly steep, and even of sulphur-waves, and the modern cone is a pile of lava, pumice and ashes, thrown up in an ancient crater which had become greatly enlarged either by a falling in of the escarpment, or by the sea. Both El Pito and Chahorra are craters which issue steam and a little sulphurious vapour. The crater on El Pito is partly surrounded by a wall of lava, which has been made white by the action of sulphur-vapour, and even contain small crystals of sulphur. The thermometer rises considerably when thrust into the ground. The crater is about 300 ft. across, with a depth of 70 ft. The crater on Chahorra has a diameter of 4000 ft.; its depth is scarcely 150 ft. The view from the highest point, when no clouds intervene, is very extensive. All the islands of the archipelago are visible, and the horizon is 140 m. distant. North of the coast of Africa nor the island of Madeira is within the range of vision.

The ascent of the peak is usually made from Orotava, on the northern side of the island. After the cultivated grounds are left, the road is crossed by an arborescent forest, in places covered with codos (Adencaphus frankenioides), and this extends to the region of retama, the first bushes of which are found at the foot of the traveller into the Llano de la Retama. The scenery here is in strong contrast with the barren volcanic bases. Instead of a steep and rugged asent among black basaltic rocks, the traveller enters upon gently sloping ground, covered to a considerable depth with a mantle of retama. One of the most impressive sights of the peak is the shower of retama. The tender shoots of this shrub serve the wild goats for food, and the flowers yield a rich honey. The entrance to the Llano at a sort of natural gateway (called Porillo) between two basaltic hills, is about 7000 ft. above the sea. Between two and three hours are consumed in crossing the Llano to the base of the cone, the lower part of which (Mamón de Trigo) is ascended to a height of 9750 ft. For the ascent of the whole, the mules are usually left, and travellers frequently pass the night. Then comes the Malpais, 1000 ft. in altitude, consisting of rough black lava streams broken up into blocks and stones. These cease at the Ramblea, the lip of an older crater over which the lava poured before the sugar-loaf cone of pumice and ashes was thrown up. The pumice is in such quantity that at a distance it has the appearance of snow covering the peak. From twenty to twenty-four hours are consumed in ascending the peak. The ascent is extremely steep.

To the north-west of the grand cone, some thousands of feet below Chahorra, there are many small cones of eruption, showing that abundant eruptions of volcanic matter have recently taken place. The view from the ridge bounding the Pumice-Stone Plains extends a chain of mountains to the north-eastern extremity of the island. The highest peaks are Izana (3734 ft.), Pereumel (6027), and Cuchillo (5674). There is no record of eruptions from either crater of the peak. In 1705 a great quantity of lava was poured out from three vents on the eastern side; and in the same year lava streams issued from a crater near Guimar, half-way between Santa Cruz and the peak. In the year 1706 a vent on the north-western side of the peak discharged a copious stream, which flowed down to the sea, and nearly reached the town of Garachico. For three months in 1768 much lava and other volcanic matter were ejected from orifices to the west of Chahorra.

Santa Cruz, the capital of Tenerife and of the Canaries (pop. 15,000), and La Laguna (13,074), the former capital, are described in separate articles. A good road connects Santa Cruz and Orotava, a town on the north coast 25 m. W.N.W. It passes through Laguncrete Matanzas—a place deriving its name from the old fort and barrack, and 7000 ft. above sea level—then adjoins the harbour of Garachico. For Guanches in 1494. All travellers speak in terms of warm admiration of the scenery in this part of the island. Date-palms form a striking feature in the landscapes. The town of Orotava (pop. 9192) is 1040 ft. above the sea. The houses are solidly built, but it has a deserted aspect. A stream of water is conducted through every street. The famous dragon-tree, which so many travellers have described, no longer exists. Port Orotava, 3 m. N. of the town, is a clean place, with about 4500 inhabitants. The streets are broad and the houses well built. The roadstead, protected by a fort and some batteries, affords little or no shelter against wind. At Icod de los Vinos, a pretty town of
TENIERS, the name of a family of Flemish artists who flourished at Antwerp and Brussels during the 17th century. Teniers the Elder (1610-1690), the most famous and successful of the Teniers family, was born in Antwerp, near the town of Laken, and grew up near the sea, the south of the town. He was the son of a baker, and his father was a member of the Antwerp guild of painters in 1606. Though his ambition led him at times to try his skill in large religious, historical and mythological compositions, his claim to fame depends chiefly on his landscapes and paintings of peasants carousing, of nervous scenes and the like, which are marked by a healthy sense of humour, and which are not infrequently confused with the work of his brother, David Teniers the Younger. David Teniers the Younger (1610-1690), the elder Teniers at St Paul's church in Antwerp, representing the “Works of Charity.” At the Vienna Gallery are four landscapes painted by Teniers under the influence of Elsheimer, and four small mythological subjects, among them “Vertumnus and Pomona,” and “Juno, Jupiter and Io.” The National Gallery has a characteristic scene of village life, “Playing at Bowls,” a “Conversation” of three men and a woman, and a large “Rocky Landscape.” Other examples of his work are to be found at the galleries of St Petersburg, Madrid, Brussels, Munich, Dresden and Berlin (“The Temptation of St Anthony”). Teniers also achieved success as a picture dealer, and is known to have attended the fair of St Germain in Paris in 1615, with a large number of paintings by himself and by his four sons. He died at Antwerp in 1690.

David Teniers the Younger, the younger (1610-1690), the more celebrated son of the last-named, almost ranking in celebrity with Rubens and Van Dyck, was born in Antwerp on the 15th of December 1610. Through his father, he was indirectly influenced by Elsheimer and by Rubens. We can also trace the influence of Adrian Brouwer at the outset of his career. There is no evidence that either Rubens or Brouwer interfered in any way with Teniers’s education, and Smith (Catalogue Raisonné) may be correct in supposing that the ambition which Brouwer’s pictures at one time excited alone suggested to the younger artist his imitation of them. The only trace of personal relations having existed between Teniers and Rubens is the fact that the ward of the latter, Anne Breughel, the daughter of John (Velvet) Breughel, married Teniers in 1637. Admitted as a “master” in the guild of St Luke in 1632, Teniers had even before this made the public acquainted with his works. The Berlin Museum possesses a group of ladies and gentlemen dated 1630. No special signature positively distinguishes these first productions from those of his father, and we do not think it correct to admit with some writers that he first painted religious subjects. Dr Bode, in a remarkable study of Brouwer and his works, expresses the opinion that Teniers’s earliest pictures are those found under the signature “Tenier.” Tenier is a Flemish version of a thoroughly Walloon name, “Taisnier,” which the painter’s grandfather, a mercer, brought with him when he came from Ath in 1598; and Dr Bode’s supposition is greatly strengthened by the circumstance that not only David the elder, but his brother Abraham and his four sons were all inscribed as “Tenier” in the ledgers of the Antwerp guild of St Luke. Some really first-rate works—the “Prodigal Son” and a group of “Topers” in the Munich Gallery, as well as a party of gentlemen and ladies at dinner, termed the “Five Senses,” in the Brussels Museum—with the above signature are remarkable instances of the perfection attained by the artist when he may be supposed to have been scarcely twenty. His touch is of the rarest delicacy, his colour at once gay and harmonious. Waagen and Smith agree that the works painted from 1645 to 1650 testify most highly to the master’s abilities; there is no doubt that a considerable number of earlier productions would have been sufficient to immortalize his name. He was little over thirty when the Antwerp gild of St George enabled him to paint the marvellous picture which ultimately found its way to the Hermitage Gallery in St Petersburg—the “Meeting of the Civic Guards.” Correct to the minutest detail, yet striking in effect, the scene, under the rays of glorious sunshine, displays an astonishing amount of acquired knowledge and natural good taste. This painting leads us to mention that in the same year (1645), the then Count of Aranjuez acquired a very fine picture of “The Village Fete” (or “La fete aux chaudrons”) (No. 952), an equally beautiful repetition of which, dated 1646, belongs to the duke of Bedford. Truth in physiognomy, distribution of groups, the beautiful effect of light and shade, command our warmest admiration. A work like this, says Waagen, stamps its author as the greatest among painters of his class. Frankness in expression and freedom in attitude guided his preference in the choice of a model, but we may suppose him occasionally to have exaggerated both. He painted too, occasionally, a number of large pictures, in the coarse amusements of the boors he is fond of painting, he himself lives in good style, looks like a gentleman, and behaves as such. He never seems tired or showing the turrets of his chateau of Perck, and in the midst, of rustic merry-making we often see his family and himself received in hand by the joyous peasants. We may also observe that he has a certain number of favourite models, the constant recurrence of whom is a special feature of his works. We have even met them in a series of life-size portrait-like figures in the Doria Pamphilj Gallery in Rome.

Teniers was chosen by the common council of Antwerp to preside over the gild of painters in 1644. The archduke Leopold William, who had assumed the government of the Spanish Netherlands, being a great lover of art, employed Teniers not only as a painter but as keeper of the collection of pictures he was then forming. With the rank and title of “ayuda de camara,” Teniers took up his abode in Brussels shortly after 1647. Immense sums were spent in the acquisition of paintings for the archduke. A number of valuable works of the Italian masters, now in the Vienna Museum, came from Leopold’s gift, one of the having belonged to Charles I, and the duke of Buckingham. De Bie (1661) states that Teniers was some time in London, collecting pictures for the duke of Fuensaldana, then acting as Leopold’s lieutenant in the Netherlands. Paintings in Madrid, Munich, Vienna and Brussels have enabled art critics to form an opinion of what the imperial residence was at the time of Leopold, who is represented as conducted by Teniers and admiring some recent acquisition. No picture in the gallery is omitted, every one being inscribed with a number and the name of its author, so that the ensemble of these paintings might serve as an illustrated inventory of the collection. Still more interesting is a canvas, now in the Munich Gallery, where we see Teniers at work in a room of the palace, with an old peasant as a model and several gentlemen looking on. When Leopold returned to Vienna, Teniers’s task ceased; in fact, the pictures also travelled to Austria, and a Flemish priest, himself a first-rate flower painter, Van der Baren, became keeper of the archducal gallery. Teniers nevertheless remained in high favour with the new governor-general, Don Juan, a natural son of Philip IV. The prince was his pupil, and de Bie tells us he painted the likeness of the painter’s son. Honoured as one of the greatest painters in Europe, Teniers seems to have made himself extremely miserable through his aristocratic indulgence.

1 Under the name of Wessius.

2 It was not until recent years that the MS. inventory of this collection was discovered among the papers of Prince Schwerzenberg in Vienna. It was published in 1883 by Adolf Berger. In 1648 Teniers published 243 etchings after the best Italian works of Leopold William’s collection, which, with the portraits of the archduke and Teniers, were brought together as a volume in 1660, under the title El Teatro de Pinturas.
TENISON

leans. Shortly after the death of his wife in 1656 he married Isabella de Fren, daughter of the secretary of the council of Brabant, and strove his utmost to prove his right to armorial bearings. In a petition to the king he reminded him that the honour of knighthood had been bestowed upon Rubens and Van Dyck. The king at last declared his readiness to grant the request, but on the express condition that Teniers should give up painting his pictures. The condition was not complied with, but it may perhaps account for the master's activity in favour of the foundation in Antwerp of an academy of fine arts to which only painters and sculptors should be admitted, whereas the venerable gild of St Luke made no difference between art and handicraft: carvers, gilders, bookbinders, stood on an even footing with painters and sculptors; the separation was not obtained till 1773.

There were great rejoicings in Antwerp when, on the 26th of January 1663, Teniers came from Brussels with the royal charter of the academy, the existence of which was due entirely to his personal initiative.

Teniers died in Brussels on the 23rd of April 1690. The date is often wrongly given as 1694 or 1695. A picture in the Munich Gallery (No. 906), dated 1680, represents him as an alchemist, oppressed with a burden of age beyond his years. From this date we hear more of his doings as a picture-dealer than as a painter, which most probably gave birth to the legend of his having given himself out as deceased in order to get higher prices for his works. David, his eldest son, a painter of talent and reputation, died in 1685. One of this Teniers's pictures, "David, Kneeling before the Blessed Virgin," dated 1666, is still to be found in the church at Freck. As well as his father, he contributed many patterns to the celebrated Brussels tapestry looms.

Smith's Catalogue raisonné gives descriptions of over 900 paintings accepted as original productions of Teniers. Few artists ever worked with greater ease, and some of his smaller pictures—landscapes with figures—have been termed "afternoons," not from the time they were produced, but from the productions of museums in Madrid, St Petersburg, Vienna, Munich, Dresden, Paris, London and Brussels have more than 200 pictures by Teniers. In the United Kingdom 150 may be found in private hands, and many other examples are to be met with in private collections throughout Europe. Although the spirit of many of these works is as a whole marvellous, their conscientiousness must be regarded as questionable. Especially in the later productions, from 1664 onwards, we often detect a lack of earnestness and of the calm and concentrated study of nature which alone prevent expression from degenerating into grimace in situations like those generally depicted by Teniers. He was perhaps the last of his race; he left no such high position to a great degree account for this. Brouwer knew more of taverns; Oostade was more thoroughly at home in cottages and humble dwellings; Teniers, throughout, triumphs in broad daylight, and, though man may not be justly compared to the CBD, still he is on an equal open-air, scenes where he has, without constraint, given full play to the bright resources of his luminous palette. In this respect he often suggests comparisons with Watteau, but his subjects taken from the Gospels or sacred legend are absurd. An admirable picture in the Louvre shows "Peter Denying his Master" next to a table where soldiers are smoking and having a game at cards. A similar example is the "Deliverance of St Peter from Prison" of which two versions, curiously altered, are in the Dresden Gallery and the Wallace Collection. He likes going back to subjects illustrated two centuries before by Jerome Bosch—the "Temptation of Our Lord" and "Dance in the Mosque"—for the simple purpose of assembling the most comic arabications. His villagers drink, play bowls, dance and sing; they seldom quarrel or fight, and, if they do, seem to be laughing. This much may be said of Teniers, that no painter shows a more enviable ability to render a conception to his own and other people's satisfaction. His works have a technical freshness, a straightforwardness in means and intent, which make the study of them the closest attention of any painter who desires to excel in the mechanical knowledge of his art.

As a portrait painter he compares very unfavourably with Ostade, Cornelia, Bega and Dusart. More than 500 plates were made from his pictures; and, if it be true that Louis XIV, judged his "baboons (magots) unworthy of a place in the royal collections, they found adequate appreciation in the same—both his contemporaries and his successors. The duke of Bedford's admirable specimen was sold for 18,930 livres (f1800) in 1768. The "Prodigal Son," now in the Louvre, fetched 30,000 livres (£3098) in 1776. Smith's highest estimates have long since been greatly exceeded. The "Archers" in St Petersburg he gives as worth £2000. The Belgian government gave £5000 in 1867 for the "Village Pastoral" in the Louvre, which is now in the Brussels Museum; and a picture of the "Prodigal Son," scarcely 16 by 28 inches, fetched £5280 in 1876.

Although van Tilborgh, who was a scholar of Teniers in Brussels, found his style, with some success, and later painters often excelled in figure-painting on a small scale, Teniers cannot be said to have formed a school. Properly speaking, he is in the last representative of the Flemish traditions of the 17th century.

His character, a most Eminent Dutch and French Painters; John Vermeers, Notice historique sur David Teniers et sa famille; L. Gallelot, Quelques renseignements sur la famille; F. H. Van der Linden, le dees of David Teniers and Un procès de David Teniers et la corruption des peintres à Bruxelles; Alph. Wauters, Histoire des enviroons de Bruxelles et Les topographies bruxelloises; F. T. Bode, Adriaen Brouwer, ein Bild seines Lebens und seines Schaffens.

TENISON, THOMAS (1636-1719), English archbishop, was born at Cottenham, Cambridgeshire, on the 29th of September 1636. He was educated at the free school, Norwich, whence he entered Christ's College, Cambridge, as a scholar on Archbishop Parker's foundation. He graduated in 1657, and was chosen fellow in 1659. For a short time he studied medicine, but in 1659 was privately ordained. As vicar of St Andrew-the-Great, Cambridge, he was conspicuous for his devoted attention to the sufferers from the plague. In 1667 he was presented to the living of Holywell-cum-Needingworth, Huntingdonshire, by the earl of Manchester, to whose son he had been tutor, and in 1670 to that of St Peter's Mancroft, Norwich. In 1672 he received the degree of D.D., and was presented by Charlemagne, vicar of the parish, to the rectory of St John the Baptist, Ipswich. Tenison, according to Gilbert Burnet, "endowed schools, set up a public library, and kept many curates to assist him in his indefatigable labours." Being a strenuous opponent of the Church of Rome, and "Whitehall lying within that parish, he stood as in the front of the battle all King James's reign." In 1678, in a Discourse of Idolatry, he had endeavoured to fasten the practices of heathenish idolatry on the Church of Rome, and in a sermon which he published in 1687 on Discretion in Giving Alms was attacked by Andrew Fulton, head of the Jesuits in the Savoy. Tenison's reputation as an enemy of Romanism led the duke of Monmouth to send for him before the execution in 1685, when Bishops Ken and Turner refused to administer the Eucharist; but, although Tenison spoke to him in a "softer and less peremptory manner" than the two bishops, he was, like them, not satisfied with the sufficiency of Monmouth's penitence. Under William III., Tenison was in 1689 named a member of the ecclesiastical commission appointed to prepare matters towards a reconciliation of the Dissenters, the revision of the liturgy being specially entrusted to him. A sermon which he preached on the commission was published the same year. He preached a funeral sermon on Nell Gwyn (d. 1687) in which he represented her as truly penitent—a charitable judgment which did not meet with universal approval.

The general liberality of Tenison's religious views commended him to the royal favour, and, after being made bishop of Lincoln in 1691, he was promoted to the primacy in December 1694. He attended Queen Mary during her last illness and preached her funeral sermon in Westminster Abbey. When William in 1695 went to take command of the army in the Netherlands, Tenison was appointed one of the seven lords justices to whom his authority was delegated. Along with Berkeley, he attended the king's court with some success, and later painters often attacked him during her reign was not in much favour at court. He was a commissioner for the Union with Scotland in 1706. A strong supporter of the Hanoverian succession, he was one of the three officers of state to whom on the death of Anne was entrusted the duty of appointing a regent till the arrival of George I., whom he crowned on the 31st of October 1714. Tenison died at London on the 14th of December 1715.

Besides the sermons and tracts above mentioned, and various others on the "Papish" controversy, Tenison was the author of The Creed of Mr Hobbes Examined (1670) and Baconia, or Certain
TEN KATE, JAN JACOB LODEWIJK (1819–1889), Dutch divine, prose writer and poet, was born at The Hague on the 23rd of December 1819. He started in life as a lawyer’s clerk. It was his friend, Dr Heldring, pastor at Hemmen, in Gelderland, who discovered in him the poetical gift of which he was conscious, encouraged him to study theology at the university of Utrecht (1838–43). Having completed his studies, Ten Kate became pastor at Middelburg, Amsterdam, and other places, meanwhile developing well-nigh ceaseless activity, both in prose and lyric poetry. Among his prose works may be mentioned the travel papers (Rhome, 1816; Italy, 1857–62), Christelijke Overdenkingen ("Thoughts of a Christian," 1849–52), and other religious studies. His early poetry was in the main original. The best known of his poems were—Ahauerus op de Grimsel ("Ahauerus on the Grimsel," 1849); Zangen de Tijds ("Songs of the Times," 1851); Legenden en Mengelgootje ("Legends and Detached Poems," 1856); In den Bloemhof ("In the Flower Garden," 1851); De Schepping ("The Creation," 1866); De Planeten ("The Planets," 1869); De Jaargeijden ("The Seasons," 1871); De Psalmen ("The Psalms," 1874); De Vrouw in het Nederlandsch Lied ("Woman in Dutch Song," 1883); Palm-takken en Dichtbloemen ("Palm-branches and Flowers of Poetry," 1884). Ten Kate reached the pinnacle of his poetic fame in The Creation, The Planets, and The Seasons. These poems certainly show a masterly grasp of his mother tongue and a wonderful facility of expression, coupled with graceful vigour and fertile fancy. These qualities he also plentifully displayed in the innumerable translations he made of many of the masterpieces of foreign poetry in nearly every European language. He had not only an extraordinary aptitude for learning alien idioms, but also the gift of translating foreign lyrics into clear, fluent and beautiful Dutch verse. Ten Kate’s versatility in this respect has never been equaled; it extended from Tasso and Andersen to Dante, Schiller, Victor Hugo, Milton, Tennyson and Longfellow. Ten Kate died at Amsterdam on the 24th of December 1889.

His complete Poetic Works were published after his death in 12 volumes (Leiden, 1891).

TENNANT, CHARLES (1768–1838), Scottish industrial chemist, was born at Ochiltree, Ayrshire, on the 3rd of May 1768. He started in business as a bleacher at Darnley, and in 1798 took out a patent for a bleach liquor formed by passing chlorine into a mixture of lime and water. This product had the advantage, as compared with the Eau de Javelles, then generally used, that a cheaper base, lime, was substituted for potash in its preparation; but when he attempted to protect his rights against infringement his patent was held invalid on the double ground that the specification was incomplete and that the invention had been anticipated at some bleach-works near Nottingham. In 1799 he patented a more convenient material in bleaching powder or "chloride of lime," formed by the action of chlorine on slaked lime, and for its manufacture founded at Glasgow in 1800 the well-known St Rollox chemical works, now merged in the United Alkali Company. He died at Glasgow on the 1st of October 1838.

His grandson the iron-master, Sir Charles Tennant (1823–1906), was M.P. for Glasgow from 1876 to 1880 and for Peebles and Selkirk from 1880 to 1886; he was created a baronet in 1885.

TENNANT, SMITHSON (1761–1813), English chemist, was born at Selby, Yorkshire, on the 30th of November 1761. He began to study medicine at Edinburgh in 1781, but in a few months moved to Cambridge, where he devoted himself to botany and chemistry. He graduated M.D. at Cambridge in 1790, and about the same time purchased an estate near Cheddar, where he carried out agricultural experiments. He was appointed professor of chemistry at Cambridge in 1813, but lived to deliver only one course of lectures, being killed near Boulougne on the 22nd of February 1815 by the fall of a bridge over which he was riding. He was a man of more promise than performance, and his chief achievement was the discovery of the elements iridium and osmium, which he found in the residues from the solution of platinum ores (1804). He also contributed to the proof of the identity of diamond and charcoal.

TENNANT, WILLIAM (1784–1845), Scottish scholar and poet, was born in the 13th of May 1784 at Anstruther, Fife, Scotland. He was late from childhood. His father sent him to the university of St Andrews, where he remained for two years, and on his return he became clerk to one of his brothers, a corn factor. In his leisure time he mastered Hebrew as well as German and Italian. His study of Italian verse bore fruit in the mock-heroic poem of Anster Fair (1812), which gave an amusing account of the marriage of "Maggie Lauder," the heroine of the popular Scottish ballad. It was written in the ottava rima adopted a few years later by the ingenious brothers Whistlecraft (John Hookham Frere), and turned to such brilliant account by Byron in Don Juan. The poem, unhampered in form, full of fantastic classical allusions applied to the simple story, and brimming over with humour, had an immediate success. Tennant’s brother, meanwhile, had failed in business, and the poet became in 1812 schoolmaster of the parish of Dunino, near St Andrews. From this he was promoted (1816) to the school of Lasswade, near Edinburgh; from that (1819) to a mastership in Dollar academy; from that (1834), by Lord Jeffrey, to the professorship of oriental languages in St Andrews. The Thane of Fife (1822), shows the same humorous imagination as Anster Fair, but the subject was more remote from general interest, and the poem fell flat. He also wrote a poem in the Scottish dialect, Papsy Stormed (1827), two historical dramas, Cardinal Beaton (1832) and John B abol (1825); and a series of Hebrew Dramas (1845), founded on incidents in Bible history. He died at Devon Grove, on the 14th of February 1848.

A Memoir of Tennant by M. F. Connolly was published in 1861.

TENNEMANN, WILHELM GOTTLIEB (1761–1819), German historian of philosophy, was born at Erfurt. Educated at his native town, he became lecturer on the history of philosophy at Jena in 1788. Ten years later he became professor at the same university, where he resided till 1815. His principal work is an encyclopaedic history of philosophy, which he began at Jena and finished at Marburg, where he was professor of philosophy from 1804 till his death. He was one of the numerous German philosophers who accepted the Kantian theory as a revelation.

In 1812 he published a shorter history of philosophy, which was translated into English in 1852 under the title Manual of the History of Philosophy.

TENNANT, SIR JAMES EMERSON, Bart. (1804–1869), English politician and traveller, the third son of William Tennant, a merchant of Belfast, was born there on the 7th of April 1804. He was educated at Trinity College, Dublin, of which he afterwards became LL.D. He took up the cause of Greek independence, and travelled in Greece, publishing a Picture of Greece (1820), Letters from the Aegean (1829), and a History of Modern Greece (1830); and he was called to the English bar at Lincoln’s Inn in 1831. In this year he married the daughter and co-heiress (with her cousin, Robert James Tennent, M.P. for Belfast, 1845–52) of William Tennant, a wealthy merchant at Belfast. He soon left the Bar, and adopted by royal licence the name of his wife in addition to his own. He entered parliament in 1832 as member for Belfast. In 1841 he became secretary to the India Board, and in 1845 he was knighted and appointed colonial secretary of Ceylon, where he remained till 1850. The result of his residence there appeared in Christianity in Ceylon (1850) and Ceylon, Physical, Historical and Topographical (2 vols., 1859). On his return, he became member for Lisburn, and under Lord Derby was secretary to the Poor Law Board in 1852. From 1852 till 1867 he was permanent secretary to the Board of Trade, and on his
retirement he received a baronetcy from Lord Palmerston. In his early years his political views had a Radical tinge, and, although he subsequently joined the Tories, his Conservatism was of a mild type. He withdrew from the Whigs along with Lord Stanley and Sir James Graham, and afterwards adhered to Peel. He died in London on the 6th of March 1869. His family consisted of two daughters and a son, Sir William Emerson Tennent, and baronet (1835-1879), who was an official in the Board of Trade, and at whose death the baronetcy became extinct.

Besides the books above mentioned, Emerson Tennent wrote Belgium in 1840 (1841), and Wines; its Duties and Taxation (1855), and was a contributor to magazines and a frequent correspondent of The Times (H. Ch.).

TENNESSEE, a South Central State of the United States of North America, lying between latitude 35° and latitude 39° 40' N. and between longitude 81° 37' and longitude 90° 28' W. It is bounded on the N. by Kentucky and Virginia along a line which, because of erroneous surveys, varies considerably, east of the Tennessee river, from the intended boundary—the line of latitude 36° 30' N.—the variations all being measured to the north of that parallel; on the E. by North Carolina along the line of the crest of the culminating ridge of the Unaka Mountains till within 26 m. of the Georgia frontier, where it turns due south, giving to Tennessee a triangular piece of territory which extends about 15 m. eastward; on the S. by Georgia, Alabama and Mississippi along the 35th parallel of N. lat.; on the W. by the Mississippi river which separates it from Arkansas and Missouri. The extreme length of the state from E. to W. is 432 m., and the extreme breadth is 109 m. its area being 42,022 sq. m., of which 335 sq. m. is water surface. Amenities —Tennessee is traversed in the east by the Unaka Ridges of the Old Appalachian Mountains and in the Great Appalachian Valley; in the middle by the Cumberland Plateau, the Highland Rim Plateau, and the Nashville Basin of the Appalachian Plateau; and in the west by the Gulf Coastal Plains and a narrow strip of the Mississippi Flood Plain. The maximum elevation of 6636 ft. at Mount Guyot on the North Carolina border, in Sevier county, the surface descends to 117 ft. or less on the Mississippi Flood Plain in the S.W. corner of the state. The general slope, however, is west by north. About 1700 sq. m. are at least 2000 ft. above the sea, but 28,200 sq. m. are less than 1000 ft. above the sea, and the mean elevation of the state is 678 ft. in median terms. In median terms the state has a belt 8 to 10 m. wide along its E. border, are a series of somewhat irregular ridges developed on complexly folded and faulted crystalline rocks. Sixteen peaks exceed 6000 ft. in height. They are Mount Curtis (6012 ft.), Mount Davis (5953 ft.), Mount Morgan (6210 ft.), and Mount Susan (6012 ft.), Mount Curtis (6568 ft.), Mount Safford (6535 ft.), Mount Love (6443 ft.), Mount Henry (6373 ft.), Roan Mountain (6153 ft.), Mount Morgan (6362 ft.), Mount Davis (6130 ft.), Mount Curtis (6012 ft.), Mount Morgan (6088 ft.), Tricorner Mountain (5910 ft.), and Mount Davis (6130 ft.). Thermometer Knob (6157 ft.), Ocoee Mountain (6135 ft.), and Master Knob (6017 ft.). This state is the Appalachian Valley which traverses Tennessee is commonly known as the Valley of East Tennessee. It consists of parallel ridges and valleys developed from erosion on folded sandstones, shales, and limestones, the valley quality predominating because the weak limestones were of great thickness. The valley areas vary in height from 600 ft. in the south-west to 1000 ft. in the north-east. In the north-east the ridges are more numerous and higher than in the south-west, where White Oak Ridge and Taylor's Mountain are among the highest points of the state. The highest mountains in the state are better known, because of their association with battles of the Civil War. Along the north-west border of the valley a steep escarpment, known as the Breakaway, descends into North Carolina. This plateau has a mean elevation of about 2000 ft., is only slightly rolling, and slopes gently toward the north-west. The W. edge of the plateau is much broken by deep indentations of stream valleys, and the elevation of the plateau is about 750 ft. above sea level. The plateau, so named from the scarp formed by its western rim about the Nashville and (farther north) Louisville basin. It is generally level except where it is cut by river valleys. The Nashville Basin, which should be called the basin, lies for the most part 400 to 600 ft. below the Rim; a few hills or ridges, however, rise to the level of the Rim. The Basin is elliptical in form, extending nearly across the state from N.E. to S.W., with an extreme width of about 60 m.; narrower and shallower toward the south-west where the Tennessee river from the north or south-west with a free sweep across the state in a direction nearly parallel with the trend of the mountains. Above these are upper currents from the north or north-west, the Plateau has an alpine or continental type of climate characterized by long severe winters and occasionally to easterly winds. The average velocity of the winds is comparatively low and violent storms are rare. Soil.—The Lowland Basin, the least elevated parts of the Valley of East Tennessee, is the most fertile of the province and the portion of the Highland Rim have a fertile limestone soil. The deep deposit of silt on the Mississippi Flood Plain is even more fertile. There are narrow strips of rich alluvium along many other rivers. The soils on the abrupt way of overlooking the Mississippi Flood Plain. The E. slope, about one-fourth the length of the W. slope, is steep and rocky, and the W. slope is broken by the valleys of numerous streams. There is a slight dip to 2000 ft. at the head of the valley and a very slight curve or gentle valley which is only about 750 ft. above sea level. Each of the state, and is the only large lake in the state. The whole of the Appalachian Province, except the northern portion of the Cumberland Plateau, the Highland Rim, and the Lowland Basin are drained southward and westward by the Mississippi river and its tributaries. The western slope of the East Gulf; it is drained directly into the Mississippi by several small streams. Fauna.—A few black bears inhabit the Unaka Mountain region. Deer are quite numerous in the forests of the east half of the state. The wolf, fox, lynx ("wildcat"), otter, mink and beaver have become rare. Squirrels, rabbits, wood-chucks, skunks, muskrat and opossums are common. Among game-birds there are a few wild turkeys, wild geese, wood-grouse, the bobwhite, and greater numbers of grous and various ducks; among shore birds the tern, loon, and eagle are numerous, and in the fall migration there are white-fronted and red-breasted geese, the commoner fish are perch, pickerel, crappies, pike, drum, buffalo, carp, suckers and eels. Rattlesnakes and moccasins, or cottonmouths, both venomous, are occasionally seen. Flora.—Originally the state was wooded, and still has about one-half of it is still woodland containing a large variety of trees. On the mountains the trees are chiefly pines, firs, spruce and hemlock are common. In the valley, the state, especially on the Mississippi Flood Plain, the cypress is dominant. In the Lowland Basin small groves of what was once an extensive forest of red cedar remain. Poplar and larch are much more abundant in the western than in the eastern portion of the state, and is much more abundant in the eastern than in the western half. But in most parts of the state there are mixed forests of white oak, red oak, ash, red gum, black gum, maple, hickory, chestnut, sycamore, sweet gum, poplar, tamarack, cypress, birch, willow, birch, sassafras, and persimmon. Birch, mulberry, linden, willow, basswood, dogwood, the sorrel tree, pawpaw and wild plum are common. Blue grass is indigenous in the Lowland Basin. Of medicinal herbs the most important is the blackberry (Rubus latifolius). Among indigenous shrubs and vines are the baneberry, blackberry, gooseberry, whortleberry, huckleberry, grape and cranberry. Bird.—Tennessee is noted for its delightful climate. The mean summer temperature ranges according to elevation from 62° F. on the Unaka Mountains to 72° on the Cumberland Plateau, to 70° on the Highland Rim, to 75° in the Lowland Basin, and to 77° in the Lowland Basin. But the mean winter temperature for each of these divisions is about 20°. The annual temperature ranges from 57° in East Tennessee to 59° in Middle Tennessee and 65° in West Tennessee. The altitude being the same, the mean annual temperature on the south border of the state is about 2° higher than that on the north border. Usually the highest temperatures of the year are in July and the lowest in January. In some regions there is no record of a temperature as high as 100°; in others there is none as low as 10°; and the average absolute range is about 90°. However, during a period of fifty-four years (1854-1908) the records show a range of extremes from 30° at Erasmus, Cumberland county, in February 1899, to 107° in several places in July 1901. Rarely there are killing frosts, especially in the southern counties, but even these minor occurrences pass without comment until the middle of October. An average annual precipitation of about 50 in. is quite equally distributed over the state and a little more than 50 in. is well distributed in the following months. The average annual snowfall is about 8 in., and the snowfalls are usually light and melt within a few days. The average number of clear, fair, or only partly cloudy days in a year is about 250. The Midland Basin of Tennessee has a dry land climate from the south or south-west with a free sweep across the state in a direction nearly parallel with the trend of the mountains. Above these are upper currents from the north or north-west. The climate of Tennessee is not regarded as especially healthy for the invalids and invalids of the constitution. The climate is comparatively low and violent storms are rare.
mountains, on the ridges of the Valley of East Tennessee, and on the E. slope of the East Gulf Plains vary greatly according to the rock strata. In the Cumberland Plateau, which constitutes the inner portion of the Highland Rim, and in the W. slope of the East Gulf Plains there is for the most part a light sandy soil, much of it too poor for cultivation.

The area of farms in the state in 1900 was 20,342,058 acres, of which about one-half was classed as "improved." The average size was 90-6 acres, and the average number of acres of improved land per farm was 45-6. Of the total farm acreage 6,435,000 was covered with coal or other mineral deposits, chiefly iron and marble; 620 m. of navigable streams; 14,000 ft. of navigation, classified as the principal navigable streams; 341 of the state, the product in 1908 being 341 short tons of metallic zinc valued at $32,054. Among the other minerals found and mined to a small extent are copper, manganese, barites, fluor spar, slate, granite and petroleum. The total value of all minerals was $19,277,031 in 1908.

Manufactures.—To an unusual degree the natural resources of the state have attracted the rapid development of industries. The establishment of industrial establishments is largely in the hands of individuals, firms, and comparatively small corporations, rather than of large combinations, the average capital per establishment in 1905 being about $3,500. This rapid industrial growth has been due in a small degree to the great natural resources of the state and its excellent transportation facilities. Judged by the value of products, regardless of cost of production, the industrial output of Tennessee in 1905 was $102,438,451, and of products to $137,950,476. Some of the principal products are shown in the table on the next page.

The carefully cultivated land area of the state in 1900 was $2,120,000; the value of the products was $102,438,451, and of products to $137,950,476. The railroad mileage of the state was 6,539,783, they employed 1,486 persons, and the value of their products was $3,428,039. The fountains and machine shops of the state had a capital of $5,695,203. The manufacturer of leather was the chief sub-division of the industry, employing 153,375 spindles, 3008 looms and 1787 knitting machines.

The printing and publishing industry of the state had an invested capital of $8,583,133, and a product valued at $6,895,203. The manufacturer of cotton and other textiles had a capital of $5,639,445. The manufacturer of leather was another important industry. Large tanneries were attracted to the state, soon after the Civil War, by the abundance of tan bark in the forests, and the cheapness of labour. In 1905 $4,013,289 was invested in the manufacture of leather products, and the value of their products was $5,939,783. They employed 1,486 persons, and the value of their products was $3,428,039. The fountains and machine shops of the state had a capital of $5,695,203. The manufacturer of leather was the chief sub-division of the industry, employing 153,375 spindles, 3008 looms and 1787 knitting machines.

The population of Tennessee increased from 1,255 m. in 1860 to 3,184 m. in 1900, and 3,480 on the 1st of January 1909. The principal railways operating in the state in 1910 were the Louisville & Nashville, the Chattanooga, & St Louis, the Cincinnati Southern and the Southern. The navigable waterways include the Mississippi river (which forms the western boundary of the state); the Tennessee river, navigable throughout its length, from Knoxville; and the Cumberland river, navigable throughout its length. The amount of capital invested in manufacturing was $3,220,890, and the value of the product was $2,400,256. Among the other important manufacturing industries of the state and the value of their products in 1905 are: men's clothing, $2,961,811; patent medicines, $2,268,000; oil, $792,000; coke, $424,000; artificial ice, $727,263; agricultural implements, $768,895; and coke, $800,801.

Karajan.—The total population in 1880 was 1,542,359; in 1890, 1,767,518; in 1900, 2,020,616; and in 1910, 2,184,789.1 Of the total population in 1900, 1,522,600 were native whites, 17,746 were foreign-born, 286,243 were negroes, 108 were Indians, 75 were Chinese and 4 were Japanese. Of the inhabitants born in the United States 35,361 were born in Georgia, 56,052 in Kentucky, 26,405 in North Carolina, 27,799 in Alabama, 55,179 in South Carolina, 25,826 in Virginia, 15,369 in Maryland, 31,372 in Pennsylvania and 11,164 were of German, 926 of Irish and 332 of English parentage on both the father's and the mother's side. Of the total population of the state in 1906, 697,570 were members of religious denominations. There

1 The populations in other census years were as follows: (1870), 35,691; (1880), 105,602; (1890), 261,727; (1892), 422,823; (1893), 891,904; (1894), 829,210; (1895), 1,002,717; (1896), 1,109,801; (1897), 1,238,520.
were 277,170 Baptists, 241,306 Methodists, 79,337 Presbyterian, 56,315 Disciples of Christ, 17,525 Roman Catholics, 7,874 Protestant Episcopalians, 3,225 Lutherans, 2,875 United Brethren and 2,426 Congregationalists. From 1890 to 1900 the urban population (i.e. the population of places having 4,000 inhabitants or more) increased from 219,792 to 283,886, or 30.1 per cent., the semi-urban population (i.e. the population of incorporated places, or the approximate equivalent, having less than 4,000 inhabitants) increased from 87,351 to 114,937, or 31.4 per cent., and the rural population (i.e. population outside of incorporated places) increased from 1,460,375 to 1,619,803, 63 per cent. of the total.

The principal cities of the state, with population for 1910, are Memphis, 131,105; Nashville, 110,364; Chattanooga, 44,604 and Knoxville, 36,346.

Government.—Tennessee has had three constitutions, but the present one, adopted in 1870, is a reproduction of the second (1834) with only a few changes. Amendments may be proposed not oftener than once in six years by a majority of the members elected to each house of the legislature, but before they can be adopted they must be agreed to first by two-thirds of the members elected to each house of the next succeeding legislature, and later by a majority of all the citizens of the state voting for representatives at the next regular election. The legislature may, also, submit to the people the question of calling a convention to amend or revise the constitution, and such a convention must be called whenever, upon the submission of this proposition, a majority of the votes cast in favour of it. Every attempt to amend or revise the present constitution has, however, been unsuccessful. The right of suffrage is given to every male citizen of the United States who has attained the age of twenty-one years and has been a resident of the state for one year, provided he has paid his poll tax and has not been convicted of bribery, larceny or other infamous crime. The election of the governor, members of the General Assembly and congressmen is held biennially, even numbered years, on the first Tuesday after the first Monday in November, but the election of judicial and county officers is held on the first Thursday in August.

The governor is the only state executive officer who is elected by the people. He is elected for a term of two years and is not eligible for more than three consecutive terms. He must be at least thirty years of age and have been a citizen of the state for the last seven years. If the president or other chief of the executive branch, or any member of the state military forces, he may call the militia into service only when there is a rebellion or invasion, and the General Assembly declares that the public safety requires it. The officers of the penitentiary and of the reformatories for boys are appointed by the governor with the advice and consent of the Senate, or an application for the pardon of an inmate of their institution, but he is not bound by their advice and there is no real restriction on his power to pardon. If the governor is impeached for bribery, larceny or other infamous crime. The governor may veto bills passed by the General Assembly, but to override his veto the vote of only a bare majority of the members elected to each house is required. His salary is $4000 a year. There is no lieutenant-governor; in case of a vacancy in the office of governor the speaker of the Senate becomes acting governor. The secretary of state, the comptroller, and the treasurer are elected by the people for a term of six years, and the secretary of state is president of the Senate. Each officer serves for a term of two years; the attorney-general is appointed by the judges of the supreme court for a term of eight years.

Both senators and representatives are elected for a term of two years, by counties or by districts having approximately the same population. The number of representatives is limited by the constitution to 99, and the number of senators to one-third the number of counties. The Legislature supplies $300 each for a term of two years; the attorney-general is appointed by the judges of the supreme court for a term of eight years.

The Legislature supplies $300 each for a term of two years; the attorney-general is appointed by the judges of the supreme court for a term of eight years.

The supreme court consists of five judges elected by joint ballot by the legislature for a term of six years, and may be removed from office by the votes of two-thirds of the members of each of the three grand divisions (eastern, middle and western) and two votes of the electorate of the state or make the state "owner in whole or in part of any bank or a stockholder with others in any association, company, corporation or municipality."

The administration of justice is vested in a supreme court, a court of appeals, chancery courts, circuit court, and justices of the peace. The supreme court consists of five judges elected by joint ballot by the legislature for a term of six years, and may be removed from office by the votes of two-thirds of the members of each of the three grand divisions (eastern, middle and western) and two votes of the electorate of the state or make the state "owner in whole or in part of any bank or a stockholder with others in any association, company, corporation or municipality."

The administration of justice is vested in a supreme court, a court of appeals, chancery courts, circuit court, and justices of the peace. The supreme court consists of five judges elected by joint ballot by the legislature for a term of six years, and may be removed from office by the votes of two-thirds of the members of each of the three grand divisions (eastern, middle and western) and two votes of the electorate of the state or make the state "owner in whole or in part of any bank or a stockholder with others in any association, company, corporation or municipality."
of a county which contains the county seat there are two constables, and in other civil districts of the county one constable elected for a term of two years. The general law for the incorporation of cities and towns vests the government in a corporation consisting of a mayor and two aldermen, and provides that the property of the city shall be exempt from the state and county tax except in the case of a failure of a court to appoint a commission for the sale of the property of the city. A mayor and a board of aldermen are elected for a term of two years by the qualified voters. The election of the aldermen, and to override his veto a two-thirds majority is required.

Miscellaneous Laws.—For the protection of the property rights of married persons, the law provides that the property of the estate shall be exempt from her husband's debts; that the proceeds of her real or personal property shall not be paid to any other person except after the death of the surviving spouse; and that she may be appointed a trustee of her own estate or a part of her estate, and treasurer as ex officio, members, and seven other members, a portion retiring every two years, and their successors being appointed by the county court. The act for establishing the Tennessee Reformatory for Boys provides that the institution shall be governed by a board of trustees consisting of the governor and five other members, one retiring each year; that boys under eighteen years special leave to be convicted of a penitentiary offence shall be sent to it; that the trustees may transfer incorrigible boys to the penitentiary, put others out in the service of citizens on probation, or recommend them to the governor for pardon. A general control of all public charities and correctional institutions is exercised by an unincorporated Board of State Charities consisting of the governor and six members appointed by him with the advice and consent of the Senate. The principal duties of this board are to examine the condition and the management of such institutions and report to the governor and county and city authorities and submit to it for criticism all philanthropic enterprises. Education.—For the administration of the common school system each county having five or more civil districts is divided into five school districts, each having five or more civil districts. In each school district constitutes the board of education, in counties having less than five school districts one or more districts can be united by the county court for this purpose. The school district elects one member of the county board of education, and in counties having less than five school districts one or more districts may be united for this purpose. The salary of the superintendent is $750 per year, and to five, besides the county superintendent who is ex officio its secretary, are elected by the county at large, and to this county board of education together with the district advisory boards is entrusted the administration of the common school funds. A special education law enacted in 1909, 25 per cent. of the gross state revenue is paid into the general education fund, 61 per cent. of this fund is apportioned among the several counties according to their school population, 10 per cent. is apportioned among all school districts in counties with less than five schools, and 24 per cent. is apportioned among eligible counties in proportion to their school population but in inverse ratio to the taxable property; to have the use of any portion of this special fund a county must levy for the maintenance of common schools a tax not less than forty cents on each $100 of taxable property, a tax of $2 on each taxable poll, and such privilege taxes as the state permits it to levy for school purposes not to exceed 25 cents on a $100 of taxable property. The establishment of high schools to be maintained in part by additional county taxes and miscellaneous funds, and 8 per cent. of the state school fund is set apart for the encouragement of counties in this matter. In 1910 the legislature created eight Negro normal schools and 10190 in each of 50 counties. The high schools are largely under the control of the state board of education, consisting of the governor and five other members appointed by the governor, and six other members appointed by the governor and five other members appointed by the governor and six members appointed by the governor. When the general education law was enacted in 1909 Tennessee had no state normal schools, but by the law 13 per cent. of the state educational fund is set apart for the establishment and maintenance of schools solely for the education and professional training of teachers for the elementary schools; one for white teachers in each of three grand divisions of the state, and one agricultural and industrial normal school for the industrial education of negroes and for preparing negro teachers for the common schools, and the management of these schools is vested in the state board of education. The state university for normal instruction which embraces a college of liberal arts, a graduate department, a college of engineering, a college of agriculture, a school of pharmacy, an industrial department, and a law department at Knoxville, and the Agricultural and Mechanical College at Nashville and the State Normal School at Maryville is governed by a board of trustees consisting of the governor, the state superintendent of public instruction, the commissioner of agriculture, the president of the university and twelve other trustees. Each county has a board of education, consisting of the mayor of the county and nine other members, elected for a term of four years. The high school is governed by a board of nine members, elected at large. The Peabody College for Teachers, at Nashville, founded (1857) and maintained chiefly with proceeds of the George Peabody Fund for the improvement of education in the South. Other institutions of learning include the State Normal School, which is governed by the Board of Education (non-sect., 1828); the Agricultural and Mechanical College of the University of Tennessee (non-sect., 1875); Washington and Lee University (non-sect., 1871); the Peabody College at Nashville; Maryville College (non-sect., 1819); Maryville; Cumberland University (Presbyterian, 1842); at Lebanon; Burritt College (non-sect., 1849), at Spencer;
TENNESSEE

623

Hiwassee College (non-sect., 1849), at Sweetwater; Bethel College (Presbyterian), Knoxville; and Tennessee College (Baptist, 1851), at Jefferson City; Walden University (Methodist, 1866), at Nashville; Fisk University (Congregational, 1866), at Nashville; University of Chattanooga (Methodist, 1867), at Chattanooga; University of the South (Episcopal Episcopal, 1866), at Sewanee; King College (Presbyterian, 1869), at Bristol; Christian Brothers College (Roman Catholic, 1871), at Memphis; Knoxville College (United Presbyterian, 1873), at Knoxville; (Chattanooga, 1882), at Milligan; South-western Presbyterian College (1889), at Clarksville; and Lincoln Memorial University (non-sect., 1895), at Cumberland Gap.

The state revenue is derived from a general property tax, a poll tax, an income tax, a tax on transfers of realty, an ad valorem tax on the average capital invested by merchants in their business, a privilege tax on merchants and many other occupations and professions, a tax on licenses to practice various professions, and a collateral inheritance tax, and fines and forfeitures. State, county and municipal taxes are assessed by a county assessor, who is elected for a term of four years, and one or more deputies whom the assessor is authorized to appoint. The law requires that all property shall be assessed at its full cash value, but personal property to the value of $1000 is exempt from taxation. Real estate is assessed biennially; personal property, privileges and polls annually. Assessments are examined and revised both by a county board of equalization and a state board of equalization. The county board consists of five members elected annually by the county court, and there is one member on the board for each corporation, and as are also all persons who have served on it within five years. The state board consists of the secretary of state, treasurer and comptroller. The clerk of the county court, the chief clerk of the offices of the state, the assessors of property and corporations subject to a privilege tax; the county treasurer the taxes of other persons. Three revenue commissioners, one of whom is an expert accountant, are elected biennially by the county court, and two books are kept for the assessment and collection of the taxes, and three state revenue agents are appointed biennially by the comptroller to examine the records of all officials charged with the collection or disbursement of state or county revenue. The state revenue for the two years ending the 19th of December 1806 amounted to $3,804,740, and the cost of conducting the state government for these two years was $3,588,977. The bonded debt of the state grew from $1,943,666 on the 1st of October 1839 to $35,069,666 on the 1st of October 1869, but by the 19th of December 1860 it had been reduced to $14,236,766.

History.—The present site of Memphis may be the point where the Spanish explorer, Hernando de Soto, reached the Mississippi river, but this cannot be determined with certainty. Father Marquette in his voyage down the Mississippi camped upon the western border, and La Salle built Fort Prud’homme upon the Chickasaw Bluffs, probably on the site of Memphis, in 1682, but it was abandoned, then rebuilt, and again abandoned. The territory was included in the English grant to Sir Walter Raleigh in 1584 and in the later Stuart grants, including that of Carolina, in 1663. No permanent settlement, however, was made until 1769, though wandering explorers and fur traders were long before in the region. The first permanent settlers were Virginians led by Dr Thomas Walker (1715-1794), in 1750 reached and named the Cumberland river and mountains in honour of the royal duke. In 1756 or 1757, Fort Loudon, named in honour of John Campbell, earl of Loudon, was built upon the Little Tennessee river, about 30 m. N. of the present site of Knoxville, as an outpost against the French, who were now active in the whole Mississippi Valley, and was garrisoned by royal troops. The fort was captured, however, by the Cherokee Indians in 1760, and both the garrison and the neighbouring settlements were destroyed.

Eastern Tennessee was recognized as a common hunting ground by the Cherokees, Creeks, Miamis and other Indian tribes, and the Iroquois of New York also claimed a considerable portion by right of conquest. In 1768 the Iroquois ceded whatever claim they had to the English, and in 1769 several cabins were built along the Watauga and Holston rivers upon what was thought to be Virginian soil. A settlement near the present Rogersville was made in 1771 and in the next year another sprang up on the Nolichucky. After the failure of the Regulator insurrection in North Carolina in 1771, hundreds of the Regulators made their way into the wilderness. When the season for planting was past, the settlers would go to the homes of their relatives and friends, that colony made no effort to assert jurisdiction or to protect the settlers from Indian depredations. Therefore in 1772 the residents of the first two settlements met in general convention to establish a form of government since known as the Watauga Association. A general committee of thirteen was elected to exercise legislative powers. This committee elected from its members a committee of five in whom executive and judicial powers were lodged. The smaller committee elected a chairman, who was also chairman of the committee of thirteen. A sheriff, an attorney and a clerk were elected, and regulations for recording deeds and wills were made. Courts were held, but any conflict of jurisdiction with Virginia or North Carolina was avoided. In 1775 the settlement on the Nolichucky was forced to join the association, and in the same year the land was bought from the Indians in the hope of averting war. With the approach of the War of Independence, the dream of becoming a separate colony with a royal governor was abandoned, and an petition of the inhabitants the territory was annexed to North Carolina in 1776 as the Washington District, which in 1777 became Washington county, with the Mississippi river as the western boundary. The population increased rapidly and soon several new counties were created.

During the War of Independence the hardy mountaineers under John Sevier and Evan Shelby did valiant service against both the royal troops and the Loyalists in South Carolina, chiefly as partisan rangers under Charles McDowell (1743-1813). Major Patrick Ferguson with several hundred Loyalists and a small body of regulars made a demonstration against the western settlements, but at King’s Mountain in South Carolina he was completely defeated by the Americans, among whom Colonel Sevier and the troops led by him were conspicuous (see KING'S MOUNTAIN).

After the War of Independence the legislature of North Carolina in 1784, offered to cede her western territory to the general government, provided the cession should be accepted within two years. The Watauga settlers, indignant at this transfer without their consent, and fearing to be left without any form of government whatever, called a convention which met at Elizabethton in the year 1784, and by which delegates to another convention to form a new state were appointed. Meanwhile North Carolina repealed the act of cession and created the western counties into a new judicial district. A second convention, in November, broke up in confusion without accomplishing anything; but a third adopted a constitution, which was submitted to the people, and ordered the election of a legislature. This body met early in 1785, elected Sevier governor of the new state of Franklin (at first Frankland), filled a number of offices, and passed several other acts looking to separate existence. Four new counties were created, and taxes were levied. In the autumn George Washington called another convention, to which the proposed constitution had been referred, adopted instead the constitution of North Carolina with a few trifling changes, and William Cocke was chosen to present to Congress a memorial requesting recognition as a state. Congress, however, ignored the request, and the diplomacy of the North Carolina authorities caused a reaction. For a time two sets of officials claimed recognition, but when the North Carolina legislature a second time passed an act of oblivion and remitted the taxes unpaid since 1784, the tide was turned. No successor to Sevier was elected, and he was arrested on a charge of treason, but was allowed to escape, and soon afterwards was again appointed brigadier-general of militia.

Meanwhile, settlers had pushed on further into the wilderness. On the 17th of March 1775 Colonel Richard Henderson and his associates extinguished the Indian title to an immense tract of land in the valleys of the Cumberland, the Kentucky and the Ohio rivers (see KENTUCKY). In 1778, James Robertson (1742-1814), a native of Virginia, who had been prominent in the Watauga settlement, set out with a small party to prepare the way for permanent occupation. He arrived at French
agreements were soon repealed, the general policy was continued, and in 1861 more than $17,000,000 of the state debt was due to these subscriptions, from which there was little return.

Though President Andrew Jackson was for many years practically a dictator in Tennessee politics, his arbitrary methods and his intolerance of any sort of independence on the part of his followers led to a revolt in 1836, when the electoral vote of the state was given to Hugh Lawson White, then United States senator from Tennessee, who had been one of Jackson's most devoted adherents. White's followers called themselves Anti-Van Buren Democrats, but the proscription which they suffered drove most of them into the Whig party, which carried the state in presidential elections until 1856, when the vote was cast for James Buchanan, the Democratic candidate. The Whig party was so strong that James K. Polk (Democrat), a resident of the state, lost its electoral vote in 1844. With the disintegration of the Whig party, the state again became nominally Democratic, though Union sentiment was strong, particularly in East Tennessee. There were few large plantations and fewer slaves in that mountainous region, while the middle and western sections were more in harmony with the sentiment in Mississippi and Alabama. In 1850 representatives of nine Southern states met in a convention at Nashville (q.v.) to consider the questions at issue between the North and the South. The vote of the state was given for Bell and Everett in 1856, and the people as a whole were opposed to secession.

The proposition to call a convention to vote on the question of secession was introduced in the first session of the 9th of February 1861, but after President Lincoln's call for troops the legislature submitted the question of secession directly to the people, and meanwhile, on the 7th of May 1861, entered into a "Military League" with the Confederacy. An overwhelming vote was cast on the 8th of June in favour of secession, and on the 24th Governor I. G. Harris (1818-1897) issued a proclamation declaring Tennessee out of the Union. Andrew Johnson, then a United States senator from Tennessee, refused to resign his seat, and was supported by a large element in East Tennessee. A Union convention, including representatives from all the western and a few of the middle counties, met on the 17th of June 1861 and petitioned Congress to be admitted as a separate state. The request was ignored, but the section was strongly Unionist in sentiment during the war, and has since been strongly Republican.

The state was, next to Virginia, the chief battleground during the Civil War, and one historian has counted 454 battles and skirmishes which took place within its borders. In February 1862, General U.S. Grant and Commodore A. H. Foote captured Fort Henry on the Tennessee river, and Fort Donelson on the Cumberland. The capture of these forts on the 6th and 7th of February was largely owing to the influence of President Lincoln. General D. C. Buell occupied Nashville. Grant next ascended the Tennessee river to Pittsburg Landing with the intention of capturing the Memphis & Charleston railway, and on the 6th-7th of April defeated the Confederates in the battle of Shiloh. The capture of Island No. 10 in the Mississippi on the 7th of April opened the river as far south as Memphis, which was captured in June. On the 31st of December and the 2nd of January General William S. Rosecrans (Federal) fought with General Braxton Bragg (Confederate) the bloody but indecisive battle of Stone River (Murfreesboro). In June 1863 Rosecrans forced Bragg to evacuate Chattanooga, Bragg, however, turned upon his pursuer, and on the 19th and 20th of September one of the bloodiest battles of the war was fought at Chickamauga. General Grant now assumed command, and on the 24th and 25th of November defeated Bragg at Chattanooga, thus opening the way into East Tennessee. There General A. E. Burnside at first met with success, but was shut up in Knoxville by General James Longstreet, who was not able, however, to capture the city, and on the approach of General W. T. Sherman retired into Virginia. Almost the whole state was now held by Federal troops, and no considerable military movements occurred until after the fall of Atlanta in September 1864. Then General J. B. Hood moved into Tennessee, expecting Sherman
to follow him. Sherman, however, sent reinforcements to Thomas and continued his march to the sea. Hood fought with General John M. Schofield at Franklin, and on the 15th-16th of December was utterly defeated by Thomas at Nashville, the Federals thus securing virtually undisputed control of the state.

After the occupation of the state by the Federal armies in 1862 Andrew Johnson was appointed military governor by the president (confirmed March 3, 1862), and held the office until inaugurated vice-president on the 4th of March 1865. Republican electors attempted to cast the vote of the state in 1864, but were not recognized by Congress. Tennessee was the first of the Confederate states to be readmitted to the Union (July 24, 1866), after ratifying the Constitution of the United States with amendments, declaring the ordinances of secession void, voting to abolish slavery, and declaring the war debt void. The state escaped "carpet bag" government, but the native whites in control under the leadership of William G. Brownlow (1805-1877) confined the franchise to those who had always been uncompromisingly Union in sentiment and conferred suffrage upon the negroes (February 25, 1867). The Ku Klux Klan, originating in 1865 as a youthful prank at Pulaski, Tennessee, spread over the state and the entire South, and in 1869 nine counties in the middle and western sections were placed under martial law. At the elections in 1869 the Republican party split into two factions. The conservative candidate was elected by the aid of the Democrats, who also secured a majority of the legislature, which has never been lost since that time. The constitution was revised in 1870. For a considerable time after the war the state seemed to make little material progress, but since 1880 it has made rapid strides. The principal occurrences have been the final compounding of the old state debt at fifty cents on the dollar in 1882, the rapid growth of cities, and the increased importance of mining and manufacturing.

1 The state furnished 115,000 soldiers to the Confederate and 31,000 to the Union Army.
2 The Constitutions of 1776, 1834 and 1879 all provided that the governor shall not serve more than six years in succession.
3 Resigned.
4 Formed to leave capital by invasion of Federal troops.
5 Andrew Johnson, the governor, was inaugurated as Vice-President, March 4, 1865, thereby vacating the office.

Malcolm R. Patterson, 1911-1917
B. W. Hooper, Republican

There is no satisfactory complete history of the state. The best is James Phelan's History of Tennessee (Boston, 1888). For the early period see John Haywood, Civil and Political History (Knoxville, 1843, reprinted Nashville, 1891); J. G. M. Ramsey, Annals (Charleston, 1853); A. W. Putnam, History of Middle Tennessee, or Life and Times of General James Robertson (Nashville, 1889); Theodore Roosevelt, Winning of the West (New York, 1889-1896); John Carr, Early Times of Middle Tennessee (Nashville, 1857). For the middle period see O. P. Temple, East Tennessee in the Civil War (Cincinnati, 1896); James W. Fertig, Secession and Reconstruction of Tennessee (Chicago, 1868); and the Report of Joint-Committee on Reconstruction (U.S. Pub. Docs., Wash., 1866).

TENNESSEE RIVER, the largest tributary of the Ohio river, U.S.A. It is formed by the confluence of the Holston and the French Broad rivers 45 miles above Knoxville, Tennessee, and flows S.S.W. to Chattanooga, through which turns W. through the Cumberland Plateau and into the N.E. corner of Alabama, continues W. across the northern part of Alabama, turns N. on the boundary between Alabama and Mississippi, and continuing N. across Tennessee and Kentucky unites with the Ohio at Paducah. Its principal tributaries rise in the Appalachian Mountains: the Holston and the Clinch on the mountain slopes that flank the Appalachian Valley in western Virginia; and the French Broad, the Little Tennessee, and the Hiwassee in the mountains of western North Carolina. The Tennessee itself is 654 m. long, and, with the Holston and the North Fork of the Holston forms a channel about 900 m. long. Its drainage basin covers about 44,000 sq. m., and its low water discharge at Paducah is 10,000 cu. ft. per second. Its average fall is 0-79 ft. per mile; 0-956 ft. from Knoxville to Chattanooga; 1-19 ft. from Chattanooga to Florence, Alabama; and 0-39 ft. from Florence to its mouth. The banks are everywhere easily accessible except at Knoxville and Chattanooga, where, for short distances, high elevations rise precipitously from the water; and as the banks are mostly of clay or rock the channel is permanent and the river is unusually free from silt.

The Tennessee is navigable by steamboats throughout its entire course of 652 m. for several months of the year; its tributaries have a nearly equal navigable mileage, and the main river and its tributaries together have a navigable mileage for rafts and flat-boats of 2400 m. At low water there are three obstructions to steamboat navigation in the main stream: the Colbert and Bee Tree shoals, just below Florence; the Muscle shoals just above Florence; and Hales Bar, 33 m. below Chattanooga. The state of Alabama aided by the Federal government, constructed a lock canal affording a depth of 5 ft., around the Muscle shoals in 1831-1836, but because of the obstructions above and below the canal was little used and was soon abandoned. The Federal government, beginning in 1868, completed the reconstruction of the Muscle Shoals Canal in two divisions (one 3-5 m. long with two locks, the other 14-5 m. long with nine locks, and both providing a depth of 5 ft.) in 1890, began in 1893 the construction of a canal, about 8 m. long, with one lock around Colbert and Bee Tree shoal, and in 1904 authorized the construction with private capital of a lock and dam at Hales Bar to provide a channel 6 ft. deep at low water between it and Chattanooga; the water power to be used by the contractors furnishing the capital. In the fall of 1896 the United States Senate recommended that future improvements of the river be made with a view of obtaining ultimately a channel having a minimum depth of 8 ft. at low water, and for the appropriate amount for a project for extending to 5 ft. at low water the channel (145 m. long) between Hales Bar and the Muscle Shoals Canal. In 1908 the commerce carried on the Tennessee between

6 Resigned to enter the U.S. Senate.
Chattanooga and Paducah amounted to 755,010 tons, valued at $18,752,180; it consisted chiefly of general merchandise, farm products, forest products and iron ore in the upper section, of general merchandise, coal, timber products in the middle section, and of general merchandise, farm products and timber products in the lower section.

During the Civil War Fort Henry was erected by the Confederates on the Tennessee river, in Tennessee just below the Kentucky state line, and on the 6th of February 1862 was captured by Com. A. H. Foote; Fort Donelson on the Cumberland, several miles east, was seized by Com. Gideon Pillow and held by General Donelson, Grant, and the two rivers were thus opened for the advance of the Federals far into Confederate territory.

TENNIEL, SIR JOHN (1820-75), English humorous and satirical artist—specially identified with Punch—was born in London in 1820. He educated himself for his career, and although he became a probationer, and then a student, of the Royal Academy, he soon left the schools, where at that time there was little teaching. In 1836 he sent his first picture to the exhibition of the Society of British Artists, and in 1845 contributed a 16-ft. cartoon, "An Allegory of Justice," to the competition, held in that year, of designs for the mural decoration of the new Palace of Westminster. For this he received a £200 premium and a commission to paint a fresco in the Upper Waiting Hall (or "Hall of Poets") in the House of Lords. In spite of his tendency towards "high art," he was already known and appreciated as a humorist, and his early companionship with Charles Keene fostered and developed his talent for scholarly caricature. At Christmas time 1850 he was invited by John Leech to contribute to the magazine, on which he was to work under the pen-name "Tenniel," in *The Comic Almanac* of 1851. For this he drew a picture of "Dropping the Pilot," which appeared in *Punch* on 20th March 1850, xcviii. 150-51. Public exhibitions of Sir John Tenniel's work were given for the first time and an edition of *Alice in Wonderland* was published. He was also the author of one of the mosaics, "Leonardo da Vinci," in the South Court in the Victoria and Albert Museum; while his highly stippled water-colour drawings appeared from time to time in the exhibitions of the Royal Institute of Painters in Water Colours, of which society he was elected a member in 1874. As an illustrator on the wood-block he stands very high; his "Lalla Rookh" is perhaps the finest of all his work in point of conception, rendering, lineower and technical excellence.

**WORKS ILLUSTRATED.—** (1) *Juvenile Verse and Picture Book,* (1846); (2) *Undine* (1848); (3) *Aesop's Fables, 100 drawings* (1848); (4) "The Great Man's Receipt Book* (1848); (5) *Quaint Illustrations of Knave* (1848); (6) *The Silver Cord* (1861); (7) Moore's *Lalla Rookh,* 69 drawings (1861); (8) Lewis Carroll's *Alice's Adventures in Wonderland* (1866); (9) *The Mirror of Life,* 1867; (10) *Carroll's Through the Looking Glass* (1891); (11) *Punch* (1840-68); (12) *Poe's Poems* (1847); (13) *Home Affections* (1858); (14) *Cholmondeley Pennell's Punch on Pegasus* (1863); (15) *The Arabian Nights* (1853); (16) *English Sacred Poetry* (1856); (17) *Legends and Lyrics* (1865); (18) *Tupper's Provincial Philosophy* (1859); (19) *Barry Cornwall's Poems,* and other books. He also contributed to *Once a Week,* the Art Union publications, &c.

**TENNIS** (sometimes called royal tennis, and, in America, court tennis), one of the oldest of ball-games, and one of the most difficult to learn. It is now played in a walled and roofed court 110 ft. by 38 ft. 8 in., the floor, however, measured 76 ft. by 32 ft. 8 in., the difference being the width of a roofed corridor, the "penthouse," which runs along the two end walls and one of the side walls. Across the middle of the court a net is stretched, and the first object of the game is to strike the ball over this with a bat or racquet. The net is 3 ft. high at the ends, 3 ft. 6 in. at the middle, and divides the floor into two equal parts, the "service" side and the "hazard" side. The floor and walls are made of cement and should be smooth but not polished.

The court is lighted from the roof and sides. The height of the court to the tie-beam is 30 ft., the height of the play-line, above the floor, is 21 ft. 8 in., and the tie-beam is at the bottom of the roof. The roof of the penthouse, which is made of wood, slopes downwards towards the court, the lower edge being 7 ft. 14 in. from the floor, the upper 10 ft. 7 in., the width 7 ft. The illustrations show that one of the walls has its own peculiarities. The "caddies" is an opening in the end wall on the service side, under the penthouse, where provision is made for spectators, who are protected by a net. It is 2 ft. 3 in. in width; at a lower edge is 6 ft. 10 in. from the floor, the lower edge 3 ft. 3 in. The opening of the caddies is 4 ft. 6 in. from the main wall, 5 ft. 6 in. from the other side wall. Looking from the caddies (i.e. from the service side), the right-hand or main side wall has a peculiar peculiarity, which the wall is built inward, reducing the breadth of that part of the court to 30 ft. 2 in. In the right-hand corner of the hazard side end wall (as viewed from the caddies) is the "grille," an opening lined with wood, 3 ft. 1 in. square; and on this wall is painted a continuation of the "pass-line." The left-hand wall, along which runs the pent-house, is not continuous, being broken by a long opening between the floor and the pent-house similar to the door described, but on the right hand side of the opening the danger is the "battery." There is no wall in front of the "marker's box," through which the court is entered and from which all through of the net-post. This long opening in the left-hand wall is divided into two, and "doors," the latter situated where the entrances to the court used to be in early times. The measurements in order from the caddies are as follows, the numbers being the feet and inches: length of the court on the middle of the roof 90 ft. 6 in.; second gallery 9 ft. 6 in.; door 3 ft. 6 in.; first gallery, 5 ft. 8 in.; marker's box or line-opening, 7 ft. 10 in.; hazard side—first gallery, 5 ft. 8 in.; door, 3 ft. 6 in.; second gallery, 9 ft. 6 in.
From the Hazard Side. Tennis-court at Crabbett Park, Sussex, in place, and are covered with white Melton cloth. The American balls, made of layers of cotton and cloth alternately, are somewhat lighter and slower than the English. A set of balls consists of six or seven dozen; the same set should not be used twice in a day. The racquet is usually about 27 in. long and weighs about 16 oz. The head is about 9 in. long and 6 in. broad, but there are no restrictions as to size or weight. The head is somewhat pear-shaped; its centre line does not correspond with the centre-line of the handle, as it is curved upwards to facilitate the stroke when the ball is taken close to the floor. The earliest racquets were strung diagonally, i.e. in diamonds; later the present vertical-horizontal stringing was adopted, then followed knotting at the points of intersection, but now the knotting has disappeared. The name racquet (or racket) appears in French as raquette and in Italian as racchetta. It is variously derived from Latin reticulata (netted), Dutch rackets (to stretch), later Latin raku (palm of the hand or wrist) or the Arabic rahkat (palm of the hand); in favour of the two last derivations is the fact that tennis is a development of a game originally played with the hand, protected by a leather glove, and later on strings were stretched violin-fashion across the palm, to give more power to the stroke. Then followed a wooden bat (battoir), and then a short-handled racquet, either strung or covered with parchment, and finally the modern implement.

Technical Terms.—Some of these have already been explained, but the following may be added. "Bisque": the privilege, given as a form of odds, of scoring a stroke during any part of the game, except after the delivery of "service" or after a fault. "Hey-up"; to hit the ball on to the side wall first. "Cut"; to strike the ball with the head of the racquet held at an angle to the ball's course instead of meeting it with the full face, thus causing backward rotation of the ball (similar to the "screw" in billiards), which alters its natural rebound from the wall. "Twist"; analogous to "cut," but the strings are drawn across the ball at the moment of impact, so as to make it rotate sideways. A ball so struck with a fore-hand stroke twists towards the other player off the floor, and away from him if it is allowed to strike the end wall; the reverse being the effect of twist from a back-hand stroke. "Rest"; a series of strokes between the two players. "Service"; the first stroke of a "rest." The server may serve from any part of the court on the service side. The ball must strike the roof of the side penthouse, and fall within the service-court. "Fault"; a ball so served that it either does not touch the side penthouse or falls outside the service-court. "Pass"; a service in which the ball drops beyond the pass-line; the service in this case does not count, but a "pass" does not annul a previous fault, as was once the case. "Force"; to strike the ball hard; a hard-hit stroke. "Volley"; to strike a ball in its flight (à la volée) before it has touched the floor. "Half-volley"; to strike a ball immediately after it touches, and before it rises from the floor. "Nick"; the angle where the floor and walls meet. "Marker"; the attendant who marks and calls the chases and other points scored in the game. Scoring and Handicapping.—A match consists of three or five "sets"; a "set" of eleven games. The winner of six games wins the set. If a player wins six games consecutively he wins a "love set," even though his opponent may have won several games. The loser of a love set, by an old custom, gives the marker a shilling. Should the score be called "Five games all," the players may arrange to play a "vantage game," the set in that case not being won till one or other has won two games in succession. A game consists ordinarily of four winning strokes, called by the marker as "Fifteen," "Thirty," "Forty," "Game"; if the score is "forty-all," the marker calls "Deuce," and two strokes have to be won in succession by one of the players. When one has won a stroke his score is called "Vantage"; if he wins the next, he wins the game; if he loses it, the score reverts to deuce. The score of the player who won the last stroke or made the last chase is called first. In handicapping the usual odds are (1) bisques, which may also be given in addition to other odds, or to balance odds received; (2) half-fifteen, or one point to be taken at the beginning of the second and every alternate game; (3) fifteen, or one point in every game; (4) half-thirty, or one point in every odd game and two points in every even game; (5) thirty, or two points in every game; (6) half-forty, or two points in every odd game and three in every even game; (7) forty, or three points in every game. Other handicaps are:—Round services, the giver of odds having to serve so that the ball hits both the side and end penthouse; "half the court," the giver of the odds confining his strokes, except service, to one side of the court as divided by the half-court line, a stroke played into the other half counting to his adversary; "touch no walls," the giver of odds confining his play except service to the floor; "bar the openings," the giver of odds losing a point if his ball goes into a gallery or into the dedans or grille; "bar winning openings," which are closed to the giver of odds, who loses a point if the ball enters them; "side walls," the giver of odds losing a point if he plays the ball on to any side wall, the end penthouses being open to him, and the dedans and grille. In these "cramped" odds the rules do not apply if the ball goes out of limits after the second bound.

The Game and Hints on Play.—The players decide who shall serve by spinning a racquet on its head. One spins and the other calls "rough" or "smooth," the "rough" side of the head of the racquet showing the knots of some of the lower
strings. The winner takes the service side, service being an advantage. He serves from any part of the court, and in any way he thinks best, and the ball must go over the net, strike the side penthouse, and fall into the service-court (see "Fault" and "Pass"). His opponent ("striker-out") tries to return the ball over the net before it has touched the ground a second time; he may volley or half-volley it. For a stroke to be "good" it must be made before the second bound of the ball, and the ball must go over the net (even if it touches it), and must not strike the wall above the play-line, nor touch the roof or rafters. The first point to be attained is to be sure of getting the ball over the net, the next to do so in such a way as to defeat the opposing player's attempt to make a "good" stroke in return.

It often happens that a player, either intentionally or from inability, does not take or touch a ball returned to him over the net. In this event, chiefly on the service side, a "chase" (in Italian accia, in French chasse) is made, the goodness or the badness of which depends upon the spot on the floor which the ball touches next after its first bound. The nearer this spot is to the end wall the better the chase. The chase lines are numbered, being one yard apart, the shorter lines representing the half-distance. The chases are noted and called by the man in charge of a ball. If a ball falls on the chase line, he would call "chase four"; if between 4 and 3, he would call "Better than four"; if it fell nearer to 4 than the short line, and "Worse than three" if it fell on the short line or between the short line and 3; for if the ball fell on a line the striker is credited with the better stroke. Strokes into the galleries and doors, with the exception of the winning gallery (last gallery, hazard side) count as chases. The making, or, in technical language, the "laying down" of a chase does not immediately affect the score: it has to be won first, i.e., the other player tries to make a return within this line. To make a return within the chase line, the striker wins. For this purpose after two chases have been laid down (or if either player's score is at 40) the players change sides, e.g., if X has been serving and Y has laid down two chases, Y becomes the server and tries to defeat them, X to win them by making the ball fall nearer to the back wall after its first bound than Y did. Either player wins the chase if he "ends" (i.e., hits the ball into) one of the winning openings, or if his opponent fails to make a good return. The winner of the chase scores a point.

The chases are played off in the order in which they are made. Since X is in trying to win a chase the same chase as Y originally played, the original chase line becomes the chase for the scores. In France the chase is played again. The "rest" goes on till one of the players fails to make a good return, or deliberately leaves the ball alone in order that his opponent may lay down a chase (a procedure to be followed at the discretion of a player in whose judgment the chase will be a bad one), or lose a chase already laid down and in the course of being played off. Either player can score, there being no "hand-in" or "hand-out" as at racquets. A point is scored by that player whose opponent fails to make a good return stroke in a rest, or who strikes the ball into a winning opening, or wins a chase, or to whom two faults are served in succession. A player loses a stroke who strikes the ball twice, or allows it to touch himself or his clothes.

"He who would excel as a tennis-player must learn to serve," is the dictum of an amateur champion, but the necessary variations, the difference between the "railroad" and the "giraffe," &c., can only be explained by an experienced player and in the court. Variety is all-important, as is the knowledge of what sort of service is most valuable in defending a particular chase. All service should be heavily "cut." For the winning of hazard-side chases, indeed for winning chases in general, the service is useful. The end of it is to make the service drop at the nick of the grille-wall and hit the floor. In attempting this service it should be remembered that it is better for the ball to hit the floor first of all, as this allows the cut to act. It is wise to cultivate one sort of service to perfection, if possible, with a reserve of others to suit the occasion.

Again, the tennis "stroke," differing essentially as it does from the racquet stroke, can only be learnt in the court from a good teacher; but it is an axiom that tennis is not a game in which hard hitting necessarily tells, though force may be usefully employed in trying to "find" the winning openings. This, however, is an important point of etiquette—it is not "correct" to force for the dedans when the striker is close to the net, unless the force is "bossed" or there is no danger of hitting his opponent. In some clubs such a stroke is forbidden by a by-law. Some modern players of tennis are a fashion of hard strokes, and their predecessors, who considered strokes "on the floor," i.e. carefully judged chases, to be the true feature of the game; but in any case the beginner should remember that it is better to save his breath and to trust to winning an easy chase by-and-by than to run after a hard-hit stroke, which if left alone would leave "chase the door" or "second gallery," to be played for afterwords. Similarly in defending a chase, he should remember during the rest what that chase is, and not endeavour to return a stroke which would have lost it. Chases act as breathing-spaces, especially to the player who can trust to his skill "on the floor," and these, together with good service, give the chance when one can play tennis, and play it well, at a time of life when cricket, racquets and other active games have to be abandoned.

History.—Tennis may well be called a royal game, having been popular with various kings of England and France, though it is fanciful to connect it with Homer's Nausicaa, princess of Phaeacia (Odyssey, vi. 115), who is represented by him as throwing, and not as hitting the ball to her maids of honour. In the ball-games of the Greeks and Romans we may see the rudiments of the French jeu de paume, which is undoubtedly the ancestor of modern tennis. Of the origin of the name is quite obscure. Some give a numerical derivation from the fact that la longue paume was played by ten players, five on each side; others regard it as a corruption of tamis (sieve), for in a form of la paume the server bounced the ball on a sieve and then struck it: there is no possible reason for connecting "tennis" with the term Tenis, or Senois; probably is a derivation from Teuau (Take it Play it), especially when Charles V. was we remember the large number of French terms that adhere to the game, e.g., grille, tambour (drum, from the sound on the board that formed the face of that buttress) and dedans. Further, a poem dealing with the game, written in Latin elegies by R. Frissart, makes the striker cry "Excipe!" (Take it!) after each stroke: this seems to correspond with the custom which enjoins on the racket-markers not to speak unless an legitimate stroke has been made.

In the "Alexiad" of Anna Comnenus (about A.D. 1120) is a reference to a game played on horseback in which a staff, curved at the end and strung with strings of plaited gut, was used. This game was played in a court called "a court for golf (sic)" (according to the Lexicon of Alexandria Greek), and some similar game, corrupted through tchango into chicane, was played in France. In A.D. 1300 the game was also known as La boude. Throughout the century indeed it was played in France and by the highest in the land: thus Louis X. died from a chill contracted, after Charles V. had devoted himself to the game, though he vainly tried to stop it as a pastime for the lower classes; Charles VI. watched the game from the room where he was confined during his attack of insanity, and Du Guesclin amused himself with it during the siege of Dinan. In England the game, or some form of it, was known, Chaucer possibly alluding to it in the words "But canstow play racket to and fro"; and hand-ball, which may have been either tennis or cricket, was proscribed with other games by Edward III. in 1365. In France the game was prohibited to priests in A.D. 1245, and also in 1245, 1252 and 1673. In 1427 we hear of a woman named Margot, who was a skilled player, both her forehand and backhand strokes being commended; hence we may infer that the racquet had now been introduced. Tennis was at this time frequently played in some crude form in the courts of castles, where Charles VIII. used to watch the game. Henri II. is described as the best
TENNIS

player in France, and worthy of the silver ball given to the finest players. Later, Henri IV, and Louis XIV. (who kept a regular staff to look after his court) were patrons and players of tennis; indeed, in Henri IV.'s reign so popular was the sport that it was said that there were "more tennis-players in Paris than drunks and in England"; in the 16th century Paris alone could boast of 250 courts, yet it is stated that in 1589 there were only six courts in the whole of France. The word "tennis"—the game having hitherto been described as lunes galice—is first found in Gower's "Balade unto the worthy and noble kynge Henry the fourth" (1400), but Shakespeare's allusion to tennis as known to Henry V. must not be omitted. In reply to messengers from the dauphin, who had sent him a present of tennis-balls by their hands, Henry says:

"When we have match'd their rackets to these balls. We will, in France, by God's grace, play a set. Shall strike his father's crown into the hazard. Tell him he hath made a match with such a wrangler That all the courts of France will be disturb'd With chases."

—(Henry V., Act i., sc. 2.)

Even if it be an anachronism that the poet should put these technical terms into the king's mouth, yet the fact is established that the terms were familiar in Elizabeth's time. Henry VII. indeed both played the game and revoked the edicts that forbade it; there was a court at Windsor Castle in his time, an open court with four bare walls, no penthouse, &c., being visible, and connected with the palace by a covered way. This court still existed in 1607. It was in that reign, possibly in that court, that the king of Castile played a match with the marquis of Gower. He played a racquet, conceiving "fifteen" to the marquis, who played with his hand. The king won the set. Henry VIII. probably built the court at Hampton Court Palace. In 1615 there were further courts in London of various sizes, and a picture of James II. as a boy represents him standing in a tennis-court holding a short-handled racquet, strung diagonally. Pepys frequently alludes to tennis at a time when there were two courts at Oxford and five at Cambridge. Though the game flourished in the 17th century, it lost some of its popularity, mainly through the demolition of courts as building operations increased; moreover, courts complete in every detail alone were built, the play being consequently confined to the members of the clubs that could afford the expense. The last of the old courts to disappear stood in Windmill Street, at the top of the Haymarket, London. King Edward VII., when prince of Wales, frequently played tennis at "Prince's" Court.

The evolution of the court as now built is not easily traced, but courts undoubtedly existed side by side which differed from each other both in detail and in dimensions. It is generally assumed that such details as the penthouse, grille, galleries, &c., were deliberately planned to elaborate the game, but it is not unreasonable to suggest that the game, played, as it must often have been, in extemporized courts, took some of its modifications from them: it is at least significant that in an old illustration of la paume a miniature penthouse appears (from which the ball is rolling), apparently a shelter for a bell. The net does not appear till the 17th century, a rope, fringed or tasselled, being stretched across the court: further, the racquet was not in universal use in 1527, since Erasmus in his Colloquies says, "Reticulum (net, or racquet) piscatoribus relictumque elegantis est palma ut." An Italian, Antonio Scano de Salo, is the first literary suggester of tennis. In his Trattato della Palla (treatise on the ball) he describes a game in which the ball was played with a racquet, and a small court for the game. The large court was 121 ft. long; it was entered by two doors, one between the first and second galleries on either side of the net; there were four galleries on each side; the dedans extended across the whole width of the court: the tambour was there and two grilles. He also mentioned chases, but these were decided by the place where the ball finally stopped, the spot being marked by a small movable standard. In another kind of court he says that there was no tambour, but two grilles.

The penthouse was sometimes confined to two walls, sometimes to one, the end wall service side. In the hand-court one side was open all its length, with the exception of the battery and some pillars that perhaps gave variety to the stroke. The Latin poem to which allusion has been made shows the similarity of the 17th-century game to the modern: the racquet is spun; the marker (signator) is there to mark the places (metes) with the movable standard; there is the grille (frenstra); the scoring by "15, 30, 40, game," the volley the time. In the 15th and 16th centuries tennis-balls were so largely imported from France that the Ironmongers' Company, who were the English manufacturers, twice petitioned—the last time in 1591—for "protection" in the matter of balls. The term "bisk" (bixgai, originally bisqaye) does not appear in English tennis till 1607 (Shadwell's True Widow), nor is the winning gallery mentioned before 1707. In the 17th century tennis became a spectacle in France, and the professional player came into existence, the most famous of that time being Le Pape, Clergé and Servo, and about the same time was formed the gild of Paulmiers-rocqueteurs (manufacturers of tennis material) with its arms, "Sable, a tennis-racquet proper; in a cross four tennis-balls of the same." De Garsault, writing in 1797, says, "La Paume is the only game that can take rank in the list of Arts and Crafts," and his book, L'art du Paumier-Racquetier, was adopted by the Académie Royale. In France very large sums of money were wagered on the game, especially at the end of the 16th century, the stakes being deposited under the cord or net, while in England, about 1759, there was so much betting and swindling, especially by professional players, that the game as played in the public courts fell into disrepute. In the middle of the 19th century, tennis-courts were rare indeed in England, the best known being those of the Marylebone Cricket Club (built in 1838), of the Messrs Prince in Hans Place, S.W., besides one at Brighton, one at Hampton Court, two at Cambridge, and one at Oxford; but the game progressed so fast that in 1910 there were between thirty and forty courts in England, each one in Ireland and Scotland, five in America, six in France, one in Melbourne (Australia) and one in Tasmania. The game has disappeared in Italy, Germany, Austria and Spain, except in Spain, which was popular in the days of Philip III. (1588-1621) who was himself fond of playing.

The great French players mentioned above were followed by others—Cabasse (who invented the "boasted force" known as the coup de Cabasse), Barcellon, Farolais and Barnéon, and in the 18th century the Charniers, Bergeron and Masson, the last-named a really great player who could give fifteen to any of his contemporaries. One of his feats was to stand in a barrel before receiving the service, spring out of it and into it before and after each stroke. Other good players of later date were C. A. Delahaye, and greatest of all, J. E. Barre, who in 1855 re-opened the Versailles court, famous for the meeting of the Tiers État on the 20th of June 1789, which body there assembled and took the celebrated "Oath of the tennis-court." Masson is supposed to have visited England in 1792 and to have played against Messrs Hawkins and Price, and a professional called Pillet (or Pilet); but of Barre's visit there can be no doubt, as he played on the new court of the Marylebone Club in 1839, meeting "Peter" Tompkins, the English champion, and beating him so severely that when they met again next year Tompkins received the odds of thirty and a bisque. As an instance of the marquis, he mentions in the dawn, Julian Marshall in his Annals of Tennis states that in Bell's Life, the leading sporting paper, Barre is reported as playing Cox and Tompkins "giving 71/2 for a bisque," the tennis term "half fifteen" being arithmetically rendered. C. G. Taylor, the great cricketer, was one of the best amateurs, about this time. Barre eventually resigned the championship in favour of George Lambert, who was beaten in 1855 by T. Pettitt, of Boston U.S.A. Athletic Association, an Englishman by birth, who
learned all his tennis in America. Charles Saunders beat Lambert in 1886, thereby becoming champion of England. Pettit and Saunders met for the championship of the world at Dublin, Pettit winning by seven sets to five. The match took place in May 1890, and during the autumn, Pettit declining to defend the title, Saunders assumed it, but five years later he was challenged by Peter Latham and beaten, Latham thus becoming the champion of the world both at racquets and tennis. An American, George Standing, challenged him in 1897 for the racquets championship, but was beaten, and next year Pettit challenged Latham at tennis. In 1904 C. Fairs ("Punch") challenged Latham for the championship, but was beaten; but in 1905 Fairs (then his title) again issued a challenge to any other player in the world to contest his right to the position of champion. The challenge was taken up in 1910 by G. F. Covey, the match for the championship, played at Brighton in the summer of 1910, being won by Fairs after a close contest, in which the younger player secured six sets to his opponent's seven, and fifty-three games to fifty-nine won by the champion. Among amateurs a formal championship was not established till 1885, the recognized champion being the winner of the gold prize annually given by the Marylebone Cricket Club to its members, the competition not being made open till 1896. For fifteen years, from 1867 to 1881, J. M. Heathcote held the title, among those whom he defeated during that period being such fine tennis-players as Julian Marshall, G. B. Crawley, the Hon. C. G. Lyttelton (afterwards Lord Cobham), R. D. Walker, C. E. Boyle, and the Hon. Alfred Lyttelton. In 1882 A. Lyttelton defeated Heathcote, only to be beaten next year by him, and to beat him in turn in 1884 and 1885; but in 1886 Heathcote (then fifty-three years of age) was again champion. From 1887 to 1895 inclusive the Hon. A. Lyttelton was champion, defeating during that time (besides Heathcote) A. J. Webb, Sir Edward Grey and H. E. Crawley. Grey's perseverance—he won the silver prize on six occasions—was rewarded with the gold prize in 1896, but he was dispossessed in 1897 by E. H. Miles, who won for the next ten years, with the exception of 1900 when he was beaten by J. B. Gribble. On six occasions during this series Sir Edward Grey was second to the winner.

In 1889 the amateur championship, open to all amateurs, was instituted at Queen's Club, West Kensington. The following list shows the winners:

1889, Sir E. Grey.
1890, E. B. Curtis.
1891, Sir E. Grey.
1892, H. E. Crawley.
1893, Sir E. Grey.
1894, E. H. Miles.
1895, A. E. Pettitt.
1896, Sir E. Grey.
1897, J. B. Gribble.
1898, Sir E. Grey.
1899, E. H. Miles.
1900, E. H. Miles.
1901, E. H. Miles.
1902, E. H. Miles.
1903, E. H. Miles.
1904, V. Penny.
1905, E. H. Miles.
1906, E. H. Miles.
1907, Jay Gould.
1908, J. B. Gribble.
1909, E. H. Miles.
1910, E. H. Miles.

It may be mentioned that Heathcote and Lyttelton, who monopolized the Marylebone Club's gold prize for twenty-nine years, were strict followers of the class-action, the winning and defending of chases and the clever placing of the ball being the leading feature of their game. A different and less attractive form, consisting of harder hitting, asserted itself in Miles's first success, which was followed by many others; but Jay Gould, an American amateur, who beat Miles for the championship in 1907 and again in 1908, owed his success to the perfection of his style in the older and more scientific tennis. He did not defend his title in 1909, when Miles again became champion in his absence, a title which Miles again retained in 1910.

The universities of Oxford and Cambridge have played two matches, not under the four-handed, rules, in 1874 and 1884, with the exception of 1886 when neither match was played. The games are played at the court of the Marylebone Club.

Tennis in America.—Few tennis-courts existed in America before 1880, about which time the buildings of the Boston Athletic Association and the New York Racquet and Tennis Club were built. There are now also courts at Chicago, Tuxedo, Lakewood and several other places, but the game is naturally played by comparatively few persons. Tom Pettitt, mentioned above as for several years champion of the world, was for many years in charge of the Boston courts. Other first-class men are Alfred Tompkins of New York, Boskies of Chicago and Forester. Richard Sears first won the American championship in 1892, and it has been won since by F. Warren, B. S. de Garmandia, L. M. Stockton (four times), Eustace Miles (champion of Great Britain), Joshua Crane, and Jay Gould (amateur champion 1907 and 1908). The older courts at Boston and New York are rather low and small, but the newer ones are perfect.

of sonnets which have been highly praised. In June 1829 Alfred Tennyson won the Chancellor’s prize medal for his poem called “Timbuctoo.” With great imperfections, this study in Miltonic blank verse displays the genius of a poet, in spite of a curious obscurity both of thought and style. Here are already both richness and power, although their expression is not yet clarified by taste. But by this time Tennyson was writing lyrics of still higher promise, and, as Arthur Hallam early perceived, with an extraordinary earnestness in the worship of beauty. The results of this enthusiasm and this labour of the artist appeared in the volume of Poems, chiefly Lyrical, published in 1830. This book would have been astonishing as the production of a youth of twenty-one, even if, since the death of Byron six years before, there had not been a singular death of good poetry in England. Here at least, in the slender volume of 1830, was a new writer revealed, and in “Mariana,” “The Poet,” “Love and Death,” and “Oriana,” a singer of wonderful though still uncastanched melody. Through these, and through less perfect examples, was exhibited an amazing reverence of fancy, at present insufficiently under control, and a voluptuous pomp of imagery, tending to an over-sweetness. The veteran S. T. Coleridge, praising the genius in the book, blamed the metrical imperfection of it. For this criticism he has himself constantly been reproved, and Tennyson (whose impatience of anything like censure was phenomenal) continued to resist it to the end of his life. Yet Coleridge was perfectly just in his remark; and the metrical anarchy of the “Madelines” and “Adelines” of the 1830 volume showed that Tennyson, with all his delicacy of modulation, had not yet mastered the arts of verse. 

In the summer of 1830 Tennyson and Hallam volunteered in the army of the Spanish insurgent Torrijos, and marched about a little in the Pyrenees, without meeting with an enemy. He came back to find his father ailing, and in February 1831 he left Cambridge for Somersby, where a few days later Dr George Tennyson died. The new incumbent was willing that the Tennysons should continue to live in the rectory, which they did not leave until six years later. Arthur Hallam was now betrothed to Emily Tennyson (afterwards Mrs Jesse, 1811–1886), and stayed frequently at Somersby. This was a very happy time, and one of great physical development on Alfred’s part. He took his share in all kinds of athletic exercises, and it was now that Brookfield said, “It is not fair that you should be Hercules as well as Apollo.” This high physical zest in life seems to have declined after 1831, when his eyes began to trouble him, and he became liable to depression. The poetical work of these three years, mainly spent at Somersby, was given to the world in the volume of Poems which (dated 1833) appeared at the end of 1832. This was certainly one of the most astonishing revolutions of finished genius ever produced by a young man of less than four-and-twenty. Here were to be read “The Lady of Shalott,” “The Dream of Fair Women,” “Oenone,” “The Lotus-Eaters,” “The Palace of Art,” and “The Miller’s Daughter,” with a score of other lyrics, delicious and divine. The advance in craftsmanship and command over the material of verse shown since the volume of 1830 is absolutely astounding. If Tennyson had died of the savage article which presently appeared in the Quarterly Review, literature would have sustained terrible losses, but his name would have lived for ever among those of the great English poets. Indeed, it may be doubted whether, in several directions, he ever surpassed the glories of this volume, to be found in this most exquisite and most precious book. It was well that its publication was not completed before the blow fell upon Tennyson which took for a while all the light out of him. In August 1833 Arthur Hallam started with his father, the great historian, for Tirol. They went no farther than Vienna, where Mr Hallam, returning to the hotel on the 15th of September 1833, found his son lying dead on a sofa: a blood-vessel had broken in his brain. His body was brought back to England, and buried at Cledendon on the 3rd of January 1834. These events affected Tennyson extremely. He grew less than ever willing to come forward and face the world; his health became “variable and his spirits indifferent.” The earliest effect of Hallam’s death upon his friend’s art was the composition, in the summer of 1834, of The Two Voices; and to the same period belong the beginnings of the Idylls of the King and of In Memoriam, over both of which he meditated long. In 1835 he visited the Lakes, and saw much of Hartley Coleridge, but would not “obtrude on the great man at Rydal,” although “Wordsworth was hospitably disposed.” Critics alike of fame and of influence, Tennyson spent these years mainly at Somersby, in a uniform devotion of his whole soul to the art of poetry. In 1837, to their great distress, the Tennysons were turned out of the Lincolnshire rectory where they had lived so long. They moved to High Beech, in Epping Forest, which was their home until 1840. The poet was already engaged, or “quasi-betrothed,” to Emily Sellwood, but ten years more had to pass before they could afford to marry. At Torquay, in 1838, he wrote Audley Court on one of his rare excursions, for he had no money for touring, nor did he wish for change: he wrote at this time, “I require quiet, and myself to myself, more than any man when I write.” In 1840 the Tennysons moved to Tunbridge Wells, and a year later to Boxley, near Maidstone, to be close to Edmund Lushington, who had now married Cecilia Tennyson. Alfred was from this time more and more frequently a visitor in London. 

In 1842 the two-volume edition of his Poems broke the ten years’ silence which he had enforced himself to keep. Here, with many pieces already known to all lovers of modern verse, were found rich and copious additions to his work. These he had originally intended to publish alone, and an earlier privately printed Morte d’Arthur, Dora, and other Idyls, of 1842, is the despair of book-collectors. Most of those studies of home-life in England, which formed so highly popular a section of Tennyson’s work—such as “The Gardener’s Daughter,” “Walking to the Mail,” and “The Lord of Burleigh”—were now first issued, and, in what we have grown to consider a much higher order, “Locksley Hall,” “Ulysses,” and “Sir Galahad.” To the older and more luxurious lyrics, as reprinted in 1842, Tennyson did not spare the curbing and pruning hand, and in some cases went too far in restraining the wanton spirit of beauty in its youthful impulse. It is from 1842 that the universal fame of Tennyson must be dated; from the time of the publication of the two volumes he ceased to be a curiosity, or the darling of an advanced clique, and took his place as the leading poet of his age in England. Among the friends whom he now made, or for the first time cultivated, were Carlyle, Rogers, Dickens, and Elizabeth Barrett. Material difficulties now, however, for the first time intruded on his path. He became the victim of a certain “earnest-frothy” speculator, who induced him to sell his little Lincolnshire estate at Grasby, and to invest the proceeds, with all his other money, and part of that of his brothers and sisters, in a “Patent Decorative Carving Company”; in a few months the whole scheme collapsed, and Tennyson was left penniless. He was attacked by so overwhelming a hypochondria that his life was despairsed of, and he was placed for some time under the charge of a hydro-pathic physician at Cheltenham, where absolute rest and isolation gradually brought him round to health again. The state of utter indigence to which Tennyson was reduced greatly exercised his friends, and in September 1845, at the suggestion of Henry Hallam, Sir Robert Peel was induced to bestow on the poet a pension of £200 a year. Never was public money expended in a more patriotic fashion. Tennyson’s health suffered considerably from this, for in 1846 he was hard at work on The Princess; in the autumn of this year he took a tour in Switzerland, and saw great mountains and such “stateliest bits of landscape” for the first time. In 1847 nervous prostration again obliged him to undergo treatment at Prestbury: “They tell me not to read, not to think; but they might as well tell me not to live.” Dr Gully’s water-cure was tried, with success. The Princess was now published, in a form afterwards considerably modified and added to. Carlyle and Fitzgerald “gave up all hopes of him after The Princess,” or
Tennyson pretended that they did. It was true that the bent of his genius was slightly altered, in a direction which seemed less purely and purely that of the highest art; but his concessions to public taste vastly added to the width of the circle he now addressed. The home of the Tennysons was now at Cheltenham; on his occasional visits to London he was in the habit of seeing Thackeray, Coventry Patmore, Browning and Macready, as well as older friends, but he avoided "society." In 1848, while making a tour in Cornwall, Tennyson met Robert Stephen Hawker of Morwenstow, with whom he thenceforth was associated; he resumed his intention of writing an epic on that theme. In his absent-minded way Tennyson was very apt to mislay objects; in earlier life he had lost the MS. of Poems, chiefly Lyric, and had been obliged to restore the whole from scraps and memory. Now a worse thing befell him, for in February 1850, having collected into one "long ledger-like book" all the elegies on Arthur Hallam which he had been composing at intervals since 1833, he lost this only MS. in the cupboard of some lodgings in Mornington Place, Hampstead Road. By extraordinary good fortune it had been overlooked by the landlady, and Coventry Patmore was able to recover it. In this way In Memoriam was dragged back from the very verge of destruction, and could be published, in its original anonymous form, in May 1850.

The public was at first greatly mystified by the nature and object of this poem, which was not merely a chronicle of Tennyson's emotions under bereavement, nor even a statement of his philosophical and religious beliefs; but, as he long afterwards explained, a sort of Divina Commedia, ending with happiness in the marriage of his youngest sister, Cecilia Lushington. In fact, the great blemish of In Memoriam, its redundance and the dislocation of its parts, were largely due to the desultory manner of its composition. The poet wrote the sections as they occurred to him, and did not think of weaving them together into a single poem until it was too late to give them real coherency. The metre, which by a curious naïveté Tennyson long believed that he had invented, served by its happy peculiarity to bind the sections together, and even to give an illusion of connected movement to the thought.

The scale of Tennyson's poems now made it safe for him to settle; and on the 13th of June 1850 he was married at Shiplake to Emily Sarah Sellwood (1813-1890). Of this union no more need be said than was recorded long afterwards by the poet himself, "The peace of God came into my life before the altar when I wedded her." Every species of good fortune was now to descend on the path of the man who had struggled against ill luck so long. Wordsworth died, and on the 19th of November 1850 Queen Victoria appointed Tennyson poet laureate. The salary connected with the post was very small, but it had a secondary value in greatly stimulating the sale of his books, which was his main source of income. The young couple took a house at Warninglid, in Sussex, which did not suit them, and then one in Montpelier Row, Twickenham, which did better. In April 1851 their first child was born dead. At this time Tennyson was brooding much upon the ancient world, and reading little but Milton, Homer and Virgil. This condition was elegantly defined by Carlyle as "sitting on a dunghill among innumerable dead dogs." In the summer of 1851 was made the tour in Italy, of which The Daisy is the immortal record. Of 1852 the principal events were the birth of his eldest son Hallam, the second Lord Tennyson, in August, and in November the publication of the Ode on the Death of the Duke of Wellington. In the winter of 1853 Tennyson entered Duke's possession of a little house and farm called Farrington, near Freshwater, in the Isle of Wight, which he leased at first, and afterwards bought: this beautiful place, ringed round with ilexes and cedars, entered into his life and coloured it with its delicate enchantment. In 1854 he published The Charge of the Light Brigade, and was busy composing Maud and its accompanying lyrics; and this volume was published in July 1855 just after he was made D.C.L. at Oxford: he was received on this occasion, which may be considered his first public appearance, with a "tremendous ovation." The reception of Maud from the critics, however, was the worst trial to his equanimity which Tennyson had ever had to endure, nor had the future anything like it in store for him. He had risen in Maud far above his ordinary serenity of style, to ecstasies of passion and audacities of expression which were scarcely intelligible to his readers, and certainly not welcome. It is odd that this irregular poem, with its copious and varied music, its splendid sweep of emotion, its unfailing richness of texture—this poem in which he wrote of "the dark dead mad," and in which he reached nowhere else, should have been received with bitter hostility, have been styled "the dead level of prose run mad," and have been reproved more absurdly still for its "ramrant and rabid bloodthirstiness of soul." There came a reaction of taste and sense, but the delicate spirit of Tennyson had been wounded. For some years the world heard nothing from him; he was at Farringford, busying himself with the Arthurian traditions. He had now become an object of boundless personal curiosity, being already difficult to find, and "the purest" of the "golden laurels." It was in 1857 that Bayard Taylor saw him, and carried away the impression of a man "tall and broad-shouldered as a son of Anak, with hair, beard and eyes of southern darkness." This period of somewhat mysterious withdrawal from the world embraced a tour in Wales in 1857, a visit to Norway in 1858, and a journey through Portugal in 1859. In 1857 two Arthurian poems had been tentatively and privately printed, as Enid and Nimue, or the True and the False, to see how the idyllic form would be liked by the inner circle of Tennyson's friends. In the summer of 1859 the first series of Idylls of the King was at length given to the world, and achieved a popular success far beyond anything experienced before by any English poet, save perhaps Byron and Scott. Within a month of publication, 10,000 copies had been sold. The idyls were four in number, "Enid," "Vivien" (no longer called "Nimue"), "Elaine" and "Guinevere." These were fragments of the epic of the fall of King Arthur and the Table Round which Tennyson was so long preparing, and which he can hardly be said to have ever completed, although nearly thirty years later he closed it. The public and the critics alike were entranced with the "sweetness" and the "purity" of the themes. A few, like Thackeray, were doubtful about "that increased quaintness of style" which two already suspected that the "sweetness" was obtained at some sacrifice of force, and that the "purity" involved a cession to Victorian conventionality. It was not perceived at the time that the four idyls were parts of a great historical or mystical poem, and they were welcomed as four polished studies of typical women: it must be confessed that in this light their even perfection of workmanship appeared to greater advantage than it eventually did in the general texture of the so-called "epic." In 1859 "Boadicea" was written, and "Rime of the " in The Times. Urged by the duke of Argyll, Tennyson now turned his attention to the theme of the Holy Grail, though he progressed with it but fitfully and slowly. In 1861 he travelled in Auvergne and the Pyrenees, with Clough, who was to die a few months later; to this year belong "Helen's Tower" and the "Dedication" of the Idylls to the prince consort, "These to his Memory." The latter led to Tennyson's presentation in April 1862 to the queen, who "stood pale and statue-like before him, in a kind of stately innocence," which greatly moved his admiring homage. From this time forth the poet enjoyed the constant favour of the sovereign, though he could never be moulded into a constitutional courtier. He now put the Arthurian legends aside for a time, and devoted himself to the composition, in 1862, of "Enoch Arden," which, however, did not appear until 1864, and then in a volume which also contained "Sea Dreams," "Aylmer's Field" and, above all, "The Northern Farmer," the first and finest of Tennyson's remarkable studies in dialect. In April of this year Garibaldi visited Farringford; in February 1865 Tennyson's mother died at Hampstead in her eighty-fifth
year; in the ensuing summer he travelled in Germany. The time slipped by with incidents but few and slight, Tennyson's popularity in Great Britain growing all the time to an extent unparalleled in the whole annals of English poetry. This universality of fame led to considerable practical discomfort; he was besieged by sightseers, and his nervous trepidation led him perhaps to exaggerate the intensity of the inflection. In 1867 he determined to make for himself a haven of refuge against the invading Philistine, and bought some land on Blackdown, above Haslemere, then a secluded corner of England; here Mr. (afterwards Sir) James Knowles began to build him a house, ultimately named Aldworth. This is the time of two of his rare, privately printed pamphlets, The Window; or, The Loves of the Wrens (1869), and The Vicar (1868). The noble poem Lucretius, one of the greatest of Tennyson's versified monographs, was published in May 1868, and in this year The Holy Grail was at last finished; it was published in 1869, together with three other idyls belonging to the Arthurian epic, and various miscellaneous lyrics, besides Lucretius. The reception of this volume was cordial, but not so universally respectful as that which Tennyson had grown to expect from his adoring public. The fact was that the heightened reputation of Browning, and still more the sudden vogue of Swinburne, Morris and Rossetti (1866-1870), considerably disturbed the minds of Tennyson's most ardent readers, and exposed himself to a severer criticism than he had lately been accustomed to endure. He went on quite calmly, however, sure of his mission and of his music. His next volume (1872), Gareth and Lynette and The Last Tournament, continued, and, as he then supposed, concluded The Idyls of the King, to the great satisfaction of the poet, who had found much difficulty in rounding off the last sections of the poem. Nor, as he was to find, was the poem yet completed, but for the time being he dismissed it from his mind. In 1873 he was offered a baronetcy by Gladstone, and again by Disraeli in 1874; in each case the honour was gracefully declined. Tennyson was through it all the time, of course, working on the Idylls; when the collection of new verses entitled Demeter and other Poems (1879), which appeared almost simultaneously with the death of Browning, an event which left Tennyson a solitary figure indeed in poetic literature. In 1891 it was observed that he had wonderfully recovered the high spirits of youth, and even a remarkable portion of physical strength. His latest drama, The Foresters, now received his attention, and in March 1892 it was produced at New York, with Miss Ada Rehan as Maid Marian. During this year Tennyson was steadily engaged on poetical composition, finishing "Akbar's Dream," "Kapiolani," and other contents of the posthumous volume called The Death of Osmon, 1892. In the summer he took a voyage to the Channel Islands and Devonshire; and even this was not his latest excursion from home, for in July 1892 he went up for a visit to London. Soon after entering his eighty-fourth year, however, symptoms of weakness set in, and early in September his condition began to give alarm. He retained his intellectual lucidity and an absolute command of his faculties to the last, reading Shakespeare with obvious appreciation until within a few hours of his death. With the splendour of the full moon falling upon him, his hard clasping his Shakespeare, and reading, as were told almost unearthly in the majestic beauty of his old age, Tennyson passed away at Aldworth on the night of the 6th of October 1892. Cymbeline, the play he had been reading on the last afternoon, was laid in his coffin, and on the 11th the 6th was publicly buried with great solemnity in Westminster Abbey. Lady Tennyson survived until August 1896.

The physical appearance of Tennyson was very remarkable. Of his figure at the age of thirty-three Carlyle has left a superb portrait: "One of the finest-looking men in the world. A great shock of rough, dusky, dark hair; bright, laughing, hazel eyes; massive aquiline face, most massive yet most delicate; of sallow brown complexion, almost Indian-looking, clothes cynically, looks very well; and when my eyes glided over him, I was struck by his musical, metallic, fit for loud laughter and piercing wail, and all that may lie between; speech and speculation free and
TENOR—TENT

plenteous; I do not meet in these late decades such company over a pipe." He was unusually tall, and possessed in advanced years a strange and rather terrifying air of sombre majesty. But he was, in fact, of a great simplicity in temperament, affectionate, shy, still exquisitely sensitive in extreme old age to the influences of beauty, melancholy and sweetness. Although exceedingly near-sighted, Tennyson was a very keen observer of nature, and at the age of eighty his dark and glowing eyes, which were still strong, continued to permit him to enjoy the delicate features of country life around him, both at Ald- worth and in the Isle of Wight. His Life, written with admirable piety and taste by his son, Hallam, second Lord Tennyson, was published in two volumes in 1897.

At the time of his death, and for some time after it, the enthusiastic recognition of the genius of Tennyson was too extravagant to be permanent. A reaction against this extravagance was perhaps inevitable, and criticism has of late been little occupied with the poet. The reason of this is easy to find. For an unusually long period this particular poetry had occupied public and professional opinion, and all the commonplace things about it had been said and re-said to satiety. It lacks for the moment the interest of freshness; it is like a wonderful picture seen so constantly that it fails any longer to concentrate attention. No living poet has ever held England—no poet but Victor Hugo has probably ever held any country—quite so long under his unbroken sway as Tennyson did. As he recedes from us, however, we begin to see that he has a much closer relation to those of his masters than we used to be inclined to admit. The distance between the generation of Wordsworth and Coleridge and that of Byron and Shelley is not less—it is even probably greater—than that which divides Keats from Tennyson, and he is more the last of that great school than the first of any new one. The qualities in which he seems to surpass his immediate predecessors are exactly those which should be the gift of one who sums up the labours of a mighty line of artists. He is remarkable among them for the breadth, the richness, the substantial accomplishment of his touch; he has something of all these his elders, and goes farther along the road of technical perfection than any of them. We still look to the earlier masters for supreme excellence in particular directions: to Wordsworth for sublime philosophy, to Coleridge for ethereal magic, to Byron for passion, to Shelley for lyric intensity, to Keats for richness. Tennyson does not excel each of these in his own special field, but he is often nearer to the particular man in his particular mastery than any one else can be said to be, and he has in addition his own field of supremacy. What this is cannot easily be defined; it consists, perhaps, in the beauty of the atmosphere which Tennyson contrives to cast around his work, moulding it in the blue mystery of twilight, in the golden light of the setting sun. In this is worthy of the past charm: this atmosphere, suffused with his poetry with inestimable skill and with a tact very rarely at fault, produces an almost unerring vision or mirage of loveliness, so that, even where (as must sometimes be the case with every poet) the thought and the imagery have little value in themselves, the fictive aura of beauty broods over the otherwise undistinguished verse. Hence, among all the English poets, it is Tennyson who presents the least percentage of entirely unattractive poetry. In his luminous subtlety and his broad undulating sweetness, his relationship with Virgil has long been manifested; he was himself aware of it. But he was also conscious that his exquisite devotion to mere lucidity and beauty might be a snare to him, and a happy instinct was always driving him to a study of mankind as well as of inanimate nature. Few English writers have known so adroitly as Tennyson how to bend the study of Shakespeare to the enrichment of their personal style. It should be added that he was a very deep and original student of literature of every description, and that the comparatively few specimens which have been preserved of his conversation contain some of the finest fragments of modern appreciation of the great poets which we possess. This is worthy of consideration in any attempt made to sketch the mind of a man who was above all other masters of recent literature an artist, and who must be studied in the vast and orbic fullness of his accomplishment in order to be appreciated at all.

(E. G.)

Alfred, Lord Tennyson: a Memoir (1897), by Hallam, second Baron Tennyson, is the authoritative source for the poet's biography, Mr. R. H. Shepherd in his Tennysoniana (1886), supplied a list of criticisms on his work, and a bibliography issued separately in 1896. Among the numerous books on the subject of his life and works that might be mentioned, A Commentary on Tennyson's In Memoriam (1901), by Prof. A. C. Bradley; Canon Rawnsley's Memories of the Tennysons (1900); Alfred Tennyson (1901), by Mr. W. A. Lang; an essay by Mr. W. S. Lilly's Studies in Religion and Literature (1904); and The Life of Lord Tennyson (1904), by Mr. A. C. Benson, who gives a more critical estimate of the poet than was possible in the Memoir by his son.

TENOR (through Fr. and It. from Lat. tenor, holding on, course, sense of a law, tone), a general course or direction, the drift or general meaning of a statement or discourse, hence, in law, the true purport and effect of a deed or instrument. The most general use of the word is, in music, for the highest kind of the natural adult male voice. This use descends from the Medieval Latin tenor, which was applied first to the chief melody, the cantus firmus, and then to the male voice to which the singing of this was assigned.

TENREC (Centetes cecaudatus), one of the largest representatives of the mammalian order Insectivora, the length being from 12 in. to 16 in.; called also the tailless ground-hog of Madagascar, to which island it is restricted. The coat consists chiefly of bristles and hairs, with an admixture of flexible spines, which in the young form longitudinal lines down the back; but in the adult they are limited to the back of the neck. The general hue is brown tinged with yellow. From twelve to sixteen young are produced at a birth, and twenty-one have been recorded. In habits the tenrec is fossorial and nocturnal; its home is in the brush in the mountain regions, and in the cool season, from May or June till December, it hibernates in deep burrows. The long flexible snout is used to root up worms and grubs, and ground-insects form part of its nourishment. These animals are very fat when hibernation begins, and are then much valued for food by the natives (see also INSECTIVORA).

TENT. A tent is a portable habitation or place of shelter, consisting in its simplest form of a covering of some textile substance stretched over a framework of cords and poles, or of wooden rods, and fastened tightly to the ground by pegs. Throughout the greater part of the interior of Asia the pastoral tribes have of necessity ever been dwellers in tents—the scantiness of water, the consequent frequent failure of herbage, and the violent extremes of seasons compelling a wandering life. Tents have also been used in all ages by armies in campaign. In ancient Assyrian sculptures discovered by Layard at Nineveh the forms of tent and tent-furnishings are similar to those which still prevail in the East, and it appears that then as now it was a custom to pitch tents within the walls of a city. The ordinary family tent of the Arab nomads of modern times is a comparatively spacious ridged structure, averaging from 20 to 25 ft. in length, but sometimes reaching as much as 40 ft. Its covering consists of a thick felt of black goat hair (cp. Cant. i. 5—4th black as the tents of Kedar''), or sometimes of alternate stripes of black and white disposed horizontally. The ridge or roof is supported by nine poles disposed in sets of three, the central set being loftier than those at each end, whereby a slope outward is formed which helps to carry off rain. The average height inside at the centre is 7 ft. and at the sides 5 ft., and the cloths at the side are so attached that they can easily be removed, the sheltered end being always kept open. Internally the tent is separated by a partition into two sections, that reserved for the women containing the cooking utensils and food. The fourt or tent of the Kirghiz of Central Asia is a very capacious and substantial structure, consisting of a wooden frame for sides, radiating ribs for roof, and a wooden door. The sides are made up of sections of laths, which expand and contract in lozenges, on the principle of lazy tongs, and to their upper extremities ribs are lashed at regular intervals. Over this
In 1789. For several years he practised as a special pleader under the bar, and was finally called at the Inner Temple in 1796. He joined the Oxford circuit and soon made rapid headway. In 1801 he was appointed recorder of Oxford. In 1802 he appeared in Law relative to Merchant Ships and Seamen, a concise and excellent treatise, which has maintained its position as an authoritative work. Its publication brought to him so much commercial and other work that in 1808 he was in a position to refuse a seat on the bench; this, however, he accepted in 1816, being made a judge of the court of common pleas. On the resignation of Lord Ellenborough in 1818 he was appointed to the bench, and, in the discharge of his duties, he developed his capacity as chief justice he presided over several important state trials, notably that of Arthur Thistlewood and the Cato Street conspirators (1826). He was raised to the peerage in 1827 as Baron Tenterden of Hendon. Never a great lawyer and with no pretence to eloquence, Tenterden made his way by sound common sense and steady hard work. He was an uncompromising Tory, and had no sympathy with the reform of the criminal law carried out by Romilly; while he strongly opposed the Catholic Relief Bill and the Reform Bill. He died on the 4th of November 1832, and was buried, by his own desire, in the Foundling Hospital, London, of which he was a governor.

Tenterden was succeeded in his title by his son, John Henry Abbott (1796-1870), then by his grandson, Charles Stuart Aubrey Abbott (1834-1882), permanent under-secretary for foreign affairs, who was made a K.C.B. in 1878. In 1882 the latter's son, Charles Stuart Henry Abbott (b. 1869) became the 4th Baron.

TENTERDEN, a market town and municipal borough in the Ashford parliamentary division of Kent, England, 62 m. S.E. by E. of London by the South-Eastern and Chatham railway, Pop. (1901) 3243. It lies on an elevation above the Newnall Channel, a tributary of the Rother, whose flat valley, called the Rother Levels, was an estuary within historic times; and even as late as the 18th century the sea was within 2 m. of Tenterden, which is a member of the affiliated Cinque Port of Rye.

The church of St Mildred is Early English and later, and its tall, massive Perpendicular tower is well known for the legend connecting it with Goodwin Sands. The story is that the Abbots of St Augustine, Canterbury, diverted the funds by which the sea-wall protecting Earl Godwin's island was kept permanent, and the purpose of building Tenterden as a stronghold, the consequence being that in 1099 an inundation took place and "Tenterden steeple was the cause of the Goodwin Sands." Attached to the church is a penitentary used in the reign of Queen Mary for the confinement of persons awaiting trial on a charge of heresy. The church of High Halden, in the neighbourhood, is remarkable for its octagonal wooden tower constructed of huge timbers, with a belfry of wooden tiles (shingles), of the time of Henry VI. Tenterden has a considerable trade in agricultural produce and stock. It is governed by a mayor, four aldermen and twelve councillors. Area, 5046 acres.
ship-money, as compared with £1o contributed by Faversham, and £6o by Hythe. Under Edward III, several refugee Flemings settled in the town and established the woollen manufacture. An old waste book, still preserved, contains entries of amounts of cloth sent from Tenterden to London. By 1835 this trade had completely died out, and Tenterden was suffering from the depression of agricultural interests.

**TENURE** (Fr. tenure, from Lat. tener, to hold), in law, the holding or possession of land. The holding of land in England was originally either *alodial or feudal*. Alodial land was land held not of a superior lord, but of the king and people. Such ownership was absolute. It possibly took its origin from the veneration of the clan; that the chief was the leader but not the owner, and was no doubt strengthened by the temporary and partial occupation by the Romans. Their withdrawal, followed by the Saxon invasion, tended, without doubt, to re-establish the principle of common village ownership which formed the basis of both Celtic and German tenure. In the later Saxon period, however, private ownership became gradually more extended. Then the feudal idea began to make progress in England, much as it did about the same time on the continent of Europe, and it received a great impetus from the Norman conquest. When English law began to settle down into a system, the principle of feudalism was taken as the basis, and it gradually became the undisputed maxim of English law that the sovereign was the supreme lord of all the land and that every one held under him as tenant, that there was no such thing as an absolute private right of property in land, but that the state alone as personified by the sovereign was vested with that right, and conceded to the individual possessor only a strictly defined subordinate right, subject to conditions from time to time enacted by the community (see also Feudalism). Feudal tenure was divided into free and non-free. Free tenures were *francium*, *knights* service, *serjeanty* and free socage. These tenures are dealt with under their separate headings. Base or non-free tenure was tenure in villenage (g.n.) and copyhold (g.s.), and see also Manor.

**TEPICY**, a territory of Mexico facing on the Pacific Ocean and bounded N., E. and S. by Sinaloa, Durango and Jalisco. Area 11,275 sq. m. Pop. (1900) 150,098. The active volcano of Ceboruco rises in the western part of the territory. The slopes and valleys are densely wooded, the lower regions being very fertile and adapted to tropical agriculture. The town of Tepic is situated, and the climate hot, damp and malarial. The Rio Grande de Lerma, or Santiago, is the principal river, whose sources are to be found on the high plateau in the state of Mexico. The next largest river is the Mezquital, which has its sources in the state of Durango, not far from the city of that name. The products of the territorial coast lands are sugar, cotton, tobacco, maize, palm oil, coffee, fine woods and medicinal plants. Mining attracts much attention in the sierras, and its mineral deposits are rich. There are cotton and cigarette factories at the town of Tepic, besides sugar works and distilleries on the plantation tenures. The capital of the territory is Tepic (pop. 15,488), attractively situated on a small plateau 2050 ft. above sea level, 26 m. E. by S. of its port, San Blas, with which it is connected by rail.

The territory of Tepic was detached from the State of Jalisco in 1889 on account of the belligerent attitude of its population, chiefly composed of Indians. A territorial form of government places it more directly under the control of the national executive.

**TEPIDARIUM**, the term given to the warm (*tepidaus*) bath-room of the Roman baths. There is an interesting example at Pompeii; this was covered with a semicircular barrel vault, decorated with reliefs in stucco, and round the room a series of square recesses or niches divided from one another by Telamones. The tepidarium in the Roman thermes was the great central hall round which all the other halls were grouped, and which gave the key to the plans of the thermes: it was probably the hall where the bathers first assembled prior to taking the cold bath or passing through the various hot baths, and was decorated with the richest marbles and mosaics: it received its light through clerestory windows, on the sides, the front and the rear, and would seem to have been the hall in which the finest treasures of art were placed; thus in the thermes of Caracalla, the Farnese Hercules, and the Tero Farnese, the two gladiators, the sarcophagi of green basalt now in the Vatican, and numerous other treasures, were found during the excavations by Paul III. In 1546, and transported to the Vatican and the museum at Naples.

**TEPLITZ** (Czech, *Teplice*), or *Teplitz-Schönau*, as it is officially called since the incorporation of the village of Schönau in 1805, a town of Bohemia, Austria, 80 m. N.N.W. of Prague by rail, 10 m. from the L. Teplice. Situated on the plain of the Biela, which separates the Erzgebirge from the Bohemian Mittelgebirge, and is a favourite watering-place, containing a large Kurhaus and numerous handsome bath-houses. The environs are laid out in pretty and shady gardens and promenades, the finest being in the park which surrounds the château of Prince Clary-Aldringen, built in 1751. The other chief buildings are the Roman Catholic Schlosskirche, built in 1568 and altered to its present form in 1790, the Protestant church, the Jewish synagogue with a conspicuous *synagogue* tower. The town contains the remains of several ancient towers, probably the remains of the Benedictine convent, but ascribed by local tradition to the knight Kolostuj, the legendary discoverer of the springs. The saline-alkaline springs of Teplitz, ten to twelve in number, ranging in temperature from 90° to 117° Fahr., are classed among what are called "indifferent" waters. Used almost exclusively for bathing, they are prescribed for gout, rheumatism, and some scrofulous affections, and their reputed efficacy in alleviating the effects of gun-shot wounds had gained for Teplitz the sobriquet of the "warriors' bath." Military baths are maintained in the town by the governments of Austria, Prussia and Saxony, and there are also bath-houses for the poor. Teplitz is much visited for the after-cure, after Carlsbad and similar spas. The number of patients is about 6000 and the passing visitors about 25,000. The presence of a bed of lignite in the neighbourhood has encouraged the industrial development of Teplitz, which carries on manufactures of machinery and metal goods, cotton and woollen goods, chemicals, hardware, sugar, dyeing and calico-printing.

The thermal springs are said to have been discovered as early as 1433, as the first mention of the baths occurs in the 16th century. The town is mentioned in the 12th century, when Judith, queen of Ladislaus I. of Bohemia, founded here a convent of Benedictine nuns, which was destroyed in the Hussite wars. In the 17th century it was a resort for the Elector of Saxony after Kinsky's murder (25th February 1634) the lordship was granted by Ferdinand II. to Johann Count Aldringen. His sister Anna, who inherited it, married Freiherr Friedrich von der ClARY, who assumed the additional name and arms of Aldringen. The family, which was raised to the rank of count in 1666 and of prince of the Empire in 1667, still retains the property. Teplitz figures in the history of Wallenstein, and is also interesting as the spot where the monarchs of Austria, Russia and Prussia first signed the triple alliance against Napoleon in 1813. It is a curious fact that on the day of the earthquake at Lisbon (1st November 1755) the main street of Teplitz collapsed under the remains of the *Tepic* hill.

**TERAMO**, an episcopal see of the Abruzzi, Italy, the capital of the province of Teramo, 16 m. by rail W.S.W. of Giulianova, a junction on the Ancona-Brindisi railway. Pop. (1901) 10,508 (town); 24,001 (commune). The town stands on the left bank of the Tordino, where it is joined by the Vezzola, at an altitude of 876 ft. above sea-level. The picturesque valley of the Tordino is here dominated by the peaks of the Gran Sasso d'Italia. The town is traversed by one straight wide street with large houses, but for the most part it consists of narrow lanes. The cathedral has a Romanesque Gothic portal of 1332 by a Roman marble worker named Deodatus, and the interior is decorated in the Baroque style, but still retains the pointed vaulting of 1134, introduced into Italy by French Benedictines; it contains a splendid silver antependium by the 15th-century goldsmith Nicolo di Guardiagrele (1433-48). The tower is fine. The church of S. Antonio is also in the Romanesque Gothic
TERAPHIM—TEREDO

637

style. Under the church of S. Anna dei Pompei remains of Roman houses and of the original cathedral have been discovered (F. Savini in Notizie degli scavi, 1898, 137). In the Communal Gallery is an altarpiece from the cathedral by the Venetian Jacobello del Fiore (1400-1439). The antiquities include remains of a gateway, a theatre and baths, as well as numerous inscriptions. The town manufactures wool and silk, and of straw hats and pottery.

The ancient Interamna Practuttiorum (so called to distinguish it from Interamna Lirenas and Interamna Nahars) was the chief town of the tribe of the Praetutti. Its pre-Roman necropolis was discovered in 1905 (F. Savini in Notizie degli scavi, 1905, 267). Of its municipal constitution little is known, indeed in an inscription of the end of the Republic it is spoken of both as a colonia and a municipium. It was situated on a branch of the Via Cæcilia (q.v.). Remains of an amphitheatre still exist. In the valley of the Vomatoe near Montorio was a Roman village, probably dependent on Interamna, with a temple of Hercules (Corp. inscr. Lat., ix, p. 484).

See V. Bindu, Monumenti degli Abruzzi (Naples, 1889), i sqq.

TERAPHIM (A.V., sometimes transcribes, e.g. Judges xvii. 5; xviii. 14 seq.; Hosea iii. 4; sometimes translates "image," 1 Sam. xix. 13; "idols," Zech. x. 2; "idolatry," 1 Sam. xv. 23; R.V. renders consistently "teraphim"), a Hebrew word, found only in the plural, of uncertain etymology. The name appears to be applied to some form of idol (cf. Gen. xxxix. 19 and 30), but details as to its precise configuration, &c., are lacking. From c. x. 14 to the 1st century B.C. it was in common use. In the early monarchical period a regular place in every household was still reserved for the teraphim; while in the 8th century Hosea (iii. 4) speaks of "ephod and teraphim" as essential elements in the national worship. Later the teraphim with other adjuncts of heathenish worship were banned by the prophets. The meaning of the Elohist story in Gen. xxxv. 2-4 clearly is that the employment of teraphim and of other heathenish practices of Aramean paganism was given up by Israel in order that they might serve Jehovah alone at Bethel. In Judges and Hosea the teraphim were closely connected with the ephod; both are mentioned in connexion with divination (cf. 2 Kings xxii. 24; Ezek. xxxi. 26; Zech. x. 2). Whether the teraphim were "consulted" by lot or not is uncertain. In view of Ezek. xxxi. 21 and Hosea iii. 4 it is difficult to suppose that the teraphim were purely household idols. The Rabbinical conceptions on the subject can be found in Buxtorff, Lex. Talm. (ed. Fischcr), 1315 seq. One of the most curious is that the teraphim consisted of a mumified human head (see also Ephod).

(W. R. S.; G. H. Bo.)

TEREBITHIA [symbol T] (atomic weight 159-2 (O=16)), a magnetic chemical element belonging to the rare earth group. It was originally called erbia by its discoverer Mo gönder (see Rare Earth). Pure terebithia compounds were obtained by G. Urbain (Compt. rend., 1904 seq.) by fractional crystallization of the nickel double nitrates, the ethyl sulphates, and the bismuth double nitrates of the terebithium earth. Terebithia appears to be trivalent. The oxide is a black or brown powder according as it is prepared from the exalate or sulphate, and when pure it is non-fluorescent, but mixed with gadolinia or alumina it possesses this property. It yields colourless salts; the crystallized sulphate has the formula Tb(SO₄)₂·12H₂O.

The terebithia earth obtained by these processes was a reddish brown powder. The element was first prepared by P. Cadet (J. Chem. Soc., 1906, 1556). It was isolated first by F. Demidoff (Loch. Minore, 1761, 1556). Thomas T. Chapman and H. E. Elbel (J. Amer. Chem. Soc., 1910, 32, 1446) obtained the element in a state of high purity.

TEREBITHYN, botanical name PISTACIA TEREBINTHUS, a member of the natural order Anacardiaceae, usually a small tree common in the south of Europe and the whole Mediterranean area. It has a purplish grey bark and compound leaves with two to four pairs, and an odd terminal one, of smooth dark green oval blunt leaflets, which when young are thin, translucent and strongly tinged with reddish purple. The very small numerous unisexual flowers are borne on panicles which spring from just above the scars of last year's leaves. The fruit is a small roundish bright red drupe with a scanty pulp. The plant has been long known in English gardens. A liquid oleo-resinous exudation, known as Chian, Scio or Cyprus turpentine, is obtained by cutting the stem. The Chian turpentine of commerce is obtained exclusively from the island of Scio; the produce is very small, a large tree yielding only 10 or 11 ounces in one year. An allied species, P. LENTISCA, is the mastich tree.

TEREDO, a genus of Lamellibranchiate Mollusca, of the order Eulamellibranchia, sub-order Adesmacea, family Terebridiacea. The animals included in this genus are commonly

when he painted the small portraits on copper of "Jan Six" and "A Young Lady" (Six Collection, Amsterdam). In 1648 he was at Münster during the meeting of the congress which ratified the treaty of peace between the Spaniards and the Dutch, and executed his celebrated little picture, painted upon copper, of the assembled plenipotentiaries—a work which, along with the "Guitar Lesson" and a portrait of a "Man Standing," now represents the master in the national collection in London. The picture was bought by the marquess of Hertford at the Demidoff sale for £250, and presented to the National Gallery by Sir Richard Wallace, at the suggestion of his secretary, Sir John Murray Scott. At this time Ter Borch was invited to visit Madrid, where he received employment and the honour of knighthood from Philip IV., but, in consequence of an intrigue, it is said, he was obliged to return to Holland. He seems to have resided for a time in Haarlem; but he finally settled in Deventer, where he became a member of the town council, as which he appears in the portrait now in the gallery of the Hague. He died at Deventer in 1681.

Ter Borch is excellent as a portrait painter, but still greater as a painter of genre subjects. He depicts with admirable truth the life of the wealthy and cultured classes of his time, and his work is free from any touch of the grossness which finds so large a place in Dutch art. His figures are well drawn and expressive in attitude; his colouring is clear and rich, but his best skill lies in his unequalled rendering of texture in draperies, the meaning of which are seen to advantage in such pictures as the "Letter" in the Dutch royal collection, and the "Patental Advice" (known as the "Satin Gown")—engraved by Wille—which exists in various repetitions at Berlin and Amsterdam, and in the Bridgewater Gallery. Ter Borch's works are comparatively rare; only about eighty have been catalogued. Six of these are at the Hermitage, six at the Berlin Museum, five at the Louvre; four at the Dresden Museum, and two at the Wallace Collection.

TERCEIRA, an island in the Atlantic Ocean, belonging to Portugal, and forming part of the Azores archipelago. Pop. (1900) 48,770; area, 224 sq. m. Terceira, i.e. "the third," was so called as being the third island of the archipelago to be discovered by the Portuguese. From its central position it was long the seat of administration, but its capital, Angra (q.v.) or Angra do Heroismo (pop. 10,788), has lost much of its commercial importance. The other chief towns are Ribeirinha (3690), and Praia da Victoria (3265). Unlike the neighbouring islands Terceira is extensively used for cattle-farming, and the summits of its mountains are generally level. It abounds in grain and cattle; but the wines are inferior, and fruits are raised merely for internal consumption. (See also Azores.)
known as "ship-worms," and are notorious for the destruction which they cause in ships' timbers, the woodwork of harbours, and piles or other wood immersed for a long period in the sea. They inhabit long cylindrical holes, which they excavate in the wood, and usually occur in great numbers, crowded together so that often only a very thin film remains between the adjacent burrows. Each burrow is lined with a layer of calcareous substance secreted by the mollusc; this lining is not usually complete, but stops short a little distance from the inner end of the burrow, where the teredo continues to take place.

In some burrows, however, the lining is complete, either because the animal has reached its full size or because some cause prevents it continuing its tunnel; in such cases the calcareous tube has a hemispherical termination. The burrows are usually driven in the direction of the grain of the wood, but not invariably so. When a knot or nail or the tube of a neighbour is reached, the course of the burrow is altered so as to bend round the obstruction. One burrow is never found to break into another.

The adult Teredo, when removed from its burrow and calcareous tube, is from a few inches to 3 ft. in length, according to the species, to which it belongs, and is cylindrical and worm-like in appearance. The anterior end, which lies at the bottom of the burrow, is somewhat enlarged and bears a pair of shells or valves, which are not completely separated by the mantle in life. The valves are triangular in shape and very concave on the side which is in contact with the animal. In front their edges are wide apart, and behind they are edge to edge. There is also a cavity or trough formed by the fold of the mantle, in front of which is a small opening, which is secreted by this part. Anteriorly this portion contains part of the body proper; posteriorly it is formed by the internal cavity of a horizontal partition in two chambers are separated by a pair of two tubular, outgrowths of the mantle called siphons, here united together. In the lower chamber are the elements of the foot, while in the upper the Lameillibranch structure. In the upper chamber anteriorly is the rectum. A thick muscular ring terminates this region of the body, and bears two calcareous plates shaped like spades or battle-axes. The expanded parts of these plates are free and project backwards; the handle is fixed in a deep socket or pit lined by epidermis. These calcareous plates are called pallets (Fr. paumeaux). Behind them are formed the pallets the tubular body burrow, and the two species to which it belongs, and is cylindrical and worm-like in appearance.

The principal organs of the animal, which belong to the branch Rhizaria—are situated in the anterior part of the body, forming a visceral mass, which extends some distance behind the valves. The heart is above the intestine and not perforated by it. These tubes are perforated by a dorsal vessel, which is rudimentary, and situated just above the mouth, while the posterior is large and passes between the middle parts of the shell-valves. The visceral mass is a distance behind the posterior adductor, and behind the rectum, and the visceral ganglia, which in most Lamellibranchs are attached to the ventral surface of the posterior adductor, are in this case at the end of the visceral mass and at the anterior end of the gills. Besides the visceral ganglia a cerebral and a pedal pair are present. The stomach is provided with a large crystalline style. The function of the pallets is to form an operculum to the calcareous tube when the siphons are withdrawn in the shell. The special tubes, which are the calcareous pallets, are in number generally two. The calcareous tube is provided with transverse laminae projecting into the lumen; and in some the external aperture is divided by a horizontal partition into two, one for each siphon.

The Teredo is dioecious, and the males are only in the proportion of 1:500 of the females. As in the case of the oyster, the ova are retained in the shell, and the male and female organs lying in the same stage of development. The segmentation of the ovum is unequal, and leads to the formation of a gastrula by epiboly. By the growth of the preoral lobe provided with a ring of cilia, and by the formation of a rudiment of the shell, the larva is provided with the calcareous shell, and the pelagic larvae, the valves of the shell have grown so large as to cover the whole of the body when the velum is retracted; the foot is also long, cylindrical and flexible, and can be protruded far beyond the shell. The valves of the stage at this are fages relates that at Guipuzcoa (N. Spain) a ferry-boat was sunk accidentally in the spring, and was raised four months afterwards, the soft timbers were already rendered useless by Teredo. How long the animals live is not accurately known, but Quatre-fages found that they nearly all perished in the winter. This cannot be so, as their last remains are usually to be found in the harbours of countries which are not subjected to the ravages of the Teredo. In Holland their most ravages are made in July and August. Iron ships have nothing to fear from their attacks, and the copper sheathing now almost universally used protects wooden hulls. A remarkable instance of the ease with which a ship could be taken from the bottom, and the wrecking taken place, is that of a ship in Russia, which went down in 1715, and was afterwards raised in 1720. The Teredo grows and burrows at an extremely rapid rate: spawning takes place in the spring and summer, and before the end of the year the animals are adult and their burrows of large size. Fourteen

FIG. 1.—Sagittal median section of Teredo a., anus; a.a., anterior adductor muscle; a.s., anal siphon; b.a., branchial siphon; c., cerebral ganglion; g., gill; h., heart; m., mantle; p.a., posterior adductor; p.g., pedal ganglion; r.a., renal opening; r.p., reno-pericardial orifice; v.g., visceral ganglion. (Partly after Grobben and Beuck, from Lankester's Treatise on Zoology.)
Near one-third of the area is occupied by hilly tracts, the remainder being undulating and flat land belonging to the depression of the Terek; one-half of this last, on the left bank of the river, is occupied by sandy deserts, salt clay steps, and arid stretches unsuitable for cultivation. The Caucasus Mountains are described under that heading. Tertiary formations, overlain by Quaternary deposits, cover a wide area in the plains and steppes. Mineral springs occur near Pyatigorsk.

The climate is continental. The mean annual temperatures are 1°.9 at Pyatigorsk (1580 ft., above sea; January 35°, July 70°) and 47° at Vladikavkaz (2345 ft.; January 23°, July 69°), but frosts a few degrees below zero are not uncommon. The mountain slopes receive an abundance of rain (37 in.), but the steppes suffer much from drought (rain between 10 and 20 in.). Nearly the whole of the government belongs to the drainage area of the river Terek, but the north-west corner is drained by the upper tributaries of the Kuma. In the lower part of its course the Terek flows at a higher level than that of the neighbouring plains, and is kept in its bed by embankments. Nevertheless inundations are frequent and cause great destruction.

The estimated population in 1906 was 1,454,880. The province is divided into seven districts, the chief towns of which are Vladikavkaz, Grozny, Kizlyar, Nalchik, Pyatigorsk, Sunzhinsk, and Khasyavurt, the last two being somad centres of administration. The culture of tobacco is important, and the area under crops being 9 per cent. of the total. Ely, wheat, oats, barley and potatoes are the principal crops. The vine is very extensively cultivated and the district of Pyatigorsk, where 1,500,000 gallons of wine are made annually. Live-stock breeding is widely engaged in, and fishing is an important source of income, especially at the mouth of the Terek. Tea is generally kept at the wholesale table, and the Sterling worth of honey and wax. Melons, cucumbers and sunflowers are extensively grown. The railway, which formerly stopped at Vladikavkaz, has been continued from the Beshan station, near Vladikavkaz, to Petrovsk on the Caspian Sea, and thence to Baku.

TERENCE. Our knowledge of the life of the celebrated Latin playwright, Publius Terentius Afer, is derived chiefly from a fragment of the lost work of Suetonius, De viris illustribus, preserved in the commentary of Donatus, who adds a few words of his own. The prologues to the comedies were among the original sources of Suetonius; but he quotes or refers to the works of various grammarians and antiquaries—Porcius Licinus, Volcacius Sedigitus, Q. Coconius, Nepos, Santra, Fenestella. There is uncertainty as to both the date of the poet's birth and the manner of his death. His last play was exhibited in 160 B.C., and shortly after its production he went abroad, "when he had not yet completed his twenty-fifth year." Cornelius Nepos is quoted for the statement that he was about the same age as Scipio Africanus the younger (born in 185 or 184 B.C.) and Laelius; while Fenestella, an antiquary of the later Augustan period, represented him as older than either. If Terence was born in 185, he published his six plays between the ages of eighteen and twenty-five. Even in an imitative artist such precocity of talent is remarkable, and the date is therefore open to legitimate doubt.

In order to have been born in Carthage, and brought to Rome as a slave. At Rome he was educated like a free man in the house of Terentius Lucanus, a senator, by whom he was soon emancipated; whereupon he took his master's nomen Terentius, and thenceforward his name was Publius Terentius Afer, of which the last member seems to imply that he was not a Phoenician (Poenus) by blood. He was admitted into the intimacy of young men of the best families, such as Scipio, Laelius and Pufius Philus; and he enjoyed the favour of older men of literary distinction and official position. In the circle of Scipio he doubtless met the historian Florus, who was brought to Italy in 168 B.C., and it is said that he have owed the favour of the Roman senators, near as much to his personal gifts and graces as to his literary eminence; and in one of his prologues he declares it to be his ambition, while not offending the many, to please the "boni."

Terence's earliest play was the Andria, exhibited in 166 B.C. A pretty, but perhaps apocryphal, story is told of his having read the play, before its exhibition, to Catullus (who, after the death of Plautus, ranked as the foremost comic poet), and of

Jefreys, in his British Conchology, gives the following species as British: Teredo norvegica, Spengler; T. navalis, Linn.; T. pedicellata, Quatrefages; T. megalota, Hanley. T. norvegica occurs chiefly in the northern counties. It was described by Thompson at Portpatrick in Wigtownshire, and occurred in Jefreys' time in abundance at Milford Haven. This species has been described by Gmelin and a number of other authors. It differs from its congeners by having the base of the pallets simple, not forked, and the tube semi-encrusted at its narrower posterior end. The length does not usually exceed a foot. It is the T. navalis of Celli, which Linnaeus referred; Celli called it T. marina. It occurs on all the western and southern coasts of Europe, from Christiana to the Black Sea, and is the species which causes so much damage to the Dutch wharves. The pallets of this species are small and forked, and the stalk is cylindrical. The tube is simple and not chambered at its narrow end. T. pedicellata was originally discovered by Quatrefages in the Channel Islands, at Toulon, in Provence and in Algeria. In T. megalota the tube is simple and the pallets like those of T. Home, and approximately 2 ft. in length. It has been recorded from both Vancouver's and Woodward's. It is known as T. fimbriata. In the Mediterranean it has also been found in the Channel Islands, at Toulon, in Provence and in Algeria. The shell of T. megalota is closely related to that of T. Home, and approximately 2 ft. in length. It has been recorded from both Vancouver's and Woodward's. It is known as T. fimbriata.
the generous admiration it manifested by Caccilius. A similar instance of the recognition of rising genius by a poet whose own day was past is found in the account given of the visit of Accius to the veteran Pacuvius. The next play was the Hecypa, first produced in 165, but withdrawn in consequence of its not having been received, and produced in 160. The Heauton Timorumenos appeared in 163, the Enneacles in 161, the Phormio in 161, and the Adelphoe in 160 at the funeral games of L. Aemilius Paullus. Of these six plays the Phormio and probably the Hecypa were drawn from Apollodorus, the rest from Menander. After bringing out these plays Terence sailed from Greek parts, either to escape from the suspicion of publishing the works of others as his own, or from the desire to obtain a more intimate knowledge of that Greek life which had hitherto been known to him only in literature and which it was his object to imitate in his comedies. The latter is the more probable motive, and we recognize in this the first instance of that impulse to visit the scenes familiar to them through literature which afterwards acted on many of the great writers of Rome. From this voyage Terence never returned. According to one account he was lost at sea, according to another he died at Stymphalus in Arcadia, and according to a third at Leucas, from grief at the loss by shipwreck of his baggage, containing a number of new plays which he had translated from Menander. An old poet quoted by Suetonius states that he was ruined in fortune through his intimacy with his noble friends. Another account has it that he was the cause of leaving behind him gardens, to the extent of about twelve acres, close to the Appian Way. It is further stated that his daughter married a Roman knight.

No writer in any literature, who has contented himself with so limited a function, has gained so great a reputation as Terence. He lays no claim to the position of an original artist painting from life or commenting on the results of his own observation. His art has no relation to his own time or to the country in which he lived. The chief source of interest in the fragmentary remains of Naevius, Ennius, Pacuvius, Lucilius, and Lucilius is their relation to the national and moral spirit of the age in which they were written. Plautus, though, like Terence, he takes the first sketch of his plots, scenes and characters, from the Attic stage, is yet a true representative of his time, a genuine Italian, writing before the genius of Italy had learned the restraints of Greek art. The whole aim of Terence was to present a faithful copy of the life, manners, modes of thought and expression which had been drawn from reality a century before his time by the writers of the New Comedy of Athens. The nearest parallel to his literary position may be found in the aim which Virgil puts before himself in his Aeneid. Another fact that will prove to his advantage is the popularity of his comedies, which were often acted on his life. To bring back the shepherds of Theocritus on Italian scenes. Yet the result obtained by Virgil is different. The charm of his pastoral is the Italian sentiment which pervades them. His shepherds are not the shepherds of Theocritus, nor are they in any sense true to life. The extraordinary result obtained by Terence is that, while he has left no trace in any of his comedies of one sketching from the life by which he was surrounded, there is perhaps no more truthful, natural and delicate delineator of human nature, in its ordinary aspect, of all leading kinds, than Lucilius is their relative to the national and moral spirit. His permanent position in literature is due, no doubt, to the art and genius of Menander, whose creations he has perpetuated, as a fine engraver may perpetuate the spirit of a great painter whose works have perished. But no mere copyist or verbal translator could have attained that result. Though without claims to creative originality, Terence must have had not only critical genius, to enable him fully to appreciate and identify himself with his originals, but artistic genius of a high and pure type. The importance of his position in Roman literature consists in this, that he was the first writer who set before himself a high ideal of artistic perfection, and was the first to realize that perfection in style, form, and consistency of conception and execution. Living in the interval between Ennius and Lucilius, whose original force and genius survive only in rude and inartistic fragments, he produced six plays, which have not only reached our time in the form in which they were given to the world, but have been read in the most critical and exacting literary epochs, and still may be read without any feeling of the need of making allowance for the rudeness of a new and undeveloped art.

While his great gift to Roman literature is that he first made it artistic, that he imparted to "rude Latium" the sense of elegance, consistency and moderation, his gift to the world is that through him it possesses a living image of the Greek society in the 3rd century B.C., presented in the purest Latin idiom. Yet Terence had no affinity by birth either with the Greek race or with the people of Latium. He was more distinctly a foreigner than any of the great classical writers of Plautus. He lived at the mediant height of three distinct civilizations—the mature, or rather decayed, civilization of Greece, of which Athens was still the centre; that of Carthage, which was so soon to pass away and leave scarcely any vestige of itself; and the nascent civilization of Italy, in which all other modes were soon to be absorbed. Terence was by birth an African, and was thus perhaps a fitter medium of connexion between the genius of Greece and that of Italy than if he had been a pure Greek or a pure Italian; just as in modern times the Jewish type of genius is sometimes found more detached from national peculiarities, and thus more capable of reproducing a cosmopolitan type of character than the genius of men belonging to other races.

The prologues to Terence's plays are of high interest. Their tone is for the most part apologetic, and indicates a great sensitiveness to criticism. He constantly speaks of the malleability and distraction of an older poet, whose name is said to have been Luscinius Lavinius or Lanuvius. The chief charge which his detractor brings against him is that of contumacito, the combining in one play of scenes out of different Greek plays. Terence justifies this practice by that of the older poets, Naevius, Plautus, and later by that of Ciceron and Quintilian, and the description of the plays to Scipio had the honour to be accepted by Montaigne and rejected by Diderot.

We learn from these prologues that the best Roman literature was ceasing to be popular, and had come to rely on the patronage of the great. A consequence of this change of circumstances was that comedy was no longer national in character and sentiment, but had become imitative and artistic. The life which Terence represents is that of the well-to-do citizen class whose interests are commonplace, but whose modes of thought and action are refined and intelligent. His characters are finely delineated and discriminated rather than, like those of Plautus, boldly conceived. Delicate irony and pointed epigram take the place of broad humour. Love, in the form of pathetic sentiment rather than of irregular passion, is the chief motive of his pieces. His great characteristics are humanity and urbanity, and to this may be attributed the attraction which he had for the two chief representatives of these qualities in Roman literature—Cicero and Horace.

Terence's pre-eminence in art was recognized in the Augustan age; and Horace expresses this opinion, though not as his own, in these words (Epistles II. i. 59):—

"Vincere Caecilius gravitate, Terentius arte."

The art of his comedies consists in the clearness and simplicity with which the situation is presented and developed, and in the
TERENTIANUS—TERM

Consistency and moderation with which his various characters play their parts. But his greatest attraction to both ancient and modern writers has been the purity and charm of his style. He makes no claim to the creative exuberance of Plautus, but he is entirely free from his extravagance and mannerisms. The superiority of his style over that of Lucilius, who wrote his satires a generation later, is immeasurable. The best judges and the greatest masters of style in the best period of Roman literature were his chief admirers in ancient times. Cicero frequently reproduces his expressions, applies passages in his plays to his own circumstances, and refers to his personages as typical representations of character.1 Julius Caesar's lines on Terence, the "dimidiatus Menander," while they complain of comic power, characterize him as "our sermons amator." Horace, so depreciatory in general of the older literature, shows his appreciation of Terence by the frequent reproduction in his Satires and Odes of his language and his philosophy of life. Quintillian applies to his writings the word elegansissima. His works were studied and learned by heart by the great Latin writers of the Renaissance, such as Erasmus and Melanchthon; and Casaubon, in his anxiety that his son should write a pure Latin style, inculcates on him the constant study of Terence. Montaigne2 applies to him the phrase of Horace: "on aura toujours le bon goût de lui." He speaks of "his fine expression, elegance and quaintness," and adds, "he does so possess the soul with his graces that we forget those of his fable." Sainte-Beuve devotes to him two papers of delicate and admiring criticism. He quotes Fénélon and Addison, "deux esprits polis et doux, de la même famille littéraire," as expressing their admiration for the inimitable beauty and naturalness of one of his scenes. Fénélon is said to have preferred him even to Molière. Sainte-Beuve calls Terence the bond of union between Roman urbanity and the Atticism of the Greeks, and adds that it was in the 17th century, when French drama possessed most truly Attic, that he was most appreciated. M. Joubert3 applies to him the words, "Le mont Hymenté est sur ses lèvres; on croirait aisément qu'il naquit sur le mont Hymenté."

The chief manuscript of Terence is the famous Codex Bembius, of the 4th or 5th century, in the Vatican. Another Vatican MS. of the 10th century contains illustrations based on an old tradition. Each play has an argument in metre by Sulpicius Apollinaris (2nd century of our era). We have also a valuable commentary newly edited by P. Wessner.) on five of the plays, derived from Eunapius and Donatus (both of the 4th century), and another of less importance by one Eugraphius. The edition was published at Strassburg in 1470. The most famous edition is that of Bentley, published at Cambridge in 1726. At present the best texts are those by K. Dziaziok (Lelzig, 1884), and A. Fleckせいten (Teubner, 2nd ed., 1898). Each of these bases its edition on English notes.

Molière mode large use of the Thermis in Les Fournières de scapin, and the subject of l'Ecole des maris is taken from the Adéphoe. Terence was translated into English verse by George Colman (1765). (W. Y. S.; E. H.)

TERENTIANUS, surnamed MAURUS (a native of Mauretania), Latin grammatical writer on prosody, flourished probably at the end of the 2nd century A.D. His references to Septimius Serenus and Aulus Avitus, who belonged to the school of "new poets" (poetae neoterici or novellii) of the reign of Hadrian and later, seem to show that he was a near contemporary of those writers. He was the author of a treatise (incomplete) in four books (written chiefly in hexameters), on letters, syllables, feet and metres, of which considerable portions have been printed on similar subjects. The most important is that which deals with metres, based on the work of Caesius Bassus, the friend of Persius. By some authorities Terentianus has been identified with the presbyter of Syene mentioned in Martial (i. 86), who would make his date about a century earlier; others, again, who placed Petronius at the end of the 3rd century (a date no longer held), assigned Terentianus to the same period, from his frequent references to that author.

Best edition, by H. Kell, Grammatici Latini, v.; with commentary by L. Santen (1829); see also Teuffel-Schwabe, Hist. of Roman Literature (Eng. tr.), 375a.

TERGESTE (mod. Trieste, q.v.), an ancient city of Istria, 26 m. by road E.S.E. of Aquileia, at the northern extremity of the peninsula of Istria, in a bay at the head of the Adriatic Sea. Its importance was in ancient days, as now, mainly due to its harbour. The dates of its foundation are uncertain; it is first mentioned about 100 B.C. as a village. In 52 B.C. it was attacked by barbarian tribes from the interior. In 33 B.C. Augustus during his Dalmatian wars built a wall and towers there, as an inscription records; in a medieval copy of it the emperor Frederick III. mentions his own restoration of the city walls for the fourth time in 1470. At this time it probably became a colony, as it certainly was in Pliny's days. It appears to have had an extensive territory assigned to it. The lofty situated cathedral of S. Giusto occupies the site of a Roman temple. An inscription of the walls and column of the basilica is still preserved in the tower. Into the façade are built fragments of sepulchral reliefs. The church itself has a curious plan which is due to its having been formed out of two distinct churches standing side by side, which were united in the 14th century. Each of these is a basilica with ancient columns and mosaics in the apse. The southern church, S. Giusto, has a central dome. The so-called Arco di Riccardo is a half-buried Roman arch with Corinthian pilasters, possibly a triumphal arch, possibly connected with an aqueduct.

The museum contains inscriptions, mosaic pavements, &c., from the ancient town, of which no remains beyond those mentioned now exist above ground.

TERLIZZI, a town in Apulia, Italy, in the province of Bari, and 18 m. by steam tramway W. from that town, situated in the midst of a fertile plain, 621 ft. above sea-level. Pop. (1891) 23,394. It has a castle which at one time was very strong, and occasionally resorted to by the Emperor Frederick II. and afterwards by the Aragonese sovereigns. The walls and towers still remain, but the fosse has been turned into boulevards. Terlizzi has some trade in the wine and fruit of the district. Near it, in an ancient tomb, was found in 1745 a fine inkaost inlaid in silver.

TERM, an English word which has various meanings, all arising from its etymology (Lat. terminus), and the idea of limiting or defining.

A term of years, in English law, is the time during which an interest in an estate for life or for years is enjoyed, also the interest itself, because such an interest must determine at a definite time. If the interest be for life, it is an estate of freehold for years, on which the tenant has the same rights in the estate, and so personally, even though the length of the term—for leases of 1000 years—may far exceed in duration any possible life estate. A term of years is of two kinds—the first that created by an ordinary lease reserving a rent, as of a house or a building lease; the second that created by a settlement or a will, usually without rent reserved, for the purpose of securing payment of money, such as portions to younger children, by the owner of the land. Both kinds have been considerably affected by the Conveyancing Acts of 1881 and 1882, which enable a mortgagee or mortgagee in possession to make certain leases. Before 1845 provision was always made in conveyances for keeping the foot and town or the siting and amount of the town or the siting and amount of the town rablear, but these fosse has been turned into boulevards. Terlizzi has some trade in the wine and fruit of the district. Near it, in an ancient tomb, was found in 1745 a fine inkaost inlaid in silver.

Both kinds have been considerably affected by the Conveyancing Acts of 1881 and 1882, which enable a mortgagee or mortgagee in possession to make certain leases. Before 1845 provision was always made in conveyances for keeping the foot and town or the siting and amount of the town rablear, but these fosse has been turned into boulevards. Terlizzi has some trade in the wine and fruit of the district. Near it, in an ancient tomb, was found in 1745 a fine inkaost inlaid in silver.
although the term had been satisfied—that is, the purpose for which the term has been created had been fulfilled. By the Assignment of Satisfied Terms Act 1843 the assignment of satisfied terms was rendered unnecessary. The Conveyancing Acts 1881 and 1882 give power to enlarge the unexpired residue of a long term in certain cases into the fee simple.

Terms, in the sense of a limited and certain period of time during which the law courts are open, used to affect only what were called in England the superior courts—that is, the king's bench, common pleas and exchequer. They were originally the leisure seasons of the year which were not occupied by great feasts or fasts of the Church or by agriculture. Their origin is no doubt to be traced back to the legislation of the early Christian emperors, the principle being adopted in England through the influence of ecclesiastical judges. Terms were regulated by many acts of parliament, the effect of which was to confine to a comparatively short period the time during which the courts could sit in banco—that is, for the decision of questions of law as distinguished from the execution of opinions of fact. There were four terms, Hilary, Easter, Trinity and Michaelmas, the average duration of each being about three weeks. All legislation on the subject previous to 1873 is now merely of historical interest, for by the Judicature Act of that year terms were abolished so far as related to the administration of justice and sittings substituted. The previous subdivisions of the legal year were, however, retained, the dates of commencement and termination being somewhat changed. The Michaelmas sittings of the high court and court of appeal are fixed by the 19th of October, the Hilary or Hilary sittings by the 14th of January to the Wednesday before Easter, the Easter sittings from the Tuesday after Easter week to the Friday before Whitsunday, and the Trinity sittings from the Tuesday after Whitsun week to the 12th of August, all dates inclusive. The old terms, with their duration as fixed by statute, are now kept alive only for the purpose of reference in all cases in which they are used as a measure of time. In the United States the terms or sittings of the courts are not limited to any fixed period of time, but vary according to the judges and the amount of judicial business which is likely to come before the courts. The dining-terms at the Inns of Court also correspond in point of time with the old terms and not with the sittings.

In universities and schools the word term is used for the period during which instruction is given to the students or pupils. University and school terms differ from law terms and from each other both in period and duration. At the university of Cambridge the academic year is divided into three terms, Michaelmas, Lent and Easter; while at the university of Oxford there are four terms in the year, Michaelmas, Hilary, Easter and Trinity. School years now generally consist of three terms, divided by Christmas, Easter and Summer holidays, the old half-years having gradually been abolished. In higher educational institutions in the United States the university or college year is generally divided into three terms called either the Fall, Winter and Spring terms, or much less frequently the first, second and third terms. In some institutions, however, the so-called semester system has been adopted, the year being divided into two terms, so far as instruction is concerned, though even in these cases vacations at Christmas time and in the early spring divide the year into three parts, which are sometimes, though not in the usual or proper sense, called terms.

In Scotland terms are the days at which rent or interest is payable. They are either legal or conventional: the legal are Whitsunday and Martinmas; the conventional are fixed by agreement between the parties. Terms as times of court sittings were defined by 6 Anne c. 53, which fixed four terms—Martinmas, Candlemas, Whitsuntide and Lammas—for the now obsolete court of exchequer, to which the winter and summer sittings of the court of session now correspond.

TERMINUS, also called "termini" or "terms," in architecture, figures of which the upper parts only, or perhaps the head and shoulders alone, are carved, the rest running into a parallelopiped, and sometimes into a diminishing pedestal, with feet indicated below, or even without them (see HERMAE).

TERMINATOR (from the Latin terminare, to limit), in astronomy, the bounding line between light and darkness on the apparent disk of the moon or of a planet.

TERMINI IMERESE (anc. Thermae Himeraeae), a seaport town of Sicily, in the province of Palermo, 23 m. E.S.E. of it by rail. Pop. (1901) 70,632. It is finely situated on a promontory above its harbour, and it is possible that it was occupied by an early Phoenician settlement; as a town, however, it was not founded until 407 B.C. by the Carthaginians, after their destruction of Himera, in the vicinity of hot springs mentioned by Pindar (Od. xii. 19) which are still resorted to and are well fitted up (temp. 110° F.). It remained a Carthaginian colony, though thoroughly Greek in character, until it was taken by Rome in the First Punic war. In the time of Cicero it was flourishing, though not of great importance. Augustus sent a Roman colony to it, and a Roman road ran from it to Catana. Its medieval castle was destroyed in 1860. The modern town presents no features of interest; there is a collection of antiquities and pictures, with a considerable number of Roman inscriptions. Scanty remains of buildings of Roman times (an amphitheatre and a so-called basilica) exist in the upper part of the town; and outside it on the S. are considerable remains of two aqueducts of the same period crossing a deep ravine. The surrounding district is fertile.

Four m. E. of Termini, about r m. W. of the railway station of Cerda, on an E. spur of the Monte S. Calogera, called Monte Castellaccio, is a Cyclopean wall, about 60 ft. long, 70 ft. thick, and 30 ft. high in the middle, blocking the only access to the summit of the spur, on the N.E. Fortifications in this style are very rare in Sicily.

See B. Romano, Antichità Terminane (Palermo, 1838); Mauceri, Archopoli Pelagie nei dintorni di Termini Imere (Palermo, 1896). (T. A.)

TERMINUS, in Roman mythology, the god of boundaries, the protector of the limits both of private property and of the public territory of Rome. He was represented by a stone or post, set up in the ground with the following religious ceremonies. A trench was dug, in which a fire was lighted; a victim was sacrificed, and its blood poured into the trench; the body, upon which incense and fruits, honey and wine were thrown, was then cast into the fire. When it was entirely consumed, the boundary stone, which had been previously anointed and crowned with garlands, was placed upon the hot ashes and fixed in the ground. Any one who removed a boundary stone was accused (sacer) and might be slain with impunity; a fine was afterwards substituted for the death penalty. On the 23rd of February (the end of the old Roman year) the festival called Terminalia, according to Wissowa a festival not of the god but of the boundary stones (termini), was held. The owners of adjacent lands assembled at the common boundary stone, and crowned their own side of the stone with garlands; an altar was set up and offerings of cakes, corn, honey and wine were made (later, a lamb or a sucking pig was sacrificed). The proceedings closed with songs to the god and a general merrymaking, in which all the members of the family and the servants took part. A similar festival was also held at the old boundary of the Roman territory between the fifth and sixth milestones on the road to Laurentum. The custom of fixing the boundaries of property and the institution of the yearly festival were both ascribed to Numa. Another Sabine prince, Titus Tatius, had dedicated a stone to Terminus on the Capitoline hill. When Tarquinius Superbus desired to build a temple to Jupiter, the auguries forbade its removal, and it was enclosed within the walls of the new sanctuary, an indication of the immovability of such stones and of the permanence of the Roman territory. Terminus was probably in its origin only an epitaph of Jupiter. The fact of the inclusion of his statue in the temple of Jupiter Capitolinus; the hole cut in the temple roof so that he might be worshipped in the open air as being, like Jupiter, a god of

1 Agathocles was a native of Thermae.
the sky; and the later assumption of a Jupiter Terminus or Terminalis (cf. the Greek Zeus' apo) support this view.

See Dion. Halic. ii. 74; Plutarch, Numa, 16, Quast. Rom., 15; Livy i. 55; Horace, Epodes, ii. 59; Ovid, Fasti, ii. 637, 677; Siculus Flaccus in Gromatici veteres, ed. Lachmanne (1848); G. Wissowa, Religion und Kultur der Körner (1902); W. W. Fowler, The Roman Festivals (1899); G. Jourde, Le Culte du dieu Terme (Paris, 1886).

**TERMITE**, the name applied to a group of insects with four wings which are developed outside the body (a large proportion of the individuals become adult, however, without wings appearing at all). The wings are of nearly one size, of long, narrow form, of paper-like consistence, and in repose are placed flat on the back of the insect so that only one wing shows. After a short time the wings are shed, and newly emerged adults remain as evidence of the individual being a winged form. The mouth has strong mandibles. Formerly termites were classed as a part of the order Neuroptera, but more recently they have been separated by certain zoologists from the true Neuroptera, and associated with some other forms as an order Corrodentia.

By Packard they have been associated with Mallophaga, and called Platypitera. They now constitute with the Embidina—a small and obscure family—the order Isoptera, of which about 300 species are known. Termites are more widely known as white ants, but as they are extremely different from true ants, and as they are rarely white, this designation is very deceptive, and should be abandoned. Termites are found only in warm climates, where they are sometimes very destructive. They are vegetarian, but occasionally eat, or destroy, dry animal matter. The basis of their alimentary regimen is woody matter. Some of them make use of fungi growing in their abodes as food; some cut and store grass; others prepare a peculiar kind of food, which is stored in a tough, dry form, so that it has to be moistened before it can be eaten. Termites are social insects; many of them construct large edifices called termittaria and often spoken of as nests. A termitarium frequently contains an enormous number of individuals forming the society or colony. Termites are totally different in structure and development from all other social insects, but their social existence exhibits numerous analogies with that of the ants and other social Hymenoptera. The most remarkable of these analogies is that the reproduction of the species in each community is confined to a single pair, or to a very limited number of individuals. The members of one society or colony, however numerous or diminutive they may be, are the descendants of a single pair. The colony is—so far as is known, and on this, as well as on many other points, authentic information is scanty—first started by a pair of winged individuals that cast their wings, secrete themselves in a suitable place, and produce young. The colony, however huge, being subsequently developed by the extreme fertility of the reproductive pair. Very little is known as to how long a colony endures, and, as there is great variety in the social conditions of different kinds of termites, it is probable that there is considerable difference as to the point in question. As a rule a family or colony has only a single termitarium, but there are cases in which a single family has several separate abodes, though usually only one of them is a real home containing reproductive individuals. The social life in termites, as well as in all other social insects, is clearly a development of the family life. It is accompanied by extraordinary modifications of the forms of the individuals constituting the society, and by a great division of labour. As regards the forms, or castes, termites differ totally from those of other social insects; in the latter case there are great differences between the males and females, and the whole of the castes are of the female sex, whereas in termites the males and females are extremely similar, and the castes are in no way related with the relatives with sex. As the termite life is a family life, and as there is normally only a single pair of reproductive individuals in each community, it is easily comprehensible that if anything goes wrong with this pair, the community is at once thrown into a state of complete disorganization. But this misfortune is mitigated by a method which termites have of keeping individuals in an undifferentiated state, and of turning some of them speedily into reproductive individuals, whereby the community is restored to something like a natural condition of activity and growth.

Apart from the forms that are merely juvenile, the following kinds of adults are normally present in a colony: (1) workers, (2) soldiers, (3) winged individuals ready to leave the nest, (4) king and queen.

(1) The worker termite resembles the young in general appearance, and, like the young, has no trace of wings (fig. 1). The two segments behind the head are more contracted, so that head, thorax, and abdomen are more differentiated than they are in the young. The colour too is different, the young being milky-white, whereas the adult worker is variously pigmented according to its species, but is never milky-white. The worker is generally blind, and in only a few species does it possess rudimentary eyes. The species of the group *Calotermitidae* have no workers. In the other species the workers look after the eggs and young, and perform most, if not all, of the industrial work of the community. They are also, in some cases, effective combatants, though quite destitute of any special structures to suit them for this purpose. The sexual organs do not undergo development, but it has been satisfactorily ascertained that both males and females are represented amongst the workers. In certain species the workers seem to be dimorphic, so far as size is concerned, but this point has apparently been only very inadequately considered. Workers form a very large but variable proportion of the members of a community.

(2) The soldier termite is the most extraordinary feature of termite biology. It is more varied than any of the other castes, so that most of the species of termites can be best distinguished by their soldiers. The chief feature of the soldier is an extraordinary development of the head, or of the head and mandibles. There are two very distinct kinds of soldiers: (a) the flat-headed or mandibulate soldier, and (b) the nasute or rostrate soldier (fig. 2). In the first kind the head is usually developed out of all proportion to the rest of the body; the mandibles are frequently enormous, and, being in many cases asymmetric, give the appearance of deformity. In the nasute form the head is thick or convex, and may be described as unicorn—that is to say, it is prolonged in the middle so as to form a single pointed horn; the mandibles are never largely developed. No species of termite has both mandibulate and nasute soldiers, although the reverse is sometimes still
stated in books. The soldiers of some species are, however, dimorphic to the extent that larger and smaller forms occur in the same nest without intermediates. In other cases soldiers of simply variable size exist. The soldier termite and winged termite, though a few soldiers minute wing-rudiments can be detected. As in the worker, the development of the sex organs is arrested, but both sexes are represented. The function of the soldiers is probably, as stated by Haviland, defence. The mandibulate soldiers use their heads as blocks to stop gaps in the nests, and employ terrifying but somewhat theatrical devices, making threatening motions and producing noises by movements of the head and thorax. The nasute soldiers emit a fluid from the tip of the rostrum, and dab it upon their enemies with some skill. Soldiers are present in all species of termites except the South American genus *Anoplotermes*. It is a remarkable fact that in the group *Calotermes* soldiers exist although there are no workers, but in this case the function of the soldier seems to be very much that of a worker. Grassi says that in *Calotermes flavicollis* all the individuals of a community work for the common welfare. Moreover, in the *Calotermes* no very great development of the heads or mandibles occurs.

(3) Adult or Winged Termites.—Such of the young as do not become workers or soldiers grow and develop after the fashion usual in exopterygote insects. Moults take place, the wing-pads gradually increase in size, eyes appear, and finally pigmentation takes place, and the winged insect is perfected at the last moult (fig. 3). In prosperous colonies these winged insects are produced in large numbers and emerge at intervals as swarms. They have extremely feeble powers of flight, and apparently scarcely any other capability. They are a favourite food of a large number of animals, including even man. They have well-developed eyes and ocelli, and differ from all the other forms by their greater pigmentation. The function of these adults is to diffuse the species, and to favour crossing outside the family circle. Attaining the size of the second end is, in some cases, favoured by the fact that the whole of the individual individuals constituting a swarm consist of one sex only. This extraordinary fact is attested by Grassi, but has not yet received the attention it merits. If a termite colony be compared with a tree or plant, the winged forms, it is clear, functionally correspond to the flowers and seeds of the tree; indeed, Fritz Müller and Grassi go further, and conclude that the modes of diffusion and reproduction of termites are analogous to the modes of plants of containing the species by means of cleistogamous as well as ordinary flowers. The force of this comparison will be better appreciated after the reader has made himself acquainted with the facts connected with the neotenic forms of termites.

(4) King and Queen.—As a rule each community includes only a single pair of individuals apt for reproduction; these are the royal pair, or king and queen (fig. 4). They are adult termites that have shed the wings they formerly possessed. The queen usually undergoes an extraordinary increase in the size of the abdomen, which may be discerned to many hundred times its original capacity (fig. 4, A). In many species the queen is a royal cell, out of which they cannot move, though the workers, owing to their smaller size, can get in and out to tend them. In other cases the queen only is so imprisoned, the king being able to leave the cell. In still other cases neither king nor queen is effectually imprisoned. Much discrepancy of opinion exists as to the invariable presence of a king in each nest; this, however, is explained by Grassi's observation that the king is active and timid, and when a nest is opened seeks safety by running away and concealing himself, so that he is sometimes only discovered when the very last fragment of the nest is brought under scrutiny. Another point on which extremely diverse opinions are expressed is the copula of the sexes. It is usually stated that the swarming of termites is analogous to that of bees and ants, in which groups of insects the conjunction of the sexes takes place at this period, and at this period only. In the termites the reverse is the case. The swarming is not at all a nuptial flight; indeed, at that time the sexes are not apt for reproduction. Copulation only takes place after pairs have lost their wings and have established themselves together. It is repeated at intervals, and is thus quite dissimilar from the corresponding phenomenon in Hymenoptera. The male may be provided with an intromissory organ, so that copula during flight is impossible. Grassi has actually witnessed the act in subsequent life. Haviland is of opinion that in some cases the male fertilizes the eggs without connection with the female.

(5) Neotenic and Substitution Forms.—When a colony of termites is deprived of king and queen it can replace them by forms specially prepared. These substitution forms are of two kinds—(a) normal adult individuals, (b) neotenic forms. The latter may be recognised by their unattractive and unnatural kings and queens possessing reproductive powers, though the wings have never been developed and some other parts of the body have not taken on the fully adult state. These individuals are removed from nests of *Termes maigaetus*, and after three or four months again examined the nests: in three out of the five cases substitution pairs exactly resembling the original ones, with well-formed wing-stumps, were present; in the other two cases they failed to find the royal cell, and believes that the loss had not been repaired. In other species the bereavement is made good by means of neotenic instead of normal individuals, for in certain species neotenic forms are abundantly found. In the case of substitution forms there is usually more than one pair present in a colony, and sometimes numerous pairs exist. Grassi says that in Sicily the colonies of *Termes lucugus* are kept up entirely by neotenic kings and queens; in other words, the swarms are nearly or quite useless. The neotenic forms are compared to cleistogamous flowers; and this curious case is paralleled with that of a species of plant whose reproduction should be accomplished entirely by its cleistogamous flowers. Grassi, although at the same time it produced perfect flowers in abundance, the condition recorded by Grassi as the case, it is probably extremely exceptional. Fritz Müller found once a colony in which a true king was acting as consort to a considerable number of neotenic queens, no true queen being present.

In order to understand the causes phenomena presented by the casts and variety of forms of a single species of termites, it is not necessary to become acquainted with their food habits, which are very peculiar and may be described as comminucious. Termites have the habit of eating their case skins and even their dead companions, and in fact their system of keeping the nest clean seems to be that of eating the refuse of their own bodies till it no longer contains any digestible matter. This cannibalism is the more remarkable, as they will not eat other termites. The most curious part of their dietary is their complex system of feeding from the matters contained in the alimentary systems of their fellows. When a termite wishes food it stroke the body of another individual with its antennae, and the specimen thus caressed exudes from the posterior or from the anterior part of the body a drop of matter, which is eaten by the hungry one. The matter exuded from the place into which the termites is not very different; for at the base of the mouth, so that there are at least two kinds of this excretory food. The proteasial food (that comes from the proctodeal part of the body) is in great favour with adult termites, but so far as is known is not used for feeding the newly born young, which are believed to be fed on matter elaborated in the bodies of the adult workers and communicated by their mouths. Subsequently the young take also proteasial food, and triturated vegetable matter.

**Origin of the Castes.**—When termites are hatched from the eggs none of the remarkable differences that are manifested in the individuals in subsequent life can be detected. The sexes are in termites extremely similar in external characters. When the young are hatched they all appear nearly exactly alike, though on careful examination the sexes can be distinguished.
But no other difference than that of sex can be detected. In the article Ant in the ninth edition of the *Encyclopaedia Britannica* it was stated that “the distinction between soldier and worker can be easily seen in the egg.” This is contradicted by all modern observations, and is certainly erroneous. It is true that considerable difference of opinion exists as to when the distinction between soldier and worker first becomes evident, but all are agreed that it is not till after the growth is to some extent accomplished. The discrepancy that exists in opinions on this point is due to the facts: (1) that different species have been under observation; and (2) that the modification of the larva to form a soldier may begin at more than one period of the development even in the same species. It being ascertained that all termites begin as undifferentiated larvae, the question arises as to what causes the differentiation into castes. This question is the more important as two of the castes (the worker and soldier) do not at all resemble their parents. Grassi, from an examination of the individuals of a large number of nests of *Termes lucifugus*, arrived at the conclusion that all start as undifferentiated larvae, and that the regular development of *Termes* up to the perfect insect may undergo a deviation at various periods of life leading to the formation of workers, of neotenic forms, or of soldiers, the last passing through the stage of the young worker. He attributes this deviation, which may take place at various periods, to the influence of food, and attaches special importance to the salivary food. The soldiers have no wings; nevertheless a larva, or young nymph that has the rudiments of wings, can be made into a soldier. Grassi has found juvenile specimens that have already assumed the soldier form, although they possess the rudiments of wings. It appears from his observations that the worker may be considered as a form with arrested development, and the soldier as a form with arrested and much diverted development, while the neotenic forms are individuals in which the reproductive organs are perfectly developed, while some of the bodily structures have suffered arrest of development and even some amount of atrophy.

The soldier form of termite presents most difficult questions to the biologist, its special structures bearing no approximation to any characters possessed by the parents. Various theories have been proposed to account for this fact, but they are mere guesses. We may, however, mention that it is possible that soldiers and workers occasionally produce young. This has never been actually observed, but specimens have been found with the sexual organs partially developed, and F. Silvestri has recorded the occurrence of workers with some of the characters of the females, in South America, in a nest of *Termes struchii*.

**Fig. 5.**—Termitarium of *Termes malayanus*: f, fungus-chamber; c, royal cell.

**Termitaria.**—There is nothing in which termites display more variety than in their dwellings. These are sometimes of great beauty, and are always remarkable for their cleanliness and perfect order. The primitive *Calotermes flavicollis*—in which there is no worker—frequently inhabits rotten places in trees; at most it increases these a little by excavation, and modifies the passages by slight and imperfect barricades. In the case of the species of the community never attains a greater number than one thousand individuals, and even this is comparatively rare. On the other hand, we have the huge solid structures, 10 or 20 ft. high, delineated by Smeathman with cattle standing on their summits. Saville Kent has observed termitaria in Australia 18 ft. high. In equatorial Africa termitaria are frequently 12 to 25 ft. high and sharp-pointed. As a rule large termitaria do not occur in considerable numbers in a restricted area, but there are exceptions even to this. At Somerset, Cape York, there is one of the most remarkable termite cities of the world. Viewed from the sea, it appears as if the plain for a mile or more in extent were covered with pointed pillars, varying, according to different accounts, from 6 to 13 ft. in height, broad at the base and tapering to the summit, forming regular symmetrical pyramids. In this part of Australia there is also found the "compass," "magnetic," or "meridian" termite, the mounds of which have somewhat the shape of a tombstone, and have always the same orientation, the wider face of the structure always extending north to south. It has been suggested that this is connected with the necessity of regulating the temperatures of the inner part of the mound, but there is no evidence whatever on the point. A termitarium on being opened displays a vast number of irregular chambers separated by thin partitions (fig. 5, f), the royal cell being placed in the middle (fig. 5, c). The material used is of an earthy nature, but the interiors of many earthy termitaria are largely composed of woody fibre, the refuse proceeding from the alimentary canals of the insects being used for this purpose. A considerable number of the larger termites use fungi for their foodstuff. There are special chambers where these are cultivated, the matter on which the fungus is grown being of a woody nature and sponge-like in its structure. The fungi make their appearance as small globules. Probably the spores or mycelium are placed in the mass when it is formed by the termites; but very little is yet known as to this fungus and its mode of treatment by them.

**TERMONDE** (Flemish *Dendermonde*), a town of Belgium in the province of East Flanders, situated 25 m. S.W. of Antwerp at the junction of the Dender and the Scheldt. Pop. (1904) 10,441. It is still one of the five fortified places in Belgium, although its defences are not modernized. It was before Termonde that Louis XIV. in 1667 was compelled to beat an ignominious retreat through its defenders opening the dikes and flooding the country. The church of Notre Dame contains two fine pictures by Van Dyck, and one masterpiece of Crayer’s.

The fonts are of the 13th century.

**TERN** (Norsk *taurin, tenne eller tende; Swedish *tarna*; Dutch *Stern1*), the name now applied generally to a group of sea-birds,

1 "Stern" was used in Norfolk in the 19th century as a name for the bird commonly known as the black-tern, thus, confirming Turner, who, in 1544, describes what seems to have been the same
the sub-family Sterninae of the gulls or Laridae, but, according to
P. J. Selby, properly belonging, at least in the Farne Islands,
to the species known by the book-name of Sandwich tern, all
the others being those called sea-swallows—a name still most
commonly given to the whole group throughout Britain from their
long wings, forked tail and marine habit. In F. Willughby’s
Ornithologia (1676), however, the word tern is used for more
than one species, and, though it does not appear in the older
English dictionaries, it may well have been from early times as
a general name as it is now.

The breeding-grounds to which are but occasional visitors to the
British Islands, six species of terns may be regarded as
indigenous, though of them one has ceased from ordinarily breeding
in the United Kingdom, while a second has become so rare and
regularly appears in so few places that mention of them must for
prudence sake be avoided. This last is the beautiful roseate tern,
Sterna dougalli; the other is the black tern, Hydrochelidon
nigra, belonging to a genus in which the toes are only half
webbed, of small size and dark leaden-grey plumage. It is
without doubt the Sterna of Turner, and in former days was
abundant in many parts of the far country, to say nothing of
other districts. Though nearly all its ancient abodes have been
drained, and for its purposes sterilized these many years past,
not a spring comes but it shows itself in small companies in the
eastern counties of England, evidently seeking a breeding-place.
All around the coast the diminution in the numbers of the
remaining species of terns is no less deplorable than
demonstrable.
The Sandwich tern, S. cantans—named from the place of its
discovery, though it has long since ceased to inhabit that
neighbourhood—is the largest of the British species, equaling in
size the smaller gulls and having a dark-coloured bill tipped with
yellow, and dark legs. Through persecution it has been
extirpated in all its southern haunts, and is become much
scarcer in those to which it still resorts. It was, however,
never so abundant as its smaller congeners, the so-called
common and the arctic tern—two species that are so nearly
alike as to be beyond discrimination on the wing by an ordinary
observer, and even in the hand require a somewhat closer exa-
mination. The former of these has the more southern range,
and often affects inland situations, while the latter, though by
no means limited to the Arctic circle, is widely distributed over
the British isles. The former resorts to the more southern
localities where, as on the Farne Islands, both meet and breed
without occupying stations apart. The minute distinction of
these two species cannot be briefly given. It must suffice here
to state that the most certain difference, as it is the most easily
recognizable, is to be found in the tarsus, which in the arctic
tern is a quarter of an inch shorter than in its kinsman. The
remaining native species is the lesser tern, S. minuta, one of the
smallest of the genus and readily to be distinguished by its
permanently white forehead. All the species already mentioned,
except the black tern, have much the same general coloration—
species as “rostati lingua sterna appellata.” In at least one
instance the word has been confounded with one of the old forms
of the modern Starling (g.v.). To Turner’s name, repeated by
Gosner and other authors, we owe the introduction by Linnaeus of
Sterna into scientific nomenclature. “Istern” is another Dutch
form of the word.

1 It was known there as carr-swallow, carr-crow (corrupted into
carr-hundo), and blue-far (g.v.).

2 Linnaeus’s diagnosis of his Sterna hirundo points to his having had an “arctic”
tern before him; but it is certain that he did not suspect that specific appellation (already used by other writers for
the “sandpiper” tern) to cover a second species. Some modern
authorities disregard his name as being insufficiently definite, and
much is to be said for this view of the case. Undoubtedly
“hundr” has now been used so indiscriminately for one species
or the other, that confusion arises, perhaps in fact, by adopting the epithets of Naumann (181, pp. 1847, 1848),
who, acting on and confirming the discovery of Nitzsch (who
first gave the specific differences), called the southern species
S. fluidissima and the northern S. macrura. Temminck’s name
S. arctica, applied to the latter a year afterwards, has, however, been
most generally used for it.

the adults in summer plumage wearing a black cap and having
the upper part of the body and wings of a more or less pale
grey, while they are mostly lighter beneath. They generally
breed in association, often in the closest proximity—their nests,
containing three eggs at most, being made on the shingle or
among herbage. The young are hatched clothed in variegated
down, and remain in the nest for some time. At this season the
parents are almost regardless of human presence and expose
themselves freely.

which half-a-dozen other species have been recorded as
occurring in British waters, and among them the Caspian tern,
S. caspia, which is one of the largest of the genus and of wide
distribution, though not breeding nearer to the shores of
England than on Sylt and its neighbouring islands, which still
afford lodgings for a few pairs. Another, the gull-billed tern,
S. anglica, has also been not infrequently shot in England. All
these species are now recognized,—though the contrary was once
maintained—as inhabitants of North America, and many go
much farther. S. forsteri is the North American, and S.
medanogaster the Indian tern.

Terns are found throughout the world, and among exotic forms may
be particularly mentioned the various species of noddy (g.v.). Often
confounded with these last are the two species called in books sooty
terns (S. fuliginosa and S. anasthetes), but by sailors “egg-birds”
and “black-legged” terns. They are found in innumerable multitude to
certain islands within the tropics, where they breed, and the wonderful assemblage known as “wide-
awake fairs” on the island of Ascension has been more or less fully
described in many very ancient times. W. Dampier in his
voyage to New Holland in 1699 particularly described and figured the sooty
tern (Voyages, iii. p. 142), discriminating it from the noddy, from
which it had not before been distinguished. (A. N.)

Ternate, a small island in the Malay Archipelago, off the north
coast of Halmahera, in 6° 48’ N., 127° 10’ E. It is nearly
circular in form, with an area of about 25 sq. m., and consists
almost entirely of a remarkable volcano (5400 ft.) formed of
three superimposed cones. Frequent destructive eruptions
have occurred. On the island is the small town of Ternate,
which, in spite of its good harbour, carried on no considerable
trade or shipping, and has only 3000 inhabitants. But it is
the headquarters of the Dutch residency of Ternate, which
exercises authority over the area of the ancient kingdoms of
Ternate and Tidore. The residency consists of the following
groups of islands: the Halmahera group, the Bachan and the
other islands on the Sula Island, with the islands near the north
of New Guinea (Gehe, Vaigen, Salawati, Misol, collectively
called the Papuan Islands), the western half of New Guinea as
far as 141° E., with the islands in Geelvink Gulf on the north
coast of New Guinea (Schouten Islands, Yapen, &c.),
along with others on the south coast. To this residency also belong
the state of Banggai in East Celebes, and the Banggai Islands.
The residency stretches from 2° 43’ N. to 5° 45’ S., and 121°
141° E., with an area of 155,800 sq. m. The Dutch government
exercises direct authority only over parts of Ternate, Halmahera,
Bachan and Obi Islands. Its rule over the other groups it
carries on through the sultans of Ternate and Tidore (g.v.).
Both the island and town of Ternate suffer from their isolation,
and have never regained the importance they had in former
centuries. Pop. of the whole residency (1905) 168,415. The
inhabitants are of Malay race and Mahommedans in religion.
The breaking up of the old government of the Moluccas tended
to make Ternate perhaps the most important Dutch-Indian
political centre of the archipelago east of Celebes. Nominally
the sultan is still ruler, but virtually his powers were greatly
curtailed by his conventions with the Dutch-Indian government,
and even as an ex-sultan he is the nominal head of his grandees,
many of his former rights to the Dutch resident, who now bears the
de facto governor of the easternmost colonial possessions of
Holland, especially since the transfer of Dutch New Guinea
in 1901. Among the rights surrendered by the sultan of
Ternate to the Dutch were those of granting monopolies and
mining concessions, now vested in the Dutch resident. The island
of Bachan is worked by a kind of chartered company. For
surrendered rights and privileges the sultan and his grandees
received monetary compensations in the shape of annual sub-
ventions, and these also have been paid for the losses formerly
incurred by the wilful destruction of the nutmeg plantations,
carried out in order to enhance the value of this commodity
and monopolize its cultivation. The restrictions on nutmeg-
growing have long since been removed, and many plantations,
with free labour, have been started in Ternate since 1885.
It is a curious fact that Christianity has declined in Ternate in
modern times, though it was an early stronghold, and the
modern Roman Catholics are strictly connected with the
churches in the town.
TERNI (anc. Interamna Nakara), a town, episcopal see, and
the seat of a sub-prefecture of the province of Perugia, Italy,
situated among the Apennines, but only 426 ft. above sea-
level, in the valley of the Nera (anc. Nar), from which the town
took its distinguishing epithet, 5 m. below its junction with
the Velino, and 70 m. N. by E. of Rome by rail. Pop. (1906)
20,230 (town), 33,256 (commune). It has important iron and
steel works and iron foundries, at which armour-plates, guns
and projectiles are made for the Italian navy, also steel castings,
machinery and rails, a royal arms factory, and steel works.
Terni lies on the main railway line from Rome to Foligno and
Ancora, and is the junction for Rieti and Sulmona. Its most
interesting buildings are the cathedral (17th century, with
remains of the earlier 13th century façade), the church of
S. Francesco (partly dating from the 13th century, with some
frescoes of the 14th), and other old churches. Its antiquities
include traces of the city walls of rectangular blocks of tra-
vertine, remains of an amphitheatre of the time of Tiberius;
a temple, theatre and baths (?), and numerous inscriptions.
Remains have also been found of a pre-Roman necropolis.
The excavations and the objects found are described by A.
Pasqui and L. Lanzi in Notizie degli scavi, 1907, 575 seq. Five
miles to the east are the falls of the Velino (Cascate delle Marmore).
Alike in volume and in beauty these take a very high place
among European waterfalls; the cataract has a total descent
of about 650 ft., in three leaps of 65, 330 and 190 ft. respectively.
They owe their origin to M. Curius Dentatus, who in 272 B.C.
first opened an artificial channel by which the greater part of
the Lacus Velinus in the valley below Reate was drained. They
supply the motive power for the factories of the town.
Terni is the ancient Interamna (inter amnes, "between the rivers," i.e.
the meeting point of its branches, signally belonging to Umbria,
and founded, according to a local tradition preserved in an inscrip-
tion, in the year 672 B.C. It is first mentioned in history as being,
and has remained, a town of great antiquity, not only to the
people among his soldiers by Sulla. Its inhabitants had frequent litiga-
tions and disputes with their neighbours at Reate in connection
with the regulation of the Velinus, the waters of which are so
strongly impregnated with iron oxides that it is impossible
by the way in which they tend to block up their own channel.
The first interference with its natural course was that of M.
Curius Dentatus already referred to. In 54 B.C. the people of Reate appealed to Cicero
to plead their cause in an arbitration which had been appointed
by the Roman senate to settle disputes about the river, and in
connexion with this he made a personal inspection of Lake Velinus
and its outlets. In the time of Tiberius there was a project for
regulating the river and its outlets from the lake, against which
the citizens of Interamna and Reate energetically and successfully
protested (Tac. Ann. i. 79). Similar questions arose as the river
formed fresh deposits during the middle ages and during the
16th and 17th centuries. A branch of the Via Flaminia passed from
Narnia to Forum Flamini, and is given instead of the direct line
in the Antonine and Jerusalem itineraries. A road led from here
to the Via Salaria at Reate. Interamna is also mentioned in Cicero's
time as being the place where Clodius wished to prove
that he was on the night when he was caught in Caesar's house
at the celebration of the games of the Lupercalia. Tertullian
and his brother Florianus were probably natives of Inter-
amna, which also has been claimed as the birthplace of Tertullian,
the historian, but with less reason. During most of the middle
ages this town seems to have been deserted. It was a scene of
the defeat of the Neapolitans by the French on the 27th of
November 1798.
TERPANDER, of Antissa in Lesbos, Greek poet and musician.
About the time of the Second Messenian war, he settled in
Sparta, whither, according to some accounts, he had been
summoned by command of the Delphian oracle, to compose
the differences which had arisen between different classes in
the state. Here he gained the prize in the musical contests at
the festival Carnea (672-2 B.C.; Athenaeus, 635 e.). He is
regarded as the real founder of Greek classical music, and of
lyric poetry; but as to his innovations in music our information
is imperfect. According to Strabo (xiii. p. 618) he increased
the number of strings in the lyre from four to seven; others
take the fragment of Terpander on which Strabo bases his
statement (Bergk, 3) to mean that he developed the citharoid
lyre (sung to the accompaniment of the cithara or lyre) by
making the divisions of the ode seven instead of four.
The seven-stringed lyre was probably already in existence.
Ter-
pander is also said to have introduced several new rhythms in
addition to the dactylic, and to have been famous as a composer
of drinking-songs.
Fragments (the genuineness of which is doubtful) in T. Bergk,
Poetis Lyrici Graeci, iii.; see also O. Löwe, De Terpandri Lesbii
natale (1856), who places him about 676 B.C.
TERPENES, in organic chemistry, the generic name of a
group of hydrocarbons of the general formula (C₅H₈)n and
the more important oxygen derivatives, mainly alcohols, aldehydes
and ketones, derived from them. They may be classified into
several distinct groups: hemiterpenes, C₅H₄n; terpenes proper,
C₅H₈n; sesquiterpenes, C₁₅H₂₀n; and polyterpenes, C₅H₈n.
In addition to these, a series of open-chain olefine terpenes is
known.
The chief sources of the terpenes and their derivatives are the
essential oils obtained by the distillation or extraction by
pressure of various plants, chiefly of the Coniferae and different
species of Citrus. Certain of these oils consist very largely of
hydrocarbons; for example, those of terepine, citron, thyme,
orange, pine-needle, eucalyptus (from Solidago canadensis) and
cypress, while others contain as their chief constituents
various alcoholic and ketonic substances. With the exception
of camphene, all the terpenes are liquids, boiling approximately
between 160° and 190° C., so that it is almost impossible
for the people to separate them from the various essential oils by
fractional distillation. In order to prepare the individual members pure,
advantage is taken of the different physical properties of
their derivatives. The terpenes all possess a characteristic odour
and are fairly stable to alkalies, but are easily decomposed by
acids or by heating to a sufficiently high temperature. Many
polymerize readily, or are transformed into isomers by boiling
with dilute alcoholic sulphuric acid. Some oxidize rapidly on
exposure to air, passing into resinous substances. The forma-
tion of addition compounds with the halogens, halogen hydrides,
and with nitrosyl chloride, is characteristic of many, whilst
others unite readily with nitrogen peroxide. According to
A. v. Baeeyer (Ber., 1895, 28, p. 648; 1896, 29, p. 10) the
nitrosochlorides are not simple addition products, but bi-
molecular compounds or bisnitrosochlorides.
HEMITERPENES
The best known is Isoprene, C₅H₈, which is obtained on distilling
cauchochue or guuta-percha. It was synthesized by W. Euler
(1897, 59, p. 199) by distilling the addition compound of methyl
iodide and 1,3-dimethylpropyliden chloride with caustic potash.
It is an unstable liquid which boils at 33.5° C. and on heating
rapidly polymerizes to dipentene, the same change being effected
by heating with a dilute acetic acid-camphor solution. It combines
with bromine to form an unstable liquid dibromide; it also unites with
one molecule of hydrobromic acid to form the tertiary bromide
as dimethyllyliden; this points to its being β-methylidivinyl,
CH₂=C(CH₃)=CH₂ (V. A. Mokiewsky, Jour. Soc. Phys. Chem.
Russ., 1900, 32, p. 207).
TERPENES PROPER
The terpenes proper may be subdivided into the simple mono-
cyclic terpenes and the more complex (usually bicyclic) terpenes.
The simpler monocyclic terpenes are called camphenes, the
tetrahydrocamphenes becoming terpenes and the hexahydroxycamphene, the
carbon atoms being numbered according to the inset formula:
In the more complex terpenes the name camphene is retained, and camphene is
used for the dibasic dibutylcamphene. G. Wagner (Ber., 1894, 27, p. 1635 Anm.)
designates the hexahydroxycamphenes, the tetrahydroxycamphenes,
and the hexahydroxycamphenes. The position
of the double linking in the molecule is shown by the use of the symbol A followed by the number of the carbon atom immediately preceding it.

**Monocyclic Terpene**

Limonene, Δ1:8(9) terpene, C_{10}H_{16}. It is known in three forms, namely, L-, D-, and d-Limonene. D-Limonene is the chief constituent of oil of oranges, and is also found in oil of lemon and oil of bergamot. l-Limonene is found in oil of fir-cones and in Russian peppermint oil. Both are pleasantly smelling liquids, which boil at 176-178 °C. They differ from each other only in rotatory power. Dry hydrochloric acid gas converts them into optically active limonene hydrochloride, while hydrobromic acid converts them into the corresponding hydrobromides. When heated to a sufficiently high temperature they are converted into dipentene. Four optically active nitrosochlorides are known, two corresponding to each of the active limonenes, and the products with alcohol have the corresponding nitrosochlorides with p-vaniloxime. Dipentene (l-limonene) is found widely distributed in many essential oils, e.g. of camphor, Russian turpentine, cubeb, bergamot, cardamom, &c., and is also a product of the dry distillation of many vegetable essences. It may be produced by heating many terpenes (pinene, camphene, sylvestrene, limonene) for several hours at 250-270 °C; or by the polymerization of isoprene at 100-104 °C. To prevent polymerization it is best to use hydrochloride with anhydrous sodium acetate and glacial acetic acid (O. Wallach, Ann. Chem. Pharm., 1887, 239, p. 3). It is a pleasant-smelling liquid, which boils at 175-176 °C, and polymerizes on heating to high temperatures. When warmed with alcoholic sulphuric acid it yields terpinene, whilst concentrated sulphuric acid or phosphorus pentasulphide converts it into para-cymene.

Dipentene dichloride, C_{10}H_{14}Cl_2, best prepared by distilling the hydrochloride on the surface of a glacial acetic acid solution of dipentene, crystallizes in rhombic plates which melt at 50 °C. and boil at 118-120 °C. (10 mm.). It is decomposed by alkali. (Ber., 1893, 269, p. 2863) has obtained a cis-dihydrochloride of melting-point 25 °C. (cineol) by the action of hydrochloric acid on cineole.

**Terpinene, Δ1:4(8) terpene, has not as yet been observed as a pure oil, but is obtained by the action of hot dilute sulphuric acid on terpinel, terpin hydrate and cineol. It is an inactive liquid boiling at 183-185 °C, and is readily converted into terpinolene by sodium.

**Terpinolene, Δ1:4(8) terpene (?), is found in cardamom oil and is one of the volatile oils of wild olive. It is obtained by the action of hydrochloric acid on terpinol, terpin hydrate and cineol.

Phellandrene is a mixture of Δ1:5 terpene and Δ2:1(7) terpene (pseudo-phenellandrene) (F. W. Semmler, Ber., 1903, 36, p. 1749). It is found as d-phenellandrene in oil of water-tan, and oil of elemi, and as l-phenellandrene in Australian eucalyptus oil and oil of bay. It is an exceedingly unstable compound, and must be extracted from the oils by distillation in vacuo. The hydrocarbons obtained by distillation and eucalyptus oil correspond to Δ1:5-terpinene.

A similar hydrocarbon was obtained by C. Harries and M. Johnson (Ber., 1905, 38, p. 1832) by converting carvone hydrobromide into d-terpinolene, then reducing the hydrogen bromide of phellandrene tetrachloride into d-phenellandrene, which is finally reduced.

**Sylvestrene, Δ1:8(9) meta-terpene, is found in Swedish and Russian oil of turpentine and in various pine oils. It boils at 175-176 °C when distilled-volatile. It is one of the most stable of the terpenes and gives a characteristic deep blue colour on the addition of a drop of sulphuric acid to its solution in acetone anhydride. On treating the hydrobromide with bromine in the presence of iodine, a product is obtained which on reduction yields meta-cymene (A. v. Baeyer and V. Villiger, Ber., 1898, 31, p. 2007).

Caryophyllene is obtained by the distillation of caryllaline or vestyanine hydrocarbon (A. Ber., 1894, 27, p. 549). It was obtained as a liquid by E. Wallach and W. Perkin (J. Chem. Soc., 1894, 58, 232) by the application of the Grignard reaction to the ethyl ester of γ-tokohexahydrobenzoic acid, (C_{10}H_{14}O_2). The mixture of magnesium methyl iodide this ester yields the lactone of γ-hydroxyhexahydro-meta-toluic acid, which is transformed by hydrobromic acid into the corresponding β-hydroxy-hexahydro-meta-toluic acid. This lactone, on reduction with magnesium and hydrochloric acid, the ester of which by magnesium methyl iodide is converted into Δ1:meta menthenol-8 (2). The meta-menthenol on dehydration by potassium bisulphate yields caryophyllene (3) of boiling-point 179-180°C.

A synthetic, monocyclic terpene, viz. 1-methyl-4-isopropyl dicyclohexene was prepared by A. v. Baeyer (Ber., 1893, 26, p. 232). Succino-succinic ester is converted into the methyl isopropyl derivative, which on hydrolysis and elimination of carbon dioxide yields 1-methyl-4-isopropylidiketohexamethylen. This ketone is then reduced to the secondary alcohol, the hydroxyl groups replaced by bromine, and hydrobromic acid is then removed from the bromo-compound by boiling it with quinoline, leaving the terpine alcohol, a liquid which boils at 174 °C. and shows a complete terpene character.

**Alcohol and Ketone Derivatives**

Menthol (terpan-ol-3), C_{10}H_{16}O. The laevo variety is the chief portion of oil of peppermint, and is isomeric with the menthone obtained by E. Beckmann and M. Pleissner (Ann., 1891, 262, p. 21) from pulegone hydrobromide with sodium and alcohol. It is readily oxidized by hydrogen peroxide in dilute acid in the cold.

When readily oxidized by chromic acid to the corresponding ketone menthone. By the action of phosphorus pentoxide, or zinc chloride, it is converted into menthone, C_{10}H_{16}O, and when heated with hydrobromic acid, the corresponding hydrobromide is formed. It is reduced by hydrobromic acid and phosphorus to hexahydrocymene. The phosphorus haloids yield haloid esters of composition C_{10}H_{16}Cl, which, according to I. L. Kondakov (Journ. pharm. Chem., 1899 [2], 60, p. 257) are to be regarded as tertiary esters; a similar type of reaction is found in the case of carvomenthol. A d-menthol has been prepared from the t-mixture obtained by reducing menthene.

**Terpineol, C_{10}H_{16}O, is an inner oxide of terpin. It is found in the oils of wormwood and isomeric with the ketone. It is formed by the action of dry hydrochloric acid gas into wormseed oil, the precipitated hydrochloride being then distilled in a current of steam (O. Wallach and W. Brase, Ann., 1884, 225, p. 297). It is an inactive liquid, which boils at 176 °C. The oxygen atom in the molecule does not appear to possess either an alcoholic, ketonic, aldehydic or acid function.

**Terpineol, Δ1-terpenol-8), C_{10}H_{16}OH.** The term "terpineol" has been used to denote what is now known to be a mixture of various isomeric alcohols. Liquid terpeneol has been isolated from the oil of dalbergia odorifera and isomeric with the ketone.

Liquid terpineol is generally prepared by the action of dilute sulphuric acid on terpene hydrate. It consists of a mixture of various isomers, from which a solid terpineol melting at 35 °C. and an isomeric terpineol melting at 80 °C. may be obtained by replacing the halogen atoms in the active monohydrobromide of limonene by the hydroxyl group; it has also been obtained by the action of acetic acid on linalool. The racemic variety has been prepared by the action of formic acid on ylang, and was synthesized by the following method (W. H. Pirkin, Journ. Chem. Soc., 1904, 85, p. 654). γ-Cypentane tricarboxylic ester (1) (prepared by the
aceton of cyanoacetic ester on β-isodopropionic ester (2) is hydrolyzed to pentane-2-tert-butylicarboxylic acid (3), which when boiled with acetic anhydride and distilled gives 3-keto-1,3-dihydroxybenzoic acid (4). The ester of this acid, when treated with the Grignard reagent, yields β-oxoxyethylenehydrolic acid (5), which is converted into the corresponding 1-terpene by means of phosphoryl hydroxotetone into the latter compound on treatment with dilute alkali or pyridine yields Δ3-tetrahydro-para-toluic acid (6), the ester of which with magnesium and methyl iodide furnishes terpeneol (6):—

\[
\text{ROCOCH₂CH₂OCOCNCH₃} \xrightarrow{\text{HOC₆H₄CH₂CH₂OCOCNCH₃}} \xrightarrow{\text{CO₂H}} \]

This synthesis determines the constitution of terpin (7) and of dipentone (8), since the former is produced by the action of 5 per cent. sulfuric acid on terpineol, and the latter by heating terpineol with acetic acid sodium sulphate.

Terpineol adds on nitrosyl chloride to form a nitrosochloride, which on elimination of hydrochloric acid yields the oxime of an unsaturated oxo ketone; this on boiling with acids is converted into a strongly dextro-rotatory d-limonene (Beckmann, Comptes rendus, 1905, 140, p. 1303); when oxidized with Caro’s reagent it yields trioxoethylene hydroxycymene (A. V. Baeyer and V. Villiger, Ber., 1899, 32, p. 1321). The isomer isoborneol (Δ3(8)-terpenol-1) see A. V. Baeyer, Ber., 1894, 27, p. 443, 815.

Menthone (terpan-one-3), C₁₃H₁₄O₂, occurs with menthol in oil of peppermint. It was first obtained by M. Mariya (Journ. Chem. Soc., 1881, 39, p. 77) by oxidizing menthol with chromic acid mixture at 120°C, and was described as an inactive compound; but R. W. Atkinson (ibid., 1882, 41, p. 50) showed that when menthol was oxidized at 130°C a strongly dextro-rotatory monoborneol was produced. For the preparation of l-methone and d-methone (Beckmann’s d-methone) see E. Beckmann, Ann., 1889, 250, p. 325; 1891, 262, pp. 21 seq. The methone obtained by Beckmann by the reduction of pulegone hydrobromide was shown by C. Martine (Ann. chim. phys., 1904 (8), 3, p. 49) to be not completely identical with l-methone; it is consequently designated P-methone. An inactive methone has been synthesized as follows. β-Methyl pimelic ester is converted by sodium ethylate into methyl-1-cyclohexanol-3-carboxylic ester-4, into which the propyl group is introduced (also in position 4) by the action of isopropyl iodide and sodium ethylate. The ester is then hydrolysed, and carbon dioxide eliminated from the (carboxyl) group; the inactive methone is obtained (A. Einhorn and L. Klages, Ber., 1901, 34, p. 3753). It boils at 204–206°C, whereas Beckmann’s methone (C. A. Haller and C. Martine (Comptes rendus, 1905, 140, p. 130) synthesized natural methone from isopropyl iodide and the sodium derivative of methyl-1-cyclohexanol-3. It has also been prepared by condensing methylene, sodium ethylate, and the acetyl derivative of methyl-1-cyclohexanol-3 being converted into the propyl derivative, yielding acetylacetone, which is then hydrolysed to methone (G. Leser, Comptes rendus, 1902, 134, p. 1115). A. Koltz and L. Hesse (Ann., 1905, 342, p. 396) convert methyleneoxide (1) by means of ethyl oxalate and subsequent hydrolysis into methyleneoxide oxalic acid (2), the isopropyl ester of which on treatment with a methyl alcohol solution of caustic potash yields d-methone (3).

O. Wallach (Ann., 1900, 312, p. 171) showed that the oximes of cyclic ketones are converted by phosphorus pentoxide into oximes, which are readily decomposed by concentrated hydrochloric acid to yield aliphatic amino-acids; in this way methone may be converted into t-amido-decyl acid,

\[
\text{CH₂CO} \rightarrow \text{CH₂CH₂CH₂CH₂CH₂OCH₃} \xrightarrow{\text{CH₂CH₂OCH₃}} \]

Pulegone (Δ3(8)-terpenone-3), C₁₀H₁₈O₂, is an unsaturated ketone found in peppery oil, from which it may be obtained by distillation with a dextro-rotatory d-limonene obtained from thujyl alcohol. It is hydrolyzed to form pulegone, which yields ammonium silver nitrate on long boiling. It is reduced by hydrogen to 1-menthol. When heated with acetic anhydride it yields 1-menthone-4-acetate (3). When methylcylohexanelone and acetone are condensed together in the presence of sodium methylate, an isomer of pulegone boiling at 215–216°C is obtained. Pulegone combines with hydrobromic acid to furnish 4-bromopulegone, which on distillation in methyl alcohol solution with basic lead nitrate is converted into isopulegone (Δ8(9)-terpenone-3) (C. Baeyer and Ber., 1899, 32, p. 3361). It is a leavo-rotatory mixture (terpenone form) is also obtained by the oxidation of isopulegone with chromic acid. On reduction with sodium yields isopulegone and no menthol (cf. pulegone).

Carvone (Δ6: 8(9)-terpdenone-one-2), C₁₀H₁₄O, an unsaturated optically active ketone which is found very widely distributed in nature. The dextro form is the chief constituent of oil of caraway, and is also found in oil of dill; the levo form is found in oil of spearmint and fennel. The dextro form is obtained practically pure by the fractional distillation of caraway oil. The levo form from the oils containing it, by first forming its addition compound with sulpherated hydrogen, decomposing this by alcoholic potassium bicarbonate, and distilling the resulting mixture, it can be synthetically prepared from fimbine nitroisoc lorohene, alcoholic potash converting this compound into l-carvone, which on boiling with dilute sulphuric acid yields l-carvone; similarly terpineol nitroisoclorohene by the action of alcoholic potassium hydroxide on the boiling mixture, which on heating with carvone acid, on which heating with carvone is converted into carvacrol (1-methyl-2-propyl phenol), and is then oxidized to phenildrene, for C. Harries and M. Johnson (Ber., 1905, 38, p. 182) by reduction of carvone hydrobromide, obtained Δ6-carpon-2, which with phosphorus pentachloride gives chloro-2-phenildrene.

Bi-Cyclic Terpene Group

A nomenclature for the bicyclic hydrocarbons was devised by A. V. Baeyer (Ber., 1900, 33, p. 3771). According to this system each hydrocarbon contains two terepene atoms, which may be combined with each other three times, either directly or by means of other intervening carbon atoms, the combination forming a series of "bridges." These bridges are distinguished by numbers, denoting the number of carbon atoms contained in the bridge, the direct union of the two tertiary carbon atoms being designated as 0; if one carbon atom intervenes, then the number 1 is used, and so on. These three numbers serve as the characteristic for the compound. Hydrocarbons of this class with five terepene atoms are termed "bicyclenentes," with six atoms of carbon "bicyclohexenes," etc. Thus, for example, the compound (1) would be called "bicyclo-(4-0 -1.4)-heptene," and (2) would be called "bicyclo-(6-0-1.4)-heptene." These names are distinguished by (t) for the true thujene; the name "t-" signifies the true thujene isoborneol, whereas "l-" signifies the natural thujene isoborneol, which is isomeric with the true thujene. It is synthesized by heating the thujylglycerol isoborneol obtained from thujyl alcohol. It is exceedingly unstable. The isomeric B-thujene was also obtained by the same investigator by the dry distillation of trimethylthyjul ammonium hydroxide. It boils at 150–151°C, and possesses a different rotary power. Another 0-bridge bicyclic acid it yields terpinenol (2)-(terpen-ol-4) (O. Wallach, Ber., 1907, 40, p. 592). Pulegone, derived from "bicyclo(1-0 -1.3)-heptene," is found in many essential oils, and is the chief constituent of oil of turpentine; the l-variety is found in French oil of turpentine, the d-variety in Russian, American, and Swedish oil of turpentine. Pinene is also a component of "oil of thujylpiperita" and "oil of thujylolibanum, bay, fennel, sassafras, rosemary and of valerian." The active varieties are obtained by the fractional distillation of the various oils of turpentine. The inactive variety is obtained by heating pineine nitroisoclorohene with an alcoholic potassium hydroxide solution. O. Wallach, Ann., 1889, 252, p. 132; 1900, 258, p. 243), or better with methylamine (W. A. Tilden). The three varieties boil at 155–156°C. The resinous reaction by absorbing oxygen from the air, resinous products being formed, together with small quantities of formic and acetic acids.
Act oxidizing agents convert it into terpene and terfolic acids, whilst alkaline potassium permanganate in dilute solution oxidizes it to pinene glycol, \( \text{C}_{10}\text{H}_{16}\text{OH} \), pinonic acid, \( \text{C}_{10}\text{H}_{16}\text{O} \), pinic acid, \( \text{C}_{10}\text{H}_{16}\text{O} \), etc. The product of the reaction varies according to the temperature (G. Wagner, Ber., 1894, 27, p. 2270; F. Tiemann and F. W. Semmler, Ber., 1895, 28, pp. 1344–1778). Concentrated sulfuric acid converts it into camphene; and an alcoholic solution of this acid gives terepin in menstruum, and when heated to 250–270°C it yields dipentene; the most halogen acids at ordinary temperature convert it into the dihalogen halides of dipentene. 

Hydrochloric acid yields pinene hydrochloride (artificial camphor), \( \text{C}_{10}\text{H}_{16}\text{Cl} \), a white crystalline solid identical with bornyl chloride which melts at 131°C. Elimination of halogen hydride by means of a weak alkali (e.g., soap, silver acetate, &c.) combines it into camphene, which on heating and conversion of pinene into its hydrochloride is probably accompanied by an intramolecular rearrangement:

\[
\text{H}_2\text{C} = \text{C} - \text{CH}_2 \rightarrow \text{H}_2\text{C} = \text{C} - \text{CH}_2\text{C} = \text{C} - \text{CH}_3
\]

Pine. 
Bornyl chloride.

Nitric acid in aqueous alcoholic solution converts it into terpin hydrate. Pinene nitrosoroctrochlorel, \( \text{C}_{10}\text{H}_{16}\text{NOCl} \), was first obtained in 1874 by W. A. Tilden (Jahresth., 1874 p. 214) from nitrosyl chloride and a mixture of pinene and chloroform. O. Wallach (Ann., 1893, 251, p. 1290) prepared it by the reaction of the former with metallic potassium and ethyl nitrite on oil of turpentine in presence of fuming hydrochloric acid. W. A. Tilden (Jour. Chem. Soc., 1904, 85, p. 759) showed that strongly active pinene gives bad yields of the nitrosoroctrol at that time. Sodium, which acts as a reducing agent, and the action of potassium and ethyl nitrite on oil of turpentine is in presence of fuming hydrochloric acid. 

Camphene, \( \text{C}_{10}\text{H}_{18} \), also a bicyclo-[1.2.2]-heptene derivative, is a constituent of the oils of camphor, frankincense, camphor, ginger and of rosemary, and also of French and American oil of turpentine. It may be obtained by the action of sulfuric acid on pinene; by heating pinene hydrobromide or hydrochloride with sodium acetate or glacial acetic acid to 200°C; or by heating bornyl chloride with aniline (O. Wallach, Ber., 1892, 25, p. 916). According to Kononowalow it is best prepared by heating borneol with a diluted sulfuric acid (1:2) for about 6–8 hours, between 60–100°C, with water in the distillation apparatus. The products of this reaction vary rather slightly according to the sources from which it is obtained, the former being about 55°C and the latter about 135°C. It is known as d-, l- and l- forms or combinations with hydrochloric or hydrobromic acid, which with reduction with sodium and alcohol yields camphene. Many different oxidation products may be obtained from camphene, partly by the conditions of the experiment (J. Brecht, W. Jegelski, Ann., 1900, 310, p. 114; G. Wagner, Ber., 1890, 23, p. 2381; S. Miyado and F. Zienkowski, Ann., 1905, 340, p. 17; J. E. Marsh and J. A. Gardner, Jour. Chem. Soc., 1891, 59, pl. 648; 1896, 60, p. 74).

Pencalene, \( \text{C}_{10}\text{H}_{18} \), a bicyclo-[1.2.2]-heptene derivative, is not found in any naturally occurring products. The hydrocarbon may be obtained by the reduction of penciline and elimination of water from the reacting fenchyl alcohol, or by the elimination of hydrogen from the pencalene hydroxyl from the fenchyl halogen compounds (O. Wallach, Ann., 1892, 253, p. 145; 1898, 302, pp. 371 seq.).

The hydrocarbons and hydroxylates of camphene are the most probably best represented by the following formulae (pinene is given above):

Alcohol and Ketone Derivatives

Borneol (Borneo camphor). \( \text{C}_{10}\text{H}_{18}\text{OH} \) occurs in the pine cavities of Dryobalanops camphora, and in the oils of spice and rosemary: esters are found in many fir and pine oils. It may be prepared by heating camphor with alcoholic potash (M. Berthelot, Ann., 1859, 12, p. 363) or by reducing camphor in alcoholic solution with sodium (O. Wallach, Ann., 1885, 230, p. 225; J. Bertram and H. Walbaum, Jour. prak. Chem. 1894 (3), 49 p. 12). L. Tschugaev (Chem. Centralblatt, 1903, 4, p. 94) obtains pure d-borneol as follows: Sulfuric d-borneol, combusting in alcoholic solution (3) in the presence of a reducing of camphor is dissolved in xylene and converted into the sodium salt by metallic sodium. This salt is then turned into the xanthate, \( \text{C}_{10}\text{H}_{18}\text{OCNa} \), which with metallic sulphate yields the camphoronic acid, which, when heated, is decomposed and yields alcohol by steam distillation, which also decomposes any methylic xanthate of isoborneol that may have been formed. The residue is crystallized as hydrobromic acid, which may be obtained. It behaves as a secondary alcohol. Nitric acid oxidizes it to camphor, and when heated with potassium bisulfate, it gives camphene. With phosphorus pentachloride it forms a bornyl chloride, identical with camphoronic acid.

Isoborneol is a tertiary alcohol which may be obtained by dissolving camphene in glacial acetic acid, adding dilute sulfuric acid and heating to 50–60°C for a few minutes, the isoborneyl acetate so formed being sublimed and then distilled. 

Chronic acid oxidizes it to camphor.

Camphene (tanacetum), \( \text{C}_{10}\text{H}_{18} \), is found in many aromatic plants. Oil of this substance contains camphene, and of its chiefly \( \beta \)-thujone. Oil of artemisia and oil of sage contain a mixture of the two, whilst oil of absinthe contains principally the \( \beta \)-variety. The \( \alpha \)-form may be obtained by the action of zinc chloride or of zinc nitrate on the oil. The oil is obtained by distillation of half of the terpene. The nitrosochloride melts at 115°C (circa) and is a white pleasant-smelling powder. Alcoholic potash converts it into its nitrosopine, \( \text{C}_{10}\text{H}_{16}\text{NO} \).

Borneol. \( \text{C}_{10}\text{H}_{18} \), derived from bicyclo-[1.2.2]-heptane, is prepared by heating borneol iodide to 170°C for several hours with a concentrated solution of alcoholic potash (G. Wagner, Ber., 1900, 33, p. 2121), or by decomposition of the methyl esters of the \( \alpha \)- and \( \beta \)-forms. The former yielding \( \alpha \)-borneoic and the latter \( \beta \)-borneol (L. Tschugaev, Chem. Centralblatt, 1905, i, p. 94).

Camphene. \( \text{C}_{10}\text{H}_{18} \), also a bicyclo-[1.2.2]-heptene derivative, is a constituent of the oils of camphor, frankincense, camphor, ginger and of rosemary, and also of French and American oil of turpentine. It may be obtained by the action of sulfuric acid on pinene; by heating pinene hydrobromide or hydrochloride with sodium acetate or glacial acetic acid to 200°C; or by heating bornyl chloride with aniline (O. Wallach, Ber., 1892, 25, p. 916). According to Kononowalow it is best prepared by heating borneol with a diluted sulfuric acid (1:2) for about 6–8 hours, between 60–100°C, with water in the distillation apparatus. The melting- and boiling-points of camphene vary slightly according to the sources from which it is obtained, the former being about 55°C and the latter about 135°C. It is known as d-, l- and l- forms or combinations with hydrochloric or hydrobromic acid, which with reduction with sodium and alcohol yields camphene. Many different oxidation products may be obtained from camphene, partly by the conditions of the experiment (J. Brecht, W. Jegelski, Ann., 1900, 310, p. 114; G. Wagner, Ber., 1890, 23, p. 2381; S. Miyado and F. Zienkowski, Ann., 1905, 340, p. 17; J. E. Marsh and J. A. Gardner, Jour. Chem. Soc., 1891, 59, pl. 648; 1896, 60, p. 74).

Pencalene, \( \text{C}_{10}\text{H}_{18} \), a bicyclo-[1.2.2]-heptene derivative, is not found in any naturally occurring products. The hydrocarbon may be obtained by the reduction of penciline and elimination of water from the resulting fenchyl alcohol, or by the elimination of hydrogen from the pencalene hydroxyl from the fenchyl halogen compounds (O. Wallach, Ann., 1892, 253, p. 145; 1898, 302, pp. 371 seq.).

The hydrocarbons and hydroxylates of camphene are the most probably best represented by the following formulae (pinene is given above):
A vast amount of work has been done on the constitution of the camphor molecule. The earlier investigations on theready forma- tion of benzaldehyde derivatives by the breaking down of camphor led to the view that the molecule was a simple six-membered carbon ring. Subsequent research, however, showed that the formula proposed by J. Bredt (Ber., 1893, 26, p. 3047) in which camphor could be regarded as a bicycle-berried derivative is correct. This formula is based on the fact that camphoronic acids yield trimethylsuccinic, isolobutyr, and carboxylic acids, and carbon on dry distillation, and Bredt suggested that it was an aS-trimethylcarballylic acid, a conclusion confirmed by W. H. Perkins, jun., and J. F. Thorpe and H. W. K. Howarth (J. Soc. Chem. Ind., 1895, 15, 353) who isolated camphoric acid and camphonic acid, the latter being converted into a camphoronic acid by heating with hydrochloric acid in quinoline, which acid yields camphoronic acid (3) and some trimethyl glutaric acid:

\[
\text{CH}_3\text{COOH} \rightarrow \text{CH}_3\text{CO}+\text{CH}_3\text{CO}+\text{CH}_3\text{CO} \rightarrow \text{CH}_3\text{COOH} \quad (2)
\]

\[
\text{Fenofene, } \text{C}_9\text{H}_{10}\text{O}, \text{ is trimethyl-(2-7-7)-bicyclo(1-2-2)-heptane-3. It occurs in } d-\text{and } l-\text{forms, the former in oil of fenugreek and bulb of onion, the latter in oil of thuya. It may be converted into a mixture of the oils by treating the fraction boiling between 190-195 °C with nitric acid and distilling the product in a current of steam. The fenofenes are pleasant-smelling oils which boil at 192-193 °C, and on solidification melt at 5-6 °C. They do not contain with sodium bisulphite. They dissolve unchanged in cold concentrated hydrochloric and sulphuric acids, and are very stable; thus the monobromofenofene is only formed by heating the ketone with bromine to 100 °C under pressure (H. Czerny, Ber., 1900, 33, p. 2287). On oxidation with potassium permanganate it yields acetic and oxalic acids together with dimethylmalonic acid. By the action of hot concentrated sulphuric acid it yields acetyl-orthoxylene,}

\[
\text{CH}_3\text{CO}(\text{CO})\text{(CH}_2\text{)(CH}_3\text{)}(1-2)
\]

(1, J. E. Marsh, Jour. Chem. Soc., 1899, 75, p. 1058). When heated with phosphorus pentachloride at 150-155 °C with metacynamene. Since it does not yield any oxymethylene compounds, it cannot contain the grouping-CH=CH in the molecule.

**Hydrocarbons, C_{n}H_{2n}, of the Terpene Series**

Meuckland, C_{10}H_{(16)}(CH}_{16})(CH}_{16})(CH}_{16})(CH}_{16})(CH}_{16})(CH}_{16})(CH}_{16})(CH}_{16})(CH}_{16})(CH}_{16})(CH}_{16})(CH}_{16})(CH}_{16})(CH}_{16})(CH}_{16})(CH}_{16})(CH}_{16})(CH}_{16})(CH}_{16})(CH}_{16})(CH}_{16})(CH}_{16})(CH}_{16})(CH}_{16})(CH}_{16})(CH}_{16})(CH}_{16})(CH}_{16})(CH}_{16})(CH}_{16})(CH}_{16})(CH}_{16})(CH}_{16})(CH}_{16})(CH}_{16})(CH}_{16})(CH}_{16})(CH}_{16})(CH}_{16})(CH}_{16})(CH}_{16})(CH}_{16})(CH}_{16})(CH}_{16})(CH}_{16})(CH}_{16})(CH}_{16})(CH}_{16})(CH}_{16})(CH}_{16})(CH}_{16})(CH}_{16})(CH}_{16})(CH}_{16})(CH}_{16})(CH}_{16})(CH}_{16})(CH}_{16})(CH}_{16})(CH}_{16})(CH}_{16})(CH}_{16})(CH}_{16})(CH}_{16})(CH}_{16})(CH}_{16})(CH}_{16})(CH}_{16})(CH}_{16})(CH}_{16})(CH}_{16})(CH}_{16})(CH}_{16})(CH}_{16})(CH}_{16})(CH}_{16})(CH}_{16})(CH}_{16})(CH}_{16})(CH}_{16})(CH}_{16})(CH}_{16})(CH}_{16})(CH}_{16})(CH}_{16})(CH}_{16})(CH}_{16})(CH}_{16})(CH}_{16})(CH}_{16})(CH}_{16})(CH}_{16})(CH}_{16})(CH}_{16})(CH}_{16})(CH}_{16})(CH}_{16})(CH}_{16})(CH}_{16})(CH}_{16})(CH}_{16})(CH}_{16})(CH}_{16})(CH}_{16})(CH}_{16})(CH}_{16})(CH}_{16})(CH}_{16})(CH}_{16})(CH}_{16})(CH}_{16})(CH}_{16})(CH}_{16})(CH}_{16})(CH}_{16})(CH}_{16})(CH}_{16})(CH}_{16})(CH}_{16})(CH}_{16})(CH}_{16})(CH}_{16})(CH}_{16})(CH}_{16})(CH}_{16})(CH}_{16})(CH}_{16})(CH}_{16})(CH}_{16})(CH}_{16})(CH}_{16})(CH}_{16})(CH}_{16})(CH}_{16})(CH}_{16})(CH}_{16})(CH}_{16})(CH}_{16})(CH}_{16}) (1899, 75, p. 1058). When heated with phosphorus pentachloride at 150-155 °C with metacynamene. Since it does not yield any oxymethylene compounds, it cannot contain the grouping-CH=CH in the molecule.

**Olefine Terpenes**

Myrcene, C_{10}H_{18}, was first isolated by F. B. Power and C. Kleber from oil of bay (Schimmel & Co., Bulletin, April 1895, p. 11); it is the principal odour in oil of sassafras leaf. It is obtained from bay oil by shaking the oil with a 5 per cent. solution of caustic soda, followed by fractionation in vacuo. It boils at 67-68 °C (20 mm.), and polymerizes when heated for some time. When oxidized by potassium permanganate it yields benzoic and isobenzoic acid, a fact strongly suggestive of the presence of a hydroxytrimethylacetic acid in the molecule, with which it is probably identical. The facts are confirmed by the formation of isobutyric and isovaleric acids during the introduction of hydroxytrimethylacetic acid, which is a crystalline solid which melts at 153 °C and boils at 160 °C.
a more drastic oxidation with potassium permanganate yields acetone and \( \beta \)-methylidipic acid.

1. **Rheinol, \( \text{C}_6\text{H}_4\text{OH} \)** or (CH\(_2\))\(_2\)C=C(CH\(_3\))\(_2\) (CH\(_2\))\(_2\) (CH\(_3\))\(_2\) CH \( \text{CH}_2\text{OH} \), which occurs in the essence of geranium oil, is of rose color and of rose. It is a structural isomer of citronellol (P. Barbier and L. Bouveault, *Comptes rendus*, 1896, 122, pp. 599, 673; *Bill. Soc. Chim.*, 1900, 19, 3, p. 499), and its inactive form has been shown (B. Wecker, *Comptes rendus*, 1896, 122, p. 540) that it is obtained from the alkyl radical with alcoholic potash and then fractionating in vacuo. The geranial fraction is then mixed with freshly dried calcium chloride and the mixture is allowed to stand in vacuo at a low temperature, when the compound \( \text{C}_6\text{H}_4\text{OH} \)-\( \text{C}_6\text{H}_5\text{CH} \) separates out. This is washed with absolute ether and finally decomposed by water, when pure geranial is liberated (O. Jacobson, *Ann.*, 1871, 157, p. 232; J. Bertram and E. Gildemeister, *Jour. prakt. Chem.*, 1897 (3), 56, p. 507). It may also be prepared by reducing the corresponding aldehyde (citral) with sodium amalgam.

**Citronellol, \( \text{C}_6\text{H}_4\text{OH} \)** was obtained in 1902 from geraniol oil by A. Hesse and H. Speck (Zeitschel, *Ber.*, 1899, 32, p. 310). It is found in eucalyptus oil, in the absolute of coriander oil, and is obtained by boiling the oil with sodium hypochlorite and acetic acid (acetone, \( \text{CH}_3\text{CH} = \text{CH} \text{CH} = \text{CH} \text{CH}_2 \text{OH} \)). When heated with concentrated acetic acid to 150 °C it is converted into dimethylheptenol (P. Barbier, *Comptes rendus*, 1899, 128, p. 455). The compound is formed in a faintly yellowish solution of acetyl phenylhydride with steam.  **Citral, \( \text{C}_6\text{H}_4\text{OH} \)** is obtained from eucalyptus oil, and is also prepared by boiling the alkaline solution of 

**Geraniol, \( \text{C}_6\text{H}_4\text{OH} \)** or (CH\(_2\))\(_2\)C=C(CH\(_3\))\(_2\) (CH\(_2\))\(_2\) (CH\(_3\))\(_2\) CH \( \text{CH}_2\text{OH} \), is a 2,6-dimethylcyclohexene-2-6-o-8, is found in the oils of geranium, citronella, neroli, petit-grain, spike, ylang-ylang, and in Turkish and German rose-geranium oil, and is obtained by distillation with alcoholic potash and then fractionating in vacuo. The geraniol fraction is then mixed with freshly dried calcium chloride and the mixture is allowed to stand in vacuo at a low temperature, when the compound \( \text{C}_6\text{H}_4\text{OH} \)-\( \text{C}_6\text{H}_5\text{CH} \) separates out. This is washed with absolute ether and finally decomposed by water, when pure geraniol is liberated (O. Jacobson, *Ann.*, 1871, 157, p. 232; J. Bertram and E. Gildemeister, *Jour. prakt. Chem.*, 1897 (3), 56, p. 507). It may also be prepared by reducing the corresponding aldehyde (citral) with sodium amalgam.

**Citronellic, \( \text{C}_6\text{H}_4\text{O} \)** is the aldehyde of citronellol. It is a constituent of many essential oils, and was first discovered in citronella oil by M. Ziegler and by F. W. W. Chappell (1891). It is also found in eucalyptus oil and in lemon-grass oil. It is a dextro-rotatory liquid which boils at 203-204 °C. It is readily reduced by sodium amalgam to citronellol, and oxidized by ammoniacal silver nitrate to hydroxy-terpenic aldehyde (W. Gildemeister, *Chem.*, 1899, 32, p. 310). It forms a dimethyl acetal, \( \text{C}_6\text{H}_4\text{OCH}_2\text{CH}_3 \), which on oxidation with potassium permanganate yields a dioxo-hydroxy-citronellal dimethyl acetal, \( \text{CH}_2\text{C(\text{CH}_3\text{CH}_2\text{OH})(\text{CH}_3\text{CH}_2\text{OH})-\text{CH}_2\text{CH}_3} \), which must possess the above composition, since on further oxidation by chromic acid it yields a keto-aldehyde of the constitution \( \text{CH}_2\text{C(\text{CH}_3\text{CH}_2\text{OH})(\text{CH}_3\text{CH}_2\text{OH})-\text{CH}_2\text{CH}_3} \). It combines with sodium bisulphite, giving a normal bisulphite and also a mono-dihydroxy-terpenic acid.

**Geraniol (citral), \( \text{C}_6\text{H}_4\text{OH} \)** is the aldehyde corresponding to geranial. It is found in the oils of lemon, orange, lemon-grass, citronella, bay, verbena, and in various eucalyptus oils. It may be obtained from the oils by means of its bisulphite compound, provided the operation is carried out at a low temperature, otherwise the unsaturated compound will be formed. The reaction may either be produced by the oxidation of geraniol with chromic acid mixture, or by distilling a mixture of calcium formate and potassium permanganate with the oil and distilling the alcohol obtained, one boiling at 165-166 °C (13 mm) and the other at 173 °C. They are distinguished by their different optical activities, one being practically inactive, the other strongly laevo-rotary (see also M. Guerbet, *Comptes rendus*, 1900, 139, p. 417; *Bill. Soc. Chim.*, 1900 (3), 23, p. 540). Carvonephyl alcohol is obtained from oil of cloves; by elimination of water it yields clovene, \( \text{C}_6\text{H}_4\text{OH} \), a lime oil.

Many di- and tri-terpenes have been described, but as yet they are not thoroughly characterized.

TERRACE—TERRACOTTA

TERRACE (Fr. terrasse, from It. terrazia, terrazzia, Lat. terra, earth), a raised platform of earth; in geology the term is used of level horizontal ridges on the side of a slope, formed by volcanic action, or more usually by the action of water; they are thus frequent along the shores of lakes or by rivers; on the sea-shore they are generally known as "raised beaches." The term is used in architecture of an artificial platform in front of a building, which is utilized as a proenade; sometimes, when the building is erected on an elevation, there may be a series of terraces rising one above the other, with flights of steps leading from one to the other, as in the Villa D'Este at Tivoli; or there may be a single terrace raised high above the ground and supported on arches, as the terrace to the Adelphi buildings in the Strand, or the river front at Somerset House, or in France at the castles at Amboise and St. Germain-en-laye, or again a low terrace like that in front of the Houses of Parliament at Westminster overlooking the Thames, which is 670 ft. long and 35 ft. wide. The terraces of the gardens at Isola Bella on the Lago Maggiore are known as hanging gardens (Porzia pensilis), and were similar to those which were built by the Assyrian king at Babylon. Though properly applied to a row of buildings on a raised level, the word is often used of any row of houses.

TERRACINA (Lat. Tarracina, Volsc. Anxur), a town and episcopal see of the province of Rome, Italy, 76 m. S.E. of Rome by rail (56 by the Via Appia), 40 ft. above sea-level. Pop. (1901) 7,755; (1911) 10,790 (comune). Its position, at the point where the Volsci from the Po reach the Mare, had a wide field for seas and land, leading to the building of the Terracine line, 320 B.c., added to its importance: the road at first crossed the hill at the back of the promontory by a steep ascent and descent. An attempt was made in 184 B.C. to get round it by an embankment thrown out into the sea: but it was probably not until early in the imperial period that a cutting in the rocks at the foot of the promontory (Pisco Montano) finally solved the problem. The depth of the cutting is indicated by marks on the vertical wall at intervals of 10 Roman ft.—figures encased in large swallow-tail tablets—the lowest mark, 3 or 4 ft. above the present road, is CXX. Not far off are mineral springs by the side of the Via Appia, called Tarracine (Terme Tarracine), known to have been in use—except one containing arsenic which was blocked up both by the ancients and again in 1839 as a precaution. The two roads met some few miles E. of Tarracina, and the Via Appia then traversed the pass of Lautulae, between the mountains and the Lake of Fondi, where the Sammites defeated the Romans with loss in 315 B.C. This pass, the frontier between the Papal States and the kingdom of Naples, was also fortified in modern days. It was probably in consequence of the cutting just mentioned that some of the more important buildings of the imperial period were erected in the low ground by the shore, and near the small harbour. The construction of the coast road, the Via Severiana, from Ostia to Tarracina, added to the importance of the place; and the beauty of the promontory with its luxuriant flora and attractive view had made it frequented by the Romans as early as 200 B.C. Galba and Domitian possessed country houses here. It appears in the history of the Gothic wars, and Theodoric is said to have had a palace here. It was sacked in 409 and 505. In 872 John VIII. brought it under the domination of the Holy See.

The picturesque modern town occupies the site of the old; the present piazza is the ancient Forum, and its pavement of slabs of travertine with the inscription "A. Aemilius A. F.," in letters once filled in with bronze, is well preserved. It is supported by massive arched substructures, which extend under the surrounding houses. The cathedral of SS. Pietro e Cesareo, fronting upon it, is ensclosed in a temple of Rome and Augustus, part of the side wall of which, with engaged columns, is still visible. The vestibule, in the Cosmatesque style, is supported by ten ancient columns resting upon recumbent lions, with a mosaic frieze upon them. The brick campanile has small columns with little pointed arches. The interior has a fine Cosmatesque pulpit supported by ancient columns resting on lions, a Paschal candlestick of 1245, and a good pavement of the same period with beasts and dragons. The sacristy contains a carved wooden nuptial chest of the 10th or 11th century. There are also remains of the town wall in the "polygonal" style, and above the town are several massive platforms for supporting buildings, in a more archaistic form of this style; these may well belong to the Roman period, and the latter even to the empire. The summit of the promontory (548 ft.) is reached by the old line of the Via Appia, which is flanked by tombs and by remains of an ancient defensive wall with circular towers (currently attributed to Theodoric, but probably a good deal earlier in date). The summit is occupied by a massive terrace, supported by arcades of fine opus incertum (traditionally, but wrongly, called the palace of Theodoric) on all sides except the E., and commanding a magnificent view seaward over the coast and over the Pompejane Marshes. On the terrace, as was ascertained in 1804, stood a Corinthian temple of the early imperial period, 110 by 65 ft.; the cela was decorated in mosaic, the engaged columns supporting an altar; the pediment, with the statue of the deity, according to some authorities Venus, but more probably Jupiter Anxur worshipped as a child—a theory confirmed by the discovery of many curious leaden toys, like those made for dolls' houses at the present day, in the fossae on the E. of the temple. Of the lower town by the harbour, which had buildings of some importance of the imperial period (amphitheatre, baths, &c.), little is now visible, and its site is mainly occupied by a new quarter built by Pope Pius VI., who restored the Via Appia through the Pompejane Marshes. The W. hill, one of the S.W. and N.W., is a group of huts inhabited in winter by labourers from the Abruzzi, as is the case in many other parts of the Campagna. Of the ancient harbour constructed by Antoninus Pius (M. R. de la Blanchère in Mélanges de l'école française de Rome, i. 322; 1881) insignificant remains exist, and it is largely silted up. Close to it is the small modern port.

The ancient site of Terracina includes a considerable extension of territory towards the N.W. with much undergrowth (macchia) valuable for charcoal burning, and a considerable extent of pasture and arable land. The ancient aqueduct, bringing water some 35 m. from the slopes of the Volscian Hills, has been repaired and is in use. Three miles to the N.W., at the foot of the Monte Leano, was the shrine of the nymph Feronia, where the canal following the Via Appia through the marshes ended. Along these 3 m. of the Via Appia are numerous ancient tombs, and the fertile valley to the N.E. was thickly populated in Roman days.

See M. R. de la Blanchère, Tarracina (Paris, 1884). (T. As.)

TERRACOTTA. Greek.—The use of clay amongst the Greeks was very varied and extensive, but we are here only concerned with one aspect of it, that in which the clay was baked without glaze, whether employed for utilitarian or ornamental purposes. The Greek term for this is ἀπόστρη σκόνη, "baked earth"; the word πτερών when applied to worked clay signifies "sun-dried" only. Among the manifold purposes to which terracotta was put by the Greeks may be mentioned parts of public and private buildings, such as bricks, roof tiles, drain and flue tiles, and architectural ornaments; tombs and coffins; statues and statuettes, for votive or sepulchral purposes or for the decoration of houses; imitations of metal vessels and jewelry; and such everyday objects as spindle whorls, theatre tickets, lamps, braziers and domestic utensils. It also supplied the potter with moulds and the sculptor with models of works of art, especially in bronze.
Use in Architecture.—In architecture terracotta was extensively employed for roof tiles and other decorative details, as has been shown by many recent discoveries, especially at Olympia. In the Heraion we have the oldest example of a terracotta roof. A 6th-century temple at Thermon in Arcacarnia is also constructed of wood and terracotta, with painted terracotta slabs in wooden frames for metopes. The generic term for the roof tile was κόραιν, and these are classified as flat square tiles (σεργαστήρια or σωλήνες) and semi-cylindrical covering tiles (καλυπτέρια). Other varieties of ornamental tiles used in buildings are (1) the covering slabs along the raking-cornice (ψείδον) of the pediment; (2) the κυμάτια or cornice above the γέφυρων; (3) the cornice along the sides with lions' head spouts to carry off rain-water; (4) the έκρυορίνα or antefix ornaments surmounting the side-tiles. These latter varieties were usually enriched with decoration in colour, the κυμάτια being painted with elaborate patterns of loto-and-honeysuckle or Greek key-pattern, in red, blue, brown and yellow, curvilinear patterns being restricted to curved, rectilinear to flat surfaces. The antefix ornaments were usually modelled in the form of an anthemion or palmette, but were sometimes adorned with reliefs or sculptured groups, as in the case of the temple of Zeus at Olympia, which has figures of Victory along the cornice. The British Museum has an interesting series of 6th-century date from Capua, with gorgons' heads, female busts, and other subjects in relief, and others come from an early 5th-century temple at Civita Lavinia. Many coloured roof tiles have been found at Olympia, and Sicily and at Naples, Italy a fashion prevailed of nailing slabs of terracotta over the surface of the stonework (a legacy from the epoch of wooden buildings which required protection from the weather). These were ornamented with loto-and-honeysuckle and other patterns, sometimes in relief but always richly coloured. They occur at Olympia in the Treasury of Gela, by a Sicilian architect, and also in a temple at Selinus. The best example of this practice is the temple at Civita Lavinia already cited, the remains of which belong partly to the 6th, partly to the 4th century B.C.

Sculpture.—The subject of Greek sculpture in terracotta is a large one, and only its brief outlines can be given here. Of large or life-size statues comparatively few examples are known, and they can only be said to be common in Cyprus, where marble was difficult to procure; they are also more frequent in Italy, as will be seen later. But the use of clay for the reproduction of the human figure was one of the earliest instincts of the race, and may be traced back as far as archaeo- logical records exist, to the days of the Minoan and Aegean supramacies. Terracotta figures of a very primitive character have been found in Crete, in Melos and at Olympia, and one series of figures from Petasos in Crete is remarkable for the very modern fashions of head-dress and costumes. Terracotta figures of more advanced style have also been found in Rhodes and other places dating from the Mycenaean period.

Greek traditions on the subject go back to one Butades of Sikyon, a potter who was credited with the invention of modelling clay in relief; and the Samian sculptor Thedorus and Rhokos, who lived about the end of the 7th century B.C., were said to have been the first to use clay models for statues. As they were supposed to have introduced hollow casting in bronze, it was obviously for this purpose that they employed clay. But this material was later superseded by wax, and for marble statues was not used until Roman times.

The small terracotta figures used as ornaments or household gods, buried in tombs or dedicated in temples, trace their pedigree from the prehistoric examples already mentioned. They have been found in large numbers on nearly all the well-known sites of antiquity, the most fruitful being Tanagra in Boeotia, Myrina in Asia Minor, Rhodes, the Cyrenaica, Athens, Sicily, and some of the towns of southern Italy. They are also found in Cyprus and Sardinia, where, as to some extent in Rhodes, they follow a peculiar development, under the domination of Phoenician influence, and many of the earlier types have a markedly oriental character. But in the Greek terracottas we may trace a steady development from the primitive types which correspond to the ἔξωάθια of primitive Greek religion, and for the most part represent actual deities, down to the purely genre figures of Tanagra and other Hellenistic products of highly-developed beauty. For beauty and charm the palm has by general consent been given to the Tanagra figures of the 5th century, which are also known as "maiden figures," as κόραι or "maidsens," from the presence of seated or standing types of girls in various attitudes. The makers of these figures were known as κορσάλλατα or κορσαλάτου, and are spoken of in literature, together with their wares, with some contempt.

Manufacture.—The processes employed in the manufacture of terracottas are five in number: (1) the preparation of the clay; (2) moulding; (3) retouching; (4) baking; and (5) colouring and glazing. The last named, though not essential, was almost universal in the earlier or archaic terracottas.

The clay used for the statuettes varies greatly in different localities, and this is an important criterion for distinguishing the different kinds of manufacture. It ranges in colour from a deep red (as in the brick-like terracottas of Naukratis) to a pale buff or drab as in Cyprus, and the fired product is generally softer than that of the painted vases. It was prepared by washing the local clay free from impurities and then adding water in the required quantity. The water was used not only for the clay as such, but also for facilitating the modelling. The modelling was done by hand in the case of the earlier figures, and small objects such as toys and dolls, which are solid; the larger ones were put up into a mass with the fingers, the marks of which may often be seen. Sometimes a base was used, and then the mould became universal, the final touches being given to the figure either with the fingers or with a graving tool. The finer statuettes, such as those of Tanagra and Naukratis, were generally modelled as small groups, and the arms and legs of the figures show traces of very careful retouching. The advantage of moulding was that the "walls" of the figure could be brought to a very regular thickness, obviating the danger of shrinkage in the baking; it also rendered them very light, and permitted great accuracy in detail. A model (σφαίρος) was first made in terracotta with modelling tools, from which the mould (σφαιρός) was taken, also in clay, and wrapped in a piece of linen. This was then baked, with the addition of a lower thickness of mould to which the machine was attached, and in this way the whole was fired. The base was usually left open, and a vent hole was left in the back, which aided the clay to dry and to be re-fired without cracking, and was also used for suspending the figure when finished. The head and arms were usually moulded separately, and attached or luted to the body with soft clay. Greek moulds for statuettes are somewhat rare. There are examples from Aegina, Smyrna, Girgenti and Tarentum; the British Museum has a series from the Orkhomenian site (PI. I. fig. 3). Most of these are for small figures only.

The shrinkage of the clay as it dried permitted the figure to be fired more quickly (from 12 hours to two days) than was possible for retouching. It is obvious, from a glance at any collection of terracottas, that there is a great similarity between the various examples of any one type, and that many are virtually, if not actually, models of each other. This is especially true of the fact that only a limited number of moulds were used, corresponding to the various types. The minute differences between them, which constitute the charming variety found amongst these figures, and prevent monotony even where the type is constant, were obtained by the process of retouching, as well as by varying the pose of the head or limbs, or by differences of attributes and colourings. Actual retouching by a skilled modeler is seldom found except in the finer examples.

The process of baking required great care and attention, for if no allowance were made for the evaporation of moisture, or if too rapid a degree was used, the figures were liable to be disfigured. The clay was exposed against drying too rapidly by preliminary exposure to air and sunshine, while the temperature employed in firing was low even lower than that used for painted vases.

The colouring of the baked statuettes was fairly universal, the chief exceptions being some of the more archaic examples, and many of the small ones. The surface on which the colour was laid was formed by a white slip or engebe of a creamy colour and consistency, with which the whole front of the figure was coated. This when dry became very flaky and has often fallen off, carrying with it the colour they had received. The fewest traces of this treatment with slip. It is very unlikely that this slip-coating was fired at all. On the white slip-facing opaque

1 Clever forgeries of Greek terracotta figures are now being produced both in France and Italy. Admitted copies are also made in Berlin and Vienna, but these are generally so inferior in artistic merit as not to deceive any one who knows the genuine article.

colours were painted in tempera colours. The colouring was usually conventional, and only aimed at imparting a certain atmosphere perhaps to the drawing. The eyes and the face were often adhered, and the form was built up by the application of the colors. The colors used were as follows: red and black were the most commonly used, the white slip serving for the nude parts and generally also for the ground-work. Blue and red were especially favoured for drapery, as in many of the Tanagra figures; the red was added either to black paint, or to a black ground. Blue was used for the eyes or details of features; yellow (varying to deep brown) for the hair, and also for jewelry. Gilding is rare but was occasionally used for heraldic or military heads, for instance in the Charlesworth collection.

In the imperial period terracottas and those of Cyprus or other centres which adhered to primitive methods, the decorrations in stripes of mat black and red paint applied in a conventional manner to their figures have been found. The types which have been advanced on this subject, some authorities having maintained that their meaning was exclusively religious or mythological, their significance is considerably complicated by the fact that these religious types were afterwards adopted for ordinary human figures symbolizing the life of the deceased beyond the tomb. The gradual change in popular taste from figures of deities to types of the human image, certainly indicates the development of this branch of art, but that the development was affected by religious ideas is more open to doubt. It is more probable that it followed the lines of artistic evolution, and that the continued usage of certain types did not as the result of religious influence less a convention. In fact, the identity of the types, under whatever circumstances they are found, seems to indicate that the significance was given to them by the purchaser, who would decide for himself whether he offered them to some appropriate deity, deposited them in the tomb of some relative, or kept them for use and decoration in his own house.

Types—The earliest beginnings of the statuettes proper show, as might be expected in primitive Greek art, a very limited range of subjects. As in other materials, so also in clay, the female deity reigns supreme. The primitive Helenic type of goddess is characterized by both determinate features, with the board-form $\sigma\nu\iota$, and the column form $\varepsilon\kappa\iota$ or $\varepsilon\sigma\kappa\ion$, both of which we find also in sculpture. The limbs are wanting, or are an imposition. The types are a development of the primitive, and the style of the local vases. Both types are found in Rhodes, but on the mainland of Greece the columnar type died out after the Mycenaean period, and only the board-type remained, being specially popular in Bosporus and at Ephesus. These figures are almost all seated and have the same style as the local vases. This type was adhered to for the bodies of figures even when the head was modelled in a more advanced style of art. The column-type is also well exemplified in the statues which stood and seated goddesses are the two principal types in archaic Greek art (Pl. II. fig. 4), and are widely distributed and of universal popularity; though the conception of the goddess may vary with the locality, the types are almost identical, and the attributes are but slightly varied. A certain proportion of these deities are differentiated as nature-goddesses, either as a nude goddess in a shrine or a seated figure with a child in her lap who may represent her in a more maternal or hispanic aspect (see Melpomene and Terpsichore). Another common archaic type is the funeral mask or bust, hollow at the back, which is found both in central Greece and Rhodes. Being almost always feminine it seems probable that these masks were worn by women at the time of the death of Demeter and Persephone, playing in the tombs the role of protectors against evil influences. We may also mention here the little figurine of a girl. These are often seen in groups of three or four, and joined dolls (μεazoγατρα) which can only have served the purpose of children's toys. In Athens, Melos and Rhodes, many of these have been found in children's graves. The evidence of finds with grave goods shows that they were also used in ordinary life, and many figures of archaic type can be shown from the contents of the tombs in which they are found not to be earlier than the 5th century B.C. The reason for this is probably hieratic. Owing to the religious associations of the types they were continued in use, whereas painted vases and the majority of sculptures of other class were not affected by such considerations. Therefore we are not surprised when we come to the later terracottas of the fine art of the 4th century B.C. to find that the old archaic types are still prominent. But the change in style is also accompanied by a change in conception, and in place of the goddesses now we have the Greek lady—in place of the mythological the genre. The tendency was not to convert a nursing goddess into a mother with her little one, or a Persephone holding a flower into a girl of Tanagra. The change in style is rather in the sense of developing a type rather than a revolution. The figures were still placed in tombs and shrines, though the old associations were less strongly felt.

In order to know what were the characteristics of the best Greek terracottas we might take three types of development: one of these which are limited products, the Tanagra statuettes (Pl. II. fig. 4). Here we have an almost unlimited variety of feminine figures illustrating the daily life of Greek women. In most cases the arms are more or less concealed by the mantle which is drawn closely across the figure, even covering the hands; but many hold a fan, a mirror, a wreath, or a theatrical mask in one hand, while with the other they gather together the tresses of coloured drapery. The lost type is called and the other type or himation, which all without exception wear, formed the typical dress of the Greek matron and girl; and to this was added for outdoor wear a large shady hat. The seated types follow on the female type illustrated above, and are also of a very limited range. From about 350 to 200 B.C., and their inspiration is probably drawn rather from the painting than the sculpture of the period. The terracottas of Etruria in Euboea and and of Myrina in Asia Minor and of Lampsakus in Asia Minor. These figures can be divided into two classes: they are freer from ancient tradition, but tend to degenerate into exaggeration of pose and conception. Here the types are mostly, but not exclusively, goddesses. One form is of particular Eros or Cupid, the one deity who exclusively taught the popular taste in the Helenic age, and in the many representations of whom we see the prototypes of the Pompeian Amorettes; other types are of Apollo, Venus and eros. Moreover, and at some times the Tanagra types are repeated here, as, with varying artistic success, in other parts of the Mediterranean littoral.

Though no Greek site has produced terracottas of such artistic quality as the Tanagran type, the art of terra cotta enjoyed great popularity, either for a comparatively brief period or through the whole history of Greek life. Some of these centres of manufacture have already received mention or less than allusion, but we may briefly call attention to a few others. From Sicily we possess a complete series, from archaic to later times, the earlier being best represented at Selinus, where a great variety of pottery was manufactured. Dionysos and Heracles are also popular types, and at times some of the Tanagra types are repeated here, as, with varying artistic success, in other parts of the Mediterranean littoral.

T erracotta work in relief, apart from definitely architectural examples, is almost limited to two small classes, both belonging to the beginning of the 5th century. These groups, known respectively as "Melian" and "Locrician" reliefs, consist of small plaques, possibly intended to be inserted in the walls of temples or shrines. The subjects of the Locrician reliefs, which relate to the myth and cult of Persephone, seem to indicate that they at least were of a votive character. They occur at Locri in Southern Italy, and similar examples dedicated to Athena have been found at the Acropolis at Athens. The Melian reliefs exhibit a wider scope of scenes of local life, but the figures are often crude and unrefined in character. Some are simple plaques; others have the figures cut out without background, or only the outer contours. They have been found on various Greek sites, the majority in Southern Italy, and belong to the Helenic period (Pl. 11. fig. 5).

There is a class of vases which comes rather under the heading of terracotta than of pottery, from its technical character and general appearance. These are found particularly in Southern Italy, and belong to the Helenic period (Pl. 11. fig. 5). They combine in a marked degree the characteristics of the vase and the statuette, some being vases with moulded reliefs or small figures in relief, while others figures in relief, while others are bowls with figures in relief or moulded. Many of the figures in relief are carefully modelled in vases form, with the addition of mouth, handle, and base. They are often of gigantic size, and do not appear to have served any practical purpose; probably they were made to express a certain mode of taste or to imitate the literary art, and among those moulded are those in the shape of the statuettes, and are often richly coloured. Some have even subjects painted in some permanent process like encaustic.
TERRACOTTA

form usually adopted is that of a spherical vase with a flat handle on the top and three tall mouths.

Etruscan Terracotta. — Some features of terracotta work are characteristic of Etruria, who employed this material both for finer works of art and for more utilitarian purposes. Several ancient writers speak of their preference for clay and their skill in its use, and Pliny, who speaks of the elaborate vases made in the 7th century, and states that the art of modelling in clay was in Etruria. Certainly for their statues the Etruscans appear to have preferred clay for the most delicate and finish. They also used clay in architecture. The Romans employed Etruscan artists to decorate their temples, and the statue of Jupiter on the Capitol was made by Volci a terracotta artist. This was in an elaborate version also of a centaur on the pediment of the temple. For the decoration of temples terracotta remained in use even down to Roman times; these buildings being usually of wood covered with slabs of marble or other material. Some terracotta remains were found in the 1st century in the temple of Diana in the Roman Forum.

Terracotta mural decoration was also largely employed by the Romans for the interior and exterior of their buildings; in the form of slabs ornamented with figures, and for graves. Cicero speaks of fixing the bas-reliefs (types) "on the cornice of his little atrium." These slabs usually measure about 18 by 9 to 12 in., and have nearly all been found in Rome, though some are also from temples in other parts of Rome and various parts of Greece.

Pompeii, it is true, has few examples of terracotta decoration; in the Roman Forum, however, there is a fine frieze of reliefs sculptured in terra-cotta, 160 in. long, which are in the British Museum. A number of other examples have been found at Rome by Charles Towneley, and there is another large collection in the Louvre. Others from the 2nd and 3rd centuries are still in situ on the Capitoline.

These terracotta reliefs were pressed in moulds, as is shown by the frequent repetition of certain subjects with at most only slight differences; moreover the relief is low, the shape and outline of figures was deliberately simplified, and a mould would produce them. They were sometimes retouched before baking, hence the variations. Reliefs entirely modelled are much rarer, but some examples exist, of considerable artistic feeling and the decoration; they are found in the Roman Forum, at Siena, and at Porta Latina in Rome.

The Roman Terracotta Work. — The Romans, who were Tarentines, and who adopted in the 3rd century B.C. the processes of the Etruscans, developed terracotta work in all its aspects and utilized it much more than the Etruscans themselves. The ground was as highly coloured as possible, and there was less use of fire, the clay being used for ornamental work; the figures were still executed in a more or less barbarian way, and to a certain extent the Greeks, and especially the Etruscan artists, had a great influence on its development.

The form of ornament which best exhibits the Etruscan fondness for terracotta as a material for sculpture is the sarcophagus, of which the Romans made a great number of perfectly fine pieces and which are the only sarcophagi of that time which survive. The sarcophagi of the Ist century B.C. are the work of a group of a man and a woman reclining, executed in the round life-size. These figures are undoubtedly genuine native work, and in the obvious inability of the sculptor to achieve success in large scale works; the reliefs of Augustan art is that it is not devoid of dignity and beauty. The figures are purely designed for beauty and the reliefs are painted in tempera, and their use is purely conventional. The figures are not usual characteristics of egg-patterns and the reliefs are painted red, yellow, purple or white, and with an edge of open-work.

The figures are mostly in low relief, grouped with large, flat surfaces between the manner of contemporary Roman art; in the 1st century B.C. terracotta work was by no means confined to the decoration of places. Some terracotta examples are found in the Louvre, and in the Metropolitan Museum, and in the British Museum. The subjects are always those of the ancient art; the subjects are mostly of Roman life and of the reign of Augustus. The reliefs are mostly of the 3rd and 4th centuries, and are executed in a more or less conventional style, and for the sake of economy and proper, more or less conventionalized. The compositions consist either of narrow friezes with rows of Cupids or masks, or groups of two or three figures resembling temple-metopes. The decoration of the whole is that of the 3rd century B.C., and the reliefs are of a more or less barbarian work; the figures are not usually painted red, yellow, purple or white, and with an edge of open-work.

The subjects cover a very wide field. Many are no doubt inspired by well-known works of art; others are closely related to the "New Art" types, including dicing and braziers, and the seasons. Others again, reflecting the spirit of the time, reproduce Egyptian landscapes. Scenes from the circus or arena, or the chariot-race, are found in terracotta. But the images of the most popular are Dionysiac scenes. Satyrs gathering and pressing grapes, and Victory slaying a bull; figures illustrating the legend of Admetus and Alcestis. They are usually painted "in tempera on a white ground, the bright colouring having a very vivid effect.

By far the finest examples of this class are those from Cervetri, where the sarcophagus which belongs to the 3rd century B.C. follow on the same lines. They invariably consist of a rectangular body or coffin with sculptured reliefs on the front and sides, and a flat cover on which rise a figure representing the deceased person. They are usually of small size, measuring not more than 18 by 12 by 2 in.; but some are large enough for a body to lie in at full length. The reliefs are executed in the style of the later Etruscan art, and are often very fine, and sometimes very beautiful. The Roman terracottas of this period are executed in relief, and exhibit the most obvious difference in style from the terracotta of the 4th century, the reliefs are all those of Augustan art; and the conventional, not to say archaic, corresponding to the classicist tendencies of another school of Augustan artists represented by the New Art" reliefs. Both groups find close parallels in the metalwork and pottery of this period, to which date they may therefore be assigned.

The subjects cover a very wide field. Many are no doubt inspired by well-known works of art; others are closely related to the "New Art" types, including dicing and braziers, and the seasons. Others again, reflecting the spirit of the time, reproduce Egyptian landscapes. Scenes from the circus or arena, or the chariot-race, are found in terracotta. But the images of the most popular are Dionysiac scenes. Satyrs gathering and pressing grapes, and Victory slaying a bull; figures illustrating the legend of Admetus and Alcestis. They are usually painted "in tempera on a white ground, the bright colouring having a very vivid effect.

Roman Sculpture in Terracotta. — Few allusions in classical writers indicate that the ancient statues of the Romans were mostly of terracotta, and Pliny notes that even in his day statuettes of clay were still preferred for temples. There are also references to terra-cotta placed on pedestals of buildings such as the Capitol of the Republic, Rome was indebted for these to Etruscan artists, but the style of the figures was probably more Greek than Etruscan. In 493 B.C. Gorgasus and Damophilos of Himera in Sicily, who had exhibited their works at the Olympic games, were presented with the prize to which they were entitled. They were awarded for their "Amuletic type" of medium holding the examples were found among the ruins at Pompeii, having formed the cult-statues of a temple; others were employed for adornment gardens, like the series from Rome known as the "Serapeum," and other series. The most interesting have been found in the Temple of Apollo in the Roman Forum, and in the Temple of Minerva Medica in the Forum. Many of these figures are of considerable size, and were found in the Russian Museum, and in the Louvre. Several were discovered in the Temple of Minerva Medica in the Forum.
TERRACOTTA

offerings on sacred sites. They were known to the Romans as Sigilla, and were used for religious or funerary purposes, particularly in shrines. Some 200 were found in the poorer quarters of Pompeii, implying that they took the place of the marble and bronze figures which the wealthier inhabitants alone could afford. At the festival of the Lupercalia on February 15th, the Luperci would battlebac and masks were in great demand. Originally these were votive offerings to Saturn, but later the custom degenerated into that of giving them as presents to friends or children, a practice indolent in the instance and of course, with the passing of time was often abused.

The makers of these figures were known as sigillari or sigillatores, and they lived in the Via Sigillaria. Their social position seems to have been rather low, for it is believed that they were chiefly patronized by the lower classes; probably many of them were slaves. The technical processes which they employed were probably those of the Greek craftsmen. Large quantities of them have been found from many places, often on a wooden frame-work known as crux or stipes; but the smaller ones were made from moulds. The range of subjects is much the same as in the later Greek terracottas. At Pompeii genre subjects, such as gladiators, athletes and slaves, and in general there is a preference for portraits and grotesques. On the whole these late works have little artistic merit. Votive figures have been found at Praeneste on the site of the temple of Fortune, and also at Nemi and Gabii.

This industry also extended from Rome to the provinces, and terracotta statuettes of local make have been found even in Britain, and on the Iberian peninsula and in the Rhine district. In northern Italy and in the Rhine district, there were very extensive manufactures of terracotta after the conquest of Julius Caesar in 58 B.C. They were made by local craftsmen for the Roman colonists, with imports from Italy. The city of Ravenna was the centre of manufacture. The district of the Allier was central to France. Pottery has been found at Moulins, as well as in other parts of France, in England, and in the Low Countries. The clay used in these areas is of a peculiar white clay, the technique resembling that of Roman work, but the modelling is heavier and often barbaric. Numerous moulds have also come to light which shows that a great number were manufactured in two pieces, and that these moulds the potters' names have frequently been scratched (to indicate ownership). Names appear on the figures as well as on the moulds, and many of these are of Gaulish origin. The centres of production are those of Pictet, Reims, and Moulins, in the north of west France, and Vindex of the Rhine. The troubles include divinities, genre figures, and animals; among these the pre-eminent type is that of a Nature-Goddess, characterized either as Venus Genetrix or as a Mother with a Child (genetrix, varia genetrix, or genetrix vulga). Both in subject and in artistic character these statuettes appear to have largely been influenced by the Graeco-Egyptian art of Alexandria during the Hellenistic period. They appear to have been used for domestic and funerary purposes and as votive offerings.

After the downfall of the Roman Empire in the west, the artistic use of terracotta was abandoned for many centuries, though, here and there, both in Italy and in the districts that had been once Roman provinces, decorated terracotta work was carried on sporadically. In the time of the Northumbrian kings, and in the eleventh century of its use came during the 14th and 15th centuries, when it was adapted once more to architectural service in the Gothic buildings of northern Italy and of Germany. In Germany the mark of Brandenburg is still to be seen on some of the works, and in England of the marquis of Northampton. England is still the centre of terracotta. The church of St. Catherine in the town of Brandenburg is decorated in the most lavish way with delicate tracery and elaborate string-courses and cornices enriched with foliage all modelled in clay; the town-hall of Brandenburg is another instance of the same use of terracotta. At Tangermunde, the church of St Stephen and other buildings of the beginning of the 15th century are wonderful examples of this method of decoration; the north door of St Stephen's especially being a masterpiece of rich and effective moulding. In northern Italy this use of terracotta was carried to an equal high pitch of perfection. The western façade of the church of St. Mary at Bologna and the Church of the Gesù at Rome are other examples of this use. Bologna and S. Maria delle Grazie in Milan are all striking examples of the extreme splendour of effect that can be obtained by terracotta work. The Certosa near Pavia is a gorgeous specimen of the early work of this kind. There is much use of terracotta in the church of St. Maria della Grazie and S. Maria degli Scalzi, built in 15th century dating from the 14th and 16th centuries, as for example, the rich cornices of the south aisle of S. Maria in Ara Coeli, c. 1300; the front of S. Cosimato in Trastevere, built c. 1490; and the monumental niche, near the Via di Tordino, which dates from the 14th century.

With the revival of terracotta as an adjunct to medieval architecture we find the sculptors of the Italian Renaissance turning to this material, and in the works of Donatello and Querchi, Donatello, and the sculptors of the next generation. For life, spirit, and realistic truth, combined with sculptural breadth, these pieces are masterpieces of invention and manipulation. The portraits of Lorenzo de Medici by Donatello and that by Torrigiano are classic examples of this respect. The use of burnt clay for sculpture has great advantages as that of marble; the soft clay is easily and rapidly moulded into form while the sculptor's thought is fresh in his mind, and parts of the work can be finished and cast at a later stage which can hardly be reproduced in laboriously finished marble.

In the 16th century a more realistic style was introduced, and this was much more in evidence by the end of the century. Many very two groups of this kind were produced by Ambrogio Poppa (Caradosso) for S. Satiro at Milan and by Guido Mazzoni and Begarelli (1479-1558) for churches in Modena. These terracotta figures are mainly in the Italian Renaissance style; but those of Begarelli were enthusiastically admired by Michelangelo. The introduction of enameled reliefs in terracotta which was closely associated with the Florentine sculptor Luca della Robbia and his descendants, is specially treated in the article DELLA ROBBIA (g.v.).

From these two centres the development of architectural terracotta spread over western Europe. The Germans have influenced the work done in the Low Countries and finally in England, where it also met the direct influence of the Italian school due to the invasion of England by Italian artists such as Terrigliano and other Florentines. At Enfield, in London, in the reign of Elizabeth, and Henry VIII. It is only in the eastern and southern counties of England that we find instances of the terracotta work of this period, and much of it is in-English in style (most-autho- rious of these terracottas is that at St. John's College, Cambridge). In Essex possesses the finest examples: such as those to be found in the Manor House at Layer Marney, and at the Church of St. Peter of St. John the Baptist, encircled by a Gothic inscription, which was evidently made at Lyon during the 16th century. The very moulds, though, together with other objects of similar type, was executed at Lyon, while in its robot it is apparent that it was Italian, the style of the modelling is entirely French in character.

France.—At about the same period the Italian modellers or sculptors carried the art into Spain, and many extraordinary works are still extant in various Spanish churches remarkable for their vivid realism and for a too pictorial style which degrades them from their true rank as architectural decoration.

During the 17th and 18th centuries the architectural use of terracotta again fell away owing to the increasing use of marble, but that the art still survived in other forms is shown by the portrait busts of Dwight (17th century), though they were made in stoneware and not in unglazed terracotta; and the charming little statuettes and groups made in Lorraine and the adjacent parts of France. In the 18th century, sculptors employed at some of the pottery factories of the period. It should be mentioned that during the 18th century ordinary clay had fallen into disuse, but the porcelain figures made at Meissen (1709) and at Mochel's factory, and the figures of Mikale and of Poldo, both by the workshop of Albert, have the same form of manufacture, clay and unglazed. We have in England, for example, some very important buildings, such as the Natural History Museum, the Albert

1 The Victoria and Albert Museum has a splendid and representative collection of these Italian terracottas.

This last and most extensive of the works in terracotta executed for the Royal Palace at Madrid during the French Revolution in 1792, but exact drawings of it are still in existence showing all the necessary details.
TERRAMARA (from Ital. terra marina, "marl"), the name given by archaeologists\(^4\) to a type of primitive culture mainly of the early bronze age, but stretching back into the later stone age. This civilization is represented by a number of mounds, formerly thought (e.g. by Venturi) to be sepulchral, but really the remains of human habitations, analogous to shell heaps (q.v.) or kitchen middens. They are found chiefly in north Italy, in the valley of the Po, round Modena, Mantua and Parma. A summary of early results as to these mounds was published by Munro (Lake Dwellings) in 1890, but scientific investigation really began only with the excavation of the terramara at Castellazzo di Fontanellato (province of Parma) in 1889. From this and succeeding investigations certain general conclusions have been reached. The terramara, in spite of local differences, is of typical form; it is a settlement, trapezoidal in form, built upon piles on dry land protected by an earthwork strengthened on the inside by buttresses, and encircled by a wide moat supplied with running water. The east front of these are parallel, and two roads at right angles divide the settlement into four quarters. Outside are one or two cemeteries. Traces of burning which have been found render it probable that, when the refuse throw down among the piles had filled the space, the settlement was burned and a new one built upon the remains. The origin of the terramara type is not definitely ascertained. The most probable inference, however, is that these settlements were not built to avoid the danger of inundation, but represent a survival of the ordinary lake dwellings.

The occupants of the terramara people as compared with their neolithic predecessors may be inferred with comparative certainty. They were parallel, still hunters, but had domesticated animals; they were fairly skilful metallurgists, casting bronze in moulds of stone and clay; they were also agriculturists, cultivating beans, the vine, wheat and flax. According to Prof. W. Ridgeway (Who were the Romans? p. 16; and Early Age of Greece, i. 496) burial was by inhumation; investigation, however, of the cemeteries shows that the bodies were burned and the ashes placed in ossuaries; practically no objects were found in the urns.

Great differences of opinion have arisen as to the origin and ethnographical relations of the terramara folk. Brizio in his *Epoca Preistorica* advances the theory that they were the original Ibero-Ligurians who at some early period took to erecting pile-dwellings. Why they should have done so is difficult to see. Some of the terramare are clearly not built with a view to avoiding inundation, inasmuch as they stand upon hills. The rampart and the moat are for defence against enemies, not against floods, and as Brizio brings in no new invading people till long after the terramara period, it is difficult to see why the Ibero-Ligurians should have abandoned their unprotected hut-settlements and taken to elaborate fortifications.

Pigerini regards the terramara people as an Aryan lake-dwelling people who invaded the north of Italy in two waves from Central Europe (the Danube valley) in the end of the stone age and the beginning of the bronze age, bringing with them the building tradition which led them to erect pile-dwellings on dry land. These people he calls the Italici, to whom he attributes also the culture known as Villanovà (q.v.). This view

---

\(^4\)Since the International Congress of Prehistoric Archaeology at Bologna in 1871, when the shortened form *terramara* (plur. *terramari*) was adopted.
is regarded as falling in with discoveries (somewhat incomplete, it is true) in Hungary and Bosnia.

**TERRANOVA**—**TERRISS**

is the seat of the Indiana State Normal School (1870), which had in 1909 a library of about 50,000 volumes, 52 instructors and an average term enrolment of 988 students, and of the Rose Polytechnic Institute, which was founded in 1874 by Chauncey Rose (1794–1877), was opened in 1883, offers courses in mechanical, electrical, civil and chemical engineering and in architecture, and in 1909 had 22 instructors and 214 students. About 4 m. W. of Terre Haute is Mary-of-the-Woods (founded in 1840 by the Sisters of Providence, and chartered in 1846), a school for girls. The Emeline Fairbanks Memorial Library (1882) contained 30,000 volumes in 1910, housed in a building erected in 1903 by Mr Crawford Fairbanks in memory of his mother. Terre Haute's industrial and commercial importance is largely due to its proximity to the valuable coal-fields of Clay, Sullivan, Park, Vermillion, Greene and Vigo counties. The total value of its factory product in 1905 was $29,291,654; both in 1900 and in 1905 it ranked second among the manufacturing cities of the state. It is the largest distilling center, and one of the largest in the country, the value of the output of this industry in 1905 being more than half the total value of the city's factory product for the year. The value of the glass product in 1905 was 4.4 per cent. of the value of all factory products of the city, and 1.6 per cent. of the value of all glass manufactured in the United States.

The first settlers at Terre Haute built their cabins near Fort Harrison, which was erected by command of Governor William Henry Harrison in the winter of 1810–11. In 1812 the fort was successfully defended by the citizens of the Indians by its commander Captain Zachariah Taylor, and in 1817 was abandoned. After the close of the War of 1812 the town grew rapidly and became an important commercial centre, owing to its river connections and to the fact that the National (or Cumberland) Road crossed the Wabash here. Terre Haute was incorporated as a town in 1838, became a city in 1853 (under a general state law of June 1852), received a special city charter in 1899, in 1905 was organized as a city of the third class, and became a city of the second class in 1909.

**TERRELL** a city of Kaufman county, Texas, U.S.A., about 32 m. E. of Dallas, and one of the largest in the country, the value of the output of this industry in 1905 being more than half the total value of the city's factory product for the year. The value of the glass product in 1905 was 4.4 per cent. of the value of all factory products of the city, and 1.6 per cent. of the value of all glass manufactured in the United States.

**TERRISS, WILLIAM** (1847–1897), English actor, whose real name was William Charles James Lewin, was born in London on the 20th of February 1847. After trying the merchant service, medicine, sheep-farming in the Falkland Isles, and tea-planting in Bengal, in 1867 he took to the stage, for which his handsome presence, fine voice and gallant bearing eminently fitted him. His first appearance in London was as Lord Cloudrays in Robertson's *Society*, at the old Prince of Wales's theatre. He quickly came into favour in "hero" parts, and appeared at the principal London theatres from 1868 onwards. In 1880 he joined Irving's company at the Lyceum, playing such parts as Cassio and Mercutio, and in 1885 he acted there with Mary Anderson as Romeo and Juliet, in 1886 to 1887 he then engaged to take the leading parts in Adelphi melodrama, and it was in this capacity that for the rest of his career he was best known, though he occasionally acted elsewhere, notably with Irving at the Lyceum. His last appearance was in *Secret Service*. On the 10th of December 1897, as he was entering the Adelphi theatre, he was stabbed to death by a madman, Richard Arthur Prince. Terriss married Miss Isabel Lewis, and his daughter Ellaline Terriss (Mrs Scymour Hicks) became a well-known actress in musical comedy, in association with
her husband Edward Seymour Hicks (b. 1871), proprietor of the Aldwych and Hicks theatres in London.

**TERRY, EDWARD O'CONNOR** (1844– ), English actor, was born in London, and began his stage career in a small and struggling way in the provinces. Between 1868 and 1875 he was the leading comedian at the Strand theatre, London, but it was not till he joined Hollingshead's company at the Gaiety in 1876 that he became a public favourite in the burlesques produced there during the next eight years. With Nellie Farren and Thorne, he formed the popular trio of Nellie Farren and Thorne. When in 1878 the house, his eccentric acting and singing creating a style which had many imitators. In 1887 he went into management, opening Terry's theatre, where his production of Pinero's *Sweet Lavender* was a great success. But in subsequent years he was only occasionally seen at his own theatre, and made many tours in the provinces and in Australia, America and South Africa. Off the stage he was well known as an ardent Freemason, and an indefatigable member of the councils of many charities and of public institutions.

**ALICIA** (1848– ), English actress, was born at Coventry on the 27th of February 1848. Her parents were well-known provincial actors, and her sisters Kate, Marion and Florence, and her brother Fred, all joined the theatrical profession, and her own first appearance on the stage was made on the 28th of April 1856, under the Kean's management, as the boy Mamillus in *The Winter's Tale*, at the Princess's theatre, London. Two years later she played Prince Arthur in *King John* with such grace as to win high praise. From 1860 to 1863 and again from 1867 to 1868 she acted with various stock companies. During this period she played, on the 26th of December 1869, for the first time with Henry Irving, being cast as Katharine to his Petruchio in Garrick's version of *The Taming of the Shrew* at the Queen's theatre. When quite a girl she married G. F. Watts the painter, but the marriage was soon dissolved. Between 1868 and 1874, having married E. A. Wardell, an actor whose professional name was Charles Kelly, she was again absent from the stage, but she reappeared in leading parts at the Queen's theatre under Charles Reade's management. On the 17th of April 1875 she played Portia for the first time in an elaborate revival of *The Merchant of Venice* under the Bancrofts' management at the old Prince of Wales's theatre. This was followed by a succession of smaller triumphs at the Court theatre, culminating in her beautiful impersonation of Olivia in W. G. Wills's dramatic version of Goldsmith's *Vicar of Wakefield*, in 1878, the result of which was her engagement by Henry Irving as his leading lady for the Lyceum theatre, and the beginning of a long artistic partnership, in the success of which Miss Terry's attractive personality played a large part. Her Shakespearean impersonations at the Lyceum were Ophelia in 1878, Portia in 1879, Desdemona in 1881, Juliet and Beatrice in 1882, Viola in 1884, Lady Macbeth in 1888, Katherine, in *Henry VIII.*, and Cordelia in 1892, Imogen in 1896, and Volumnia, in *Coriolanus*, in 1901. Other notable performances were those of the Queen in Wills's *Charles I.* in 1879, Camma in Tennyson's *The Cup* in 1881, Margaret in Wills's *Faust* in 1885, and the title-part in Charles Reade's one-act play *Nance Oldfield* (1893), Rosamund in Tennyson's *Becket* (1893), Madame Sans-Gêne in Sardou's play (1897), and Carlisse in *Robespierre* (1898). With the Lyceum company she several times visited the United States. In 1902, while still acting with Sir Henry Irving, she appeared with Mrs Kendal in Beerbohm Tree's revival of *The Merry Wives of Windsor*, at His Majesty's theatre, and she continued, after Sir Henry Irving's death, to act at different theatres, notably at the Court theatre (1905) in some of G. Bernard Shaw's plays. In 1906 her stage-jubilee was celebrated in London with much enthusiasm, a popular subscription in England and America resulting in some £800 being raised. In 1907 Miss Terry married James Carew, an American actor.

Her sister Marion Terry (b. 1850) became only less distinguished on the English stage than herself; and her brother Fred Terry (b. 1865) also became a leading actor, and a successful manager in association with his wife, the actress Julia Neilson.

See Charles Hiatt, *Ellen Terry and her Impersonations* (1898); Clement Scott, *Ellen Terry.*

**TERSTEEGEN, GERHARD** (1667-1769), German religious writer, was born on the 25th of November 1667, at Mörs, at that time the capital of a countship belonging to the house of Orange-Nassau (it fell to Prussia in 1702), which formed a Protestant enclave in the midst of a Catholic country. After an academic career at the gymnasium of his native town, Tersteegen was for some years apprenticed to a merchant. He soon came under the influence of Wilhelm Hoffman, a pietistic revivalist, and devoted himself to writing and public speaking, withdrawing in 1728 from all secular pursuits and giving himself entirely to religious work. His writings include a collection of hymns (*Das geistliche Blumengärtlein*, 1729; new edition, Stuttgart, 1868), a volume of *Gebeite*, and another of *Briefe*, besides translations of the writings of the French mystics. He died at Mühlheim in Westphalia on the 3rd of April 1769.

**TERTIARIES** (Lat. *tertiiarii*, from *tertius*, third), associations of lay folk in connexion with the Mendicant Orders. The old monastic orders had had attached to their abbeys confraternities of lay men and women, going back in some cases to the 8th century. The Confraternity Book of Durham is extant and embraces some 20,000 names in the course of eight centuries. Emperors and kings and the most illustrious men in church and state were commonly confraters of one or other of the great Benedictine abbeys. (On this subject see article by Edmund Louis Bevan in *Downside Review*, 1886.) The confraters and consores were, made partakers in all the religious exercises and other good works of the community to which they were affiliated, and they were expected in return to protect and forward its interests; but they were not called upon to follow any special rule of life.

Although something of the kind existed among the Humiliati in the 12th century, the institution of Tertiaries arose out of the Franciscan movement. It seems to be certain that St Francis at the beginning had no intention of forming his disciples into an Order, but only of making a great brotherhood of all those who were prepared to carry out in their lives certain of the greater and more arduous of the maxims of the Gospel. The formation of the Franciscan Order was necessitated by the success of the movement and the wonderful rapidity with which it spread. When the immediate disciples of the saint had become an order bound by the religious vows, it became necessary to provide for the great body of laity, married men and women, who could not leave the world or abandon their avocations, but still were part of the Franciscan movement and desired to carry out in their lives its spirit and teaching. And so probably in 1221 St Francis drew up a Rule for those of his followers who were beheaded from being members of the order of Friars Minor. At first they were called "Brothers and Sisters of the Order of Penance"; but later on, when the Friars were called the "First Order" and the nuns the "Second Order," the Order of Penance became the "Third Order of St Francis"—whence the name Tertiaries: this threefold division already existed among the Humiliati.

In 1901 Paul Sabatier published a "Rule of Life of the Brothers and Sisters of Penance," which probably contains, with additions, the substance of the original Rule of 1221. It prescribes severe simplicity of dress and of life, and certain abstinences and prayers and other religious exercises, and forbids the frequentation of the theatre, the bearing of arms and the taking of oaths except when administered by magistrates. In 1289 Nicholas IV. approved the Third Order by a Bull, but made some alterations in the Rule, and this form of the Rule remained in force until our own day.

Immediately on its establishment in 1221 the Third Order
TERTIARY—TERTULLIAN

spread with incredible rapidity all over Italy and throughout western Europe, and embraced multitudes of men and women of all ranks from highest to lowest. Everywhere it was connected closely with the First Order, and was under the control of the Frisians Minor.

In time a tendency set in for members of the Third Order to live together in community, and in this way congregations were founded which in the usual course of things grew into a fully organized religious life based on the Rule of the Third Order with supplementary regulations. These congregations are the "Regular Tertiaries" as distinguished from the "Secular Tertiaries," who lived in the world, according to the original idea. The Regular Tertiaries are in the full technical sense "religious," and there have been, and are, many congregations of them, both of men and of women.

There can be little doubt, whatever counter claims may be set up, that the Third Order was one of St. Francis' creations, and that his Third Order was the exemplar after which the others were fashioned; but at an early date one of the ancient orders formed Third Orders on the same lines, and so there came into being Dominican Tertiaries, and Carmelite, and Augustinian, and Servite, and also Premonstratensian and many others. These followed the same lines of development as the Franciscan Tertiaries, and for the most part divided into the two branches of regular and secular Tertiaries. The Rules of the various Third Orders have proved very adaptable to the needs of modern congregations devoted to active works of charity; and so a great number of teaching and nursing congregations of the Third Order have been founded, and it received a great impetus and a renewed vogue from Leo XIII., who in 1883 caused the Rule to be recast and made more suitable for the requirements of devout men and women at the present day. In consequence it is estimated that the number of lay Franciscan Tertiaries now exceeds two millions.

BIBLIOGRAPHY.—The most serviceable authority on the Franciscan Tertiaries is probably Max Heimbucher, Orden und Kongregationen (1907), lii. §§ 103, 104, 105, where an ample bibliography is supplied. The same work gives information on the other Tertiaries at the end of the sections on the various Orders. Similarly information will be found in Tertiaries of the provinces of the different Orders. Heimbucher names Tachy, Les Tiers Ordres (1897), and Adderley and Marson, Third Orders (1917) (E. C. B.)

TERTIARY, in geology, the time-division which includes the Eocene, Oligocene, Miocene and Pliocene periods, in other words, it is the earlier portion of the Cainozoic era. By some authorities the term Tertiary is made to embrace in addition to the foregoing periods those of the Quaternary (Pleistocene and Holocene), i.e. "Tertiary" is made the equivalent of Cainozoic. On logical grounds there is much in favour of this interpretation; but having in view the 'state of geological literature, it is certainly better to restrict the use of the term in the manner indicated above. Tertiary rocks were among the latest to receive the careful attention of geologists, and the name was introduced by G. Cuvier and H. Brongniart in 1810 (Essai sur la geographie stratigraphique des environs de Paris, 1810-11, 1st ed.).

Deshayes (1839) worked out the percentages of recent fossils found at several horizons in those strata, and upon this Sir C. Lyell (1832) founded the main periods, viz. the Eocene with 31 per cent. of recent forms, the Miocene 17 per cent., the Pliocene 35 to 59 per cent. Subsequent investigations naturally modified the numerical values upon which this nomenclature was based, but without altering the order of the periods. Later, E. Beyrich introduced the Oligocene period, and some geologists recognize a Palaeogen or earlier period. European geologists very generally use the grouping adopted by R. Hörnes:—

The great number and variety of mammalian remains has made it possible for the Tertiary rocks to be classified by their means:—we may say, Les encacllements des mammifères—les Tertiaries (1857), by J. B. de C. Quenstel; Q. Geo. Soc. Lond. (1860); Forsyth Major, Geol. Mag. (London, 1889); and H. F. Osborn, J. L. Wortman, G. F. Matthew, for western North America, Bull. Am. Mus. Nat. Hist., xii. (1899).

During the Tertiary era the geographical configuration of the globe was steadily approaching that of the present day; but in part of the time there still existed the great equatorial ocean "Tethys," and in the present level of the sea, the world of the Pliocene ("Tethys") the crust began to be folded up, giving rise to the Alps, Carpathians, Caucasus, Himalayas and other mountains, some of the early Tertiary marine formations being now found raised more than 100 fathoms above the modern level. In the seas, bony fish and crab-like decapods increased in numbers and variety; while pelagics and gastropods took the prominent place previously occupied by ammonites and belemnites, and, leaving behind such forms as Rusistes, Mecoceras, etc., they generally developed in the direction of the modern regional groups. In the plant world, the dicotyledonous angiosperms generally assumed the leading rôle which they occupy to-day.

The climate in northern latitudes seems to have passed from temperate to sub-tropical, with minor fluctuations, until at the close a rapid lowering of temperature ushered in the glacial period (J. A. H.).

TERTULLIAN (c. 155-c. 222), whose full name was QUINTUS SEPTIMIUS FLORENS TERTULLIANUS, is the earliest and after Augustine the greatest of the ancient church writers of the West. Before him the whole Christian literature of the Latin language consisted of a translation of the Bible, the Octavians of Minucius Felix (q.v.—an apologetic treatise written in the Ciceronian style for the higher circles of society, and with no evident effect for the church as a whole, the brief Acts of the Scillitan martyrs, and a list of the books recognized as canonical (the so-called Muratorian fragment). Whether Victor the Roman bishop and Apollonius the Roman senator ever really made an appearance as Latin authors is quite uncertain. Tertullian in fact created Christian Latin literature; one might almost say that that literature sprang from him full-grown, alike in form and substance, as Athena from the head of Zeus. Cyprian polished the language that Tertullian had made, sifted the thoughts he had given out, rounded them off, and turned them into current coin, but he never ceased to be aware of his dependence on Tertullian, whom he designated as kai 'Egwy, his master (Jér., De vir. ill. 53). Augustine, again, stood on the shoulders of Tertullian and Cyprian; and these three North Africans are the fathers of the Western churches.

Tertullian's place in universal history is determined by (1) his intellectual and spiritual endowments, (2) his moral force as a personal figure, (3) the course of his personal development, (4) the circumstances of the time in the midst of which he worked.

(1) Tertullian was a man of great originality and genius, characterized by the deepest pathos, the liveliest fancy, and the most penetrating keenness, and was endowed with ability to appropriate and make use of all the methods of observation and speculation, and with the readiest wit. His writings in tone and character are always alike "rich in thought and destitute of form, passionate and hair-splitting, eloquent and pithy in expression, energetic and condensed to the point of obscurity. His style had been characterized with justice as dark and resplendent like ebony. His eloquence was a vehement order; but it wins hearers and readers by the strength of his passion, the energy of its truth, the pregnancy and elegance of its expression, just as much as it repels them by its heat without light, its sophistical arguments, and its elaborate hair-splittings. Though he is wanting in moderation and in luminous warmth, his tones are by no means always harsh; and as an author he ever aspired with longing after humility and love and patience, though his whole life was lived in the atmosphere of conflict. Tertullian both as a man and as a writer had much in common with the apostle Paul.

(2) In spite of all the contradictions in which, he involved
himself as a thinker and as a teacher, Tertullian was a compact ethical personality. What he was he was with his whole being. Once a Christian, he was determined to be so with all his soul, and to shape himself to love all things divine and philosophical with the world. It is not difficult to lay one's finger upon many obliquities, self-deceptions and sophisms in Tertullian in matters of detail, for he struggled for years to reconcile things that were in themselves irreconcilable; yet in each case the perversities and sophisms were rather the outcome of the peculiarly difficult circumstances in which he stood. It is easy to convict him of having failed to control the glowing passion that was in him. He is often outrageously unjust in the substance of what he says, and in manner harsh to cynicism, scornful to grumeterners. He was in no battle that he forsook, was ever actuated by selfish interests. What he did was really done for the Gospel, as he understood it, with all the faculties of his soul. But he understood the Gospel as being primarily an assured hope and a holy law, as fear of the Judge who can cast into hell and as an inflexible rule of faith and of discipline. Of the glorious liberty of the children of God he had nothing but a mere presentiment; he looked for it only in the world beyond the grave, and under the power of the Gospel he counted as loss all the world could give. He well understood the meaning of Christ's saying that He came not into the world to please men, but to be reviled. Whence, when he had introduced into the church that conformity to the world which had seized the churches he maintained the "vigor evangelicus" not merely against the Gnostics but against opportunists and a worldly-wise clergy. Among all the fathers of the first three centuries Tertullian has given the most powerful expression to the terrible earnestness of the Gospel.

(3) The course of Tertullian's personal development fitted him in an altogether remarkable degree to be a teacher of the church. Born at Carthage of good family—his father was a "centurio pro consularis"—he received a first-rate education both in Latin and Greek. He was also a man of the world, and gives evidence of familiarity alike with its prose and with its poetry; and his excellent memory—though he himself complains about it—enabled him always to bring in at the right place an appropriate, often brilliant, quotation or some historical allusion. The old historians, from Herodotus to Tacitus, were familiar to him, and the accuracy of his historical knowledge is astonishing. He studied with earnest zeal the Greek philosophers; Plato in particular, and the writings of the Stoics, he had fully at command, and his treatise De Anima shows that he himself was able to investigate and discuss philosophical problems. From the philosophers he had been led to the medical writers, whose treatises plainly had a place in his working library. But no portion of this rich store of miscellaneous knowledge has left its characteristic impress on his writings; this influence was reserved for his legal training. His father, whose military spirit reveals itself in the whole bearing of Tertullian, to whom Christianity was above everything a "milicia," had intended him for the law. He studied in Carthage, probably also in Rome, where, according to Eusebius, he enjoyed the reputation of being one of the most eminent jurists of the time. This statement derives confirmation from the Digest, where references are made to two works, De Castroini Peculio et Quaestionum Libri VIII., of a Roman jurist named Tertullian, who must have flourished about 180 A.D. In point of fact the quondam advocate never disappeared in the Christian presbytery. This was at once his strength and his weakness: his strength, for as a professional pleader he had learned how to deal with an adversary according to the rules of the art—to pull to pieces his theses, to reduce him ad absurdum, and to show the defects and contradictions of his statements,—and was specially qualified to expose the irregularities in a lawsuit taken by the state against the Christians; but it was also his weakness, for it was responsible for his litigiousness, his often doubtful shifts and artifices, his sophisms and argumentationes ad hominem, his fallacies and surprises. At Rome in mature manhood Tertullian became a Christian, under what circumstances we do not know, and forthwith he bent himself with all his energy to the study of Scripture and of Christian literature. Not only was he master of the contents of the Bible: he also read carefully the works of Herma, Justin, Tatian, Melitides, Minucius, Irenaeus, Tertullian, Chrysostom, as well as many Gnostic treatises, the writings of Marcin in particular. In apologetics his principal master was Justin, and in theology proper and in the controversy with the Gnostics, Irenaeus. As a thinker he was not original, and even as a theologian he has produced but few schemes of doctrine, except his doctrine of sin. His special gift lay in the power to make what had been traditionally received impressive, to give it to its proper form, and to gain for it new currency. From Rome Tertullian visited Greece and perhaps also Asia Minor; at any rate we know that he had temporary relations with the churches there. He was consequently placed in a position in which he could check the doctrine and practice of the Roman church. Thus equipped with knowledge and experience, he returned to Carthage and there laid the foundation of Latin Christian literature. At first, after his conversion, he wrote Greek, but by and by Latin almost exclusively. The elements of this Christian Latin language may be enumerated as follows:—(i.) it had its origin, not in the literary language of Rome as developed by Cicero, but in the language of the people as we find it in Plautus and Terence. (ii.) it has an authority derived by Greek, particularly through the Latin translation of the Septuagint and of the New Testament, besides being sprinkled with a large number of Greek words derived from the Scriptures or from the Greek liturgies; (iv.) it bears the stamp of the Gnostic style and contains also some military expressions; (v.) it owes something to the original creative power of Tertullian. As for his theology, its leading factors were: (i.) the teachings of the apologists; (ii.) the philosophy of the Stoics; (iii.) the rule of faith, interpreted in an anti-Gnostic sense, as he had received it from the Church of Rome; (iv.) the Soteriological theology of the Council of Nice; and (v.) the Montanist prophets (in the closing decades of his life). This analysis does not disclose, nor indeed is it possible to discover, what was the determining element for Tertullian; in fact he was under the dominion of more than one ruling principle, and he felt himself bound by several mutually opposing authorities. It was his desire to unite the enthusiasm of primitive Christianity with intelligent thought, the original demands of the Gospel with every letter of the Scriptures and with the practice of the Roman church, the sayings of the Paraclete with the authority of the church, the law of the Gospel with the law of the Montanist with all the utterances of the New Testament and with the arrangements of a church seeking to set itself up within the world. At this task he toiled for years, involved in contradictions which it took all the finished skill of the jurist to conceal from him for a time. At last he felt compelled to break off from the church for which he had lived and fought; but the breach could not clear him from the contradictions in which he found himself entangled. Not only did the great chasm between the old Christianity, to which his soul clung, and the Christianity of the Scriptures as juristically and philosophically interpreted remain unbridged; he also clung fast, in spite of his separation from the Catholic church, to his position that the church possesses the true doctrine, that the bishops per successionem are the repositories of the grace of the teaching office, and so forth. The growing violence of his latest works is to be accounted for, not only by his burning indignation against the ever-advancing secularization of the Catholic church, but also by the incompatibility between the authorities which he recognized and yet was not able to reconcile. After having done battle with heathens, Jews, Montanists, Gnostics, Monarchians, and the Catholics, he died an old man, carrying with him to the grave the last remains of primitive Christianity in the West, but at the same time in conflict with himself.

(4) What has just been said brings out very clearly how important in their bearing on Tertullian's development were the circumstances of the age in which he laboured. His activity
Respecting its relation to the Octavius of Minucius Felix much has been written; to the present writer it seems unquestionable that Tertullian’s work was De spectaculis, see his De spectaculis haereticorum, in which the jurist is more clearly heard than the Christian. It is the chief of the dogmatic or theological works, and Tertullian does not use it as much more tolerant than his latter. To learn something of his Christian temper we must read the De oratione and the De patre.

2. Tertullianus, De spectaculis haereticorum, is of special interest from the archaeological point of view.

II. Works written between 202–203 and 207–208.—De virginibus velandis, De corona militis, De juxta persecutione, De exhortatione presbyterorum, De spectaculis haereticorum, De spectaculis. In his De spectaculis he compares to scorpions; it is written in praise of martyrdom.

Adversus Heresem, De censu animae adv. Heresem (lost), Adv. Valentinianos, Adv. Apelleias (lost), De paradiso (lost), De jure (lost), De anima (the first book on Christian psychology), De carnis Christi, De resurrectione carnis, and De spe fideliem (lost), were all written after Tertullian had the prophetic claim of the Montanists, but before he had left the church.

III. Works later than 207–208.—To this period belong the five books Adv. Marcionem, his main anti-Gnostic work (in the second form—the first of the five was written in 207–208), Ad Scapulam (190), De spectaculis (190), De spectaculis haereticorum, De spectaculis, and two praescriptione; we also know that he became a presbyter in Carthage and was married. His recognition of the Montanist prophecy in Phrygia as a work of God to which all others who suffered and died for the church was the doctrine of his conversion to Christianity is quite certain; there is much in favour of the years between 190 and 195. How long he remained in Rome after becoming a Christian, whether he had any influence on the church, and where he was when the event of his conversion happened, is a problem yet unsolved. The date of his visit to Greece—on these points also we remain in ignorance. It is certain that he was settled in Carthage in the second half of 197, the date of his writing his Apologiae and (shortly after) his other works. We also know that he became a presbyter in Carthage and was married.

the Tagus (q.v.); the Guadalaviar, which rises in the Montes Universales and flows south-east to enter the Mediterranean at Valencia; the Jıloca, which flows north from the lake of Cellla to join the Jalón at Calatayud; the Guadalo, Martin and Matarraña, tributaries of the Ebro.

Notwithstanding the fertile character of the plains and the abundance of mineral wealth, the trade of the province is unimportant and civilization in a backward state, owing to the lack of means of transport, want of enterprise and imperfect communication with the outer world. Much land is devoted to pasture that could be cultivated. Extensive forests with fine timber are neglected, as are some important coal beds in the eastern districts. The chief products are corn, wine, oil, cheese, fruits, timber, flax, hemp, silk, wool and saffron, together with cattle, sheep and swine; while in the busier centres some slight manufacture of coarse cloth, paper, leather, soap, pottery and esparto goods is carried on. The road from Murviedro, on the Gulf of Valencia, to Calatayud.

TERUEL, the capital of the Spanish province of Teruel; on the left bank of the river Guadalaviar, at its confluence with the Alfamba, and on the Murviedro-Calatayud railway. Pop. (1900) 10,797. The older part of Teruel is a walled city with narrow gloomy streets and crumbling medieval houses, but modern suburbs have been built outside the walls. Some of the numerous churches are worth seeing, with their paintings by the 17th-century artist Antonio Visquert. In the cloisters of San Pedro lie the remains of the celebrated “lovers of Teruel,” Juan de Marcilla and Isabella de Seguca, who lived in the 13th century and whose pathetic story has formed the subject of many songs and romances. The place is called Terz de Salas, Hartzenbusch and others. The cathedral dates from the 13th century. The great aqueduct of 140 arches was erected in 1555-60 by Pierre Bedel, a French architect. Teruel has several good hospitals and asylums for the aged and children, an institute, a training school for teachers, primary schools, a public library, an atheneum, a meteorological station, and a large prison. The see was created in 1577, and forms part of the archiepiscopal province of Saragossa.

TERUVEREN, a small town in Belgium in the province of Brabant, midway between Brussels and Louvain. Pop. (1904) 4017. It contained an ancient abbey and a hunting château belonging to the dukes of Brabant. The fine park of Teruveren is really part of the forest of Soignes. The Colonial Museum and World’s Colonial School are established here, and Teruveren is connected with Brussels by a fine broad avenue, traversed by an electric tramway as well as by carriage and other roads, and between 6 and 7 m. in length.

TERZA RIMA, or “third rhyme,” a form of verse adapted from the Italian poets of the 13th century. Its origin has been attributed by some to the three-lined ritornel, which was an early Italian form of popular poetry, and by others to the sirventes of the Provencal troubadours. The sorventese incatenato of the latter was an arrangement of triple rhymes, and unquestionably appears to have a relation with terza rima; this connexion becomes almost a certainty when we consider the admiration expressed by the Tuscan poets of the 13th century for the metrical inventions of their forerunners, the Provençals. In Italian, a stanza of terza rima consists of three lines of eleven syllables, linked with the next stanza, and with the next, and so on, by a recurrence of rhymes; thus abs, bcd, ded, &c., so that, however long the poem is, it can be divided nowhere without severing the continuity of the rhyme. Schuchardt has developed an ingenious theory that these successive terzines are really chains of ritornel, just as ottava rima, according to the same theory, is a chain of rispetti. There were, unquestionably, chains of interwoven triple rhymed lines before the days of Dante, but it was certainly he who raised terza rima from the category of folk-verse, and gave it artistic character. What this character is may best be seen by an examination of the austere and majestic lines with which the Inferno opens, no more perfect example of terza rima having ever been composed:—

"Nel mezzo del camin di nostra vita
Mi retrovai per una selva oscura,
Che la diritta via era smarrita.
Ahi quanta a dir qual’era cosa dura!
Questà selva selvaggia ed aspra e forte,
Chè nel pensier rinnova la pauri!"

It is impossible, however, to break off here, since there is no rhyme to forte, which has to be supplicd twice in the succeeding terzina, whereby rhyme schemes are introduced, linking the whole to a still further terzina, and so on, indefinitely. The only way in which a poem in terza rima can be closed is by abandoning a rhyme, as at the end of Canto i of the Inferno, where no third rhyme is supplied to Pietro and dietro. Boccaccio wrote terza rima in close following of Dante, but it has not been a form very frequently adopted by Italian poets. Nor has the extreme difficulty of sustaining dignity and force in these complicated chains of verse made writers in other languages very anxious to adventure on terza rima. In the age of Elizabeth, Samuel Daniel employed it in his "Episoc to the Countess of Bedford," but he found no followers. Probably the most successfully sustained poem in terza rima in the English language is Mrs Browning’s Casa Guidi Windows (1851). The Germans have always had an ambition to write in terza rima. It was used by Paul Schele, a writer of whom little is known, before the close of the 16th century, and repeatedly by Martin Opitz (1597-1639), who called the form dritreime. Two centuries and a half later, W. Schlegel had the courage to translate Dante in the metre of the Italian; and it was used for original poems by Chamisso and Rückert. Goethe, in 1826, addressed a poem in terza rima to the praise of Schiller, but there is a possible in this metre at the beginning of the second part of Faust.

See Hugo Schuchardt, Ritournell und Terzine (Halle, 1875).

TESCHEN (Czech, Těšín; Polish, Cieszyn), a town in Austria, in Silesia, 50 m. E. of Troppau by rail. Pop. (1900) 19,142, of which over half is German, 43 per cent. Polish and the remainder Czech. It is situated on the Olsa, a tributary of the Oder, and combines both Polish and German peculiarities in the style of its buildings. The only relic of the ancient castle is a square tower dating from the 15th century. There are several furniture factories and large saw-mills.

Teschin is an old town and was the capital of the duchy of Teschin. It was at Teschen that Maria Theresa and Frederick II. signed, in May 1779, the Peace, which put an end to the war of Bavarian succession. The duchy of Teschen comprises Upper Silesia, and since 1919 it stood under the suzerainty of Bohemia. It became a direct anappage of the Bohemian crown in 1625 at the extinction of the male line of its dukedom, and since 1767 it has borne the name of Count of Teschen. Under the taxing of his eldest son, and, at his death, in 1805 it passed into the hands of his nephew, the Archduke Frederick.

TESSELLATED (Lat. tessellatus), formed of tessellae, or small tesserae, cubes from half an inch to an inch square like dice, of pottery, stone, marble, enamel, &c. (See Pavement and Mosaic.)

TESSIN, CARL GUSTAF, Count (1695-1770), Swedish statesman, son of a great architect, Nicodemus Tessin, began his public career in 1723, at which time he was a member of the Holstein faction. In 1725 he was appointed ambassador at Vienna, and it is said that he counteracted the plans of the Swedish chancellor, Count Arvid Horn, who was for acceding to the Hanoverian Alliance. During the riksag 1726-27 and 1731 he fiercely opposed the government, and his wit, eloquence and imposing presence made him one of the foremost protagonists of the party subsequently known as "The Hats" (see Sweden: History). From 1735 to 1736 he was again Swedish ambassador at Vienna. During the riksag 1738 he was elected marshal of the diet and contributed more than anyone else to overthrow the Horn administration the same year. On the division of the spoil of patronage he chose for himself the post of ambassador extraordinary at Paris, and from 1739 to...
TEST ACTS

1743 delighted Versailles with his brilliant qualities of grand seigneur, at the same time renewing the traditional alliance between France and Sweden which had been interrupted for more than sixty years. His political ability, however, was by no means commensurate with his splendid social qualities. It was his sanguine credulity which committed the "Hats" to their rash and unprecedented war with Russia in 1741-42, though in fairness it must be added that Tessin helped them out of their difficulties again by his adroitness as a party leader and his stirring eloquence. He gained his arm-chair in the senate as a reward for his services on this occasion. In 1743 Tessin composed the long outstanding differences between Sweden and Denmark in a special mission to Copenhagen. In the winter he kept the hounds at an extended residence to Berlin to escort to Stockholm Frederick the Great's sister, Louisa Ulrica, the chosen bride of the Swedish crown-prince, Adolphus Frederick. As overhofmarskyl of the young court, Tessin speedily captivated the royal pair. He also succeeded in withdrawing the crown-prince from beneath the influence of the Russian empress Elizabeth, to whom Adolphus Frederick owed his throne when he became king of Sweden in 1713, thereby essentially contributing to the maintenance of the independence of Sweden. From 1746 to 1752 Tessin presided over the Royal Academy, and as a matter of fact the minister was called in those days His "system" aimed at a rospromotion with Denmark with the view of counterbalancing the influence of Russia in the north. It was a dignified and prudent policy, but his endeavour to consolidate it by promoting a matrimonial alliance between the two courts alienated the Swedish crown-prince, who, as a Holstein, nourished an ineradicable hatred of everything Danish. As, moreover, on the accession of Adolphus Frederick in 1751, Tessin refused to countenance any extension of the royal prerogative, the rupture between him and the severe penalties imposed on him by the occasion of the coronation (1752) he resigned the premiership, and in 1754 the governorship of the young crown-prince Gustavus also, spending the rest of his days at his estate at Åkerö. Tessin was one of the most brilliant personages of his day, and the most prominent representative of French culture in Sweden. He was also a fine orator, and his literary style is excellent.

His principal works are his autobiographical fragments (1st ed. Stockholm, 1809) and his Frälsningsrecensionen, 3 vols. (Stockholm, 1822), both of them extracts from his voluminous MS. memoirs in 29 volumes; and his famous En gammal mans bref til en ung Prins (Stockholm, 1753; English edition, 1755 and 1759), addressed to his pupil, afterwards Gustavus III., one of the most delightful books for the young that ever saw the light.

See R. Nisbet Bain, Gustavus III. and his Contemporaries (London, 1895), vol. 1; Bernhard von Beskow, Minne of Griefe K. G. Tessin (Stockholm, 1886) and Bernhard Elis Malmskog, Sveriges publika historia från Konung Karl XIII.'s död till statsflykningen, 1772 (Stockholm, 1893-1901).

TEST ACTS. The principle that none but persons professing the established religion were eligible for public employment was adopted by the legislatures of both England and Scotland soon after the Reformation. In England the Acts of Supremacy and Uniformity, 1558, were a notable instance of this principle. The Scottish Test Act was 1681, c. 6, rescinded by 1690, c. 7. Re-nunciation of popery was to be made by persons employed in education (1708, c. 3). A motion to add, after the 18th article of the 1709 Act, the words: "and the saecular as well as the spiritual offices of the United Kingdom were negatived by the Scottish parliament. A similar fate awaited a proposal that while a sacramental test was in force in England all persons in public office in Scotland should subscribe their adhesion to the Presbyterian Church government. By 1707, c. 6, all professors, principals, regents, masters or others bearing office in any university, college or school in Scotland were to profess full subscription to the Confession of Faith. All persons were to be free of any oath or test contrary to or inconsistent with the Protestant religion and Presbyterian Church government. The reception of the communion was never a part of the test in Scotland as in England and Ireland. The necessity for subscription to the Confession of Faith by persons holding a university office (other than that of principal or professor of theology) was removed by 16 & 17 Vict. c. 89. The act provided that in place of subscription every person appointed to a university office was to subscribe a declaration according to the form in the act, promising not to teach any opinions opposed to the divine authority of Scripture or to the Doctrines and Covenants of the Presbyterian Church of Scotland or its doctrines and privileges. All tests were finally abolished by an act of 1889 (52 & 53 Vict. c. 59). Ireland.—An oath of allegiance was required by the Irish Act of Supremacy (o Eliz. c. 1). The English Act of 1712 (Will. & M. c. 2) substituted other oaths and enforced in addition on peers, members of the House of Commons, bishops, baronets, attorneys and others a declaration against transubstantiation, invocation of the Virgin Mary and the saints, and the sacrifice of the mass—a special exception being made in favour of the duke of York. The provisions of the Test Act were violated in 1742 by the late James II., and the Earl of Derwentwater's declaration against transubstantiation, &c., were repealed by the Roman Catholic Relief Act of 1829 (10 Geo. IV. c. 7). This general repeal has been followed by the special repeal of the Corporation Act by the Promissory Oaths Act 1871, of the Test Act by the Statute Law Revisio Act 1863, and of the act of 1678 by an act of 1866 (29 & 30 Vict. c. 19). Religious tests remained in the English universities until 1871, in Dublin University until 1873, and the Scottish universities until 1889. To be a member of the Church of England was a necessary condition of holding any public or university college offices by the Act of Uniformity of 1662, and such official appointments were abolished by the Toleration Act of 1688 and the Roman Catholic Relief Act of 1829. In 1871 the University Tests Act abolished subscriptions to the articles of the Church of England, all declarations and oaths respecting religious belief, and all compulsory attendance at public worship in the universities of Oxford, Cambridge and Durham. There is an exception confining to persons in holy orders of the Church of England degrees in divinity and positions restricted to persons in holy orders, such as the divinity and Hebrew professorships.

Scotland.—A religious test was imposed immediately after the Reformation. By 1557, c. 9, no one was to be appointed to a public office who had not subscribed to a declaration against enemies of the new religion. The Scottish Test Act was 1681, c. 6, rescinded by 1690, c. 7. Re-nunciation of popery was to be made by persons employed in education (1700, c. 5). A motion to add, after the 18th article of the 1709 Act, the words: "and the saecular as well as the spiritual offices of the United Kingdom were negatived by the Scottish parliament. A similar fate awaited a proposal that while a sacramental test was in force in England all persons in public office in Scotland should subscribe their adhesion to the Presbyterian Church government. By 1707, c. 6, all professors, principals, regents, masters or others bearing office in any university, college or school in Scotland were to profess full subscription to the Confession of Faith. All persons were to be free of any oath or test contrary to or inconsistent with the Protestant religion and Presbyterian Church government. In 1871 the University Tests Act abolished subscriptions to the articles of the Church of England, all declarations and oaths respecting religious belief, and all compulsory attendance at public worship in the universities of Oxford, Cambridge and Durham. There is an exception confining to persons in holy orders of the Church of England degrees in divinity and positions restricted to persons in holy orders, such as the divinity and Hebrew professorships.
...author addresses two Messianic hymns. The writer already sees the Messianic kingdom established, under the sway of which the Gentiles will in due course be saved, Beliar overthrown, sin disappear from the earth, and the righteous dead rise to share in the blessedness of the living. Alas for the vanity of man's judgment and man's preciosity! Our book had hardly been published, when Hyrcanus, owing to an injury done him by the Pharisees, broke with their party, and, joining the Sadducees, died a year or two later. His successors proved themselves the basest of men. Their infamy is painted in lurid colours by contemporary writers of the 1st century b.c., and by a strange irony the work, or, rather, fragments of the work of one of these assailants of the later Maccabees, has achieved immortality by finding a covert in the chief manifesto that was issued on behalf of one of the earlier members of that dynasty. This second writer singles out three of the Maccabean priest kings for attack, the first of whom he charges with every abomination; the people itself, he declares, is apostate, and chastisement will follow speedily—the temple will be laid waste, the nation carried afresh into captivity, whence, on their repentance, God will restore them again to their own land, where they shall enjoy the blessedness of God's presence and be ruled by a Messiah sprung from Judah. When we contrast the expectations of the original writer and the actual events that followed, it would seem that the chief value of his work would consist in the light that it throws on this obscure and temporary religion, in which the Christian expectations of the world were born and developed to the close of the 2nd century. But this is not so. The main, the overwhelming value of the book lies not in this province, but in its ethical teaching, which has achieved a real immortality by influencing the thought and dictions of the writers of the New Testament, and even those of our Lord. This ethical teaching, which is indefinitely higher and purer than that of the Old Testament, is yet its true spiritual child, and helps to bridge the chasm that divides the ethics of the Old and New Testaments.13

In the early decades of the Christian era the text was current in two forms, which are denoted by H and Ap in this article and in the edition of the text published by the Oxford University Press. "The former of these was translated not later than A.D. 50 into Greek, and this translation was used by the scholar who rendered the second Hebrew recension into Greek. The first Greek translation was used by our Lord, by St Paul, and other New Testament writers. In the second and following centuries it was interpolated by Christian scribes, and finally condemned indiscriminately along with other apocryphs. For several centuries it was wholly lost sight of, and it was not till the 13th century that it was rediscovered through the apocryphal work of Robert Grosseteste, bishop of Lincoln, who translated it into Latin, under the misconception that it was a genuine work of the twelve sons of Jacob, and that the Christian interpolations were a genuine product of Jewish prophecy. The advent of the Reformation brought in critical methods, and the book was unjustly disparaged as a mere Christian forgery for nearly four centuries. The time has at last arrived for this book, so noble in its ethical side, to come into its own.17

---

1 From § 1 of the Introduction to R. H. Charles's The Testaments of the Twelve Patriarchs, translated from the Editor's Greek Text (A. & C. Black, 1908).

3 Some of the evidence for this conclusion will be given later.
Again we have two recensions $S'$ and $S''$, but the one may be on the whole reasonably described as an abbreviation of the other.

The relations of the above authorities are too complicated to be treated of in detail, but they are represented on the subjacent diagram.

Original Language.—Apart from Grabe, till within the last fifteen years no notable scholar has advocated a Hebrew original. Nitzsche, Dillmann, RitcheI and Sinker were convinced that the book was not a translation but was written originally in Greek. To Kohler and Gaster belongs the honor of re-opening the question of the Hebrew original of the Testaments. Only the latter, however, offered any linguistic evidence. In his article on the question he sought to establish a Hebrew original of all the Testaments and to prove that the Hebrew text of Napthali which he had discovered was the original testament, and that the Greek Napthali was a late and corrupt reproduction of it with extensive additions from other sources. But he failed in establishing either thesis. The subject was next taken in hand by R. H. Charles, who in a preliminary form in the Enzyklopaedie Biblica (i. 241, 1890), and later, with considerable fullness, in his edition of the Greek text of the Testaments (1906), brought to light a number of facts that put the question of a Hebrew original beyond the range of doubt. We will now place a few of the grounds before the reader.

(a) Hebrew constructions and expressions are to be found in every page. Though the vocabulary is Greek the idiom is frequently HEBRATIC and foreign to the genius of the Greek language. Thus in T. Heb. vi. 11, in atov eljisth vj v. 12. In T. Jud. xx. 4, for sthe d4Tov avrov—an utterly unmeaning phrase—becomes intelligible on eterev (T. Jud. x. 11), e'v eljisth vj v. 14. "ye shall dwell securely with me"; for here is 'eljisth, as several times in the Septuagint, is a wrong rendering of nve.

(b) Differing renderings in the Greek of the same Hebrew expression—also differential expressions in the Greek implying differential in the Hebrew. See Introduction to R. H. Charles's Text, § 11.

(c) Paronomasia which are lost in the Greek can be restored by transliteration into Hebrew. There are over a dozen of such instances. We will now place a few of the grounds before the reader.

(c) Paronomasia which are lost in the Greek can be restored by transliteration into Hebrew. There are over a dozen of such instances. We will now place a few of the grounds before the reader.
When Hen was translated we have no definite meanings of determining. It was in all likelihood done subsequently to Hen. The translator of Hen appears to have had the translation of Hen before him, and to have followed it generally unless where there were marked differences between Hen and other versions.

Jewish Additions to the Text.—(a) A large body of these additions can be classed under one head as written with a well-defined object and at a definite period. This period was about 70-40 B.C., and the main points of additions were the kings of the本领—priestly high-priesthood, which in the 1st century B.C. had become guilty of every lewdness. T. Lev. x. xiv.—xvi.; T. Jud. xvii. 2—xviii. 1 (f., x., xvi., and xv.) and T. Zeb. iv. 1-21 (f., x., xii., and xiv.) contain a great deal of the later additions. T. Naph. iv.; T. Gad. viii. 2; T. Asb. vii. 4-7. These additions are identical in object and closely related in character and dictum with the Psalms of Solomon.

Christian Additions to the Text.—These additions are to be found in the Septuagint text as a regular practice made at different periods. The existence of these Christian elements in the text misled many scholars for the past four hundred years into believing that the book itself was a Christian apocrypha. To Grabe, Schnapp and Conybeare belongs the credit of showing that the Christian elements were interpolations—to Conybeare especially of the three, since, whereas the two others showed the high probability of their derivation on internal evidence, Conybeare proved by means of the Armenian Version that when it was made many of the interpolations had not yet found their way into the text. For a full treatment of these passages see R. H. Charles's Testament of the Twelve Patriarchs.

Influence on the New Testament.—We have already shown that St Paul twice quoted from the Greek text of the Testaments. These two quotations are interesting; first, on account of the degree of his indebtedness in thought and phraseology in several of his Epistles, especially that to the Romans. But of still greater interest are the passages in the Gospels which show the influence of the Testaments, and these belong mainly to the sayings and discourses of our Lord. We may mention two of the most notable of these. Thus Matt. xviii. 15, 35, which deal with the great question of forgiveness, are clearly dependent on our text.

Matt. xviii. 15. 'Εσάης δη διαρθήσθη ὁ ἄνδρος ὁ κατὰ σοῦ κατ᾽ τὸν κόσμον τὸν σωτῆρα, καὶ μετανοήσῃ καὶ ἀφεθήσῃ ὁ πατήρ σου. . . . καὶ ἐὰν μὴ μετανοήσῃ καὶ μὴ ἀφεθῇ, καὶ ἀποκαλόθησαι ὁ σωτήρ ὁ πατήρ σου καὶ ὁ κόσμος κατὰ τὸν κόσμον καταρρεῖ.'

T. Gad. vii. 3. 'Εαν μὴ διαρθησθήσθη ὁ ἄνδρος τῷ σωτῆρι τοῦ κόσμου καὶ μετανοήσῃ καὶ ἀφεθήσῃ ὁ πατήρ τοῦ κόσμου καὶ τῶν κόσμων κατὰ τοὺς κόσμους.'

v. 7. 'Αφεθήσετο ὁ πατήρ τῶν κόσμων.'

Next, the duty of loving God and our neighbour is already found in T. Dan. v. 3, which is the oldest literary authority which enjoin these two great commands. The form is very similar in Matt. xxii. 37-40, but the matter is already in the Test. Dan. See Intro. § 4 for the connection.

Literature.—(a) Texts.—Sinkier, Testamenta XII Patriarcharum (1866); [this work gives the text and a of the footnotes; subsequent, and with variations of the Greek versions]; Charles, The Greek Versions of the Testaments of the XII. Patriarchs from nine MSS., with the Variants from the Armenian and Slavonic Versions and the Hebrew Fragments (1968). Comentary.—On the T. The Testaments of the Twelve Patriarchs (1898). Critical Inquiries.—See Schürer, G. J. V. ill. 261-262: Charles, The Test. XII. Patriarchs, pp. xxxvi.-xlii. (R. H. C.)

TESTAMENTUM DOMINI (“The Testament of Our Lord”).

Extracts from the book which bears this title, contained in an 8th-century MS. at Paris, were published by Lagarde in 1856 (Reliquiae uris ecclesiasticæ antiquissimæ 80-89; and a Latin fragment, edited by Dr Montague James, appeared in 1893 (Texts and Studies, i. 154). The whole book was first published in 1886, with a Latin translation by J. M. Rahmani, the Uniat Syrian Patriarch of Antioch. His text is that of a 17th-century MS. at Mosul, the colophon of which says that the Syriac text was translated from the original Greek "a Jacobo pares," evidently James of Edessa, in A.D. 687; but he makes use of other material, including an Arabic version made from a Coptic copy written in A.D. 927. The Mosul MS. contains the whole Bible in the Peshito version, followed by the Syrian "Clementine Octateuch," i.e., the collection of ecclesiastical law, in eight books, which was used by the Nestorians and Jacobites.

Of this the Testament forms the first two books; and according to the title (which, apparently by an error, is written "Testamentum," and not "Testament," or words which Our Lord spake to His holy Apostles when He rose from the dead," Plainly, it is one of that series of writings, claiming to embody the fundamental rules of the Church, which culminates in the Apostolical Constitutions (q.v.).

It falls into three distinct parts: an apocalyptic introduction (book i., chapters 1-16; the division into books, however, is clearly that of a later editor); the narrative of the life of Jesus, with his appointment of the Twelve Apostles, his death, and his resurrection. He is represented as unfolding to them, at their request, the signs of the end, and giving them instruction on various other topics. Incidentally, the fact becomes plain that this section is composed from the standpoint of Asia Minor and Syria; it dates from soon after the time of Maximin (235-38) and Decius (249-51), and that it springs from a Christian community of a strictly puritan type. (b) The Church Order follows the general lines of the Canons of Hippolytus and similar documents. It describes the Church and its buildings (l. 19); the office of the bishop and his functions (l. 19-27); the mystagogic instruction (l. 28-30) common to all churches; the arrangements for the celebration of Pentecost (l. 31-33), and in an earlier form, and based in part upon the Gnostic "Acts of Peter"; the presbyter (l. 39-32): the deacon (l. 33-38); the deacons (l. 39-40); the succession of bishops (l. 40-43), apparently the same persons with different titles. Elsewhere as "presbyters" (l. 35, ii. 19); the subdeacon (l. 44) and the reader (l. 45), the order of whose offices seems to have been as follows, "first presbyter, then subdeacon, then charismata or spiritual gifts (l. 47). Next come the regulations for the laity, including the whole course of preparation for and admission to baptism (l. ii. 9), confirmation (l. 9), and the eucharist (l. 10); after which there follows a series of miscellaneous regulations for Easter and Pentecost (l. 11-12), the fasting (l. 13), the funds of the Church (l. 17-20), the visitation of the sick (l. 21), the distribution of the alms (l. 22-23), and the hours of prayer (l. 24). (c) The Conclusion (l. 25-27) repeats the entire book, in the first person, and comprises the salutations of the twelve Patriarchs, and Matthew, and sent to Jerusalem by the hands of Dosithaeus, Sillias, Magnus and Aquila.

In all this there is much that is peculiar to or characteristic of the Testament. First and foremost is its ascription to the Lord Himself, which we can hardly be mistaken in regarding as an attempt to claim yet higher sanction than was claimed by the various compilations which were styled "apostolic." It is true that it was once longer, and that portions of the book are manifestly, and of a certain of the latter. Again, the whole tone of the Testament is one of highly strung asceticism, and the regulations are such as point by their severity to a small and strictly organized body. They are "the wise," the "perfect," the "sons of light"; but this somewhat Gnostic phraseology is not accompanied with any signs of Gnostic doctrine, and the work as a whole is orthodox in tone. They are set in the midst of "wolves," despised and slighted by the careless and worldly; there is frequent mention of "the persecuted," and of the duty of "bearing the cross." These means to be no locus poenitentiarum for serious sins except in the case of catechumens, and there is a notable "perfectionist" tone in many of the prayers. Charismata, and above all exorcisms, occupy a very important place: there is a vivid realization of the ministry of angels, and the angelic hierarchy is very complete. Great stress is laid upon virginity (although there is not a sign of monasticism), upon fasting (especially for the bishop), upon the regular attendance of the whole clerical body and the "more perfect of the laity at the hours of prayer. The church buildings are very elaborate, and the baptismery is oblong, a form found apparently only here in the East, in the Arabic church. Those who are members of the church are the Epiphany, Easter and Pentecost. With regard to the prayers, they are based upon forms common to this and other Church orders, but have many lengthy interpolations of an inflated and rhapsodic kind. The bishop appears to rank far above the presbyters (more conspicuously so, for example, than in the Canons of Hippolytus), and the presbyters are still divided into two classes, those who are more learned and those
TESTAMUR-TETANUS

who are of mature age. The deacons have functions in the Eucharist and about the altar which point to an early date; they have also much administrative work of an important kind, and especial provisions are made for the care of the sick and the dead, and the burial of those who perish by shipwreck. One of the deacons is to be chosen as “chief deacon” (protopsostoros, i. 19, cf. i. 34), and is charged with the care of pilgrims. There are no doorkeepers or singers, who begin to appear circa A.D. 345. The honour given to confessors is very conspicuous, and points back to an early date. But remarkable above all is the point of giving to three presbyters, three in number, deaconesses, virgins, and widows who are in receipt of the alms of the Church; and the first-named occupy a place of very great dignity, which is almost unequaled elsewhere (excepting in the earlier form of the apochryphal and Montanistic Acts and Martyrology of Matthew, where the relation of the psalms and deaconesses corresponds with that of the Testament), and which was formally condemned by the Council of Laodicea in Phrygia.

What conclusion is to be drawn, then, as to the age and character of the Testament? Mgr Rahmani’s view, that it is a work from the 2nd century, is generally discredited; nor has Funk’s contention found acceptance, that it and the Canons of Hippolytus are alike derived ultimately from the eighth book of the Apostolic Constitutions. Some scholars think that the Apocalypse at the beginning is pre-Nicene (A.D. 250–325), and that it originates from Asia Minor, probably from Montanistic circles. Harnack formerly contended that this was an independent work, upon which the Church Order had been grafted, and that as a whole it dated from circa A.D. 400. But the unity of thought and atmosphere is such as to show that the work is one whole (subject no doubt to a certain amount of redaction and interpolation), and that the apocalyptic part was composed as an introduction to the rest. As to the central portion (i. 19–ii. 24) it is a Church Order of the same kind as the Canons of Hippolytus (c. 220) and the Egyptian (c. 310) and Ethiopic (c. 335) Church Orders, standing nearer to the two latter than to the former, and especially to the Verona Latin Fragments, part iii. (c. 340), published in 1909 by Dr Hauler. The precise relation in which these documents stand to one another still remains in a measure doubtful, but it seems probable that they are based upon a lost Church Order, to which the inhabitants of the 4th century, in the reference to the Epiphany, which is first heard of elsewhere at the beginning of the 4th century. The suggestion has been hazarded that this revision was due to the school of Apollinaris of Laodicea (died circa A.D. 390).

TESTAMUR, Latin for “we testify” or “certify” (testari). The name given in English universities to a certificate given to a student signifying that he has passed an examination, so called from the word with which the certificate begins.

TESTER (Fr. têtre, head-covering, from tête), anything placed horizontally over the head, as the sound-board of a pulpit, the flat boards over an old-fashioned bed, &c.

TETANUS (from Gr. réwa, I stretch, on the tension of the fibres of the affected muscles), or LOCKJAW, a disease caused by the bacilli Tetani (see Parasitic Diseases). The home of these bacilli is the earth, and so it comes about that if a man is thrown off his bicycle and grazes his unglowed hand upon the road, or running without shoes cuts his foot, there is a curious fibre change. This (it has been called the lockjaw) is a disease, of the bacilli entering the wound and giving him lockjaw. It is popularly thought that wounds in the region of the thumb are most often followed by the disease, but this is not a fact. Wounds about the thumb are of common occurrence, but they are not, in proportion, more often the starting point of tetanus.

Acute traumatic tetanus is very deadly, and up to the present time nothing has been discovered to check or its almost certainly fatal course. It often picks out the young and vigorous as its victims—the athlete, for instance, who meets with some mishap in the field or on the road, the gardener who picks his hand with a gunshot wound, or the wounded soldier on the field of battle. The violent muscular contractions are distressingly painful; and the brain remaining perfectly clear throughout, the unhappy individual feels that the vice-like gripping of his muscles is steadily exhausting him and bringing him down. The spasms of tetanus differ from those caused by the administration of strychnine in that the muscles are all the time hard from rigid contraction, the acute spasmodic attacks being superseded, as it were. In poisoning by strychnine the muscles are quite relaxed between the spasmodic attacks.

Tetanus may follow a mere prick of scratch or a severe surgical operation. It is not seldom complicated by gunshot wounds and injuries caused by the untimely explosion of fire-works. It may be met with in the woman in child-bed or in the newly-born infant. But wherever it occurs it is due to one cause—to the reception into some wounded surface of the specific germs.

In hot countries tetanus is more common and more acute than it is in temperate climates, and a case has been recorded in which a man in the West Indies cut his hand on a broken plate at dinner and was dead of tetanus before the day was out. Prick is easily the swimmer who cuts his foot, to wound him with a gun-shot, and to give him lock-jaw in cold. It was formerly the custom to speak of idiopathic tetanus—that is to say, of the disease occurring without any wound having been received. But modern teaching is to the effect that there must have been some wound, however slight, by which the germs found entrance. Rheumatic tetanus is as unreal a disease as that just mentioned. The germs themselves do not wander from the wound to multiply in the blood as in infecting diseases, but remaining at the wound elaborate a terribly poisonous substance (a toxin) which makes its way along the nerve-tracks to the spinal cord. Even prompt amputation, however, is likely to prove ineffectual as regards cure, for the germs in the wound have in this growth set free so virulent a poison (toxin) that the nerves of the voluntary muscles all over the body are hopelessly under its influence.

The first symptom of the disease is discomfort in the back of the neck; the man waking up in the morning, for instance, complains of “stiff neck” and of obscure pains, and wonders if he has been lying in a draught. Then the muscles of the jaw and of the face become affected, there being a difficulty in opening the mouth, and the corners of the mouth are drawn downwards and backwards, and fixed in that position (rictus). The law is from hence that it is impossible to pass anything between the teeth. All food, therefore, has to be fluid, and being poured into the pouch of the cheek, finds its way into the mouth by the servicable gap which exists behind the wisdom-teeth. Soon, however, a difficulty in swallowing comes on because of the muscles of the throat being involved.

The muscles of the abdomen becoming contracted are rigidly fixed, and on laying the hand upon the front of the abdomen
they feel as "hard as a board." The muscles of the limbs are also attacked with fearful cramps, and, last of all, the muscles of the chest are involved. Though all these muscles are in a continuous state of contraction, spasmodic contractions, as already remarked, come on in addition, and occasionally with such distressing energy that the patient is doubled up forwards, backwards, or sideways, and, may be, some of the muscles tear across. The patient is bathed in perspiration, and sinks worn out and exhausted, or, perchance, slowly suffocated by the locking of the muscles of respiration.

As regards the prospect of recovery in tetanus it must be said that though the patient recovers he may suffer from the after-effects of an injury the prospect of recovery is extremely remote. If they occur within ten days the prospects are bad. But if there is an interval of three weeks or a fortnight before their occurrence the case may be regarded more hopefully.

In the treatment of tetanus the first thing to do is to try to make the wound by which infection has taken place surgically clean. For though a wound free from the germs of suppuration may be the inciting place of the bacilli of tetanus, in most cases there is also an invasion of septic germs, and the double infection makes the action of the tetanic poison the more virulent. In order to prevent the germs of the wound from the free use of the knife or of the cautery or of pure carbolic acid may be resorted to, or an amputation may be performed. But even the early amputation of the infected part may not avail for the presence of these germs in the wound have already set free a lethal dose of their toxin.

The wound having been cleansed the further treatment of the disease demands absolute quiet in a darkened room. There must be no slamming of the door, shaking of the bed, or the sudden bringing in of a light, for any such act might cause the outbreak of a violent spasm. Morphia may be given by the hypodermic syringe, and if the spasms are causing great distress chloroform may be administered; indeed, in certain severe cases it may be necessary to keep the patient almost continuously under its influence. If there is difficulty in swallowing fluid, rectal feeding must be employed. Though this present one is unenthusiastically or with confidence about the antitoxin treatment of lockjaw, still it is a method which should certainly be given trial and that early. The tetano-antitoxin is prepared from the blood of animals which have been rendered immune to repeated injections of the poison elaborated by the cultivation of the tetanus bacilli. The bacilli themselves are not injected, the injections being rendered sterile. By passing the sterile injections into one of the lower animals the blood of that animal prepares an antidote to them known as an antitoxin.

The antitoxin may be injected into the nerve trunks or into the meninges of the cerebrum or of the brain. But as much as the nerves and the nerve-ends are under the influence of the toxin before the antitoxin is administered—as evidenced by the occurrence of the symptoms—the injection-treatment has but a poor chance of producing a good effect. (E. O.)*

**TETRADYMITE**, a mineral consisting of bismuth telluride and sulphide, Bi₂TeS₅, also known as "telluric bismuth." Sometimes sulphur is absent and the formula is then Bi₂Te₅; traces of selenium are usually present. Crystals are rhombohedral, but are rarely distinctly developed; they are twinned together in groups of four; hence the name of the mineral, from the Greek, tetradymos, fourfold. There is a perfect cleavage parallel to the basal plane; and the mineral usually occurs in foliated masses of irregular outline. The colour is steel-grey, and the lustre metallic and brilliant. The mineral is very soft (H=1) and marks paper; the specific gravity is 7.2 to 7.6. It was first found, in 1815, at Telemarken in Norway; crystals are from Schubkau near Schenitz in Hungary. It often occurs in quartz associated with native gold. Other ore bodies similar to tetradymite, but with different formulae, are: josite, from San José near Marriana in Brazil; grünlingite (Bi₅S₅Te), from Coldbeck Fells in Cumberland; and wehrite, from Hungary. (L. J. S.)

**TETRAGRAMMATON** (τετράγραμμα, four; γράμμα, letter), a Greek compound, found in Philo and Josephus, which designates the divine name composed of the four Hebrew letters J H V H (יְהוָֹה). The derivation and pronunciation of the Tetragrammaton is still doubtful. The form "Jehovah" (q.v.) used in some of the English Versions is an error which arose in the 16th century. It is now generally assumed that the word is the causative form (ῥίπτον) and should be pronounced Yahweh or Yahweh (accent on second syllable). The Jews quite early ceased to pronounce the Tetragrammaton, substituting (as the Books of the Chronicles and the LXX translation already indicate) the word Lord ("Adonai"). The priests continued to use the name in the Benediction of the People (Numbers vi. 22–27), and on the Day of Atonement the High Priest pronounced it (Leviticus xvi. 30) amidst the prostrations of the assembled multitude. It is recorded in the Talmud that Rabbis communicated the true pronunciation to their disciples once in seven years (Qiddusin, 71a). The Jews called the Tetragrammaton by a Hebrew denomination, שֵׁם הָמוֹמֶרֶשֶׁךְ (יְהוָֹה יִהְיָה), i.e. the distinctive excellent name. It was considered an act of blasphemy for a layman to pronounce the Tetragrammaton. This avoidance of the original name was due on the one hand to reverence and on the other to fear lest the name be desecrated by heathens. Partly in consequence of this mystery and partly in accord with widespread superstitions, the Tetragrammaton figures in magical formulae from the time of the Gnostics, and on amulets. Many a medieval miracle-worker was supposed to derive his competence from his knowledge of the secret of the Name.

**TETRAHEDRITE**, a mineral consisting typically of copper sulph-antimonite, Cu₃Sb₅S₃, but often of complex composition. The copper is usually isomorphously replaced by variable amounts of silver, iron, zinc, mercury, lead or cobalt, and the antimony by arsenic or bismuth. In general, the formula is K₃Sb₅S₃+ₓ where x = Cu, Ag; X = Sb, As, Bi; R = Fe; Zn, and x is a small fraction, often ½ or ⅔. Numerous special names have been applied to varieties differing in chemical composition; the arsenic compound, Cu₃AsS₅, is known as tennantite (after Smithson Tennant). The old German name Fäbriers includes both tetrahedrite and tennantite, and so does the term "grey copper ore" of miners. Tetrahedrite is an important ore of copper, the formula Cu₃Sb₅S₃, corresponding with 57.5% of this metal; it is also largely worked as an ore of silver, of which element it sometimes contains as much as 30 per cent. Well-developed crystals are of frequent occurrence; they belong to the tetrahedral class of the cubic system, and their tetrahedral form is a very characteristic feature of the mineral, which for this reason was named tetrahedrite. Fig. 1 shows a combination of a tetrahedron and a triakis-tetrahedron [211], and fig. 2 a tetrahedron with the rhombic dodecahedron. Interpenetrating twinned crystals sometimes occur. The colour is steel-grey to iron-black, and the lustre metallic and brilliant. The streak is usually black; sometimes, however, it is dark cherry-red, and very thin splinters of the mineral then transmit a small amount of blood-red light. The hardness is 4½, and the specific gravity varies with the composition from 4.4 to 5.1. There is no cleavage, and the fracture is conchoidal. The material is very often impure owing to intimate inter-mixture with chalcocyprite.

Tetrahedrite occurs in metalliferous veins associated with chalcocyprite, pyrites, blende, galena, &c. Fine groups of crystals, coated on their surface with brassy or brilliantly tarnished chalcocyprite, were formerly found at Herodhos' mine, near Liskead in Cornwall. Good crystals are also met with at Kapnik-Hany in Hungary, in the Harz, Peru, and other places. Tennantite occurs as small crystals of cubic or dodecahedral habit in many
TETRAHEDRON, in organic chemistry, a group of compounds containing the ring system C-N-N C-N-C C-N-N C-N-C or N-N-C or N-N-N;

only derivatives of the first two types are known. The members of the first series may be prepared by oxidizing osazones (i.e., dihydroazones of a-diketones), dihydrotetrazines resulting. Dihydro-derivatives of the second type are formed by hydrazine and imino-ethers (A. Pinner, Ber., 1893, 26, p. 2126; 1894, 27, p. 984); these easily oxidize to the corresponding tetrazines, which are stable towards acids; their dihydro-derivatives, however, are decomposed by the group-NH-NH—being eliminated as hydrazine, and replaced by oxygen, with consequent formation of the five-membered oxybiazole ring. Concentrated acids convert the dihydro-tetrazines into isodihydtetrazines, thus:

\[ \text{R-CN-NH-NH} \rightarrow \text{R-CN-NH} \]

where R is the N-alkyl derivatives of which type may be prepared by the action of alcoholic potash and chloroform on aromatic hydrazines.

Much discussion has circulated about the decomposition of diazo-acetic ester, from which A. Hantzsch and O. Silberrad (Ber., 1900, 33, p. 58) obtained what they considered to be a dihydro-tetrazine, thus:

\[ \text{HCO-R} \rightarrow \text{HOC-CH-CN} \]

triazole derivative (I) being due to the ring opening on the addition of the elements of water and then closing again to the five-membered ring with elimination of water again. The decompositions of diazo-acetic ester were then again examined by T. Curtius and his students (Ber., 1907, 40, pp. 652, 350, 450, &c.), who showed that both triazole and tetrazine derivatives might be obtained from the bisdiazo-acetic acid which is formed by the action of alkali on diazo-acetic ester.

TETRAZOLES, in organic chemistry, a group of heterocyclic compounds, capable of existing in two isomeric series (formulae 1 and 2), although the methods of preparation do not always permit discrimination between the possible isomers. They are prepared by the action of nitric acid on cyanamidrazide (dieryanophenylhydrazine) and hydrolysis of the resulting nitrile, from which J. A. Bladin by elimination of the phenyl group (by nitration, reduction, &c.) and of carbon dioxide obtained free tetrazole, CH₄N₂; from amidines by the action of nitrous acid, followed by the reduction of the intermediated formed dioxytetrazoc acids with sodium amalgam; from amidoguanidine by diazotization, the diazonium nitrate on treatment with acetates or carbonates yielding aminotetrazole (J. Thiele, Ann., 1892, 270, p. 1); from the action of nitric acid on phenylthiosemicarbazide; and by the action of arylazomides on the hydrazones (O. Dimroth, Ber., 1897, 40, p. 2402). The tetrazoles behave as strong monobasic acids, but are exceedingly stable. A series of tetrazolium bases (formula 3) have been obtained by H. V. Peckham (Ber., 1894, 27, p. 2920) starting from formyazol compounds (formula 4), which are oxidized by means of amyl nitrite and hydrochrolic acid. They are strong bases, which in aqueous solution absorb carbon dioxide readily. The free bases have not been isolated, but their salts are well-crystallized solids.

TETRASTOÖN (Gr. τετράς, four, and στόιχων, a portico), the term in architecture given to a rectangular court round which on all four sides is carried a covered portico or colonnade; the same as peristyle (q.v.).

TETRASTYLE (Gr. τετράς, four, and στυλός, a column), the term in architecture given to a portico of four columns which forms the main front of a temple (q.v.).
TETUAN (TETTAWAN), the only open port of Morocco on the Mediterranean, a few miles S. of the Strait of Gibraltar, and about 40 m. E.S.E. of Tangier. Population about 25,000, of whom a fifth are Jews. It is picturesquely situated on the northern slope of a fertile valley, which flows from the Védiat, with the harbour of Tetuan, Martil, at its mouth. Behind rise rugged masses of rock, the southern wall of the Anjera country, practically closed to Europeans, and across the valley are the hills which form the northern limit of the still more impenetrable Rif. In point of cleanliness Tetuan compares favourably with most Moorish towns. The streets are fairly wide and straight, and several of the houses belonging to aristocratic Moors, descendants of those expelled from Spain, have fine courts surrounded by arcades, some with marble fountains and planted with orange trees. Within the houses the ceilings are often elaborately carved and painted in Mannerist style, such as are found in the Albambra, and the tile-work for which Tetuan is known may be seen on floors, pillars and dados. The principal industries are tilework, inlaying with silver wire, and the manufacture of thick-soled yellow slippers, much esteemed by flintlocks, and artistic "towels" used as cape and skirt by Moorish country girls. The Jews live in a mellah, separated from the rest of the town by gates which are closed at night. The harbour of Tetuan is obstructed by a bar, over which only small vessels can pass, and the roadstead, sheltered to the N., N.W. and S., is exposed to the E., and is at times in danger of being transformed into a lagoon.

The present town of Tetuan dates from 1492, when the Andalusian Moors first reared the walls and then filled the enclosure with houses. It had a reputation for piracy at various times in history, and was taken on the 4th of May 1860 by the Spaniards under Don Antomill, and almost transformed by them into a European city before its evacuation on the 2nd of May 1862, but so hateful were the changes to the Moors that they completely destroyed all vestiges of alteration and reduced the city to its former state. (K. A. M. *)

TETZEL, JOHANN (c. 1460-1519), preacher and, on 1499, son of Hans Tetzel, a goldsmith of Leipzig, was born there about 1460. He matriculated at the university in 1482, graduated B.A. in 1487, and in 1489 entered the Dominican convent at Leipzig. He early discovered his vocation as a preacher of indulgences; he combined the eloquentatory gifts of a revivalist orator with the shrewdness of an auctioneer. He painted in lurid colours the terrors of purgatory, while he dwelt on the cheapness of the indulgence which would purchase remission and his prices were lowered as each sale approached its end. He began in 1501 in the service of the Cardinal-legate Raymond Perandri; and in the next few years he visited Freiberg (where he extracted 2000 gulden in two days), Dresden, Pirna, Leipzig, Zwickau and Görlitz. Later on he was at Nuremberg, Ulm and Innsbruck, where he is said to have been condemned to imprisonment for adultery, but released at the instance of the elector of Saxony. This charge is denied by his apologists; and though his methods were attacked by good Catholics like Johann Hass, he was elected prior of the Dominicans in Giana in 1505. He published his momentous ninety-five theses on the subject of indulgences on October 31, 1517 (see Luther).

Even Albrecht was shamed by Luther's attack, but he could not afford to relinquish his profits already pledged for the repayment of his debts; and Tetzel was encouraged to defend himself and indulgences. Through the influence of Conrad Wimpina, rector of Frankfurt, Tetzel was created D.D. of that university, and with Wimpina's assistance he drew up, in January 1518, a hundred and six theses in answer to Luther's. But the storm overwhelmed him; some Catholics felt that his teaching was contrary to Catholic doctrine, and Miltitz, who was sent from Rome to deal with the situation, administered to him a severe castigation. He hid himself in the Dominican convent at Leipzig in fear of popular violence, and died there on the 4th of July 1519, just as Luther was beginning his famous dispute with Eck.

Many lives of Tetzel have been published on the Protestant and on the Catholic side, the most recent being Körner's (1880), K. W. Hermann's (2nd ed. 1884), and N. Paulin's Geschichte der deutschen Biographie; Gесs's Geheim und Briefe zu der Kirchenpolitik Horszov Georg von Sachsen, vol. i. (1903), Intro. pp. 76-8, &c.; H. Barge's Andere Bodenstein von Carlstadt (2 vols. 1905), J. Janz's Leben der German People, and An meine Kritiker (M. Creighton's Hist. of the Papacy, vol. vi.; and H. C. Lea's Hist. of Ancilla Confession and Indulgences (3 vols. 1866). All the histories of the Reformation in Germany and all the lives of Luther deal at greater or shorter length with Tetzel; in the index to vol. ii. of the Cambridge Mod. History he is confused with a later Tetzel of Nuremberg. (A. F. P.)

TEUFFEL, WILHELM SIGMUND (1820-1878), German classical scholar, was born at Ludwigswburg in the kingdom of Württemberg on the 27th of September 1820. In 1849 he was appointed extraordinary, in 1857 ordinary professor in the university of Tübingen, which post he held till his death on the 8th of March 1878. His most important work was his Geschichte der römischen Literatur (1870; 5th ed. by L. Schwabe, 1890; Eng. tr. by G. C. Warr, 1900), which, although written in an unattractive style, is indispensable to the student, the bibliographical information being especially valuable. After the death of A. Pauly, the editor of the well-known Real-Encyclopädie der classischen Altertumswissenschaft, Teuffel, at first assisted by E. C. Walz, undertook the completion of the work, to which he also contributed numerous articles.

He was also the author of "Prologomena zur Chronologie der homerischen Gedichte" (in Zeitschrift für die Altertumswissenschaft, 1842); Charakteristik des Horaz (Leipzig, 1842); Horan, the literaristorische Uberlieferung in Giugul in 1849; The History of the Clouds of Aristophanes (1856) and the Persae of Aeschylus (1866). His Studien und Charakteristik (1871; 2nd ed., 1889).
TEUTOBURGER WALD — TEUTONIC LANGUAGES

possess only to give a brief summary of the chief characteristics of these languages as a group, and of the chief divergences noticeable in early times between the various members of the group. It should be noted at the outset that the written records of the various languages date from very different periods. Gothic is known to us almost entirely from Úlfríðs' translation of the Bible; which dates from the 4th century. English written literature starts with the beorhtþryht Ælfric; Latin, from the 1st century, though earlier matter may be preserved in certain poems. The earliest

The Teutonic languages form a distinct and well-defined group of the Indo-European family. Their nearest affinities are on the one side with the Celtic and Italic (Latin, &c.) languages, and on the other with the Slavonic and Baltic languages. In regard to the fundamental distinction, however, by which the Indo-European languages as a whole fall into two main divisions, namely according to the treatment of certain guttural and palatal consonants, the Teutonic group belongs definitely, together with Celtic, Italian and Greek, to the western of these divisions.

The chief characteristic of the Teutonic languages as a whole lies in their divergence from the Indo-European sounds. This characteristic, generally known as Grimm's Law, is due to sound-changes peculiar to Teutonic, though somewhat similar changes may be traced both in Armenian and Celtic. The most noteworthy phenomena are as follows: —

(1) The Indo-European voiced aspirates, bh, dh, gh (Lat. f, f h; Gk. φ, ϑ, χ) became voiceless spirants, b, d, g. After nasals these spirants became explosive (b, d, g); and in the first two cases the voiceless sound took place palato-alveolar, though hardly during the early centuries of our era, e.g. A.S. berere; O.C. berere; Lat. berere, Gk. βερερε; A.S. stigan; Gk. στιγε; O.N. mérðr (A.S. medr); Gk. μύδρ.

(2) The I.-Eur. voiceless explosives, p, t, k, were preserved only after s (also in the I.-Eur. groups pt and kt); e.g. A.S. stede; Goth. stás; Gk. στάσ; Goth. nátus; Lat. vocem. In all other cases they became voiceless sps, f, p, k, e.g. Gk. stikis, O.H.G. sehs; Lat. sex; Goth. nátum; (ii) immediately after the (original) accent, e.g. Goth. bropar; A.S. brore; O.H.G. bro; Goth. tahan; O.H.G. sehan; Lat. decem, Gk. δέκα. In all other cases they became voiceless sd ("Verner's Law"), identical with those arising from L.-A. in ðh, dh, gh (see above); e.g. A.S. fæder; Lat. pater, Gk. πάτερ; A.S. ægware, O.H.G. sw这个游戏(mother-in-law); Gk. ἐγώ.

(3) The I.-Eur. voiced (un spirated) explosives, b, d, g, became voiceless sps, f, p, k; e.g. A.S. etan; Lat. edere; A.S. æcær, Goth. æhru; Lat. ager, Gk. ἀγρός.

Among other consonantal changes we may note especially the following: —

(4) 3w arising from 1.-Eur. ghw ow cw (see above) was reduced (except after nasals) before υ (perhaps also before 1.-Eur. ο) to ι, and in all other cases to ν; e.g. A.S. gub (war); O.H.G. de-saros (cf. θυσία); A.S. smihet (snows); Lat. nīvem, Gk. νείβαι.

(5) The I.-Eur. cons. group arising from combination of dental sound ðt became ðz, as in Celtic and Latin, e.g. A.S. sess (seat); sittan, Lat. sedere (cf. Sanskr. pp. satyas, Lat. obesity).
(6) The treatment of 1.-Eur. i was precisely parallel to that of the voiceless spirants ʃ, χ (arising from I.-Eur. ʃ, χ; see above). It was therefore, probably, the original spirantization which is not well preserved; e.g. A.S. cozen, pp. coren (gēnus-gēnus); Gk. γεώμαι (cf. Lat. gustus); A.S. snarh, O.H.G. snarh (daughter-in-law); Sanscr. snad, Gk. xeoid. Most of the other consonantal changes are in the nature of assimilation.

(7) bn, da, 3n before the accent became bb, dd, gg (probably through the intermediate voiced bb, dd, gg); e.g. A.S. liecan, I.-Eur. liekan (from liecan); Gk. ἀγείαω (cf. Goth. bi-laigon). In became ii; e.g. A.S. full, Goth. fullis: Lith. pilnas.

(8) Final consonants also underwent change; e.g. A.S. byne, O.N. banno; Lat. tenenis.

(9) At ii, ii became ii; e.g. A.S. stei(i)l, O.N. steilr, Lat. stabulum (from stabulum).

(11) In some combinations consonants are lost or new consonants developed; e.g. Goth. (scar). O.H.G. kunnno (centurion) from hundrn, cf. Goth. hund: Lat. centum; A.S. stream, O.N. strum from strum-, cf. Gk. παῦν, Old Irish straim.

The following changes are found in all Teutonic languages, but took place apparently later than those enumerated above—

(i) n was lost before (h), with compensatory lengthening of the vowel; e.g. A.S. pēhā, Goth. pāha beside A.S. pencan, Goth. pahai.

(ii) Final explosives and nasals were lost; e.g. A.S. vele, Goth. willi: Lat. velīt; A.S. ea, Goth. ahwau: Lat. aquam; Goth. kustuam: Lat. custumam.

In the vowel-system the earliest known form of Teutonic did not differ greatly from the other 1.-Eur. languages. Its chief peculiarities seem to have been as follows—

(1) (h) corresponded in the two vowel systems a, o found in the other 1.-Eur. languages; e.g. Goth. ahrs, O.N. áhr: Ager, Gk. ἀγχαρχα: Goth. ahtau, O.H.G. ahko: Lat. octo, Gk. ὀκτώ.

(2) It had also one vowel (e) corresponding to the two vowels ą, ę found in the other 1.-Eur. languages, e.g. A.S. brōdr, Goth. brōpar: Lat. frater, Gk. φίλαπα; A.S. rōw (rest), O.H.G. rōwau: Gk. ῥωπον (rūpion).

The 4th and 5th Teuton. vowels, ę, ą, ę, were preserved in the earliest Teutonic. Soon after the beginning of our era, e began to change to i before a nasal followed by a consonant; e.g. PtoL. Φιάλα, A.S. Fén, O.N. Fān; against Tac. Φέλα, A.S. fela. The dipthong ei became i; e.g. A.S., O.H.G. stigan, O.N. stiga: Gk. στίγμα (the ei of Goth. stiegn is merely graphic).

The reduced nasal sounds generally written u, m, arising from er, er, er, etc., in unaccented syllables, became un, um (rarely unu, unus), e.g. A.S., Goth., Æ.- un- (negative prefixes); Lat. iv-, Gk. ἵ-; A.S. hund: Lat. centum: Gk. ἱ-κτόρ. Similarly the reduced liquid sounds ù, ù, û, became ur, ur, û, e.g. A.S. wurh: Lat. fūrca; Goth. fuls: Lat. tellus, Gk. τῆλη.

Accent.—In the I.-Eur. languages the position of the accent was originally free—i.e., any syllable in the word could bear the chief accent—variation occurring very frequently, e.g. between different cases of the same noun. The liberty of the free accent must have been retained in Teuton and 1.-Eur. at the time when voiceless spirants (ʃ, χ, s) became voiced (see above). Eventually, however, as in Gaelic (Irish) and at one time also in the Italic languages, the first syllable of every word came to bear the chief accent, the only noteworthy exceptions being certain compound words, more especially verbs compounded with prepositions, which were probably long regarded as more or less independent words. This system of accentuation was intimately connected with the principle of alliteration, the essential characteristic of early Teutonic poetry and the dominant factor in family nomenclature. Alliteration in family names certainly dates from the very beginning of the Christian era, e.g. the S-names in one of the princely families of the Cheruici frequently mentioned by Tacitus, and there is also some evidence that Teutonic poetry was alliterative by this time. It is probable, therefore, that the change in the system of accentuation took place not later than the 1st century B.C.

The description of the phonetic characteristics given above applies in general to the Teutonic group of languages as a whole. So far as one can judge from the proper names, etc., which occur in Latin works, the description would probably be true for the time about the beginning of the Christian era. Dialectical differences no doubt already existed, but few of them were so clearly marked that they can now be traced with anything like certainty. The language of the earliest Runic inscriptions does not differ very markedly from this type. The principal changes which we can now detect are as follows:

(1) e became ę, i (in the unaccented syllable of dissyllabic and in the nasals (n), preserved in the Italic languages and nasals (n) of the vowel ę, and we n; e.g. A.S. eñoher, O.N. enner (stem wen-); A.S. eoloher, O.N. eoher (stem eol-.)

(2) u became o when the following syllable contained a, ę, ę; e.g. (i) sing. pret. (2s.); A.S. wero(h)er, O.H.G. wer(a)hia: A.S. wuro, O.H.G. wurchen.

(3) e became ä always; e.g. *märīs (inscr.): Gt. mērs.

(4) final a, e, were lost; e.g. (1, 3 sing. pret.) waz (inscr.); cf. Gk. ἔπεσε, L. desper.

(5) final long vowels were (in general) shortened (i-ä, ò-ö) e.g. liuhtu (inscr.).

(6) final nasals and explosives were lost; e.g. varothā, i sing. pret. (cf. Gk. ἱππέτη).

These changes appear to have operated in all the northern and western Teutonic languages during the first four centuries of our era, except the change ę-ä, which in the extreme west (Frankish) seems not to have taken place until the latter part of the 6th century. Several of them can be traced more or less clearly in Latin writings of the 1st century. The Gothic language, however, seems to have developed on quite different lines. The more important of its changes are as follows:

(1) e became i always; e.g. wegs (road): A.S. weg. But, i later became e (written as in Ulfilas' orthography) before r, h; e.g. hairdeis (hardman): O.H.G. herdei.

(2) u became o (written au) before r, h; e.g. baurges: A.S. burg. (In Ulfilas' orthography the letters transcribed e, o are used for long vowels only.)

(3) i, au became ę, ę but the digraphs were still written.

(4) Short vowels (except u) in final syllables were lost; e.g. dags, gastu: (N. inscr.) daga, -taske.

(5) final nasals and explosives were lost; e.g. sumu (Acc. sing.): Sanscr. samanam.

(6) Final long vowels (including those which had become final through the last change) were (in general) shortened (i-ä, ò-ö, ù-ö); e.g. warbote (1 sing. pret.): (N. inscr.) whoradā: liuhtu (N. sing. fem.): (N. inscr.) liubu.

(7) voiceless spirants when final (also before s) became voiceless; e.g. ðap (3 sing. pret. of bidjan).

All these changes appear to have taken place before or during the 4th century. The effect of them must have been to render the Gothic language hardly intelligible to a person who spoke a northern or western Teutonic language. Nevertheless there is little differences among the latter languages themselves. At a later date Gothic underwent further changes which do not appear in Ulfilas' version, or only to a slight extent.

(i) i became a closed e-sound; e.g. Venethae (Jordanae), for Winia-

(2) u became a closed o-sound; e.g. Fyrow (Procopius): Rugii; later o became a in unaccented syllables; e.g. āros (for -sos).

(3) e became i; e.g. leiskes for leikes (not unfrequently in the MSS.).

(4) ò became ą; e.g. sunjas for sunjas.

The chief sound-changes in the northern and western languages seem to have taken place in the 6th and 7th centuries. Some of these changes were common to all the languages in question, some to English and Scandinavian, some to English and German, while others again occurred in only one of these languages or a portion of it.

I. Among the chief changes common to English, Scandinavian and German we may reckon (1) the loss of final a (in Scandin. also for nasal consonants); e.g. A.S., O.N., O.H.G. korn (N. inscr. korn); (2) the loss of unaccented i, u after long syllables, e.g. A.S. hund, O.N. hond, O.H.G. hant: Goth. handus; (5) the change s-w (in the above relations); e.g. A.S. dier, O.N. dier, O.H.G. tier: Goth. (plur.) disra.

II. Among the most important of the changes common to English and Scandinavian must be classed (1) the affection (unattested) of the vowels (generally i, u) of following syllables; e.g. A.S. cyn(n), O.N. kyn: O.H.G. kunni; A.S. geofu, O.N. gof: O.H.G. geba.

In early German the only case of this kind was the affection of a by a following i and even this seems to have taken place much later. To the same category we must reckon (2) the early loss of h
between sonants, e.g. A.S. *sien, sian, O.N. *síð: O.H.G. *sehan;
(3) the loss of n before s, e.g. A.S. *sís, O.N. *sí: O.H.G. *As-
nei.

Many of the vowel-changes are indistinguishable forms. The Swedes who were the following: (1) The loss of final s; e.g. A.S. *dæg, O.H.G. *tag: O.N. *dag (N. inscr. *dæs). In short monosyllables, however, *s became r in High German, as in Scandinavian; e.g. mir (Datt.): A.S. *mita, O.N. *miða, O.H.G. *mor. Such change did not take place before d (whereas assimilation took place in Scand.), e.g. A.S. hord, O.H.G. hort: O.N. hodd, Goth. hund. (3) The change d-s=d in all positions, e.g. A.S. dêd, O.N. dêð, O.H.G. *ddieh, O.Fr. dèd, O.Fr. *sant (O.H.G. *fiter): O.Fr. *sant. (4) The lengthening of all consonants (except r) before j (in Scand. only gutturals), e.g. A.S. biddan, O.H.G. *bilen: O.N. *blita.

The treatment of the English, Scandinavian and German are treated in the articles dealing with these languages. It should be noted that the Frisian dialects agree with English not only in the phenomena enumerated above, but also in a number of changes peculiar to that language. Thus the change of nasal syllables, e.g. A.S. *mêna, O.Fr. *môna; O.H.G. *mân; (2) the change d-s=d (later e) in other positions, e.g. A.S. rôd, O.Fr. réd; (3) the presence of *s in Frisian, e.g. A.S. sêda, A.S. *sêdê (O.H.G. *kneht); (4) the lengthening of r in Frisian, e.g. A.S. *bairif, the plur. *-a (2) a general feature in the Teutonic languages. In the earliest Anglo-Saxon there is no trace of the diphthongisation of vowels before e, e.g. A.S. *steaf, O.Fr. stef: O.H.G. *steip; (5) the labialisation of Frisian words in -er; e.g. A.S. *ger, O.Fr. *gère: O.H.G. *erator; (6) the palatalization of Frisian syllables, e.g. A.S. *gêldan, gêldan (Engl. yield), O.Fr. Baldwin: O.H.G. gelan. The actual records of the Frisian changes in the earliest Anglo-Saxon seem to have been very few: (1) a, e, i, o, u are diphthongised after r followed by a consonant in English, but not in Frisian, e.g. A.S. ear, A.S. oer, A.S. eor: O.Fr. ore, O.H.G. eor; (2) the change of e in English everywhere, but in Frisian only in open syllables (e in close syllables); e.g. A.S. eft: O.Fr. eth (Alto sax., Goth. eht), but A.S., O.Fr. āþun (Goth. āþan); (3) the diphthongisation of words like bairift, the plur. *-a has taken place in English everywhere, but in Frisian only in open syllables (e in close syllables); e.g. A.S. *sêda, A.S. *sêdê (Alto sax., O.H.G. *kneht); (4) it was labialized in Frisian, but not in English, before (original) w in the following syllable: e.g. O.Fr. sîngan: A.S. *sîgan (cf. Goth. *singan). Frisian texts of the 13th and 14th centuries show many characteristic changes which must have rendered the language almost, if not wholly, unintelligible to an Englishman of the same period; but it is hardly probable that these changes were for the benefit of any great antiquity.

Dative. — The I.-Eur. languages seem originally to have had three numbers and eight cases, though it is by no means certain that each of the latter had a distinct form in every class of stems. In Teutonic there is scarcely any trace of the dative case in nouns. Of the cases all the early Teutonic languages preserved four, viz. the Nominative, Accusative, Genitive and Dative. The Vocative also was kept in Gothic and the Instrumental to a considerable extent early in German, while the earliest Anglo-Saxon preserved many traces of the locative.

The case endings are best preserved in the earliest Northern inscriptions and Gothic. As an illustration we may take those of the I.-Eur. -dedened verbal formations:

As examples of the forms found in the inscriptions may be given N. erlaz, A. staina, G. A(n)-arztaslaz, D. Wodaridaz. In the other cases of stems the dative-declension conforms to the general I.-Eur. types. Whatever changes have taken place have usually tended towards simplification; thus there are but few traces of stem-variation (ablaut) between different cases of the same noun.

The treatment of adjectives was somewhat more peculiar. In addition to the old type of declension which conformed to that of the demonstrative pronoun and not, as in Greek and Latin, to that of substantives, almost every adjective was derived from a verb. The characteristic of the type of inflection occurs chiefly in conjunction with the demonstrative pronoun (definite article) and it is thought that its origin is to be found in substantival (positional) sage.

The comparative of adjectives is formed partly by a suffix -eiun (e.g. Goth. suilzan, A.S. lengae), which is apparently extended from the suffix -is, -is found in the other I.-Eur. languages and probably in Old Norse, which is the root of the -is-a (e.g. Goth. suivispo) which is peculiar to Teutonic. Similarly the superlative is formed partly by a suffix -is (e.g. Goth. huzilisz, A.S. lenghæ), corresponding to -iis in other I.-Eur. languages (Gk. ighro), as partly by a new formation -iis (e.g. Goth. armast). Most of the I.-Eur. demonstrative pronouns are found in Teutonic, and the peculiarities of the inflection are in general typical of A.S. noun, O.H.G. *tawn (related to Gk. *au), and probably identical with the Pret. A.S. sing, dode (dyde), plur. dodezen; O.H.G. sing, tet, plur. tütan. The short reduplication-suffix, however, is lost in the singular, while the long reduplication-suffix is preserved only in Gothic. The inflection of the dative is as follows:—

Goth. 1 sing. basi, 2 -basí, 3 -bási, 1 dual -budás, 2 -bidás, 3 -budán; cf. Gk. 1 sing. obá, yegómov, 2 eó, 3 eó, 2nd, 1 pl. tézor, ýeýamov. Except in Gothic and Scandinavian the 2 sing. has generally a form (originally Aorist) similar to the plural, e.g. A.S. bude. The stem of the Conjunctive also agrees with that of the present.

The "weak" Preterite seems originally to have arisen out of a periphrastic formation of which the second part consisted of imperfect or Aorist forms of the verb seen in A.S. dón, O.H.G. tawn (related to Gk. *au), and probably identical with the Pret. A.S. sing, dode (dyde), plur. dodezen; O.H.G. sing, tet, plur. tütan. The short reduplication-suffix, however, is lost in the singular, while the long reduplication-suffix is preserved only in Gothic. The inflection of the dative is as follows:—

Goth. 1 sing. nasida, 2 -des, 3 -das; A.S. nerede, -des(1), -de, O.H.G. nerila, -des, -des; O.N. nátla (early inscr. 3), 4. -d.

It is to be observed that the stem of the weak Preterite almost always conforms to the formations of the singular. The forms of A.S. *wasreda, -erhsa (stem wasrhoht-) on the analogy of pret. nasida beside past part. natis (stem nasidos), where the resemblance between the two formations is due to the regular operation of the sound laws.
The inflection of the Conjunctive agrees with that of the strong Preterite, e.g. Goth. nasidafulan. 

This is derived from the present stem with an ending -an (A.S. beran), and probably was originally a case-form of a verbal noun. In the western languages we find also the Dative of a stem -ranga- used after a preposition; e.g. A.S. to besciéen, O.H.G. sihmen.

The Present Participle has a stem -ond- (I.-Eur. -ont-) identical with the ending of the 3 plur. Indic., as in the other I.-Eur. languages; but the Participles in -ai- (Teut. -aia, -ai-) are formed as -on- or -ja- stems, e.g. G. bartandra, A.S. berende. The unextended stem survives only in substantives, e.g. A.S. wigend, "warriors."

The stem of the Past Participle (Passive) is formed by the suffixes -lo- and -ling- (Teut. -aia, -aia), as in the other I.-Eur. languages. The first stem occurs as a living formation only in connexion with the verbs whose present stem ends in -ja, -ja, -ja (in Gothic also -ja); e.g. Goth. nand, sound, nadj, G. nagen. The Past Participle in usage is formed with the class of verbs has a stem -aun- or -aun- and was replaced in English and Scandinavian, the latter in Gothic and German; e.g. A.S. borne, O.N. bornin, Goth. bournan, O.H.G. (gi)beran. 

Remains of old Participles in -ja, -ja formed otherwise than in living use may be found in adjectives; e.g. A.S. (e)ald: alan (cf. Lat. alius), full: Lat. pleo (cf. Lith. pilnas).

The above sketch will suffice to show that in regard to morphology the Teutonic group of languages has many characteristic features which distinguish it from other languages of the same stock. On the other hand the morphological differences which exist among the Teutonic languages themselves are on the whole comparatively slight and due mainly to the operation of syncretism and other simplifying processes. In more recent times these processes have been carried still further, so that e.g. the Danish verb has lost all inflection and the German has practically disappeared in English. In the earlier stages of the Teutonic languages differences of phonology are more marked than those of morphology, and afford surer criteria for determining the relations of these languages to one another. It is customary among scholars to classify the whole group in three main divisions, an eastern or Gothic, a northern or Scandinavian, and a western which includes English, Frisian and German.

We have noticed above that Gothic began at an early date to show marked divergences from the other languages. The Scandinavian languages also certainly underwent a considerable number of peculiar changes before the beginning of their literatures. But it is to be remembered that from the 6th century to the 9th the Scandinavian peoples were practically cut off from communication with other Teutonic nations by the Slavonic occupation of Mecklenburg and eastern Holstein.

The earliest of the more striking sound-changes peculiar to Scandinavian, viz. the loss of initial j-, is not thought to have taken place before the 7th century, while the most characteristic features in its morphology, i.e. the development of the post-positive article and the new, more numerous, forms of the participle, are practically of a later period. If we confine our attention to changes which probably took place before the middle of the 7th century it will be seen that the English and Frisian languages may fairly be described as lying about midway between Scandinavian and German, though they had already developed well-marked characteristics of their own. They are doubtless to be regarded as the representatives of the old language of the maritime districts, and it is probable that languages of this type were at one time spoken along the whole of the coast between the present frontiers of Belgium and Denmark. On the other hand the special characteristics of German in all probability developed in the interior and those of Scandinavian round the Baltic and the Cattegat. From the 8th century onwards the High German (southern) dialects of German differed greatly from those spoken further north owing to the operation of the changes generally known as the "second sound-shifting."

The northern dialects, however (Old Saxon and Low Frankish), were essentially German, though both were more or less affected by Frisian influence.

The Gothic and Scandinavian languages have one or two characteristics in common, the most important of which is the treatment of intervocalic j and w in a number of words. In the former case we find Goth. jidd- and O.N. -ggi-, whereas in German a diphthong developed; e.g. Goth. twaddje (Gen. of twad, "twow"), O.N. tvegg: O.H.G. zweiio. In the latter case both Gothic and Scand. had g(w) (O.N. ggr), while a diphthong appears both in English and German, e.g. Goth. iriggus ("true"), O.N. trygger: A.S. ge-tr Vue, ge-true, O.H.G. gilruniu. It may also be noted that Gothic and Scandinavian preserved the ending -am in the first plural, while in the singular that of the strong Preterite, whereas in English and German there was a different form, having in each of the plur. (see above). On the ground of these common characteristics some scholars hold that Gothic and Scandinavian are more closely related to one another than to the other Teutonic languages. But, whatever may have been the case originally—and the evidence is far from conclusive—it is clear that by the 4th or 5th century the Scandinavian languages had far more resemblance to English and German than to Gothic.

The languages of the Vandals, Gepidae and other eastern tribes seem to have been practically identical with Gothic. That of the Burgundians, so far as we can judge from the slight evidence at our disposal, had at least as much in common with southern German as with Gothic, which may be due to the fact that this tribe, though originally located in the basin of the Oder, had moved westwards by the 4th century. The early divergence of the eastern languages in general from those of the north and west is perhaps to be ascribed in part to the great extension southwards of the territories of the eastern tribes in the 3rd and 4th centuries. Yet it is not to be overlooked that the geographical and ethnic divisions which today are the subject of discussion were of relatively recent origin, as compared, e.g., with the special characteristics of some of the Greek dialects. Indeed there is scarcely one of them of which we can say with certainty that it dates from before the beginning of our era.

TEUTONIC ORDER, THE, or Teutonic Knights of St Mary's, Hospital at Jerusalem (Der deutsche Orden, Deutsche Ritter) was one of the three great military and religious orders, i.e. the Knights of the Hospital of St John of Jerusalem, the Hospitalers (see above), and the Teutonic Order, which dominated by 1240 the last Crusade and the latter century. Its original numbers remained large, and the knights of the Order retained their lands in the Holy Land even after the fall of Acre in 1291. Its order continued to exist, however, under the control of the Portuguese, and the Teutonic Knights of St Mary's, Hospital at Jerusalem (Deutsche Ritter), and the Hospital of St John in Jerusalem. The Teutonic Order was founded by the Teutonic Knights, who took the name of the Order of St John and St Mary. The Teutonic Order traces its origins to the 3rd Crusade. The Teutonic Order was founded in 1190 by the Emperor Frederick II. The order was formed in the Rhineland in the 13th century. It was composed of knights who had joined in the last Crusade and who had taken the name of the Teutonic Knights of St Mary's, Hospital at Jerusalem. The Teutonic Order was founded on the foundations of a hospital in a

1 Rübricht, Geschichte des Königreichs Jerusalem, p. 242.
vessel which they had drawn ashore. Within a few years the foundation apparently became attached to the German Church of St Mary the Virgin at Jerusalem; and in March 1198 (thoc being present in the Holy Land a number of Germans, the relics of Henry VI.'s projected crusade), the great men of the army and the kingdom raised the brethren of the German Hospital of St Mary to the rank of an order of knights. The original members were thus ennobled; and henceforth it was the rule that only Germans of noble birth could join the Order. The Order was chosen the first, therefore, by those who joined in the west of the Order the privileges of Crusaders; and the knights, supported by numerous donations and large accessions to their ranks, rapidly increased their territories. By 1260 they ruled the eastern bank of the Vistula from Kulm to its mouth, and the northern shore of the Baltic from the mouth of the Vistula to Königsberg. Livonia they held after 1237; and during the 14th century they gained the Lithuanian territory of Samogitia, which lay between Livonia and their Prussian dominions, while they also added, to the west of the Vistula, Pomerellen and the Neumark (see under PRUSIA). Already by the beginning of the 14th century these conquests had fundamentally changed the character of the Order. It lost any connexion with the East: after the fall of Acre in 1291, the grand master (whose seat had been at Acre, while the German master (Deutschmeister) had controlled the Order in Germany) moved first to Venice, and then in 1308, to Marienburg on the Vistula. Again, with the accession of large territories, the Order became a governing aristocracy; the original care for the sick, and even the later crusading zeal of the period of conquest, gave way, when conquests were gained and administration was needed, to the problem, half military, half political, of governing a frontier state. The statutes of the Order were altered to suit the new conditions, and a whole system of administration arose. At Marienburg the grand master maintained a magnificent court; round him were the five great dignitaries of the Order, the Grand Commander, the Marshal, the Hospitaler, the Treasurer (Tressler) and the Keeper of the Wardrobe (Trapier) to see to the clothing of the Order. There was a Landmeister for Livonia, and another (the Deutschmeister) for the German province, with his seat at Mergentheim in Swabia. Over each of the twenty districts of the Order was set a commander (Kontor), with the brethren of his own district as his subordinates, and the help of the advice of his brethren; and in the same way the general chapter of the Order, consisting of the landmeisters and the great dignitaries, formed an advisory board to the grand master in matters such as treaties and internal legislation. It was government by an aristocracy almost Venetian in character. The individual was merged in the Order: each brother must pray four times in the day, and four times at night, and he must at all times pay an unquestioning obedience to his superiors. The Order was at once supreme ecclesiastical and political authority. There were no struggles of Church and State in its dominions: the state was also the church: the bishops and the canons of the four bishoprics (with the exception of Ermland) were priests of the Order. The lay subjects of the Order consisted of two classes; on the one hand there were the conquered Prussians, in a position of servitude, bound in time of war to serve with the brethren in foreign expeditions; on the other hand there were the German immigrants, both urban and rural, along with the free Prussians who had voluntarily submitted and remained faithful. The towns were large and flourishing; as many as sixty arose in the period between 1233 and 1416, including Thorn and Elbing, Danzig and Königsberg (named after Ottokar of Bohemia, who took part in the Order during which it was founded). The towns possessed the rights of Magdeburg, or (like Elbing) those of Lübeck; the most important of them soon came to join the Hanseatic League. The Order only imposed customs duties: it levied no tolls within the land; and though its consent was necessary to any change in municipal ordinances, it allowed the towns a large amount of self-government. The Concord of the Order with the towns and the Hanse was one great cause of its prosperity.

In 1229 the Order began the conquest of Prussia, founding fortresses at each step to rivet its conquests (for instance, at Thorn, named after Toron in Palestine), much as the Anglo-Normans had done in their conquest of Wales. Frederic II. gave the Order the rights of a prince of the Empire in its territories: Conrad of Masovia gave it the whole of Kulmerland in 1230; while in 1234 the Order established its independence of all authorities except the Papacy, by surrendering its territories to the Holy See and receiving them back again as a fief. The Order gave to those who joined in the work of the Order the privileges of Crusaders; and the knights, supported by numerous donations and large accessions to their ranks, rapidly increased their territories. By 1260 they ruled the eastern bank of the Vistula from Kulm to its mouth, and the northern shore of the Baltic from the mouth of the Vistula to Königsberg. Livonia they held after 1237; and during the 14th century they gained the Lithuanian territory of Samogitia, which lay between Livonia and their Prussian dominions, while they also added, to the west of the Vistula, Pomerellen and the Neumark (see under PRUSIA). Already by the beginning of the 14th century these conquests had fundamentally changed the character of the Order. It lost any connexion with the East: after the fall of Acre in 1291, the grand master (whose seat had been at Acre, while the German master (Deutschmeister) had controlled the Order in Germany) moved first to Venice, and then in 1308, to Marienburg on the Vistula. Again, with the accession of large territories, the Order became a governing aristocracy; the original care for the sick, and even the later crusading zeal of the period of conquest, gave way, when conquests were gained and administration was needed, to the problem, half military, half political, of governing a frontier state. The statutes of the Order were altered to suit the new conditions, and a whole system of administration arose. At Marienburg the grand master maintained a magnificent court; round him were the five great dignitaries of the Order, the Grand Commander, the Marshal, the Hospitaler, the Treasurer (Tressler) and the Keeper of the Wardrobe (Trapier) to see to the clothing of the Order. There was a Landmeister for Livonia, and another (the Deutschmeister) for the German province, with his seat at Mergentheim in Swabia. Over each of the twenty districts of the Order was set a commander (Kontor), with the brethren of his own district as his subordinates, and the help of the advice of his brethren; and in the same way the general chapter of the Order, consisting of the landmeisters and the great dignitaries, formed an advisory board to the grand master in matters such as treaties and internal legislation. It was government by an aristocracy almost Venetian in character. The individual was merged in the Order: each brother must pray four times in the day, and four times at night, and he must at all times pay an unquestioning obedience to his superiors. The Order was at once supreme ecclesiastical and political authority. There were no struggles of Church and State in its dominions: the state was also the church: the bishops and the canons of the four bishoprics (with the exception of Ermland) were priests of the Order. The lay subjects of the Order consisted of two classes; on the one hand there were the conquered Prussians, in a position of servitude, bound in time of war to serve with the brethren in foreign expeditions; on the other hand there were the German immigrants, both urban and rural, along with the free Prussians who had voluntarily submitted and remained faithful. The towns were large and flourishing; as many as sixty arose in the period between 1233 and 1416, including Thorn and Elbing, Danzig and Königsberg (named after Ottokar of Bohemia, who took part in the Order during which it was founded). The towns possessed the rights of Magdeburg, or (like Elbing) those of Lübeck; the most important of them soon came to join the Hanseatic League. The Order only imposed customs duties: it levied no tolls within the land; and though its consent was necessary to any change in municipal ordinances, it allowed the towns a large amount of self-government. The Concord of the Order with the towns and the Hanse was one great cause of its prosperity.
in Livonia; the towns, such as Danzig; the native aristocracy, organized in a league (the Eidechsenbund, or League of the Lizard), all sought to use their opportunity. It was in vain that the heroic grand master, Henry of Plauen (1440-1453) sought to stem the tide of disaster; he was deposed by the chapter of the Order for his pains. The success of the Hussite raids in Germany gave fresh confidence to the Slavs of Poland. The Order was at variance within itself; some of the houses of the brethren refused to obey the marshal, and the grand master quarrelled with the German master. Above all, there arose in 1440 the Prussian League (Preussischer Bund), in which the towns of Germany and Prussia united together, nominally for common protection of their rights, but really against the Order. The League naturally sympathized with Poland, not only because Poland was the enemy of the knights, but also because under Poland it hoped to enjoy the practical liberty which Polish anarchy already seemed to offer. The ultimate result was that in 1454 an embassy of the League offered Prussia to the Polish king, and that, after many years of war, the Peace of Thorn (1466) gave to Poland West Prussia, with Marienburg, Thorn, Danzig and other towns, in full possession, and, while leaving East Prussia to the Order, made the Order the vassal of Poland for the territory which it retained. Henceforth the grand master was to sit in the Polish diet on the left of the king, and half of the knights of the Order were to be Polish.

From 1466 to 1526 grand masters of the Order ruled in East Prussia as vassals of Poland. But the master of the Livonian province and the German master would not obey a Polish vassal, and went their own way; the German master took the grand master's place as a prince of the Empire. The brethren of East Prussia, however, still sighed for independence; and they pursued the policy of choosing German princes to be grand masters of the Order, in the hope of regaining liberty by their aid. Frederick of Saxony held the office from 1468 to 1511; and he was succeeded by the Hohenzollern Albert of Brandenburg-Anspach. When Lutheranism arose, it spread rapidly in Prussia; Albert himself came into contact with Luther, and turning Protestant he secularized his territories, and (1526) made them into an hereditary duchy, still held as a fief of the king of Poland. Few of the brethren resisted; and the Order quietly ceased from the land where for three hundred years it had had its being.

Henceforth the Teutonic Order lived in Germany and in Livonia. The master of the latter province had beaten off an attack of the Russians in 1502, and secured a fifty years' peace. But in 1561 another master followed the example of Albert, and received Courland as an hereditary fief from Poland. Henceforth the Order was confined to Germany alone. The German master—now grand master and German master in one—had his headquarters at Mengenthal in Swabia; the revenues of the states scattered throughout the twelve bailiwicks of Germany sustained him and his Order. The Order, clinging to its rights with the conservatism of an ecclesiastical corporation, still maintained its claims to East Prussia, and pressed them tenaciously even against the electors of Brandenburg themselves, when they inherited the land on the failure of Albert's descendants in 1618. The French Revolution finally deprived the Order of all its estates, and for a while of its existence. In 1801 the bailiwicks to the west of the Rhine were absorbed by France; in 1809 the Order was entirely suppressed, and its lands went to the secular principalities in which they lay. But in 1840 the Order was resuscitated in Austria, where it now exists as a semi-religious knighthood, closely connected with the Habsburgs.

It has remembered its earliest objects, and has of late years engaged during war in the ambulance service. "At the foot of sunny vineyards," says Treitschke, "the house of the Teutonic Order now stands at Botzen; on its door is still emblazoned the black cross—in the middle of the shield of the Habsburg-Lorrainers." Whatever its connexion with the Habsburgs, the Order has its real heirs in the Hohenzollerns of Prussia. When Frederic the Great gained West Prussia by

1 Every house of the Order had two learned brethren, one learned in the law, one in theology. There were also elementary schools, and municipal foundations in which Latin was taught, in the dominions of the Order.
The first partition of Poland (1772), he was uniting together once more the dominions of the Order, sanded since 1466; and it is the kings of Prussia who have inherited the Order’s task of maintaining German influence on the banks of the Vistula.

Literature.—The article is chiefly based on H. von Treitschke’s Das deutsche Ordensland Preussen, in Historische und politische Aufsätze, vol. ii. (Leipzig, 1870–71), and on J. Loserth, Geschichtedes spätern Mittelalters (Munich and Berlin, 1903). Loserth gives a bibliography of authorities dealing with the history of the Order on pp. 331, 365 to 368. The original evidence is to be found in E. Scholz, Tabulae Ordinis Teutonicorum (Berlin, 1869), and in Scriptores rerum Prussicarum (Leipzig, 1861–1870). J. Voigt has traced the history of the Order previous to 1526 in his Geschichte Preussen (Berlin, 1877–78); J. Loserth, Geschichte des Teutonic Order, and with its history in Germany from 1525 to 1858, in his Geschichtedes deutschen Ritterorden in seinen zwölf Büchern in Deutschland (Berlin, 1857–1859). More recent writers are Loserth, Geschichtedes Ost- und Westpreussen (Gotla, 1880), and Prutz, Geschichte Preussen (Stuttgart, 1900). For monographs on the grand masters, the various territories, and the different epochs in the history of the Order see the references in Loserth’s work (E. Br.)

**TEUTONIC PEOPLES,** a comprehensive term for those populations of Europe which speak one or other of the various Teutonic languages, viz., the English-speaking inhabitants of the British Isles, the German-speaking inhabitants of Germany, Austria-Hungary and Switzerland, the Flemish-speaking inhabitants of Belgium, the Scandinavian-speaking inhabitants of Sweden and Norway and practically all the inhabitants of Holland and Denmark. To these we have to add small German and Flemish-speaking communities in Italy and France and some in Switzerland and Silesia.Outside Europe we have to include also the very numerous populations in America, Africa, Australasia, &c., which have emigrated from the same countries. The statement that the Teutonic peoples are those which speak Teutonic languages requires a certain amount of qualification on one side. In the British Isles, especially Ireland, there is (in addition to the Celtic-speaking elements) a considerable population which claims Celtic nationality though it uses no language but English; and further all Teutonic communities contain to a greater or less degree certain immigrant (especially Semitic) elements which have adopted the languages of their neighbours. On the other hand there does not appear to be any considerable population anywhere which claims Teutonic nationality without using a Teutonic language. We know indeed that France, Spain, Italy, &c., contained within historical times large populations which were Teutonic both by origin and by language, but these have now been completely absorbed. Similarly, there is no doubt that the inhabitants of England and of the German-speaking regions of the Continent are descended largely from peoples which two thousand years ago spoke non-Teutonic languages. Yet on the whole the definition given above may be accepted as generally true for the present time.

It is to be observed that the term “Teutonic” is of scholastic and not of popular origin, and this is true also of the other terms (“Germanic,” “Gothic,” &c.) which are or have been used in the same sense. There is no generic term now in popular use either for the languages or for the peoples, for the reason that their common origin has been forgotten. In Tacitus’s time, however, when the area occupied by the Teutonic peoples was, of course, considerably less than now, a consciousness of their relationship to one another was fully retained. He cites native poetry which showed that the language elements, Herminic and Istaæones—the three main branches of the Germani (see below)—were sprung from three sons of a certain Mannus (perhaps “Man”), who was himself the son of the god Tuisto; the son of Earth; and in a Frankish document at least four centuries later we hear again of three brothers named Erminius, Ingus and Istio, from whom many nations were descended. In English documents also we find eponymous national ancestors grouped together in genealogical trees, and there is reason to believe that the common origin of the various Teutonic peoples was remembered to a certain extent until comparatively late in the middle ages.

The linguistic characteristics of the various Teutonic peoples have been dealt with under TEUTONIC LANGUAGES. In regard to physical features they present at the present time very many varieties both of stature and of pigmentation, though on the whole they are probably the tallest and fairest of European peoples. These characteristics are noted by a number of ancient writers in language which seems to show that they must at that time have been at least as pronounced as at any of the present time. The Teutonic peoples, however, the tallest and dolichocephalic which now specially mark the more northern peoples of the group appear very prominently in cemeteries of the migration period in Switzerland and other neighbouring countries. On the whole, however, the skeletons found in German and Scandinavian tombs dating even from the earliest period do not show any very remarkable differences from those of the present day. But whether we are justified in speaking of a Teutonic race in the anthropological sense is at least doubtful, for the most striking characteristics of these peoples occur also to a considerable extent in the eastern and western neighbours, where they can hardly be ascribed altogether to Teutonic admixture. The only result of anthropological investigation which so far can be regarded as definitely established is that the old Teutonic lands in northern Germany, Denmark and southern Sweden have been inhabited by people of the same type since the neolithic age, if not earlier.

The results of investigations in prehistoric archaeology are treated in the articles GERMANY and SCANDINAVIAN CIVILIZATION. As no Teutonic inscriptions are extant from before the third century B.C., the Teutonic peoples became important only after this time. What types of objects are characteristic of Teutonic civilization in the bronze and earliest iron ages. Yet throughout the bronze age it is possible to trace a fairly well-defined group of antiquities covering the basin of the Elbe, Mecklenburg, Holstein, Jutland, southern Sweden and the islands of the Belt, and archaeologists have conjectured with much probability that these antiquities represent the early civilization of the Teutonic peoples. The civilization was, of course, not wholly of native growth. Strong foreign influence, first Aegean and later Etruscan, can be distinguished; but the types introduced from the south have generally undergone considerable modification and expansion. The somewhat surprising degree of wealth and artistic skill of which many of the earliest antiquities give evidence is probably to be explained by the importance of the amber trade. Both in eastern and in western Germany the objects found are of somewhat different types and seem to point to a lower standard of civilization. What peoples inhabited these regions can only be conjectured, but there is a certain amount of evidence from place-names—not altogether satisfactory—that the Celtic peoples at one time extended eastwards throughout the basin of the Weser. With the beginning of the iron age (perhaps c. 500–500 B.C.) Celtic influence becomes apparent everywhere. By this time, however, the great Celtic movement towards the south-east had probably begun, so that the Teutonic peoples were now cut off from direct communication with the centres of southern civilization.

1. History.—The first recognition that the inhabitants of Germany, Holland, &c., were a people distinct from their Celtic neighbours dates from about the middle of the 1st century B.C., when Caesar’s conquest of Gaul rendered a knowledge of northern Europe more generally accessible to the Romans. Certain notices relating to individual Teutonic tribes come down from still earlier times. Thus there can be little doubt that the Cimbri (g.v.) and their allies, who invaded Illyricum, Gaul and Italy in the last years of the preceding century, were for the most part of Teutonic nationality. The Bastarnae also, who in the 3rd century B.C. invaded and settled in the regions between the Carpathians and the Black Sea, are said by several ancient writers to have been Teutonic by origin, though they had largely intermarried with the native inhabitants. Again, individual travellers from the time of Pytheas onwards had visited Teutonic countries in the north. In none of the early records, however, do we get any clear indication that the
Teutonic peoples were distinguished from the Celts. From the time of Caesar onwards the former were known to the Romans as “Germani,” a name of uncertain, but probably Gaulish origin. It is said to have been first applied to certain Belgic tribes in the basin of the Meuse, who may formerly have come from beyond the Rhine.

At the beginning of our era the Teutonic peoples stretched from the Rhine to the Vistula. Before Caesar’s arrival in Gaul they had advanced beyond the former river, but their further progress in this direction was checked by his campaigns, and, throughout the first half of the century, they were checked by Teutonic tribes throughout the greater part of its course, most of these tribes remaining in definite subjection to the Romans. The easternmost Teutonic tribe was probably that of the Goths, in the basin of the Vistula; while the farthest to the south were the Marcomanni and Quadi, in Bohemia and Moravia. These latter districts, however, had been conquered from the Boii, a Celtic people, shortly before the beginning of our era. Towards both the south and west the Teutonic peoples seem to have been pressing the Celts for some considerable time, since we are told that the Helveti had formed a common arrangement as far as the Main, while, according to our Celtic tribe, the Vorni Teutones, occupied a still more remote position, which it is impossible now to identify. How far the Teutonic peoples extended northwards at this time cannot be determined with certainty, but it is clear that they occupied at least a considerable part of the Scandinavian peninsula.

It has already been mentioned that the Teutonic peoples of this period seem to have been fully conscious of their common origin. What exactly the grouping into Inguaeaeus, Herminos and Istaeques was based upon can only be conjectured, though probably its original basis was to be sought rather in religion than in political union. The name of the Herminos, who are defined as “central” or “interior” peoples, is probably connected with that of the Irmisus, the sacred pillar of the Old Saxons. The Inguaeaeus again are defined as being “next to the ocean,” but the name can be traced only in Denmark and Sweden, where we find the eponymous hero Ing and the god Yngvi (Frey) respectively. It is likely that the name really belonged only to the peoples of the southern Baltic. Very probably there were many tribes which did not regard themselves as belonging to any of these groups, Tacitus himself records a variant form of the genealogy (see above), according to which Mannus had a larger number of sons, who were regarded as the ancestors of the Suebi, Vandili, Marsi and others (see Suebi, Vandals). In two at least of these cases we hear of sanctuaries which were resorted to by a number of tribes. It is not to be doubted that such religious confederations were favourable to the existence of political unions. Generally speaking, however, each tribe formed a political unit in itself, and the combinations brought together from time to time in the hands of powerful kings were liable to fall to pieces after the first disaster. For a few years at the beginning of the Christian era the part of Germany which lies west of the Elbe was under Roman government; but after the defeat of Varus (A.D. 9) the Rhine and the Danube formed in general the frontiers of the empire. Roman influence, however, made itself felt both by way of trade and especially by the employment of German soldiers in the auxiliary forces. In the age of national migrations—from the 4th to the 6th century—the territories of the Teutonic peoples were vastly extended, partly by conquest and partly by arrangement with the Romans. These movements began in the east, where we find the Goths ravaging Dacia, Moesia and the coast regions as early as the 3rd century. In the following century the Vandals settled in Pannonia (western Hungary), while the Goths occupied Dacia, which had now been given up by the Romans, and subsequently took possession also of large territories to the south of the lower Danube.

The 5th century was the time of the greatest national movements. In 406–9 the Vandals and other tribes invaded Gaul from the east and subsequently took possession of Spain and north-western Africa. Immediately afterwards the Visigoths invaded Italy and captured Rome; then turning westwards they occupied southern Gaul and Spain. The southern Suebic peoples, the Alamanni and Bavarians, extended their frontiers as far as the Alps probably about the same time. Not much later a considerable portion of northern Gaul fell into the hands of the Franks, and before the middle of the century the eastern part was occupied by the Burgundians. Several of these movements were due, without doubt, to pressure from the Huns, an eastern people who had conquered many Teutonic tribes and established the centre of their power in Hungary. Their empire, however, speedily fell to the share of their king Attila in 453. The chief events of the latter part of the century were the conquest of the eastern part of Britain by the Angli, the invasion of Italy by the Ostrogoths and the complete subjugation of northern Gaul by the Franks. By this time, with the exception of Brittany and the southern part of the Balkan peninsula, practically the whole of southern and western Europe was under Teutonic government.

It is customary to attribute this great expansion partly to the increasing weakness of the Romans and partly to pressure of population in the regions of their expansion. It may contain a residue of truth; but there is also doubt whether the military strength of the Teutonic nations was far more formidable now than it had been in the time of the early empire. Not only is it clear, both from literary and archaeological evidence, that they were better armed (see below), but also their power was much more concentrated. Thus during the 1st century we hear of about a dozen different tribes in and around the lower part of the basin of the Rhine. In later times, with one or two possible exceptions, these were all included under the general term Franks, and by the end of the 5th century all had become subject to one king. Similar processes can be traced elsewhere, e.g. among the Alamanni and in the northern kingdoms. Their effect, of course, must have been to provide the kings with greater wealth and with larger permanent bodies of armed men. The motive force towards expansion of territories was supplied by military ambition; especially we have to take account of the growth of a warlike spirit in the North, which was constantly driving young warriors to seek their fortunes in the service of continental princes. Where the movement was really of a migratory character it may generally be ascribed to external pressure in particular from the Huns and the Avars.

The first half of the 6th century saw the subjugation of the Burgundian and Visigothic portions of Gaul by the Franks and the recovery of Africa by the Romans. This latter event was soon followed by the overthrow of the Ostrogothic kingdom; but not many years later Italy was again invaded by the Langobardi (Lombards), the last of the great Teutonic migrations. By this time the extension of Teutonic dominion towards the south and west had brought about its natural sequel in the occupation of the old Teutonic lands in eastern Germany, including even the basin of the Elbe, by Slavonic peoples. Before the end of the century Bohemia also and Lower Austria, together with the whole of the basins of the Drave and the Save, had become Slavonic countries.

The story of the succeeding centuries may briefly be described as in general a process of return to the ethnographical conditions which prevailed before the migration period. The Franks and the Langobardi remained in Gaul and Italy, but they gradually became denationalized and absorbed in the native populations, while in Spain Teutonic nationality came to an end with the overthrow of the Visigothic kingdom by the Moors, if not before. Yet throughout the west and south-west the Teutonic frontier remained from fifty to two hundred miles in advance of its position in Roman times. In south-eastern Europe also the Teutonic elements were swallowed up by the native and Slavonic populations, though a small remnant lingered in the Crimea until probably the 17th century. On the other hand the political consolidation of the various continental Teutonic peoples (apart from the Danes) in the 8th century led to the gradual recovery of eastern Germany together with Lower Austria and the greater part of Styria and Carinthia, though
Bohemia, Moravia and the basins of the Vistula and the Warthe have always remained mainly Slavonic. In the British Isles the Teutonic element, in spite of temporary checks, eventually became dominant everywhere. Lastly, from the very beginning of the 9th century bodies of Scandinavian warriors began to found kingdoms and principalities in all parts of Europe. The settlers, however, were not sufficiently numerous to preserve their nationality, and in almost all cases they were soon absorbed by the populations (Teutonic, Celtic, Latin or Slavonic) which they had conquered. Their settlements in Greenland and Canada likewise came to an end, but Iceland, which was formerly uninhabited, remained a Scandinavian colony. The permanent expansion of the Teutonic peoples outside Europe did not begin till the 16th century.

2. Form of Government.—From the evidence at our disposal it is difficult to determine how far the Teutonic peoples were under kingly government in early times. Tacitus speaks of tribes which had kings and tribes which had not, the latter apparently being under a number of princes. On nearer examination, however, it appears that kingship was intermittent in some tribes, while in others, which had no kings, we find mention of royal families. All such cases were perhaps peculiar to the western peoples; in the east, north and centre we have no evidence for kingless government. Further, while Tacitus represents the power of Teutonic kings in general, with reference no doubt primarily to the western tribes, as being of the slightest, he states that among the Goths, an eastern people, they had somewhat more authority, while for the Swedes he gives a picture of absolutism. It is quite in harmony with these statements that many Northern and probably all the Anglo-Saxon kingly families traced their origin to the gods. The Swedes, indeed, and some of the eastern peoples seem to have regarded their kings themselves as at least semi-divine (see below, § Religion). As the west was the side most open to foreign influence during the Roman period, it is likely that the form of government which prevailed there was less primitive than the other, especially as we know that kingship had by this time died out among the Goths. In later times we very frequently find a number of "kings," generally belonging to one family, within the same tribe; and it is not improbable that the early princes were persons of similar position. The kingless state may therefore have arisen out of kingship through divisions of the royal power or through failure on the part of the leading men to agree on a head acceptable to all. On the other hand the conditions of the migration period were doubtless favourable to monarchical government, and from this time onwards kingship appears to have been universal, except among the Old Saxons and Franks.

The comitum or tribal assembly figures largely in Tacitus's account of the Germani, and he represents it as the final authority on all matters of first-rate importance. Further, it was here that the princes were chosen, serious charges brought against members of the tribe and youths admitted to the rights of warriors. The duties of opening the proceedings and maintaining order belonged not to the king but to the priests, from which we may probably infer that the gathering itself was primarily of a religious character and that it met, as among the Swedes in later times, in the chief's dwelling (Gaulh of the Latins, sanctuary). Such religious gatherings were no doubt common to all Teutonic peoples in early times, but it may be questioned whether among the eastern and northern tribes they were invested with all the powers ascribed to them by Tacitus. After his time tribal assemblies are seldom mentioned, and though we hear occasionally, both in England and elsewhere, of a concourse of people being present when a king holds court on high days or religious festivals, there is no evidence that such concourses took part in the discussion of state affairs. Indeed, considering the greatly increased size of the kingdoms in later times, it is improbable that they were drawn from outside the immediately adjacent districts. When we hear of deliberations now they are those of the king's council or court, a body consisting partly of members of the royal family and partly of warriors old and young in the personal service of the king. Such bodies of course had always existed (see below) and exercised at all times a powerful influence upon the kings, frequently even forcing them into war against their own wishes. That they were more prominently now than in earlier times is due to the fact that owing to the increased size of the kingdoms, they had become both more numerous and more wealthy. The principle of representation for the unofficial classes, i.e. for those not under the immediate lordship of the king, scarcely begins before the 13th century.

Of all the institutions of the Teutonic peoples probably none exercised a greater influence on their history than the comitatus. From Caesar we learn that it was customary at tribal assemblies for one or other of the chiefs to propose an expedition. He the exact position of the god who embraced his service were held bound to accompany him to the end, any who drew back being regarded as traitors. Incidents illustrative of this custom are of frequent occurrence in early history and tradition. Moreover, kings and other distinguished persons kept standing bodies of young warriors, an honour to them in time of peace, as Tacitus says, as well as a protection in war. Chiefs of known prowess and liberality attracted large retinues, and their influence within the tribe, and even beyond, increased proportionately. The followers (called by Tacitus comites, in England anlrusites, 8 c.) were expected to remain faithful to their lord even to death; but 40 close was the relationship between the two that it seems to have reckoned as equivalent to that of father and son. According to Tacitus it was regarded as a disgrace for a comites to survive his lord, and we know that in later times they frequently shared his exile. Perhaps the most striking instance of such devotion was that displayed at the battle of Strassburg in 357, when the Alamannic king Chonodomarius was taken prisoner by the Romans, and his two hundred comites gave themselves up voluntarily to share his captivity. In return for his services the chief was expected to reward his followers with treasure, arms and horses. If he were a king the reward might take the form of a grant of land, or of jurisdiction over a section of the population subject to him—in early times a village, in later, perhaps, a considerable district. Further, since the grantees as a rule naturally sent their sons into the service of their own lords, such grants tended to become hereditary, and in them we have the origin of the baronage of the middle ages. The origin of the earls or counts, on the other hand, is to be found in the governors of large districts (Tacitus's principes), who seem at first generally to have been the sons of the royal family, though later they were drawn from the highest barony.

3. Social Organization.—As far back as the time of Tacitus we hear of three social classes, viz. nobles, freemen and freedmen. The same classes are met with in later times, though occasionally one of them disappears, e.g. the nobility among the Franks and the freedmen (as a distinct class) in the Anglo-Saxon kingdoms, except Kent. Each of these classes was, to a large extent at least, hereditary and had separate rights and privileges of its own. Among the chief of these must be reckoned the wergeld or "man-price." When homicide took place vengeance was regarded as a sacred duty incumbent on the relatives, and sometimes at least the lord also, of the slain man; but, as in the case of any other injury, compensation could be made by a fixed payment. From the evidence of later custom it is probable that the normal payment for a freeman was a hundred head of cattle. The sums paid for members of the other classes were more variable; for the freedman, however, they were always lower, and for the noble higher, sometimes apparently three or four times as high. Similar gradations occur in the compensations paid for various injuries and insults, in fines and, among some tribes, in the value attached to a man's oath. There is a good deal of uncertainty in regard to the exact position in society of the husbandman of Tacitus's age. It is probable, however, that the latter, like
the liti or lati of later times, consisted not only of manumitted slaves but also of whole communities which had forfeited their liberty through unsuccessful warfare or other causes. In addition to these classes there was also a considerable population of slaves, who had no legal status or wergeld and were regarded as the property of their masters. In general, however, their lot seems to have struck the Romans as favourable, since they were not attached to their masters' households but lived in homes of their own, subject to fixed payments in corn, live stock, and cash.

Groups of family and kindred occupy a prominent position in the accounts of Teutonic society given by Caesar and Tacitus. It was regarded as a universal duty to afford protection to one's kinsmen, to assist them in the redress of wrongs and to exact vengeance or compensation in case of death. Hence to have a numerous kindred was a guarantee of security and influence. The large amounts fixed for the wergelds of nobles and even of freemen were paid no doubt, as in later times, not only by the slayer himself, but by every member of his kindred in proportion to his wealth or remoteness of his relationship like manner they were distributed among the kindred of the slain. The importance of the kindred, however, was not limited to purposes of mutual protection. It appears also in the tenure of land, and according to Tacitus the tribal armies were drawn up by kindreds. As to the nature of these organizations the evidence is not altogether consistent. It is clear that agnatic succession prevailed among the princely families of the Cherusci, and the general account given in the Germania seems to imply that this type of organization was normal. On the other hand there are distinct traces of cognation not only in Teutonic works but also in Nordic tradition, and the kindred was more especially in the Salic law. On the whole it seems not unlikely that at the beginning of the Christian era the Teutonic peoples of the continent were in a state of transition from cognatic to agnatic organization.

All the usual forms of marriage were known, including marriage by capture and marriage by purchase. The latter appears most prominently in Kent and among the Old Saxons, Langobardi and Burgundians. In other nations, e.g. the Franks, we find the payment of a very small sum or of no sum at all. Frequently the only price required was a sum of gold or purchase. Yet this explanation is open to question owing to the very early date at which the regulation appears, and to the fact that in the case of widows the sum specified had to be paid to relatives of the widow herself on the female side, and by preference to those of a younger generation. Again, Tacitus states that the presents of arms and oxen given by the bridegroom at marriage were made to the bride herself and not her guardian, and such appears to have been the case in the North also from early times. It is not certain, therefore, that marriage by purchase was a universal and primitive Teutonic custom. Of the actual ceremonies practised at marriage not very much is known. It was preceded, however, by a formal betrothal and accompanied by a feast. Moreover, even among those peoples with whom purchase prevailed it was customary for the bridegroom to present the bride with a "morning-gift," which in the case of queens and princesses often took the form of considerable estates. There is no doubt that the marriages of heathen times were often of a kind which could not be permitted after the adoption of Christianity. Among these may be mentioned marriages with brothers' widows and stepmothers, the latter especially in England. Polymy was known, but limited, both in early and late times, to persons of exceptionally high position, while of polyandry there is hardly any trace. Indeed, the sanctity attached to marriage seems to have struck the Romans as remarkable. On the other hand strife between persons connected by marriage appears to have been of extremely frequent occurrence, and no motive plays a more prominent part in Teutonic traditions.

4. State of Civilization.—It is a much disputed question whether the Teutonic peoples were really settled agricultural communities at the time when they first came into contact with the Romans, shortly before the beginning of our era. That agriculture of some kind was practised is clear enough from Caesar's account, and Strabo's statement to the contrary must be attributed to ignorance or exaggeration. But Caesar himself seems to have regarded the Germani as essentially pastoral peoples and their agriculture as of quite secondary importance, while from Tacitus we gather that even in his time it was of a somewhat primitive character. For not only were the husbandmen in North Germany expressly told that late in the spring apparently the ploughlands were changed from year to year without any recognition of a two-course or three-course system. Caesar, moreover, says that the clans or kindreds to whom the lands were allotted changed their abodes also from year to year—a statement which gives a certain amount of colour to Strabo's description of the Germani as quasi-nomadic. Yet there is good reason for believing that this representation of early Teutonic life was by no means universally true. We have evidence, both archaeological and linguistic, that the cultivation of cereals in Teutonic lands goes back to a very remote period, and that even the earliest of the ox-ploughs is attested by the rock-carvings at Tegneyb in Bohuslän (Sweden), which are believed to date from early in the bronze age. Further, that the tribes were not normally of a migratory character, as Strabo seems to imply, is shown by the existence of sanctuaries of immemorial age and by frontier ramparts such as that raised by the Angariumi against the Cherusci. It would seem that Julius Caesar encountered the Germani under somewhat abnormal conditions. Several of the tribes with which he came into collision had been expelled from their own territories by other tribes and in North Germany expressly told that late in the spring they had not entered a house for fourteen years. Further, there is satisfactory evidence that the basin of the Rhine, perhaps also a considerable area beyond, had been conquered from Celtic peoples not very long before—from which it is probable that western Germany was still in a more or less unsettled condition. Indeed Caesar himself seems to have regarded the prevalence of the military spirit as the chief hindrance to the development of agriculture. From this time onwards it was from the west mainly that Roman civilization made its way into Germany; but in earlier ages, as we have already noticed, there are more abundant traces of civilization in the basin of the Elbe than in the districts farther to the west. Hence it is not so surprising as might at first sight appear that at the remote Aestii, a non-Teutonic people settled about the mouth of the Vistula, are represented by Tacitus as keener agriculturists than any of the other inhabitants of Germany.

All ancient writers emphasize the essentially warlike character of the Germani. Yet Tacitus seems to represent their military equipment as being of a somewhat primitive type. Swords, helmets and coats of mail, be says, were seldom to be seen; in general they, were armed only with huge shields, unwieldy spears and darts. Here again he appears to be thinking of the western tribes; for elsewhere he states that some of the eastern peoples were armed with short swords and round shields—which probably were of comparatively small size, like those used in later times. This latter type of equipment prevailed also in the North, as may be seen, e.g. from the figures of warriors on the inscribed golden horn found at Galliche (Jutland) in 1734. The favourite method of attack was by a wedge formation (known later in the North as stenvykling), the point being formed by a chosen band of young warriors. Certain tribes, such as the Tencteri, not only for their horses but for the Germani in general preferred to fight on foot. Sometimes also we hear of specially trained forces in which the two arms were combined. Naval warfare is seldom mentioned. The art of sailing seems to have been unknown, and it is probable that down to the 3rd century the only peoples which could truly be described as seafaring were those of the Baltic and the Cattegat.

There is no doubt that Roman influence brought about a considerable advance in civilization during the early centuries of our era. The cultivation of vegetables and fruit trees seems to have been practically unknown before this period, and almost
all their names testify to the source from which they were derived. We may notice also the introduction of the mill in place of the quern which hitherto had been in universal use. In all such cases the tribes subject to the Romans, in the neighbourhood of the Rhine, probably the chief channel by which Roman influence made its way, though account must also be taken of the fact that considerable numbers of warriors from remoter districts were attracted to serve in the Roman armies. Great improvements took place likewise in armour and weapons; the equipment of the warriors whose relics have been found in the Schleswig bog-deposits, dating from the 4th and 5th centuries, appears to have been vastly superior to that which Tacitus represents as normal among the Germans of his day. Yet the types, both in armour and dress, remained essentially from Teutonic or rather Chetic-Teutonic. Indeed, when in the course of time uniformity came to prevail over the greater part of Europe, it was the Teutonic rather than the Roman fashions which were generalized.

The antiquity of the art of writing among the Teutonic peoples is a question which has been much debated. Tacitus says that certain marks were inscribed on the divining chips, but it cannot be determined with certainty whether these were really letters or not. The national type of writing, generally known as Runic, must have been fully developed by the 4th century, when some of its letters were borrowed by Ulfilas (Wulfila) for his new alphabet (see Gotius: § C.). Indeed, by this time it was probably known to most of the Teutonic peoples, for several of the inscriptions found in Jutland and the islands of the Belt can hardly be of later date. As to the source from which it was derived opinions still differ, some thinking that it was borrowed from the Romans a century or two before this time, while others place its origin much farther back and trace it to one of the ancient Greek alphabets. Many of the earliest inscriptions read from right to left, and the βουκραφος' type is also met with occasionally. It is clear from the time of their use that the character was chiefly used for writing on wood, but the inscriptions which have survived are naturally for the most part on metal objects—in Sweden, Norway and England also on monumental stones. In Germany very few Runic inscriptions have been found, and there is nothing to show that the alphabet was used after the 8th century. In England also it seems not to have lasted much longer, but inscriptions are far more numerous. On the other hand, in Scandinavian countries it continued in use through the greater part of the middle ages—in Gotland till the 16th century; indeed, the knowledge of it seems never to have wholly died out. In the course of time it underwent many changes, and the earliest inscriptions must have been unintelligible for over a thousand years until they were deciphered by scholars within the last half century. The Roman alphabet first came into use among the western and northern Teutonic peoples after their adoption of Christianity.

5. Funeral Customs.—Icelandic writers of the 12th and 13th centuries distinguished between an earlier "age of burning" and a later "age of barrows," and the investigations of modern archaeologists have tended in general to confirm the distinction, though they failed to establish any evidence that the character of the ceremony was antecedent to the age of burning. Throughout the stone age inhumation appears to have been universal, many of the neolithic tombs being chambers of considerable size and constructed with massive blocks of stone. Cremation makes its appearance first in the earlier part of the bronze age, and in the latter part of that age practically displaces the older rite. In the early iron age there is less uniformity, some districts apparently favouring cremation and others inhumation. The former practice is the one recognized by Tacitus. In the national migration period, however, it fell into disuse among most of the continental Teutonic peoples, even before their conversion, though it seems to have been still practised by the Heruli in the 5th century and by the Old Saxons probably till a much later period. It came into Britain with the Anglo-Saxon invaders and continued in use in certain districts perhaps until nearly the close of the 6th century. In Scandinavian lands the change noted by Icelandic writers may be dated about the 5th and 6th centuries, though inhumation was certainly not altogether unknown before that time. After the 6th century cremation seems not to have been common, if we may trust the sagas, but isolated instances occur as late as the 10th century. It is to be observed that cremation and the use of the barrow are not mutually exclusive, for cremated remains, generally in urns, are often found in barrows. On the other hand inhumation below the surface of the ground, without perceptible trace of a barrow, seems to have been the most usual practice during the national migration period, both in England and on the continent. A special form of funeral rite peculiar to the North was that of cremation on a ship. Generally the ship was drawn up on land; but occasionally we hear, in legendary sagas, of the burning ship being sent out to sea. Large ships containing human remains have sometimes been found in barrows of the viking age. Arms and ornaments are frequently met with, sometimes also horses and human remains which may be those of slaves, the belief being that the dead would have all that was buried with him at his service in the life beyond.

6. Religion.—The conversion of the Teutonic peoples to Christianity was a gradual process, covering some seven centuries. The first to accept the new religion seem to have been the Goths, beginning about the middle of the 4th century, and the Vandals must have followed their example very quickly. In the course of the 5th century it spread to several other nations, including the Gepidae, Burgundians, Rugii and Langobardi. In all these cases the Arian form of Christianity was the one first adopted. The first conversion to the Catholic form was that of the Franks at the end of the 5th century. The extension of Frankish supremacy over the neighbouring Teutonic peoples brought about the adoption of Christianity by them all, partly under compulsion, and these and these are generally in no way comparable to the detailed accounts given in Icelandic writings. Hence it is often difficult to decide whether a given rite or legend which is mentioned only in Icelandic literature was really peculiar to that country alone or to the North generally, or whether it was once the common property of all Teutonic peoples.

A number of gods were certainly known both in England and among many, if not all, the Teutonic peoples of the continent, as well as in the North. Among these were Odin (Woden), Thor (Thunor) and Tyr (Ti); so also Frigg (Frig), the wife of Odin (see Frigg, Odin, Woden, Thor, Tyr). Some scholars have thought that Baldur, the son of Odin, was once known in Germany, but the evidence is at least doubtful. Heimdalr, the watchman of the gods and Ullr, the stepson of Thor, as well as Hoenir, Bragi and most of the other less prominent gods,
were also probably peculiar to the North, though Ullr at least was known in Denmark. Some of these deities may originally have been quite local. Indeed, such may very well have been the case with Frey, the chief god of the North after Thor and Odin. Tradition at all events uniformly points to Upsala as the original home of his cult. But it is probable that both he and his sister Freyja were really specialized forms of a divinity which had once been more widely known. Their father, Njörðr, the god of wealth, who is a somewhat less important figure, corresponds in name to the goddess Nerthus (Hertha), who in ancient times was worshipped by a number of tribes, including the Angli, round the coasts of the southern Baltic. Tactus describes her as "Mother Earth," and the account which he gives of her cult bears a somewhat remarkable resemblance to the ceremonies associated in later times with Frey. This family of deities were collectively known as Vanir, and are said to have once been hostile to the Asir, to whom Odin belonged. Their worship was generally connected with peace and plenty, just as that of Odin was chiefly bound up with war. Gefjon was another goddess who may represent a later form of Nerthus. In her case tradition points distinctly to a connexion with Denmark (Sjælland). On the other hand, the portrayal of Skáddi, the wife of Njörðr, seems to point to a Finnish or Lappish origin. The rest of the northern goddesses are comparatively unimportant, and only one of them, Fulla, the handmaid of Frigg, seems to have been known on the continent.

Some of the deities known to us from German and English sources seem always to have been of a blended character. Such a god was Fúit, to whom Helgaland was sacred. Saxnot (Seaxneat), from whom the kings of Essex claimed descent, was probably a god of the Saxons. Holda, who is known only from the folklore of later times, appears to have been a German counterpart of Nerthus. Ing, who is connected with Denmark in Anglo-Saxon tradition, was in all probability the eponymous ancestor of the Ingueanos (see above). His name connects him, too, with the god Frey, who was also called Yngvifreyr and Ingunnarfreyr, and he must at one time have been closely associated with Nerthus. The relationship of Ing to the Ingueanos is paralleled by that of Ieuan in the Harp (see above). He may be the deity whom Tacitus called "Heracles."

Some of these eponymous ancestors may be regarded as heroes rather than gods, and classed with such persons, as Skíöldr, the eponymous ancestor of the Danish royal family, who is not generally included in the Northern pantheon. But the line of division between the human and the divine is not very definite. The royal family of Norway claimed descent from Frey, and many royal families, both English and Northern, from Woden (Odín). Indeed, several legendary kings are described as sons of the latter. Sometimes, again, the relationship is of a conjugal character. Skíöldr, though hardly a god himself, is the husband of the goddess Gefjon. So we find Freyja's priest described as her husband and Frey's priestess as his wife, and there is no reason for regarding such cases as exceptional.

If it is not always easy to distinguish between gods and heroes, there is still greater difficulty in drawing a line between the former and other classes of supernatural beings, such as the "giants." (O.N. jötnar, A.S. ēotenās). Here again we have intermarriage. Skáddi, the wife of Njörðr, and Gerðr, the wife of Frey, were the daughters of the giants Thialzi and Gymir respectively, though Skáddi is always reckoned as a goddess. Loki also was of giant birth; but he is always reckoned among the gods, and we find him constantly in their company, in spite of his malevolent disposition. In general it may be said that the giants were regarded as hostile to both gods and men. Often they are represented as living a primitive life in caves and desolate places, and their character is usually ferocious. But there are exceptions even among the male giants, such as Aegir, whom we find on friendly terms with the gods. It is worth noting also that some of the leading families of Norway are said to have claimed descent from giants, especially from Thrymr, the chief opponent of Thor. In such cases there may be some connexion between the giants and the semi-civilized (Finnish or Lappish) communities of the mountainous districts. This connexion is more clear in the case of Thórgárður Hólgabráður, who is known chiefly from the extreme veneration paid to him by Haakon, earl of Lade (+993). According to one story she was the daughter of Hólgi, the eponymous king of Halogaland (northern Norway); according to another she was the wife of Hólgi and daughter of Gusi, king of the Fins. She ought perhaps to be regarded rather as a goddess than as a giantess, but she is never associated with the other deities.

Another class of supernatural beings was that of the dwarfs. They were distinguished chiefly for their cunning and for skill in working metals. More important than these from a religious point of view were the elves (O.N. alf, A.S. yfel), who certainly received worship, at all events in the North. They are almost always spoken of collectively and generally represented as beneficent. In some respects, e.g. in the fact that they are often said to inhabit barrows, they seem to be connected with the souls of the dead. In other cases, however, they are hardly to be distinguished from spirits (the Icel. landvættir, &c.), which may be regarded as genii locorum.

In addition to the above there were yet other classes of supernatural beings (see Norns and Valkyries). Mention, however, must be made here of the fylgur and hammering of Northern belief. These are of two kinds, though the names seem not always to be clearly distinguished. Sometimes the fylgia is represented as a kind of attendant spirit, belonging to each person, who may be seen, generally in animal form, in visions or by persons of second sight. In another case the fylgia is a sign of impending death. In other cases the fylgur (or perhaps more correctly the hamingur) apparently belongs to the whole family. These generally appear in the form of maidens.

Human beings, especially kings and other distinguished persons, were not infrequently honoured with worship after death. In Sweden during the 9th century we have trustworthy record of the formal deification of a dead king and of the erection of a temple in his honour. In general the dead were believed to retain their faculties to a certain extent, and in the place where they were buried, and stories are told of the resistance offered by them to tomb-robbers. It would seem, moreover, that they were credited with the power of helping their friends (and likewise of injuring other people) very much in the same way as they had done in life. Hence the possession of the remains of a chief who had been both popular and prosperous was regarded as highly desirable.

The blessings which kings were expected to bestow upon their subjects, in life as well as after death, were partly of a supernatural character. Chief among them was that of securing the fertility of the crops. The prevalence of paling among the Swedes was attributed to the king's remissness in performing sacrificial functions; and on more than one occasion kings are said to have been put to death for this reason. Under similar circumstances Burgundian kings were deposed. In connexion with this attribution of superhuman powers, we may mention also the widespread belief that certain persons had the faculty of "changing shape," and especially of assuming the forms of animals.

Besides the various classes of beings to the worship of which we have already referred, we hear occasionally also of sacred animals. Tacitus tells of how he consecrated to the service of the gods, and of omens drawn from them, and we meet again with such horses in Norway nearly a thousand years later. In the same country we find the legend of a king who worshipped a cow. Besides the anthropomorphic "giants," mentioned above, Northern mythology speaks also of theriomorphic demons, the chief of which were Midgarðsormr, the "world-serpent," and Fenrisulfr, a monster wolf, the enemies of Thor and Odin respectively. These beings are doubtless in part to poetic imagination, but underlying this there may be a substratum of primitive religious belief. In contrast with later Scandinavian usage Tacitus states that the ancient Germans
had no images of the gods. But he does speak of certain sacred symbols which he defines elsewhere as figures of wild beasts. One of the chief objects of veneration among the Cimbri is said to have been a brazen bull.

Figures of human, however, were not the only inanimate things regarded in this way. The Quadi are said to have considered their swords divine. More important than this was the worship paid, especially in the North, to rocks and stone cairns, while springs and pools also were frequently regarded as sacred in all Teutonic lands. But, on the whole, there is perhaps no characteristic of Teutonic religion, both in early and later times, more prominent than the sanctity attached to certain trees and groves, though it is true that in such cases there is often a doubt as to whether the tree or a perpetual sacrifice or whether it was regarded as the abode of a god or spirit. The sanctuaries mentioned by Tacitus seem always to have been groves, and in later times we have references to such places in all Teutonic lands. One of the most famous was that in or beside which stood the great temple of Upsala. Here also must be mentioned the Swedish Vårdrträd or "guardian tree," which down to our own time is supposed to grant protection and prosperity to the household to which it belongs. One of the most striking conceptions of Northern mythology is that of the "world-tree," Yggrnasl's Ash, which sheltered all living beings (see Yggdrasil). The description given of it reveals in many respects that of a particularly holy tree which stood beside the temple at Upsala. For the idea we may compare the Iermnsol, a great wooden pillar which appears to have been the chief object of worship among the Old Saxons, and which is described as "universalis columna quasi sustinens omnia."

The Northern sanctuaries of later times were generally buildings constructed of wood or other materials. A space apparently partitioned off contained figures of Thor or Frey and perhaps other gods, together with an altar on which burned a perpetual fire. This is believed to have held the sacrificial feasts. The presiding priest seems always to have been the chief to whom the temple belonged, for there is no evidence for the existence of a special priestly class in the North. In England, however, the case was otherwise; we are told that the priests were never allowed to bear arms. There is record also of priests among the Burgundians and Goths, while in Tacitus's time they appear to have held a very prominent position in German society. Among all Teutonic peoples from the time of the Cimbrini onwards we frequently hear also of holy women whose duties were connected with the worship and divination. Some of these, as in the case of Veleda, a prophetess of the Bructeri, during Vespasian's reign, they were regarded practically as deities. After the adoption of Christianity, and possibly to a certain extent even before, such persons came to be regarded with disfavour—whence the persecutions for witchcraft—but it is clear from Tacitus's works and other sources that their influence in early times must have been very great. In the North the sanctuaries called hørgar seem to have been usually under the charge of the wives and daughters of the household. But there is some evidence also for the existence of special priestesses among the Germanic peoples.

Of religious ceremonials the most important was sacrifice. The victims were of various kinds. Those offered to Odin (Woden) were generally, if not always, men, from the time of Tacitus onwards. Human sacrifices to Thor and the other gods are not often mentioned. Of animals, which were consumed at the sacrificial banquets, we hear chiefly of horses, but also of oxen and boars. At human sacrifices, however, dogs and hawks were often offered with the men. At all sacrifices it seems to have been customary to practise divination; in conjunction with human sacrifice we have record of this rite from the time of the Cimbri. One barbarous custom which was regarded as a sacrifice was the dedication of an enemy's army to the gods, especially Odin. This custom, which is likewise known to have prevailed from the earliest times, involved the total destruction of the defeated army, together with everything belonging to them. In general the chief sacrificial festivals seem to have taken place at fixed times in the year, one in early or mid-autumn, another at mid-winter and a third during the spring. The sacrifices on an exceptionally large scale were held at Upsala and Leire every nine years, at the former place about the time of the spring equinox, at the latter in the early part of January. Besides these fixed festivals sacrifices could of course be offered in all time of public or private need. In the latter case resort was very frequently had also to sorcery and necromancy.

Mention has been made above of the belief that the dead retained a conscious existence in or near the place where they were buried, and that they were able to confer blessings upon their families. It is also possible, however, that this belief seems hardly to be compatible with it, viz., that the souls of the dead passed to the realm of Hel, who in Northern mythology is represented as the daughter of Loki. Again, those who had fallen in battle were supposed to go to Valhalla, where they became warriors in Odin's service. This last belief seems to have been connected at one time with the practice of cremation. In conclusion it must be mentioned that even the life of the gods was not to be for ever. A day was to come when Odin and Thor would fall in conflict with the wolf and the world-serpent, when the abode of the gods would be destroyed by fire and the earth would be swallowed up by the sea. Hence it is said that in the future the gods of a younger generation would govern a better world. How far these beliefs were common to the Teutonic peoples as a whole cannot be determined with certainty. Some scholars hold that they were peculiar to the mythology of Norway and Iceland and that they arose at a late period, largely through Christian influence. But a serious objection to this view is presented by the fact that very similar ideas in some respects were current among the ancient Gauls.

AUTHORITIES.—I. Ancient. The most important of the early authorities is Tacitus (A.D. 55-118). He wrote Germania (II. 31-54, iv. 1-19; vi. 21-24), Strabo (esp. p. 290 ff.), Pliny, Hist. Nat. (esp. iv. 96 ff., xvi. 1 ff., xxxvii. 42 ff.), Tacitus (esp. Germania, Breviarium, Marmor, and Polyhistor, Geogr. ii. 11). Among later writers whose valuable information is given by Ammianus Marcellinus, Jordanes, Procopius, Gregory of Tours, Bede, Paulus Diaconus, Widukind, Thietmar, Adam of Bremen and Saxo Grammaticus, as well as by the early laws and charters. To these must be added a large number of Old Norse writings including the elder Edda and the prose Edda (the chief authorities for Northern mythology), Islanda Landnámabók and many sagas dealing with the history of the Teutonic peoples in Iceland (such as Ærbyggja Saga) or with the lives of Norwegian and other kings, both historical and legendary (in Heaeringskringla, Foramanna Sogur and Rafa's Forntafsar Sogur Norfa). For further references see BRITAIN (Anglo-Saxon), Germany (Ethnography and Early History), and ScANDINAVIAN CIVILIZATION.

TEVIOT, ANDREW RUTHERFORD, EARL OF (d. 1664), was the son of William Rutherford of Quarrelhoses, Roxburghshire. His education was received in Edinburgh, and he took up the career of soldier of fortune. His services were given to the French government, which maintained regiments of Scottish mercenaries. On the restoration of Charles II., Rutherford was taken into employment by his own king on the recommendation of Lord Lovat of Lovat, a colonel of cavalry, and soon became a lieutenant-general in France and had a high reputation for personal courage. Charles II. gave him the Scottish title of Lord Rutherford and the government of Dunkirk, which had been acquired by the Protector Oliver Cromwell. When Charles II. sold the town to France in 1662 Rutherford was consoled by the command of the 2nd or Tangier regiment, was made earl of Teviot in the peerage of Scotland, and was sent in 1663 as governor to Tangier. His tenure of office was very short, for on the 4th of May 1664 he allowed himself to be entrapped into an ambush by the Moors, who carried off incessant irregular warfare against the English garrison and was killed, together with nineteen officers and nearly five hundred men of his garrison.

TEVIOTDALE, the valley of the Teviot, Roxburghshire, Scotland. In a limited sense the word usually describes the stretch above Hawick, (9 ft.), in a wider sense the whole valley extending in a north-easterly direction from Teviethed near to the confines of the parish of Roxburgh, a distance of 23 m. It is sometimes incorrectly used as an alternative name for the shire, much of the area of which, in point of fact, lies outside the Teviot drainage basin. There are numerous points of interest in the vale. Henry Scott Riddell (1798-1870), the poet, was buried at Teviethed. Almost side by side in the churchyard are the obelisk near his grave and the memorial stone erected in the cemetery wall to John Armstrong of Gilnockie, the soldier, and whose son up to his death was treacherously seized in 1530 and hanged at Caerlarnigan, in the immediate vicinity, by order of James V. Riddell is further commemorated by a monument on Dryden hill. Branthom tower, the peak of Goldielands, and Harden castle (on Harden burn, a tributary of Northwick) water are spots familiar through the writings of Sir Walter Scott and many Border ballads. Five m. to the east of Hawick stands the hill of Ruberslaw (1392 ft.). Among the crags on its summit is the rock, still called, "Peden's chair," from which Alexander Peden preached to congregations of Covenanters. Below Hawick in the principal villages and centres around the Teviot, on the De Hazeldean of Sir Walter Scott's song, "Jock o' Hazeldean," and Ancrum.

TEWFIK PASHA (1852-1892), khevide of Egypt, son of the Khevide Ismail, was born on the 15th of November 1852. His mother was a fellah woman. Although the eldest son, he was not sent to Europe to be educated, like his younger brothers, but was left to grow up in his native country. In 1866 Ismail succeeded in his endeavour to alter the order of succession to the khedivate. The title, instead of passing to the eldest living male descendant of Mehemet Ali, was now to descend from father to son. Ismail sought this alteration mainly because he disliked his uncle, Halim Pasha, who was his heir-presumptive, and he is supposed to have imagined that he would be able to select whichever of his sons he pleased for his successor. But he found, after the change had been made, that the powers interpreted the new arrangement as applying strictly to the eldest son. Tewfik therefore became heir-apparent. He was given a palace near Cairo to live in, and for twelve years he passed an uneventful life, farming and establishing a reputation for good sense and fair dealing with his fellah tenants. In 1878 he was appointed president of the council after the dismissal of Nubar Pasha. He held this office only for a few months; but this was long enough to show that, if he was unambitious and not particularly intelligent or energetic, he had the wisdom to refrain from taking part in the intrigues which then formed the chief part of political life in Egypt. He went back to his estate, and settled down once more to a quiet country life. He was not left undisturbed for long. On the 26th of June 1881, at the instance of Great Britain and France, was deposed by the sultan, who sent orders at the same time that Tewfik should be proclaimed khedive. The new viceroy was so little pleased by the news of his accession that he soundly boxed the ears of the servant who first brought the tidings to him. Egypt at that time was involved in financial and political troubles brought about by the policy of Ismail (q.v.), and the situation was made worse by the inaction of England and France for some months following Tewfik's accession. Tewfik's people were dissatisfied, his army deserted; his advisers were nearly all of the adventurer class, with their selfish object; and he himself had neither the strength nor the experience that would have enabled him to secure an orderly administration of affairs. Disorder prevailed until November 1879, when the dual control was re-established by the governments of Great Britain and France. For over two years Major Baring (afterwards Lord Cromer), Mr. (afterwards Sir) Auckland Colvin, and M. de Bignières practically governed the country, endeavouring to institute reforms while possessing no means of coercion. During all this time the disaffection in the Egyptian army was increasing. Tewfik has been blamed for his failure to take a firm line with the men of the army, but his position was difficult. The Great Powers had been concerned by the relations of Great Britain and France, and he was unable to control events. The dissatisfaction culminated in the anti-foreign movement headed by Arabi Pasha (q.v.), who gained complete command of the army. In July 1882 the attitude of Arabi, who was carrying out defensive works on a large scale, made it necessary for the British admiral (Sir Beauchamp Seymour, afterwards Lord Alcester) to declare that he would bomb hard the forts of Alexandria unless they were handed over to him. Before the bombardment began it was suggested to Tewfik that he should at once strike for Egypt, and if he failed to reach Alexandria he was to throw himself on the mercy of the Great Powers. When it was found that Arabi had reached Cairo after the battle of Tel-el-Kebir, had consented to the reforms insisted upon by Great Britain, and had assumed the position of a constitutional ruler under the guidance of Lord Dufferin, the British special commissioner. When
Tewkesbury—Texarkana

the cholera broke out, he insisted upon going to Alexandria. His wife accompanied him, and he went round the hospitals, setting an excellent example to the authorities of the city, and encouraging the patients by kind and hopeful words. In 1864 Sir Evelyn Baring went back to Egypt as diplomatic agent and consul-general of Great Britain. His first task was to demand that Tewfik should abandon the Sudan. Tewfik gave his consent with natural reluctance, but, having consented, he did everything he could to ensure the success of the policy which Baring had been sent to carry out. He behaved with equal propriety during the negotiations between Sir H. Drummond Wolfe in the Turkish Empire, Montefiore (1859) and Evelyn Baring, by Tewfik's knowledge of the divergence of views between Nubar and the British agent. Baring encouraged Tewfik to show his activity in matters of administration, and he took a great interest in all matters connected with irrigation, education and justice. He was not a particularly strong man either in mind or in character, but he showed a genuine desire to govern his country for its own benefit. He understood the importance to Egypt of British assistance and support; his natural shrewdness made him accept the British conditions; his natural good feeling kept him from any inclination to intrigue. In private life he was courteous and amiable. He had no desire to keep up the unapproachable state of an oriental ruler. Indeed, in many ways his manners and habits were less oriental than European. He married in 1873 his kinswoman, Amina Hanem, with whom he lived very happily. She was his only wife and Tewfik was a strong advocate of monogamy. He died on the 7th to January 1892, at the Heliouan palace near Cairo, and was succeeded by his eldest son, Abbas II. (q.v.)

A warm tribute to Tewfik's many admirable qualities was paid by Baring (Lord Cromer) in his report on the administration of Egypt for 1891 (see Egypt, No. 3. 1892, pp. 1 and 2).

Tewkesbury, a market town and municipal borough in the Tewkesbury parliamentary division of Gloucestershire, England, 15½ m. N.E. of Gloucester by the Midland railway. Pop. (1901) 5419. It lies in a flat pastoral district, with low hills to the south, on the Warwickshire Avon, close to its junction with the Severn. The Severn is crossed by an iron bridge with a flattened arch of 170 ft. span, erected by Telford in 1824. Of the great Benedictine abbey, one of the richest foundations in England, refounded and enlarged by Sir Robert Fitz-Hamon in the 12th century on the site of an ancient hermitage and Saxon monastery, there only remain the gate and a few other fragments. The only portion of the abbey church that was discovered in 1125, is a magnificent specimen of early Norman. This elaborate cruciform building consists of nave and side aisles, with transepts united by a great central tower richly arcaded. The choir terminates in an apse and is surrounded by an ambulatory. One of the most remarkable features of the building is the unique western front, the central part of which is occupied by one vast arch extending from the ground to the roof. Originally it was filled in with Norman windows, but a Perpendicular window now occupies the space. The whole building underwent restoration in the Decorated period, and of this style it is one of the finest existing examples. The Norman windows in the nave were replaced, and stone groining was substituted for the carved wooden ceiling, a like transformation taking place in the transepts. The Norman columns in the choir still exist; but above them rises a grand superstructure of Decorated work. The elegant clerestory windows are of the 14th century, with stained glass of the same date. The ambulatory was rebuilt some distance farther out, and from it projected a beautiful series of chapels. The elaborate tombs include those of Sir Robert Fitz-Hamon, the De Spencers, Alan Prior of Canterbury, Sir Guy de Brien, and the vault of George Duke of Clarence (murdered in the Tower) and his wife Isabella. Edward, prince of Wales, slain after the battle of Tewkesbury (1471) by the Yorkists, is also buried in the church. Of the two organs, one, dating from the early 17th century, is of singularly beautiful tone. In the High Street there are several ancient timbered and gabled houses. Remains of an ancient wall have been discovered adjoining the town. There are a free grammar school (1541) and a number of charities and almshouses. Tewkesbury is chiefly dependent on its agricultural trade. Below the junction of the rivers there is a great lock and weir on the Severn, up to which the stream is sometimes reversed by the tidal bore. The borough is under a mayor, 4 aldermen and 12 councillors. Area, 5232 acres.

Remains of Roman encampments and roads prove that the earliest settlement near Tewkesbury (Theotestub, Theochebus, Thoocksbury) of which we have evidence was a military encampment against the British. It was the site of a Saxon church, however, which in the 10th century was refounded by Odo, the Norman lord, and became a minster. The church, which was the site of a battle in 1087 when it was part of the royal domain. It was subsequently granted by Earl Robert of Gloucester, who granted a charter before 1107, which exempted the borough from certain tolls and from suit at the hundred court. Edward III confirmed this charter in 1337, and made Tewkesbury free from tolls throughout England. The borough was incorporated by Elizabeth by a charter of 1574, which was confirmed in 1604, 1605, 1609 (when the manor and borough were sold to the corporation) and 1685, when the town was governed under the charter granted by William III. In 1688 until the corporation was remodelled in 1835, the modern government consisting of a mayor, 4 aldermen and 12 councillors. Tewkesbury returned two members from 1604 to 1867, when it lost one member, and in 1885 the representation was merged in that of the county. A fair on July 20 was granted in 1323, and fairs on September 21 and August 24 in 1440, and on April 25 in 1574. For the last May 3 was substituted in 1605, and two more fairs on June 11 and September 29 were granted in 1609. All these grants were confirmed by the charter of 1685. One fair only is now held, on October 10. It is a pleasure fair and a fair for hiring servants, and has lost the commercial importance of the early wool fairs. The long-existing provision trade along the four rivers declined through railway competition. Cloth-making lasted from the 11th century until the beginning of the 18th; gloving in the 17th century was followed by worsted-combing in the 18th. Cotton-thread lace-making, introduced in 1825, collapsed about 1862. Tewkesbury was once celebrated for the manufacture of mustard, which ceased to be important at the end of the 18th century. Stocking-frame knitting was the chief trade in 1830, but has been replaced by the boot and shoe trade. Tewkesbury was strategically important in the Wars of the Roses, and was the site of a battle in 1471, and in the Civil War was four times besieged.

See Victoria County History, Gloucestershire; James Bennet, History of Tewkesbury (1850); William Wyde, History of Tewkesbury (1797).

Texarkana, two adjoining cities forming one community, situated on either side of the boundary line between Arkansas and Texas, U.S.A., about 165 m. E. by N. of Dallas, Texas; Texarkana, county-seat of Miller county, Arkansas, pop. (1900) 4914, of whom 130 were foreign-born and 3978 were negroes; (1910) 5655; Texarkana, Bowie county, Texas, pop. (1900) 5236, of whom 192 were foreign-born and 1964 were negroes; (1910) 9700. Texarkana is served by the Kansas City Southern (Port Arthur Route), the Texas & Pacific (of which it is the eastern terminus), the St Louis, Iron Mountain & Southern (Iron Mountain Route, the southern terminus), and the St Louis South-Western (Cotton Belt Route) railways. The public buildings are two city halls, a well-designed Post Office, which stands on the
state line and serves both cities, a county court house (on the Arkansas side), and a Federal court building (on the Texas side). The chief trade is in lumber (especially hard woods, such as white pine and ash), and cotton. The oil and gas is piped here from the Caddo gas-fields, about 48 miles, in Louisiana. The first permanent settlement here was made in 1874; Texarkana, Texas, was incorporated in 1875, and Texarkana, Arkansas, in 1881.

**Texas.** A south central state of the United States of America, extending from lat. 26° 51' N. to lat. 36° 39' N. and from long. 93° 30' W. to long. 106° 30' W. A western projection is bounded N. by New Mexico, but the main portion of the state is bounded N. by Oklahoma, from which it is separated in part by the Red river; and the E. by Louisiana, from which it is bounded E. by Oklahoma, but the main portion is bounded E. by Texas and Louisiana, and the Sabine river separating it in part from Louisiana; on the S.E. the state is bounded by the Gulf of Mexico; on the S.W. by Mexico, from which it is separated by the Rio Grande; on the W. by New Mexico. Texas is much the largest state in the Union. Its length and breadth are nearly equal—about 750 m. and its area is 262,398 sq. m., of which 3,498 sq. m. are water surface.

**Physical Features.** Texas is crossed by four physiographic provinces: the Prairies and Coast Plains, the Rocky Mountains, the Gulf Lowlands, and the Trans-Pecos Province. The Prairies and Coast Plains form the western half of the state and extend from the Panhandle in the N.W. to the Gulf of Mexico in the S.E. The Rocky Mountains are in the S.W., and the Gulf Lowlands, which form much of East Texas, extend from the Gulf of Mexico in the S. to the Panhandle in the N.W. The Trans-Pecos Province is located in the S.W. The prairie and Coast Plains are characterized by their flatness, with some rolling hills, and by the absence of forests. The Rocky Mountains have a rugged topography with numerous peaks and valleys. The Gulf Lowlands are characterized by swamps and marshes.

**Climate.** The climate of Texas is classified as humid subtropical with mild winters and hot summers. The state experiences a wide range of temperatures throughout the year, with an average of 66°F (19°C) in January and 79°F (26°C) in July. The state has a well-defined growing season, with most of the state having at least 280 frost-free days.

**Vegetation.** The vegetation of Texas is diverse, with a mixture of grasslands, forests, and desert habitats. The plains are dominated by grasses, while the mountains have a mix of grasses and coniferous forests. Texas is home to several species of cacti, as well as various grasses, shrubs, and wildflowers. The state is also home to a variety of birds, including raptors, shorebirds, and waterfowl.

**Fauna.** Texas is home to a wide variety of wildlife, including mammals, birds, reptiles, and amphibians. Some of the most notable species include the white-tailed deer, the armadillo, the bobcat, the alligator, and the kingfisher. The state is also home to several species of fish, including catfish, bass, and trout. Texas is a popular destination for bird watchers, with over 450 species recorded in the state.

**Geology.** The geology of Texas is characterized by the presence of sedimentary rocks, with the Permian basin being the largest in the state. The state is also home to several major oil and gas fields, including the Caddo gas-fields.

**History.** Texas has a rich history, with the state gaining its independence from Mexico in 1836 and becoming a state of the United States in 1845. The state has played a significant role in the history of the United States, including its role in the Civil War and its role in the development of the oil and gas industry.

**Economy.** Texas is one of the largest and most economically diverse states in the United States. The state is home to several major industries, including agriculture, oil and gas, and manufacturing. Texas is also a major center for high-tech and biotechnology companies.

**Transportation.** Texas has a well-developed transportation network, with major highways, interstates, and railways connecting the state. The state is also home to several major airports, including Dallas/Fort Worth International Airport, Houston International Airport, and San Antonio International Airport.

**Education.** Texas has a robust education system, with both public and private schools. The state is home to several major universities, including the University of Texas, Rice University, and Texas A&M University.

**Sports.** Texas is known for its sports, particularly football and basketball. The state is also home to several professional sports teams, including the Dallas Cowboys and the Houston Rockets.
is the most common of Texas lizards, except in the western counties where the Texas rock lizards (Sceloporus torquatus; S. clarkii; S. spitiosus; S. consobrinus; S. dispur) are numerous. The tree swift, or scaly lizard, is also an inhabitant of western and Texas. The greater grasshopper whip-tailed lizard (Chromisaurus gularis; C. sexlineatus; C. tessellatus, &c.) are widely distributed. The Gila Monster (Heloderma suspectum), a poisonous species, is also widely distributed the west and south-west, and the middle man, also occurs in the desert regions. The blow snake, or spreading adder (Heterodon platyrhinos), black snake (Bacascunon constrictor), coach whip (Bacascunon flagidum), and prairie bull snake (Pituophis) are common; the greater green water snake (Natrix fasciata) is found along creeks; the king snake (Lampropeltis getula), in central and southern Texas; and the pilot snake (Callopelis obsotulus), mostly in the woods of the McLennan county. Among venomous reptiles of the Trans-Pecos region are the harlequin, or coral snake (Claviceps), copperhead along the coast; the copperhead (Agris istron constrictor) along the wooded banks of creeks and rivers; the cottonmouth (Agris istron piscatorius), the latter which is the Trans-Pecos with a tendency to garter snake, and the "sidewinder," or massasauga (Sistrurus cassinus constrictor), some called Crotalephporus ligerius) and the ground rattlesnake (Sis-

1The average annual rainfall decreases quite regularly westward and south-westward from 47-6 in. at Galveston to 9-3 in. along the coast. The autumn months are the driest; for example, at Galveston the rainfall amounts to 5-7 in. in September and only 2-9 in. in August. The western and south-western sections of the state are the driest; thus, at El Paso the rainfall amounts to 2-2 in. in July and only 0-2 in. in April. The average annual snowfall for the state is about 5 in., ranging from 19 in. in the highlands to 0 in. in the coastal region. The first snows usually appear in November along the Trans-Pecos and in the lower Rio Grande Valley. there were 1,909,000 sheep in the state. The wool product of the state in 1907, 303,972 lb., was washed and unwashed and 3,040,875 lb. scoured. In this number of chickens (13,562,302 in 1900) the state ranked fifth, and in the number of ducks, geese and turkeys (1,399,044 in 1900), ranked first.

The cereals grow generally throughout the state, excepting in the arid western lands. The crop of Indian corn is especially large in a belt of counties beginning near the north-eastern corner of the state and extending as far westward as Austin. Sparsc scrub timber, of little value except for posts, poles and rough beams and for fuel, occupies the region westward to approximately the longitude of the Pease river. Outside of these general areas, the hardest products are of relatively little value, the exceptions being the dense growths, in certain restricted areas, of live-oak, which is in demand for ship timbers; and scattering patches of hickory, which is valuable for manufacturing. In fine-wood lumbering, the forests are of great economic value because of the density of their growth, and there are at hand the means of profitable development of this industry in the numerous watercourses which make logging cheap. The rivers—the Brazos, the Rio Grande, the Trinity, the Neches, the Sabine, the Sabine Neches, the Trinity—feed gum, sycamore, hickory and poplar, found on the southern slope of the Osage highlands, on the uplands about the source of the Neches river, and to a much less extent, in the pine-timbered area south of those points not reached by the railways. Another important undertaking is the deepening of the Trinity river to Dallas, a distance of 51 m., thereby affording a navigable waterway almost to the northern boundary of the state. Congressional appropriations for the survey, improvement and maintenance of waterways began in 1852; amounted to $15,055,688 between 1891 and 1896 inclusive, and $6,813,829 between 1897 and 1907; the total appropriated being $32,540,410. The ports of entry of Texas are Galveston, Corpus Christi, Eagle Pass, El Paso and Brownsville.

Population.—The population in 1880 was 1,591,749; in 1890, 2,235,523; in 1900, 3,045,710; and in 1910, 3,869,542, 1907, 3,869,542. 2 Of the population in 1900, 94.1 per cent. was native born, 70.6 per cent. was white and 20.4 per cent. (or 620,722) was negro, or of negro descent. There were in 1900, 2,249,688 native whites, 179,357 persons of foreign birth, 836 Chinese, 470 Indians and 133 Japanese. Of the inhabitants of the United States 132,389 were natives of Tennessee; 129,945 of Alabama, 90,863 of Mississippi, 77,950 of Georgia and 75,033 of Arkansas; and of the foreign-born,71,626 were Mexicans, 48,295 Germans, 9,204 Bohemians, 8,313 English, 6,870 Austrians and 6,173 natives of Ireland. Of the total population 471,572 were of foreign parentage—i.e. either one or both parents were foreign-born, and of those both of whose parents were foreign-born 70,736 were of German, 10,967 of Bohemian, 7,759 of Irish and 6,536 of Austrian parentage. In 1906 1,226,906 inhabitants of the state were members of religious societies. Of these 401,720 were Baptists; 102,935 Methodists; 98,136 Roman Catholics; 62,009 Presby- terians; 39,550 Disciples of Christ; 34,006 members of the Churches of Christ; 27,437 Lutherans; 14,245 Protestant Episcopalians; 7745 members of the German Evangelical Synod of North America, and 186 Congregationalists. The principal cities are San Antonio, Houston, Dallas, Galveston, Fort Worth, Austin, the capital, Waco, El Paso, Laredo, Denison and Sherman.

Manufactures.—The value of the manufactures of Texas in 1905 was $190,257,383, the capital invested in manufacture in 1907 being $226,805,185. In 1907 the value of the products of the cotton-seed oil and cake product Texas surpassed all other southern states. Four and one-half million bushels of cottonseed oil were produced in 1906, valued at $11,945,556 in 1900 to $22,683,136 in 1905. The values of other products in 1905 were as follows: slaughtering and meat packing (wholesale), $15,620,931; lumber and timber products (wholesale), $4,153,938; brick and clay products, $2,653,415; cement, $1,293,415; mill lumber, $4,153,938; saddlery and harness, $1,293,415; cotton, $3,251,255. The highest average quantity of rough milled rice per establishment in the United States in 1905 was for Texas, where 54.8 bushels were produced. Cottonseed meal was valued at $148,040, valued, together with that of other rice products, at $4,638,867.

Transportation.—Until the middle of the 19th century transportation facilities remained practically undeveloped in Texas. In 1840 there were 2,746 miles of railroad in the state. In 1880, 3,244 m.; in 1890, 8,709 m.; in 1905, 11,949 m.; in 1907, 12,877 m.; and in 1908, 13,066 m. Most of this mileage is in the eastern part of the state, the western and southern portions having slight railway facilities. The principal railway systems are the Southern Pacific, the Santa Fe, the Texas & Pacific and the Colono & Southern. The inland waterways include the 25 ft. ship canal from the Gulf to Port Arthur (the Port Arthur Canal), opened in 1869, and transferred to the United States government in 1906; the Galveston and Brazos River canal, 29.5 m. long and of a ruling depth of 3 ft., also acquired by the government in 1902, but of which the cost of construction was $250,400. Another important waterways which have been authorized by the United States government and on which work was proceeding in 1910 are commercial canals, 15 ft. in depth, extending from Corpus Christi to Aransas Bay. Other important waterways which have been authorized by the United States government and on which work was proceeding in 1910 are commercial canals, 15 ft. in depth, extending from Corpus Christi to Aransas Bay. Other important waterways which have been authorized by the United States government and on which work was proceeding in 1910 are commercial canals, 15 ft. in depth, extending from Corpus Christi to Aransas Bay. Another important undertaking is the deepening of the Trinity river to Dallas, a distance of 51 m., thereby affording a navigable waterway almost to the northern boundary of the state. Congressional appropriations for the survey, improvement and maintenance of waterways began in 1852; amounted to $15,055,688 between 1891 and 1896 inclusive, and $6,813,829 between 1897 and 1907; the total appropriated being $32,540,410. The ports of entry of Texas are Galveston, Corpus Christi, Eagle Pass, El Paso and Brownsville.

2 The statistics given in the text for 1900 from this point are for factory products and are thus comparable with those given for the same years. The census of 1890 for the last year was limited to the manufactures under the factory system.
3 In other census years the populations were: 1850 (first under the United States), 212,592; 1860, 604,215; 1870, 818,579.
governed under the constitution of 1876, with amendments of 1879, 1883, 1890, 1891, 1897, 1904 and 1906. All male citizens not twenty-one years of age and resident in the state for one year are eligible for the general electorate, which includes the courts immediately preceding election (except paupers, idiots, lunatics, felons, United States soldiers, marines and seamen, and persons who have taken part, either as principal or second, in fighting a duel or in sending a challenge) have the right of suffrage. The constitution originally forbade the registration of voters, but an amendment of 1891 permits it in cities having a population of ten thousand or more, and the Australian ballot system was adopted in such cities by an act of the twenty-second legislature in 1892. An amendment to the constitution in 1892 required a two-thirds vote of the members elected to each house of the legislature, and is adopted if it is approved by a majority of the popular vote on the amendment.

The executive department consists of a governor, lieutenant-governor, secretary of state, comptroller of public accounts, treasurer, commissioner of the general land office, and attorney-general. Contrary to the usual custom in other states, the secretary of state is appointed by the governor. The other officialists, elected by popular vote for two years' terms. The governor and lieutenant-governor must be, at the time of election, at least thirty years of age, and the United States must have been a citizen of the United States for the preceding five years. The governor receives an annual salary of $4000 and the use of the governor's mansion. His functions are rather more extensive than those of the average American executive. He exercises the government of the state, proclaims public meetings and reprieves, he controls considerable patronage, and possesses a power of veto which extends to separate items in appropriation bills. At least two-thirds majority in each house is necessary to override a veto.

The legislature of the state is composed of a Senate and a House of Representatives. The Senate consists of thirty-one members, chosen at-large for four years, one-half retiring every two years. Representatives are elected biennially. Their number, originally ninety-three, is determined by apportionment bills passed after the publication of each Federal census, but under the constitution it can never exceed two-thirds of the members elected in the preceding five years. The governor receives an annual salary of $4000 and the use of the governor's mansion. His functions are rather more extensive than those of the average American executive. He exercises the government of the state, proclaims public meetings and reprieves, he controls considerable patronage, and possesses a power of veto which extends to separate items in appropriation bills. At least two-thirds majority in each house is necessary to override a veto.

colleges; the Sam Houston Normal Institute (1879) at Huntsville, the North Texas State Normal (1901) at Denton, the South-west Texas Normal (1903) at San Marcos, the School of Industrial Arts for Colored (1887) at Austin, the Prin- cipal National Training School (1876) for negroes near Hempstead. The system is not unified or organized: the university's department of education, the school for girls at Denton and the negro normal school all issue together and are not controlled by the Department of Education or the State Board of Education. The state library and museum are a part of the Department of Banking, State and Commerce, an organization under the unified university Department of Statis- tical and Educational Statistics.

The state in 1824, the school for girls at Belton; the medical department at Waco; St Edward's College (Roman Catholic, under the Congrega- tion of the Holy Cross; 1885), at Austin; St Mary's University (1854; since 1884 under the Society of Jesus), at Galveston; St Basil's College (under the Basilians Fathers; 1890), at Waco; for girls, the Institute for Domestic Science (1845), at Belton; the Antonio Female College (Methodist Episcopal, South; 1894), at San Antonio; North Texas Female College (Methodist Episcopal, South; 1877), at Sherman; and the Academy of Our Lady of the Lake, at Austin (1866). The first public school for negroes Paul Quinn College (African Methodist Episcopal; 1881), at Waco; Tillotson College (Congregational; 1881), at Austin; the Polytechnic College (Baptist; 1885), at Marshall; Wiley University (Methodist Episcopal; 1873), at Marshall; and Texas College (Coloured Methodist Episcopal; 1895), at Tyler.

The state, therefore, has done more than any other Southern state for the humane and scientific treatment of its dependent and defective classes. There are insane asylums at Austin (the State Lomatnic Asylum), San Antonio (the Southwest Insane Hospital); at Tyler, the Texas Insane Institution (Baptist; 1845) at Belton; the Antonio Female College (Methodist Episcopal, South; 1894), at San Antonio; North Texas Female College (Methodist Episcopal, South; 1877), at Sherman; and the Academy of Our Lady of the Lake, at Austin (1866). History.—The history of Texas may be regarded as a step in the great struggle between England, France and Spain for the possession of America. The earliest explorations were made by the Spaniards, Cabeza de Vaca, 1528-36, and Francisco Vasquez de Coronado, 1540-47, but the first colony was that planted on Matagorda Bay in 1685 by the French under the Sieur de la Salle. This was, however, soon abandoned, and the field left to the Spanish. Beginning in 1690 they established several ecclesiastical, military and civil settlements known respectively as missions (Franciscan), presidios, and pueblos. In or near the city of San Antonio are the ruins of five missions built of stone; and missions were more numerous in east Texas, but they were built of wood and nothing remains to mark their location. In 1777 the territory, with vaguely defined limits, was formed into a province and named Tejas, or Texas, a corruption of the tribe or by private contract sold them for less than 200 years old. The first campaign under the French control was a successful revolt against Spain in 1762, when the French captured San Antonio and defeated several Mexican armies, but was finally overpowered; the third, under James Long, an ex-officer of the United States army, 1819-21, was less formidable. The year 1821 marks a significant turning-point in the history. By the Florida treaty, finally ratified at that time, the claims of the United States to Texas, based on the Louisiana purchase, were given up, and the eastern and northern boundaries of the province were determined. They were to be, in general terms, the Sabine river, the 49th meridian (approximate), the Red river, the 100th meridian, the Arkansas river, and the 122nd parallel. So far as Spain was concerned this was only a formality, inasmuch as Mexico, of which Texas formed a part, was just completing its long struggle for independence (1810-21).

In that year also (December 1821) Stephen F. Austin established the first permanent Anglo-American settlement at San Felipe de Austin on the Brazos river. This was followed by an extensive immigration from the United States during the period of Mexican rule (1821-36). It is estimated that the population, exclusive of Indians, increased from four thousand in 1821 to ten thousand in 1827, and nearly twenty thousand in 1830. Settlements and communities extended in the southern section of the Union and of course brought their slaves with them, but there is no evidence to show that their object was the territorial extension of slavery, or that the revolt against Mexico was the result of dissatisfaction with that country's anti-slavery policy. Texas was joined to Coahuila in 1827 to form a state of the Mexican federation. Although the attempt to force the Roman Catholic religion upon the people, the federal decree of 1830 forbidding further immigration from the states, and the reckless grants of land to Mexican favourites aroused some ill-feeling, the government on the whole was fairly liberal. The peace party, led by Stephen F. Austin, was able to restrain the more warlike followers of William H. Wharton and Henry Smith (1794-1851) until 1835, when Santa Anna overthrew the federal constitution of 1824 and established a dictatorship. A consultation of representatives from the various settlements met at San Felipe de Austin, October to November 1835. Under Austin's influence the delegates rejected an independence resolution and recommended a constitution with the Mexican Liberals for the restoration of the constitution of 1824. A provisional government was organized with Henry Smith as governor and James W. Robinson (d. 1853) as lieutenant-governor. Sam Houston as mayor-general, and the armies of Texas; and Austin, Wharton and Branch T. Archer (1790-1858) were elected commissioners to seek aid in the United States. Hostilities had already begun. The Texans routed the Mexicans near Gonzales on the 2d of October. About a hundred men under Colonel James Bowie and Captain J. W. Fannin defeated a Mexican force near Mission Conception on the 28th of October; and after a campaign of nearly two months Béjar was surrendered to them on the 11th of December.
In the Matamoros expedition the Texas forces were severely crippled on account of a quarrel between Governor Smith, who desired independence, and the majority of his council, who favoured union with the Mexican Liberals. The command was divided between Houston, who was supported by the governor, and two leaders, Frank W. Johnson and J. W. Fannin, who were appointed by the council. The Mexicans under Santa Anna captured the Alamo on the 6th of March 1836 and slaughtered its garrison of 183 men; on the 20th of the same month they captured Fannin and his force of 371 men, and a week later slaughtered all except twenty who escaped. Houston now assumed active command and retreated before Santa Anna until he reached the San Jacinto, where he dealt the enemy a crushing blow and brought the war to an end; nearly all of Santa Anna’s army were killed, wounded or taken prisoners, and even Santa Anna himself was captured the next day, while the Texans lost only two killed and twenty-three wounded.

The weakness of the Mexican Liberals and the necessity of securing aid in the States led the Austin party to abandon their opposition to independence. A convention, assembled in the town of Washington on the 1st of March, adopted a declaration of independence on the 2nd and a republican constitution on the 17th. Houston was elected president in September 1836, and the independence of the republic was recognized in 1837 by the United States, Great Britain, France and Belgium. After a long conflict over the slavery question, the state was admitted into the Union under a joint resolution of Congress adopted on the 1st of March 1845, on condition that the United States should settle all questions of boundary with foreign governments, that Texas should retain all of its vacant and unappropriated public lands, and that new states, not exceeding four in number, might be formed within its limits. The western boundary claimed by the republic was the Rio Grande to its source and the meridian of longitude from that point to the forty-second parallel, although as a political division Mexico its limits never extended farther west than the Nueces and the Medina. The United States government asserted the Rio Grande claim and prepared to enforce it at the cost of war; at the same time the Mexican government considered annexation, regardless of the boundary question, a declaration of war by the United States. An army of 2000 men under Zachary Taylor (g.v.) arrived on the north bank of the Rio Grande, opposite Matamoras, on the 28th of March 1846. The Mexican commander, Pedro de Ampudia, demanded Taylor’s withdrawal beyond the Nueces within twenty-four hours. He did not obey, and Mariana Arista, Ampudia’s successor, opened hostilities. The Americans, outnumbered three to one, made a successful stand at Palo Alto (May 8th) and Resaca de la Palma (May 9th). The war terminated in the treaty of Guadalupe Hidalgo (February 7, 1848) by which Mexico accepted the Rio Grande boundary. By the Compromise of 1850 Texas received $10,000,000 for its territory lying north and west of a line drawn from the 100th meridian to the Rio Grande, following 36° 30’ N., 103° W. and 32° N. The final step in the determination of the present boundaries of the state was taken in 1896, when the Supreme Court of the United States decided the Greer case (g.v.). Under the terms of the treaty of 1819 the boundaries of the Red river were to be the northern boundary of Texas east of the 100th meridian, but as there are two branches of the river meeting east of the meridian the enclosed territory (Greer county) was in dispute. The decision of 1896 selected the southern branch and thus deprived Texas of a large tract of fertile land over which it had previously exercised jurisdiction.

In the crisis of 1860–61 Texas sided with the other Southern States in spite of the strong Unionist influence exerted by the German settlers and by Governor Sam Houston. An ordinance of secession was adopted February 1, 1861, and Governor Houston was deposed from office on March 16th. The state was one of the four seceding states during the Civil War (1861–65), although it is interesting to note that the last battle of the conflict was fought on its soil, at Palmito, near Palo Alto, on the 13th of May 1865, more than a month after the surrender at Appomattox. In conformity with President Johnson’s plan of reconstruction, a constitution recognizing the abolition of slavery, renouncing the right of secession, and repudiating the war debt was adopted in 1869, and J. W. Throckmorton, Unionist Democrat, was elected governor. When, in 1873, the Congressional plan of reconstruction was substituted, Texas was joined to Louisiana to constitute the fifth military district, and the first commander, General P. H. Sheridan, removed Throckmorton from office as “an impediment to reconstruction ” and appointed E. M. Pease in his place. Delegates to a new constitutional convention were elected in 1868, the constitution framed by this body was ratified in November 1869, state officers and congressmen were elected the same day, the new legislature ratified the Thirteenth and Fourteenth Amendments, and on the 30th of March 1870 Texas was readmitted to the Union. But the state remained under the rule of negroes and carpet-baggers, supported by United States troops until the inauguration of Governor Richard Coke in 1874. It has since been consistently Democratic. The supremacy of the party was threatened for a time by the growth of Populism, but the danger was avoided by the acceptance of free silver, and the partial adoption of the Populist local programme. This surrender aroused strong opposition among the conservative or Cleveland Democrats, which culminated in the Hogg-Clark gubernatorial campaign of 1893.

The victory of the Radicals resulted in the establishment of a railway rate commission, based upon a constitutional amendment of 1890 and a statute of 1891, the passage of an alien land law in 1891, which was declared unconstitutional and amended in 1892, the adoption of the Australian ballot system for cities and towns of more than 10,000 inhabitants (1892), the retirement of Roger Q. Mills from the United States Senate (1899) and the sending of free silver delegations to the national conventions of 1896 and 1900.

GOVERNORS

Spanish Period (1690–1821)

Domingo Terán de los Ríos.
Don Gasparo de Anaya.
Don Martín de Alartón.
Marquis San Miguel de Aguayo.
Fernando de Alamanz.
Melchor de Medialvilla y Arcona.
Juan Antonio Bustillos y Cevallos.
Manuel de Sandoval.
Carlos de Franquis.
Pradencio de Oribio de Basterra.
Juez Bonito.
Jacinto de Barrios y Jaurequi.
Antonio de Martos y Navarrete.
Juan María Barón de Ripperda.
Domínguez Caballero.
Rafael Pacheco.
Manuel Muñoz.
Juan Bautista Elizegaray.
Antonio Cordero.
Manuel de Salcedo.
Manuel de Salcedo.
Christoval Domínguez.
Antonio Martínez.

Mexican Period (1821–36)

Trespalacios.
Don Luciana García, provisional.
Rafael Gonzales, provisional.
Vctor Blanco.
José María Viesca.
José María Letona.
Francisco Vidaury y Villaseñor, provisional.
José María Goríbar.
José María Elizagibar.
Augustín Viesca.
Henry Smith, provisional.

Period of the Republic (1836–46)

David G. Burnet, provisional.
Sam Houston.
Mirabeau B. Lamar.
San Houston.
Anson Jones.

2 Coahuila and Texas, 1690–1725, Texas alone 1725–1824.
3 Coahuila and Texas, 1824–35.
4 The state was annexed to the Union in 1845, but the government of the Republic continued in existence until early in 1846.
is used by students as the standard book on the subject which they may be studying.

**TEXTILE-PRINTING.** "Textile" (see Weaving) is a general name for all woven fabrics (Lat. *textere*, to weave), and the art of ornamenting such fabrics by printing on designs or patterns in colour is very ancient, probably originating in the East. It has been practised in some form, with considerable success, in China and India from time immemorial, and the Chinese, at least, are known to have made use of engraved wood-blocks many centuries before any kind of printing was known in Europe. That the early Egyptians, too, were acquainted with the art is proved not merely by the writings of Pliny but by the discovery, in the Pyramids and other Egyptian tombs, of fragments of cloth which were undoubtedly decorated by some method of printing.

The Incas of Peru, Chile and Mexico also practised textile-printing previous to the Spanish Invasion in 1519; but, owing to the imperfect character of their records before that date, it is difficult to say whether they discovered the art for themselves, or, in some way, learnt its principles from the Asiatics.

There is no doubt that India was the source from which, by two different channels, Europeans derived their knowledge of block-printing. By land its practice spread slowly westwards through Persia, Asia Minor and the Levant, until it was taken up in Europe—during the latter half of the 17th century. Almost at the same time the French brought directly by sea, from their colonies on the east coast of India, samples of Indian blue and white "resist" prints, and along with them, particulars of the processes by which they had been produced.

I. Technology

Textile-printing was introduced into England in 1676 by a French refugee who opened works, in that year, on the banks of the Thames near Richmond. Curiously enough this is the first print-works on record; but the nationality and political status of its founder are sufficient to prove that printing was previously carried on in France. In Germany, too, textile printing was in all probability well established before it spread to England, for, towards the end of the 17th century, the district of Augsburg was whether they discovered the art for themselves, or, in some way, learnt its principles from the Asiatics.

Almost at the same time the French brought directly by sea, from their colonies on the east coast of India, samples of Indian blue and white "resist" prints, and along with them, particulars of the processes by which they had been produced.

Textile-printing was introduced into England in 1676 by a French refugee who opened works, in that year, on the banks of the Thames near Richmond. Curiously enough this is the first print-works on record; but the nationality and political status of its founder are sufficient to prove that printing was previously carried on in France. In Germany, too, textile printing was in all probability well established before it spread to England, for, towards the end of the 17th century, the district of Augsburg was whether they discovered the art for themselves, or, in some way, learnt its principles from the Asiatics.

There is no doubt that India was the source from which, by two different channels, Europeans derived their knowledge of block-printing. By land its practice spread slowly westwards through Persia, Asia Minor and the Levant, until it was taken up in Europe—during the latter half of the 17th century. Almost at the same time the French brought directly by sea, from their colonies on the east coast of India, samples of Indian blue and white "resist" prints, and along with them, particulars of the processes by which they had been produced.

Textile-printing was introduced into England in 1676 by a French refugee who opened works, in that year, on the banks of the Thames near Richmond. Curiously enough this is the first print-works on record; but the nationality and political status of its founder are sufficient to prove that printing was previously carried on in France. In Germany, too, textile printing was in all probability well established before it spread to England, for, towards the end of the 17th century, the district of Augsburg was whether they discovered the art for themselves, or, in some way, learnt its principles from the Asiatics.

There is no doubt that India was the source from which, by two different channels, Europeans derived their knowledge of block-printing. By land its practice spread slowly westwards through Persia, Asia Minor and the Levant, until it was taken up in Europe—during the latter half of the 17th century. Almost at the same time the French brought directly by sea, from their colonies on the east coast of India, samples of Indian blue and white "resist" prints, and along with them, particulars of the processes by which they had been produced.

Textile-printing was introduced into England in 1676 by a French refugee who opened works, in that year, on the banks of the Thames near Richmond. Curiously enough this is the first print-works on record; but the nationality and political status of its founder are sufficient to prove that printing was previously carried on in France. In Germany, too, textile printing was in all probability well established before it spread to England, for, towards the end of the 17th century, the district of Augsburg was whether they discovered the art for themselves, or, in some way, learnt its principles from the Asiatics.

There is no doubt that India was the source from which, by two different channels, Europeans derived their knowledge of block-printing. By land its practice spread slowly westwards through Persia, Asia Minor and the Levant, until it was taken up in Europe—during the latter half of the 17th century. Almost at the same time the French brought directly by sea, from their colonies on the east coast of India, samples of Indian blue and white "resist" prints, and along with them, particulars of the processes by which they had been produced.

Textile-printing was introduced into England in 1676 by a French refugee who opened works, in that year, on the banks of the Thames near Richmond. Curiously enough this is the first print-works on record; but the nationality and political status of its founder are sufficient to prove that printing was previously carried on in France. In Germany, too, textile printing was in all probability well established before it spread to England, for, towards the end of the 17th century, the district of Augsburg was whether they discovered the art for themselves, or, in some way, learnt its principles from the Asiatics.
decorative work, viz., appropriateness of pattern and excellency of workmanship. If, occasionally, the earlier designers permitted themselves to indulge in somewhat bizarre fancies, they at least carefully refrained from any attempt to produce those pseudo-realistic effects the undue straining after which in later times ultimate failure and even disaster was due in part to their desire to avoid or injure it during the cutting of the coarser parts. When large masses of colour or the corresponding parts on the block are usually cut in outline, the object being filled in between the outlines with felt, which not only absorbs the colour but also tends to fill in parts of the design. From this it is not possible to obtain with a large surface of wood. When finished, the block presents the appearance of flat relief carving, the design standing out like letterpress type.

Frequently, too, the process of "coppering" is used for the purpose of making a mould, from which an entire block can be made and used as often as desired, by casting. In this case the metal strips are driven to a predetermined depth into the face of a piece of lime-wood cut across the grain, and, when the whole design is completed in this way, the block is placed, metal face downwards. The outer edges of the metal plates are then heated to a temperature sufficient to enable them to carbonize the wood immediately in contact with them, and, at the same time, firmly attaches itself to the outstanding portions. When the strip is removed slightly the outline of the design becomes detached from the block, the wood being left behind. The block is then heated, and the metal plate is removed and cast into a mould of the design, which may consist of any sort of metal, brass being the most commonly used. A block of malleable iron or iron and copper is made, on the surface of which is drawn a line of dimensions to be cut, and then the surface is covered with soft black ink. This is allowed to dry, and a fine object is covered with iron dust, which is then filled between the edges of the iron plate and the block, and the surface is cleansed with a brush. When the line is of the design is repeated, the work is again continued, and the process is repeated until the whole design is completed.

The blocks are then transferred to the printing press, and the paper is drawn over the design. The process of printing is then repeated until the desired effect is obtained. The paper is then removed, and the block is cleaned with a brush, and the process is repeated until the desired effect is obtained.

In addition to the above method of printing, there are several other methods which are used. One of these is the use of a lithographic stone, which is used to produce prints of very high quality. The stone is used in the same way as a wood block, and the design is transferred to it in the same manner. The stone is then treated with a varnish, and the design is printed on to the paper in the usual way.

Another method of printing is the use of a photolithographic process, in which the design is transferred to a plate of metal, and the paper is then printed on to the plate. This method is used in the production of engravings, and is very useful for producing prints of high quality.

The printing process is then repeated until the desired effect is obtained, and the paper is then removed, and the block is cleaned with a brush, and the process is repeated until the desired effect is obtained.

Having thus received a tracing of the pattern the block is produced, and the design is transferred to the plate. The plate is then struck with a hammer, and the design is transferred to the paper by the process of "printing." The design is then printed on to the paper in the usual way.

The process of "printing" is then repeated until the desired effect is obtained, and the paper is then removed, and the block is cleaned with a brush, and the process is repeated until the desired effect is obtained.

The above methods are all used in the production of prints of high quality, and are very useful for producing prints of high quality. The process of "printing" is then repeated until the desired effect is obtained, and the paper is then removed, and the block is cleaned with a brush, and the process is repeated until the desired effect is obtained.

The process of "printing" is then repeated until the desired effect is obtained, and the paper is then removed, and the block is cleaned with a brush, and the process is repeated until the desired effect is obtained.
TEXTILE-PRINTING is textiles should the three too is, Machine-Printing. surface, the advantages in the original mode for speaking the proper faces of the three faces of a specially constructed printing table over which the cloth passes (together with its backing of printer's blanket) after each impression. The faces of the table are arranged at right angles to each other, and may be moved in any desired direction, so that the machine is in motion. The first effect of starting the machine is to cause the colour sieves, which have a reciprocating motion, to pass over, and receive a charge of colour from the rollers, fixed to revolve, in the colour troughs. They then return to their original position between the tables and the printing blocks, coming in contact with the way with the distributing brushes, which spread the colour evenly over their entire surface. Meanwhile, the blocks advance and are gently pressed twice against the colour pads (or sieves) which then retreat once more towards the colour troughs. During this last movement the cloth to be printed is drawn from the printing table by a series of wooden or iron levers, and the colour is transferred to the cloth. The printed cloth is then carried through a series of rollers which press the colour firmly into the fabric. The design is repeated for each colour, and the process is repeated for each colour, until the entire pattern is complete.

(2) PERROTTE PRINTING. The "perrotte" is a block-printing machine invented by Messrs. Levesque in 1834, and practically similar to the block-printing machine employed for this purpose. For some reason or other it has rarely been used in England, but its value was almost immediately recognized on the Continent, where it has been employed in a variety of forms. It is similar to such an enormous extent by roller-printing, the "perrotte" is still largely employed in French, German and Italian works. The construction of this ingenious machine is too complex to describe here without the aid of several detailed drawings, but its mode of action is roughly as follows:—Three large blocks (3 ft. long by 3 to 5 in. wide), with the pattern cut or cast on them in relief, are brought to bear successively on the three faces of a block-printing machine invented by Messrs. Levesque in 1834, and practically similar to the block-printing machine employed for this purpose. For some reason or other it has rarely been used in England, but its value was almost immediately recognized on the Continent, where it has been employed in a variety of forms. It is similar to such an enormous extent by roller-printing, the "perrotte" is still largely employed in French, German and Italian works. The construction of this ingenious machine is too complex to describe here without the aid of several detailed drawings, but its mode of action is roughly as follows:—Three large blocks (3 ft. long by 3 to 5 in. wide), with the pattern cut or cast on them in relief, are brought to bear successively on the three faces of a specially constructed printing table over which the cloth passes (together with its backing of printer's blanket) after each impression. The faces of the table are arranged at right angles to each other, and may be moved in any desired direction, so that the machine is in motion. The first effect of starting the machine is to cause the colour sieves, which have a reciprocating motion, to pass over, and receive a charge of colour from the rollers, fixed to revolve, in the colour troughs. They then return to their original position between the tables and the printing blocks, coming in contact with the way with the distributing brushes, which spread the colour evenly over their entire surface. Meanwhile, the blocks advance and are gently pressed twice against the colour pads (or sieves) which then retreat once more towards the colour troughs. During this last movement the cloth to be printed is drawn from the printing table by a series of wooden or iron levers, and the colour is transferred to the cloth. The printed cloth is then carried through a series of rollers which press the colour firmly into the fabric. The design is repeated for each colour, and the process is repeated for each colour, until the entire pattern is complete.

(4) ROLLER-PRINTING, CYLINDER-PRINTING, OR MACHINE-PRINTING. This elegant and efficient process was patented and worked by Bell in 1785 on fifteen years after his application of the engraved plate to textiles. It will probably remain a moot question as to whether he was the originator of the idea, but it is beyond doubt that he was the first man to put into practice the continuous printing of cloth from engraved copper rollers. Bell's first patent was for a machine to print six colours at once, but, owing probably to its incomplete development, this was not immediately successful, although a second improvement, introduced in 1786, was shown to be practical by the printing of one colour with perfectly satisfactory results. The difficulty was to keep the six rollers, each carrying a portion of the pattern, in perfect register with each other. This defect was overcome by Mr. Parkinson of Manchester, and in 1785, the year of its invention, Bell's machine with Parkinson's improvement was successfully employed by Messrs. Livesey, Harrows, Hall & Co., of Bamber Bridge, Preston, for the printing of calicoes from two to six colours in its operation.

What Parkinson's contribution to the development of the modern roller-printing machine really was is not known with certainty, but it was probably the invention of the delicate arrangement known as "the box wheel," whereby the rollers can be turned, whilst the machine is in motion, either in or against the direction of their rotation.

The simplest form of the roller-printing machine consists of a strong cast iron cylinder mounted in adjustable bearings capable of sliding up and down slots in the sides of the rigid iron framework. Beneath this cylinder the engraved copper roller rests in stationary bearings and is supplied with colour from a wooden roller which revolves in a colour-box below it. The copper roller is mounted on a stout steel axle, at one end of which a cog-wheel is fixed to gear with the driving wheel of the machine, and at the other end a smaller cog-wheel to drive the colour-furnishing roller. The cast iron pressure cylinder is wrapped with several thicknesses of a special material made of wool and cotton—lapping—the object of which is to ensure a constant and uniform pressure is brought to bear on the face of the cylinder. As the rollers revolve, handkerchiefs, or the like, are placed between them to prevent the cloth from being printed the lines of engraving. A further and most important appliance is the "doctor"—a thin sharp blade of steel which rests on the engraved roller and serves to remove any surplus of ink on the engraved roller and to prevent the ink fromimpinging on the cloth. Instead of "doctoring" the engraved roller, the "lint doctor" from its purpose of cleaning off loose filaments or "lint" which the roller picks off the cloth during the printing process. A steel or "cleaning doctor" is pressed against the roller by means of weighted plates which is "lifted" by the "lint doctor" when the plates are not required and the roller is "doctoring". The machine is so constructed that it is just allowed to rest upon it by its own weight and as its function is merely to intercept the nap which becomes detached from the cloth and would, if not cleaned from the roller, mix with the colour and give a bad effect in the future.

The working of the machine will be best understood by referring to the accompanying diagrammatic sketch of a single colour (fig. 1).
TEXTILE-PRINTING

A is the cast iron pressure cylinder; B the lapping with which it is connected; C, the steam chest, and D the sex of the "doctor"; E the brass "lent doctor"; F the colour-furnishing roller; G the colour-trouch or "box" in which the latter (F) works partly immersed in colour; X an engraving machine; Y a "box" or bevelled contact to the force spur all of the machines for the purpose of adjusting the cylinders in vertical direction. Connecting the only part of the machine directly connected with the motor or main drive of the works through the cog-wheel on its axle—

(1) the mandril—all the other parts deriving their motion from it, either directly or indirectly. In the case of the cylinder or by a spur wheel as in that of the colour-furnishing roller. The mode of printing is almost self-evident; the roller C revolving in the direction of the arrow takes colour from the furnisher F, the excess is scraped off by the "doctor" G and, in continuing its course, it comes in contact with the cloth K, which being pressed by the cylinder A into the engraving abstracts the colour therefrom and forms the exact impression of the engraved part.

Larger machines printing from two to sixteen colours are precisely similar in principle to the above, but differ somewhat in detail and are naturally more complex and difficult to operate. In these cases the "box" (Y) is in two or more sections each carrying one portion of the design, are arranged round a central pressure cylinder, or bowl, common to all, and each roller is driven by the corresponding weight when the bellows are actuated, in most cases, by its own steam-engine or motor. Another difference is that the adjustment of pressure is transferred from the cylinder to the rollers which work in specially constructed bellows, instead of the old fashioning windings which, of course, are not so accurately actuated, in most cases, by its own steam-engine or motor. Notwithstanding the great latitude of movement thus provided each roller is furnished with a "box-wheel," which serves the double purpose of transferring the printing work to the "doctor" and affording a fine adjustment. Each roller is further furnished with its own colour-box and doctor.

With all these delicate apparatus at his command a machine-printer may set to work to fill all the various parts of the most complicated patterns with ease, dispatch and precision which are remarkable considering the complexity and size of the machine.

In recent years many improvements have been made in printing machines. A most important of these is the introduction of the "intermittent" and the "Duplex" machines. In the former any or all of the rollers may be stopped to permit of the pattern being passed, and at certain intervals. Such machines are used in the printing of shawls and "saris" for the Indian market. Such goods require a wide border right across their width at varying distances—sometimes even requiring a different one for each part of the design. To meet this, with rollers of ordinary dimensions, that "interruption" machines are used. The body of the "sari" will be printed, say for six yards with eight rollers; these then drop away from the bed, and each roller having been given an impression, immediately fall into contact and print a border or crossbar, say one yard wide, across the piece; they then recede from the cloth and the first eight again return and print another six yards, and so on continually.

The "Duplex" or "Reversible" machine derives its name from the fact that it prints both sides of the cloth. It consists really of two ordinary machines so combined that when the cloth passes, fully printed on one side from the first, its plain side is exposed to the rollers of the second, which print an exact duplicate of the first impression upon it in such a way that both printings coincide. A piece of cloth 36 inches wide in its face will pass, through the corresponding part of the design printed on the back if the two patterns are in good "fit." The advantages possessed by letter-printing over all other processes first its high productivity—10,000 to 12,000 yds. being commonly printed in one day of ten hours by a single-colour machine; secondly, by its capacity of being applied to small and medium sized goods. From the nature of the design, delicate lines of copperplate engraving and the small "repeats" and limited colours of the "perrotine" to the broadest effects of block-printing and to patterns varying in "repeat" from 1 to 800; in addition to which these machines are capable of printing any portion of an elaborate multicolour pattern can be fitted into its proper place, and the entire absence of faulty joints at its points of "repeat" or repetition—a consideration of the utmost importance for delicate work, where such a blur would utterly destroy the effect.

(5) Stencilling.—The art of stencilling is very old. It has been applied to the decoration of textile fabrics from time immemorial. The process is really very simple, and is being used in Europe for certain classes of decorative work on woven goods for furnishing purposes.

The pattern is cut out of a sheet of stout paper or thin metal, with the exception of certain points—"tie" points, that is to say, the part that is to be "reserved" or left uncoloured. The sheet is now laid on the material to be decorated and colour brushed through the open spaces to give the required design.

It is obvious that with suitable planning an "all over" pattern may be as easily produced by this process as by hand or machine printing, and that moreover, if several plates are used, as many different patterns may be produced as there are plates, each plate being used to print a different part of the design. What stencilled patterns is that they have to be held together by "ties," that is to say, certain parts of them have to be left open, so as to connect them with each other, and prevent them from falling apart, and this is done by a number of "ties." These may be cut without its centre dropping out, and, consequently, its outline has to be interrupted at convenient points by "ties" or uncut portions. Similarly with other objects. The necessity for "ties" exercises great influence on the design, and in the hands of a designer of indifferent ability they may be very unsightly.

On the other hand, a capable man utilizes them to supply the drawing, which works in contact with colour-furnishing rollers and the other part with the cylindrical block. This block is known as a "surface" or "pey" roller. Many attempts have been made to print multicolour patterns with "surface" rollers alone, but little success, owing to their irregularity in action and to the difficulty of preventing them from warping. These defects are not present in the printing of linoleum in which opaque oil colours are used—colours which neither sink into the body of the printing roller nor tend to warp the roller. The printing of yarns and warps is extensively practised. It is usually carried on by a simple sort of "surface" printing machine and it may be the same as that for textiles.

Lithographic printing, too, has been applied to textile fabrics with somewhat qualified success. Its irregularity and the difficulty of printing "all over" patterns to "repeat" properly, have retarded its use in contact with colour-furnishing rollers and its application to the different parts of the pattern in such a way as to complete themselves.

ENGRAVING OF COPPER ROLLERS

The engraving of copper rollers is one of the most important branches of textile-printing and on its perfection of execution depends, in great measure, the ultimate success of the design. Roughly speaking, the operation of engraving is performed by three different methods, viz.: (1) By hand with a graver which cuts the metal away; (2) by etching, in which the pattern is dissolved out in nitric acid; and (3) by machine, in which the pattern is simply indented.

Engraving by hand is the oldest and most obvious method of engraving, but is the least used at the present time on account of its slowness. The design is transferred to the roller from an oil-paper block, or by cutting out, with a steel graver, precisely in section, and sharpened to a bevelled point. It requires great steadiness of hand and eye, and although capable of yielding the finest results it is only now employed for very special work and in the production of patterns which are too large in scale to be engraved by mechanical means.

(2) In the etching process an enlarged image of the design is cast upon a zinc plate by means of an enlarging camera and transferred by means of a transfer paper to the zinc plate. This is roughly approximating to those in the original, and the outlines of each colour are carefully engraved in duplicate by hand. The necessity of this is, however, of which will be greatly reduced, as is generally reduced to its original size and, if the outlines on the zinc plate were too small at first, they would be impracticable either to etch or print. The reduction of the design and its transfer to a varying number of copper or zinc plates is an operation in the pantograph machine. This machine is capable of reducing a pattern on the zinc plate from one-half to one-tenth
TEXTILE-PRINTING

of its size, and is so arranged that when its pointer or "stylus" is moved along the engraved lines of the plate a series of diamond points are raised or depressed and rubbed against the paper, upon which the roller is covered. These diamond points vary in number according to the number of times the pattern is required to repeat along the length of the roller. Each colour of a design is transferred in this way to a separate roller. The roller has then been placed in a shallow trough containing nitric acid, which acts only on those parts of it from which the varnish has been scraped. To ensure evenly the acid is distributed during the process, the roller is rolled in the acid. When the etching is sufficiently deep the roller is washed, the varnish dissolved off, any parts not quite perfect being retouched by hand.

The machine engraving the pattern is impressed on the roller by a small cylindrical "mill" on which the pattern is in relief. It is an indirect process and requires the utmost care at every stage. The machine is arranged so that it is never allowed to repeat exactly round the roller. One repeat of this pattern is then engraved by a small highly polished soft steel roller, usually about 3 in. long and 1 in. to 3 in. in diameter; the size varies according to the size of the "mill," repeat with which it must be identical. It is then repolished, painted with a chalky mixture to prevent its surface oxidizing and exposed to a red heat in a box filled with chalk and charcoal; then it is plunged in cold water to harden it and finally tempered to the proper degree of toughness. In this state it forms the "die" from which the "mill" is made. To produce the actual "mill" with the design in relief a softened steel cylinder is screwed tightly on to the "moe" of the "mill," so that the pattern is transferred to the "mill" by screwing it in the roller, with several replicas of what was cut on the original "die." When the full circumference of the roller is engraved, the "mill" is moved sideways along the length of the roller, the process is repeated and the whole roller is fully engraved.

PREPARATION OF CLOTH FOR PRINTING

Goods intended for calico-printing ought to be exceptionally white, the size and other impurities, are certain to arise during subsequent operations. Particles of bleaching will be found in the article BLEACHING (q.v.).

The chemical preparations used for special styles will be mentioned. For general purposes a "preparation," or "preparation," for most colours that are developed and fixed by steaming only, consists in passing the bleached calico through a weak solution of "sulphate" or "torrey red oil containing from 2 to 3 per cent. to 5 per cent. of the dyestuff. "Preparation" gives the bleached cloth, but all patterns containing allamine, red, rose and salmon shades, are considerably brightened by the presence of oil, and indeed very few, if any, colours are detrimentally affected by it.

Apart from wet preparations the cloth has always to be brushed, to free it from loose nap, flocks and dust which it picks up whilst being handled. Frequently, too, it has to be "screwed" by being passed over rapidly revolving knives arranged spirally round an axle, which rapidly and effectually cuts off all filaments and knots, leaving the cloth perfectly smooth and clean and in a condition fit to receive the "preparation." The preparation, in oiling or steaming, makes the fabric, especially those woven in checks, stripes and "cross-overs," require very careful stretching and straightening on a special machine, known as a "stenter," before they can be printed. It is usual, certain formal styles of pattern which are intended in one way or another to correspond with the cloth pattern. Finally, all descriptions of cloth are wound round hollow wooden or iron centres in rolls of convenient size for mounting on the printing machines.

PREPARATION OF COLOURS

The art of making colours for textile-printing demands both chemical knowledge and extensive technical experience, for their ingredients must not only be properly proportioned to each other, but they must be combined in such a way as to give the particular style of work in hand. For a pattern containing only one colour any mixture whatever may be used so long as it fulfils all conditions as to shade, quality and fastness; but where two or more colours are associated in the same design each must be capable of undergoing without injury the various operations necessary for the development and fixation of the others.

There are four main styles of colouring matter or not are known technically as "colours," and are referred to as such in the sequence.

Colours vary considerably in composition. The greater number of them is made up of all the elements necessary for the development and fixation of the colour-lake. Some few contain the colouring matter alone and require various after-treatments for its fixation; the latter are called "dyes." In addition to the essential dye, which is the metallic salt or other substance which combines with the colouring principle to form an insoluble colour-lake, either directly by steaming, or indirectly by dyeing.

It should always be remembered that two folds of cloth may be printed, for the twofold object of enabling them to be transferred from colour-box to cloth without loss and to prevent them from "running" or spreading beyond the limits allowed by the rollers.

Dyeing Agents.—The thickening agents in most general use as colouring matter in printing, are starch, flour, gum arabic, gum senegal and gum tragacanth, British gum or dextrine and albumen.

Starch Paste.—This is made by mixing 15 lb. of wheat starch with a little cold water to a smooth creamy paste; a little olive oil is then added and sufficient water to bring the whole up to 10 gallons. When ready for use, it is being boiled for about an hour, and, after cooking, is ready for use.

Starch is the most extensively used of all the thickenings. It is applicable to all but strongly alkaline or strongly acid colours. When it is not thickened up to a stiff unworkable jelly, it is usually mixed with mineral acids or acid salts convert it into dextrine, thus diminishing its thickening power. Acetic and formic acids have no action on it even at the boiling point.

FLOUR Paste is made in a similar way to starch paste. At the present time it is rarely used for anything but the thickening of aluminium and iron mordants, for which it is eminently adapted.

"Gum arabic and gum senegal" are both very old thickenings, but they have been superseded by certain preparations of tragacanth, which are far more delicate and effective. They are especially useful thickenings for the light ground colours of soft muslins and satins on account of the property of being able to absorb completely out of the fibres of the cloth in the washing process after printing. Starch and artificial gums always leave the cloth somewhat harsh in "feel" unless they are treated specially, and are moreover incapable of yielding the pleasantly clear and perfectly even tints resulting from the use of natural gums. Very dark colours cannot well be obtained with gum senegal or gum arabic thickenings; they come away too much in washing, the gum apparently preventing them from coming out of the cloth together, and at other times being highly torrefied, and almost completely soluble in cold water and very dark in colour. Its thickening power decreases and its "gummy" nature increases as the temperature at which it is roasted is raised. The lighter coloured gums or dextrines will make a good thickening with from 2 to 3 lb. of gum to one gallon of water; the darkest and most highly calcined require from 4 to 10 lb. per gallon to give a substantial paste. Between these limits all qualities are obtainable. The darkest qualities are very useful for strongly acid solutions, and with the exception of gum senegal, and gum tragacanth, for starch paste.

Like the natural gums, neither light nor dark British gums penetrate into the fibre of the cloth so deeply as pure starch or flour, and are therefore unsuitable for very dark strong colours.

"Gum tragacanth," or "Dragontree gum," is one of the most inexpensive thickening agents possessed by the textile printer. It may be mixed in any proportion with starch or flour and is equally useful for pigment colours and mordant colours. When added to starch pastes it renders them "gummy," and, if a certain amount of gum be added, diminishes its thickness, makes it easier to wash out of the fabric and produces much more level colours than starch paste alone. It is better to use it with other gums rather than to add it to goods which are required to retain their soft cloth feel. A tragacanth mucilage may be made either by allowing it to stand a day or two in contact with cold water or by soaking it for twenty-four hours in water. After being dried and powdered it becomes smooth and homogeneous. If boiled under pressure it gives a very fine smooth mucilage (not a solution proper), much thinner than if made in the cold.

Albumen.—Albumen is both a thickening and a fixing agent for
insoluble pigments such as chrome yellow, the ochres, vermilion and ultramarine. Alum is always dissolved in the cold, a process which takes several days when large quantities are required. The usual strength of the solution is 4 lb per gallon of water for both alum and logwood extract. The latter is expensive and only used for the lightest shades. For most purposes one part of alum solution is mixed with one part of tragacanth mucilage, this proportion of alum being found amply strong. After that, for the ordinary pigment colours and special instances the blood alum solution is made as strong as 50 per cent., but this is only in cases where very dark colours are required to be absolutely fast to washing. After printing, alum-bent toner and mordant colours are exposed to hot steam, which coagulates the alum and effectively fixes the colours.

Formerly colours were always prepared for printing by boiling the requisite dye or mordant for several hours in water. In the ordinary pigment colours, as well as in the blood solution, the fibres of the fabric are treated with a solution of the acid and alkali, and then waiting, and cooling and adding the various fixing agents. At the present time, however, concentrated solutions of the colouring matters and other adjuncts are often simply added to the cold toner, and the whole left in a large vessel to cool.

Colours are reduced in shade by simply adding more starch or other paste. For example, a dark blue containing 4 oz. of methylene blue per gallon may readily be made into a pale shade by adding to it thirty times its bulk of starch paste or gum, as the case may be. Similarly with other colours.

Before printing it is very essential to strain or sieve all colours in a fine manner. The fabric is placed on a straining frame and the solution is forced through, the coloured filaments, fine sand, &c., which would inevitably damage the highly polished surface of the engraved rollers and result in bad printing. Every scratch on the surface of a roller prints a fine line in the cloth, and too much care, therefore, cannot be taken to remove, as far as possible, all grit and other hard particles from every colour.

The straining is usually done by squeezing the colour through fine cotton or silk cloths. Mechanical means are also employed for colours that are used hot or are very strongly alkaline or acid.

**Styles of Printing**

The widely differing properties of the hundreds of colouring matters now on the market give rise to many different styles of textile-printing. Generally speaking, these fall into the following four great divisions:—

1. Direct printing.
2. The printing of a mordant upon which the colour is afterwards dyed.
3. The discharge style.
4. The resist or reserve style.

The fact that each of these divisions is further sub-divided into many smaller divisions renders it out of the question to give more than a few typical examples of the various styles they include.

**Application of Mordant Dye-Stuffs.**—Mordant colours include both artificial and natural dye-stuffs (see also DYEING), the most important of all being alizarine, an artificial preparation of the colouring-principle of the madder root. With different metallic oxides alizarine forms different colour-lakes all exceedingly fast to light and soap. Alum mordant gives red and pink lakes; iron mordant, purples and lavenders; chromium yields maroon; and uranium gives grey shades. Mixtures of iron and alum produce various tones of chocolate and brown.

In addition to alizarine the following are a few of the more important mordants employed in textile-printing:

- Alizarine orange with aluminium and chrome mordants for orange and warm brown shades respectively; alizarine bordeaux, with alumina, for violets; alizarine blue with chrome and zinc for quiet blue shades; coeruleine and alizarine viridite for greens and olives with chromium mordants; gallochine, chrome violet blue, alizarine cyanines, &c., with chromium for various shades of blue and violet; alizarine yellows and anthracene brown for yellos and fawn shades especially with aluminium or chrome mordants. The natural dye-stuffs belonging to this series are chiefly: logwood, with chromium and iron mordants; logwood extract, with chromium and alum mordants; catechu, with chromium, for very fast dark browns; and, occasionally, in mixture with logwood extract, with alum and chromium mordants; and divi-divi extracts with any of the above-mentioned mordants.

The mordants are mostly in the form of acetates which are stable in the cold but decompose during the steaming process, and combine as hydrides with the colours, forming and fixing on the fabric the insoluble lake.

Alizarine reds and pinks are the most complicated of the mordant colours, requiring for their proper production the addition of brightening agents, such as oxalate of tin, oils, tartric acid, and also acetate of lime. This also applies to alizarine orange, but all the other colours are very simple to prepare and are stable for a long time after making. Reds, pinks and oranges are best prepared freshly each day; their constituents are liable to combine if the colour stands twenty-four hours before printing. The following types of recipes will give some idea of the way in which colours are mixed:

**Red.**
- 64 gallons thick starch and tragacanth paste.
- 14 " alizarine (20 per cent. commercial paste).
- 1 nitrate of alumina, 18° Tew.
- 10 " oxalate of lime, 28° Tew.
- 10 per cent. solution of tartaric acid.

**Pink.**
- 64 gallons starch-tragacanth paste.
- 1 blue shade alizarine (20 per cent. paste).
- 1 " red shade chrome, 18° Tew.
- 1 " acetate of lime, 28° Tew.
- 10 " oxalate of tin.
- 10 " citrate of alumina, 40° Tew.

For reds and pinks the nitrate, sulphoanide and citrate of alumina are generally preferred in practice to the acetate though the latter is also largely used. Oranges from alizarine orange are made similarly.

**Purple.**
- 64 gallons starch paste.
- 1 " blue shade alizarine, 20 per cent.
- 1 " acetic acid.
- 1 " acetate of lime, 28° Tew.
- 1 " acetate of iron, 24° Tew.

**Maroon.**
- 64 gallons paste.
- 1 " alizarine, 20 per cent.
- 1 " acetate of chrome, 32° Tew.
- 1 " acetate of lime, 28° Tew.

Blues and the other colours are made by leaving out the lime in the last recipe and replacing the alizarine with another colour.

**Alizarine Blue.**
- 64 lb alizarine blue shade (powd.).
- 1 gallon water.
- 13 " thick paste.
- 5 " citrate of chrome, 40° Tew.

**Light Shade.**
- 1 gallon water.
- 13 " thick paste.
- 5 " acetate of chrome, 40° Tew.

**Logwood Black.**
- 15 lb starch.
- 10 " British gum.
- 4 " gallons water.
- 4 " alum.
- 4 " logwood extract, 48° Tew.
- 4 " quercitrin extract, 48° Tew.
- 1 " salt.
- 2 " water.
- 11 " starch.
- 2 " salt.
- 11 " water.

Boil, cool and add:
- 1 lb red prussiate of potash.
- 1 lb alizarine.
- 2 " acetic acid.
- 2 " acetate of chrome, 40° Tew.
- 2 oz. chloride of potash.

**Quercitrin Yellow.**
- 64 lb quercitrin extract, 48° Tew.
- 6 " water.
- 11 " starch.

Boil, cool and add:
- 1 gallon solution of chrome, 30° Tew.

The proportions here given are liable to variations according to circumstances. Indeed, no two works employ quite the same recipes, although the proportion of mordant to dye-stuff is pretty generally known and observed.

After printing, these goods are dried, steamed for one hour, and then washed and finished.

**Application of Basic Amtine Dye-Stuffs.—**These colours all form insoluble lakes with tannic acid; hence tannic acid is the common fixing agent of the group. Arsenic in combination with alumina also gives basic-colour lakes, but their poisonous character and their inferior fastness to most reagents considerably limit their application.

The more important basic dye-stuffs are: methylene blue, methyl violet, rhodamine, auramine yellow, safranine, emerald green and indigo blue. Most of them are fairly fast to soaping, but towards the action of light they vary a good deal, methylene blue being perhaps as good as any, and the malachite green the least stable.

Their application is simple. A solution of the colouring matter is added to the required quantity of starch paste or gum, and, when well mixed in, the tannin is added in the form of a solution also. If desired they may be boiled up like the extract dye-stuffs (logwood, &c.), but this is not necessary unless large quantities of the common fixing agent of the group are added.

Boil the whole at once to three small batches by hand.
Methylene blue will serve as a type of the method by which all basic colours are compounded.

Blue. 2 gallons water, 5 oz. Methylene blue, 10 per cent. solution in water and acetic acid.

6 oz. thick starch paste.
1 oz. tragacanth mucilage.
3 oz. tannic acid solution, 50 per cent.

10 gallons.

All other basic colours are made up for printing in a similar way by replacing the blue with the required dye-stuff.

After printing, goods containing basic dyes are "steamed," and passed through a solution of tartar emetic, or other salt of antimony, whereby an insoluble double tannate of antimony and colouring matter is precipitated, and constitutes a much faster colour than the single tannate of the dye-stuff.

Basic colours may be printed along with "mordant" and albumen colours.

(c) Application of Direct Dyeing Colours.—These colours have a natural affinity for the cotton fibre and therefore require no mordant. They are not very "fast," however, and, though used enormously in the dyeing of plain shades, they find but little employment in printing except for the tinting of printed goods, and for the "crepon" style, where the colours must be able to withstand the action of caustic soda.

They are printed with the addition of a slightly alkaline salt (phosphate of soda) and sulphate of soda. Amongst the hundreds of direct colours equally suitable for printing mention may be made of erica for pink; diamine, sky-blue for blues; diamine, red for reds; and diamin and chloramine from the yellow dyes. In fact, most of the benzenide, diamine, diamin and Congo dye-stuffs can be used for printing, but with the exception of the yellows none of them will resist the action of light and washing, and only the extent that the "fastness" of the basic colours will.

The general formula for printing these colours is as follows:

\[ \text{4 oz. colouring matter.} \]
\[ \text{1 oz. gum.} \]
\[ \text{1 oz. starch or tragacanth thickening.} \]
\[ \text{3 oz. phosphate of soda.} \]
\[ \text{3 oz. sulphate of soda.} \]

After printing and drying, the goods are first steamed, then slightly washed in a weak tepid soap solution and finally finished.

(d) Application of Pigment Colours.—Before the introduction of coal-tar colours, pigments and lakes played a much more important part in textile-printing than they do at present, though they are still largely used for certain styles of work. They form a series of colours more difficult to work than those already mentioned, but very fast to soap and light.

Pigment colours, being insoluble mineral precipitates or lakes, can only be fixed on the fibre mechanically; consequently they require to be applied in conjunction with vehicles which cause them to adhere to the fabric in much the same way that paint adheses to wood.

Of these vehicles, albumen is the most important and the best. It forms a smooth viscous solution with cold water, mixes readily with all the colouring matter in printing, and possesses the property of coagulating when heated to the temperature of boiling water. When cloth printed with colours containing albumen is passed through hot steam or hot acid solutions, as in the indigo discharge style, the albumen coagulates, forming a tough insoluble colloidal deposit, which firmly fixes on the fibre any colour with which it is mixed.

The colours chiefly employed in pigment printing are: chrome yellow and orange, Guignet's green or chrome green; artificial ultramarine; lamp black for greys; the various ochres for golds and browns; zinc oxide; vermillion and its substitutes, and occasionally vegetable dyes, as the purple from the indigo-root. All these substances are employed in exactly the same way and may be mixed together in any proportion to form compound shades. The amount of albumen necessary to fix them varies according to the density of shade required (between 2 and 3 oz. of whole weight of the made-up printing colour), and although it is usually considered in text-books as a thickening agent it is rarely used as such in practice on account of its expense. As a rule the colouring matter is beaten up into a smooth paste with water, and a strong solution of albumen, and then reduced to its proper strength by the addition of tragacanth mucilage or starch paste.

The following formula for printing any of these direct pigment dyes is their printness of division; the finer they are the better they print and the more beautiful is their quality of colour. If they are too coarse they give rise to innumerable defects, either by sticking in the roller or by extruding the rollers; by staining the roller, or, if they print at all, by yielding uneven masses of colour, granular and speckled in appearance and quite unsaleable. Even when finally ground for printing, they are well to clog the engraving of the rollers—a defect which is more or less successfully overcome by replacing the colour-furnishing roller in the printing machine by a revolving brush.

The following formula of dark ultramarine blue will serve as a type of all other pigment printing colours:—

\[ \text{20 lb. artificial ultramarine blue.} \]

Place in grinding machine and beat up gradually with

\[ \text{4 gal. water, 40 per cent. blood albumen solution.} \]

\[ \text{2 gal. tragacanth mucilage, 8 oz. per gal.} \]

\[ \text{\textit{Ba} = ammonia.} \]

\[ \text{\textit{Gly} = glycerin.} \]

\[ \text{\textit{Tr} = turpentine.} \]

\[ \text{\textit{OL} = olive or cotton-seed oil.} \]

Make to 8 gallons with tragacanth or water, and grind the whole until perfectly homogeneous.

The small quantities of ammonia, turpentine, glycerin and oil are added to prevent the colour from frothing during the printing process.

Chlorine yellows and oranges are frequently mixed with a little calcium nitrate to counteract the action of sulphuretted hydrogen on the lead salts.

The great disadvantage of pigment colours is that although extremely fast to light and soap they are liable to rub off, if the fabric is subjected to more friction in washing. They also impart considerable stiffness to the goods, and for these two reasons they are therefore restricted to the printing of small patterns, or are used for such styles as window-blinds where the stiffness is not objectionable. The pale shades they are used for printing the grounds or "blotsches" of multicolour patterns, the small quantity of albumen they then contain being insufficient to appreciably affect the softness of the cloth. In several discharge styles too notably indigo—they find extensive use, and on the whole they constitute a most useful class of colours.

(e) Application of Indigo.—Indigo is printed on cloth by several different methods, the chief of which are: (1) Schlieper and Baum's glucose process; (2) the hydrolysulphite process; and (3) the production of indigo on the fibre itself by means of Kalle's indigo salt and several other artificial preparations. The first and second processes depend upon the facts that indigo in presence of a calcium alkali may be converted into indigo-white by reducing agents, and that the indigo-white, being soluble in the alkali, penetrates into the fibres of the cloth, where it is subsequently re-oxidized to the insoluble indigo-blue state.

In Schlieper and Baum's process (also known as the glucose process) the cloth is first prepared in glucose, and then printed with a colour containing finely ground indigo, caustic soda and dezincing thickening (also made with caustic soda). After printing the cloth is "aged," that is, passed through damp steam for a few minutes to effect the reduction and solution of the indigo, and is then hung up in a cool chamber for a day or two, in order to re-oxidize the indigo-white to indigo by the action of the oxygen in the air. A wash in cold water finally completes the fixation of the indigo, and the cloth may then be soaked and finished as usual.

Either the printed or printed and air-dried state, or, if printed containing a metal, a brown containing 30 per cent. solution of glucose in water; the excess is squeezed out in a mangle, and the cloth dried. It is then printed with the following colours according to shade required:

<table>

10 gals. 10 gals. 10 gals.

The printed goods should be dried quickly, and "aged" as soon as possible to prevent the absorption of carbonic acid gas from the air, after which the operations already mentioned may be proceeded with at leisure.

The well-known blue and red pattern produced by this process, the only difference being that, instead of white cloth, turkey red cloth is used, the strong alkali dissolving out, or "discharging," completely the colour from the parts of the cloth upon which it falls, and leaving the indigo as a blue pattern on a red ground.

In the hydrolysulphite process, which is much quicker than the preceding, the reducing agent, the indigo and the alkali are all printed together on unprepared white cloth. The goods are then "aged," and allowed to lie a short time, after which they are washed in cold water, a box containing a little indigo is thoroughly re-oxidized, and then in hot water or soap.

The hydrolysulphite printing colour is as follows:

\[ \text{200 parts hydrolysulphite N.F. (or 100 of the concentrated product).} \]

\[ \text{150 oz. alkaline dextrine paste.} \]
\[ \text{150 oz. indigo 20 per cent. paste (ground up in gum).} \]
\[ \text{200 oz. alkaline dextrine paste.} \]
\[ \text{Thickening 5 oz. ultramarine or British gum.} \]
\[ \text{50 oz. caustic soda, 70° Tw.} \]

Print, dry, "age" and wash off in a copious supply of cold water.
The third process with Kalle’s salt is not properly speaking the printing of indigo, but of a special preparation capable of forming indigo when treated with caustic alkalis. The salt is merely dissolved and thickened with gum or starch, printed, and then passed directly through a solution of caustic soda, when the indigo is immediately developed. Instead of being passed through the alkali, which is apt to cause the colour to run before it is properly developed, the cloth is more commonly printed with thickened caustic soda, whereby the indigo is equally well produced without any fear of "washing." Besides indigo, other vat dye-stuffs, such as indanthrenes, the algols, heindone and certain dyes, thin-indigo scarlet, &c., are also printed largely at the present time, yielding colours of hitherto unattained fastness to washing and to light.

(1) **Tintable Azo-Colours.** These colours do not exist as such, but require to be precipitated from the fibre itself from their components. They form a range of exceedingly fast colours, including orange, red, pink, maroon, brown, chocolate, blue and black, and are produced by the combination of various diazo-bodies with phenols, the most important of which latter is β-naphthol (beta-naphthol).

The practice of application is briefly as follows:—The bleached cloth is prepared in a solution of β-naphthol in caustic soda (naphtholate of soda), then gently dried and printed with the thickened diazotized amine required to produce the desired shade. The printing colour must be cooled with ice to prevent its decomposition; hence such colours are sometimes known as "ice colours." The two colours most extensively used are para-nitraniline red and α-naphthylamine maroon, both of which are bright fast colours, only equalled by turkey red and madder chocolate for general usefulness.

**On β-naphthol prepare the following colours may be obtained:**

Red with para-nitraniline.
Maroon with α-naphthylamine.
Orange with orthoformololuidene.
Pink with azo pink 2 B.
Chocolate with benzidine.
Brown with benzidine and orthoformololuidene.
Blue with dianisidine.
Black with dianisidine and benzidine.

Other naphthols and other bases give a still greater variety of shades. The β-naphthol requires to be freshly made, and the cloth prepared with it carefully dried, if good results are to be obtained.

Para-nitraniline is made up for printing by dissolving in hydrochloric acid. Nitrite of soda is then added, and, after standing a short time to complete the reaction, the resulting diazo-solution is mixed with thickening, and acetate of soda is then added to neutralize any free mineral acid still remaining, the presence of which would prevent the formation of the colour.

In practice the following formula have given good results:

(1) **Para-nitraniline Red**

Prepare the bleached cloth in:

\[
\begin{align*}
47 \text{ parts} & \beta\text{-naphthol.} \\
3 & \text{naphthol R.} \\
107 & \text{caustic soda, } 5^\circ \text{Tw.} \\
400 & \text{hot water.} \\
10 & \text{tartar emetic.} \\
12 & \text{tartaric acid.}
\end{align*}
\]

Make up to 1000 parts with hot water.

The cloth is passed through a trough containing this solution, the excess is squeezed out between two wooden rollers, and the cloth is gently dried and then printed with:

\[
\begin{align*}
36 \text{ parts} & \text{para-nitraniline C.} \\
100 & \text{ice.} \\
100 & \text{hydrochloric acid, } 30^\circ \text{Tw.} \\
70 & \text{water.}
\end{align*}
\]

Mix and add quickly:

\[
\begin{align*}
24 \text{ parts nitrite of soda, } 93 \text{ per cent.} \\
70 & \text{water (cold).}
\end{align*}
\]

And just before printing add further:

100 parts acetate of soda.
100 parts ice in large pieces.
400 parts tragacanth mucilage, 12 per cent.

Print, dry and wash.

A similar prepare without the naphthol R. may be used for α-naphthylamine manoons, the printing colour for which is made up as follows:

\[
\begin{align*}
36 \text{ parts} & \text{α-naphthylamine.} \\
93 & \text{hydrochloric acid, } 30^\circ \text{Tw.} \\
171 & \text{tragacanth mucilage.}
\end{align*}
\]

Grind till perfectly smooth in a mill and then add:

\[
\begin{align*}
100 & \text{parts ice.} \\
20 & \text{nitrile of soda of } 93 \text{ per cent. strength.} \\
80 & \text{water.} \\
400 & \text{starch and tragacanth thickening.} \\
25 & \text{benzine.} \\
75 & \text{acetate of soda.}
\end{align*}
\]

Print, dry and wash.

Immediately these diazo-colour pastes come in contact with the naphthol prepared cloth the colour itself is formed and fixed and requires no further treatment except that of washing to remove the naphthol from the unprinted parts of the cloth.

The other bases are diazotized in precisely the same way, the quantities of acid and nitrite of soda being varied according to the molecular weights of each base.

Several processes of printing azo-colours directly, without any previous preparation of the cloth, have been proposed, but they are not yet general as yet; those which have passed the experimental stage are not very successful on the large scale, and have, for the most part, been abandoned.

(2) **Application of Sulphur Dyes.** Of late years the class of colours known as "sulphur colours" have assumed a prominent place in textile-printing. They are really direct dyeing colours, but their special properties entitle them to be classed apart from those usually known as dyestuffs of this nature.

There are now an enormous number of sulphur-colours on the market under many different names, but, as they are all similar in general properties, it is needless to mention more than one series. The Lighter dyes are known as Biester, Lucius and Bruning will serve as well as any to exemplify the application of these dye-stuffs in printing. They comprise yellows, golds, browns, violets, blues, greys and blacks, all fairly, and some very, fast to light and soap, and, under proper conditions, easy of application to a variety of styles.

The general recipe for printing is as under:

\[
\begin{align*}
30 & \text{parts by weight of colouring matter.} \\
90 & \text{gls. water.} \\
50 & \text{china clay beaten up with} \\
50 & \text{water.} \\
40 & \text{concentrated hydro sulphur} \\
& \text{N.F., } 50 \text{ per cent. solution.} \\
700 & \text{alkaline British gum thickening.}
\end{align*}
\]

This paste is printed on unprepared bleached cloth, gently dried and then passed through a rapid steam ager, in from 4 to 7 minutes in dry steam at 212° F. to 220° F. (or twice for 3 minutes), after which the cloth is passed in the open width through the washing and soap machines, and finally dried up and finished.

The sulphur colours may be used in combination with the azo-colours, on naphthol-prepared cloth, for the production of multi-colour effects, and are entirely adapted also to the production of coloured discharges on paraintraniline red and the direct-dyeing colours.

(2) **Aniline Black.** Aniline black was discovered and first used by Lichtfuss in 1865. It is one of the fastest blacks known, and is equally useful for direct printing by itself, and for working along with printed mordants and discharge pastes. Aniline black is formed by the oxidation of aniline.

As a great deal of care is required in printing these two blacks, as if over-dried they take fire and have occasionally caused considerable damage to buildings in consequence. The blacks made with ferrocyanide, on the contrary, may be printed in conjunction with "steam" colours, and, after a preliminary passage through a rapid steam ager, and an ammonia "gassing" box, will withstand the long steaming necessary for alluring colours.

A copper aniline black may be made as follows:

\[
\begin{align*}
15 & \text{lb starch.} \\
8 & \text{lb British gum or dextrine.} \\
51 & \text{gals. water.} \\
80 & \text{lb chlorate of soda.} \\
4 & \text{gal olive oil.}
\end{align*}
\]

Boil, cool and add:

\[
\begin{align*}
8 & \text{lb aniline salt.} \\
3 & \text{lb aniline oil.} \\
3 & \text{lb sulphide of copper (precipitate pressed to a 30 per cent. paste).}
\end{align*}
\]
This black may be either hung to develop, which is the safer course, or it may be oxidized by the introduction of oxygen through steam for 2 to 3 minutes. Whenever method is adopted the printed cloth must afterwards be passed through hot bichromate—chroming—and then well washed.

The black of ferrocyanide works well in practice:

10 lb starch.
2 lb British gum.
6 lb yellow prussiate (ferrocyanide) of potash.
7 gals. water.

Boil, turn off the steam, and add:
2½ lb chlorate of soda in powder.

Cool and add:
8¼ lb aniline salt.

Print, age 4 minutes through the rapid agor, chrome, wash, and soap. If printed with alizarine steam colours it must be passed through ammonia vapour after "aging," and then be steamed for one hour before chroming and washing. The black is omitted, but the colour is then apt to become green after a short time owing to the action of sulphur dioxide present in the air.

Aniline black is now used almost exclusively for printing with all mordants for the artificial colour, or black ground goods that were formerly dyed with logwood on an iron mordant. Shirtings and all single-colour black dress goods are also executed in aniline black, which is faster to light, washing, and perspiration than all other black dyes. It must not be used in the same bath with any other black dye.

(2) Printing of Mordants.—This, the second of the great styles of textile printing, was, at one time, the most extensively practised of all, and is still the most important for all classes of work where the fastest colours are required. It may be conveniently divided into two branches: (a) the madder style, and (b) the printing of other mordants such as chrome, tannic acid, β-naphthol, etc. (a) The Madder Style.—In this style the only mordants used are those of aluminium and iron.

Aluminium alone yields various shades of red and pink when dyed up in mordants for its artificial colour, or purple and maroon. Iron alone yields with the same dye-stuffs shades varying from black to the palest lavender. Iron and aluminium mordants in combination yield colours ranging in shade from claret through all gradations of brown to the deepest blues and purples, according to which of the two mordants predominates in the mixture. Browns and allied colours may be dyed on the same mordants with either nitrocellulose alone, or with alizarine itself mixed with dyeextractions—logwood, Persian berry or quercitron bark, etc.

Both aluminium and iron mordants consist of the acetates of their respective metals. The iron mordant which gives the best results is known as "black liquor." It is a crude acetate containing a good deal of organic matter which appears to regulate the speed of its oxidation and so produce much more level colours than have ever been obtained from any other iron mordant.

Aluminium acetate in the pure state is also rarely employed, the crude commercial "red liquor" being found in practice to yield the best results, both as regards colour and ease of working. The "red liquors" vary considerably in composition, some being normal sulphate-acetates, others basic acetates, some normal sulphate-acetates, others basic sulphate-acetates, but their mode of application is always the same, that is, they are thickened, printed, aged and dyed. In all cases they are basic they decompose on boiling, or on dilution, and become utterly useless; but this rarely happens nowadays and need not be further gone into. Many difficulties occur in the printing of mordants and their subsequent dyeing, but if the following points are observed most of them may be surmounted: (1) after printing the cloth must be gently dried, otherwise the mordants become dehydrated or "burnt," and instead of dyeing up evenly they appear patchy and very light in the over-dried parts; (2) the cloth should not be used in excess; and (3) the temperature of the dye-bath must be kept as low as is consistent with the fixation of the colour. If these last two points are neglected the printed parts of the cloth, which should remain a pure white when it is finished, will be soiled beyond repair unless indeed the "whites" are cleared at the expense of weakening the colour. Iron mordants especially are liable to unevenness due to the oxidation being too slow; and this is not only noticeable in purples and lavenders, the pyrolygnite of iron or "black liquor" is frequently boiled for half an hour or more with 1 per cent. of its weight of arsenious acid, or "white arsenic," a substance which retards the oxidation when dry. Sometimes the dyes are mixed with either aluminium or iron acetates, and hung or "aged" for 2 to 3 days in a brick chamber containing moist air at about 30°C. dry bulb, and 27°C. wet bulb thermometer. In this operation the gals, lb may pass through a mixture of an anilinum powder, and chalk at a temperature of about 50°C. In this "dunng" bath they are worked altogether about ½ hours, at the end of which the mordants are thoroughly fixed, and all the thickening agents perfectly eliminated, thus leaving the cloth in the best condition to absorb the dye-stuff.

The dyeing is carried out by working the goods at 60°C. in a mixture of alizarine, a little chalk, and glue size for 1 to 1½ hours. They are then well washed, soaped, and the whites cleaned by a passage through weak bleaching powder solution, followed by a passage through steam. Further soaping and washing is then resorted to until the goods are quite clear and bright.

In the case of cloth dyed in red and pink alone the goods after dyeing are well washed, passed through a bath of alizarine oil containing oxalate of ammonia, and then steamed for one hour at 15 lb pressure. This brightens the colours by removing the brown appearance they possess after dyeing. When reds are associated with chocolates and purples, however, the oiling process must be carefully conducted, otherwise the latter suffer; frequently it is omitted altogether, the brightening being effected by vigorous soaping.

By printing the following mordants a six-colour design may be produced with a single dye-stuff and in one dyeing:

<table>

</table>

The above mordants are printed on white bleached cloth, dried, hung 2 to 3 days, "dunng," dyed, washed, well soaped and washed again; then "chemicked" through weak bleaching powder solution, and finished.

The "dunng" is performed in vats through which the cloth circulates continually during the operation. As a rule dunning is done twice, the second bath being weaker than the first. The vats or "becks" contain a mixture of:

- 100 gals. water
- 10 lb chalk
- 25 lb cow-dung

at 60°C.

100 gals. water
5 lb chalk
25 lb cow-dung

This duning bath is continued until the cloth hangs in the dye liquor. When about 700 yds. of cloth have been entered in this way the two ends of it are knotted together, thus forming an endless rope which circulates continuously in and out of the dye-liquor. The vat or beck is then charged with alizarine, chalk and glue, the proportions varying according to the amount of space covered by the mordants on the cloth. If, for instance, half the surface is printed then the dye-liquor might be made up as follows, the quantities being calculated on the weight of the cloth:

- 4½ per cent. alizarine (blue shade), 20 per cent. in a sufficiency
- 14½ per cent. acetate of lime, 26½° Tw.
- 10 ', glue solution, or size, 15 per cent. of water.

The goods are entered into this solution cold. The temperature is gradually raised to 60°C., and the dyeing continued at this for several hours. The goods are then washed in a similar machine, soaped well and finished off by drying.

Aniline black may be printed along with "red liquor" and iron liquor, and many other modifications also employed, but the principle of dyeing is as before stated.

(b) The Printing of other Mordants.—Of these the most important are tannic acid, chrome mordants and β-naphthol.

For printing tannic acid the following is used:

- 5 lb tannic acid dissolved in a sufficient amount of
- 1 gal. acetic acid and added to
- 9 ' starth and tragacanth paste.
The goods are simply dried after printing and the tannic acid immediately fixed by passing through a solution of—

1 oz. tartar emetic.
1 oz. chalk.
1 gal. water at 60° C.

After washing they may be dyed up in any of the basic aniline colours. Various chrome mordants are employed in printing, amongst which may be mentioned chromium chloride, and chromium acetate. The latter is thickened with starch or gum, printed, and fixed by being passed through boiling sodium carbonate. The latter is applied in the same way but, after printing, is steamed before the carbonate treatment. Both these mordants are suitable for dying with any of the basic dyes. It is mentioned under the direct printing of mordant colours, such as alizarine, alizarine bordeaux, coeruleine and the natural dye-wood extracts. They are dyed similarly to the madder colours, with an addition of glue size to preserve the white of the unprinted parts of the cloth.

(g) The Discharge Style.—This style is now one of the most important produced. Its range is so extensive, and its modifications so numerous, that it is impossible to mention more than a few of its chief applications. It may be used for locally destroying either the colours dyed on cloth, or the mordants with which they have been prepared. In both cases the resulting pattern appears in white, or colours, on a full rich ground the beauty of which cannot be equalled by direct printing. The discharging agents consist of organic acids, caustic alkalis, oxidizing agents and reducing agents, each used according to the kind of colour or mordant to be discharged.

(a) Discharge of Iron and Aluminium Mordants.—The cloth is padded with a solution of these mordants, dried in hot air, and then padded with either the acid or acid citrate of soda, mixed with china clay to prevent the pattern running. It is then passed through the rapid ager once or twice, "dunged," washed, and dyed in the usual way for madder colours. Wherever the discharge has been printed the mordant is dissolved out, leaving a white pattern on a dyed ground.

(b) Tannate of antimony mordant is similarly discharged by printing or caustic soda. The goods are passed in like manner through the ager, well washed in water, and dyed-up in any basic aniline dye.

(c) The chrome discharge is produced by padding the goods in chromium bichromate; then drying them, and printing-on citric acid, or citrate or acid citrate of soda. They are then steamed, passed through chalk and water, well washed and dyed up in any mordant dye.

(d) Turkey red may be discharged in both white and coloured patterns by either oxidizing agents or caustic alkalis. (1) The dyed cloth is printed with strong citric acid, or arsenic acid, at 180° Tw., and then run through bleaching powder solution, whereby the phenol parts are completely decolorized. If colours are required, the citric acid is mixed with lead salts and Prussian blue, and the fabric after passing through the bleaching powder solution, is further treated in a bath of bichromate of potash which forms with the lead salts the insoluble chromates. Green is obtained by the combination of Prussian blue with the chrome yellow.

Examples:

White. 6 lb citric acid or tartaric acid.
1 gal. water.
4 lb British gum or dextrose.
Boil together.
Yellow. 15 lb British gum.
1 gal. dark British gum paste, 30 per cent.
2 lb. water.
20 lb tartaric acid.
12 lb nitrate of lead.

Print, dry, discharge through bleaching powder solution,
18° Tw., and chrome.

(e) The dyed cloth is printed with strongly alkaline discharge pastes, passed through the "ager" two or three times, and then washed off in silicate of soda. If blue, yellow and green discharges are desired they must first be passed through glucose solution, well dried, printed with the colours, aged, passed through silicate of soda,chromed in bichromate, well washed and dried. Examples:

White. 10 lb stannous chloride dissolved cold in
8 gal. alkaline thickening.
2 lb. silicate of soda, 70° Tw.

Blue. 15 lb indigo pure 20 per cent. paste.
3 gal. turpentine.
9 gal. water.
10 lb British gum paste.
7 lb alkaline thickening.
Green. 8 parts of the yellow without silicate.
1 part of blue.

If Paranitraniline red is discharged by means of the new hydro sulphate-formaldehyde compounds. The dyed cloth is printed with the following:

25 lb hydro sulphite N.F. conc., or hydralide conc.
14 lb. British gum paste.
Heat till dissolved and add—
3 lb. gal. glycerin
4 lb. starch-tragacanth thickening.

After printing, age twice for 4 minutes through dry steam at 220° F., then wash well and soap. Coloured discharges are obtained by mixing hydro sulphite, tannic acid, aniline or phenol, and basic colouring matters together. Mordant dyed fixed with chromium acetate may also be used. On a-naphthylamine maroon the above discharge white requires the addition of indulin scarlet, patent blue or anthraquinone, before it becomes effective; otherwise the procedure is the same as for paranitraniline red.

(g) Indigo is usually discharged by oxidation. For this purpose the dyed cloth is printed in two different ways. Firstly, with chloride of soda, and red or yellow prussiate of potash together with a little citric acid or citrate of soda; secondly, with chrome of potash. In the first instance, the cloth is "aged" through the rapid ager after printing, and, in the second, is passed through a vat containing hot sulphuric and oxalic acid. Coloured discharges may be obtained in both methods by adding aluminun and pigment colours to the discharging agents.

(1) Discharge by steaming—
12 lb citric acid, dissolved in:
7 lb caustic soda, 70° Tw., and add:
12 lb sodium chlorate.
5 gals. British gum paste.
Heat till dissolved, cool and add—
4 lb British gum paste.
12 lb yellow prussiate of potash.
Print, steam and wash.
Chlorate of aluminium is also used for this process, but it acts very energetically and is apt to tender the cloth.

(2) Chrome discharge.
White. 8 lb British gum paste.
12 lb bichromate of soda.
1 lb. gal. turpentine.
Yellow. 32 lb chrome yellow pigment.
3 gals. 50 per cent. albumen solution.
3 lb. thick tragacanth mucilage.
1 lb. (oil) vegetable.
12 lb bichromate of soda neutralized with
3 gal. caustic soda, 70° Tw.
1 lb. water.
Print, dry, pass through a "beck" (i.e. a bath) containing—
100 gals. water.
50 lb sulphuric acid (168° Tw).
50 lb oxalic acid.

Then wash well and dry.

With these oxidation discharges it is impossible to prevent the fibre being attacked by the discharge pastes, and it is impossible that it is partially converted into oxycellulose. Recently a method has been brought out for the production of a white discharge on indigo which is said to do away with the formation of oxycellulose and which consists in printing on a thickened solution of sodium nitrate and, after drying, running through sulphuric acid of 50° Tw.

Another method of producing white discharges on indigo consists in printing the dyed cloth with hydro sulphite N.F., then steaming and running through a boiling solution of caustic soda. Good results are thus obtained without the formation of oxycellulose, but the process is expensive.

(b) Direct dying or substantive colours can be easily discharged with the hydro sulphite discharge used for paranitraniline red (see above). It must be reduced in strength to about one-fourth for dark shades, and much weaker for lighter colours. Direct colours were formerly discharged by stannous chloride or acetate, but the hydro sulphite has almost entirely displaced these salts for white discharges.

(g) Discharges on manganese bronze are of little importance at the present time. They are effected by means of stannous chloride, colours being obtained by the addition of basic dyes and dyeweed dyes.

(j) Sulphur-colours, dyed basic colours, and some alizarine colours, are discharged with chrome and prussiate like indigo.

(a) The British or Reserve Style.—Reserves are substances which, when printed, prevent the fixation or development of mordant and colour solutions subsequently applied, and are used to produce effects similar to those obtained by discharge printing.

One method reserves these uses either madder dyed goods, steam alizarine reds and pinks, steam basic colours, vat indigo blue, insoluble azo colours, sulphur-colours and aniline black. 

TECHNOLOGY
(c) Reserves under Aluminium and Iron Mordants.—For the production of this important class of goods, use is made of the fact that alkaline citrates prevent the fixation of the mordants. The cloth is first printed with certain of the usual, or sometimes citric and tartaric acids for iron mordants), then dried, and again printed over the previous impression, with either a fine "all over" pattern or flat uniform ground, in iron or aluminium mordants. The fabric is then aged, "dunged," washed and dyed as already described, with the result that wherever the "reserve" of citrate or acid was printed a white pattern is left on a fixed process ground. The fine patterns printed over "reserves" are called "covers" and the plain grounds "pads," hence the name "cover and pad" style in cases where, as frequently happens, a design of "pads" and a light "pad" are both printed over a white "reserve." The "cover and pad" style is, for the most part, restricted to dyed alizarine purples under which red, black, dark purple and white can all be reserved at the same time, thus giving rise to very pleasing effects. For example: white cloth is first printed with four "colours," viz., citrate of soda and citric acid for the white; logwood and iron for the black; logwood and iron for the purple; and aluminium acetate at 6° T. with 8 oz. per gallon of stannous chloride for the red. (The stannous chloride acts as a resist for iron mordants.) The whole is then "covered" in a fine pattern printed with a fairly strong iron mordant, dried, and again printed, in a very weak iron mordant, with a pad roller, that is, a roller which prints a uniform ground over the whole surface of the cloth. After this last printing, the cloth is "aged" for a day or two, by being hung in "dung," washed and dried, "dunged," washed and dyed in a blue shade of alizarine. When finally washed, washed and "dunged" in bleaching powder solution the first printing pad, or red, indigo pad, is seen to stand out, clearly and sharply, from a figured background in two lighter shades of purple. This "cover and pad" style of reserve printing constitutes one of the staple processes of nearly all print-works, and is produced in enormous quantities for both home and foreign markets. Red is not often introduced as in the above example, the usual colours being white, black and two purples. The same method of working can be adopted with aluminium mordants for red and pink covers and pads, but they are better produced with the steam alizarine colours as below.

(b) Reserves under Steam Alizarine Red and Pink.—In this case a reserve composed of citrate of chromium alone, or in conjunction with the citrate of soda, gives the best results. The cloth is first prepared in alizarine oil and then printed with the following:

10 lb. china clay.
4 gal. citrate of soda, 54° T.
1 gal. citrate of chromium, 42° T.
1 gal. water.
2 lb. British gum paste.

After printing the above, the goods are dried and again printed either with "cover" or "pad" or both, in alizarine pink, dried, steamed for 1½ hrs., well washed and soaped. On leaving the stenter frame the colour with the reserve is yellow, but become quite white on soaping. Like the purples, the alizarine pinks can be reserved in colours. For blue, green, yellow and violet the ordinary steam basic colours are used with additions of citric or tartaric acid.

Example:
7 lb china clay.
62 lb British gum paste.
2 lb. methylene blue.
1 lb. citric acid.
1 gal. citric acid.
Boil, cool, and add:
1½ gals. 50 per cent. tannic acid solution in acetic acid.

Red with steam alizarine red; yellow with thioflavine in place of methylene blue in above; green a mixture of blue and yellow. These colours with the white reserve may all be printed at once. Then steam as usual, pass through a solution of tartar emetic and chalk, wash, wash and steep.

(c) Reserves under Insoluble Azo-Colors.—These are based upon the action of stannous chloride, which prevents the combination between the diazo- and &-naphthol, and the diazotized solutions of paranitraniline for red grounds; &-naphthylamine for maroon; ortho-nitrothiophene for orange, &c., &c. The cloth is then washed and soaped until the "whites" are clean.

White Resist. 5 gals. gum senegal solution.
30 lb. tin crystals.
5 lb. tartaric acid.

For heavy rollers this may be reduced with more gum.

Potassium sulphate is also used as a white reserve under insoluble azo-colours with good results.

(d) Reserves under Steam Basic Colours.—The white cloth is printed with:

20 lb china clay.
2½ gals. water.
15 lb. British gum.
20 lb. sodium tartar emetic.
20 lb. zinc sulphate.

All boiled well together, and then covered, or over-printed, with any steam basic colour—steamed one hour, passed through tartar emetic, then washed and soaped, when the reserve white above comes away, bringing along with it the colour printed upon it and leaving a white pattern on a printed ground.

(e) Reserves under vat Indigo Blue.—This was formerly a very important style, but at present is only used in special cases. Resist or reserve effects are obtained by printing the white cloth with oxidizing agents, &c., and subsequently dyeing it in the indigo vat. In addition to oxidizing agents the reserve pastes contain lead sulphate, barium sulphate, resins, fats and thickenings in various proportions. The following is a good white reserve:

15 lb. flour.
6 gals. water.

Boil, cool a little, and add:
18 lb copper sulphate powdered.
2½ lb copper nitrate, 90° T.
1 pint alizarine oil.

Yellow. 2½ gals. British gum paste.
33 lb lead sulphate, 66 per cent. paste.
18 lb zinc sulphate.
22 lb lead nitrate.

Print the white and yellow, dry, dye in the indigo vat—sour slightly in sulphuric acid, wash, and pass into a hot solution of bichromate of soda, which develops the lead yellow. Reserve whites also contain lead salts when used for white alone, but obviously the white given is best suited to white and yellow reserves, as its alkaline copper sulphate wash out before the "chroming" stage is imposed by the vat.

(f) Reserves under Sulphur Colours.—These are obtained with zinc chloride. They are not much used, but are capable of yielding fine effects.

(g) Reserves under Aniline Black.—Reserves under aniline black are produced with caustic alkalis, alkaline carbonates, silicates and sulphites, sulphocyanides, oxide of zinc and the acetates of magnesia, zinc and soda. The white and coloured reserves may be printed upon either the undeveloped black or upon the cloth before the black is applied.

In the former case the cloth is slop-padded through a mangle-box with the following black:

7½ lb aniline hydrochloride.
5 lb potassium carbonate.
4 lb potassium ferrocyanide.
10 gals. water.

It is then very carefully dried in hot air so that it becomes no darker than a pale yellow; if it is green before printing, the white is sure to be bad.

The dried padded cloth is then printed with the "resist" colours, dried and steamed 3 to 4 minutes in a rapid ager, chromed through warm bichromate of potash, and finally washed and soaped. During the steaming the black is developed all over the cloth except where the colours are printed. Here its development is prevented by the alkali or the reducing agent, whichever may be present, in the colour, and instead of a plain black dyed piece a coloured design on a black
The following formulae may be employed for white and coloured resists:

**White.**
- 8 lb starch.
- 8 lb British gum.
- 30 lb potassium sulphite, 90° Twp.
- 3 gals. water.
- 15 lb soda acetate.
- 10 lb bisulphite of soda, 66° Twp.
- ⅛ lb ultramarine blue.

Boil together.

Print on the padded cloth, age, chrome and wash. The resist paste is as under:

**Resist Paste.**
- 10 lb zinc oxide.
- 1½ gals. magnesium acetate, 40° Twp.
- 2½ lb tragacanth mucilage (dragon).
- 1 starch paste.

For reducing the colours take 6 parts resist paste.

- 4 " starch paste.
- 4 " white resist.

Very good results can be obtained by the alternative method, i.e., printing the resists on white cloth and applying the black afterwards. The basic colours are chiefly used, though chrome yellow and ultramarine are also employed for some styles. The following formulae will serve as types of the composition of white and colours:

**White.**
- 20 lb precipitated chalk.
- 5 lb potassium sulphite, 90° Twp.
- 5 lb acetate of soda.
- ½ lb ultramarine blue for lightening.
- 1 gal. water.
- 6 " starch paste.

The whole ground together in a mill.

**Colour.**
- 2 lb basic dye-stuff.
  - 1 gal. water.
  - 2½ " starch paste.
- 17 lb zinc oxide.
- 1 gal. water.
- ½ " glycérine.
- ½ " turpentine.
- ½ " bisulphite of soda.
- 3 " starch paste.

Print on white cloth, allow to lie a day or two, then strop-pad in the Prud'homme black already given, dry, age, chrome and soap.

Pigment colours may be applied on black padded cloth as follows:

**Yellow.**
- 40 lb chrome yellow, &c. &c.
- 2½ gals. 40 per cent. albumen.
- 2½ lb tragacanth water, 6 oz. per gal.
- 6 lb stock ash.
- 1 gal. rate of citrate of soda, 40° Twp.

Other methods, varying in detail, have been used from time to time, but the above two are at the present time generally employed—especially the former, by which many fine patterns have been produced in all sorts of delicate and artistic shades.

The Treatment of Cloth after Printing.

After printing, the various classes of goods undergo many different treatments according to the character of the colours printed. These treatments include steaming, hanging in the ageing chamber, passing through tartar emetic, the chalk bath, washing, soaking, "chimming" or clearing and finishing.

1. The operation of steaming is necessary for all styles except those with the insoluble azo-colours, at dyes discharged, and some colours that are precipitated on the fibre. The short steaming necessary for most discharges, indigo blue prints, and aniline black is effected in the Mather and Platt ager, of which a sketch is here given (fig. 2) showing its principle.

It consists of an iron box A A A through which the goods (indicated by the dotted line) pass in the direction of the arrows. They enter at B, and traverse the whole chamber over a series of top and bottom rollers C C C, finally emerging at the same point B, whence they are drawn forward, by mechanical means, and plaited down on a waggon placed conveniently near. Steam enters the chamber A A A by the steam pipe D at the bottom, and escapes through the same slot (B) that the cloth enters and leaves by. An engine or electric motor drives the gearing, and the whole process is continuous.

This ager affords quite a sufficient steaming for aniline blacks, printed indigo, chlorate discharges, and for some mordants, but alizarine reds and pinks, mordant dyes generally and basic colours require much more than the 2 to 3 minutes' exposure to steam which is all that can be given in the ordinary Mather-Platt ager, although they are frequently passed through it to eliminate the greater part of the volatile acids they contain. Paranitramine red discharged with hydro sulphite also requires a modification of the ager for its success—for the steam must be very hot and very dry if any of the azo-colours are to be effectively discharged by the hydro sulphite method.

2. A longer exposure to the action of steam is obtained by means of the continuous steamer and the continuous steamer, in both of which goods may be steamed for any length of time. The cottage steamer consists (1) of a cylindrical iron box or chamber fitted with a false bottom on which rails are laid, and under which lie the pipes for the admission of steam, and for the drawing off of the condensed water; and (2) of a carriage or iron framework mounted on wheels and furnished with a series of removable rods capable of being revolved by means of spur wheel gearing. Convenient lengths of the cloth to be steamed, together with a ¼ " back grey" (a piece of unbleached calico) are then wound in the open width, into a sort of broad hank on a folding frame. As each hank, so to speak, is completed it is removed from the winding frame and hung over one of the rods, which is then placed in position on the carriage.

![Fig. 2](https://via.placeholder.com/150)

When the latter is fully loaded in this way it is run into the "cottage," the doors are closed, and steam turned in. The steaming is continued for various periods of time—from ¼ hour to 2 hours—according to the style of work in hand, and either with or without pressure, as may be required. The carriage is then withdrawn and the goods unwound in readiness for subsequent operations.

The object of enveloping the printed goods in a "back grey" is to prevent the colour from setting off from the face of one fold on to the back of the next, and also to minimize the risk of damage from drops of condensed water. This latter defect is further guarded against by heating up for an hour or so every morning before any goods are introduced.

In works where the modern continuous steaming apparatus is installed the cottage steamer is reserved for the treatment of red alizarine reds and for goods, such as heavy printed velvets, which are difficult to manipulate to the "grey." It is too complex to be adequately described without the aid of detailed sketches. Generally speaking, it may be said to consist of a long,
high, narrow chamber of brick, through which the cloth passes continuously in the form of long loops suspended from rods resting upon, and carried forward by travelling chains, situated at the top, and close to the sides, of the chamber. Steam is admitted to the chamber, and, by the ‘steam’ or power, which is carried by loops of cloth entering and emerging through slots at the top of its opposite ends.

On entering, the cloth falls over one of the slowly travelling rods and continues to run downwards until a sufficient length to form the loop is available. By this time the first rod has moved forward and a second taken its place, with the result that the cloth now falls over the second rod and commences to form the second loop. At this point—the commencement of a second loop—the second rod is raised a little by means of small pivots fixed in the bottom, and is allowed to fall in its place, and so on. The object of this bar, which clips the continuously entering cloth firmly between itself and the rod until the second loop is formed, is to prevent the cloth from being fed into the first loop, and to prevent the weight of the first loop from pulling the cloth over the second rod during the formation of the second loop. By the time this latter is complete the second rod has moved sufficiently far forward to escape contact with the pivoted brass bar, which thereupon swings back and takes up a similar position on the third rod. In this way each rod in turn is supplied with cloth in which a forward movement is continued until the other end of the steamer is reached, where both cloth and rods emerge—the former through the top of the chamber and the latter through a slotted opening at the top of the end wall.

The cloth, when passing through the steamer, may be conveyed, until the other end of the steamer is reached, where both cloth and rods emerge—the former through the top of the chamber and the latter through a slotted opening at the top of the end wall.

The cloth, when passing through the steamer, may be conveyed, until the other end of the steamer is reached, where both cloth and rods emerge—the former through the top of the chamber and the latter through a slotted opening at the top of the end wall.

The cloth, when passing through the steamer, may be conveyed, until the other end of the steamer is reached, where both cloth and rods emerge—the former through the top of the chamber and the latter through a slotted opening at the top of the end wall.
FIG. 1.—Linen, dyed blue, the "reserved" parts represent the Annunciation; above the reclining figure of the Virgin Mary is the word MAPIA. Coptic, probably 6th or 7th century. 18 in. X 2 ft. 5 in.

FIG. 2.—Child's Tunic of linen dyed blue, the pattern being "reserved." Coptic, 4th century (?). 18 in. X 2 ft. 5 in.

FIG. 3.—Piece of red silk, printed in black from wood blocks, with a repeating pattern of black circles or roundels containing pairs of animals and dragonets; floriated crosses in the interspaces. Rhenish, 13th or 14th century. 15\(\frac{1}{2}\) in. X 13\(\frac{1}{2}\) in.

FIG. 4.—Piece of red silk, printed in red, green, and black from wood blocks, with a repeating pattern of black circles or roundels containing pairs of animals and dragonets; floriated crosses in the interspaces. Rhenish, 13th or 14th century. 8\(\frac{1}{2}\) in. X 13\(\frac{1}{2}\) in.

FIG. 5.—Piece of linen, printed in black from a wood block, with a pattern composed of repetitions of a lady on a turret, leafy sprays, a hound, and a bird on the wing. Rhenish, 14th century. 9\(\frac{1}{2}\) in. X 19\(\frac{3}{4}\) in.

FIG. 6.—Strip of linen printed in deep purple from a wood block, with a repeating pattern of eagles and conventional leaf and fruit forms. Rhenish, 14th or early 15th century. 20\(\frac{1}{2}\) in. X 6\(\frac{1}{2}\) in.
FIG. 7.—Portion of reddish linen lining for a chasuble printed in black from wood blocks, with a repeating pattern composed of five-lobed shapes enclosing conventional fruit device surrounded by small blossom and leaf forms. Rheinish, 15th century; from the neighbourhood of Düsseldorf. 3 ft. 8 in. x 24½ in.

FIG. 8.—Cotton print in colours. Dutch, 17th century. About 14 in. x 9 in.

FIG. 9.—Part of a coverlet of cotton, printed at Genoa, in colours, from metal plates engraved with trees, flowers, birds, and animals in the style of Indian palampores or printed calicoes, 18th century. About 6 ft. x 3 ft.

FIG. 10.—Part of a hanging of cotton, printed in red from metal plates engraved with repetitions of pictorial scenes. At the bottom is printed "D & T. P. Meißler & C. de Beutierne près Bordeaux" Bon Teint, MF. 3 ft. × 3 ft. French, second half of 18th century. 4 ft. 6 in. × 3 ft. 4 in.

FIG. 11.—Part of a cotton chair back, printed in red from a metal plate engraved with a Chinese pagoda in a landscape; in front is a woman kneeling on the ground, while a priest stands to the left holding up an image. Marked "Collins Woolmers." English, dated 1796. 2 ft. 13 in. × 24½ in.

FIG. 12.—Linen panel, with a stipple engraving printed in colours, for use as a small fire-screen. English, late 18th century. 2 ft. 4½ in. × 2 ft. 4¼ in.
**Textile-Printing**

II. Art and Archaeology

Printing patterns on textiles whether of flax, cotton or silk, by means of incised wooden blocks, is so closely related in its ornamental effects to other different methods of similar intention, such as by painting and by processes of dyeing and weaving, that it is almost impossible to determine from the picturesque indications afforded by ancient records and writings of Christian, classical or even earlier times, how far, if at all, allusion is being made in them to the blocks-printing process. Hence its original invention must probably remain a matter of inference only. As a process, the employment of which has been immensely developed and modified in Europe during the last hundred years by machinery and the adoption of stereotypes and engraved metal plates, it is doubtless traceable to a primeval use of blocks of stone, wood, &c., so cut or carved as to make impressions on surfaces of any material; and where the existence of these can be traced in ancient civilizations, e.g. of the Chinese, Egyptians and Assyrians, there is a probability that printing on permanent materials may have been practised at a very early period. Nevertheless, highly skilled as the Chinese are, and for ages have been, in ornamental weaving and other branches of textile art, there seem to be no direct evidences of their having resorted so extensively to printing for the decoration of textiles as peoples in the East Indies, those, for instance, of the Punjab and Bombay, from whose posterity 16th-century European and especially Dutch merchants bought goods for Occidental trade in "Indiennes" or printed and painted caliccoes.

The earlier history of stamping patterns by hand on to textiles in the East has still to be written, a serious attempt which has recently been made to account for the existence of this decorative process in Europe during several centuries prior to the introduction of the "Indiennes" above mentioned. As in the case of weaving and embroideries, specimens of printed stuffs have of recent years been obtained from disturbed tombs in Upper Egypt (Akhniml and elsewhere) and tell us of Egyptian-Roman use of such things. Some few of them are now lodged in European museums. For indications that earlier Egyptians, Greeks and Romans were likely to have been acquainted with the printing of textiles painted by Egyptians there are many actual examples. Apart from these there are wall paintings, e.g., those of Beni Hassan—about 2100 B.C.—in which are represented certain Asiatic people wearing costumes irregularly patterned with spots, stripes and zigzags, which may have been more readily stamped than embroidered or woven. A rather more complicated and orderly pattern well suited to stamping occurs in a painting about 1520 B.C., of Hathor and King Menepthah I. Herodotus, referring to the garments of inhabitants of the Caucasus, says that representations of various animals were dyed into them so as to be irremoveable by washing. Pliny describes "a very remarkable process employed in Egypt for the colouring of tissues. After pressing the material, which is white at first, they saturate it, not with colours, but with mordants that are calculated to absorb colour." He does not explain how this saturation is done. But as it is clearly for the purpose of obtaining a decorative effect, stamping or brushing the mordants into the material may be inferred. When this was finished the cloth was "plunged into a cauldron of boiling dye" and "removed the next moment fully coloured." It is a singular fact, too, that although the dyeing of the patterns of one uniform colour, the material when taken out of it is of various colours according to the nature of the mordants that have been respectively applied to it." Egypto-Roman bits of stuffs from Akhmim exhibit the use, some three hundred years later than the time of Pliny, of boldly cut blocks for stamping figure-subjects and patterns on to textiles. Almost concurrent

1 When Cortes conquered Mexico he sent to Charles V. cotton garments with black, red, yellow, green and blue figures. The Dutch and American Indians have a method of applying patterns in different colours to cloth (see Parnell's Dyeing and Calico Printing, p. 12).
with their discovery was that of a fragment of printed cotton at Arles in the grave of St. Caesarius, who was bishop there about A.D. 542. Equal in archaeological value are similar fragments found in an ancient tomb at Quedlinburg. These, however, are of comparatively simple patterns. Other later specimens establish the fact that more important pattern-printing on textiles had become a developed industry in parts of Europe towards the end of the 12th and the beginning of the 13th century.

According to Forrer (Die Kunst des Zeugdrucks, 1898) medieval Rhenish monasteries were the cradles of the artistic craft of ornamental stamp or block cutting. In rare monastic MSS. earlier in date than the 13th century, initial letters (especially those that recur frequently) were sometimes stamped from hand-cut blocks; and German deeds of the 14th century bear names of block cutters and textile framers as those of witnesses. Between the 11th and 14th centuries there was apparently in Germany no such weaving of rich ornamental stuffs as that carried on in Spain and Italy, but her competitive and commercial instincts led her to adapt her art of stamping to the decoration of coarse textiles, and thus to produce rather rough imitations of patterns woven in the Saracenic, Byzantine and Italian silks and brocades. Amongst the more ancient relics of Rhenish printed textiles are some of this stuff, impressed with crude and simplified versions of such patterns in gold and silver foil. Of these, and of a considerable number of later variously dyed stout linens with patterns printed in dark tones or in black, specimens have been collected from reliquaries, tombs and old churches. From these several bits of evidence Dr. Forrer propounds an opinion that the printing of patterns on textiles as carried on in several Rhenish towns preceded that of printing on paper. He proceeds to show that from about the 13th century increasing luxury and prosperity promoted a freer use of wovens and embroidered stuffs in all forms of decoration, and the sudden rise of trade into neglect, and it was not until three centuries later that it revived, very largely under the influence of trade importation into Europe quantities of Indian printed and painted calicoes.

Augsburg, famous in the 17th century for its printing on linens, &c., supplied Alsace and Switzerland with many craftsmen in this process. After the revocation of the edict of Nantes, French refugees took part in starting manufactories of both painted and printed cloths in Holland, England and Switzerland; some of the refugees were allowed back into France to do the same in Normandy; manufactories were also set up in Paris, Marseilles, Nantes and Angers; but there was still greater activity at Geneva, Neuchâtel, Zürich, St. Gall and Basel. The first textile-printing works in Great Britain are said to have been begun towards the end of the 17th century by a Frenchman on the bank's of the Thames near Richmond, and soon afterwards a more considerable factory was established at Bromley Hall in Essex; many others were opened in Surrey early in the 18th century. At Mulhouse the enterprise of Koechlin, Schmatzer and Dollfus in 1746, as well as that of Oberkampf at Jouy, led to a still wider spread of the industry in Alsace. In almost every place in Europe where it was taken up and followed, it was met by local and national prohibitions or trade protective regulations and acts, which, however, were gradually overcome.

Towards the end of the 18th century a revolution in the British manufacture of printed textiles was brought about through the invention of cylinder or roller printing from metal plates. This is usually credited to Oberkampf of Jouy, but it seems to have also occurred to a Scotsman named Bell, and was successfully applied in a large way about 1785 atMossey near Preston. From this and the calico-printing works at Manchester in 1763, and in Scotland in 1768, the present huge proportions of the industry in the United Kingdom have grown.

Illustrations accompanying this brief account merely indicate a few types of patterns used in various European countries up to the beginning of the 19th century. Typical specimens of East Indian painted and printed calicoes for coverlets and other draperies are shown in the Indian division of the Victoria and Albert Museum. These are sui generis, and therefore differ from the block of work of the 12th century, which together with a less quantity of printing on satin, silk, taffeta, crêpe and the like are principally from adaptations of weaving patterns. An interesting series of over 2500 patterns, chiefly of this character, was made by M. Corimand between 1846 and 1860, and is preserved in the National Art Library at South Kensington. For many years of the latter part of the 19th century, William Morris designed and produced attractively ingenious floral and bird patterns, admirable in contrasts of bright colours, frequently basing his arrangement of crisply defined forms in themes such as that of Persian surface ornament. The colour printing, which on its appearance in 1890, has very considerably affected numbers of British and foreign designers of printed patterns whether for textiles or wall papers.

The portion of linen hanging or valance given in Fig. 1 (Plate I.) comes from an ancient cemetery at Akhmim in Upper Egypt. The linen dyed blue bears ornamentation with figures undyed or留白 and arranged in broad branches. All are enclosed in an engraved block, of some such saturating fluid as that mentioned by Pliny. The design and cutting of the block were no doubt the work of Coptic artificers, the style of the composition being that of late antique or early Byzantine work, the dyed blue (Fig. 2) the simple trellis and blossom pattern is similarly produced by the "reserve" process, and the specimen is of the 4th century B.C. The linen in Fig. 3 is of date, i.e. 4th century A.D. Fig. 3 is from a fragment of red silk printed in red, green and black from wood-blocks, thus illustrating another method of applying colours to textiles. It is probably of Rhenish work in the 12th or 13th century, and came from the Eiffel district. The ornament, however, is a survival of a scheme of pattern which was in use in Perso-Roman weavings as early as the 7th century A.D. Fig. 4 shows a piece of red silk printed with a Rhenish adaptation of a 14th century North Italian weaver pattern possessing earlier Byzantine features. The design in Fig. 5 is another Rhenish version of a richer style of 14th-century North Italian weaving. An example of the same kind is seen in Fig. 6, a Rhenish adaptation of a 14th century North Italian pattern often employed in brocade weaving of that period. The pattern in Fig. 7 (Plate II.) is typical of a style introduced during the 15th century in sumptuous damask satins, and velvets woven at Florence, Genoa and Venice. Very different is the style exemplified in Fig. 8, taken from a Dutch 17th century "Indienne," the trade name for such prints. The repeated wide and narrow stripes recall a scheme of design which the Siculo-Saracens of the 11th century employed for brocades; the intertwining floral ornament closely resembles such as occurs in 16th-century Indian cottons; the ornamental border around the field in Fig. 9 shows the reproduction of the Persiansesque spreading tree device often used in Indian palampores from the 16th century onwards to the present day. These, however, were either painted or printed from wood-blocks. The same was the case with the"figures" for the"trellis" patterns, which were used, after the manner of the process which was started, as already mentioned, by Oberkampf and Bell in the 18th century. The remaining figures 10, 11 and 12 are from stuffs mostly printed with subjects of a pictorial character which had a vogue for some time. In Fig. 10—a French print—are family groups: shepherds and shepherdesses with their flocks; children at play; buildings, rocks, trees, Æ_; the decorative effect of which, for the purposes of curtains and furniture covers, resulted mainly from the ordered repetition of these somewhat unrelated details. A landscape with a Chinese pagoda was repeated in lengths of the English cotton printed in red and blue, the ground being of white. This may be seen in Fig. 11. Fig. 12 is from a linen panel printed in colours with a stipple engraving to be used as a small fire screen. The style reflects the pseudo-classical taste of the end of the 18th century in England. Beneath the group of figures in the original is an inscription, "London, engraved and published, August 1, 1799, by A.—Bost No. 207 Piccadilly." This sort of printing has practically disappeared; it was only done on a small scale.

TEXTUAL CRITICISM, a general term given to the skilled and methodical application of human judgment to the settlement of texts. By a "text" is to be understood a document written in a language known, more or less, to the inquirer, and assumed to have a meaning which has been or can be ascertained.
TEXTUAL CRITICISM

The aim of the "textual critic" may then be defined as the restoration of the text, as far as possible, to its original form, if by "original form" we understand the form intended by its author.

Texts may be either autographs or they may be transmitted texts; the latter, again, being immediate copies of autographs or copies of copies in any degree.

Autographs (which may be taken to include whatever, though not actually in the writing of its author, has been revised and attested by him) are not exempt from the operations of textual criticism. Editors of journals remove the slips of the pen of their contributors; editors of books, nowadays usually in footnotes, the similar lapses of their authors. With this branch of textual criticism, however, modern scholarship is not largely concerned. So not with immediate copies. Textual criticism is called upon to repair the mischief done to inscriptions (texts inscribed upon stones) by weathering, maltreatment or the errors of the stone-cutter. Any great collection, such as the Corpus of Latin inscriptions or the similar Corpus of Greek, will show at once its activity and ability in this direction.

The chief field of textual criticism is elsewhere. The texts of the MSS., as we have seen, were written for the most part not on stone but on papyrus, parchment or other perishable material. Of these several copies had to be made, both by way of prevention against the wear and tear of use and as a means of satisfying the desire of other persons than the original possessor to be acquainted with their contents. Had the copies made of ancient writings been mechanical reproductions of the originals, such as the photographic fac-similes of modern times, there would have been little here for textual criticism to do. The ancient texts have not come to us in this way, but through copies made by the human hand, directed more or less by the human intelligence. Now a copy made thus can in no circumstances be a quite exact rendering of that from which it is copied or its exemplar. A copy, qua copy, can never be the equal of the exemplar, and it may be much its inferior. This deterioration increases with the number of successive copyings. Let us suppose that from a text which we will call A a copy has been made which we will call B, and from this again a copy which we will call C. If the copyist of B goes wrong once and the copyist of C twice in a hundred times, then, assuming that there is no coincidence or cancelling of errors, the relative correctness of the three texts A, B, C will be 100 (absolute correctness), 99 and 97-02. If C had made his copy direct from A, his percentage would have been 98.

The importance of this must be borne in mind when we are dealing with transmitted texts, which have passed through many stages of copying.

In the Epitomé of Plautus, 1. 1. 10, the right reading habilitor, "more portly," has been preserved to us by Donatus, an ancient commentator on Terence (Ennuchus, 2. 2. 11). It was corrupted to abolitor by omission of the h and confusion of l and t, and this corruption, which is attested by the oldest extant copy, the Ambrosian palimpsest, was still further corrupted in the other copies to agilitor.

The first step towards the restoration of a text is the examination of the evidence upon which it is or is to be based. This begins with the investigation of its traditional or transmitted form. For this we have usually to rely upon manuscripts (MSS.). By manuscripts (q.v.) we understand copies of the text made before the art of printing came into general use. These may be either extant or non-extant. The evidence of extant manuscripts must be ascertained by collation. To collate a manuscript is to observe and record everything in it which may be of use towards determining what was written in the source or the sources from which it is derived. A manuscript is not usually a clean or single piece of writing; it is commonly found to contain alterations by erasure, addition or substitution. Such alterations may be due to the writer or writers of the MS., called the scribe or scribes, or to some other person or persons (for there may be several) called correctors. The relative importance of these corrections, it is obvious, may be very different. It is therefore necessary to distinguish the different hands which have been at work on the manuscript. Account must also be taken of the number of lines in each page, the number of pages in each quire, of gaps or lacunae in the manuscript, and so forth. The work cannot be considered complete till all the extant manuscripts have been collated or at least examined.

When this is done we shall have the materials for pronouncing a judgment upon the text as directly transmitted. Perhaps there is only one extant MS. of the text, as in the case of the Mss. of the Annals and Histories of Tacitus. Then this part of our work is done.

But often we have to take account of a number, and it may be a large number, of manuscripts, whose respective claims to attention we must determine. In the first place we shall discard all manuscripts which are derived by copying from other extant manuscripts. If a MS. is immediately or ultimately derived by copying from another MS., it cannot, qua copy, tell us anything that we do not know already if the latter MS. is known to us. But how can we tell that a MS. is so derived? The clue we shall have to follow is that the more the differences between them must be such as to permit of no other explanation. In the absence of explicit dates the relative age of MSS. is often hard to determine, and hence the criterion of unmistakable resemblance is one of special importance. If the MSS. agree in singular though trivial mistakes, if they omit, apparently without motive, words and passages which other MSS. preserve, we shall be safe in pronouncing that there exists a close bond of connexion between them, and if one of them shows errors which, though strange in themselves, are quite intelligible when we see what stands in the other, then we shall be justified in concluding that the second is that from which the first is derived. For the proper consideration of such points a personal examination, autopsia, of the MSS. or of facsimiles of them, is very often indispensable. It was thought at one time that a MS. of the Latin poet Propertius at Naples (Neap. 268) might have independent value as an authority for the text. But its claims were disposed of when (amongst other facts) it was observed that at book iv. 8, 3, the MS. with which it most closely agreed (F, No. 36, 49 in the Laurentian library) had a gap at the beginning of the line and only the end words "utus est tutela draconis," with the marginal note "non potuit legi" and that Neap. 268 gives the line as follows, "non potuit legi utus est tutela draconis." Accident apart, identity of reading implies identity of sources. The source of a transmitted reading may undoubtedly be the author's autograph: but if not, then it is some MS. in the line of transmission.

The peculiar resemblances of two MSS., though not sufficient to warrant the derivation of either from the other, may be sufficient to establish some connexion between them. From the axiom which has just been cited it follows that this connexion can be due only to community of source, and we thus arrive at the idea of families of MSS. Suppose that a text is preserved in seven MSS., A, B, C, D, E, F, G. If we find that of these A stands apart, showing no great similarity to any of the other six, while B, C, D on the one side, and E, F, G on the other, much resemble each other though differing considerably from the rest, we may express this by saying that B, C, D form a "family" descended from a hypothetical common "ancestor" which we may call X, and E, F, G another "family," descended from a hypothetical "ancestor" which we may call Y. The readings of X which can be deduced from considering the agreements in B, C, D will be of higher antiquity and of greater external authority than any of the readings in B, C, D taken singly. And similarly for the readings of Y and those of E, F, G. Nor shall we stop here: but we shall further compare the readings of X and Y with each other and with those of A, and thus deduce the readings of a still more remote ancestor which we may call Z. Z will be the archetype of all our existing MSS., and we may embody our results in a pedigree of manuscripts or stemma codicum as follows—
If we have done our work properly, the texts that we arrive at for X and for Y will be freer from error than the texts of the separate members of the families B, C and D, and E, F, G respectively, and that of Z freer from error than that authenticated by any existing MS.

The procedure, however, is by no means always so simple. That a text may be improved by the comparison of different MSS. is not a modern discovery. It has long been known, and the knowledge has led to the production of what are known as conflated manuscripts or Misch-codices. These are MSS. produced by "crossing" or "intermixture." In the following stemma M and N are "mixed" or "conflated" MSS., being formed by the blending of readings from the "pure" or "unmixed" codices A, B and D, E respectively.

Intermixture may take place to any extent, and the more of it there has been the more difficult does it become to trace the transmission of a text.

Whether crossing improves a given text or not depends ultimately on the knowledge and the judgment of the crosser, and these will vary indefinitely. On the whole it is probable that it does, provided it is not accompanied by other attempts at improvement. If it be, as may very well be the case, the text will probably suffer. For but a small proportion of scholars' corrections are really amendments, and a far smaller proportion of scribes'.

The "genealogical" method, as we may call it, cannot in strictness be applied to conflated MSS., as their mutual relations can rarely be with certainty disentangled. But it is often possible to detect in such MSS. a common strain, shown by their agreement in peculiar corruptions or in probable readings which these latter would have had to be discovered by conjecture. This is practically an application of the method to a portion of such manuscripts.

A special value attaches to a conflated codex when one of the MSS. from which it has been compounded has perished and its readings are thus otherwise irrecoverable. This is exemplified in the Neapolitanus of Propertius, a manuscript now at Wolfenbüttel.

It not unfrequently happens that good or instructive readings are found in manuscripts which are in general of small trustworthiness (see below), and whose relations to the general tradition it is not worth while to investigate. These readings may be cited by the name of the MS., or if still greater brevity is required as the readings of inferior MSS. (deteriores), or, as is frequently done, by the symbol S.

Non-extant Manuscripts.—Some of the most valuable of ancient MSS. have disappeared since their discovery in modern times. When this has happened we have to rely upon mere copies, many times of inferior quality, or upon the information which old scholars have given us respecting them. In the latter case what we have are not "collations," for the art of collation was not understood till the 19th century, but selections or "excerpts" of readings which we have reason to fear are often imperfect and erroneous. Further, it must not be assumed that all readings which are cited as being "ex utroque codicibus" are necessarily from older or better MSS. than we now possess or indeed from MSS. at all. Scholars since the Renaissance have not always been above inventing codices to obtain currency for their own conjectures. The codices of Bosius (1535-1580) are just as imaginary as the "old plays" which appear as the source of so many of the quotations that head the chapters of the Waverley novels, and suspicion rests on Barth, Lambinus and others.

Some texts and portions of texts of ancient writers are now only known from printed books. The metrical treatise of Terentianus is now preserved in the editio princeps (1497) alone. All known MSS. of Silius Italicus have a considerable gap in the 8th book, first filled up on the authority of Jac. Constantius (1503), and not printed with the rest of the poem till the edition of Aldus (1553). The early printed books are often called by old scholars codices impressi (lypis), "printed manuscripts," a phrase which at first seems curious to us but becomes perfectly intelligible when we examine these codices impressi and observe how closely they follow the codices scripti. By the methodical employment of these means we shall arrive at a text different from any existing one. It will not be the best one, possible or existing, nor necessarily even a good one. But it will be the most ancient one according to the direct line of transmission, and the purest in the sense of being the freest from traceable errors of copying and unauthorized interpolation.

The textual critic has occasionally to deal with the effects of oral transmission. A text so transmitted must in the lapse of time be profoundly though insensibly modified, its forms and expressions modernized, and, if widely disseminated, local variations introduced into it. This is the case with the Homeric poems, the ascription of the original form of which is a task beyond the powers of criticism. Even where, as in the Vedas, the sacred books of India, there is proof that the work has been transmitted without change through many centuries, the existence of unintelligible passages and metrical verses shows that here too there is work for textual criticism to perform, though in the opinion of most scholars it should be confined to the restoration of such forms as would be unconsciously and inevitably corrupted through changes of pronunciation and the like.

The invention of printing has naturally limited the province of textual criticism, and modified its operations. The writer's autograph, if it is preserved after it has been through the hands of the printer, has seldom more than an antiquarian value. As a source for the text it is superseded by the printed edition, and if there is more than one, then by the latest printed edition, which has been revised in proof by the author, or, in certain cases, by his representative; and the task of the textual critic is restricted to the detection of "misprints," in other words, of errors which the compositor (the modern analogue to the scribe) has made in setting up the manuscript, and which have escaped the notice of the proof-reader and the author or his representative. If, however, this revision has been neglected or incompetently performed, the number of such mistakes may be considerable.

Another question with which the textual critic of modern authors must be prepared to deal is the relative importance of different editions, each of which may have a prima facie claim to be considered authentic. Thus Shakespearean criticism must decide between the evidence of the first folio and the quartos: the critic of Shelley's poems must consider what weight is to be attached to the readings in the posthumous edition by Mrs. Shelley, and in unpublished transcripts of various poems. Where there is great or complicated divergence between the editions, as in the case of Marlowe's Faustus, the production of a resultant text which may be relied upon to represent the ultimate intention of the author is well-nigh impossible.
according to the degree in which the volition of the copyist is absent or present, as involuntary or mechanical, semi-voluntary and voluntary; or again as they affect single signs (letters, figures or symbols), words, lines or even larger units such as sentences or paragraphs.

Simple Errors of the Eye.—(a) Confusions of letters. These are very numerous, and different in different scripts or styles of writing (see Palaeography). Thus the Roman letters E and P are liable to be confused in capital script, but not in cursive (cf., C, G, in capitals, c, e in the cursive writing called Caroline in the 13th century, p, P in the angular cursive of the 13th century and later. Texts which have had a long history will often show by the letter-confusions which they exhibit that they have passed through several distinct stages of copying. It is to be observed that two different styles of writing are often found in the same manuscript, the difference being utilized for the purposes of distinction. Thus in Greek cursive MSS. notes were often written in uncials; the use of majuscules or capitals for headings and for the initial letters of titles is well known. (b) Omissions of letters. (c) Shiftings of letters, sometimes by syllables. This is common in half intelligent or half mechanical copying. In printing we find another kind which is known as "pie." (d) Confusions of symbols and abbreviations.

Examples of confusion of capital letters from Shelley's poems are: "Prometheus, i. 553, "Mark that outcry of despair" for "Hark"; Helias, 472, "Hold each to the other in loud mockery" for "Tell." Of cursive letters: Marenghi, 130, "the dim ocean" for "the dim ocean"; "the limpid" for "limpid"; "the drudge" for "drudge." Of letter-mistakes: above [One chasm of Heaven smiles like the age of Love | On the unquiet world] for "eye." (b) Translations from Goethe's Faust, i. 26, "To live more beautifully than any beast," for "beautifully;" i. 165, "eye" for "eye" (in spite of the rhyme with 163). (c) "Prometh., iv. 572, "Neither to change, nor Hatter, nor repent," for "faller." In Latin MSS. we often find a mere transposition of letters. (d) Confusion of words through abbreviations is very common in ancient MSS., where they were much employed. At a famous place in the dactylopa of 1 Timothy iii. 16, the MSS. vary between [297] or [298] and [299]. In uncial writing OC [88] might be written as [OC] or [OC].

Loss of Letters, Syllables, Words or Lines, through Similarity of Writing: Homoeographon.—When similar letters or groups of letters stand next to each other, one of these is liable to be omitted. This is the simplest case and is called haplography.

Similarity operates differently if the similar groups stand in different lines of the exemplar. Then the copyist's eye is apt to slip from the first of two similarly written groups to the second; and he will thus omit all that is between. The term homoeoteleuton ("similarity of ending") is often used of these omissions, but it is not adequate, as similarity anywhere may produce the same result.

Examples of homoeographon and haplography. Shelley's Cenci, v. 4, 130, "whose love was [a] bond to [a] kub our loves"; a similar omission in Witch of Atlas, 590. In Stanzas written in Dejection near Naples the two lines 4, 5, "The purple noon's transparent might, | The breath of the moist earth is light," were printed in the 1st edition. "The purple noon's transparent light," owing to the homoeographon "might," for "light."Omissions through Simple Negligence.—Groups of letters, words, syllables and lines are often omitted without any contributory cause. Short words or such as are not necessary to the sense are especially prone to thus disappear.

Examples of omission. Shelley's Prometheus, iii. i, 70, "No refuge! No appeal! Sink with me [then]!" Cenci, i. i, 26, "A refuge [me] from Hell!" So may the Devil! Despite their souls from Heaven!"; Helias, 657, "Bask in the [deep] blue noon divine"; Julian and Maddole, 218, where "Moans, shrieks, and curses, and blaspheming prayers" is absent in the earlier editions. The omission required for the rhyme; so lines 299-301 of the Letter to Maria Gisborne.

Repetitions: Ditography.—Letters, groups of letters, words and lines may be written twice (or even oftener) instead of once. Other repetitions of words already written and anticipations of words yet to be written are also found, through the scribe's eye wandering into the preceding or the following context. Wherever the word or group of words repeated is not the one that he has just copied loss is liable to occur.
Dittography is common enough in manuscripts but is usually detected in reading proofs. In the unique MS. of Cicero's treatise De legibus, secutus appears as "secutatus secutus." Other kinds of repetition are Shelley's Witch of Atlas, 611 seq., "Like one asleep in a green hermitage, | With gentle sleep about its eyelids playing | (sleep for smiles has come from the previous line) | Book II. 195. Where a new copyist instance in Horace, Odes, ii., 11 seq., "festus in pratis vascul ovis et canem pugnus" | where some MSS. give herdus, a reminiscence of Isaiah xi. 6, "The leopard (pardus) shall lie down with the kid." In iv. i, 20, for "trobe citræ|many MSS. have 't robin' in the old text." A curious instance in Homer's Iliad, xii. 338, "suffertur, an explanation of monstri. The celebrated passage about the three heavenly witnesses inserted in the Epistle of St John (v. 2) seems to have been originally a comment explanatory of the text.

Confusions of Words.—Words are not only changed through confusion of single letters or abbreviations, but also through general resemblance (or a semi-voluntary change) through similarity of meaning.

Shelley, Prometheus, ii. 2, 53: "There streams a plume-uplifting wind | For 'streams' In Shelley's lines, When the lamp is shivered, vv. 5-6. "Where the lust is broken, | Sweet tones are remembered not," the printed edition had "notes" for "tones." In Mrs Gaskell's Cranford, ch. xiv. (near the end), "The lunch—a hot savoury mustard-chop and a little of the cold lion sliced and fried —was now brought in 'is the reading of most if not all the editions; but 'join' should be 'lion,' the reference being to the padding, a lion with curvant eyes," described earlier in the chapter. In Shelley's The Cloud, Poets ed., 266: "For barriers of enormous cloud" for "cinereous"; "Hymn to Memory" (trans.), 57, "And through the tortoise's hard strong skin | For 'By the leopard's skin.' The Boat on the Serchio, 117, "woods of stunted trees" for "pine" ("the rhyming variety"; Prince Alphonso, 250, "And sea buds burst beneath the waves serene" for "under."

The same character frequently attunes to transpositions of words and parts of words. The copyist does not as a general rule consciously intent a change, but he falls into one through the influence of dominant associations. He substitutes an order of words which, in respect of syntax, metre or rhythm is more familiar to him. The transposition of words, if not purely accidental, as in Chaucer, "Parson's Tale," p. 689 (ed. Skeat), "God yaf (gave) his benison to Laban by the service of Jacob and to Pharao by the service of Joseph," where the MSS. transpose Laban and Pharao, are generally to a more usual order, as in Shelley's Witch of Atlas, 65, "She first was changed" to "she was first changed." A multitude of transpositions of words in part is in Shelley's: "Invocation to Misery, I. 27, And mine arm shall be thy pillow," the word 1ed. have third and "my pillow." With this we may class faulty division of sentences. Wrong punctuation is a common error and usually easy to correct.

As an example of mispunctuation we may take Shelley's Triumph of Life, 188 seq., "If thou canst, forbear | To join the dance, which I had well forborne | Said the grim Feature of my thought | "Against thee," said the grim Feature (of my thought aware) "I will unfold.""

Grammatical Assimilations.—These are often purely mechanical errors: but they may be semi-voluntary or even voluntary, the copyist desiring to set the syntax right.

Examples: Shelley: Rosalind and Helen, 63, "A sound from thee, Rosalind dear! instead of there; Blast of Arachny, 280 seq., "A sound from thee, Rosalind dear! Instead of there, Blast of Arachny," which bow the human heart with tares," for "tours.

Insertions (or Omissions) of Seemingly Unimportant Words.—These, inasmuch as they must often import some judgment on the sense of the passage copied, will be frequently semi-voluntary if not voluntary.

Examples: Shelley, Prometheus, iii. i, 5, "The soul of man like | [unextinguished fire.]" So in Triumph of Life, 265, "Whom from the flock of conquerors! | Fame singled out for her thunderbearing | union, out seems to be due to the composer.

False Recollections.—The passage which a copyist is reproducing may suggest to him something else and he will write down what is thus in his mind instead of what is before his eyes.

This is very likely to occur in a new copyist instance in Horace, Odes, ii., 11 seq., "festus in pratis vascul ovis et canem pugnus" | where some MSS. give herdus, a reminiscence of Isaiah xi. 6, "The leopard (pardus) shall lie down with the kid." In iv. i, 20, for "trobe citræ|many MSS. have 't robin' in the old text." A curious instance in Homer's Iliad, xii. 338, "suffertur, an explanation of monstri. The celebrated passage about the three heavenly witnesses inserted in the Epistle of St John (v. 2) seems to have been originally a comment explanatory of the text.

Transpositions of Lines and Passages.—This kind of transposition is really arrested loss. An accidental omission is discovered, and the person responsible, or another, places what is omitted in the margin at the foot of the page or in some other part of the text, usually adding a mark to show where it ought to have been. The next copyist may easily overlook this sign and thus the passage may be permanently displaced. In Chaucer's Canterbury Tales, most MSS. place the couplet, "And eek of many another manner crynse | Which nedyth nat referenc to this tryme," which should stand after v. 8 of the "Friar's Tale," in the Prologue to the Tale before the fourth line from the end. In the "Monk's Tale" a block of 88 lines (3565-3652) is transposed in most MSS. to follow 3596.

Interpolation.—This is the deliberate alteration of an exemplar by a semi-voluntary substitution of an omission, but when it takes the particular form of omission it is naturally very hard to detect. Interpolation then always has a motive. The most frequent motive is the removal of some difficulty in the sense, expression or metre of the text, and especially obvious gaps or corruptions which the interpolator endeavours to fill or to heal. Fraudulent interpolation, whether the fraud be pious or otherwise, does occur, but is comparatively rare. The removal or the mitigation of objectionable matter is also occasionally found. Interpolation is then a voluntary alteration, but in practice it is often hard to distinguish from other changes in which its motive is "incorrect.

The usual character of scribes' alterations is well illustrated by a passage in Bacon's Advancement of Learning, II. xix., "For these critics have often presumed that that which they understand not is false set down as: the Priest that where he found it written of St Paul Demissus est per sportam | [Acts ix. 25] "memorized his book, and made it Demissus est per postram, because sporta was an hard word, and out of his reading." Shelley in Triumph of Life, 201 seq., wrote, "And if the spark with which Heated on my spirit | Had been with proper nutriments supplied," but the printed editions made it "sentiment." The transcript used for the printed edition of Morengi apparently often corrupted what was rare and strange to what was commonplace; e.g., i. 119, "dweglobes" to "dewdrops." Interpolation is sometimes due to an inopportunely use of knowledge, as when a quotation or a narrative is made to agree with what the interpolator has read elsewhere. The text of the Bible, for example, is interpolated (as the text of the Odes, ii., iii. and iv., 250 seq., the Old Testament of the Old Testament, etc., older than those accessible to Origen, was much altered by him in order to make it conform more closely to the Hebrew text with which he was familiar, and in the Synoptic, Gospels changes are found, the aim of which is to "harmonize" the accounts given by the different evangelists. Deliberate alteration is occasionally due to disapproval of what stands in the text or even to less creditability. The interpolator leaves the text as he finds it, and introduces nothing. Interpolation is that some lines in Homer's "Catalogue of the Ships," Iliad, ii., 553-555 and 558, were introduced there to gratify the vanity or the disapproval of the Athenians. Insertions of this or of a similar character may be made by a copyist from a few words to a whole chapter or a complete poem. Literary forgery has never set any bounds to itself, and the history of every literature will supply examples of entire works being forged for the benefit and personages of repute. A notable one was the Epistles of Phalaris, a late Greek forgery, demonstrated to be such by Bentley in a treatise which is a model of what such a demonstration should be.
TEXTUAL CRITICISM

Special Conditions conducing to Corruption.—The chief of these is strangeness or difficulty in the matter to be copied. Proper names, technical expressions, quotations from foreign languages, and frequent change of subject, are all likely to cause difficulty to a scribe and error in his work.

Careful and continuous regard to the various kinds of error and defaults that are found in transcription will enable us to judge whether a reading which it is suggested stood in the archetype of our text is likely to have been corrupted to the reading, or readings, which stand in the present manuscripts or editions. If it is, we say of this reading that it is transcriptionally probable.

Some precautions must be observed. First we must rule out any proposal which assumes confusions of letters and abbreviations which are not attested for the particular tradition. Secondly, since different scribes are prone to different kinds of error, we must ever bear in mind the particular failings of the scribes responsible for the transmission of our text as these failings are revealed in the apparaus criticus.

Maxims of criticism to which we may here refer are that “harder readings are better than easier” and that “the shorter reading is generally the truest.” The first maxim is indisputable, provided we understand by “harder” harder to the scribe, and by “easier” easier to the scribe. The characteristic of scribes’ emendations or interpolations is that they are superficial. Their mark is that at the time of their making they “combine the appearance of improvement with the absence of its reality” (Westcott and Hort, New Testament, i. p. 27). The second maxim refers to the well-known fact that accretions from marginalia, &c., lengthen and at the same time weaken a text.

The virtues of a scribe are honesty and care (or in a single word fidelity) and intelligence. But it is rare to find these combined in a very high degree, and out of them we can least easily dispense with fidelity. Paradoxical as it may seem, the mechanical corruptions of a stupid but faithful copyist may tell us more than the intelligent copyings of a less faithful one.

A nice question is how far any alteration of the text of the exemplar is compatible with fidelity. Is a scribe, who recognizes under a corruption the word certainly intended, to perpetuate the error of the exemplar? Considering the liability of corruption to breed corruption we can hardly blame him if he does not, and we may say that it is no infraction to his fidelity if he makes self-evident corrections. But with these he must stop.

At certain epochs in the transmission of literature systematic efforts have been made to improve the transmitted texts, and these efforts have naturally been accompanied by a good deal of emendation both successful and unsuccessful. Such an epoch was the revival of Latin and Greek learning in the 15th century, and a modern scholar would for that reason naturally prefer to have a manuscript to work on, which was written immediately before this epoch to one which was written immediately after it.

The fidelity of a scribe has to be judged chiefly by internal tests, and these are best applied to his work in passages where there is no reasonable doubt of the correctness of the transmitted text. But there are two tests of a more objective character that may be used—orthography, and indication of lacunae or other faults in his exemplar. A scribe who preserves in his spelling the traces of a bygone age is probably trustworthy. If faithful in small things, he is likely to be faithful in great. A scribe again who scrupulously records the presence of a lacuna or illegibility in what he is copying, inspires us with confidence in the rest of his work.

As regards the use of testimonia, it may be observed to begin with that they do not of themselves depend on the trustworthiness of the texts of the writers from whom they are taken, and further upon that of the text used by the translator, the excerpator or the quota, about which we can know nothing for certain, though we may sometimes make probable inferences. In the case of quotations we must allow for failures of memory.

Many times in the course of his investigations the critic will be confronted with problems which cannot be resolved by considerations of transcriptional or documental probability. To take an instance already referred to, it is not clear at first sight whether in the couplet from Propertius Scythiae is more likely to be a misrecollection of some text of the 1st century A.D., or Scythicis some scribe’s assimilation which made its way into the transmitted text in the course of the next thousand years.

This leads us to consider Intrinsic Probability. By this is meant the likelihood that the writer of our text would at the time of writing have written, or not have written, a particular rendering. Two questions which may be separated, though they are not entirely distinct, are here involved. What was the meaning of the writer? And how did he express it? The sense may be clear though the words may no longer be determinable.

A reading may be impugned on a number of grounds: that it gives no sense or an inappropriate sense, that it involves a usage or an idiom not current at the assumed time of writing, or foreign to the reputed author, or to the style in which he then was writing, that it involves some metrical or rhythmical anomaly, or that the connexion of thought which it produces is incorrect or disorderly. These charges cannot be played off against each other. It is no answer to the objection that a reading in some Roman poet makes nonsense to say that its Latinity is perfect or its metre excellent. But they may reinforce each other, and to such corroboration great weight must be assigned.

To set the meaning of a passage in a foreign language before us we must frequently have recourse to translation. But this method of representation is a very imperfect one; we may easily impose on ourselves and others by strained and ambiguous renderings. A more subtle danger to which we are especially liable is that the correct reading of a text, which we believe to be correct in a sense which satisfies us but which would not have satisfied the ancient writer, above all we must avoid applying our own standards of taste, style and morality to the judgment of the text before us. The textual critic has no concern with what the writer ought to have thought or said; his business is solely with what he did say or think or might have said or thought.

Amongst the legitimate reasons for suspecting the correctness of a text are patent contradictions in a passage or its immediate neighbourhood, proved and inexplicable deviations from the standards for forms, constructions and usages (mere rarity or singularity is not enough), weak and purposeless repetitions of a word (if there is no reason for attributing these to the writer), violations of the laws of metre and rhythm as observed by the author, obvious breaks in the thought (incoherence) or disorderly sequence in the same (double or multiple incoherence).

Where the critic has ascertained the earliest form of a reading in his text, he will apply to it the tests of intrinsic probability. No part of a text can be considered exempt from this scrutiny, though for a very large part of it it may be dispensed with. It should, however, be here observed, that whoever takes a reading without investigation, on the authority either of a manuscript or of a great scholar, or of a number of scholars, ceases for the time being to be a textual critic.

After every such critical examination four conclusions are possible—acceptance, doubt, rejection and alteration. In other words, a critic may deliberately pronounce that what stands in the text represents what the author wrote or might well have written, that it is doubtful whether it does, that it certainly does not, or, in the last event, that it may be replaced with certainty by something that does. In the three first cases his judgment will be governed by considerations of intrinsic probability alone: but in the last it must regard transcriptional probability as well. No alteration of a text, or emendation, is entitled to approval, unless in addition to providing the sense and diction required, it also presents a reading which the evidence furnished by the tradition shows might not improbably have been corrupted to what stands in the text. These tests, and these alone, are emendations bound to satisfy; but others are often tacitly imposed upon them. Of this the transposition of lines is the most notable example. This kind,
of change is troublesome to estimate and inconvenient to adopt, as it involves placing passages where we are not accustomed to look for them; but to the question, did the author write the passage here or there? the matter of our trouble or inconvenience is wholly irrelevant. There is, however, one class of cases in which no conclusion can be drawn, documental and intrinsic probability both failing us. This is where two alternative readings, neither of which can have come from the other, have equal external support and equal intrinsic merit. Isolated discrepancies of this kind may be due to some accident to our text at a period now beyond our power to trace. Numerous and doubtfully decisive discrepancies may also be due to the fact that there was more than one edition or recension of it in early times, or to the author leaving his work in such a condition that such discrepancies must inevitably gain currency. In the case of dramas, different acting editions will give rise to them.

Up to this point all schools of textual criticism are theoretically at least in accord. But here begins a divergence which has done more than anything else to discredit the study with the outside world. It emerges because in all judgments on textual matters it is presupposed that they will be acted on, that a reading accepted will remain in printed text, and that a rejected one, enclosed between in brackets or removed, and, in this last case, something else substituted in its place.

The "conservative" critic's chief concern is for the safety of the traditional and by preference the transmitted text. He urges very rightly that if alteration is carried beyond a certain point it cuts away its own foundation, and so all certainty is destroyed. His objective is the minimum of change. And as the need of making a text compels some sort of decision in every case, the "doubtful" readings of the tradition, some of which on the evidence would be doubtlessly accepted, and others doubtfully rejected, will all appear with the accepted in the text. As to alterations (emendations) that are less than certain, his attitude is clearly if somewhat crudely expressed in the dictum that it is better to leave in the text "what if not the original reading is at least the remains of it." The corresponding thesis of the opposite school would be that it is better to present to the reader something which the author might have written than something which he could not: or, in other words, that "stopgaps" should be preferred to débris.

An editor of a corrupt and disputed text may reasonably adopt either of two methods of emendation. He may proceed on the principle that the external evidence warrants, and place all plausible suggestions for its improvement in notes or appendices. The text will be faithful but unreadable, and his work will be that of an honest man but of a textual antiquarian, not a textual critic, since he declines the duty of "the restoration of the text, as far as possible, to its original form." On the other hand, the editor will provide all necessary information about the evidence for the text in the notes of his critical apparatus; but in the text itself he will give whatever in each case is supported by the balance of the probabilities. Each and every case he will decide on its own merits and without reference to decision upon the other cases not now before him. Special consideration will be paid to "doubtful" readings, which will be distinguished in his work as "doubtfully accepted" or "doubtfully rejected." Legitimate doubt arises when the evidence pro et contra of documental and intrinsic probability is equal, or nearly equal, or when documental probability points strongly to one side and intrinsic probability to another. Illegitimate doubt is the uncertainty of the doubter as to whether he has examined the whole of the evidence. Such doubt is much more frequently felt than acknowledged, and its effect upon critical work is highly injurious. On the one hand, it is apt to take refuge in an uncritical acceptance of the traditional readings, and on the other hand, to produce a crop of hesitant and mutually destructive conjectures which a reader naturally resents as a needless waste of his time.

The so-called "conservative text" is neither an antiquarian's text nor a critic's text, but a compromise between the two. When it is conscientiously obtained, it is arrived at by handling capping, more or less heavily, intrinsic probability as compared with documental probability, or by raising the minimum of probability which shall qualify a reading for admission into the text until it is in agreement with the notions of the editor. Both of these procedures are arbitrary in their principle, and liable to be erratic in their application. The text will suffer whichever course is adopted, and it will suffer the more the more conservative is the editor, as may easily be shown. Thus, to take the latter one, if we suppose that of two editors of equal competence A requires a probability of four-fifths to admit a reading and B only three-fifths, we see that in all the cases in which the probability lies between these two fractions B will be right seven times to A's three, while outside these limits there will be no difference between them.

Many persons appear to suppose that decisions upon doubtful points can be avoided by the expedient of leaving the traditional reading in possession of the text. The rule is a simple one and easy to apply. But owing to the constitution of the human mind it has consequences which possibly they have not contemplated. The great works of classical literature are not studied for their textual specimens, and they will be studied the more the more they contain to repel and disquiet the reader. If a corruption is left in a text when something might be substituted which would at least, as a "stopgap," give the sort of sense required, then one of two things must happen. Either the sense of the passage is blotted out for the reader and the conservation of the corruption is tantamount to the expunging of the rest of the sentence, or else he will obtain the required sense by wresting the meaning of the other constituents of the context until it furnishes it. So far so good: the requisite sense has been obtained, but the price has now to be paid. And the price is that the reader's perception of the signification of the word or words so wrested is dimmed and impaired, and his power of discriminating and understanding them when he meets them again is shot with doubt and error.

In dealing with writings in dead languages this is particularly mischievous.

There are two reasons in particular why the part which emendation plays in the shaping of Greek and Latin texts is apt to be overlooked. Most people take their notions of a classical book not from its traditional form but from a "received" or revised text. The text so revised is readable, because it has been purified by the continuous emendation of scholars during several centuries. But the received conjectures which make this text acceptable have no more authority in themselves than equally good conjectures which have not yet won their way into the text, and it is clearly illogical to treat a text largely built upon conjectures as if it were now beyond the reach of conjecture. Again, it has often happened that readings which have been discovered by conjecture, and as such received into a text, have afterwards been found to have the support of MSS. Thus in one speech of Cicero, pro Caecillo, some thirty conjectures of critics were found to be attested by a single recently discovered MS. Such readings it is now commonly the practice to transfer to the credit of the MS. and to suppress the fact that they were originally discovered by emendation. These confirmanions, as they are called, should be carefully recorded in all critical texts, inasmuch as they constitute the most striking justification of the critical method.

Some examples from Shelley's poems are Prometheus, ii. 3, 50, "See st, than shapes within the mist" (Epitaph for "I see thin shapes"); 10, iv, 442, "Purple and azure, white and green" (and inserted by Rossetti); Prince Anthanor, 150 sqq. "the rugged path | Where she once saw that horsemann toil, with brief | And blighting hope, who with the news of death | Struck back body and soul as with a mortal blight" (Blighting, condemned by Rossetti, is cancelled in the Bodleian MS.).

It is a weakness of conservative critics to extol interpretation (or exegesis) at the expense of emendation. Some have even ventured to say that the successful defence of a passage in a text is a greater service than its successful correction. This is not true. The service to the text is the same, what was previously dark being now made clear. But the emendation
TEXTUAL CRITICISM

deserves the higher praise as being in most instances the more difficult achievement. The fault of the opposite school, on the other hand, lies in dispisting conjectural and to regard corrections as the proper field of a scholar and gentleman. This bias is reflected in the maxim that "correction should precede interpretation," which is no more than a half-truth. For emendation must inevitably fail unless it express the meaning which the proper interpretation of the passage has shown to be required. Further, a corrector may propose the right word with the wrong meaning. Yet the custom is to give the credit of the emendation to him, and not to a successor who has seen what the right sense was and that this was the true one. This must be considered once if not twice, first assigning the wrong sense to the passage and then selecting what (in most cases) would be the wrong word to express it. The proper course would be not to mention the first conjecturer or to mention him only for his error.

One of the most vexed questions of textual criticism, and one which divides scholars more perhaps than any other, is the question to what extent admitted imperfections and inconsistencies may properly be left in a text as due to the default of an author rather than of a scribe or compositor. No universal rule is here determinable. Each case must be considered on its merits and the critic's procedure must of necessity be "eclectic." An epitaph often used with a tinge of reproach, the ground for which it is not easy to discover. Two general considerations may be indicated. If the autograph of a work is not accessible, there is no means of distinguishing between the involuntary errors of a scribe and the involuntary errors—"slips of pen"—of an author. For the latter are in fact only scribe's mistakes, the author being his own amanuensis. To take the example given under Confusions of Words above, *loves* in Cranford is probably a printer's error, but *love* is the expression that it is, an involuntary and the author's mind or pen through the accidental proximity of the "mutton chop."

Passing over this class we come to one about which there may frequently be serious doubt. What is clearly erroneous or faulty may as clearly be intended, and therefore not be removed by the critic. In Chaucer's "Miller's Tale" (3457, 3457) *astronomy* is used for *astronomie,* and *Noël* and *Noël* (Christmas) confused, "Nowell's food" (3457, 3457), because the speaker is an illiterate carpenter. In the Prologue to the "Parson's Tale" 10 there is, on the other hand, a mistake of his own, which no judgment on interpolation or removing, the context will make. The speaker being said to be "the moon's exaltation when it should be Saturn's. But this error in an astrological detail would not warrant us in assigning to the poet the blunder about Jacob and Laban in the same tale (see above). Much depends on the precision with which an error can be corrected: wherever there are more plausible ways than one of doing this, the faulty reading must be allowed to remain. Collateral as well as direct evidence must be obtained. If there are a number of instances where there is faultiness which is hard to remove, it is probable that the evil lies too deep for emendation. The author's own carelessness may be to blame, or, as in the case of Virgil and Lucan, he may not have been allowed to put the finishing touches to his work.

Certain lapses from grammatical correctness and metrical regularity that we find in the poems of Shelley are undoubtedly due to the author, though the number of these has been reduced (as Mr. Buxton Forman has pointed out) with our improved knowledge of the sources of the text. Amongst the sources we have *Probable Writings* (297), "The shadow of thy moving wings imbus / its deserts and its mountains," "To a Skylark" (86), "Thou lovest— / but never knew love's sad satisety." The solecism in the Preface to *Prometheus Unbound* (27) an interpolation, a reminiscence to the narrow principles of taste on which several of his earlier compositions were modelled *prove* at least that I am an impartial judge," would probably have been corrected by the poet if his attention had been called to it, but the two first verses, with others, cannot be removed. We may detect occasional laxity also in his handling of his verse. Lines are left unrhymed: e.g., *Julian and Maddalo* (311); *Rosalind and Helen* (366). Or the same word is used in place of another rhyming word: *Revol of Islam* (3573 and 3576, 3829 and 3831). In the * Daemon of the World* (342), Shelley himself cancelled a metrical reading for one that makes the verse a syllable too short. It is in this department of criticism that the personal equation has the freest play, and hence the natural adherents of either school of critics should be specially on their guard against their school's peculiar bias.

The part which conjectural emendation should play must obviously be very different in different texts. In the New Testament, for example, this part is very small indeed, though it cannot be altogether excluded. Colossians ii. 18 is corrupt as it appears; but the adoption of a correction recommended by Bishop Lightfoot and Dr. C. Taylor will restore it to sense. It has been maintained that emendation (being guessing) is no part of textual criticism at all, though judgment upon which this is, the case it must of course be, is not likely to be generally accepted. But it does contain an element of truth and indicates a well-founded reproach against the majority of those who practise conjecture. Nothing has discredited emendation as a means of improving texts more than the want of method, common care and research, which those addicted to it show. Some of the most distinguished scholars have offended worst. The * Millon of Bentley, England's* greatest critic, is a by-word. To examine all the causes which may vitiate emendations would mean writing a treatise upon human frailty. But it may be said that the vast majority of them should never have been made at all. Their proposers do not take even elementary precautions to be right. An inquirer who examines the stars with a shilling telescope is not likely to make observations of value, and even a trained astronomer has to allow for his "personal equation"—a point to which even a finished critic rarely attends. Successful emendation requires a rare union of qualifications—insight, prudence, patience and familiarity with the author emended and the conditions of his text. If any of these is absent, the work is apt to be worse. What is certain is that the absence of editors in a reading is no proof and often no presumption either that their agreement is independent or that their reading is right; and on the other that, though independence may generally be granted to coinciding emendations of different scholars, yet from the general constitution of the human mind it is likely that not a few of these will be coincidences in error rather than in truth.

One of the marks of a great textual critic is his attention to details. He will not consider his work upon the text complete until he has made it, as far as he can, such as the author would approve in every particular. Accordingly he will restore the spelling of the author if that can be ascertained: he will not accept the corruptions which have been introduced into it by copyists or printers, even though these may not affect its sense, nor will he modernize it so as to bring it into harmony with that of a later and to him a more famous age. Thus, to take an example, he will not print a critical text of Plautus with two letters (Y and Z) which were not part of the Latin alphabet in the age of that comedian; still less will he introduce into Latin texts distinctions, such as € and ç, which were not used till long after the middle ages.

As time goes on, textual criticism will have less and less to do. In the old texts its work will have been performed so far as it is possible. What is left will be an obstinate remainder of difficulties, for which there is no solution or only too many. In the newer texts, on the other hand, as experience has already shown, it will have from the outset but a very contracted field.
TEZPUR—THACKERAY

TEZPUR, or Tezpur, a town of British India, the administrative headquarters of Darrang district, Eastern Bengal and Assam, on the right bank of the Brahmaputra. Pop. (1901) 50,47. It is the centre of a flourishing tea industry, and contains many houses of English residences. Communications are maintained by river steamer, while a light railway runs northward through the tea-growing tract.

THA‘ALĪBI [Abu Ma‘ṣūr ‘Abd ul-Malik ibn Mahommed ibn Isma‘īl ud-Tha‘alībi] (961–1035), Arabian philologist, was born in Nishāpūr, and is said to have been at one time a furrier. Although he wrote prose and verse of his own, he was most famous for his anthologies and collections of epigrams. Like many other Arab writers, he does not always distinguish between his own and other people's work. Of the twenty-nine works known to have been written by him, the most famous is his Kitāb Ya‘imat ud-Dahr, on the poets of his own and earlier times, arranged according to the countries of the poets, and containing valuable extracts (published at Damascus, 4 vols., 1887). Another of his works, the Kitāb Fīgh ud-Lughāta, is lexicographical, the words being arranged in classes. It has been published at Paris (1861), Cairo (1867), and Beirut (1885, incomplete).

For other works see C. Brockelmann’s Geschichte der Arabischen Literatur, vol. i. (Weimar, 1898), pp. 284–296. (C. W. T.)

THACKERAY, WILLIAM MAKEPEACE (1811–1863), English novelist, only son of Richmond and Anne Thackeray (whose maiden name was Becher), was born at Calcutta on the 18th of July 1811. Both his father and his grandfather (W. R. Thackeray) had been [Indian civil servants.] His mother was only nineteen at the date of his birth, was left a widow in 1816, and afterwards married Major Henry Carmichael Smyth. Young Thackeray was brought home to England from India as a child, and was sent to private schools, first in Hampshire and then at Cambridge. He was soon removed to Charterhouse, a school which he has often referred to in a letter passage of the letter quoted by Trollope: “When I knew him better, in later years, I thought I could recognize the sensitive nature which he had as a boy.” Another illustration of this idiosyncrasy is found in the statement, which will be recognized as exact by all readers of Thackeray, that “his change of retrospective feeling about his school-days was very characteristic. In his earlier books he always spoke of the Charterhouse as Slaughter House and Smithfield. As he became famous and prosperous his memory softened, and Slaughter House was changed into Grey Friars, where the Colonel Newcome ended his life.” Even in the latter that references the bitterness which has often been so falsely read into Thackeray is not to be found. In “Mr and Mrs Frank Berry” (Men’s Wives) there is a description of a fight at Slaughter House following on an incident almost identical with that used in Vanity Fair for the fight between Dobbin and Cuff. In both cases the brutality of school life, as it then was, is very fully recognized and described, but not to the exclusion of the chivalry which may go alongside with it. In the first chapter of “Mr and Mrs Frank Berry,” Berry himself and old Hawkins both have a touch of the heroic, and in this story the bully whom Berry gallantly challenges is completely defeated, and one hears no more of him. In Vanity Fair Cuff the swaggerer is defeated as completely as is Berry's opponent, but regains his popularity by one well-timed stroke of magnanimity, and afterwards shows the truest kindness to his conqueror. Thackeray left Charterhouse in 1828 to join his mother and her husband at Larkbeare in Devonshire, near Ottery St Mary. Ottery St Mary is the “Clavering St Mary,” as Exeter and Sidmouth are respectively the “Chatteris” and “Baymouth” of Pendennis.

In February 1829 Thackeray went to Trinity College, Cambridge, and in that year contributed some engaging lines on “Timbuctoo,” the subject for the Prize Poem (the prize for which was won in that year by Tennyson), to a little paper called The Snob, a title which Thackeray afterwards utilized in the famous Book of Snobs. The first stanza has become tolerably well known, but is worth quoting as an early example of the direct comic force afterwards employed by the author in verse and prose burlesques:

“In Africa—a quarter of the world—
Men's skins are black; their hair is crisp and curled;
And somewhere there, unknown to public view,
A mighty city lies, called Timbuctoo.”

One other passage at least in The Snob, in the form of a skit on a paragraph of fashionable intelligence, seems to bear traces of Thackeray's handiwork. At Cambridge, James Spedding, Monkton Milnes (Lord Houghton), Edward FitzGerald, W. H. Thompson (afterwards Master of Trinity), and others who made their mark in later life, were among his friends. In 1830 he left Cambridge without taking a degree, and went to Weimar and to Paris. His visit to Weimar bore fruit in the keen sketches of life at a small German court which appear in Fitz-Gredy’s Confessions and in Vanity Fair. In G. H. Lewes's Life of Goethe is a letter containing Thackeray's impressions of the German poet. On his return to England in 1831 he entered the Middle Temple. He did not care to pursue the study of the law, but he found in his experience of the Temple the material for some capital scenes in Pendennis. In 1832 he came of age, and inherited a sum which, according to Trollope, “seems to have amounted to about five hundred a year.” The Arabian Nights, which was some in an Indian bank, some to play and some in two newspapers, The National Standard (with a long sub-title) and The Constitutional. In Love the Widerse these two papers are indicated under one name as The Museum, in connexion with which our friends Honeyman and Sherrick of The Newcomes are briefly brought in. Thackeray's adventurous and losses at play were utilized in his literary work on three occasions, in “A Caution to Travellers” (The Paris Sketch-Book), in the first of the Deuceace narrations (The Memoirs of Mr C. J. Yellowplush), and in Pendennis, vol. ii. chap. v., in a story (wherein Deuceace reappears) told to Captain Strong by “Gordon Almartan.” As to Deuceace, Sir Theodore Martin has related how once in the playrooms at Spa Thackeray called his attention to a certain man and said presently, “That was the original of my Deuceace.”

In 1834 or at the end of 1833 Thackeray established himself in Paris in order to study art seriously. He had, like Clive in The Newcomes, shown talent as a caricaturist from his early boyhood. His gift proved of great value to him in illustrating much of his own literary work in a fashion which, despite all incorrectness of draughtsmanship, conveyed vivid suggestions that could not have been so well given by anyone but himself. Perhaps his pencil was at its best technically in such fantastic work as is found constantly in the initial letters which he frequently used for chapters in his various kinds of work, and in those drawings made for the amusement of some child friends which were the origin of The Rose and the Ring.

In 1836 Thackeray married Isabella, daughter of Colonel Matthew Shawe. There were three daughters born of the marriage, one dying in infancy. The eldest daughter, Anne Isabella (b. 1837), married in 1877 Mr Richmond Ritchie, of the India Office, who in 1907 was created a K.C.B. She inherited literary talent from her father and wrote several charming works of fiction, notably Miss Angel (1875), and subsequently edited Thackeray's works and published some volumes of criticism and reminiscences. The younger daughter, Harriet Marion (b. 1840), married (Sir) Leslie Stephen in 1867 and died in 1875. Thackeray's own family life was early broken, for Mrs Thackeray, to quote Trollope, “became ill and her mind
Thackeray

717

failed her," in 1840, and he "became as it were a widower to the end of his days"; Mrs Thackeray did not die till 1892.

In 1837 Thackeray came to London, worked at various kinds of journalism, and became a regular contributor to Fraser's Magazine. In this he in 1841 appeared The History of Mr Samuel Titmarsh and the Great Hoggarth Diamond, a work filled with instances of the wit, humour, satire, pathos, which found a more ordered if not a fresher expression in his later and longer works. For freshness, indeed, and for a fine perception which enables the author to perform among other feats that of keeping up throughout the story the curious simplicity of its supposed narrator's character, The Great Hoggarth Diamond can scarcely be surpassed. The characters, from Lady Drum, Lady Fanny Rakes, Lady Jane and Edmund Preston, to Brough, Mrs and Miss Brodge, Mrs Roun Grind, Gus Hoggs, and least, Samuel Titmarsh's aunt, Mrs Hogarty, with her store of "Rosolio," are full of life; the book is crammed with honest fun; and for pure pathos, the death of the child, and the meeting of the husband and wife over the empty cradle, stands, if not alone in its own line, at least in the company of very few such scenes in English fiction. The Great Hoggarth Diamond, oddly enough, met with the fate that afterwards befell one of Lever's best stories which appeared in a periodical week by week—it had to be cut short at the bidding of the editor. In 1840 came out, The Porit Sketch-Book, much of which had been written and published at an earlier date. The book contains among other things some curious divagations in criticism, along with some really fine critical work, and a very powerful sketch called "A Gambler's Death." In 1838 Thackeray had begun, in Fraser, The Yellowplush Papers, with their strange touches of humour, satire, tragedy (in one scene, the closing one of the history of Mr Deuceace), and their sublimation of fantastic bad spelling (M'Aroney for macaroni is one of the typical touches of this); and this was followed by Catherine, a strong story, and too disagreeable perhaps for its purpose, founded closely on without the ken of a criminal named Catherine Hayes, and intended to counteract the then growing practice of making ruffians and harlots prominent characters in fiction. Now, when Pendennis was coming out in serial form (1839), Miss Catherine Hayes, a singer of Irish birth and a famous prima donna (Sims Reeves described her as "the sweetest Lucia [di Lammermoor] he had ever sung with") was much before the public. A reflective passage in a number of Pendennis referred indignantly and scornfully to Catherine Hayes, the criminal of old time, coupling her name with that of a then recently notorious murderer. It would appear that Thackeray had for the moment, oddly enough, omitted to think of Miss Catherine Hayes, the justly famed soprano, while certain Irish folk were obviously ignorant or oblivious of the history of Catherine Hayes the murderess. Anyhow, there was a great outcry in the Irish press, and Thackeray was beset by private letters of indignation from enthusiastic contemporaries of the prima donna. In deference to susceptibilities ingeniously outraged Thackeray afterwards suppressed the passage which had given offence. The thing is worth mention if only because it explains the initial letter drawn by Thackeray for chap. xv., vol. ii., of Pendennis. The drawing is in itself highly comic, but must quite seem meaningless without the text.

There soon followed Flitz-Boodle's Confessions and Professions, including the series Men's Wives, already mentioned; and slightly before these, the Shabby Gentled Story, a work interrupted by Thackeray's domestic affliction and afterwards republished as an introduction to The Adventures of Philip, which took up the course of the original story many years after the supposed date of its catastrophe. In 1843 also came out the Irish Sketch-Book, and in 1844 appeared the account of the journey From Cornhill to Grand Cairo, in which was included the excellent poem of "The White Squall." In 1844 there began in Fraser the Memoirs of Barry Lyndon, called in the magazine "The Luck of Barry Lyndon, a Romance of the Last Century." "Barry Lyndon" has, with a very great difference in treatment, some resemblance to Smollett's "Ferdinand, Count Fathom"—the hero, that is to say, is or becomes a most intolerable scoundrel, who is magnificently unconscious of his own iniquity. The form and pressure of the time depicted are sought with striking verisimilitude, and in the boisterous career of Barry Lyndon there are at least the elements of a wild chivalry, simplicity, generosity, which mingle naturally with those worse qualities that, under the influence of abominable training, afterwards corrupt his whole mind and career. The man is so infatuated with and so blind to his own ruggery, he has so much clack and daring, and is on occasions so infamously treated, that it is not easy to look upon him as an entirely detestable villain until, towards the end of his course, he becomes wholly lost in brutal debauchery and cruelty. His latter career is founded on that of Andrew Robinson Stoney Bowes, who carried the widow of John, of early St. John's. There is also no doubt a touch of Casanova in Barry Lyndon's character. Thackeray became a contributor to Punch within the first year of its existence. John Leech, who was one of the earliest contributors, had been at Charterhouse with Thackeray and the two men were friends through life. Thackeray's first series contributed to Punch did not attain or indeed deserve signal success. He made his first hit with Joeamy's Diary, begun in November 1845, and may be said to have established his reputation by the Snob Papers (1846), now better known as The Book of Snobs. These, besides greatly improving Thackeray's position, provoked much discussion of various kinds. Thackeray himself was naturally accused of being a snob. To this charge he had partly given an anticipatory answer (in the third chapter) in the statement that "it is impossible, in our condition of society, not to be sometimes a Snob," and in giving the name of "Mr Snob" to the supposed historian of snobs throughout the series. Thackeray's connexion with Punch came practically to an end in 1851. The separation was due partly to differences in political opinion. His personal relations with the staff of Punch always remained friendly. The Book of Snobs, which took up to a quarter of a year, seemed to have become a portion of the picture of his to the paper, "Punch's Prize Novelists," containing some brilliant parodies of Edward Lytton Bulwer, Lever, Benjamin Disraeli (in "Coldingbby," perhaps the most perfect of the series), and others. Among minor but admirable works of the same period are found A Legend of the Rhine (a burlesque of the great Dumas's Otho's Archer), brought out in George Cruikshank's Table Book, edited by Gilbert Abbott A Beckett, Cox's Diary (on which has been founded a well-known Dutch comedy, Janus Tulp), and The Fatal Boots. This is the most fitting moment for naming some of the burlesques and parodies which Thackeray's letters give as a result of the influence of Fanny Trollope on his powers in the Edinburgh Review. It is probable that on Vanity Fair has been largely based the foolish cry, now heard less and less frequently, about Thackeray's cynicism, a cry which he himself, with his keen knowledge of men, foresaw and provided against, ample enough as one might have thought, at the end of the eighth chapter, in a passage which is perhaps the best commentary ever written on the author's method. He has explained how he wishes to describe men and women as they actually are, good, bad and indifferent, and to claim a privilege.

"Occasionally to step down from the platform, and talk about them: if they are good and kindly, to love and shake them by the hand; if they are silly, to laugh at them confidentially in the reader's sleeve; if they are wicked and heartless, to abuse them in the strongest terms politeness admits of. Otherwise you might fancy it was I who was sneering at the practice of devotion, which
THACKERAY

Miss Sharp finds so ridiculous; that it was I who laughed good-
humouredly at the rolling old Silenus of a baronet—whereas the
laughter comes from one who has no reverence except for pros-
perity, Vanity Fair and himself besides. Such people
there are living and flourishing in the world—Faithless, Hopeless,
Charityless: let us have at them, dear friends, with might and
main. Some there are, and very successful too, mere quacks and
fools: and it was to combat and expose such as those, no doubt,
that laughter was made."

As to another accusation which was brought against the
book when it first came out, that the colours were laid on too
thick, in the sense that the villains were too villainous, the good
people too goody-goody, the best and completest answer to
that can be found by anyone who chooses to read the work
with care. Osborne is, and is meant to be, a poor enough
creature, but he is an eminently human being, and one whose
prowess of character is developed as he allows bad influences
to tell upon his vanity and folly. The good in him is fully recog-
nized, and comes out in the beautiful passage describing his
farewell to Amelia on the eve of Waterloo, in which passage
may be also found a sufficient enough answer to the statement
that Amelia is absolutely insipid and uninteresting. So with
the companion picture of Rawdon Crawley's farewell to Becky
Sharp: who that reads it can resist sympathy, in spite of Rawdon's
Pendennis, who has his similar, bravery and devotion to his wife? As for Becky, a character
that has since been imitated a host of times, there is certainly
not much to said in her defence. We know of her, to be
sure, that she thought she would have found it easy to be good
if she had been rich, and we know all what happened when
Rawdon, released without her knowledge from a spunging-
house, surprised her alone with and singing to Lord Steyne
in the house in Mayfair. After a gross insult from Steyne,
"Rawdon Crawley, springing out, seized him by the neckcloth,
undulating, and bent under his arm, 'You lie, you dog,' said Rawdon, 'I will lie and
you villain!' And he struck the peer twice over the face with
his open hand, and flung him bleeding to the ground. It was
done all before Rebecca could interpose. She stood there
seemingly before him. She admired his husband, strong,
brave, and victorious." This admiration is, as Thackeray himself thought it, the capital touch in a scene which is as
powerful as any Thackeray ever wrote—as powerful, indeed,
as any in English fiction. Its full merit, it may be noted in
passing, has been curiously accented by an imitation of it in
Alfred Daudet's "Jeune et Vétére," where a minor character,
under the ism of the miserable Becky's guilt in the Steyne matter,
Thackeray leaves it practically open to the reader to form what
conclusion he will. There is, it should be added, a distinct
touch of good in Becky's conduct to Amelia at Ostend in
the last chapter of the book, and those who think that too little
punishment is meted out to the brilliant adventuresses in the end
may remember this to her credit. It is supreme art in the treat-
ment of her character that makes the reader understand and
feel her attractiveness, though he knows her extraordinarily
evil qualities; and in this no writer subsequent to Thackeray
who has tried to depict one of the genus Becky Sharp has even
faintly succeeded. Among the minor characters there is not
one—and this is not always the case even with Thackeray's chief
figures—who is incompletely or inconsistently depicted;
and no one who wishes fully to understand and appreciate
the book can afford to miss a word of it.

Vanity Fair was followed by Pendennis, Esmond and The
Newcomes, which appeared respectively in 1839, 1852 and 1854.
It might be more easy to pick holes critically in Pendennis than in
Vanity Fair. It赡ishes itself, after his wayish passion
and university escapades, has disagreeable touches of flabbyness
and worldliness; and the important episode of its relations
with Fanny Bolton, which Thackeray could never have treated
otherwise than delicately, is so lightly and tersely handled that
it is a little vague even to those who read between the lines.
It can hardly be said that there is adequate preparation for the
final announcement that those relations have been innocent,
THAÏS—THALE

719

Rooms in the same year, and re-delivered in the United States in 1852 and 1853, as was afterwards the series called The Four Georges. Both sets were written for the purpose of lecturing. In 1854 was published a most delightful burlesque, The Rose and the Ring, whereof the origin has already been mentioned. In 1857 Thackeray stood unsuccessfully as a parliamentary candidate for Oxford against Mr Cardwell, and in the same year appeared the first number of The Virginians, a sequel to Esmond. This is a most unequal work—inferior, as sequels are apt to be, to Esmond as an historical romance, less compact and coherent, prone to divagation and desultoriness, yet charming enough in its lifelikeness, in the wit and wisdom of its reflections, and, as has been said, in its portrait of Beatrice grown old. The last number of The Virginians came out in 1859, and in the same year Thackeray undertook the editorship of the Cornhill Magazine. This was a task which, as readers of his Roundabout Paper "Thorns in the Cushion" will remember, the kindliness and sensitivity of his disposition made him to, and he resigned the editorship in April 1862, though he continued to write for the magazine until he died. In the Cornhill appeared from his pen Love of the Widow, previously written, with different names for some of the personages, in dramatic form; The Adventures of Philip (1861–62); the Roundabout Papers; and (1860–63) the story, unhappily never finished, called Denis Duval. Love of the Widow, changed from the dramatic to the narrative form, remains a piece of high comedy in which the characters are indicated rather than fully worked out with a bold and frank touch. The Roundabout Papers, a small storehouse of some of Thackeray's best qualities as an essayist, came out in the Cornhill Magazine simultaneously with Love of the Widow and with The Adventures of Philip. Among these papers is one differing in form from the rest, called "The Notch on the Axe—a Story at a Modita." It is an almost perfect specimen of the author's genius for burlesque story-telling; but it contains an odd instance, which a careful reader will not fail to discover, of that odd habit of inaccuracy of which Thackeray himself was conscious. The Adventures of Philip is, as has been before said, in the nature of a sequel to or a completion of A Story of Gentle Life. As with the other direct sequel, it is a work of great inequality. It contains scenes of humour, pathos, satire, which rank with Thackeray's best work; some old friends from others of the novels make brief but pleasant reappearances in its pages; there are fine sketches of journalistic, artistic and diplomatic life, and the scene from the last-named in Paris is inimitable. The Little Sister is altogether delightful; the Twysden family are terribly true and vastly diverting; the minor characters, among whom old Ridley, J. J.'s "father, should be mentioned, are wonderfully hit off; nor did Thackeray ever write a better description of the scene in that of the quarrel between Bunch, Baynes and M'Whirter in the Paris pension. Philip himself is impossible; one cannot say that the character is ill-drawn—it is not drawn at all. It is an entirely different personage in different chapters; and it has here and there a very unpleasant touch which may perhaps have come of rapid writing. Yet so admirable are many parts of the book that Philip cannot be left out of the list of Thackeray's most considerable works. Denis Duval, which reached only three numbers, promised to be a first-rate work, more or less in the Esmond manner. The author died while it was in progress, on the day before Christmas day 1863. He was buried in Kensal Green, and a bust by Marochetti was put up to his memory in Westminster Abbey.

Little has yet been said of Thackeray's performances in poetry. They formed a small but not the least significant part of his life's work. The grace and the apparent spontaneity of his versification are beyond question. Some of the more serious efforts, such as "The Chronicle of the Drum" (1841), are full of power, and instinct with true poetical feeling. Both the half-humorous, half-pathetic ballads and the wholly extravagant ones must be classed with the best work in that kind; and the translations from Béranger are as good as verse translations can be. Thackeray had the true poetical instinct, and proved it by writing poetry which equalled his prose in grace and feeling.

There can be little doubt that Thackeray will always be ranked among the foremost English writers of fiction, or that his more infrequent work as essayist and poet will go hand in hand with his wider achievements as a novelist. Many attempts have been made at many times to institute a comparison between Thackeray and Dickens as novelists. In truth it would be as much to the purpose, to borrow a homely metaphor, to compare chalk with cheese. The two authors were so radically different in their purviews, in their modes of thought, in their methods of expression, that critical comparison between them is of its nature absolutely unprofitable. It is better to recognize simply that the two novelists stood, each in his own way, distinctly above even their most distinguished contemporaries. As to preference, that is a matter with which criticism has nothing, and individual inclination has everything to do.

The books of reference that can be best commended to the student of Thackeray's life and works are Merivale's and Marzials Life of Thackeray (1891); R. H. Shepherd, Bibliography of Thackeray (1880); C. P. Johnson, The Early Writings of Thackeray (1888); Charles Whibley's Thackeray (1905), a critical commentary; the edition of Thackeray's Works with biographical introductions (1897–1900), by his daughter, Lady Ritchie; the Life of Thackeray (1880) by John Forster; the Life of Thackeray (1899) by Antony Trollope. It is curious that Trollope showed in his own autobiography far more appreciation of Thackeray's great qualities than is apparent in his Life of Thackeray. (W. H. F.)

THAÏS, Greek courtisan, who lived during the time of Alexander the Great. She accompanied him on his Asiatic campaign, and is chiefly known from the story which represents her as having persuaded the conqueror to set fire to the city of Persepolis. This anecdote forms the subject of Dryden's Ode to Saint Cecilia's Day. But its authenticity is doubtful, since it is based upon the authority of Cleitarchus, one of the least trustworthy of the historians of Alexander. Thaïs subsequently became the wife of Ptolemy Lagus, king of Egypt. Numerous anecdotes and witticisms attributed to her will be found in Athenaeus.

See Diod. Sic. xvii. 72; Plutarch, Alexander, 38; Athenaeus xiii. 576, 585; Quintus Curtius v. 7.

THALBERG, SIGISMOND (1812–1872), German pianist and composer, was born at Geneva in 1812 (May the 5th or January the 7th). In 1822 he was taken to Vienna, where, under the watchful care of Count Dietrichstein, his education was completed. He made his first appearance as a pianist at Prince Metternich's in 1826, and published his first composition—a Fantasie on Airs from "Euryanthe"—in 1828, but it was not until 1830 that he was first fairly introduced to the public, with the success of his Variations on the Air of Haspil. That time forward his only rival was Liszt (q.v.). In 1834 he was appointed "kammer-virtuus" to the emperor of Austria. He first appeared in Paris in 1837; and in 1838 he went to England, astonishing his hearers with the novel effects produced in his Variations on God Save the Queen, while he charmed them with his delicate touch and the purity of his expression. Thenceforward his career was a succession of triumphs. In order to dispense the popular idea that he could execute no music but his own, he played Beethoven's Concerto in C minor (Op. 37) at the London Wednesday Concerts, held in 1846−47 at Exeter Hall, with a keen intelligence which proved his power of interpreting the works of the great masters to be at least on a level with his wonderful technique. Besides his pianoforte compositions, which are almost innumerable, Thalberg produced two operas—Cristina, which proved a complete failure, and Florinda, which fared but little better at Her Majesty's Theatre in 1851. He played in London for the last time in 1863, and afterwards retired to his estate near Naples. He died at Naples on the 27th of April 1871.

THALE, a town of Germany, in the Prussian province of Saxony, charmingly situated under the northern declivity of the Harz Mountains, 8 m. by rail S.W. of Quedlinburg, at the entrance to the romantic gorge of the Bode, and in the
immediate vicinity of the Rosstrappe, the Hexentanzplatz and other notable points in the Harz. Pop. (1905) 13,194. It is largely frequented as a summer resort and for its saline springs. It is also a brisk manufacturing centre, its chief products being enamelled goods, iron-work and machinery. THALES OF MILETUS (649–546 B.C.), Greek physical philosopher, son of Examyus and Cleobuline, is universally recognized as the founder of Greek geometry, astronomy and philosophy. He is said by Herodotus and others to have been of Phoenician extraction, but the more common account (see Diogenes Laërtius) is that he was a native Miletian of noble birth. Zeller thinks that his ancestors belonged to the Cadmean tribe in Bocotia, who were intermingled with the Ionians of Asia Minor, and thus reconciles the conflicting statements. The nationality of Thales is certainly Greek and not Phoenician. The estimation in which he was held by his contemporaries is shown by the place he occupied as chief of the seven "wise men" of Greece; and in later times amongst the ancients his fame was quite remarkable. It is well known that this name (σοφός) was given on account of practical ability; and in accordance with this we find that Thales had been occupied with civil affairs, and indeed several instances of his political sagacity have been handed down. Of these the most remarkable is the advice, praised by Herodotus, which he gave to his fellow-countrymen "before Ionia was ruined, that the Ionians should constitute one general state in Teos, as the most central of all their cities, and that the remainder should be governed as independent states" (Herod. i. 170). It is probable, however, that in the case of Thales the application "wise man," which was given to him and to the other six in the archonship of Damasius (586 B.C.),1 was conferred on him not only on account of his political sagacity, but also for his scientific eminence (Plut. Salom. c. 3). To about the same time must be referred his celebrated prediction of the eclipse of the sun, which took place on the 28th of May 585 B.C. This event, which was of the highest importance, has given rise to much discussion. The account of it given by Herodotus (B. H. 74) contains two statements:—(1) the fact that the eclipse did actually take place during a battle between the Medes and the Lydians, that it was a total eclipse (Herodotus calls it a "night battle") that it caused a cessation of hostilities and led to a lasting peace between the contending nations; (2) that Thales had foretold the eclipse to the Ionians, and fixed the year in which it actually did take place. Various dates—ranging from 625 B.C. to 583 B.C.—have been assigned by different chronologists to this eclipse; but, since the investigations of Airy,2 the date 585 B.C. has been generally accepted (for later authorities see Eclipse and Astronomy). This date agrees nearly with that given by Piny (H. N. ii. 12). The second part of the statement of Herodotus—the reality of the prediction by Thales—has been frequently called in question, chiefly on the ground that, in order to predict a solar eclipse with any chance of success, one should have the command of certain astronomical facts which were not known until the 3rd century B.C., and then merely approximately, and only employed with that object in the following century by Hipparchus. The question, however, of the accuracy of the account as given by Herodotus (B. H. 74) has been generally accepted by most of the ancients, and with any chance of success—much whether he could state beforehand at what places the eclipse would be visible, as some have erroneously supposed, and which of course would have been quite impossible for him to do, but simply whether he

1 Breternicher (Die Geom. vor Euklides, p. 40), without stating his authority, gives "between 585 and 583 B.C." as the date of the archonship of Damasius. In this he is followed by some other recent writers, who infer the name "wise man" was conferred on Thales on account of the success of his prediction. The date 586 B.C., given above, which is taken from Clinton, is adopted by Thales, the Eclipses of Agathocles, Thales, and Xenocrates," Phil. Trans. vol. cxliii. p. 179 seqq., 1853.

3 Athenæum, Untersuchungen der wichtigeren Finsternisse, &c., p. 57., 1853.
THALES OF MILETUS

that he discovered many things himself, and communicated the beginnings of many to his successors, some of which he attempted in a more intuitive or sensible manner (σύμμετρας ὑποδοχήν) (op. cit., p. 65).

From these indications it is no doubt difficult to determine what Thales taught in his philosophy. This is due to his generation.

This difficulty has, however, been lessened since the translation and publication of the papyrus Rhind by Eisonlohr; and it is now generally admitted that, in the distinction made in the last century between the two forms of his work-συμμετρικά and τέχνη-recto pointing to what he derived from Egypt or arrived at in an Egyptian manner, while the invention of the discoveries which he made in accordance with the Greek spirit. To the former belong the theorems (1), (2), and (3), and to the latter especially the theorem (4), and also, probably, his solution of the two practical problems. We may suppose that Thales made use of the first of these, and inferred from the sum of the three angles of a triangle are equal to two right angles. This inference is made from (4) taken along with (2). No doubt we are informed by Proclus, on the authority of Eudemus, that the theorem Euclid I. 32 was first proved in a general way by the Pythagoreans; but, on the other hand, we learn from Geminus that the ancient geometers observed the equality to two right angles in each of the triangles - the equilateral triangle, then, in the isosceles, and lastly in the scalene (Apoll. Conica, ed. Halleius, p. 9), and it is plain that the geometers older than the Pythagoreans can be no other than Thales and his school. The theorem may have been thought by him to be evident, or may have been suggested by the contemplation of floors or walls covered with tiles of the form of equilateral triangles, or squares, or hexagons. [2] We see also in the theorem (4) the first trace of a spherical geometry. The observation of the zodiac, which is often attributed to Thales. It is worth noticing that it was in this manner that this remarkable property of the circle, with which, in fact, Euclid's postulate, was inaugurated, presented itself to the imagination of Dante:

"O se del mezzo cerchio far si puote
Triangoli sì, ch'un retto non avesse." - Par. c. xiii. 101.

3. Thales discovered the theorem that the sides of equiangular triangles are proportional. The knowledge of this theorem is distinctively attributed to Thales by Plutarch, and it was probably made use of also in his determination of the distance of a ship at sea.

Let us now consider the importance of the work of Thales. 1. In a scientific point of view: (a) we see, in the first place, that by his two theorems he founded the geometry of lines, which has ever since remained the principal part of geometry; (b) he may, in the second place, be fairly considered to have laid the foundation of algebra, for his first theorem establishes an equation in the sense of the word, while the second institutes a proportion.

2. In a philosophic point of view: we can see in these two theorems of Thales the first type of a natural law, i.e., the expression of a fixed dependence between different quantities, or, in another form, the expression of a proportional dependence, all of which is distinctly arisen.

3. Lastly, in a practical point of view: Thales furnished the first example of an application of theoretical geometry to practice, and laid the foundation of an important branch of geometrical knowledge - the heights and distances. For the further progress of geometry see PYTHAGORAS.

As to the astronomical knowledge of Thales we have the following notices:—(1) besides the prediction of the solar eclipse, Eudemus attributes to him the discovery that the circuit of the sun between the solstices is not always uniform; (2) he called the last day of the month the thirtieth (Diog. Laert. i. 24); (3) he divided the year into 365 days (Ld. i. 27); (4) he determined the position of the sun to be the 720th part of the zodiac; (5) he appears to have pointed out the constellation of the Lesser Bear to his countrymen, and instructed them to steer by it (as nearer the parts farther south). [3] (6) Thales asserted the claims of fire, and on the contrary, he conceived it to be a flat disk, and in this supposition he was followed by most of his successors in his schools, including Anaxagoras.

The doctrine of the earth, for which the researches of Anaximander had prepared the way, 2 was in fact one of the great discoveries of Pythagoras, was carried out by Plato, and remained for a long time the exclusive property of the Italian schools. 3

Philosophy.—Whilst in virtue of his political sagacity and intellectual eminence Thales held a place in the traditional list of the wise men, on the strength of the disinterested love of knowledge which appeared in his physical speculations he was accounted a "philosopher" ( αρχιτέχνης), and perhaps the genius that he usually summed up in the dogma "water is the principle, or the element, of things"; but, as the technical terms "principle" (αρχή) and "element" (ετερον) had not yet come into use, it may be conjectured that the phrase "all things are water" (πάντα ὅπως λιμέν) more exactly represents his teaching. Writings which bore his name were extant in antiquity; but as Aristotle, when he speaks of Thales's doctrine, always depends upon tradition, there can be little doubt that they were forgeries.

From Aristotle we learn (1) that Thales found in water the elements of many things; (2) that he concealed from the earth to float in the sea of the elementary fluid; (3) that he supposed all things to be full of gods; (4) that in virtue of the attraction exercised by the magnet he attributed to it a soul. Here our information ends. Aristotle's suggestion that Thales was led to his fundamental dogma by observation of the part which moisture plays in the production and the maintenance of life, and Simplicius's, that the impressibility and the binding power of water were perhaps also in his thoughts, are by admission purely conjectural. Simplicius's further suggestion that Thales conceived the element of water to be produced by thinning and thickening is plainly inconsistent with the statement of Theophrastus that the hypothesis in question was peculiar to Anaximenes. The assertion preserved by Stobaeus that Thales recognized, together with the material element "water," "mind," which penetrates and sets it in motion, is refuted by the precise testimony of Aristotle, who declares that the early physicists did not distinguish the moving cause from the material cause, and that before Hermetismus and Anaxagoras no one postulated a creative intelligence.

It would seem, then, that Thales sought amid the variety of material causes that he found such a one as was most familiar to him, namely, water, and accordingly regarded the world and all that it contains as water variously metamorphosed; and that he asked himself no questions about the manner of its transformation.

The doctrine of Thales was interpreted and developed in the course of three succeeding generations. First, Anaximander chose the "air" (αέρ) as his element, which he called "the boundless" (ἄμαλλος) and which he conceived as the original of the rest of the world. Second, Anaximenes, taking the "air" as a corporeal element intermediate between fire and air on the one hand and water and earth on the other. Lastly, Heracles, asserting the claims of fire, went on to conceive it to modify itself, not occasionally, but perpetually.

Thus Thales recognized change, but was not careful to explain it; Anaximander attributed change to two directions; Anaximenes conceived the two sorts of change as production and condensation; Heraclitus, perceiving that, if, as his predecessors had tacitly assumed, change was occasional, the interference of a moving cause was necessary, made change perpetual. All four are noticed in tracing the variety of things to a single material cause, corporeal, endowed with qualities and capable of self-transformation. A new departure was taken when the Eleatic Parmenides (q.v.), who, expressly noting that when Thales and his successors attributed to the supposed element changing qualities, they became pluralists, required that the superficial variety of nature should be distinctly distinguished from its fundamental unity. Hence, whereas Thales and his successors had confounded the One, the element, and the Many, in its modifications, the One and the Not-One or Many became with Parmenides matters for separate investigation. In this way two hitherto mixed categories (wasserige Dinge) were separated. In the same way Anaxagoras, abandoning the pursuit of the One, gave themselves to the scientific study of the Many; on the other hand, abandoning the pursuit of the Many, gave himself to the dialectical study of the One. Both successful were doomed to failure; and the result

5 Theonis Smyrnaii Platonici Liber de Astronomia, ed. Th. H. Mannhardt, C.F. Weisse u. Dr. v. Heimann, ii. 23; cf. Aratus, Phaenomena, v. 36 seq. Other discoveries in astronomy are attributed to Thales, but on authorities which are not trustworthy. He did not, for example, that "the earth is a sphere," as erroneously stated by Plutarch (Plut. Isis, i. 10; Plato, Crito, 23; cf. Aratus, Phaenomena, v. 36 seq.).
6 This is the revised interpretation of the passage in Diogenes Laëritius, i. 24 (see Wolf, Gesch. der Astron., p. 169), where σκηναὶον is probably a scribe's error for ἥκωνον. Cf. Apuleius, Florida, iv. 18, who attributes to Thales, then old, the discovery "quotiens sol magnitude sua circum quem permutat materiam." 7 In likening the earth to a cylinder Anaximander recognized its circular figure in one direction.
THALLIUM

was a scepticism from which the thought of Greece did not emerge until Plato, returning to Parmenides, declared the study of the One and the Many, jointly regarded, to be the true office of the philosopher. Thus, measure and number as the doctrine of Thales was, all the Greek schools, with the solitary exception of that of Pytha-
gorus, took their origin from it. Not in name only, but also in fact, the Ionian philosophers, was the founder of the philosophy of Greece.

Kricsche, Forschungen, pp. 34-42 (Göttingen, 1840).

THALLIUM [symbol Tl, atomic weight 204-0 (O = 16)], a metallic element. It was discovered in 1861 by Sir William Crookes, who, during a spectroscopic examination of the flue-dust produced in the roasting of seleniferous pyrites occurring at Tilkerode in the Harz, observed a green line foreign to all then known spectra. He concluded that the mineral contained an element, now known as thallium, that gave the name of thallus, from thālλus, a green twig. Crookes presumed that his thallium was something of the order of sulphur, selenium or tellurium; but Lamy, who anticipated him in isolating the new element, found it to be a metal. Our knowledge of the chemistry of thallium is based chiefly upon the labours of Crookes.

The chemical character of thallium presents striking peculiarities. Dumas once called it the "ornithorhynchus paradoxus of metals." As an elementary substance, it is very similar in its physical properties to lead; it resembles lead chemically in its monovalent state, and it is more soluble in cold water. The thallous, Tl2, is a yellow or greenish-yellow, and the thallous, TlH, a dark green powder, resplendent with the formation of a reddish or violet vapour. When exposed to the air it becomes quickly covered with a film of oxide; the tarnished metal when plunged into water reassumes its metallic lustre, the oxide film being quickly dissolved. When kept in contact with water and air it is gradually converted into hydroxide, TlOH. It decomposes water at a red heat, liberating hydrogen and being itself converted into the hydrate. It is readily soluble in nitric and sulphuric acids, but less so in hydro-

Thallium forms two series of salts: thallous, in which the metal is monovalent; and thallic, in which it is trivalent. In the thallous series many analogies with lead compounds are observed; in the thallic some resemblance to aluminium and gold.

Thallous hydroxide, TlOH, is most conveniently prepared by decomposing the solution of the sulphate with baryta water. It crystallizes from its solution in long yellow needles, TlOH or TlOH·H2O, which dissolve readily in water, forming an intensely alkaline solution, which acts as a caustic, and like it greedily absorbs carbonic acid from the atmosphere. Unlike the alkali, it readily loses its water at 100° C. and even at the ordinary tempera-
ture, to form the oxide Tl2O, which is black or black-violet.

Thallous oxide, TlO or Tl2O, was obtained by O. Rabe (Abst. Jb., 1877, 1, 44%; 1886, 2, 260). It is obtained by evaporating an alkaline solution of thallous sulphate at low temperatures, an initial red precipitate rapidly changing into a bluish-black compound. It melts at 184° C. and decomposes on being heated in vacuo with oxygen and thallous oxide. Thallous chloride, TlCl, is readily obtained from the solution of any thallous salt, by the addition of hydrochloric acid, as a white precipitate similar in physical character to silver chloride. It is obtained by the reaction of the hydrochloric acid and the thallous chloride, and fuses below redness into a (yellow) liquid which freezes into a horn-like flexible mass. It is also formed when the metal is burnt in chlorine. The specific gravity of this "horn" thallium is 7-02. One part of the precipitated chloride is precipitated at 5° C. in 100 parts of water, and in 70 parts at 100° C. It is less soluble in dilute hydrochloric acid. Carbonate of soda solution dissolves it pretty freely. Thallous iodide, TlI, is obtained as a yellow precipitate which requires 16,000 parts of cold water for its solution, its addition of potassium iodide to a solution of a thallous salt, or by the direct union of its components. The yellow crystals melt at 100° C., and when cooled it forms a mass of a yellowish colour, changing to the original yellow on standing. Thallous bromide, TlBr, is a light yellow crystalline powder; it is formed analogously to the chloride. Thallous fluoride, TlF, forms white glistening octahedra; it is obtained by crystallizing a solution of the carbonate in hydro-

flouric acid. It resembles potassium fluoride in forming an acid salt, TlHF3. Thallous chloroplatinate, TlPtCl4, readily obtainable from thallous salt solutions by addition of platinum chloride, is a yellowish, precipitate soluble in cold water than hot.

Thallous perchlorate, TlClO4, and periodate, TlO4, are interesting inasmuch as they are isomorphous with the corresponding potassium salts. The thallous perchlorate and periodate crystals are insoluble in water, but are destroyed in cold solutions of the alkalis, but readily dissolves in the mineral acids. On thallous sul-

phides see H. Pélabon, Abst. J. C. S., 1907, ii, 770. Thallous nitrate, TlNO3, is obtained as white, rhombic prisms by crystallizing a saturated solution of the metal, or by fusing Tl2O or Tl2O·H2O, and cooling. The thallous phosphates are known. The normal salt, TlPO4, is soluble in 200 parts of water, and may be obtained by precipitation. On thallous phosphate see M. Abaye, Abst. J. C. S., 1897.

Thallic oxide, Tl2O, is obtained as a dark reddish powder, insoluble in water and alkalis, by plunging molten thallium over oxygen, or by electrolysis of water, using a thallium anode. Thallic oxide, Tl2O, is used in the preparation of thallous oxide, TlO, which is obtained by the reaction of the hydrochloric acid and the thallous chloride, and fuses below redness into a (yellow) liquid which freezes into a horn-like flexible mass. It is also formed when the metal is burnt in chlorine. The specific gravity of this "horn" thallium is 7-02. One part of the precipitated chloride is precipitated at 5° C. in 100 parts of water, and in 70 parts at 100° C. It is less soluble in dilute hydrochloric acid. Carbonate of soda solution dissolves it pretty freely. Thallous iodide, TlI, is obtained as a yellow precipitate which requires 16,000 parts of cold water for its solution, its addition of potassium iodide to a solution of a thallous salt, or by the direct union of its components. The yellow crystals melt at 100° C., and when cooled it forms a mass of a yellowish colour, changing to the original yellow on standing. Thallous bromide, TlBr, is a light yellow crystalline powder; it is formed analogously to the chloride. Thallous fluoride, TlF, forms white glistening octahedra; it is obtained by crystallizing a solution of the carbonate in hydro-

flouric acid. It resembles potassium fluoride in forming an acid salt, TlHF3. Thallous chloroplatinate, TlPtCl4, readily obtainable from thallous salt solutions by addition of platinum chloride, is a yellowish, precipitate soluble in cold water than hot.

Thallous perchlorate, TlClO4, and periodate, TlO4, are interesting inasmuch as they are isomorphous with the corresponding potassium salts. The thallous perchlorate and periodate crystals are insoluble in water, but are destroyed in cold solutions of the alkalis, but readily dissolves in the mineral acids. On thallous sul-

phides see H. Pélabon, Abst. J. C. S., 1907, ii, 770. Thallous nitrate, TlNO3, is obtained as white, rhombic prisms by crystallizing a saturated solution of the metal, or by fusing Tl2O or Tl2O·H2O, and cooling. The thallous phosphates are known. The normal salt, TlPO4, is soluble in 200 parts of water, and may be obtained by precipitation. On thallous phosphate see M. Abaye, Abst. J. C. S., 1897.
obtained by treating the monochloride with chlorine under water; evaporation in a vacuum gives colourless deliquescent crystals of TlCl2·H2O. By heating the metal or thallous chloride in chlorine, TlCl, a yellow powder is obtained which on further heating gives 3TlCl/TlCl2, as a yellowish brown mass. The chloride when anhydrous is a crystalline mass which melts at 24°. It forms several double salts, e.g., with hydrochloric acid and the alkaline chlorides, and also with hydrobromic acid, nitric acid, phosphoric acid, and with silver nitrate in nitric acid solution; the ionization apparently not proceeding to all the chloride atoms. Thallie titide, TlI, is interesting on account of its isomorphism with rubidium and cesium tri-iodides, a resemblance which suggests the formula TlI12 for the salt, in which the metal is obviously monovalent. On the halogen compounds see V. Thomas, Abst. J.C.S. (1897), 2143; (1899), 3123 and (1900), 1593. Tl(NO3)2·8H2O, are obtained as colourless crystals on the evaporation of a solution of the oxide in the corresponding acid. The sulphate decomposes into sulphuric acid and the trioxide on warming with water, and differs from aluminium sulphate in not forming alums.

Analysis.—All thallium compounds volatile or liable to dissociation at the temperature of the flame of a Bunsen lamp impart to such flame an intense green colour. The spectrum contains a bright green wave-length 5351. From solutions containing it as thallous salt the metal is easily precipitated as chloride, iodide, or chloroplatinate by the corresponding reagents. It is precipitated as hydrogen, in the presence of free mineral acid, gives no precipitate; sulphide of ammonium, from neutral solutions, precipitates Tl2S4 and Tl2S5, and black precipitate, insoluble in excess of reagent. Thallium salts can easily be reduced by means of copper, metal of sulphur, and thus rendered amenable to the above reactions. The chloroplatinate serves for the quantitative estimation of thallium. The soluble chloroplatinate, Tl2[PtCl6], is precipitated as thallium as TlSnS4, insoluble in water, and which may be dried on a Gooch filter at 105°. It may be noted that all thallium compounds are poisonous.

The atomic weight of thallium was determined very carefully by Crookes, who found Tl = 204.2 (O = 16); this figure was confirmed by Lepierre in 1893.

THALWEG—THAMES

THALWEG (a German word compounded from Thal, valley, and Weg, way) in physical geography, a term adopted into English usage signifying the line of greatest slope along the bottom of a valley, i.e. a line drawn through the lowest points of a valley in its downward slope. It thus marks the natural direction of a watercourse.

THAMES, the chief river of England, rising in several small streams among the Cotswolds Hills in Gloucestershire. Its source is generally held to be at a place known as Thames Head, in the parish of Coates, 3 m. W. by S. of Cirencester; but claims have been made from the source of the Evenlode to that of the Evenlode tributary, the head waters of the river Churn, 5 m. S. of Cheltenham. The length of the river from Thames Head Bridge to London Bridge is 161 1/4 miles, and from London Bridge to the Nore, 471 m., a total of 209 m. The width at Oxford is about 150 ft., at Teddington 250 ft., at London Bridge 750 ft., at Gravesend 2100 ft., and between Sheerness and Shoeburyness, immediately above the Nore, 55 m. The height of Thames Head above sea-level is 336 ft., but that of Seven Springs, the adoption of which as the source would extend the length of the river by several miles, is 700 ft. The height of the river at Lechlade is 237 ft., the average fall between Lechlade and London, 143 m., being rather less than 20 in. per mile. The drainage area of the Thames is 9242 sq. m., including that of the Medway, which, as it joins the estuary immediately above Sheerness, may be considered a tributary of the Thames. The Thames forms part of the Gloucestershire-Wiltshire boundary to a point below Lechlade, thence for a short distance it separates Gloucestershire from Berkshire; after which it separates successively Oxfordshire and Berkshire, Buckinghamshire and Berkshire, Middlesex and Surrey, and finally, at its estuary, Essex and Kent. In the subsequent figures the broken figures indicate the distance in miles above London Bridge.

The upper course lies through a broad valley, between the foot-hills of the Cotswolds on the north, and the slight elevations dividing it from the Vale of White Horse on the south. The scenery is rural and pleasant; the course of the river winding. Before reaching Oxford the stream swings north, east and south to encircle the wooded hills of Wytham and Cumnor, which overlook the city from the west. The Windrush joins from the north (left) at New Bridge (1261), the Evenlode near Eyesham (119), and the Cherwell at Oxford (112). Between Lechlade and Oxford the main channel sends off many narrow branches; the waters of the Windrush are similarly distributed, and the branches in the neighbourhood of Oxford form the picturesque "backwaters" which only light pleasure boats can penetrate. The river then follows a valley confined between the hills on either side of Oxford, passes the pleasant woods of Nuncham, and at Abingdon (103) receives the Ock from the Vale of White Horse. At Dorchester (305) the Thames enters on the left, and the river then passes Wallingford (901) and the Thames tributaries from Oxford its course, though greatly winding, has here generally a south-easterly character, but it now bends eastward, and breaches the chalk hills in a narrow gap, dividing the Chilterns from the downs of Berkshire or White Horse Hills. From this point as far as Taplow the southern slopes of the Chilterns descend more or less closely upon the river; they are finely wooded, and the scenery is peculiarly beautiful, especially in early summer. The charm of the Thames is indeed maintained throughout its course; the river is narrow, and is often threaded by a road which winds through the rich valley from Richmond Hill, of the outskirts of London. The river is practically the only physical attribute to the beauty of the modern metropolitan landscape; with its burden of shipping and its industrial activity, it is less admirable. At Pangbourne (802) the Thames receives the Pang on the right, and at Reading (744) the Kennet on the same side. After passing Reading it bends northward to Henley (63), eastward past Great Marlow (57) to Bourne End (54), and southward to Taplow and Maidenhead (491), receiving the Loddon on the right near Shiplake above Henley. Winding in a south-easterly direction, it passes Eton and Windsor (432), Datchet (411), Staines (369), Kingston (32), Shepperton (30) and Sunbury (261), receiving the Coln from the left at Staines, and the Wey from the right near Shepperton. Flowing past Hampton Court, opposite to which it receives the Mole on the right, and past Kingston (204), it reaches Teddington (183). Passing Richmond (16) and Kew the river flows through London and its suburbs for a distance of about 25 m., till it has passed Woolwich. Gravesend, the principal town below Woolwich, is 264 m. from London Bridge. The estuary may be taken to extend to the North Foreland of Kent. In the vicinity of the Thames the Chartist and the Tweed have their sources; the Chars and the Tweed are the Brent at Brentford, the Wandle at Wandsworth, the Ravensbourne at Deptford, the Lea at Blackwall, the Darent just below Erith, and the Inglesbourne at Rainham, besides the Medway.

The basin of the Thames is of curiously composite character. Thus, the upper portion of the system, above the gap at Goring, is a basin in itself, defined on the west and south by the Cotswold and the Chiltern Hills, and by the Chilterns and the uplands of Northamptonshire. But there are several points at which its division from other river basins is only marked by a very low parting. Thus a well-marked depression in the Cotswolds brings the head of the (Gloucestershire) Con, one of the head-streams of the Thames, very close to that of the Isbourne, a tributary of the upper Avon; the parting between the head-streams of the Thames and the Bristol Avon sinks at one point, near Malmsbury, below 300 ft.; and head-streams of the Great Ouse rise little more than two miles from, and only some 300 ft. above, the middle valley of the Cherwell. The White Horse Hills and the Chilterns strike a direct course to this basin, but almost their entire drainage from either flank lies within it, and similarly a great part of the low-lying Weald, though marked off from the rest of the basin by the North Downs, drains into it through these hills. It may be noted further that the Kennet continues upward the line of the main valley below the Goring gap, and the Cherwell that of the main valley above it. The basin thus presents interesting problems. The river is the breasting of the Severn, Dee and other rivers of the west. The question, in fact, involves that of the development of a large part of the hydrography of England.
The Thames about Oxford is often called the Isis. Camden gave currency to the derivation of the word from the combination of the names Thame and Isis. But it can be shown conclusively that the river has borne this present designation from the earliest times. Caesar (De Bell. Gall. v. 11) says that at the time of his invasion of Britain it was called Tamesis. Dion Cassius (xl. 3) and Tacitus (Ann. xiv. 32) both call it Tames, and in no early authority is the name Isis used. In early Saxon times the river was called Thamis, as may be seen in a grant before A.D. 675 to Chertsey Abbey by the sub-king Frithwald. In the first statute passed for improving the navigation of the river near Oxford (21 Jac. I.) it is called the river of Thames, and it was only in a statute of George II. (1751) that the word Isis is used for the first time in a statutory title; but this title is rhyming verse, and as applied to the Thames in its course above Dorchester (Faerie Queen, Bk. iv. canto xi. stanza 24), but there is ample evidence to show that long before his time the name of the river throughout its course was not Isis but Thames. The word Isis is probably an academic rendering of Ouse or Isca, a common British river name, but there is no reason to suppose that it ever had much vogue except in poetry or in the immediate neighbourhood of Oxford.

The flow of the Thames varies greatly, according to the season of the year. The average flowings at Teddington for the summer months of the years 1883 to 1900 were in July 413,000,000 gallons a day, in August 395,000,000 gallons, and in September 375,000,000 gallons. The average for the whole of the years is about 350,000,000 gallons a day, and of this, after the companies have taken 130,000,000, only 220,000,000 gallons are left to pass over Teddington Weir. After a long period of dry weather the natural flow has been known to fall considerably below 200,000,000 gallons, whilst, on the other hand, in the rainy winter season, the flow in 1894 rose for a short time to as high a figure as 20,000,000,000 gallons, and the ordinary flow in winter months may be put down as 300,000,000 gallons. The importance of storage reservoirs is manifest under such conditions of flow, especially bearing in mind the growth of population in the London district and of its increasing need for water for regattas and other purposes. The Thames remains the chief source of supply for the metropolis, but apart from this the corporation of Oxford and two companies in the Staines district have powers to draw water from the river, though not in any large quantities. Throughout the whole of the Thames watershed, and especially in the 3800 sq. m. above the intakes of the water companies (at Hamptons) a title above Lechlade, the Thames Conservancy Board has the requirements of parliament that no sewage or other pollution shall be allowed to pass into the Thames, into its tributaries streams, or into the navigable watercourses. An efficient and substantial staff of inspectors constantly visiting the various parts of the watershed, and in spite of many difficulties arising from vested interests, the work is chiefly one of maintaining the quality of the Thames, and its banks are now much more picturesque than in the earlier days. So recently as 1890 the state of the river below London was such as to be dangerous to the public health. The metropolis has since then managed to improve. The work is now chiefly one of maintaining its present condition and of improving the tidal part of the river.

The Thames is navigable for rowing-boats as far upwards as Cricklade, except in dry seasons, and for barges at all times as far as Lechlade, 18 m. below Thames Head. At Ingham, three-quarters of a mile above Lechlade, the Thames and Severn canal has its junction with the Thames. This canal is the link between the two great rivers from which it takes its name, and, in other words, takes the course of the Severn. It runs to the last of the three important locks of the Severn. It is entered by the old water-bailiffs, and its importance in connexion with the navigation of the Thames was increased by the construction of a lock which prevents the water-bailiffs passing below the lock. The river was called the Seal when it was navigable, a name that is still used in connexion with the public hall of the town.

It is a common saying that the Thames was not navigable to the right of navigation, it was not until the last quarter of the 18th century that any systematic regulation of its flow in the upper reaches was attempted. Complaints of the obstructions in the Thames were not uncommon, and John Taylor, the Water Poet (1580-1653), in a poem commemorating a voyage from Oxford to London, bewails the difficulties he found on the passage. No substantial measures to remedy such state of things were adopted till 1771, when an act of parliament was passed authorizing the construction of pound locks on the Thames above Maidenhead bridge. In pursuance of this act several locks were built, and the Thames was made navigable to London, as far down as Teddington. These pound locks were arranged by the Act of 1771 to ensure an efficient head of water during the drier seasons of the year, and facilitate the escape of winter floods. The number of locks which have been made is now 724, of which the uppermost lock is at St John's, below Lechlade; the lowest is Richmond, but this is a half-tide lock, keeping the water above at a level corresponding to half of that of flood tide. Under ordinary circumstances, the sluice on this lock is shut, so that a half flood to half ebb, so that the river remains tidal up to Teddington, the next lock.

The canals in use communicating with the Thames, in addition to the Thames and Severn canal, are the Oxford canal, giving communication from that city with the north, the Kennet and Avon canal from Reading to the Bristol Avon, the Grand Junction at Brentford, the Regent's canal at Limehouse, and the Grand Surrey canal at Rotherhithe. A short cut connects Gravesend with Higham. Navigation is also carried on by the Medway to Tonbridge, on the lower parts of the Darent and Cray, from Dartford and Crayford, and on the Wey up to Guildford and Godalming. The navigation of the upper Thames above Aldermaston is little used. The Wilts and Berks canal, joining the Thames at Abingdon, is disused. By means of the Grand Junction and Oxford canals it is possible to convey goods between the Thames and the great industrial centres of England.

The trade on the upper Thames is steady, though not extensive. The vast trade at the estuary, which lies within the bounds of the city of London, continues.

The utility of the river is great in the opportunities for exercise and recreation which it affords to the public, especially to Londoners. The scene on any part of the river from Oxford down on public holidays and on Saturdays and Sundays during the summer is found to be sufficient to show how it contributes to the public enjoyment. It is only since about 1870 that this popularity has grown up. Ten years earlier even rowing-boats were few excepting at Oxford, at Oxford on the Henley Royal Regatta days, and at Putney on the eights. Steam launches did not exist on the river before 1866 or 1867, and houseboats only in the form of college barges at Oxford. But in 1890 there were 541 launches, 162 house-boats, and 11,284 rowing-boats. Each boat is registered, a small tax being charged; while there are fixed prices for the passage of locks. During the season regattas take place at many of the towns and larger villages. Of these the Henley Royal Regatta is pre-eminent by the number and importance of the entries, and by its comparative antiquity. The regattas at Molesey, Kingston, Reading, Marlow and Oxford, as well as many others, attract numerous competitors and spectators. The Oxford races at Henley, Henley races, Oxford races on Putney tideway, the summer eights and the "tories" at Oxford University, and the school races at Eton and Radley should also be mentioned.

A committee of 1393 was granted to the citizens of London to remove weirs on the Thames, and empowered the Lord Mayor to enforce its provisions. For the next four centuries it acted through the civic officials, till in 1771 a committee of the Corporation of London took over the work. In 1857 the Thames Conservancy Board was established. Its powers were increased and its constitution varied in 1864, 1866 (till which year the jurisdiction of the river above Staines was under a large body of commissioners), and 1894, but the creation of the Port of London Authority (see LONDON) limited its jurisdiction.

Fish are abundant, especially coarse fish such as pike, perch, rouget, bream, and barbel. Of trout there are many fine specimens, especially at the weirs. Salmon are known to have existed at Maidenhead so recently as 1812, but they disappeared soon after. The fish were not allowed to pass below the weir. It was the duty of Mr W. H. Grenfell, M.P., with the object of reintroducing this fish into the river, and in April 1901 and on subsequent occasions a number of young salmon were placed at Teddington by the Fishery Board. The operations of the Board have been frequently in dispute, but a committee of the House of Commons, which took much evidence on the question in the year 1884, came to the conclusion that "it is impossible to recognize anything as a genealogical record to the Thames salmon." They added that the public at large have only to know that their rights are imaginary to induce them also to be content with the present mode of extinction under which the Thames fisheries, by being given to the public for angling on the more frequented parts of the Thames." These conclusions are interesting in face of the fact that the question has arisen from time to time since 1884.

The fisheries are under the regulation of by-laws made by the Thames Conservancy, which apply to the riparian owners as well
as to the public generally. These by-laws are carried into effect by officers of the conservators, assisted by the river-keepers of the various fishing associations. The principal associations are those at Oxford, Reading, Henley, Maidenhead and Windsor, and the Thames Angling Preservation Society, whose district is from Staines to Brentford.

THAMES, a seaport and gold-mining centre in North Island, New Zealand, in the county and at the mouth of the river of its name, on the Firth of Thames, a deep inlet of the Hauraki Gulf of the east coast. Pop. (1906) 3750. It comprises under one municipality the settlement formerly called Grahamstown, with its suburbs Shortland and Tararu. It lies 42 m. S.E. of Auckland by the steamer-route, a pleasant journey among the islands of the Gulf. There is also railway communication with the Auckland (but by a circuitous route of 170 m.), and with the neighbouring districts by branch lines. The harbour is good; the industries include foundries, shipbuilding yards and saw-mills. The sea fisheries are valuable, a large part of the yield being exported to Auckland. The inland district watered by the Thames river is auriferous; Waitakiri (40 m.) and Karangahake (28 m. S. of Thames) are centres of operations. The small town of Te Aroha (32 m. by rail), on the river, besides being the centre of mining and agricultural industries, is a favourite health resort on account of its hot medicinal springs. The river is navigable for steamers of light draught. The scenery along its course is pleasant, and at Ohinemuri (70 m. from Thames it flows through a fine gorge.

THANA, or TANNA (= a fort, or police-station), a town and district of British India, in the Northern division of Bombay. The town is on the west of the Salsette creek or Thana river, just where the Great Indian Peninsula railway crosses to the mainland, 21 m. from Bombay city. Pop. (1901) 16,011.

The District of Thana has an area of 3573 sq. m. It extends along the coast for 105 m., with a breadth of 50 m., and is confounded between the Western Ghats and the sea, at the mouth of the N. territory of Damaun and by Surat district, and on the S. by Kolaba district. The district is well watered and wooded, and, except in the north-east, is a low-lying rice tract broken by hills. Most of the hills were once fortified, but the forts built on them are now dilapidated and useless. Matheran (q.v.) is a favourite summer resort for the citizens of Bombay. The only rivers of any importance are the Vaitarna and the Ulhas, the former being navigable for a distance of about 20 m. from its mouth; the latter is also navigable for parts of small craft. There are no lakes, but the Vaitarna is divided into two branches, the Ulhas; and the Tulu, formed by its confluence, supplies the city with water. In 1901 the population was 87,433, showing a decrease of 1 per cent. in the decade. The staple crop is rice. Fishing supports many of the people, and the forests yield timber and other produce. Salt is largely manufactured by evaporation along the coast. At Kurla, in Salsette island, there are cotton mills and rice mills. The district is traversed throughout its length by the Bombay and Baroda railway, and also crossed by the two branches of the Great Indian Peninsula line.

The territory comprised in the district of Thana (apart from Sambhar and the acquisitions, 1862) formed part of the dominions of the peshwa, and was annexed by the British in 1818 on the overthrow of Baji Rao. Since then the operations to put down the Koli robbers, which extended over several years, have been the only cause of serious trouble.

THANESAR (= "place of the god"), an ancient town of British India, in Karnal district of the Punjab, on the river Sarswati, 100 m. by rail N. of Delhi; pop. (1901) 5066. As the centre of the tract called Kurukshetra in the Mahabharata, it has always been a holy place, and was in the seventh century the capital of King Harshavardhana, who ruled over all northern India. The bathing-fair held here on the occasion of a solar eclipse is said to be attended by half a million pilgrims.

THANET, ISLE OF, the extreme north-eastern corner of Kent, England, insulated by two branches of the river Stour, and forming one of the eight parliamentary divisions of the county. Its name is said to be derived from Saxon tena, a beacon or fire (probably from the number of watch-fires existing on this easily ravaged coast), and numerous remains of Saxon occupation have been found, at Ostend near Ramsgate. Thanet is roughly oblong in form, its extreme measurements being about 8 m. from E. to W., and 5 m. from N. to S. The branches of the Stour dividing near Sarre take the place of the former Wantsum, a sea-passage which had diminished in breadth to half a mile in the time of Augustine. The Wantsum was guarded by the Roman strongholds of Regulibium (Reculver) in the north and Rutupiae (Richborough) in the south, and was crossed by ferries at Sarre and Wade. With the drying up of this channel and the closing of Sandwich harbour in the 12th century, the present marshlands or level to the south and west of the Isle except left. The sea-face of Thanet consists mainly of bold slopes or sheer cliffs, and the eastern extremity is thefine headland of thenorth Foreland. Containing the popular seaside resorts of Ramsgate, Broadstairs, Margate and Westgate, Thanet is served by the South-Eastern & Chatham railway, and Minster is a junction station of the lines to Ramsgate and Sandwich respectively.

THANKSGIVING DAY, in the United States, the fourth Thursday in November, annually set apart for thanksgiving by proclamation of the president and of the governors of the several states. This day is observed with religious ceremonies in the churches, and, especially in New England, as an occasion for family reunion. The Pilgrims set apart a day for thanksgiving at Plymouth immediately after their first harvest, in 1621; the Massachusetts Bay Colony for the first time in 1630, and frequently thereafter until about 1680, when it became an annual festival in that colony; and Connecticut as early as 1639 and annually after 1647, except in 1675. The Dutch in New Netherland appointed a day for giving thanks in 1644 and occasionally thereafter. During the War of Independence the Continental Congress appointed one or more thanksgiving days each year, except in 1777, each time recommending to the executives of the various states the observance of these days in their states. President Washington appointed a day of thanksgiving (Thursday, the 26th of November) in 1789, and appointed another in 1795. President Madison, in response to resolutions of Congress, set apart a day for thanksgiving at the close of the War of 1812. One was annually appointed by the governor of New York from 1817. In some of the Southern States there was opposition to the observance of such a day on the ground that it was a relic of Puritanic bigotry, but by 1858 proclamations appointing it were issued by the governors of twenty-five states and two Territories. President Lincoln appointed the fourth Thursday of November 1864, and since that time each president has annually followed his example.

THAN, a town of Germany, in Upper Alsace, 15 m. by rail N.W. of Mulhausen. Pop. (1905) 7901. It is the seat of cotton, calico and machine weaving, soap, and flax industries, and excellent wine is grown there. The (Roman Catholic) church of St Theobald (1351) is an elegant specimen of Gothic, and has a remarkably fine tower (1450-1516), 266 ft. high. Above the town are the ruins of the castle of Engellburg, destroyed by Turenne in 1675.

THAPSACUS, the "large and prosperous city" on the Arabian side of the Euphrates where Cyrus the Younger revealed to the Greeks the object of his expedition (Xen. Anab. i. 4, 11). No such place has yet been found mentioned in cuneiform texts. We may have a Semitic form of the name in the Hebrew Tiphah; but it is impossible to determine whether the one phrase "from Tiphah to Gaza" (1 Kings v. 4—iv. 24 in the English version), where the name seems to occur, is as early
as the Persian period: the Greek text is quite discrepant. Thapsus was the crossing-place of Darius Codomannus, before and after his defeat (Arrian ii. 13), and of Alexander (iii. 7), and in Strabo's time it was the usual crossing-place (xvi. 1, 21); but Tiglat-pileser I. and Assur-nasir-pal crossed considerably farther north, and we have no reason to suppose that they were not simply following the practice of those earlier times; and we do not know when the custom of crossing at Thapsus which the Hebrew text of the passage in 1 Kings may presuppose sprang up. Xenophon's army had to be content with fording the stream. Alexander, however, effected his crossing (Arrian, iii. 7) by two connected bridges (of boats?), and it was from this place that later he had the material for his fleet sent down (Arrian vii. 19; Strabo xvi. 741) to Babylon. His successors must also have valued the place, for according to Pliny (v. 87) it bore later the name of Amphipolis, perhaps bestowed on it (Steph. Byz., Appian Syr. 57) by Seleucus I., although the name, like so many others, probably failed to win acceptance; and in the time of Eratosthenes the position of Thapsus had become so central that he chose it as the point from which to make his measurements for all Asia (Strabo ii. 79, 80), and in the time of Strabo himself it was there that Arrian's harkened for transport down the Euphrates (Q. Curt. x. 1), and landed after having come by stream from lower districts (Strabo xvi. 1, 23). After Pliny the city is not again mentioned.1

After various attempts at identification (see Ritter, Erdkunde) it has apparently been correctly identified by J. P. Peters (Nation, May 23, 1890) and B. Mortiz (Sitz.-Berl. Akad., July 23, 1889). The name may survive in Kal'at Diban, "a small ruin 8 m. below Meskene, and 6 m. below the ancient Barbalissus." See J. P. Peters, Nippur, 196 ff. (H. W. H.)

THAPSUS, a low peninsula, now known as Magnisi, joined by a narrow isthmus to the mainland of Sicily, about 7 m. N.N.W. of Syracuse. The founders of Megara Hyblea settled here according to Thucydides, in the winter of 729–728 B.C., but it seems to have been deserted almost by 707, not entirely uninhabited until the Athenians used it as a naval station in their attack on Syracuse early in 414 B.C. A number of tombs were excavated in 1804, containing objects belonging to a transitional stage between the second and third Sicel period, attributable roughly to 1000-900 B.C., and with a certain proportion of Mycenean importations. See Orsi in Monumenti dei Lincei (1897), vi. 89–150.

THAR AND PARKAR, or Thur and Parkar, a district of British India in the Sind province of Bombay. Area, 13,941 sq. m. The district is divided into two portions. The western part, called the "Pat," is watered by the Eastern Nara and the Mithrau canals, which constitute the sole water-system of the district, and the presence of water has created a quantity of jungle and marsh; the other part, called the "Thar," is a desert tract of rolling sand-hills, running north-east and south-west, composed of a fine but slightly coherent sand. To the south-east of Thar is Parkar, where there are ranges of rocky hills, rising to 350 ft. above the surrounding level, and open plains of stiff clay. This portion contains the ruins of several old temples. The climate subject to considerable extremes in temperature, being excessively hot in the summer and very cold in winter, the cold increasing as the sand-hills are approached. In 1901 the population was 389,714, showing an increase of 22 per cent. in the decade. The principal crops are millets, rice, wheat, oil-seeds and cotton. Cultivation is made possible by the narrow-gauge railway from Hyderabad to Shadipalli, connected with the North-Western main line by a bridge across the Indus at Kotri, and with the Rajputana system at Jodhpur. Umarkot, the administrative headquarters of the 1 Stephanus of Byzantium gives it in a list of cities as a "Syrian town on the Euphrates," quoting from Theopompos, without noting that he has already referred to it under the name Amphipolis.

district, is on the edge of the desert. Pop. (1901) 4924. It is historically interesting as the birthplace of the emperor Akbar in 1542.

Very little is known of the early history of the district. The Suda Rajputs, said to be descendants of Parmar Soda, are supposed to have come into this part of Sind about 1226, when they quickly displaced the rulers of the country, though, according to other authorities, they did not conquer the country from the Sumnas, the dominant race, before the beginning of the 16th century. The local dynasty of the Sodas succumbed to the Kalhora's about 1750, since which period the district has been a scene of lawless and lawless to Sind. The Talpur jirga succeeded the Kalhora, and built a number of forts to overawe the people, who were lawless and addicted to robbery. On the British conquest of Sind in 1843 the greater part of the district was made over to Cutch, but in 1856 it was incorporated in the province of Sind. In 1859 a rebellion broke out, which was quickly suppressed.

THARANDT, a town of Germany, in the kingdom of Saxony, romantically situated on the Wilde Weisseritz, 9 m. S.W. of Dresden, on the Dresden-Reichenbach railway. Pop. (1905) 7130, of which there is a Protestant church, a high school, and the oldest academy of forestry in Germany (founded by Heinrich Cotta in 1811) with about sixty students. Tharandt is a favourite summer resort of the people of Dresden, one of its principal charms being the magnificent beech woods which surround it. See Donner, Tharandt (Tharandt, 1890).

THARGELIA, one of the chief Athenian festivals in honour of the Delian Apollo and Artemis, held on their birthdays, the 6th and 7th of the month Thargelion (about the 24th and 25th of May). The name, which was derived by the ancients from θαργήλη τύρων γίγαι ("to reap the land "), is more probably connected with τερα-θρανος (cf. Lat. torreco, tostus), signifying the produce of the earth "baked" by the sun. Essentially an agricultural festival, the Thargelia included a purifying and expiatory ceremony. While the people offered the first-fruits of the earth to the god in token of thankfulness, it was at the same time necessary to propitiate him, lest he might ruin the harvest by excessive heat, possibly accompanied by pestilence. The purification preceded the thanksgiving service. On the 6th a sheep was sacrificed to Demeter Chloræ on the Acropolis, and perhaps a swine was offered at the same time. The rite was performed by the woman who bore the first child born in the year. The ritual was the following. Two men, who were called φαρακις or θεμακος, the ugliest that could be found, were chosen to die, one for the men, the other (according to some, a woman) for the women. On the day of the sacrifice they were led round with strings of figs on their necks, and whipped on the genitals with rods of figwood and squills. When they reached the place of sacrifice on the shore, they were stoned to death, their bodies burnt, and the ashes thrown into the sea (or over the land, to act as a fertilizing influence). The whipping with squills and figwood was intended to stimulate the reproductive energies of the φαρακις, who represented the god of vegetation, annually slain to be born again. It is agreed that an actual human sacrifice took place on this occasion, replaced in later times by a milder form of exiliation. Thus at Leucas a criminal was annually thrown from a rock into the sea as a scapegoat; but his fall was checked by live birds and feathers attached to his person, and men watched below in small boats, who caught him and escorted him beyond the boundary of the city. Similarly, at Messalia, on the occasion of some heavy calamity (plague or famine), one of the poorest inhabitants volunteered as a scape- goat. For a year he was fed up at the public expense, then cited to be put to death, the pretense being that he was the cause of the present calamity, clothed in sacred garments, led through the city amidst executions, and cast out beyond the boundaries. The ceremony on the 7th was of a cheerful character. All kinds of first-fruits were carried in procession and offered to the god, and, as at the Pyanepsia (or Pyanopsia), εἰρήνειαν (branches of olive bound with wool), borne by children, were affixed by them to the doors of the houses. These branches, originally intended as a charm to avert failure of the crops, were afterwards regarded as forming
THARRAWADDY—THASOS

part of a supplicatory service. On the second day choruses of men and boys took part in musical contests, the prize for which was a tripod. Further, on this day adopted persons were solemnly received into the genos and phratria of their adoptive parents (see APATURA).

W. Mannhardt, Antike Wald- und Feldkultur (2nd ed. by W. Heuschkel, 1904—5).

THARRAWADDY, a town and district in the Pegu division of Lower Burma. The town has a station on the railway, 68 m. N.W. from Rangoon. Pop. (1901) 1643. The district has an area of 2851 sq. m. The Pegu Yoma range separates it from Toungoo district, and forms the water-parting between the rivers Irrawaddy and Sittang; there are also many small elevations. The Irrawaddy is the principal navigable river. Another important river is the Hlaing, which runs through the district from north to south, receiving from the east, through numerous channels, the drainage of the Pegu Yoma Mountains, which fertilizes the plain on its eastern bank. There are teak forests and fuel reserves, covering an area of 732 sq. m. Among the wild animals found in the mountains are elephant, rhinoceros, bison and various kinds of feathered game. The rainfall in 1905 was 91-63 in. Pop. (1901) 905,570, showing an increase of 17 per cent. in the decade. The railway runs through the centre of the district, with ten stations. The chief towns are Gyobingauk (6076) and Thonze (6578). The staple crops are rice, but orchards and gardens are also common. The history of the district is identical with that of Hzenada (q.v.). Tharrawaddy was formed in 1878 out of that portion of Hzenada lying east of the Irrawaddy.

THARROS, an ancient town of Sardinia, situated on the west coast, on the narrow sandy isthmus of a peninsula at the north extremity of the Gulf of Oristano, now marked by the tower of S. Giovanni di Sinis. It was 12 m. W. of Othoca (Oristano) by the coast road, which went on northwest to Corsus (a milestone of 1 ft is given). In 3 Car. Insr. Ins. 1, 297, and Ins. 1, 396 it is given. In Car. Insr. Ins. 1, 415, and Ins. 1, 429, it is called "Turris in Sinis." It was of Phoenician origin, but continued to exist in Roman times, as the inscriptions show, though they give but little information (Mommsen in Car. Insr. Ins. 1, 832). It was destroyed by the Saracens in the 12th century. Scanty traces of Roman buildings may be seen, and an ancient road paved with large blocks of stone. A part of the site of the town is now invaded by the sea. The church of S. Giovanni di Sinis is a heavy building of the 8th (?) century A.D. originally cruciform, with a dome over the crossing; the transapse and dome are still preserved, but the nave with its two aisles is later. It is naturally built of materials from the old town. Close to it is a watch-tower and a spring of fresh water. The importance of Tharros may be inferred from the extent of its necropolis, which lies on the basaltic peninsula of S. Marco to the S.; on the summit of it are the remains of a nuraghe. Casual excavations are mentioned under the Spanish viceroy, but regular exploration only began in 1838, when the Roman tombs were examined. In 1850 Spano excavated many Phoenician tombs; they are rectangular or square chambers cut in the rock, measuring from 6 to 9 ft. each way, in which inhumation was the rule. The objects found—pottery, scarabs, beads, amulets, &c.—were of considerable interest. In 1872 Louis Veron opened fourteen tombs, and after that the whole countryside ransacked the necropolis, without any proper records or notes being taken, and with great damage to the objects found. Some of these objects are in the museum at Cagliari, others in private collections, and many scarabs are in the British Museum, all of which by the coins found with them are dated later than the Roman occupation (Catalogue of Gems, London, 1888, pp. 13 sqq.). In 1885—86 regular excavations were made, the results of which may be seen in the museum at Cagliari. One tomb contained some fine gold ornaments, with Roman coins of the 1st to 3rd century A.D. (F. Vivante in Notizie degli Scavi, 1886, 127; 1887, 46, 124). The objects, like those found at Sukis, show considerable traces of Egyptian influence, but are probably all of Phoenician importation—the theory of the existence of Egyptian colonies in Sardinia being quite inadmissible. Some 3 m. to the N. is the church of S. Salvatore, with underground rock-cut chambers below it, used as a baptistry (?) by the early Christians, though the walls are decorated with paintings of a decidedly pagan order.

THASOS, an island in the north of the Aegean Sea, off the coast of Thrace and the plain of the river Nestus (now the Kara-Su). The island was colonized at an early date by Phoenicians, attracted probably by its gold mines; they founded a temple of Heraclis, which still existed in the time of Herodotus. Thasus, son of Phoenix, is said to have been the leader of the Phoenicians, and to have given his name to the island. In 720 or 708 B.C. Thasos received a Greek colony from Paros. In a war which the Thracian colonists waged with the Saian, a Thracian tribe, against the Thasians, they were defeated by the Saian, who compelled them to give up their mines which had been more valuable than those on the island. From these sources the Thasians drew great wealth, their annual revenues amounting to 200 or even 300 talents. Herodotus, who visited Thasos, says that the best mines on the island were those which had been opened by the Phoenicians on the east side of the island facing Samothrace. The place was important during the Ionian revolt against Persia. After the capture of Miletus (494 B.C.) Histiaeus, the Ionian leader, landed siege to Thasos. The attack failed, but, warned by the danger, the Thasians employed their revenues to build war ships and strengthen their fortifications. This excited the suspicions of the Persians, and Darius compelled them to surrender their ships and pull down their walls. After the defeat of Xerxes the Thasians joined the Delian confederacy; but afterwards, on account of a difference about the mines and marts on the mainland, they revolted. The Athenians defeated them by sea, and, after a siege that lasted more than two years, took the capital, Thassos, probably in 463, and compelled the Thasians to destroy their walls, surrender their ships, pay an indemnity and an annual contribution (in this they was 33 talents, from the Greeks 25 talents), and resign their possessions on the mainland. In 417 B.C., at the time of the oligarchical revolution at Athens, Thasos again revolted from Athens and received a Lacedaemonian governor; but in 407 the partisans of Lacedaemon were expelled, and the Athenians under Thrasybulus were admitted. After the battle of Aegospotami (405 B.C.), Thasos again fell into the hands of the Lacedaemonians under Lysander who formed a decarchy there; but the Athenians must have recovered it, for it formed one of the subjects of dispute between them and Philip II. of Macedonia. In the embroilment between Philip III. of Macedonia and the Romans, Thasos submitted to Philip, but received its freedom at the hands of the Romans after the battle of Cynoscephalae (197 B.C.), and it was still a "free" state in the time of Pliny. After a period of Latin occupation, it was captured by the Turks in 1462; it was given by the Sultan Mahmoud II. to Mehmet Ali of Egypt, and still remains the property of the khedive. Thasos, the capital, stood on the north side of the island, and had two harbours, one of which was closed. Archilochus described Thasos as "an ass's backbone crowned with wild wood," and the description still suits the mountainous island with its forests of fir. The highest mountain, Ipsario, is 3428 ft. high. Besides its gold mines, the wine, nuts and marble of Thasos were well known in antiquity. The mines and marble quarries are no longer worked; and the chief exports are now fir timber for shipbuilding, olive oil, honey and wax. The imports consist of manufactured goods, beasts of burden and corn, for the island is too mountainous to grow enough corn for the inhabitants. The population, distributed in ten villages, is estimated at
The people are Greek Christians, and do not differ in appearance from the inhabitants of the other Greek islands. The villages are mostly situated at some distance from the sea; for the island suffered from pirates. Even in the early part of the 19th century sentinels stood on duty night and day, and at a signal of alarm the whole population, including the Turkish aga himself, used to hide in the woods.

For a description of the island and its remains of antiquity, see A. Conze, Reise auf den Inseln des thrakischen Meeres (Hanover, 1866). The island is fully described by J. H. Baker-Penoyre in "Journal of Hellenic Studies," xxix. (1909).

THATCH (O. E. thac) the word is common to many Teutonic languages in the sense of "roof," "cover"; cf. Du. dakk, Ger. Dach; from Du. dekken comes "deck"; the Indo-European root is stag, whence Gr. στέγη, roof, Lat. tegere, to cover; the French equivalent is chaume), the material employed sometimes for roofs in the place of tiles or slates; it consists of wheat straw, for which several layers are required, to the depth of from 12 to 14 in., or even extending to 18 in. Unthreshed straw is said to last from twenty-five to thirty years, and the layer of it employed, which is not marshalled, is allowed, and they constitute a durable thatch lasting from thirty to forty years or more. Thatched roofs are not now allowed in London or other towns and their vicinity, but if saturated with a solution of lime the thatch is said to be incombustible. It forms an extremely good roof, warm in winter and cool in summer.

THATON, a town and district in the Tenasserim division of Lower Burma. The town is situated below a hill range, 10 m. from the sea. It was formerly the capital of the Talay kingdom and a sea-port. Pop. (1901) 14,342. The district has an area of 1970 sq. m.; pop. (1901) 543,510, showing an increase of 29 per cent. in the decade. It was formerly a subdivision of Amherst district, but was formed in 1895 out of part of that and of Shweygin district, which has now ceased to exist. The staple crop is rice, but a good deal of tobacco also is grown. The railway from Pegu to Martaban, recently opened, passes through this district and is calculated to increase its prosperity and population.

THAXTER, CELIA (1836-1894), American poet, was born at Portsmouth, New Hampshire, on the 29th of June 1836. Her father, Thomas B. Lathig, betrothed himself with one of his associates in state politics, and retired about 1841 to the barren and isolated Isles of Shoals, ten miles off Portsmouth, where for about ten years he was keeper of the White Island lighthouse; and his daughter's girlhood was therefore spent in marine surroundings, which coloured the best of the verse she afterwards wrote. Her poems, mainly in lyrical form, deal with the beacon-light, the sea-storm, the glist of sails, the sand-piper, the flower among the rocks, &c., in characteristic and sympathetic fidelity. She also wrote prose sketches of life and scenery, Among the Isles of Shoals (1873); stories and poems for children and letters; besides a book about floriculture, An Island Garden (1894). In 1896 appeared a complete edition of her poems, edited by Sarah Orne Jewett. She married in 1831 Levi L. Thaxter (d. 1884), a devoted student of Robert Browning's poetry, and spent most of her life on Appledore, one of the Isles of Shoals, where she died on the 26th of August 1894. Her son Roland Thaxter (b. 1858), a well-known crypto- gamic botanist, became professor of botany at Harvard in 1891.

THAYER, ABBOTT HANSDON (1849- ), American artist, was born at Boston, Massachusetts, on the 12th of August 1849. He was a pupil of J. L. Gérôme at the Ecole des Beaux Arts, Paris, and became a member of the Society of American Artists (1879), of the National Academy of Design (1901), and of the Royal Academy of San Luca, Rome. As a painter of portraits, landscapes, animals and the ideal figure, he won high rank among American artists. Among his best-known pictures are, "Virgin Enthroned," "Caritas," "In Memoriam, Robert Louis Stevenson," and "Portrait of a Young Woman"; and he did some decorative work for the Walker Art Building, Bowdoin College, Maine. Thayer is also well known as a naturalist. He developed a theory of "protective coloration" in animals (see "Colours of Animals"), which has attracted considerable attention among naturalists. According to his theory, "animals are painted by nature darkest on those parts which tend to be most lighted by the sky's light, and vice versa"; and the earth-brown of the upper parts, bathed in sky-light, equals the skycolours of the belly, bathed in earth-yellow and shadow.

THAYER, JAMES BRADLEY (1831-1902), American legal writer and educationist, was born at Haverhill, Massachusetts, on the 13th of January 1831. He graduated at Harvard College in 1852, and at the Harvard Law School in 1856, in which year he was admitted to the bar of Suffolk county and began to practise in Boston. In 1873-83 he was Royall professor of law at Harvard; in 1883 he was transferred to the professorship which after 1893 was known as the Weld professorship and which he held until his death on the 14th of February 1902. He took an especial interest in the historical evolution of law. He wrote: The Origin and Scope of the American Doctrine of Constitutional Law (1883); Cases on Evidence (1892); Cases on Constitutional Law (1895); The Development of Trial by Jury (1896); A Preliminary Treatise on Evidence at the Common Law (1898), and a short life of John Marshall (1901); and edited the two volumes of Kendall's Law of Evidence (1884) and Jeremy Wright (1887), and A Westward Journey with Mr Emerson (1884).

THAYER, JOSEPH HENRY (1828-1901), American biblical scholar, was born at Boston on the 7th of November 1828. He studied at the Boston Latin School, and graduated at Harvard in 1850. Subsequently he studied theology at the Harvard Divinity School, and graduated at Andover Theological Seminary in 1857. He preached in Quincy, and in 1859-64 in Salem, Massachusetts, and in 1862-63 was chaplain of the 40th Massachusetts Volunteers. He was professor of sacred literature in Andover Seminary in 1864-82, and in 1884 succeeded Ezra Abbot as Bussey professor of New Testament criticism in the Harvard Divinity School. He died on the 26th of November 1901, soon after his resignation from the Bussey professorship. He was a member of the American Bible Review Committee and recording secretary of the New Testament company. His chief works were his translation of Grimm's Clavis Novi Testamenti (1887; revised 1889) as A Greek-English Lexicon of the New Testament, and his New Testament bibliography (1890).

THAYETMYO, a town and district in the Minbu division of Upper Burma. The town is situated on the right bank of the Irrawaddy, opposite Allamny. Pop. (1901) 15,824. The cantonment contains the wing of a British battalion and a native regiment. It enjoys a high reputation for healthiness. There is a special industry of silver work.

The district has an area of 4750 sq. m.; pop. (1901) 239,706, showing a decrease of 4 per cent. in the decade. The total rainfall in 1905 was 41-30 in. On the west is the Arakan Yoma range, and on the east the Pegu Yomas; and the face of the country, where it does not rise into mountains, is everywhere broken by low ranges of hills, many of which are barren and destitute of all vegetation. The greater part of the district is wooded, and the Yomas east and west are covered with forests, now mostly preserved. The chief river is the Irrawaddy, which traverses Thayetmyo from north to south. The drainage finds its way to the Irrawaddy by three main streams (the Pwone, Ma-h'tün and Ma-de) on the west, and by two (the Kyé-ni and Hput) on the east. Several salt and hot springs occur in many localities; petroleum is also found, and extensive lime quarries exist a few miles south of Thayetmyo. The principal wild animals are elephants, rhinoceroses, tigers, leopards, black bears and wild hog. Silver pheasants and partridges are found in large numbers, especially in the mountains. The chief products are rice, cotton, oil-seeds and tobacco; cutch is also very abundant, and the manufacture of the dyes-stuff is carried on extensively. Coal has been found in the district, and earth
THEATRE

729

oil-wells exist, but neither coal nor oil has yet been extracted in any quantity. There are 403 sq. m. of reserved forest. Three oil-wells were sunk in 1883 at Pedaukip, but they were found unprofitable and abandoned.

On the annexation of Pegu by the British in 1852-53, Thayetmyo was formed into a subdivision of Province district; and in 1870 it was erected into a separate jurisdiction and placed under a deputy-commissioner. It was formerly in the Irrawaddy division of Lower Burma, but was transferred to Upper Burma for administrative purposes in 1896.

THEATRE (θεάτρον, "a place for seeing," from θεάω, to see), a building specially devised for dramatic representations. The drama arose from the choric dances in honour of Dionysus, which were held in a circular dancing-place (δρυγάρια, Lat. orchestra) in his precinct at the foot of the Acropolis at Athens. When the leader of the chorus held a dialogue with the remaining choreutae he mounted the table which stood beside the altar of Dionysus in the centre of the orchestra; but as the number of actors and the importance of the dialogue increased, it became necessary to erect a platform at the side of the dancing-place and a booth in which the performers could change their dresses and masks. At the same time temporary wooden stands (ἱππα) were set up for the spectators, who no longer ranged themselves around the whole ring, but only on the slope of the Acropolis, facing southward. We are told that the collapse of the ἱππα, in 449 B.C. led to the erection of a permanent theatre; this, however, was a stone building. Embankments were made for the support of the spectators' benches; the stage buildings were of wood, and, although some traces of a stone theatre belonging to the end of the 5th century have been pointed out, the "theatre of Dionysus," whose remains may still be seen (Pl. I. and II.), is in the main a work of the 4th century. It was completed soon after 340 B.C. under the administration of the statesman and financier Lycurgus. Alterations were made in the stage-buildings in the Hellenistic period, under Nero, and again in the 3rd century A.D. Although the prototype of Greek theatres, it is not the most perfectly preserved. Amongst those of purely Greek design the most typical is that of Epidaurus (Pl. I.), which was built in the latter part of the 4th century B.C. by Polyclitus the Younger. The largest known to Pausanias was that of Megalopolis, excavated by the British School at Athens in 1889-91, in which the stage buildings were replaced by the Thersilion, a large council-chamber. Others of importance for the study of the ancient theatre have been excavated at Delos, Eretria, Sicyon and Oropus. None of these, of course, is contemporary with the classical period of the Greek drama, and their stone stage-fronts belong to the Hellenistic period.

In Asia Minor we find a type of theatre (belonging to a somewhat later date) with a broader, lower and deeper stage; and the Roman theatre (see below) carries these changes still further. Before discussing their significance it will be best to describe the parts of the ancient theatre, the fullest account of which is to be found in the fifth book of Vitruvius (written in the Augustan period). Its three main divisions were the auditorium (Lat. cavea; it had no technical name in Greek), the orchestra, and the stage buildings (ἐσχήδω, literally "tent" or "booth" Lat. scena). As the orchestra was the germ of the theatre, so it determined its shape, and in the Greek theatre preserved its circular form in many instances (as at Epidaurus). In the scheme of proportions given by Vitruvius, however (see fig. 1, which carries its own explanation), a segment (ἀγγείον, prosenium) was cut off by the stage-front (προκρίνων, prosenium). The auditorium was divided by flights of seats into wedge-shaped blocks (εσχήδων, κεντρα) and also longitudinally by a gangway (δικόνων, προκριατίς). In Greece the slope of a hill was always chosen for the auditorium and furnished with stone seats in tiers like steps. The slope of the Acropolis faces south, which (as Vitruvius points out) was the worst aspect for the spectators; but this was unavoidable for religious reasons, since the performances had to be held in the precinct of Dionysus. At Athens the inner boundary was a semicircle with the ends prolonged in parallel straight lines, which gave the spectators in the wings a better view of the stage than that obtainable in those theatres where (according to the Vitruvian rule) the boundary was segmental. At Epidaurus

**FIG. 2.**

From Dörpfeld and Reichel, Das griechische Theater.

- a, double western wall.
- b, single wall.
- c, walls terminating wings of auditorium.
- d, e, diazoma.
- f, g, western boundary wall.
- h, h', wall of Neronian stage.
- i, fragment 5th-century orchestra.
- j, k, ancient masonry (?) of supporting walls.
- n, old stage buildings.
- o, Stone prosenium (1st or 2nd century B.C.)
- p, foundations of Neronian side wings.
- q, r, fragments 5th-century orchestra.
- s, 4th-century portico.
- t, old Dionysus temple.

A compromise was effected by prolonging the ends of the semicircle as segments of a curve with a longer radius. The best seats were in the lowest row; at Athens this was formed by a series of marble thrones assigned to various priests or officials whose titles may be read on those (60 out of 67) which are now preserved. The priest of Dionysus occupied the central throne. In some theatres benches with backs took the place of separate thrones. The right of sitting in reserved places was called ἀγγείον.
THEATRE

...imply according to Pliny, whose account is the only one in existence. The orchestra was of course necessary to the natural hill-slope of Greek theatres. The Roman theatre thus became an organic whole; the auditorium and stage-buildings were structurally connected, and the orchestra was entered from the wings, not by open passages (παράθεσις) as in Greece, but by vaulted corridors. The orchestra was no longer used for the performances (whether dramatic, musical or merely spectacular), but was reserved for senators and other persons of distinction. Hence (as Vitruvius points out) arose the necessity for lowering and enlarging the stage. It is hard to say when this change was made or at what date it was first introduced into Italy (if it did not originate in the west). The larger of the two theatres at Pompeii dates from the Hellenistic period, but was thrice reconstructed, and it is not clear to what date we are to assign the low stage of Roman pattern; perhaps it belongs to the 1st century B.C. The theatre of the Roman colony of Pompeii founded by Sulla (B.C. 80). The theatre of Pompeii (see below) is said by Plutarch to have been copied from that of Mytilene, which suggests that the Roman theatre was derived from a late Greek model; and this is made probable by the existence of transitional forms.

During the Republican period the erection of permanent theatres with seats for the spectators was thought to savour of Greek luxury and to be unworthy of the stern simplicity of the Roman citizens. Thus in 134 B.C. Scipio Nasica induced the senate to demolish the first stone theatre which had been begun by C. Cassius Longinus ("tuanquam intutile et nocturnum publicus moribus," Liv. Epit. 48). Even in 55 B.C., when Pompey began the theatre of which remains still exist in Rome, he thought it wise to place a shrine to Venus Victrix at the top of the cavea, as a sort of excuse for having stone seats below it— the seats theoretically serving as steps to reach the temple. This theatre, which was completed in 52 B.C., is spoken of by Vitruvius as "the stone theatre," par excellence: it is said by Pliny to have held 40,000 people. It was also used as an amphitheatre for the bloody shows in which the Romans took greater pleasure than in the purer intellectual enjoyment of the drama. At its inauguration 500 lions and 20 elephants were killed by gladiators. Near it two other theatres were erected, one begun by Julius Caesar and finished by Augustus in 13 B.C., under the name of his nephew Marcellus, and another built about the same date by Cornelius Balbus (Suet. Aug. 39; Pliny, H. N. xxxvi. 59). Scanty remains exist of this last theatre, but the ruins of the theatre of Marcellus are among the most imposing of the buildings of ancient Rome.

A long account is given by Pliny (H. N. xxxvi. 5 and 114) of one of the most magnificent temporary theatre built by the aedile M. Aemilius Scaurus in 58 B.C. It is said to have held the incredible number of 80,000 people, and was a work of the most costly splendour. Still less credible is the account which Pliny gives (H. N. xxxvi. 176) of two wooden theatres built by C. Curio in 50 B.C., which were made to revolve on pivots, so that the two together could form an amphitheatre in the afternoon, after having been used as two separate theatres in the morning.

All Roman provincial towns of any importance possessed at least one theatre; many of these are partly preserved. On

1 Huelsen has shown that this statement is exaggerated, and estimates the number of spectators at 9000 to 10,000.
2 According to Livy (xl. 51), the theatre of Marcellus was built on the site of an earlier one erected by Aemilius Lepidus.

Fig. 3.—Diagram showing the principle on which the Roman theatre was planned according to Vitruvius.

ATHENS, THE THEATRE OF DIONYSUS FROM THE ACROPOLIS.
PLATE II.

THEATRE

ATHENS, PRINCIPAL SEATS IN THE THEATRE OF DIONYSUS.

ASPENDUS, THE STAGE WALL.

INTERIOR OF THEATRE, ORANGE.
Pl. II. will be found reproductions of two of the most important—that of Aspendus in Pamphyllia, which illustrates the Eastern type showing Hellenistic influence, and that of Acharnai (Orange) in South Gaul. Covered theatres were sometimes built, whether on account of climatic conditions (as at Aosta) or more commonly for musical performances. These latter were generally called Odeon (Gr. ὀδέαω, a place for singing). The best preserved is the Odeum of Herodes Atticus, at the south-west angle of the Athenian Acropolis, which has a semicircular orchestra. It was built in the reign of Hadrian by Herodes Atticus, a wealthy Greek, who spent enormous sums in beautifying the city of Athens, in honour of his wife Regilla. Its cavea, which is excavated in the rock, held about 6000 people; it was connected with the great Dionysiac theatre by a long and lofty passageway. This, which it is probable remains still exist, probably a late restoration of the stoa built by Eumenes II. of Pergamum. It was also a common practice to build a small covered theatre in the neighbourhood of an open one, where performances might take place in bad weather. We have an example of this at Pompeii. The Romans used scenery and stage effects of more elaboration than was the custom in Greece. Vitruvius (iii. 7) mentions three sorts of movable scenery:—(1) for the tragic drama, façades with columns representing public buildings; (2) for comic plays, private houses with practicable windows and balconies; and (3) for the satyrlic drama, rustic scenes, with mountains, caverns and trees.

BIBLIOGRAPHY.—By far the fullest account of the Greek theatre is given in Dörpfeld and Reichel's Der Theater (Athens, 1896). Its main thesis is, however, rejected by many archaeologists on the grounds stated above. Puchstein, Die griechische Bühne, endeavours to prove that a stone theatre was built at Athens in the 4th century B.C., and that the proscenium usually supposed to be Hellenistic dates from the time of Lycurgus (above). For English readers the best account of the Greek theatre is to be found in A. E. Haigh's Attic Theatre (3rd ed., revised by A. W. Pollard-Cambridge, 1920), which, if a biographical sketch of the voluminous literature of recent times is given. Albert Müller's Lehrbuch der griechischen Bühnenaltarfiguren (Freiburg, 1886) is indispensable to the student. For the Roman theatre reference may be made to Durm, Baukunst der Römer, ed. 2, pp. 645 ff.

J. H. M.; H. S. J.)

The Modern Theatre

During the middle ages miracle plays with sacred scenes were the favourite kind of drama; no special buildings were erected for these, as they were represented either in churches or in temporary booths. In the 16th century the revival of the secular drama, which was so important a part of the literature of England, was carried on in tents, wooden sheds, or courtyards of inns, mostly by strolling actors of a very low class. It was not till towards the close of the century that a permanent building was constructed and licensed for dramatic representations, under the management of Shakespeare and Burbage. The first building specially erected in London for dramatic purposes was built in 1576–77 by the actor James Burbage. It was constructed of timber, and stood in Holywell Lane, Shoreditch, till 1598, when it was pulled down; it was known as "The Theatre" by excellence. Of almost equally early date was the "Curtain," theatre, also in Shoreditch; so called from the plot of ground, known as "The Curtain," on which it stood. It probably continued in use till the general closing of theatres by order of the parliament in 1642. The "Globe" theatre, famous for its association with Shakespeare, was built by James Burbage, who used the materials of "The Theatre," in the year 1599. Its site was in Southwark, in the Bankside, near the "Bear Gardens." It was an octagonal structure of wood, with lath and plaster between the main framework. It was burnt in 1613, rebuilt, and finally pulled down and its site built over in 1644. Its name was derived from its sign of Atlas supporting the globe. Near it were two less important theatres, "The Rose," opened in 1592 by Henslowe, and "The Swan" (see below), opened in 1598 and partly owned also by Henslowe; but the Globe, the latter was an octagonal wood-and-plaster building. The "Blackfriars" theatre, another of the Burbages' ventures, was built in 1596, near the old Dominican friary. The "Fortune" theatre was built by Edward Alleyn, the actor, in 1599, at a cost, including the site, of £1320. It stood between Whitecross Street and Golding Lane. It stood as late as 1819, when a drawing of it was given by Wilkinson (Londina illustrata, 1819). The "Red Bull" theatre was probably originally the galleryed court of an inn, which was adapted for dramatic purposes towards the close of Elizabeth's reign. Other early theatres were the "Hope," or "Paris Garden" theatre, the "Whitefriars" and the "Salisbury Court" theatres, and the "Newington" theatre. A curious panoramic view of London, engraved by Visscher in 1616, shows the Globe, the Hope and the Swan theatres.

The plan of the first English theatres appears to have had no connexion with those of classical times, as was the case in Italy: it was evidently produced in an almost accidental way by the early custom of erecting a temporary platform or stage in the middle of the open courtyard of an inn, in which the galleries all round the court formed boxes for the chief spectators, while the poorer part of the audience stood in the court on all sides of the central stage. Something similar to this arrangement, unsuitable though it now seems, was reproduced even in buildings, such as the Globe, the Fortune and the Swan, which were specially designed for the drama. In these and other early theatres there was a central platform for the stage, surrounded by seats except on one side, where there was a "green-room" or "tirenye-howe." The upper galleries or boxes completely surrounded the stage, even the space over the girders being occupied by boxes. This being the arrangement, it is easy to understand that stage pictures of the most cases, though not in all—the Fortune theatre, for example, was square. An interesting specification and contract for the building of the Fortune theatre (see below) is printed by Halliwell-Phillipps (op. cit. infra, p. 164). In all its details the Fortune is specified to be like the Globe, except that it is to be square in plan, and with timbers of heavier scantling. The walls are to be of wood and plaster, the roof tiled, with lead gutters, the stage of oak, with a "shadow" or cover over it, and the "tirenye-howe" to have glazed windows. Two sorts of cases are mentioned for scenery, in one of which the audience is to see "theatrical penny rooms." A woodcut showing this arrangement of the interior is given in a collection of plays edited by Kirkman in 1672. The vexed question of the construction of these theatres has been much discussed in recent years. In 1888 a drawing of the Swan theatre (fig. 4), apparently copied from a rough drawing in a London letter from the traveller Johannes de Witt, was discovered by Dr Karl Gaedertz in a manuscript volume in the Utrecht University library, consisting of the commonplace book of Arend van Buchell (1565–1641). While undoubtedly authentic, and probably broadly accurate, this copy of a sketch can be regarded, however, as giving the regular or typical plan of the contemporary theatre, as in some respects it does not fulfil the known conditions of the stage. What that typical plan was, if (as is probable) one actually existed, has led to much learned conjecture and great difference of opinion as regards the details required by the interpretation of contemporary stage directions on the necessities of the action in contemporary drama. The ingenious reconstruction (fig. 5), drawn by W. H. Godfrey in 1907, the Fortune theatre, following the builder's specifications, appears to approach very nearly to satisfying all the requirements. See "The Elizabethan Stage," in the Quarterly Review (London, April 1908).

In the 16th and 17th centuries a favourite kind of theatrical representation was in the form of "masques," with processions of grotesquely attired actors and temporary scenic effects of great splendour and mechanical ingenuity. In the reigns of James I.
and Charles I., Ben Jonson and the architect Inigo Jones worked together in the production of these "masques," Jonson writing the words and Inigo Jones devising the scenic effects, the latter being very costly and complicated, with gorgeous buildings, landscapes, and clouds or mountains, which opened to display mimic deities, thrown into relief by coloured lights. These masques were a form of opera, in which Ben Jonson's words were set to music. Ben Jonson received no more for his libretto than Inigo Jones did for his scenic devices, and was not unnaturally annoyed at the secondary place which he was made to occupy; he therefore revenged himself by writing severe satires on Inigo Jones and the system which placed the literary and mechanical parts of the opera on the same footing. In an autograph MS. which still exists this satirical line occurs—"Painting and carpentry are the soul of masque" (see Cunningham, Life of Inigo Jones, London, 1848).

In Italy, during the 16th century, the drama occupied a more important position, and several theatres were erected, professedly on the model of the classic theatre of Vitruvius. One of these, the Teatro Olimpico at Vicenza, still exists; it was designed by Palladio, but was not completed till 1584, four years after his death. It has an architectural scena, with various orders of columns, rows of statues in niches, and the three doors of the classic theatre; but the whole is painted with strong perspective effects which are very unclassical in spirit. Scamozzi, Palladio's pupil, who completed the Teatro Olimpico, built another pseudo-classical theatre in 1588 at Sabbionetta for the duke Vespasiano Gonzaga, but this does not now exist.

In France the miracle play developed into the secular drama rather earlier than in England. In the reign of Louis XI., about 1467, the "Brothers of the Passion" had a theatre which was partly religious and partly satirical. In the 16th century Catherine de' Medici is said to have spent incredible sums on the dresses and scenery for the representation of the Italian ballet; and in the middle of the 17th century the regular opera was introduced at Paris.

At the end of the 18th century the theatres of San Carlo at Naples, La Scala at Milan, and La Fenice at Venice were the finest in Europe; all these were rebuilt in the 19th century,

![Fig. 5.—The Fortune Theatre; restoration of Walter H. Godfrey.](image)

but have been eclipsed by the later theatres of London, Paris, St. Petersburg and other great cities of Europe and America, both in size and architectural splendour.

**Authorities.**—Much valuable information about the early theatres of London is given by Wilkinson, Londina illustrata (1819), in which are engravings of some of them. See also Collier, Hist. of Dramatic Poetry (1879); Halliwell-Phillips, Life of Shakespeare (1883); R. Lowe, Life of T. Betterton; Malone, History of the Stage (1790), republished by Boswell in 1821; the publications of the New Shakespeare Society; the Ninth Report of the Historical MSS. Commission; and a series of articles on early London theatres, by T. F. Ordish, in The Antiquary, vols. xi., xii., and xiv. (1885-86).

Reynolds, Some Principles of Elizabethan Staging (Chicago University, 1905); E. K. Chambers, "The Stage of the Globe," in vol. x. of the Stratford Shakespearean Stage (New York, 1908).

**Modern Stage Mechanism.**

A movement known as "Stage Reform" originated in Austria about 1880, with the primary object of encouraging the greatest possible imitation of nature in the presentation of opera and drama. The rudiments of art as understood by painters, sculptors, architects and the cultured public of the day were to be applied to the stage, and a true scenic art was to take the place of the nondescript mounting previously given. To facilitate the efforts of the scenic artist, the fullest application of modern science, notably of mechanics and hydraulics, and the introduction of up-to-date methods of lighting were considered essential. The numerous fatal conflagrations which had originated on the stage caused the question of protection from fire to be closely associated with this movement,
and the enterprise made great headway, more particularly on account of the protective measures against fire proposed soon after the burning of the old Ring Theatre at Vienna. The movement gradually developed throughout Austria and Germany and spread beyond the frontiers of these countries. Concurrently, independent movements originated elsewhere, and from 1883 to 1895 a transitional period may be said to have existed for the stage, both in Europe and in the United States, but by the close of the 19th century the necessity for reform was recognized in every country. During the transition time various unsatisfactory experiments were made, some of the boldest experiments proving costly failures, yet serving, because of such features as were valuable, as a basis for further developments. Great Britain and France were almost the last countries touched by this movement, although in England throughout the 'nineties there was considerable improvement in actual scenic art and stage-mounting, as far as this could be brought about without the aid of improved stage mechanism.

Among those primarily responsible for this new epoch in scenic art in Great Britain were Sir Henry Irving and Mr Beerbohm Tree, both actor-managers, Mr Hubert von Herkomer, R.A., Sir L. Alma-Tadema, R.A., and Mr Edwin O. Sachs, architect. Although almost last in the application of stage reform in its best sense, England really completed the experimental period with the modernization of the Royal Opera House, Covent Garden, where, by the opening of the season of 1902, the directorate were provided with the latest improvements of mechanical skill for the almost complete re-equipment of stage scenery. This work of remodelling was carried out by the Grand Opera Syndicate, with Mr Edwin O. Sachs as technical adviser and architect. Modern mechanism has also been applied at the Apollo Theatre, London, where, however, the stage equipment was bodily imported from the Continent and does not include any mechanically or electrically driven parts, manual labour alone being used. The stage mechanism which was employed in the equipment of the Royal Opera House, Covent Garden, embodies the Sachs system of dividing the stage-floor into a few large sections and working them with the aid of electrical power; the Brandt system of counter-weighting for the suspension of all scenery from above, the application of light in four colours by electricity, and the designing of all scenery to accord as much as possible with nature, the whole mounting being built up on the basis of a flat stage as distinct from the sloping stage of old.

The classification of stages generally, both home and foreign, whether for the production of opera or plays, should be made as follows: wood stages, wood and iron stages, and iron stages, with subdivisions according to the power chiefly employed in working the appliances. These subsections are: manual labour, hydraulics and electricity. Owing to the almost entire absence of steam for motor power in connexion with stage machinery, a separate subdivision for appliances where steam is employed is not required. With the wood stage and the wood and iron stage manual labour alone is utilized. But in the iron stage manual labour, hydraulic power and electric power are either used individually, or a combination of any two or three of these classes is applied. The first series of stages built in accordance with the principles of Stage Reform was erected on what was termed the "asphaleia" system, in which direct hydraulic power was utilized throughout. The stage-floor is divided into innumerable small sections supported on rams (some working telescopically), whilst everything suspended from above is also worked mechanically by hydraulic power. Nearly every country, and the Budapest Opera House and the Municipal Theatre at Wiesbaden, used the "asphaleia" system, showed somewhat larger sections. These are suspended by cables and worked indirectly by small hydraulic rams placed at the side, whilst the whole of the top work is manipulated by manual labour with the partial assistance of counter-weights. The next type is the Brandt type, where the number of divisions of the stage is further reduced to a few medium-sized sections, worked by means of a combination of a central hydraulic ram and suspended cables duly counter-weighted. The top work in this case is entirely counter-weighted, and requires the least possible manual labour for manipulation. An example will be found at the Wiesbaden Court Theatre. We next have the Sachs system, where electric power is substituted for hydraulic power, the number of stage divisions limited to several large sections, suspended on cables partly counter-weighted and partly worked by electric motors, while the whole of the top work is balanced on a system similar to that of the Brandt, with intermediate electric motors for the manipulation of particularly heavy loads. It is this last system that has been adopted at the Covent Garden Opera House, with the modification that the top work is entirely operated on the latest development of the Brandt system of manual labour and counter-weights. Another example of the Sachs system, as far as individual stage sections are concerned, will be found in a portion of the Theatre Royal, Drury Lane.

Regarding the question of expense and practicability, the hydraulic system has generally been found to be expensive and impracticable. The system of the Court Theatre, Vienna, though practicable, is costly both in capital and annual outlay. The Brandt method of equipping the upper stage mechanism has been found particularly suitable for medium-sized theatres, and not expensive. The Sachs system has been found practicable, of moderate initial cost and minimum annual outlay. The advantages of electricity over hydraulic power have been most marked both in capital and in annual expense. There is of course a far greater initial outlay required to-day than with the wooden stages of old but the saving in staff and wear and tear of the scenery, and the absence of expensive temporary make-shifts, repairs and reinstatements, compensate for this by a material reduction of annual charges. It is known as a fact that upon an overhaul of the Covent Garden equipment being ordered after five years' running, the contractors could not find anything to do in the way of repairs or reinstatements. The stage carpenter has long reigned supreme in England and France, although in England there are already one or two notable exceptions of men who are advancing to the position of engineers rather than carpenters. In Germany and Austria the stage carpenter is already being replaced in most theatres by men of engineering or technical training, as the more complex arrangements of a modern stage demand intelligent and careful control. It is merely a question of time for the engineer to obtain general control in these matters.

Regarding the actual designing and painting of the scenery, the English scene-painter may now be considered in advance of his Continental and American colleagues, although the productions of some notable ateliers at Vienna and Munich run the English scene-painter's work very closely. In 1890 Vienna was in advance of England in scene-painting, but the English scene-painters have since then rapidly come to the front, and it is to be anticipated that it will never again be necessary to import scenery from Austria, as has been the case, both at the Theatre Royal, Drury Lane, and at the Royal Opera House, Covent Garden. As a matter of fact, scenery from Covent Garden and Drury Lane is already exported to the United States. The position of the scene-painter is particularly difficult, inasmuch as whilst artistic temperament and thorough knowledge of art are essential for the practice of his vocation, it is equally essential that he should be thoroughly practical, and to a considerable extent a mechanical artist. In recognition among artists and there is unfortunately a tendency to depreciate his work.

During the period of interregnum in stage reform there appeared a number of faddist inventions which, while creating public interest, cannot be considered of lasting practical utility. Thus in the United States an attempt was made to have a large platform constructed like a lift, bodily rising and falling, with three different tiers or stages on which scenery could be mounted at different levels
and then raised or lowered into position. Again, at Munich, a scheme of turn-tables based on the Japanese revolving stage was put forward, but this can only be looked upon as an interesting experiment of little practical value.

Numerous methods of illuminating the stage have similarly been attempted, with the aid of search-lights, and prosenium lights, or by the absence of foot-lights, and the like, but the general method of lighting the stage from the top with battens, from the side with wing-ladders, and from below with foot-lights, if carefully regulated and skilfully handled, produces excellent results. The lighting arrangements as practised at the Royal Opera House, Covent Garden, in which building the lighting engineer is Mr. Crawshaw and the consulting engineer for the lighting installation was Mr. Bowles, leave nothing to be desired from an artist's point of view. The great difficulty of the light coming too strongly from below, i.e., from the foot-lights, can be overcome by the regulation and colouring of the lights.

As examples of modern mechanism, two photographs have been reproduced showing views of the electrical stage "bridges" of the Royal Opera House, Covent Garden, and of the Theatre Royal, Drury Lane, respectively, both on the Sachs system (see Pl. III.). A small general plan and section of the Covent Garden stage are also shown (see fig. 6), and another illustration (see Pl. IV.) presents the "gridiron" at Covent Garden on the Brandt system.

The following is a detailed description of the Covent Garden installation.

The stage may be described as consisting of a series of six horizontal sections running parallel with the curtain line from front to back, each section being 8 ft. wide, and the whole being followed by a large back or rear stage. The first section contains nothing but a plain "carpet cut," and openings to take the old-fashioned "grave" trap, "star" trap, or other similar contrivances. The second and third sections comprise large bridges, which can be raised 6 ft. above the stage or lowered 8 ft. below the stage, constructed in two levels, on the lower level of which appliances can be installed for the purpose of raising minor platforms above stage level or sinking traps and the like. The fourth, fifth and sixth sections comprise large bridges running right across the stage front, which can be raised 5 ft. above the stage or lowered 8 ft. below it. The back stage has no openings or mechanism beyond certain trap-doors to a scenery store. An electrical mechanism for raising and lowering scenery for storage purposes. Between the various sections of the stage, long longitudinal flaps, 2 ft. wide, are formed, which can be easily opened to allow scenery to pass in and through the stage, or be lowered below for transformation scenes and the like.

Each section is equipped with what is termed a "chariot," to hold "wing" lights placed on so-called wing ladders. All the electrical bridges are worked from the "mezzanine" level and from ordinary switch-boards, and can be raised and lowered at various speeds, and take loads up to 2 tons. They can be moved without vibration or noise at a cost of about 4d. for power on a full rise when loaded.

Above the stage level each section has its series of lines to take cloths, borders, &c. Each section has a battery, from which the electric battens are suspended, and has also a large wooden lattice girder, from which heavy pieces of scenery can be hung. There are, on the average, about ten lines for ordinary battens, a girder batten, and a light batten to each section; besides these lines, there are the equipments of flying apparatus and the like, whilst in front there are, of course, the necessary lines for tableaux curtains, act-drops and draperies. Everything that is suspended from above can be worked at stage level or at either of the gallery levels, every scene being counter-weighted to a nicety, so that one man can easily handle it. No mechanical contrivance is required, and in practice quite a number of scenes can be rapidly changed in a very short time. Throughout the structure and mechanism steel has been used, with iron pulleys and wire cable; and the inflammable materials have been abolished to the flooring of the gridiron and galleries and the hardwood flooring of the stage and mezzanine. In other words, an absolute minimum of inflammable material replaces what was almost a maximum; and seeing that the electric light has been installed, the risk of an outbreak of fire or its spread has been materially reduced.

No mention of stage mechanism would be complete unless mention were made of the necessity of providing a carefully made and easily worked fire-resisting curtain of substantial but light construction. On the Continent metal curtains are favoured. In England the double asbestos curtain is more common. The London County Council prefer a steel framing with asbestos wire-wove cloth on both faces, the intervening space being filled with slag wool, well rammed and packed. Such curtains are somewhat heavy and require counter-weighting to a nicety, but if well made and fitted may be deemed satisfactory. It is advisable to fit drenchers above fire-resisting curtains and to arrange the working of the curtain that it can be lowered from four points, i.e., from both sides of the stage, from the prompt side flies and from the stage door. According to the Lord Chamberlain's rules, fire resisting curtains must be lowered once during a performance. This is a wise measure for testing the efficiency of the appliances.

SACHS' ELECTRICAL STAGE "BRIDGES," ROYAL OPERA HOUSE, COVENT GARDEN.

SACHS' ELECTRICAL STAGE "BRIDGES," THEATRE ROYAL, DRURY LANE.
"Spectacle"

The appeal to the eye has been the essential feature of dramatic production in its many stages of development from the earliest times of the miracle plays and "moralties," mummers and morris-dancers, down through the centuries, in the form of masques and ballets, to the luxuriance of scenic and costume display that is lavished on the latest forms of theatrical entertainment. Considering the enormous advance that has been made in mechanical appliances, more especially in the increased powers of illumination supplied by gas and electricity, as compared with oil and candles, we must acknowledge that the artistic achievement of spectacle has barely kept pace with the times. If we may credit the veracity of contemporary chroniclers, the most elaborate effects and illusions were successfully attempted in the various courtly entertainments that are recorded under the Tudor and Stuart dynasties, and found perhaps their most sumptuous expression in the courts of Louis XIV. and Louis XV. It would be a difficult task for the most experienced of modern stage managers to rival the splendours of apparel and the ingenious devices that were exploited in increasing magnificence during successive periods, as described by Froissart, Holinshed, Cavendish, Stow, Pepys and other writers. The sums expended on these entertainments were prodigious, and a perusal of the extraordinarily detailed descriptions of such lavishly appointed masques as those designed by Inigo Jones in particular renders credible the statement that a certain masque presented before Charles I. at the Inns of Court in 1633 cost £21,000. Spectacle in its earlier phases appears to have existed chiefly in connexion with court and civic ceremonial; as evidenced in the wonderful pageantry of the Field of Cloth of Gold; in such princely entertainments as the Revels at Kenilworth, when the Earl of Leicester welcomed Queen Elizabeth to his magnificent fêtes; and in the blend of the imaginings of Ben Jonson, decorated by Inigo Jones, such as the Inns of Court masque, already cited. The scenic effects and illusions which had evidently been brought to great perfection in these masques were not devoted to the service of the drama in the public theatres until Davenant introduced them at the period of the Restoration, although simple scenery, probably mere background "cloths," had been seen on the stage as early as 1605. The built-up stage pictures, familiar to us as "set-scenes," are said to owe their origin to Philip James de Loutherbourg, R.A., and to have been first used in 1777; but it is probable that some such building as that anticipated by the plans of the sensations had not already enjoyed a term of popularity in view of the contemporary paintings and engravings of the epoch of Louis XIV., who was himself not averse from appearing (in 1653) as "Le Roi Soleil" in the midst of an entourage combining much that was artistic and fanciful with the most pompous and most absurd incongruities of character and costume. A greater measure of elegance and refinement distinguished the spectacles of the reign of Louis XV., inspired by the delicate art of Watteau, Boucher and Lancret, and preserved for our delectation in their delightful canvases. Under the French Revolution the spectacular ballet lost much of its prestige. Only the few scenic features were for a time principally associated with the fêtes inaugurated by the Republic and presented in the classic costume, which the severity of the new régime adopted as a reaction, or as a protest against the frivolities and furbelows of the obliterated monarchy. The Festival of the Supreme Being, decreed by the National Convention, designed by David and conducted by Robespierre, was perhaps the most impressive spectacle of the close of the 18th century.

The 19th century saw spectacle devoted almost exclusively to theatrical entertainment. In London, melodrama, both of the grand and comic, clothed itself with the most elaborate picturesque display. Among the earlier, its chief exponents were the Adelphi and Astley's, was first illuminated by gas in 1817-18, the Cataract of the Ganges, with its cascade of real water and its prancing steeds, made a great sensation in 1823, and the same stage in 1842, under Macready's management, displayed the "moving wave" effect in the Sicilian views, painted by William Clarkson Stanfield for Acts and Galatea. The Lyceum Theatre from 1847 to 1855 introduced a long series of elegant extravaganza from the pen of J. R. Planché, elaborately illustrated tableaux of extraordinary variety. The Golden Branch, the King of the Peacocks and the Island of Washington were the most remarkable of these productions, and were noteworthy as originating the fantastic fairy pictures that became known as "transformation scenes," and were copied and popularized in all directions. Beverly's skilful brush was at a later date employed at Drury Lane to enhance the attractions of a succession of spectacular versions of Sir Walter Scott's novels, Amy Robsart (1870), Rob Roy (with a beautiful panorama of the Rhine scenery), Rebecca, England in the Days of Charles II., and others. Later still, under the régime of Sir Henry Irving, the spectacle at Drury Lane assumed even more costly proportions. In modern melodramas, representing well-known localities with extraordinary fidelity and all kinds of disasters from earthquakes to avalanches, have been alternated with sumptuously mounted pantomimes (so-called), in which the nominal fairy-tales were almost smothered by the paraphernalia of scenery and costume. It is remarkable that, for a "run" of ten weeks only, such a sum as £15,000 each can have been profitably expended on more than one of these productions.

London playgoers will recall the processional glories of A Dream of Fair Women, designed by Alfred Thompson; The Land of Fairy Tales, with the Slide and the Mirror; The Paradise of the Birds (Babes in the Wood), and The Gods and Goddesses of Olympus (Jack and the Beanstalk), for which Mr Wil helm was responsible. The Armada, a historical drama (1888), also deserves to be remembered for its spectacular features. In addition to the names of Clarkson Stanfield and Beverly, already cited as masters of scenic art, it must not be forgotten that David Roberts was also devoted to the embellishment of the stage; and the names of Grieve, the Tellbins (father and son), Hawes Craven, and J. Harker have in successive years carried on the best traditions of the art. Alfred Thompson was one of the first to revive the conventionalities of fanciful stage costume, and to impart a French lightness of touch and delicacy of colour. A ballet, Yolande, which he dressed for the Alhambra in 'the sixties, was the first Japanese spectacle to grace the English stage; and Sir Henry was also mainly responsible for the attractions of Babu and Bijou, which cost upwards of £11,000 at Covent Garden Theatre in 1872, and was at the time considered to have surpassed all former spectacle accomplishments. It achieved, however, merely a succès d'estime, and has bequeathed to a later generation only the recollections of its Spring "choir of boys, and of the brilliant dances, Henriette d'Hervilly (who delighted the great days of the ballet, when Taglioni, Cerito, Elsler, Duverney and other "Déeses de la Danse," appeared under Lumley's management at the old Her Majesty's Theatre in the Haymarket. Since the memorable season of 1884-5, when Sir Henry Irving, Sir John Philip and the Spaister and spectacle have been honourably associated. Charles Kean's revivals at the Princess's Theatre (1850-59) deservedly attracted considerable attention for the splendour and accuracy of their architecture. Byron's Sardanapalus was also a triumph for the same management in 1853; and the same theatre three
decades later witnessed the production (December 1883) by Wilson Barrett, in the rebuilt Haymarket Theatre, of The Statues and the Man, a trashy modern melodrama, and a sensation. It was promptly mounted so exquisitely as to gain Ruskin's enthusiastic praise. But undoubtedly the earliest noteworthy alliance of spectacle with Shakespeare was made by Sir Henry Irving at the Lyceum. The art of the producer had reached a peak by 1882, after a celebration of 12 years' production and artistic distinction to his productions. "Ravenswood" and the sumptuously presented 

Henry VIII., (1892) owed much to the co-operation of Mr. Arthur Cecil, and the rarest credit can be given to the collaboration of 

Mrs. Patrick Campbell and Coriolanus (1901), whilst Sir Edward Burne-Jones inspired the decoration of King Arthur (1895). In Tennyson's Cup (produced in January 1881) and in the beautiful revival of Romeo and Juliet, and Other Plays, at the Haymarket in 1894 (produced by Mr. Daly), Shakespeare's poetic drama were also finely illustrated by Mr. Beerbohm Tree, who secured Sir Lawrence Alma-Tadema's interest for Hypatia at the Haymarket, and Julius Caesar at the new His Majesty's; whilst for his later productions, King John, A Midsummer Night's Dream, Herod (by Stephen Phillips), Twelfth Night (1901), and such later plays as his revival of Antony and Cleopatra (1907), he was assisted by the designs of Percy Anderson, an artist who made his mark in the costume and scenery field as no other. The Theatres were attended by the 15th century dresses for the Beauty Stone. Spectacular features of exceptional refinement distinguished the pantomime of Cinderella, presented by Mr. Oscar Barrett at the Lyceum Theatre (1896) and produced by Mr. Daly. This production also enjoyed a prosperous season in New York.

The system of international exchange seems to hold good in stage spectacle as in other cases, and in return for English successes the American Enterprise's "Eliza Doolittle" and "Spain" were successfully produced in London. Other entertainments of a more absolutely spectacular order found acceptance in London. In conjunction with Barium and Bailey's Hippodrome, Mr. Kraly, the "show" of the day, produced a still more stupendous, fantastic and audacious entertainment the following season, Venit, designed by the same artist. A spectacle on these lines may be regarded as the outcome of such ballets as have long been popular on the continent of Europe—especially in Italy, where grace of movement and spontaneity of gesture are natural to the people, and greatly facilitate such an enterprise as the famous Excisior ballet of Manzotti, which lasted a whole evening, in several acts, and required the services of hundreds of figures. Excisior was originally produced at La Scala, Milan, in January 1881, and was subsequently given with great success at the Eden Theatre, Paris, in 1883. The revival of this ballet at the Empire Theatre, London, has been associated with some memorable triumphs of spectacle with which the name of Mr. Wilde was closely identified as designer. (C. Wl.)

**Law Relating to Theatres.**

It was not until comparatively late in Roman history that acting became a distinct calling. The troops of public actors (ministeria publica) were generally slaves, and their earnings enriched their masters more than themselves.

The regulation of the theatre by legislation (except as to structure, which belongs chiefly to the upper class, in Roman law, depended almost wholly upon constitutions of Theodosius and Valentinian, incorporated in the Theodosian Code (Tit. xxv, 5, 6, 7), and a century later to a large extent adopted by Justinian. In the end, it is an administrative law between the doctrines of Christianity and the old Roman love of public spectacles of all kinds. It deals less with theatrical representations proper than with gladiatorial contests and chariot races.

The first code ordained that the sadistic tendencies were to be made to serve the good of society and to be administered to actors save where death was imminent, and only on condition that the calling should be denounced in case of recovery. The death penalty was not to be imposed to the stage provided they lived an honest life. An actress was to be allowed to quit the stage in order to become a nun. There were also numerous sumptuary regulations as to the dress of actors. None of these laws, however, are as direct as those of the later Justinian, but what follows was incorporated in Cod. xi. 40 (De Spectaculis et Sceniciis), which consists entirely of extracts from the Theodosian Code of a very miscellaneous nature. Provision was made for the better regulation of the theatre's administration at certain periods, but only in the proscription of a theatre. A governor of a province was entitled to take the money raised for public games for the purpose of repairing the city walls, provided that he gave a receipt for them. Theatres were to be built or adopted for the public at the expense of the governor, and religious ceremonies were encouraged to build theatres (Dig. i. 10, 3). By Novell cxvii., it was grounded for divorce if a wife went to the theatre with her husband. No licence was required for the construction of the building committed to certain magistrates (Novell cxviii. 2).

**England.**—In England, as in other countries of western Europe, theatrical legislation was of comparatively recent introduction. Such legislation was unnecessary as long as the theatre was under the control of the Church and actors under its protection, the Church having turned to its own uses what it was powerless to prevent. The earliest regulations were therefore, as might be expected, made by the Church rather than by the state. The ecclesiastical ordinances were generally in opposition to the introduction of plays, sometimes even extending to the suppression of the act of playing, and at other times to the prescription of particular parts of the play, such as the necessity of adding religious materials, as well as provisions for the safety of the building and the audience (Tacitus, Anm. iv. 63; Leone Const. ii. 25). The seats were also protected by the building of the building committed to certain magistrates (Novel cxvii. 2).

The Reformation marks the period of transition from the ecclesiastical to the non-ecclesiastical authority over the drama. Precautions began to be taken by the crown and the legislature against the acting of unauthorized plays, by unauthorized persons, and in unauthorized places, and the acting of plays objectionable to the designation of churches, though they were sometimes extended to permitting attendance of the faithful as spectators at plays even of a harmless kind. Sacraments and Christian burial were denied by the canon law to actors, whose gains, said St Thomas, were acquired ex turpi causa, and who, if they exceeded what was proper, might be in mortal sin. It was a doubtful point as to whether spectators might not be in similar case. The same law forbade plays to be acted by the clergy, even under the plea of custom, as in Christmas week, and followed the code of Justinian in enjoining the clergy not to conspire with the actors or be present at plays (see Decretals, iii. 13, 15. De Vi de et Honestate Cleric. At least as varied as canon lxxxv. of the canons of the Church of England enacted that churchwardens were not to suffer plays in churches, chapels or churchyards. The latest occurrence of such a play seems to have been at Oxford in 1592.

The legislation refers to the period of transition from the ecclesiastical to the non-ecclesiastical authority over the drama. Precautions began to be taken by the crown and the legislature against the acting of unauthorized plays, by unauthorized persons, and in unauthorized places, and the acting of plays objectionable to the designation of churches, though they were sometimes extended to permitting attendance of the faithful as spectators at plays even of a harmless kind. The history of the legislation on this subject is very curious. An act of the year 1572 enacted that "all fencers, bearers, common players of interludes, and minstrels (not belonging to any baron of this realm, or to any other honourable person of greater degree), wandering abroad without the licence of two justices at the least, were subject to be grievously whipped and burned through the girtle of the right ear with a hot iron of any convenient weight," and authorized any person to be punished by 39 Eliz. c. 4, under which the punishment of the strolling player is less severe, and there is no mention of justices. The jurisdiction of justices over the theatre disappears from legislation.

1 The word ludi seems sometimes to include, sometimes to exclude, dramatic performances. Its meaning in a particular instance depends on the context.

2 If one may judge from Horace's line (Sat., i. 10, 38): Quae neque in aede somni certantia justica Tarpa.

3 A large number of such ordinances will be found cited in P. Codini, Opr. Roman., c. 22, De ludis dramaticis, et Spec. jact. ad monumenta mariana, De Spectaculis. They followed the almost unanimous condemnation by the Christian fathers. See, for example, Chrysostom, Contra Ludos et Thesaur.; Tertullian, De Spectaculis; Augustine, De Civ. Diet. i. 31, Confessions, ii. 2; Dill, Roman Society, pp. 47, 117.

4 For this reason it appears to have been the custom in France for noblemen to be married under the name of musicians. See Hist. parlementaire de la Bretagne, xvi. 38. The difficulties attending the burial of Molière are well known.
from that time until 1788. In 39 Eliz. c. 4 there is a remarkable exception in favour of persons licensed by Dutton of Dutton in Cheshire, in accordance with his claim to liberty and jurisdiction in Cheshire and Chester, established in favour of his ancestor by proceedings in quo warranto in 1499.1 The stricter wording of this act as to the licence seems to show that the licence had been abused, perhaps that in some cases privileges had been assumed without authority. In 14 Eliz. c. 30 the privileges of a player attached by service of a noble or licence from justices, in the later act only by service of a noble, and this was to be attested under his hand and arms. The spirit of the acts of Elizabeth frequently appears in later legislation, and the unauthorized player was a vagabond as late as the Vagrancy Act of 1744, which was law till 1824. He is not named in the Vagrancy Act of 1824. The Theatre Act of 1737 narrowed the definition of a player of interludes, for the purposes of punishment as a vagabond, to mean a person acting interludes, &c., in a place where he had no legal settlement. Before the Restoration there were privileged places as well as privileged persons, e.g. the court, the universities, and the inns of court. With the Restoration privilege became practically confined to the theatres in the possession of those companies (or their representatives) established by the letters patent of Charles II. in 1662. In spite of the patents other and unprivileged theatres gradually arose.2 In 1735 Sir John Barnard introduced a bill "to restrain the number of playhouses for playing of interludes, and for the better regulation of common players."3 On Walpole's wishing to add a clause giving parliament the privileges of a player attached by service of a noble or licence from justices, the mover withdrew the bill. In 1737 Walpole introduced a bill of his own for the same purpose, there being then six theatres in London. The immediate cause of the bill is said to have been the production of a political extravaganza of Fielding's, The Golden Rump. The bill passed, and the act of 10 Geo. II. c. 28 regulated the theatre for more than a century. Its effect was to make it impossible to establish any theatre except in the city of Westminster and in places where the king should in person reside, and during such residence only. The act did not confine the prerogative within the city of Westminster, but as a matter of policy it was not exercised in favour of the non-privileged theatres, except those where the "legitimate drama" was not performed. The legitimate drama was thus confined to Covent Garden, Drury Lane and the Haymarket from 1737 to 1843. In the provinces patent theatres were established at Bath by 8 Geo. III. c. 10, at Liverpool by 11 Geo. III. c. 16, and at Bristol by 18 Geo. III. c. 8, the act of 1737 being in each case repealed pro tanto. The acting of plays at the universities was forbidden by 10 Geo. II. c. 19. It is not a little remarkable that the universities, once possessing unusual dramatic privileges, should not only have lost those privileges, but have in addition become subject to special disabilities. The restrictions upon the drama were found very inconvenient in the large towns, especially in those which did not possess patent theatres. In one direction the difficulty was met by the lord chamberlain granting annual licences for performances of operas, pantomimes and other spectacles not regarded as legitimate drama. In another direction relief was given by the act of 1738 (28 Geo. III. c. 39), under which licences for occasional performances might be granted in general or quarter sessions for a period of not more than sixty days. The rights of patent theatres were preserved by the prohibition to grant such a licence to any theatre within eight miles of a patent theatre. During this period (1737–1843) there were several decisions of the courts which confirmed the operation of the act of 1737 as creating a monopoly. The exclusive rights of the patent theatres were also recognized in the Disorderly Houses Act, 1751, and in private acts dealing with Covent Garden and Drury Lane, and regulating the rights of parties, the application of charitable funds, &c. (see 16 Geo. III. cc. 13, 31; 50 Geo. III. c. cxcv.; 52 Geo. III. c. xix.; 1 Geo. IV. c. lx.). The results of theatrical monopoly were beneficial neither to the public nor to the monopolists themselves. In 1832 a select committee of the House of Commons recommended the legal recognition of "stage-right" and the abolition of theatrical monopoly. The recommendations of the report as to stage-right were carried out immediately by Bulwer Lytton's Act, 3 & 4 Will. IV. c. 15 (see COPYRIGHT). But it was not till eleven years later that the Theatres Act, 1843, was passed, a previous bill on the same lines having been rejected by the House of Lords. The act of 1843 inaugurated a more liberal policy, and there is now complete "free trade" in theatres, subject to the conditions imposed by the act. The growth of theatres since that time has been enormous. Nor does the extension seem to have been attended with the social dangers anticipated by some of the witnesses before the committee of 1832.

The suppression of objectionable plays was the ground of many early statutes and proclamations. While the religious drama was drying out, the theatre was used as a vehicle for enforcing religious and political views not always as orthodox as those of a miracle play. Thus the act of 34 & 35 Hen. VIII. c. 1 made it criminal to play in an interlude contrary to the orthodox faith and practice, or to have the books of that kind. In theatres seems to have been a crying evil of the time. Stephen Gosson attacked it as early as 1579 in his School of Abuse. The first business of the government of Edward VI. was to pass an act reciting that the most holy and blessed sacrament was named in plays by such vile and unseemly words as Christian ears did abhor to hear rehearsed, and infecting fine and imprisonment upon any person advisedly contemning, despising or reviling the said most blessed sacrament (1 Edw. VI. c. 1). A proclamation of the same king in 1549 forbade the acting of interludes in English on account of their dealing with sacred subjects. In 1556 the council called attention to certain lewd persons in the livery of Sir F. Leke representing plays and interludes reflecting upon the queen and her consort and the formalities of the mass. The same queen forbade the recurrence of such a representation as the mask given by Sir Thomas Pope in honour of the Princess Elizabeth at Hatfield, for she "misliked these follies." By the Act of Uniformity, 1 Eliz. c. 2, it was made an offence punishable by a fine of a hundred marks to speak anything in the derogation, degrading or despising of the Book of Common Prayer in any interludes or plays. In 1605 an Act to restrain the Abuses of Players 4 made it an offence punishable by a fine of £10 to jestingly or profanely speak or use certain sacred names in any stage play, interlude, show, may-game or pageant (3 Jac. I. c. 21). In consequence of the appearance of players in the characters of the king of Spain and of Condor, an ordinance of James I. forbade the representation on the stage of any living Christian king. The first act of the reign of Charles I. forbade acting on Sunday. Puritan opposition to the theatre culminated in the ordinance of 1648, making it a crime even to be present as a spectator at a play. After the Restoration there are few royal proclamations or ordinances, the necessary jurisdiction being exercised almost entirely by parliament and the lord chamberlain. Among the few post-Restoration royal proclamations is that of 25th of February 1664–5, restraining any but the company of the Duke of York's theatre from entering at the attiring house of the theatre, and that of the 27th of February 1668–9 against immorality in plays. Preventive censorship of the drama by an officer of state dates from the reign of Elizabeth. The master of the revels (see REVETS) appears to have been the dramatic censor from 1545 to

---

1. The "advowsey" as it was called, over the Cheshire minstrels lasted until 1756, when the latest minstrel court was held at Chester.

2. Interludes were acted in the open air at Berriew in Montgomeryshire as late as 1819, when the players were indicted before the Great Sessions of Wales. They had been prohibited in the Declaration of Sports (1633) and in the Propositions of Ussbridge (1644).

4. For the anti-theatrical Puritan literature see Courthope, History of English Poetry, ii. 381.
1624, when he was superseded by his official superior, the lord chamberlain. In some cases the supervision was put into commission. Thus with Tilney, the master of the revels in 1581, were associated by order of the privy council a divine and a statesman. In other cases it was delegated, as to Daniel the poet by warrant in 1603. The proposal to give statutory authority to the jurisdiction of the lord chamberlain led, as has been already stated, to the withdrawal of Sir John Barnard's bill in 1735, and to considerable debate before the bill of 1737 became law, to which Lord Chatham's objection to the bill in the House of Lords was not unreasonable. "If the players," said he, "are to be punished, let it be by the laws of their country, and not by the will of an irresponsible despot." A stage play must now be duly licensed before performance. § 12 of the act of 1843 prescribes that a copy of every new play and of every addition to an old play, and of every new prologue or epilogue or addition thereto (such copy to be signed by the master or manager), shall be sent to the lord chamberlain, and, if the lord chamberlain does not forbid it within seven days, it may be represented. § 13 empowers the lord chamberlain to fix the scale of fees for examination; the fee is now two guineas for a play of three or more acts, one guinea for a play of less than three acts. All plays represented previously to the act are held to be licensed. A play once licensed is licensed once for all unless the licence be revoked under § 14. The examination is the duty of a special officer of the lord chamberlain's department, the examiner of stage plays. In spite of occasional lapses of judgment, a belief in the wisdom generally shown in the exercise of the censorship has been confirmed by the report of the select committee of the House of Commons in 1879 and the joint committee of both Houses in 1909. The censorship has been consistently supported in recent years by theatrical managers, but violently opposed by an advanced section of dramatic authors. There have been instances, no doubt, where perhaps both the lord chamberlain and his subordinate officer, the examiner of stage plays, have been somewhat nice in their objections. Thus, during the illness of George III., King Lear was not performed. George Colman, when examiner, showed an extraordinary antipathy to such words as "heaven" or "angel." The lord chamberlain's powers are still occasionally exercised against scriptural dramas, less frequently for political reasons. Later instances are Oscar Wilde's Salomé (1892), Joseph of Canada (1896), Maeterlinck's Monna Vanna (1902), Housman's Bethlehem (1902), Gilbert and Sullivan's Mikado (temporarily in 1907), and a play by Laurence Housman dealing with George IV. (1910). Before 1866 the lord chamberlain appears to have taken into consideration the wants of the neighbourhood before granting a licence, but since that year such a course has been abandoned. The joint committee in 1909 recommended that it should be optional for an author to submit a play for licence, and legal to perform an unlicensed play whether submitted or not, the risk of police intervention being taken. They also recommended that the reasons for which a licence should be refused should be: indecency, offensive personalities, the representation of an invidious manner of a living person or a person recently dead, violation of the sentiments of religious reverence, the presence of anything like conducing to crime or vice, or to cause a breach with a friendly power, or a breach of the peace.

A theatre may be defined with sufficient accuracy for the present purpose as a building in which a stage is regularly performed, to the following in the law that there are a considerable number of different persons, corporate and unincorporate, with jurisdiction over theatres. A consolidation of the law and the granting of jurisdiction in the province of a chamberlain for the United Kingdom would probably be convenient. The committee of 1866 recommended the transfer to the lord chamberlain of the regulation of all places of amusement, and an appeal from him to a higher authority in cases, and the suspension of his authority to preventive censorship in all public entertainments; but no legislation resulted. The committee of 1909 recommended the abolition of any distinction between theatres and music-halls. Several bills for the amendment of the law have been introduced, but without success in the face of more burning political questions. Building.—A theatre (at any rate to make it such a building as can be licensed) must be a permanent building, not a mere tent or temporary building. Regulations as to conditions of structural fitness from the county council necessary as a condition precedent for licence in the case of all theatres of a supercificial area of not less than 500 sq. ft. It is licensed after the passing of an examination of the building and its equipment. The regulations prescribe the excitement of emotion and the representation of action. The question whether a performance is a stage-play or not seems to be one of fact, and any building which is not likely to be usually by itself or its arrangement, and its performance, to be considered a stage-play, but it would be otherwise with a ballet divertissement. § 14 empowers the lord chamberlain to forbid the acting of any stage-play in Great Britain whenever he may recommend such a step by reason that it is or may become... more than notice of the local acts of 1888. To regulate the price of their articles, or if so much noise be heard in the neighbourhood as to interfere with the ordinary occupations of life. Very curious instances of proceedings at common law are recorded. In the case of the local acts of 1888, 1904, 1905 and 1915, players were indicted for riot and unlawful assembly. In the grand jury of Middlesex presented the two play-houses; and the old garden on Bankside, the Paris garden of Henry VIII. act v. 33 as riotous and disorderly nuisances. Performances on Sunday, Good Friday, and Christmas day are illegal. Regulations as to the sale of intoxicating liquors during the performances, and the making of provisions for the sanitary maintenance of the places, as well as by local acts and rules made by county councils. It is frequently a condition of the licence granted to provincial theatres that no excisable liquors shall be sold or consumed on the premises. The examination which takes place according to the annual value of the theatre up to a maximum of £20. The Dangerous Performances Acts, 1879 and 1897, forbid under a penalty of £10 any public exhibition or performance whereby the life or limbs of a child under the age of sixteen, or a boy, eighteen if a girl, shall be endangered. It also makes the employer of any such child indictable for assault where an accident causing actual bodily harm has happened to the child, and enables the court on conviction of the employer to order him to pay the child compensation not exceeding £20. The Prevention of Cruelty to Children Act 1904 forbids a child to appear in any public enter- tainment to the tune of any licence under a penalty of £20. The performance must be for hire. § 16 of the act of 1843 makes a building one in which acting for hire takes place, not only where money is taken directly or indirectly, but also where the purchase or hire of the stage space is a matter. Where there is no hire or purchase performed in a place in which excisable liquor is sold. In the case of Shelley v. Bethell, 1883 (Law Reports, 12 Q.B.D. 11), it was held that the proprietor of a private theatre was liable to penalties under the act, though he lent the theatre gratuitously, because tickets of admission were sold in aid of a charity.

**Licensed Building.**—By § 2 of the act of 1843 all theatres (other than patent theatres) must be licensed. By § 7 no licence

---

1 It was probably through his influence that the expletives in Shakespeare were edited. The quarto of 1622 contains more than the folio of 1623.  
2 Dryden's words in the "Essay on Satire" (addressed to the earl of Dorset, lord chamberlain) still describe the duties of the office. As lord chamberlain I know you are absolute by your own will, in that which you can by any force make the stage. You can banish from thence scurrility and proflaenacy, and restrain the licentious insolence of poets and their actors in all things that shock the public quiet or the reputation of private persons under the notion of humour."
is to be granted except to the actual and responsible manager, who is to be bound by himself and two sureties for due observance of rules, and to the management of the theatre where the plays were produced, in addition to the licence for each metropolitan theatre other than the patent theatres (as far as at least as they are included in the boroughs named in the act of 1843) are licensed by the lord chamberlain. By § 4 his fee on granting such licences is fixed at £10, but if he grants the licence from the asylum it shall be £15. In case the theatre is licensed, the lord chamberlain appears to have no power to make such rules for enforcing order and decency. He can only issue regulations for the management of the theatre where any riot or misbehaviour has taken place. He has issued a code of regulations.

Provincial theatres fall under three different licensing authorities. The lord chamberlain has power to confer a licence for the larger and theatres situated in the places where the king occasionally resides, but only during the time of such occasional residence (§ 3). Theatres and halls in London, Cambridge, or within 44 miles of London licensed by the justices having power but before any such licence can come into force the consent of the chancellor or vice-chancellor must be given. The rules made by the justices for the management of the theatre are subject to the approval of the chancellor or vice-chancellor, who may also impose such conditions upon the licence as he thinks fit. In case of any breach of the rules or conditions, he may annul the licence (§ 10). All other provincial theatres are licensed by the county councils or county borough councils under the act of 1888, in case of a special and temporary performance, where justices shall, in all cases for special performances for the time being, licence the same into operation. The regulations of the London County Council are dated the 27th of July 1897. Penalties are imposed by the act for keeping or acting in an unlicensed theatre, and for producing or exhibiting upon any unlicensed theatre is unenforceable.

Music Halls.—Music was at no time the object of restrictions as severe as those imposed upon the drama. The present English act governing music halls, the Prohibitory Houses Act 1751, was passed probably in consequence of the publication in 1750 of Fielding's Inquiry into the Causes of the late Increase of Robbers. It is remarkable that the two works were of the same writer should from opposite causes have led to both theatre and music-hall legislation of lasting importance. The act was originally passed for a term of three years, but was made perpetual by 3 Geo. II. c. 10. It applied to all places within 20 miles of London, and to the walls of such houses as were not used for religious worship, and where no body of music was allowed to perform. Every such music hall must be licensed at the Michaelmas quarter sessions, the licence to be signed under the hands and seals of four or more justices. The licence may be granted for a year or quarter only. Public notice of the licence is to be given by affixing over the door the inscription "Licensed in pursuance of act of parliament for," with the addition of words showing the purpose. The penalty for keeping an unlicensed music hall is £100. This act is amended as to Middlesex by the Music and Dancing Licences (Middlesex) Act 1894, putting the licensing into the hands of the county council. Regulations were made by the county council for the security of those using the premises, and by other county councils and the City of London in June 1901. Music halls beyond the radius of 20 m. from London and Westminster are mainly governed by the Public Health Act 1890, the licensing authority being the licensing justices. There is no penalty in the act for keeping music halls open later than 2 a.m., though the only remedy for anything objectionable is for the licensing authority to withdraw the licence or refuse to renew it.

Scotland.—In Scotland the theatre has always exercised a considerably more influence than in England, and there has been little exclusively Scottish legislation on the subject. 1555, c. 40, disallowed certain amusements of a semi-theatrical kind by enacting that there was to be chosen Robbers Hereby, but John, abbot of unreason, or queen of May. A proclamation of James VI. in 1574, and 1579, c. 12, followed the lines of English legislation of 1642. Dancing in public places, such as ball-rocks, was prohibited. In 1674 the General Assembly claimed to license plays, and forbade representations on Sunday. As in England, the licensing power seems then to have passed from the Kirk to the Lords, and the Lord George was a theatre at Edinburgh. 1672, c. 21, exempted comedians while upon the stage from the summmary provisions of the act respecting apparel. The chamberlain of Scotland, while such an office existed, was not obliged to license plays. In certain police jurisdiction over theatres. The Theatres Act 1843 extends to Scotland, as did also the previous act of 1737, and further provisions are made by the Burgh Police Act 1867.

Ireland.—Theatrical legislation, as far as it went, was based upon English models. Thus ridicule of the liturgy was forbidden by 2 Eliz. c. 2 (Ir.); common players of interludes and wandering minstrels were deemed vagabonds, 10 & 11 Car. I. c. 4 (Ir.). In 1785 an act was passed to enable the crown to grant letters patent for erecting new public halls or theatres to be used for the amusement and entertainment of the inhabitants of Dublin, with the grant of an annual revenue of £200, of which the majority of entertainment for the benefit of the Dublin lying-in hospital and exhibitions of horsemanship or puppet-shows. The existing theatres of Dublin did not apply to Ireland, except the Public Health Act 1890, s. 51.

British Colonies.—There is a large amount of legislation. An example is the Victoria Act, No 1430 (1857), giving the chief secretary the power to cancels the licence of any theatre if used on Sunday without special permit.

United States.—Public entertainments, dramatic or other, are usually regulated by the counties or municipalities, and are not subject to federal legislation. It is extremely rare that there is no act of Congress on the subject, except one in 1897 imposing a temporary war tax on the theatres. In most states there is state legislation, requiring places of public entertainment to be licensed by the proper authority. In many states it is a condition of the licence that intoxicating liquors shall not be sold in such places. Other conditions, more or less usual, are that there shall be no Sunday or dangerous performances, that acrobats shall be properly protected, and that female waiters shall not be employed. Structural qualifications are in some cases made necessary. Thus in 1883 the New York legislature passed an act containing many sections conferring powers on the police authorities, and there is a characteristic piece of legislation is the New York Act of 1873, c. 186, enacting that no citizen is to be excluded from a theatre by reason of race, colour or previous condition of servitude. This has been merely a confirmation of the prohibitions already in force in art. xiv. of the amendments to the constitution of the United States. There are two curious and conflicting decisions of other states on the matter. Michigan held that a manager could discriminate against a person of colour, Michigan that he could not (see Green's Digest, vol. i. 642).

Continental Europe.—The principal points in which the continental theatre differs from the English are that Sunday is the most important day, and that the theatre is often owned or subsidized by the state or a municipality. In France there has been much legislation since the days of the Revolution, the principal law being one of 1876, which has a long list of regulations, and there has been the subject of much discussion. The censure préalable was abolished in 1906. The object is attained by police penalties. Most of the authorities will be found in Dallor, Supplices, vol. xviii., and, for the older law, Lacan, La Legislation et la jurisprudence des théatres (1853), and Maugrás, Les Comédiens hors de la loi (1887), may be consulted. Italy has produced at least two modern works on the subject, Rivalta, Storia e Sistema del Diritto dei Teatri (1886), and Tabanelli, Codice del Teatro (1901). What strikes one in how little special legislation is there on the subject. The penal code meets most cases. Spain retained the autos sacramentales much longer than France. The new law of 1868 observes the censure and, for the position begins very early. The Siete Partidas enacts that the clergy are not to take part as actors or spectators in scurrilous plays (conjuraciones), the canon of Toledo regrets that the government had not appointed a censor to prevent the acting of plays not only injurious to morals but also offending against the classical rules of the drama. The concern is considerable, and theITU of Lawyer of the Ottoman Empire, the details will be found in G. Young, Corps de droit ottoman, vol. ii. 320 (1904).

THEBES (Θῆβαι), the Greek name of the ancient capital of Upper Egypt, presumably an Egyptian name (e.g. Zemi, seen in αἰγυπτικά, ζημιά assimilated to that of the Greek city. It occurs in Homer (II. ix. 351-4) where it has the epithet ἐκατονθυλῶς, "hundred-gated," probably derived in the first place from the gateways of its endless temples, though perhaps misunderstood if it referred to a city with a hundred gates in the circuit of its walls. Thebes was always called Semele, and its vast temple enclosures in different quarters would form as many fortresses in case of siege or tumult. Its Egyptian name was Wesi (or Wisi?), later Ne, "the city" (sometimes Ne-Amun, hence No-Amon in Nahum iii. 8), and different quarters were known by special names. In non-literary Greek Thebes was regularly called Diospolis the Great. Ammon, Amen-Rê, or Amenronasher ("Ammon-Rê king of the gods") was its deity, with his consort Mut and their child Khons. Mont also was a local deity and Hathor presided over the western cliffs of Thebes. In very ancient times the city lay on the east bank of the Nile, although the necropolis was still confined to the west bank, a vast city of temples, priests and necropolis people, to which

1 The councils may delegate their authority to justices, a district council, or a committee of their own body, such as the Theatre and Music Hall Committee of the London County Council.
were added royal palaces and their accompaniments, covered the western shore as far back as the desert hills. The chief nucleus of the ancient Wési was a town about the temple of Karnak; it probably reaches back to the prehistoric period. At Dra\b\'ab\'u\'l nagg, opposite to it, are tombs of its princes under the 19th Dynasty. The temple of Karnak is no doubt of immemorial antiquity. Perhaps no sculpture earlier than the 19th Dynasty has survived there, but Senwosret I. changed statues to his predecessors of the 19th Dynasty who had probably showed their devotion to Ammon in a substantial manner, and Cheops of the 19th Dynasty was named in it. After the end of the Old Kingdom Thebes grew from an obscure provincial town to be the seat of a strong line of princes who contended for supremacy with Heracleopolis and eventually triumphed in the 18th Dynasty of Manetho. The most important monument of the Middle Kingdom now extant at Thebes is the funerary temple of Menthotep III. of this dynasty, which has been revealed by the excavations of the Egypt Exploration Fund at Deir el Bahri (see Architecture, section Egyptian, fig. 4); and the period is well represented by an abundance of statues of the 19th and 20th dynasties from the temple of Karnak. The name Amenemhe, so common in the 19th Dynasty, shows the importance of the Theban god at this time. It was not, however, till the 20th Dynasty, the beginning of the New Empire, that the whole site began to be occupied by monuments which have survived to the present day. The early rulers of this dynasty down to Tuthmosis III. developed Karnak, and on the west bank built the great funerary temple, of which fragments of temples and sections of the Medinet Habu, and began the long series of royal tombs in the famous Valley of the Tombs of the Kings far back in the desert behind Deir el Bahri. Amenemhe III. continuing, transformed western Thebes monumentally: built three great temples in addition, that of Mont on the north of Karnak, the temple of Mut on the south and the temple of Ammon at Luxor, and connected the last two with the state temple of Karnak by avenues of sphinxes. On the west bank of the huge colossi of Memnon marked the entrance of his funerary temple, a magnificent building which was afterwards destroyed, and the great lake of Birket Habu was dug and embanked in front of his brick palace at the extreme south. The chief energies of this king in fact were expended on developing the south extremity of Thebes on both banks. The city and its monuments now covered an area about three miles square. After this Thebes experienced a serious set-back with the heresy of Akhenaton, the son of Amenemhe III. He moved his capital northward to Akhetaton (El Amarna) and strove to suppress the worship of Ammon, doing infinite damage to the monuments of Thebes by defacing his name and figure. After about twenty years, however, the reaction came, Thebes was again the capital, and a little later under Seti (Sethos I.) and Rameses II. of the 20th Dynasty it was raised to greater architectural magnificence than ever. These two kings built the great columnar hall of Karnak, added a large court with pylons to Luxor, and on the west bank built the funerary temple of Seti I. Karnu, and the Ramessum with its gigantic colossus, besides other edifices of which only traces remain. Under the 20th and 21st Dynasties Thebes was at the height of its greatness. Conquering Pharaohs brought home trains of prisoners and spoil, embassies came thither of strange people in every variety of costume and of every hue of skin, from Ethiopia, Puoni (Punt), Mesopotamia, Asia Minor, Libya, and the islands of the Mediterranean, bringing precious stones, rare animals, beautiful slaves, costly garments and vessels of gold and silver, while the ground shook with the movement of colossal architraves, statues and obelisks. The tombs of the 20th Dynasty on the west bank and the sculptures in the temples reflect the brilliancy of these days, but even the reign of Rameses II. marks the beginning of the decline of Thebes. The enormous constructive energy of the proud Pharaoh, instead of being concentrated on the capital, was expended with almost equal lavishness on other parts of the country. In every city he left his mark. A great temple at Tanis boasted a larger colossus than existed in Thebes: Helopolis and Memphis must have been lavishly adorned, and the temples of Abu Simbel (q.v.) alone would have been sufficient to satisfy the ambition of many of the great Pharaohs. After, Rameses II. the efforts of all his successors combined could add little to the wonders of Thebes. The temple and tower of Rameses III. (XXth Dynasty) at Medinet Habu, his tomb in the Biban el Moluk, the temple of Khons (Rameses III. and later) and the court of Sheshonk I. (XXIInd Dynasty) at Karnak are the only great achievements.

For the rest there are the tombs of many kings in the Biban el Moluk and a good deal of comparatively petty construction and tinkering, with the help of stone robbed from older structures. Earlier and greater kings had remorselessly destroyed buildings which interfered with their own plans. The "Memnon" temple of Amenemhe III. had already gone, sacrificed perhaps to Akhenaton's god. Rameses II. had plundered his predecessors' monuments for materials. Hitherto Thebes had been glorified by the process, but henceforth it was rather to perish. The tide of prosperity was flowing northward and such monumental energy as remained was expended more widely. For several centuries after the fall of the New Empire Thebes was but one of several alternating or contemporaneous capitals. Memphis, Tanis, Bubastis, Sais, Heracleopolis had at one time or another at least equal claims. The Ethiopian conquerors of Egypt made Thebes their Egyptian capital, but the wide decision of the Nile-Pontic route for the trade and commerce of the Mediterranean, brought in anew the long-pausing hopes of Egypt, and the Persian king Cambyses II. in the reign of Darius I. did not neglect it, and during the XXVth Dynasty Ptolemaios, a wealthy priest and official, excavated for himself the greatest private tomb that ever was made. Probably every king that included Thebes in his realm, except the Assyrians and the Persians, left his memorial there in chapels erected or sculptures added. Of the Persians, however, not even Darius is traceable at Thebes; on the other hand, there is no support for the tradition that Cambyses destroyed its monuments. Ptolemy I. gave a new capital to the upper country in the Greek foundation of Ptolemais, and thus struck a fresh blow at the prosperity of Thebes. For a short period in the reign of Euphrates II., when Upper Egypt was in rebellion against the Ptolemaic rulers, Thebes was the capital of independent native dynasts. In a later rebellion, Thebes was captured after a three years' siege and severely punished by Lathyrus (Ptolemy X., Soter II.).

In the reign of Augustus, having joined in the insurrection against the tax-gatherers, it was destroyed by Cornelius Gallus and became a collection of villages. Though its vast buildings have since served as quarries for mill-stones and for the limeburner, Thebes still offers the greatest assemblage of monumental ruins in the world.

The following paragraphs enumerate the principal groups of monuments. On the east bank at Karnu stand the great east temple of Amen-Rê with its obelisks of Hatshepsut and Tuthmosis I. and the vast columnar hall of Rameses II.; the temple of Mut and the well-preserved temple of Khons; the temple of Luxor and avenues of rams and sphinxes connecting all these. These temples are described in the articles KARNAK, LUXOR and Architecture: Egyptian. On the west bank, in front of the necropolis, on the edge of the desert or projecting into the cultivation, was a low row of temples: the northernmost, placed far in front of the others, is the well-preserved temple of Seti I. at Karnu; then follow the Ramessum and Medinet Habu; and the foundations of many others can be traced. The temple of Amenemhe III., to which the colossal of "Memmon" were attached, was again far forward of the line. The Ramessum contains the remains of a stupendous seated colossus, in black granite, of its builder Rameses II., thrown on its face. When perfect it was probably 57 ft. high and weighed about 1000 tons, surpassing the "Memnon" statues of Amenemhe III. in size and weight. The temple of Rameses III. at Medinet Habu, sculptured with very interesting scenes from his Syrian, Libyan and other wars and from religious festivals, is remarkable also for the unique entrance-tower.
which probably formed part of the royal palace. Northward
and far back in the foot-hills is the Ptolemaic temple of Deir el
Medina, and beyond under the cliffs of Deir el Bahri the terrace
of Queen Hatshepsut, the walls of which are adorned
with scenes from her expedition to Puoni (Somailand) in search
of incense trees, and many other subjects. The necropolis
extends from Kurna in the north through Drau abu'l Nagga,
the Assasif, and Sheikh abd el Kurna to Kurnet Murrai of Medinat el-Fedwa. The tombs of the XVIIIth Dynasty
Far behind Medinet Habu are the Tombs of the Queens, where
royal relatives of the XXth Dynasty are buried; and imme-
diately behind the lofty cliffs of Deir el Bahri, but accessible
only by a very circuitous route from Kurna, are the tombs of
the kings (from Tethmosis I. onward to the end of the XXth
Dynasty) in the Biban el Moluk and the Western Valley. They
are decorated with religious scenes and texts, especially those
which describe the passage of the sun through the underworld.
Those of Seti I. and Rameses III. are the most remarkable.
These royal sepulchres are long galleries excavated in the rock
with chambers at intervals: in one of the innermost chambers
was laid the body in its sarcophagus. In the XXIst Dynasty,
when tomb robberies were rife and most of their valubales had
been stolen, the royal mummies were removed from place to
place and at last deposited for safety in the tomb of Amen-
ophis II. and in the burial-place of the priest-kings at Deir el
Bahri. The finding of the two cachettes nearly intact has been
among the greatest marvels of archaeological discovery, and
the systematic exploration of the Valley of the Tombs of the
Kings by Theodore M. Davis has been annually rewarded with
results of the highest interest.

THEBES (anciently Thесае, or in poetry sometimes Θῆβαι,
in modern Greek Θήβα, or, according to the corrected pronunciation, Thееае), an ancient Greek city in Boeotia, is
situated on low hilly ground of gentle slope a little north of the
range of Cithaeron, which divides Boeotia from Attica, and on
the north-western slope of the Bеoetian plain, about 44 m. from Atbeine, whence it is reached by two carriage-roads and by railway since 1904. It has about 4800 inhabitants, and is the seat of a bishop. The present town occupies the site of the ancient citadel, the Cadmea; two fragments of ancient wall are visible on the north, and another, belonging either to the citadel or the outer wall, on the south. Two streams, rising a little south of the town, and separated by an average distance of about half a mile, flow on the two sides, and are lost in the plain. These are the ancient Ismerus on the east and Dirce (Διρέα) on the west, which gave to the town its name Διρεάων. The Dirce, now Plakōtissas, has several springs. From the west side of the Cadmea another copious fountain (Paraporti) falls to the Dirce. In a suburb to the east is another (Fountain of St Theodore), and north-west are two more. The Cadmea itself is supplied
with water brought from an unknown source to the south by
works supposed of prehistoric antiquity. It now enters the
town by an aqueduct of twenty arches of Frankish construction.
The waters of Thebes are celebrated both by Pindar and by
the Athenian poets, and the site is still, as described by Dicae-
archus (3rd century B.C.), "all springs," κάθε χώρος ῥάζα. One, from which emerges a spring still supplied his table, is still called "the spring of the cadis." Some
of the marble basins, seats, &c., remain, and, with the fragments
of wall above mentioned, are the only relics of the classic time.
The most curious of later buildings is the church of St Luke,
south-east of the Cadmea, believed to contain the tomb of the
evangelist. From the abundance of water the place is favour-
able to gardens, and the neighbouring plain is extremely fertile.
But the population is scanty, and the town at present of no
importance.

History.—The record of the earliest days of Thebes was pre-
served among the Greeks in an abundant mass of legends
which rival the myths of Troy in their wide ramifications and
the influence which they exerted upon the literature of the
classical age. Five main cycles of story may be distinguished:
(1) the foundation of the citadel Cadmea by Cadmus, and the
growth of the Spartan or " Sown Men" (probably an etiological
myth designed to explain the origin of the Theban nobility
which is named in historical times); (2) the building of a
"seven-gated" wall by banquet, and the formation of
the seven gates of Zethus, Antiope and Dirce; (3) the tale of the "house
of Lauis," culminating in the adventures of Oedipus and the wars
of the "Seven" and the Epigon; (4) the advent of Dionysus;
and (5) the exploits of Heracles. It is difficult to extract any
historical fact out of this maze of myths; the various groups
cannot be fully co-ordinated, and a further perplexing feature
is the neglect of Thebes in the Homeric poems. At most it
seems safe to infer that it was one of the first Greek
communities to be drawn together within a fortified city, that it
reputed its importance in prehistoric as in later days to its mense,
and that its original "Cadmean" population was distinct from other inhabitants of Boeotia such as the Minyae of
Orchomenus.

In the period of great invasions from the north Thebes
received settlers of that stock which in historical times was homo-
geneously spread over Boeotia. The central position and
military security of the city naturally tended to raise it to a
commanding position among the Boecotians, and from early
days its inhabitants endeavoured to establish a complete
supremacy over their kinmen in the outlying towns. This
centralizing policy is as much the central fact of Theban
history as the counteracting effort of the smaller towns to
resist absorption forms the main chapter of the story of
Boeotia. No details of the earlier history of Thebes have been preserved,
except that it was governed by a land-holding aristocracy who
secured their integrity by rigid statutes about the owner-
ship of property and its transmission. In the late 6th century
the Thebans were brought for the first time into hostile con-
tact with the Athenians, who helped the small fortress of
Plataea to maintain its independence against them, and in 506
reduced it into a tributary of Attica. The aversion to Athens
served to explain the unpatriotic attitude which Thebes dis-
played during the great Persian invasion. Though a
contingent of 700 was sent to Thermopylae and remained there
with Leonidas to the end, the governing aristocracy soon after
joined the enemy with great readiness and fought zealously
on his behalf at the battle of Plataea (479). The victorious Greeks
subsequently punished Thebes by depriving it of the presidency
of the Boeotian League, and an attempt by the Spartans to
expel it from the Delphic amphictyony was only frustrated by
the intercession of Athens. In 457 Sparta, needing a counter-
poise against Athens in central Greece, reversed her policy
and reinstated Thebes as the dominant power in Boeotia. The
great fortress served this purpose well by holding out as a
base of resistance when the Athenians overran and occupied the
rest of the country (457-447). In the Peloponnesian War the
Thebans, embittered by the support which Athens gave to the
smaller Boeotian towns, and especially to Plataea, which they
vainly attempted to reduce in 431, were firm allies of Sparta,
which in turn helped them to besiege Plataea and allowed them
to destroy the town after capture (427). In 424 at the head
of the Boeotian levy they inflicted a severe defeat upon an invading
force which came from Athens and Thespiae, and for the first
time had a distinct seat of the effects of that firm military organization which eventually
raised them to predominant power in Greece. After the
dowfall of Athens at the end of the Peloponnesian War
Thebans, finding that Sparta intended to protect the states
which they desired to annex, broke off the alliance. In 404
they had urged the complete destruction of Athens, in 403
they secretly supported the restoration of its democracy in order
in which the aeronautic against Sparta. A few years
later, influenced perhaps in part by Persian gold, they forced on the
so-called Corinthian War and formed the nucleus of the league against Sparta. At the battles of Haliautos (395) and Coronela (394) they again proved their rising military capacity by standing their ground against the Spartans. The result of the war was especially disastrous to Thebes, as the general settlement of 387 stipulated the complete autonomy of all Greek towns and so withdrew the other Boeotians from its political control. Its power was further curtailed in 382, when a Spartan force occupied the citadel by a treacherous coup-de-main. Three years later the Spartan garrison was overthrown, and the Athenian constitutions were set up in place of the traditional oligarchy. In the consequent wars with Sparta the Theban army, trained and led by Epaminondas and Pelopidas (q.v.), proved itself the best in Greece. Some years of desultory fighting, in which Thebes established its control over all Boeotia, culminated in 371 in a remarkable victory over the pick of the Spartans at Leuctra (q.v.). The winners were hailed throughout Greece as champions of the oppressed. They carried their arms into Peloponnesus and at the head of a large coalition permanently crippled the power of Sparta. Similar expeditions were sent to the Epirotan and Macedonian coasts to settle the affairs of those countries. But the predominance of Thebes was short-lived. The states which she protected were indisposed to commit themselves permanently to her tutelage, and the renewed rivalry of Athens, which had been linked with Thebes since 395 in a common fear of Sparta, but since 371 had endeavoured to maintain the balance of power against her ally, prevented the formation of a Theban empire. With the death of Epaminondas in 362 the city sank again to the position of a secondary power. In a war with the neighbouring state of Phocis (356-346) it could not even maintain its predominance in Greece, and was aided by inviting Philip II of Macedon to crush the Phocians it had extended that monarch's power within dangerous proximity to its frontiers. A rebellion of feeling was completed in 338 by the orator Demosthenes, who persuaded Thebes to join Athens in the Theban attempt fought bravely on behalf of Grecian liberty in the decisive battle of Chaeronea, and bore the brunt of the slaughter. Philip was content to deprive Thebes of her dominion over Boeotia; but an unsuccessful revolt in 335 against his son Alexander was punished by the Macedonians, who sent Thebes to the house of the poet Pindar. Though restored in 315 by Cassander, Thebes never again played a prominent part in history. It suffered from the establishment of Chalcis as the chief fortress of central Greece, and was severely handled by the Roman conquerors Mummium and Sulla. Strabo describes it as a mere village, and in Pausanias's time (A.D. 170) its citadel alone was inhabited. During the Byzantine period it served as a place of refuge against foreign invaders, and from the 10th century became a centre of the new silk trade. Though severely plundered by the Normans in 1146 it recovered its prosperity and was selected by the Frankish dynasty de la Roche as its capital. In 1337 it was destroyed by the Catalans and passed out of history.

The most famous monument of ancient Thebes was the outer wall with its seven gates, which even as late as the 6th century B.C. was probably the largest of artificial Greek fortresses. The gates vary in names; but the same ones are the bastions of Proeitides, Electra, Neistae or Neitae, and Homoloiades; Pausanias gives the others as Oggyiae, Hyspistae, Crenaeae. There is evidence that the gate Electra was on the south, and near it was the tomb of the Thebans who fell at the capture by Alexander. The gates were shown to Pausanias as Neitae and Proeitides led respectively north-west and north-east. Two of the springs have been identified with some probability. The chief of these is the Ligma, which Oedipus is said to have purged himself from the pollution of homicide, and the Paraporti with the dragon-guarded fountain of Ares (see CADMUS). Diaecaurus, referring to the town of Caria, says (De re divina, ii. 56), "The circuit of the city is 1,170, 35 m. and 55 m.; the smaller fairly corresponds to the 45 m. over which the extant remains have been traced; it consisted of sun-dried brick on a stone foundation. Beyond this the topography is wholly uncertain. From the interest of the site in history and still more in literature, as the scene of so many dramas, the temptation to fix details has been specially strong. Conjectural plans or descriptions, differing widely, are given by Leake, Forchhammer, Ulrichs, Burrian, Fabriusc and others (references below). There are two main difficulties: the authenticity of Caro and the place and time of the catastrophe. It was written at a time when the lower city was deserted, and only the temples and the gates left; and the references to Thebes in the Attic dramatists are, like those to Mycenaean and the Ilium, a later device. The sequel of Thebes is centred in the poet Pindar. It had a flourishing school of painting in the 4th century, of which the most famous representation was Aristides, who excelled in pathetic subjects. Thebes was written about 300, 300 B.C. by Thucydides, Xenophon (Hellanico, passim), Diodorus xii., xii.; Pausanias ix. 5-17; M. Müller, Geschichte Thebens (Leipzig, 1879); E. v. Seeck, Geschichte Wandels (ambrosianische Heiligen) (Dorpat, 1884). pp. 44-246; E. Fabricius, Theben (Freiburg im Breisgau, 1890); E. Funk, De Thebanorum actis, 378-362 (Berlin, 1890); B. V. Head, Historia Numorum (Oxford, 1887), pp. 259-599. See also Boeotia throughout.

THEBES, ROMANCE OF. The French Roman de Thèbes is a poem of some 10,000 lines which appears to have been based, not on the Thebaid of Statius, but on an abridgment of that work. This view is supported by the omission of incidents and details which, in spite of the altered conditions under which the poem was composed, would naturally have been preserved in any imitation of the Thebaid, while again certain modifications of theStatian version can hardly be due to the author's invention but point to an ancient origin. As in other poems of the same kind, the marvellous disappears; the Greeks adopt the French methods of warfare and the French code of chivalric love. The Roman dates from the 12th century (c. 1150-155), and is written, not in the iroades of the chansons de geste, but in octosyllabic rhymed couplets. It was once attributed to Benoît de Sainte-Mère; but all that can be said is that the Thèbes is prior to the Thébaïdes of Philipe de Thèbes, of which Benoît de Sainte-Mère was the compiler. The Thèbes is preserved also in several French prose redactions, the first of which, printed in the 17th century under the name of Edipus, belongs to the early years of the 15th century, and originally formed part of a compilation of ancient history, Histoire ancienne jusqu'à César. The first volume of Les histoires de Paul Crosse traduites en français contains a free and amplified version of the Thèbes. The Romance of Thèbes, written about 1420 by John Lydgate as a supplementary Canterbury Tale, was printed by Wynkyn de Worde about 1490. From the Roman de Thèbes also were possibly derived the French romans d'aventures, such as Le ciel d'un bout, and the English romans d'aventures, such as about the end of the 12th century by Hue de Rotelande, an Anglo-Norman trouvère who lived in Credenhill, near Hereford. The author asserts that he translated from a Latin book lent him by Gilbert Fitz-Baderon, 4th lord of Monmouth, but in reality he has written romances of chivalry on the usual lines, the names of the characters alone being derived from antiquity.

See L. Constans, La Légende d'Oedipe étudiée dans l'antiquité au moyen âge et dans les temps modernes (Paris, 1881), and in the section "L'Épopée antique" in De Julleville's Histoire de la langue de la litt. française; Le Roman de Thèbes, ed. L. Constans (Soc. des anciens textes français (Paris, 1890); G. Ellis, Specimens of Early English Mevilsh Romances, iii. (1805).

THECLA, ST., one of the most celebrated saints in the Greek Church (where she is commemorated on the 24th of September) and in the Latin Church (where her festival is the 23rd of September). She is honoured with the title of "protomartyr." The centre of her cult was Seleucia, in Isauria. Her basilica, south of Seleucia, on the mountain, was long a very popular place of pilgrimage, and is mentioned in the two books of St. Basil of Seleucia. The great popularity of the saint is due more particularly to her Acta, which in all their forms derive from the apocryphal work known as the Acta Pauli et Theclae. According to her Acta, Thecla was born of illustrious parentage at Iconium, and came under the personal teaching of the Apostle Paul. In her eighteenth year, having broken her engagement with Thamyris, to whom she had been betrothed, she was accused by her relations of being a Christian. Armed with the sign of the cross, she threw herself on the pyre, but the flames were extinguished by a sudden rain. She then went to
THEFT—THEINNI

743

Antioch, where she was exposed to wild beasts, then fastened to bulls in order that she might be torn asunder, and finally thrown into a pit full of serpents; but she was delivered from all these perils. She converted many heathen. Returning to Iconium, she withdrew into a mountain solitude, and became distinguished by many virtues and miracles. In spite of their highly fabulous character, which caused them to be more than once condemned by the Church, the Acts of Paul and Thecla, which date back to the 3rd century, affording the most interesting monuments of ancient Christian literature.

See Acta Sancctorum, September, vi. 546–568; J. A. Lipsius, Acta apostolorum apocrypha (Leipzig, 1891), i. 235–269; C. Schmidt, Acta Pauli (Leipzig, 1903), where an attempt is made to prove that Paul himself was the author of the Thecla Acts, considered as an integral part of the Acta Pauli; see also APOCRYPHAL LITERATURE.

THEFT, the act of stealing or robbing. In English legal usage the term is still used to denote robbing or stealing or of cattle. The O.E. word pœfes or piefes is formed from pœf, thief or pœf, to steal, and cognate with Gr. πιθεω, to deprive. The O.E. stelan, to steal, appears also in other Teut. languages, cf. Du. stelen, Swed. stjåla, Goth. stílan, &c. It has been doubtfully connected with Gr. ἀπορρίπτω, to deprive.

THEGN, or Thane, an Anglo-Saxon word meaning an aristocratic person or chief. The O.E. deor, to speak, and cognate with Gr. ῥιχων, a child. From the first, however, it had a military significance, and its usual Latin translation was miles, although minister was often used. J. Bosworth (Anglo-Saxon Dictionary, new ed. by T. N. Toller) describes a thane as "one engaged in a king's or a queen's service, whether in the household or in the country," and adds, "the word in this case seems gradually to have acquired a technical meaning, and to become a term denoting a class, containing, however, several degrees." The precursor of the thane was the geateth, the companion of the king or great lord, the member of his comitatus, and the word thane began to be used to describe a military geateth. It is only used once in the laws before the time of Aethelstan (c. 985–1014), but more frequently in the charters. H. M. Chadwick (Studies on Anglo-Saxon Institutions, 1905) says that "the sense of subordination must have been inherent in the word from the earliest time, but it has no connexion with the German dienien, to serve. In the course of time it extended its meaning and was more generally used. The thane became a member of a territorial nobility, and the dignity of thegead was attainable by those who fulfilled certain conditions. Thus from a document of uncertain date, possibly about the time of Alfred the Great, and translated by Stubbs (Select Charters) as "Of people's ranks and laws," we learn—"And if a ceorl throwe, so that he had fully hies of his own land, church and kitchen, bellhouse and burgh-gate-seat, and special duty in the king's hall, then was he thanecorth of thane-right worthy." And again—"And if a merchant throwe, so that he farre thred over the wide sea by his own means, then was he thanecorth of thane-right worthy." In like manner a successful thane might hope to become an earl. In addition to the thanes there were others who were thanes on account of their birth, and thus thanehood was peculiarly associated with the nobility. The superior or inferior to the earl, the member of a kingly family, but he was superior to the ceorl, and, says Chadwick, "from the time of Aethelstan the distinction between thane and ceorl was the broad line of demarcation between the classes of society." His status is shown by his wergild. Over a large part of England this was fixed at 1200 shillings, or six times that of the ceorl. He was the twelfthynd of men, the laws, divided from the twywynde man or ceorl.

The increase in the number of thanes produced in time a subdivision of the order. There arose a class of king's thanes, corresponding to the earlier thegns, and a larger class of inferior thanes, some of them the thegns of bishops or of other thanes. A king's thane was a person of great importance, the contemporary idea being shown by the Latin translation of the words as comes. He had certain special privileges. No one could save the king who had the right of jurisdiction over him, while by a law of Canute we learn that he paid a larger heriot than an ordinary thane.

But, like all other words of the kind, the word theng was slowly changing its meaning, and, as Stubbs says (Const. Eng., vol. i.), "the very name, like that of the geateth, has different senses in different ages and kingdoms, but the original idea of military service runs through all the meanings of them, as that of personal association is traceable in all the applications of geateth." After the Norman Conquest the thegns appear to have been merged in the class of knights.

The twelve senior thegns of the hundred play a part, the nature of which is rather doubtful, in the development of the English system of justice. By a law of Athelred they "seem to have acted as the judicial committee of the court for the purposes of accusation" (W. S. Holdsworth, History of English Law, vol. i. 1903), and they have some connexion with the grand jury of modern times.

The word thane was used in Scotland until the 15th century, to describe an hereditary non-military tenant of the crown.

(A. W. H.)

THEINNI, or HSENWI, one of the Northern Shan States of Burma. It is called by the Shan Hsenwi, and also officially so designated, but is better known by the Chinese name of Theinni. It was by far the largest of the cis-Salween Shan states, and at one time included not only all the territory of the present states of North and South Hsenwi, but also Kehsi Mansam, Mong Haung, and Mong Nawng, besides having a sort of protectorate over Mang Lèn and other Wa states east of the Salween. These had, however, fallen away in Burmese times, and at the period before the British annexation Theinni was divided into five parts by name; but there was no central authority, and the whole state was in hopeless disorder. This continued until the appearance of British troops in March 1888, when it was divided into two states—North Theinni, which was assigned to a successful adventurer, Hkun Sang, of Tôn Hông, and South Theinni, which went to Nawmpong, of the old Shan ruling house. North Theinni has an area of 6330 sq. m., and a population (1901) of 118,325 persons; estimated revenue, £6000. South Theinni has an area of 2400 sq. m., with a population (in 1901) of 67,836; estimated revenue, £4000.

The northern part of North Theinni is a mass of hills affected by the west-north-west fault which divides the Nam Tu or Myit-nge valley, and has thrown up a series of parallel ranges which extend northwards to the Shweli (Lung Kiang), without altogether destroying the north and south trend which is the characteristic of the Shan hills as a whole. In the valleys between these hills are numerous tracts under rice cultivation, some circular or oval, some mere ridges along the river banks. The southern portion is much more flat land, along the sides of the Nam Tu, its tributaries the Nam Yao and the Nam Nim, and the Nam Yek flowing into the Salween. This was formerly populated, and still remains the most valuable portion of the state. A large thane residence was built near the head of the Salween, and marking the southern border of the rift in the hills, divides North from South Theinni. Both north and south of the Nam Tu there are many peaks which rise to 6000 ft., and several over 7000 ft. The northern portion is almost consistent enough in its altitude of about 4000 ft. to be called a plateau. It has large, grassy, upland downs. This part of the state has fallen almost entirely into the hands of the Chinese, who has divided it into the Shan and Hsenwi (Nam Tu and Kiang) valley, and in the Nam Tu and other valleys in the southern part of the state. The line of the Nam Mao is the lowest portion of North Theinni, being little over 2000 ft. above sea-level. The other peaks are over 4000 ft. above sea-level, and by the spurs which that peak sends north and south. Apart from this it consists of broken hill-country of no great extent, but open terrean, in the latter consisting of the half of the state. It is watered by numerous streams, of which the chief is the Nam Pang, an affluent of the Salween. The chief river in the northern state, apart from the Salween, is the Nam
Tu or Myit-nge, which rises on the Irrawaddy-Salween watershed, not far from the latter river, and flows westwards through the state into Taungbaing or Thilaw, and eventually into the Irrawaddy at Amarapura. The three first of these rivers form a considerable tributary, the Nam Paw, which has its entire course in Theinni territory, and is large enough to be fordable in the dry weather, and only passable by boats in the rains. Its delta or small delta, caused by the alluvial deposits which it has dried up many of the springs, but as a whole North Theinni is very well watered. Considerable deposits of coal, or rather of lignite, exist in both North and South Theinni, but do not appear to be so valuable in quality. Gold is washed in many of the streams in a fictitious way. Limestone exists in large quantities. No valuable timber exists to any considerable extent. There is some teak in the lower part of the North Theinni forests, and the pine tree and great forest redwood are found in this part. The forests cover some of the ranges, but, as elsewhere in the Shan states, varieties of the oak and chestnut are the commonest forest trees. The climate of the state as a whole is temperate. In the plain of the uplands there are yearly frosts in January, February, and March, but in the greater part of the state the thermometer rarely falls to freezing-point, and in the hot weather does not exceed ninety degrees for any length of time. The average rainfall seems to be about 60 in. yearly. After the disruption of the ancient Shan empire at Tali by Kubbai Khan, Theinni seems to have been the centre of the independent Shan kingdom, with various capitals in the Shwe and Nath Shan States. This last capital was probably named from the Burmese about 1738, and the country was divided into various estates, with appointment orders from Ava. Numerous rebellions and civil wars have reduced Theinni from its position as the centre of Shan independence to a condition of mere desolation. It has regained much population since the British occupation in 1888, but is still far from its old prosperity. Much may be expected from the art works that have been made, from the English and British influence. The Shan are a tall, long-haired people.

Aseni, the capital of North Theinni, stands near the north bank of the Nam Tu. The ruins of the old capital lie at a short distance, and show it to have been a large and well-built town, with a number of houses variously estimated at from three to ten thousand. Mong Yai is the capital of South Theinni, with a population of about 2000. Lashio, the headquarters of the southern Shan State, is in North Theinni. The races found in Theinni comprise Shans, Kachins, Chinese, Burmese, Lihsaws, Wa, Palungs and Yanglam. The Shans and Kachins vastly predominate, and are nearly equal in numbers. (J. G. Sc.)

**THEISM (Gr. θεία, god), literally, and in its widest sense, the belief in a supernatural First Cause. The term has several changed meanings. (1) It appears for the first time in 18th-century English as an occasional synonym for "deism" (q.v.), and therefore as applying to those who believed in God but not in Christianity. Later criticism, orthodox and heterodox, upon the English deists inclines to charge them with the conception of a divine absentee, who wound up the machine of nature and left it to run untended. That was the general 18th-century way of thinking. God was apt to be thought of as purely transcendent, not immanent in the world. (2) In the 19th century theism is generally used of positive belief in God, either in a personal or a great First Cause; its most explicit form is a declaration, but unassociated with any peculiarities of 18th-century deities. If the word "deism" emphasizes a negative element—rejection of church Christianity—"theism" generally emphasizes the positive element—belief in God. (3) There is also a third usage. "Theism" was reclaimed by Theodore Parker, F. W. Newman, Frances Power Cobbe, and others, for their more modern speculative belief in God, which, while non-Christian or at least non-orthodox, held to an immanent God, continually revealing himself—in the moral consciousness. The ambiguity cannot be cured. We use the word in this article in the second sense.**

1. From this point of view theism is a synonym for Natural Theology, or almost so. But the expression Natural Theology itself has a history. (1) The "three theologies"—Natural, Apologetic, and Catholic—theology, recognized by the early Roman Stoics—probably on the suggestion of a passage in Aristotle's *Metaphysics*, xi. 8—are named by St Augustine (Latinizing the Greek terms) as the "three theologies." (2) Another sense of "theism" may be found in the *Critique of Pure Reason*, "Transcendental Dialectic," Book II, chaps. iii. and vii. It is curious, but, unless for the study of the "abstract" or unquestioned faith of a philosophical theologian, it cannot be pressed. (3)"Cf. Theology," Natorp's article quoted there gives the reference to the passage in Aristotle, but does not recognize its connexion with the last Stoical distinction.
THEISM

745

Theologians generally after him). The name "theism" makes that requirement less emphatic (see below).

Another kindred term is "Natural Religion." We meet with this in the titles of two Latin works by German authors Natu-Religion. in reply to Lord Herbert of Cherbury. They use it with strong condemnation, from the standpoint of rigorous Christian orthodoxy; but it comes into England within very few years upon the Christian side—religion against irreligion—in Bishop John Wilkins's Principles and Duties of Natural Religion (1678). The author died 1672, and left the book unfinished; but the language of the title occurs in the first sentence; so it is undoubtedly Wilkins, as well as sanctioned by his editor and connexion through marriage, Tillotson, afterwards the archbishop. We meet with "Natural Religion" again in Samuel Clarke's works, and notably in Bishop Joseph Butler's Analogy (1736). Thus, as employed by most writers, "Natural Religion" connotes neutrality or even friendliness towards Christianity; just as is the case with theism in sense (2), or with Natural Theology. "Deist," or sometimes "theist" in sense (1), or Naturalist, is a term of repugnance with English 18th-century apologists, but not with Natural Religion. If there is any reference between their "theism," or "Natural Theology" on the one hand, and Natural Religion on the other, it is to be found in the more practical character attaching to natural "religion." While Romans i. 19 and 20 (yet cf. Acts xiv. 17, xvii. 24, &c.) is the main New Testament passage which seems to recognize a Natural Theology, Rom. ii. 14. 15 may be said to assert Natural Religion. When the expression Natural Theology comes to the front one more with Archdeacon W. Paley (1802), this is a sort of after-birth or anachronism.

Natural Law.—We do not pretend that Law of Nature—the jurist's term, not of course that of inductive science—is Natural Law. It is a term of distinction, of great importance historically, bearing the marks of the Stoic doctrine of "nature," and helping to turn men's minds towards a "natural" theology. A pantheist may believe in Law of Nature and go no further; a theist who accepts Law of Nature has a large instalment of natural theology ready made to his hand; including an idealist, or else an intuitionist, scheme of ethics. Both jux naturale and lex naturalis are as early as Cicero, and the jux generium of the Roman lawyers is earlier still. Ambrose of Milan (Epistles ix. 71) quotes it. It is intelligible in its main—i.e., the passage already referred to, under "Natural Religion"—as an attempt of St Paul's words suggest that form of thought and may conceivably have been suggested by it. J. G. Ritchie's Natural Rights, from the point of view of a very hostile (evolutionary) idealism, sketches the early history of the phrase Natural Law.

The philosopher in Abelard's Dialogus inter Judaeum Philosophum et Christianum expects to be saved ex sola legi naturali; here "law of nature" is fully equivalent to Natural Religion, and the word sola sets it in contrast with Christianity. Not to speak of the canonists, Thomas Aquinas gives natural law an important place; while Melanchthon, drawing from Aquinas, gives it an entrance into Protestant thought. Zwinglei and Calvin on the other hand prefer the positive view of law as instituted by God far back in history in the days of the Old Covenant; but, when excesses or controversy puts pressure upon them, they fall into line and reiterate the appeal to a Natural Law. Richard Hooker, again with traces of Aquinas, uses the conception as a weapon against Puritanism, with its aggressive positivism of scriptural precept. Natural Law, he claims, leaves room for discretionary arrangements like episcopacy; Scripture does not mean to supersede the light of reason. It is intelligible that Locke (Treatises of Civil Government) should have a relish in quoting Hooker against the divine-right royalism of Sir John Filmer; but in Locke there is already a revival of belief in the (beau-ideal) "state" of nature and a growing emphasis upon natural rights; ideas which, heralded by Rousseau, echoed round the world in the French Revolution. Locke had spent some years in Holland, the country of Grotius, who, with help from other great lawyers, and under a misapprehension as to the meaning of the Roman jus gentium, shaped modern concepts of international law by an appeal to law of nature. This moral ideal rendered considerable services to civilization; we must not forget these, in the offence which the myth of a primitive golden age may offer to our historic sense. The kernel is sound enough though the husk is a poor thing. Finally, it is of some interest to note that Chr. Wolff, in the intervals of his chequered theological career, lectured and wrote as a jurist upon the Law of Nature.

"Philo-phy of religion" is the modern term. It is again not exactly a synonym, though more nearly so than the last. The new phrase indicates that we are to approach the thought of God through a study of religious beliefs and practices; "theism" tended to make God a purely scientific inference from the facts of nature. But "philosophy of religion" can be construed in many different ways. An investigating historian might set out to find out perhaps one who definitely disbelieves and rejects theism—may yet interest himself in tracing out the psychology of religion. Or a philosopher like Hegel, armed with a metaphysical theory, may descend upon the facts of religion and interpret them in its light, till they almost lose their original significance, which we might provisionally define as consisting in this, that the believer in any religion finds himself helped or (as he claims) saved by it. Again, we must not be misled by verbal idiosyn-krases. What James Martineau calls A Study of Religion is really in the main a re-statement of old theological arguments.

[Wallace's Gifford Lecture may be consulted upon this phrase also. He observes with truth that Natural Theology, if you remove from it the idea of subordination to Christianity as (claiming to be) a special revelation, tends to pass into a philosophy of religion. But it does not follow that the new standpoint involves what Wallace seems to hint, though he conceals his meaning behind complimentary rhetoric—rejection of church Christianity. A. M. Fairbairn's Phil. of the Christian Religion shows by its very title that an effort is being made to combine great confidence in metaphysics with strong belief in the uniqueness of Christianity and the effort will be found to fail. Possibly, fuller study of religions may help theologians to formulate the imperial claims of Christianity more happily than in the dry contrast between what is "revealed" and what is "natural." But that contrast is traditional; and it is implied in the ordinary theological usage of such phrases as "natural theology" or "natural religion" and almost of theism."

Comparative religion, or, as some call it, history of religion, is yet another modern study, closely akin to the last discussed, although more strictly confined to registering the sequence of religious phenomena and less disposed towards criticizing them or seeking in them for the keys of our present religion. Comparative religion is a special locus in the history of religion. The historian observes and records, in different lands and ages, the rise or explicit utterance of belief in one God.

Some uncertainty may be felt whether pantheism should rank as a theism. Is unity the main point? Or is it personality rather of prime importance, though doubtless presupposing unity? (Usage does not allow us to rank polytheism simply as a form of theism.) E. Troeltsch, Kultur der Gegenwart, Teil I, Abs. 4, p. 170, finds that the wisdom of the priests, in one land after another, rises to the thought of divine unity. That suggests pantheism, the usual form of such esoteric wisdom. Professor T. W. Rhys Davids (American Lectures, P. 37) sums up that, when the name of an earlier deity is

1 Recorded in J. G. Walsh's Bibliotheca Theologica Selecta (1751).

THEISM

attached to the object of supreme worship, monothelism proper is approached; while, when a new thought-construction is put in the supreme place, there is a tendency rather towards pantheism. So far as this is true, theism (proper) would seem to be an accident of language.

There is a further problem; whether monothelism is of very early occurrence. Belief in a primitive historical revelation, once universal among Christians, has almost disappeared; but belief in a very early and highly moral theism is stoutly defended, chiefly on Australian evidence, by Andrew Lang (The Making of Religion and other works). If Lang is right—"primitive" peoples drew typical theistic inferences, and argued to God from nature and from conscience, though without displacing other types of religious belief and practice. In many regions—Egypt, Babylonia, &c.—individual investigators of the great religions have thought they found traces of an early—one hesitates to write, of a "prIMITIVE"—monothelism. Perhaps J. Legge, who finds true theism at the dawn of Chinese history, is the most authoritative representative of such views.

Passing to later times, we can watch a theory of monothelism rising, and dying down again, during what our scholars distinguish as the Brahmanical period of Indian religion.

Brahmanism, as distinguished from the Brahmanical period of Indian religion.

The supreme god, Isvara, has the personal name Prajapatı, Visvakarman or some other. But this theism is lifeless—a "palace and shallow deism, which India has often confessed with the lips, but which has never won the homage of her heart." The thought of India is upon the side of pantheism. Again, the heretical Egyptian king Amenophis IV., or Akhenaton, one of the sovereigns to whose government the celebrated Tell el-Amarna letters from Palestine were addressed, was a zealous champion of the exclusive claims of the sun-disk God, Ra; but his policy died with him. In Babylonia a mutilated inscription printed by T. Pinches (Transactions of Victoria Institute, vol. 26), identifying (so far as preserved) thirteen other Gods with Marduk, has been hailed by Friedrich Delitzsch (Babel und Bibel) as the great fountain-head of monothelism, and has influenced the bold if very precariously conjectures of H. Winckler.

Of more assured importance was the Zoroastrian faith—"pure moral dualism if not theism" (L. H. Mills)—which proved its seal by persecutions. But later times nearly strangled Zoroastrian piety, not only by laws of ritual purity but also by newly evolved secondary deities—personified attributes, and the like. So that here again theism, if theism it was, did not continue in strength. If we understand by theism not simple belief in a divine unity, but such faith in one divine person as will constitute the basis for a popular religion, then—unless we allow a doubtful exception in Zoroastrianism—we must agree with those historians of religion who affirm that the world has known only a single living monothelism, viz. that of the Old Testament, along with what are historically the daughter faiths, Christianity and Islam.

The theist believes that he can further trace many incomplete workings of the monotheistic instinct in the history of religion.

Incompleteness of theist impulse.

Not only is it true, as A. Mensies observes, that "Reason knows only God, not Gods"; if we take religion as saving help, no worshipper possesses religion in full security until he has gone straight to the fountain-head, and gained the friendship of the God of Gods. Indian Vedic henotheism (otherwise called kathenotheism);

Semitic monolatry, so important as the probable starting-point of religious development in Israel; the Greek use of "Zeus" almost as we say "God"—even the attempt to arrange deities in a monarchical pantheon, all show the tendency, though it so seldom attains a real victory.

1 A. Barth, Religions of India, Eng. trans., pp. 29, 30, 69. We may probably extend this hostile judgment to the theism of the modern Sámsé-as.

2 The centralizing of worship at Babylon by its last king, Nabonidos, hardly seems to have amounted to monothelism.

The two terms are explicitly identified by F. Max Müller, their inventor (e.g. Hibbert Lectures, chap. vi. p. 271).

II. We have already suggested that theism covers more ground than the name at first may suggest. It can never quite confine attention to the problem of the being of God. Where God is believed in at all, it is believed that upon God everything else depends. With the thought of God, accordingly, there is correlated a modification in thoughts upon all other subjects; and a full system of theism must discourse of "God, of the world, of the Soul," like Matthew Arnold's Moses. In other words there must be doctrines regarding matter and mind, the world and the self, as well as those about God. Absolute theism, which is believed to exist behind both, revealing Himself through them. This way of approaching theism is illustrated in A. C. Fraser's Gifford Lectures, or in earlier times in the writings of Christian Wolff, whose sciences, according to the slightly different nomenclature which Kant imposed on them, were "rational psychology," "rational cosmology," and "rational theology." Kant swept away, so far as his influence extended, such "dogmatic metaphysics" and the old-fashioned theism which it constituted or included; but Kant himself introduced, in his own more sceptical yet also coherent system of doctrine, a new type of theism. He defines God, Freedom, Immortality, the three "postulates" of the "practical reason." It is tempting to try to correlate the members of this triad with the individual members of the older triad. But that would only mislead us; free will and immortality are really predicates ascribed—on whatever grounds—to the soul; and it is natural that in theism the soul of man should be a topic second in importance only to God Himself. Every theistic system, or almost every one, makes provision in some way for Kant's three postulates. Accordingly, even in a hurried survey of the history of theism, we must try to question the systems we are reviewing upon their attitude towards human freedom and immortality, as well as upon their doctrine of God. Sometimes it will be found that free will is asserted as an assured fact, as a datum, and so as a ground of inference to God. But sometimes free will is rather a probandum. In Christian theology, much labour has been spent upon vindicating man's freedom against God's intrusion, or upon blotting out human power in order to leave room for the divine. Theism suggests at the very outset that we should rather expect to find a correlation between the two. If there is a God at all, he must be thought of as the guarantee of freedom in man and as the pledge of his immortality.

The mention of Christian theology may remind us that, for the majority of theists in medieval and modern times, theist proper has ranked only as a secondary wisdom. It is possible for Christians to work out natural theology in separate detail; but we cannot wonder if they rarely attempt the task, believing as they do that they have a fuller revelation of religious truth elsewhere. In point of fact, as we look to history, we find that theism has been much simplified and cut down. First of all, attention has been concentrated upon God. One does not suggest that this concentration was an error. On the contrary, even Christian theology makes at least the effort to show that the thought of God regulates the whole system of belief. Yet while an adequate doctrine of God may settle everything in principle, we ought to remember that there are applications of the principle, apart from which we do not see our way clearly. As a second step in concentration, attention is almost confined to the question "Does God exist?" and to theistic proofs as answering "Yes." The further question "What is God?" is shunned, as if there could be no two opinions regarding that; whereas in truth there are two hundred opinions. A. B. Hulse feels that so strongly that the natural theology section of his Apologetics entirely omits the question "Does God exist?" in favour of the question "What is God?" Perhaps that is equally one-sided. When we do find theism dealing with the question "What is God?" it tends to borrow from scholastic forms of Christian theology the scheme of Being and Attributes (see e.g. Wolff). But such a scheme gives at best an

Subordinate elements of theism.
external preliminary description of the object to which it is applied.  

So our wealth of material narrows down in the ordinary handling to a single question. God, the world, the soul, free will, immortality, optimism; What then is God? All these questions, and perhaps others, tend to conceal themselves behind a single discussion: Does God exist? But further still. Either the fuller or the narrower way of dealing with theism will differ according to the philosophical standpoint of the particular theist who speaks to the question. As long as the battle of the philosophies endures, theism can hardly be unified. Its history is not so much that of a single evolving doctrine, but rather the history of many and diverse theistic schemes.

III. It may help us if we rapidly review at this point the leading types of philosophy in their application to the theistic problem. Grouping and naming are fixed here for one special purpose. From other points of view they may perhaps appear open to blame; but it is hoped they will throw light upon our present study.

The simplest basis for philosophy is empiricism. Such a philosophy makes little serious attempt at constructive work in antiquity; but, upon the first great victories of physical science in modern times, a desire arose to extend the new and wonderfully fruitful method to the ultimate problems of speculation. Let us take experience as our teacher! Let us stand upon realities—upon facts! Difficulty may be found in carrying out this empiricist programme; but at the outset no one dreams of failure. Beginning with the certainties of everyday experience, it reaches theism at last by means of an analogical argument. Many objects in nature, organisms especially, seem to resemble the works of human design; therefore with high probability we infer a designing mind behind nature, adequate to the production of these special results. Having got such a mind, we may next inquire whether, on the principle of parsimony, it will not account for more; perhaps for everything in nature! But the starting-point of the argument in question is the purely empirical evidence of a single fact or set of facts; it proceeds by way of analogy, not of strict demonstration; and it claims for its results nothing more than probability. From Socrates, in Xenophon's Memorabilia, downwards, the argument is tolerably common; it is notable in Cicero; in the modern discussion it dominates the 18th-century mode of thought, is confidently appealed to though not worked out by Butler, and is fully stated by Paley. The argument does not necessarily imply empiricism in philosophy; still, it is peculiarly characteristic of empiricism. In ethics empiricism begins by recognizing that man possesses sensations, and so is liable to pleasures and pains. Hence, early empiricism makes ethics simply a calculus of pleasures ("hedonism"). We may doubt, with W. E. H. Lecky, whether such a philosophy affords a basis for natural theology at all; but the attempt is made. As J. S. Mill tried to reconcile criminal law and its punishments with his very hard type of determinism by saying that law was needed in order to weight the scale, and in order to hold out a prospect of penalties which might deter from crime and impel towards good citizenship, so Paley held that virtue was not merely obedience to God but obedience "for the sake of eternal happiness." A second type of hedonism—less ignoble, but perhaps also less logical—calls men to seek the happiness of others. Paley includes that too; virtue is "doing good to mankind," in obedience to God, for the sake of heaven.

The second type of philosophy, for our purpose, is intuitionism. It finds its chance in the misadventures of empiricism. The Scottish philosophy of Thomas Reid and his successors is immediately related to David Hume's scepticism. It is no more than the genuine outcome of Locke's sensationalist appeal to experience when ripened or forced on by the imaterialism of Bishop Berkeley—God and the soul alone; not God, world and soul. And so the Scotsmen fell back upon the witness of consciousness. They did not make much use of the word "intuition," which may indeed be taken in different senses, e.g. of visionary experiences as well as of the principles of "common sense" (i.e. universal beliefs). They spoke of 'natural realism' and a 'natural dualism' of mind and matter (restituting here the element which Berkeley had struck out). Still, they do not repudiate the word "intuition," and kindred writers make it prominent. The term is borrowed from, Sight, of all the physical senses the one which most rapidly instructs the mind. You see, at a glance, that things are so. Indeed, there is a further implication, when the term intuition is borrowed for mental vision; you see at a glance that things must be so. Here then characteristically intuitionism occupies a half-way house between empiricism, with its appeal to real given fact, and idealism, with its appeal to necessity. The senses, in perception as contrasted with sensation, are held to give us immediate knowledge. The prejudice for, and possibility of, doubt, that things are so and so. This is Reid's first reply to Hume. Define more carefully than Locke did, with his blunder about "ideas," the process of perception, and you cut up scepticism from the roots! So far, this philosophy has little bearing upon theism. But Intuitionism has further arguments for the doubter. Besides testimony from outer sense, we have testimony and teachings from consciousness within—"first principles," as Reid generally calls them. There are some principles which, as soon as they are presented to the mind, and not merely grasped, must be assented to; we see the truth! Two regions become prominent in the working out of intuitionism, if still more prominent in the widely differing philosophy of Kant—the regions of mathematics and of morals. Though J. S. Mill boldly affirmed that there might be remote realms in space where 2 + 2 did not make 4 but some different total, even empiricists may hesitate to concur; and yet Mill's assertion is at least the most obvious empiricist reading of the situation. If all knowledge is drawn from experience, statements universal in form are but generalizations, holding within the limits of actual experience, or advanced beyond them at our peril. Geometry again is regarded by thoroughgoing empiricists as hypothetical. It deals, according to Mill, with arbitrary and imaginary constructions. If there were such a thing as a triangle contained by absolutely straight lines, its three angles would no doubt measure what Euclid says; but straight lines and true triangles nowhere exist in rerum natura. Kant's point is ignored, that deductions from these "imaginary" figures apply to the "real" world of experience. Every time we survey a field, we go upon the principles, not of special experience, but of a priori necessity. Given certain linear and angular measurements, the area must be so and so. Great as the difference in the mathematics to morality, yet there are striking similarities, and hence his arguments for "immediate knowledge" claims to find much support. If we accept moral ideals at all, we are no longer in the world of mere phenomenal sequences, but in a new world. It is a problem for empiricism; given a world where nothing but phenomenal sequences exist, to account for moral ideals. Vulgar materialism sneers at the problem; duty is a fraud or hogbobbin, a mere superstition. Even Jeremy Bentham, restive under appeals to vague and intangible standards, breaks out in despairing indignation against the word "ought" as "the talisman of arrogance, indolence

1 Criticism of the scheme, from the point of view of an idealist, theism, will be found in John Caird's Introduc to the Phil. of Religion, chap. viii. Yet the formula is serviceable. Perhaps it is even indispensable as a preliminary statement. We find it substantially repeated in the famous sentence sented in a useful book, A. Calcott's study of The Phil. of Relig. in England and America.

2 An outline of the history of theism is reserved for Section IV.; but it has not proved possible to sketch the types of philosophy without introducing references to the history of philosophy and sometimes even to the history of theism as well.

3 Of course the Design Argument was well known in antiquity, but not the type of philosophy which stands or falls by that line of "proof."

and ignorance," and as "an authoritative imposition." Later ethical empiricism is more refined. J. S. Mill recognizes an ultimate difference in quality between higher and lower pleasures. A. Bain finds that benevolence is one given element in man's original constitution. H. Sidgwick holds that intuition must justify the claims of the general happiness upon the individual, though everything subsequent is hedonistic calculus. Herbert Spencer finds that the modern individual has intuitions of duty which represent the inherited experience of what has been good for the race in the past. Sir Leslie Stephen finds that moral laws are the conditions needful for the good of the social organism, and are imposed as such by society upon its individual members. The problem has altered its form. What the modern empiricist needs is a rational bond uniting the individual with the community or with the aggregate of individuals—a rational principle distinguishing high pleasures from low, sanctioning benevolence, and giving authority to moral generalizations drawn from conditions that are past and done with. The non-empirical moralist will not of course admit that duty to the community or to mankind is a final definition of the ethical ideal. He will accept it as a stage, of no small importance, in progressive definition; but he will seek to go further.

We have already remarked that the difficulties of empiricism constitute the strength of intuitionism. A critic of intuitionism might add that they are its whole strength; intuitionism is sound upon the intellectual and moral plane of human activity, but in its lower stages, it does not justify them. It reasserts them, with resolute loyalty; but if philosophy ought to vindicate, to explain, perhaps incidentally to modify, even it may be, to purify our primary beliefs, intuitionism is hardly a philosophy at all. For good or evil, so far as there is an accepted line of theistic doctrine, that doctrine is intuitionist. Other schools of philosophy pay flying visits to theism; intuitionism is at home there. Its leading argument is the cosmological, concluding to "God as cause" (Martineau). When David Hume (Dialogues concerning Natural Religion) protests that the universe is a "singular effect" and that we have no right to affirm a cause for it, unless we have experience of the origin of many universes, and can generalize upon the conclusion, They all have causes—he may be unassailable upon empiricist grounds. But intuitionism claims to allege a higher certainty; everything (or every change) must have a cause—this is not merely actual fact but necessary truth. The universe exists—or, as otherwise stated, the universe is "contingent"—therefore, even without detailed knowledge of many universes, we can affirm that it must be caused, and in its "Great First Cause" we recognize God. It is generally stated that this argument was for the first time definitely formulated in Aristotle's philosophy. Of course the cosmological argument is rare or never left to stand quite alone. The design argument is available for the slightly bolder philosophy of intuitionism as well as for empiricist theism. But there is yet another argument which is even more important. Moral elements must enter into theism at some point: and, as against empiricism, intuitionism is morally strong. Hence it has a moral argument in reserve. Moral law implies a law-giver; "we are conscious of moral dependence" (Robert Flint). Still the main weight of the intuitionist theism rests upon the conception of God as First Cause.

As a philosophy, intuitionism leaves the mind in all the embarrassment of an indefinite number of separate starting-points. Every percept is such a starting-point; it is an immediate certainty, remaining with us unmodified as the basis of reliable inference. Every First Principle of the mind is a starting-point too. Reid—certainly a very unsystematic thinker—furnishes long and random lists of "first principles"; a later writer, J. M'Cosh, in his Intuitions of the Mind, attempts a more systematic study. (For ethics we may also compare Miss F. P. Cobbe. Contemporary with Reid and even more popular in treatment was James Beattie; Dugald Stewart with trivial modifications followed Reid; but in Sir W. Hamilton and H. L. Mansel there were sweeping changes in the direction of agnosticism—changes due partly or primarily to the influence of Kant.) Memory is included among First Principles. Testimony is also a First Principle (this is aimed against Hume's Essay on Miracles). Inevitably the question forces itself upon the mind, is not some fuller synthesis possible? All these isolated starting-points of thought are said to be, one by one, necessary. Is there no higher or broader necessity? Can we not attain to some further-reaching philosophy?

If we swerve "Yes" to that question, we pass on from intuitionism to idealism—an idealism not on the lines of Berkeley (matter does not exist) but of Plato (things objects an ascertainable rational necessity). This third possibility in philosophy does not enter at all into Lecky's grouping referred to above; in fact, it is very generally strange to older British thinking, which, if it conceives any tertium quid besides empiricism and intuitionism, is apt to think of scepticism. The fixed given points of intuitionism furnish Hamilton with one of his "starting-points," and he goes on to formulate a "faith" or "faith philosophy." You cannot prove any first principle. You accept it by "faith." So—for this among other reasons—we infer that knowledge has narrow limits, beyond which doubt, or faith, presently begins. But is it really a matter of faith that two and two make four? Do we believe where we cannot prove that the whole is greater than its part? A less sophisticated intuitionism would rejoin with great force, "These are matters of sight; it could not be otherwise, and you see that it could not!" Hamilton's line of thought may, however, impress on us the conviction that it is extremely natural for philosophy to pass beyond the limitations of a purely intuitionist programme. It does so notably in Kant. He is a most difficult writer; different readers understand him differently; and he uses in the earlier parts of his Critique of Pure Reason much of the language of intuitionism. But nothing is more certain than that his thought is a strong solvent of the intuitionist way of thinking; and he has had an immense influence in many directions. We may state his chief results in our own words. First he breaks up the percept. It is no ultimate given point of perception or intuition; it is due to the reaction of thought upon sensation. Sense alone will never create orderly experience, as empiricism supposed; but a group of sensations reacted on by thought does so; it becomes, it is, a percept. Secondly: the "forms" of time and space, not referable to any sensation, and presupposed in every experience, come from the mind ("Transcendental Aesthetic"). Thirdly: we cannot explain how these three elements—sensation; time and space; thought—work together. True, Kant refers often to the idea of a "perceptive" or "intuitive understanding," whose thought would produce the whole of knowledge out of its native contents. But our understanding, he is convinced, is of a different and inferior type. Incomprehensibly, we are dependent upon sensation; and incomprehensibly, we place our sensations in time and space. Fourthly: if we try to think of objects not built up out of sensations and not in time and space, we are

1 Deontology, p. 42. F. H. Bradley (Ethical Studies, p. 2) quotes an even plainer specimen on the conceptions as well as the terminology of ethics in a Westminster Review article (Oct. 1873, p. 311) which describes "responsibility" or (sic) "moral desert in the vulgar sense" as "horrid figurments of the imagination."

2 As Aristotle says, "cause" may be taken as pointing to a truth here, but inadequately, would lead us beyond intuitionism into some phase of idealism. To revise one's first principles is to be an intuitionist no longer.

3 Austin's Jurisprudence explicitly assumes that the dilemma of "intuitive" and "utilitarian" is exhaustive. Hence F. H. Bradley's characteristic protest (Ethical Studies, pp. 82, 83): "If we wished to cross an unknown bog, and two men came to us of opposite opinion, one said there must be a way, and one said there must be a way, and you see there is no one here beside us two, and therefore one of us two must be able to guide you. And the other man does not know the way, as you can soon see; therefore I must—should we answer, 'Lead on, I follow?'"
baffled by contradictions or absurdities. Kant admits that we necessarily aspire to think of such objects—"God, the World, the Soul"—possibly this alleged tendency of our thought is already implied in the dream of a "perceptive understanding." But speculative knowledge breaks down or breaks off at an earlier point. If we try to know the soul, we grasp at a phantom. The "soul" is subject to all the objections of Hobbes and Locke, and never comes an object of knowledge ("Paralogism of Pure Reason").

If we try to know the real world, we find ourselves distracted by opposite arguments ("Antithetic of Pure Reason"), plausible and resistless in attack, helpless in defense. The only thing which the "Ideas" of "Reason" can do for theoretic knowledge is to exert a "regulative" function. They teach the inferior but working part of our intellect, the "Understanding," that its picture of sensuous reality envisaged in time and space must be as fully articulated as is possible—as much differentiated into a detail, and as perfectly integrated again into unity and system. God, for Pure Reason, is an illegitimate personification of the idea of perfected experience ("Ideal of Pure Reason").

Fifthly, there are fixed limits to the possibility of improving the quality of experience. Sense-knowledge is an endless process, inconsistent with the requirements of thought. We can by no means regard the physical world as the real world. But we possess knowledge of the physical world and of it alone. "Things in themselves"—whether defined by Kant, illogically enough, as causes of sensations, or again defined by him as the ultimate reality of a "reality," which thought vaguely points—in either case, "things in themselves" are unattainable by finite knowledge.

Our "reach" exceeds our "grasp" with a vengeance.

So far as a remedy for scepticism is found at all, Kant places it, not within theoretic knowledge, but in moral or "practical" experience. Pure knowledge, for man, moves among a world of appearances, and in that world duty is certain. Mansel charger to "regulative" duty, as we call it, with inconsistency in this preferential treatment of the moral consciousness: all our knowledge, even in moral things, was 'an appearance.' But, wrote Kant, "a regulative or inconsistent" duty was deliberate in differentiating between the ethical and the theoretic knowledge of man. "Analytic" or tautological thought does not become "synthetic" or capable of embracing a real content except under the sting of sensation; why sensation should thus help it is obscure, yet the fact is plain. But analytic thinking is victorious in morals, where the test of "formal self-consistency" distinguishes virtue from vice. The greatness of it is partly that it directs our attention to moral man; and that is a full account of virtue, though Kant proceeds to reinterpret it still further in a much more positive sense as implying the service of morality. True, at a later stage, the moral idea has become itself substantial in Kant's thought, Kant even in ethics. We are allowed moral certainty, but are forbidden the hope of genuine moral victory. Just as our knowledge never gains the assurance of science, so our moral consciousness is immanent, not as a determinate system, but as a regulative one, in which our will is never once able perfectly to obey the law of reason. There is always a taint of feeling in man's goodness. This portion of the ethical theory does curious service in Kant's doctrine of religion. That doctrine runs, briefly, as follows. Duty must be accepted as a given certainty, or it is vindicated—unsatisfactorily enough, perhaps—in the way just explained. Next, from the certainty of duty we infer as our first moral postulate free will—"I can because I ought"; which, primarily at least, means "I know I can because I know I ought." But this strong assertion is greatly qualified when Kant recasts to what he considers the shape of things of our knowledge of the world of phenomena, not freedom rules but determinism. Causality is one of the "categories" which our mind uses in building up orderly experience. So we are left with a see-saw. Will is noumenally free of all phantasies, and all our laws of will, which determine by the past. Secondly: from the discrepancy between the pure abstract law of self-consistent reason and the pleasure-tinged nature of man, we infer or postulate Immortality. As we never see the bull's eye, we must have imperfectly enunciated our conditions of aiming at it, so as to get indefinitely nearer the central spot. If we did hit the exact mark, apparently we never need any longer be immortal. Lastly, God. We must not, we dare not, aim at happiness and the pleasure of ourselves as moral ends. But it makes us constantly shrink aside from the thought of duty towards the forbidden motive—wining under pain, or hungering after joy.

Yet, if the motive is forbidden us, it is plain from another point of view that good persons ought to be happy. And, as nature must conceived great care of the world as an end of itself, not beyond nature to a power who shall make good men as the last as they deserve to be. And this power is God. Such the train of thought as stated for us in the Critique of Practical Reason.

In the Critique of Judgment, Kant restates his new type of theoretic argument in a way which has had great subsequent influence. We must conceive great care over the real end of itself, not for the sake of man's happiness as for the sake of his moral development. Or, to state this as a theoretic argument: we are bound to postulate a God who overrules nature for moral ends. This new statement has at least the merit of bringing God into touch with man's goodness as well as with his happiness. But the train of thought is developed and analyzed as a whole, and so as to imply a sceptical hesitations. In spite of the various details of the Judgments Critique (as to beauty; and as to the "internal" or as Hegel subsequently phrased it "immanent" adaptations seen in living organisms) Kant regards as extremely precarious all these hints of a higher view of nature. Nature as a machine, governed by changeless causal law, is necessary to thought. Were no such machine recognized, the thread of consciousness would be cut and orderly experience impossible; we would all go mad. But nature not, of course, directly or, however faintly, of a God immanent in the whole process, and shaping it towards moral purposes—that is or may be no better reason. Cultivating a "regulative" or "synthetic" duty, we don't have guarantees, as compared with our knowledge of the mechanism of nature. And, after all, nor even our knowledge of the mechanism of nature is a knowledge of reality. Things as they truly are lie wholly beyond our poor human vision.

Kant then has broken away from intuitionalism by substituting one system of necessity for the many necessary truths or given experiences from which intuitionalism takes its roots. But the other key to Kant's thought is the gap between sensation and the sense-forms of time and space; a gap between sense-forms and thought: a gap between the lower but practicable processes of the Understanding and the higher but unrealizable ideas of Reason. And thus Kant's idealism is incomplete. On one side, the world we know by valid processes of thinking cannot, we are told, be the real world. Or, beginning from the other side; neither the reality which ideal thought reaches after, nor yet the reality which our conscience postulates, is the valid world of orderly thinking. The great critic of scepticism has diverged from idealism towards scepticism again, or has given his idealism a sceptical colour, mitigated—but only mitigated—by faith in the moral consciousness. If there arises a system of philosophy in which all truths are grasped in unity, and it is seen that the principles of things must be what they are, such a philosophy will give us in perfection the idealistic conception of reality and the idealistic guarantees of truth which Kant gave brokenly. The Absolute Idealism of G. W. F. Hegel was such a system. It ranks, up to our own day, as the last of the great philosophies, and the boldest of all. Kant had fewer isolated parts of genuine truth into his system, yet gaps and isolation recurred in Kant, and helped to make him the father of modern agnosticism. In the later intuitionalism of Hamilton, recollected from Hegel, the many subjective necessities of the intuitionalist scheme were made to breathe the new agnostic suggestions. We necessarily think as we do—but only because of our entangling faculties. It is a mental "impotence" that makes us believe in such a law as Cause and Effect. Kant had substituted one great necessity, sprung from an ideal source. Reason—under conditions of sensation—created the world of (valid) knowledge; Reason created the practical world of duty. It was said to Kant men went on to the last the idealistic suggestion. The whole coherent necessary world of his philosophy became "our world," as we necessarily think it, but not by any means of necessity the world as it is. Hegel bridges these all these hesitations. His Philosophy of Nature—one of the last admired parts of his system—is the answer from his point of view to Kant's assertion that a "perceptive understanding" is for us impossible. Hegel offers a supposed proof that Time and Space, Matter, Nature, are ascertaining and definable

1 Mansel's term for Kant's "practical." It must be carefully distinguished from Kant's "regulative," which refers to knowledge—regulative in contrast to constitutive of knowledge—not to practice.

2 This is Kant's positive refutation of Hume's scepticism.
necessities in a reasonable universe. Rational system is the first and last word in this philosophy. The element of given-
ness, dominant in empiricism, and partially surviving through
intuitionism even into Kant, is submerged in Hegel's thinking.
Everything is to be exhibited, in outline or in essence, as the
working of necessary truth. You need not wish anything in
the universe to be other than it is; as well grumble at once
that it is; as well grumble at once that
Hegel, while pantheistic,
will not emanate from
theology of fact and principles. Nothing is bare fact. Philo-
sophy will show you that everything has to be so and so.
The effect of this point of view in regard to moral perceptions is that
they represent an important relative truth, but that philosophy
"passes" beyond them into a higher region, where imputa-
tion of guilt is absolutely meaningless.2 Is the "judgment of
Good and Bad." More peculiarly his own is Hegel's great doctrine
of contradiction, whereby opposing views of truth
rank as stages in one progressive definition. We
may explain this to ourselves as an extraordinarily
vehement recoil from Kant's delusion of formal
logic with its principle of "analytic" tautology. As a result,
Hegel's system undertakes to show candid minds that
incompatible assertions not only may but must both be true.3
Through this unexpected and obscure principle of "dialectic"4
Hegel claimed to fulfill his programme of interpreting everything
as manifest necessary truth of ideal relationship. It all must
be so and you see it must.

Hegel wrote extensively upon religion, especially in his Philo-
sophy of Religion.3 It remains doubtful whether he was a
theist with large pantheistic elements—such as every
 speculative mind will be likely to incorporate in theism—
or a pantheist rejecting theism altogether. We may
regard his ambitious programme as the last logical
development of idealism and indeed of philosophy itself. If
perfect knowledge be possible for us, it must take the form of such
a system as Hegel offers. If the world exists purely to be
known, and if every other working of reason comes into con-
sideration qua incomplete knowledge, Hegel is right with his sweep-
ing idealism. Or at least he has rightly seen what are the
assertions to aim at; it is difficult to accept the principle or method
upon which his answer to the riddle proceeds, the dialectic method.
Perhaps it was necessary for human thought to try how far it
would carry out this programme. And may not its failure, as
such a programme, be neither possible nor desirable. If such
are our conclusions, we return to a possible basis for theism not very far removed
from that of intuitionism. Certainly history shows that theism has
generally been associated with some reduced or limited form of
philosophy, usually with the intuitionalist scheme. It is not the
first runnings of the stream of religious thinking which have given
the world its theistic philosophies. Theism is an afterthought
—the result of the attempt to defeat the absolute justification of the
world, which was announced itself at first as a prophetic certainty. But no more
is theism the first runnings of the stream of philosophy. It is
philosophy harnessed to a practical and religious interest. It is
philosophy designed to answer this question:

Theism then has its most habitual affinities with intu-
tonism, but may fall under any one of our philosophical or
quasi philosophical types. We have distinguished three types or
tendencies: empiricism, intuitionism, idealism. They deal
respectively with what is—with what is and partly with
what must be—with what must be. They are based on facts—
upon facts in the light of principles—upon principles purely
and ultimately upon one principle. They claim probability—
moral certainty—mathematical certainty. They incline to the
Design Argument and Analogy—to the Cosmological argument
(with other elements in a subordinate place) and proof by
inference—to the Ontological argument. This last and boldest
argument is a system of idealistic philosophy in a nutshell,

1 It may be asked, Why can God not create a triangle whose
three angles shall not be equal to two right angles? To abstraction
and ignorance everything is possible." From notes of a class lecture
by Dr E. Ca.3

2 F. H. Bradley, Ethical Studies, p. 4.

3 J. E. MacTaggart (Studies in Hegelian Dialectic) contends that
direct contradiction is confined to the elementary portions of Hegel's
Logic. In the more mature portions, every eventuality is, though his inter-
pretation, could one accept it, softens the paradox.

4 Used by Kant sceptically of the limitations of reason, dialectic
in Hegel becomes constructive; and scepticism itself becomes a
stage in knowledge.

When such a system is worked out in full detail, it essays or
ought to essay a proof of the following points: (1) God or the
Absolute necessarily exists; (2) He necessarily is what He is;
(3) He or it necessarily manifests itself in the finite, (4) and
necessarily manifests itself in just this finite which we know
from experience. If philosophy is able to fill up that pro-
gramme, it justifies itself; it raises all limits of necessary truth;
contrasted, indeed, with something of the same kind in German
philosophy, this would also be theistic or pantheistic, or
theism, whichever turns out victorious, must hereafter rank as
a demonstrated certainty.

Again, these contrasted philosophies throw light upon the
meaning of a posteriori and a priori in Kant and subsequent
writers.5 To empiricism, all is a posteriori. To in-
tuitionism, half is a posteriori and half a priori. To
idealism, all is a priori. Not that a posteriori is denied,
or that idealism even in Hegel tries to evolve reality
out of the philosopher's inner consciousness. Mere given
fact may be the starting-point; but it is supplemented. We see by
degrees—in general outline or upon general principles—that
what is is no other than what must be.

There is another conception of necessity which has estab-
lished itself in the history of science and philosophy. We may
call it mechanical necessity. If this conception is
regarded as full and absolute truth, it involves
materialism. When we collect the empiricist start-
ing-point of science, it is curious to observe with what vehemence
the average man of science now rejects free will. To him, it
appears almost an absurdity. But is it not true that man is in the
process of preparing to go anywhere at the bidding of apparent facts,
unconcerned about rational probabilities. On this ground James
is a libertarian. The fact appears to be so; he reports it.
Similarly, James is willing to believe in many universes
neben-
einander or durcheinander but not ineinander. Dualism,
pluralism, manifold parallel inconsistency may belong to the
nature of fact. Does our intelligence demand unity? That
may be a mere subjective fancy. Even polytheism,6 or some-
ting indistinguishable from it, is suggested to this doggedly
empiricist mind by the Varieties of Religious Experience; they
are all good to those in whom they appeal; and we accept
right have we to talk of objective standards?8 Ordinary "in-
ductive" empiricism shows that it has travelled far from
this unprejudiced credulity when it asserts its hard determinism—
uniform law, never broken, never capable of being broken.
But what is mechanical necessity, if we admit that in some
sense it exists? It is a relative necessity. The present and
the future have to be what the past and the absent make them.
Past events, "happening" to be what they were, have fixed
subsequent processes to their channels. But you can never, at
least, say from the scientific or materialistic
standpoint, this "had to be."9 The relative necessity
never passes into an absolute one. A different primitive
"collocation," as T. Chalmers10 put it, would have yielded,
by the same process of natural law as ours, quite a different
universe from ours.11 T. H. Huxley admitted that this contention
would have to be ruled out as impossible. Again, in the scheme of
mechanism, everything is determined by everything else—in

5 (1) Aristotle and the schoolmen meant by a priority reasoning from cause to effect. (2) Kant is often supposed to mean by a priori—see Hamilton's Reid, p. 762—"innate" as opposed to "acquired from experience" (as the Contradiction of the Absolute, which, if he accepts the suggestion offered above—that a priori in Kant and later thinkers
necessary—we place ourselves on the track which leads from
intuitionism to some form of idealism. (3) We have not been able to
answer this argument in such general terms? But this limitation is always
taken for granted.

6 It does not seem as if James's "Pragmatism" could lend itself to anything so concrete as a theistic conclusion.

7 A very different thinker, Dr J. E. MacTaggart, works round from idealism to an eternal quasi polytheistic society of equal souls.

8 H. Spencer's "Instability of the Homogeneous" is perhaps an attempt to perform this trick. (4) Principles (chaps. xii., xiii.

9 Quoted in J. S. Mill's Logic, and with fuller sympathy in W. S.

10 Jevons's Principles of Science.

11 God has ordered the original "collocation"—a new statement of the argument which traces Design in nature.
THEISM

space as well as in time; nothing does anything for itself. Yet again, nature is broken up into co-operating parts; the whole is the sum of these parts; or, if you prefer to say so, there is no whole. But, if we should take the view that nature is infinitely extended—part of the "Antithesis" in Kant’s first "Ananthology"—nature will, whether broken down by the last analysis, since boundless nature may overwhelm that sequence which we thought most securely established. Who can say what may emerge from an infinite background? We reach such conclusions when we recognize that the laws of nature are general or hypothetical; not in Mill’s sense ("If you had such a non-existent thing as three perfectly straight lines united in a triangle"); but in a sense noted in F. H. Bradley’s Logic; "If? or? As often as you have the cause working unimpeded, you get the effect."); Pure scientific theory cannot tell you when you have got such a fact, or cause, or whether you ever get it at all. No law of nature contains in itself a promise that it shall pass into operation. Its doing so depends upon the totality of conditions. Materialism supposes that this mechanical order is the real world and the only real world—mechanical monism. stabilization monism supposes that there are two realms—of necessity and freedom, of nature and will, of matter and mind; contiguous, independent, yet interacting—dualism. Idealism in one way or other supposes that mind is more real than matter. And thus its first programme—All is in accordance with reason—may partly contain the more doubtful programme All is reason. In one of the two forms (a) nothing exists but mind (e.g. Hegel, as often interpreted—pantheistically?) or (b) nothing exists but minds (e.g. Hegel, as interpreted by Dr MacTaggart). Anyhow, whatever the method or interpretation is to be, idealism, even more fully than materialism, is pledged to monism and to the rejection of dualism. The valid or scientific but metaphysically untrustworthy knowledge, to which Kant shut us up, was knowledge of a mechanical universe. His reply to Hume was this—Mechanical causation is as real as the unity of consciousness. It is false to suggest that Kant’s reply was a free will and no dualism, to be rejected in dualism. Apart from the very same consciousness, there could be no consciousness of sequences. Over against this "valid" mechanism, in some truer but vaguer region, Kant placed free will; and so left things. The English thinkers influenced by Hegel are inclined to assert mechanism unconditionally, as the very expression of reason—the only thinkable form of order. Thus libertarian free will has to disappear from their belief. In this interpretation of the universe, the difference between mechanical or relative necessity and absolute or ideal necessity is slurred, or dogmatically affirmed to be non-existent. This might be suggested to reply that free will, whether or not it be ultimate truth, is true to the same degree of analysis as mechanical necessity itself. Mechanism is that which obeys impulses from outside. It is profoundly unsatisfactory to regard mechanism as the whole ultimate truth. For such a role it is in no sense fitted. If it is ultimate truth in its own region, that region cannot be accepted as more than half the entire universe of reality (common sense intuitionism; dualism). If mechanical determination applies to the whole universe, it cannot be ultimate truth at all (cf. H. Lotze; more drastic in Ward’s Naturalism and Agnosticism). Quite a different feature of nature and mind is a fragment pointed to by Kant’s "Practical Reason." And, as the sympathizers with Hegel try to force mechanical necessity into the glibber of absolute or ideal necessity, so they seek to show that moral necessity is only an inferior form of absolute or ideal or, we might say, mathematical necessity. Theists, on the other hand, will contend that the distinctiveness of moral necessity is vital to religion. Thus we might restate our group of philosophies in terms of the views they take regarding necessity. Theism is directly interested in this, since it affirms the necessity of God’s existence.

At least, it would be hard to name any school of theists which was content to affirm that there “happened” to be a God. On the other hand, theism does not desire to see necessity—or Fate—ranked as superior to the living God.

One great change and only one since Kant’s day has affected the outlook upon theistic problems—the increasing belief in evolution. It is a manifest weakness in intuitionism that it finds such difficulty in leaving room for evolutionary change. All men may perhaps be aiming everywhere at the same moral ideal, but it is absurd to say that all men actually formulate the same moral judgments. On the other hand, many evolutionists ignore the certainty that there must be a continuum in any real evolutionary process. In the light of that truth, a reformed intuitionism might justify itself. But fuller conceptions of evolution raise further difficulties applied to problems of human conduct, and knowledge cannot be divided into the two components—immediate certainties, precarious inferences. The starting-point is reconsidered, modified, transformed, in the light of subsequent acquisitions. Knowledge grows, not by mechanical addition, but by organic transformation. This may help us to appreciate the meaning of Hegel’s Dialectic. His thought then is not wholly paradox, whatever the expression may be. Hegel’s system is, in its own way, a great evolutionary philosophy of an ideal type. Evolution, repelled by the older intuitionism, was thus incorporated in the great I of all Idealisms. It has also been largely applied to empiricism. Sometimes one questions whether empiricism is really still empiricist; so much of the a priori has come in under the name of evolution (e.g. in Herbert Spencer). But the change, if it has taken place, is unrecognized.

IV. Greek philosophy for our purpose begins with Socrates, who formulated the Design Argument. His ethics have sometimes been regarded as pure utilitarianism (so e.g. H. Schulte); but it is surely significant that the great Idealism of Plato was developed from his suggestions. The new method of definition which Socrates applied to problems of human conduct was extended by Plato to the whole universe of the knowable. In the light of this, it may be possible (with J. R. Seeley in Ecce Homo) to call Socrates the "creator of science." The man who inspired Plato deserves that name. Those Ideas according to which all reality is objectively shaped—and therefore too, as a modern would add, subjectively construed—include the idea of the Good, which Plato identifies with God. We might mislead ourselves if we interpreted this expression as referring to moral goodness; on the other hand, Plato more in the great of all Idealisms. It has also been largely applied of God. With all its Idealism, Greek thought had difficulty in regarding rational necessity as absolute master of the physical world. Matter was a potentially recalcitrant element. Hence there are tendencies even in Plato to build up the ideal world in sharp contrast to the actual world—to the half interpreted or half tamed world of matter. His suggestions as to immortality are affected by this. The body is the soul’s prison. He teaches (whether suggestively, metaphorically or deliberately), pre-existence as well as survival; perhaps he is moved to this by non-Greek influences. Thus at several points theism and evolution are combined, though not yet fully formulated as a problem. Aristotle has impressed the ordinary mind chiefly by his criticism of Plato’s ideal theory; and therefore he is often ranked as the father of empiricism. But those who treat him as the great

1 Ernst Haeckel will not allow us to call his system “Materialism,” because he affirms that the rudiments of matter are also rudimentary “mind stuff” (to use W. K. Clifford’s term). But in spite of this its materialistic affinities are unmistakable.

2 Still, Lotze’s criticism of the cosmological argument reveals his realist side. On the other hand, in discussing the ontological argument, Lotze confesses to himself a convinced belief.

3 We are all embarked upon a troublesome world, the children of one Father, striving in many essential points to do and to become the same (R. L. Stevenson).

4 The idea of evolution in time (physical evolution) was laughed at by Hegel.

A belief hinted again at the close of Lessing’s Education of the Human Race; also more definitely by J. E. MacTaggart (Studies in Hegelian Cosmology, p. 45; and elsewhere).
Theism

Realist make him almost if not quite intuitionalist; while there is also an idealist reading possible. The threatened dualism of ideal and material becomes for Aristotelian mainly a contrast of matter and form; the lower stage in development desires or aims at the higher, matter more and more tending to pass as form. God is form without any matter, but this God of Aristotle’s is a cold consciousness, imitated only by the contemplative virtue of the philosopher, not by the morally active citizen. And the chief contribution of Aristotel to theism is a theory, found in his Physics as well as in his Metaphysics, of God as first mover of the universe, himself unmoved. This theory is generally ranked as the earliest appearance in European thought of the cosmological argument. Free will is shaping itself towards discussion in Aristotle’s Ethics, but is hardly yet a formulated problem. For anything like personal immortality the medieval Schoolmen searched him anxiously but in vain.

 Epicureanism need not detain us. It is a system of empiricism and materialism, remarkable only for teaching free will. Atoms swerved as they fell endways downwards, and thus introduced an indeterminate or irrational element into the processes of the world. There is no special interest in Epicurean particular type of free doctrine, or again in Epicurus’ profession of the existence of the gods—made of atoms: inhabiting the spaces between the worlds; careless of men. Stoicism is a much more important system, but harder to classify as a particular type of free will doctrine; or, again, in the Stoics’ profession of the existence of the gods: the whole world is one body, the whole body is the soul of the world, even the gods of the Stoics: God, the wise, appears in the history of the world as the being who supervises it. Stoicism is the whole trend to deny free will. There is perhaps a certain religious enthusiasm in the teaching of being passively determined by Fate, the Universe, Zeus. Finally, the Stoics’ definition of the process of knowledge is sensationalist and empiricist.

 So far as a coherent body of theistic doctrine exists, it did not grow out of the great systems, but out of the lesser men who stood nearer to the apprehension of practical citizens. Perhaps the most important of these popular thinkers was Marcus Tullius Cicero, no great philosopher, but a graceful and effective man of letters.

 Cicero.

 It has been truly observed that the lineaments of intuitionalism are very clear in him. He also gives us “natural law”—a Stoic inheritance, preserving the form of an idealist appeal to systematic requirements of reason, while practically limiting its assumptions to those of intuitionalism. Cicero adhered to the Academic philosophy during its “middle” or almost sceptical period. (The senses are so far from truth that we must be content with reaching probability.) However, the natural law doctrine of Cicero is not altogether on the Stoic interlocutor. The conclusion, “academically” recognizing the contending of one disputant as more “probable,” is imitated in D. (Diotima of the Symposium.) Cicero was not the only Roman Stoics—Seneca, Epictetus; less material for theism perhaps in Marcus Aurelius—we see the partial softening and religious deepening of the system, and a doctrine of the man’s power over passion and circumstance which has all the essentials of Libertarianism. Philo of Alexandria should also be mentioned. He blends the tradition of the Old Testament with Greek philosophy, and, within the lines, exhibits that union of Platonism with Stoicism, especially in the doctrine of the Logos, which became dominant in the Christian apologists and the great theologians of the ancient church. Philo is in one important respect only truly Stoic: in the theory of signs he preserves the main outlines of Old Testament theism. He teaches free will and immortality; and the design and cosmological arguments are both traceable in him. Augustine of Hippo transfigured the Stoic and the Epicurean views, and left a great mark on the Western church. Against Manichean dualism he had vindicated free will; but as against Pelagianism he taught the bondage of sinful man—a position accepted in the East, but never established in the West and half rejected in the West. From this theological entanglement the problem of free will did not escape for long centuries. In spite of some waverings towards the Pelagian view by late Augustine himself (see Apologiæ) the doctrine of “natural immortality” championed by Augustine became dominant in the church; an institution of what was afterwards to be called Natural Theology; and a Greek theologian or supposition to-day—like free will—in Roman Catholic apologetics.

The middle ages, in the person of Anselm of Canterbury, contributed a first clear form of the Ontological argument for Theism. If our grouping of philosophies, as given above, is sound, every idealist scheme contains potentially an ontological argument. In other words; whether pantheists or re-established a doctrine such as Platonism, and perhaps even whether logically it can be. But the Christian bias is sure to make theologians, who borrow a doctrine of the Absolute, interpret it in a Christian sense; hence we may consider it something of an accident that every philosopher exactly to put the argument in form. Anselm tells us that a perfect being must exist, since the perfection which includes existence is manifestly greater than a perfection confined to an accidental thought. Something else, imperfectly expressed, but quite clear to Anselm’s teaching, was the Absolute simply as one among many other beings, and to his treating existence simply as one element in the quantitative sum of perfections. At least, idealist philosophy will hold that the substance if not the form of the argument is sound 4 though the question of its interpretation remains. In Anselm’s case we have the further sanguine hope of justifying not theism merely but all Christian doctrine to the scientific reason. Thomas Aquinas, following Albertus Magnus, but with greater power and greater influence, occupies substantially intuitionalist ground. He will not have the Ontological argument; but he asserts Natural Law, and relies on the contingency of the universe, of the world, with various refinements and distinctions, differently stated in his two Summæ. In declaring the supreme doctrines of Christianity to be mysteries abstract of the human mind, he marks a low point in the development of a great system. He exercises their acumen in multiplying difficulties; but all such questionable doctrines are presently re-established from a different point of view as truths of faith or findings of church authority. The Church of Rome has discouraged these daring tactics in favour of the more cautious and probably more defensible positions of Aquinas. In Raymond of Sabunde’s form of moral theologian it is true that the existence of a will in the human life is not to be “vain”—we see the kinship of that argument to the argument from design.

René Descartes, a faithful though not an unsuspected Roman Catholic, founded modern philosophy by his starting-point of universal doubt and by his arguments in reply. One may regard him as an idealist, though Scottish intuitionalism—especially in the writings of Professor John Vellech—has claimed him for its own; and indeed Descartes’s two substances of active mind and passive extended matter are very much alike. Whether or not he marks a lower region, the tendency of Descartes’s system is to idealist traits, as when he refutes the ontological argument with clearer emphasis on the perfect being as “necessarily” existent—relying that a shade less quantitative or a shade more subtle than Anselm’s. Descartes’s preliminary statement of the argument in somewhat popular form brings it very near the lines of the cosmological proof. 6 There must be a cause for nature, but particularly for the idea of perfection in us—that cause must be God. The radical side of Descartes appears again in his offering his own type of theism as a substitute for the old proofs—not a supplement. Design especially was under suspicion with him, and he was even more definitely opposed to “final causes” than Francis Bacon, who excluded them from science but admitted them to theology. All this was connected with zeal for physical and mathematical science. Descartes was an expert; Bacon was the prophet of a great, if half comprehended, future; and the science they loved was struggling for its infant life against a mass of traditional prejudices, which sought to foreclose every question by confident assertions about the purposes of God and Nature. A difficult question arose for Descartes’s philosophy, when it had to explain the union in man of the absolutely opposite substances, 7

4 Cf. J. E. MacTaggart in regard to Hegel, Studies in Hegelian Cosmology, chap. iii.

5 See Meditation 3., at least in the French version. Again: “Existence cannot be separated from the essence of God”; compare Spinoza’s ethics, definition 1; “By causa sui I understand that the cause of the existence of which involves the cause of that—which by its own nature can only be conceived as existing.”
THEISM

mind and matter. Malebranche gave all causation to God; and the acosmist—as Hegel called him, in repudiation of Bayle's nickname "atheist"—Spinoza, from the premises of Car- 

telianism, and from other suggestions of the past, 

developed that great system of determinist pantheism 

which was a scandal and a terror to his generation. Really, 

he urged, there could be only one substance—Descartes himself 

had drawn a strong hint at the basis of his determinist reasoning 

of Spinoza's Ethics, in process if not in result, betrays its kinship to the ontological argument, with its affirma-

tion of what must be. Thought and extension are peacable 

attributes in this one substance; there are infinitely many 

other attributes, but these only are known to us. 

In a different region, the tradition of Descartes passes on to 

G. W. Leibnitz. He accepts the ontological argument with a 

qualification—almost like his disciple Wolff, who 

tries to use it for defining the divine attributes. Leib-

nitz's Monadology—which has little influence on his theism—

may be viewed as a strong recoil from Spinoza's all-sufficient 

substance. The more Spinozistic side of Leibnitz's thought—

God as Monad of Monads—is a theistic postulate if hardly a 

theistic proof. The free will which Leibniz teaches is not 

libertarian but determinist. Each monad works out necessary 

results, but these flow from its own nature; and so in a sense 

it is free. Reciprocal action is explained away into a "pre-

established harmony" between every monad and all others. 

In his Theodiçy Leibnitz argues, like not a few predecessors, 

that this universe must be regarded as the best of all possible 

universes. Pain and sin must have been reduced to a minimum 

determined by God; though they are so ingrained in the finite that 

we have to make up our minds even to the endless sin and endless 

punishments of hell. It has been truly said that such optimism is 

a profound relative pessimism. The best? Yes, perhaps the 

best possible; in familiar speech, the best of a very bad business. 

But why must universes be so bad? Leibnitz's philosophy 

has no answer for us. In another direction, Leibnitz—and 

Wolff—give emphasis to the contrast between the necessary and 

the contingent; with important results for popular philosophy, 

and indirectly for theism. The disciple, Christian 

Wolff, is one of the most typical figures in the history of 

theistic thought. He is a pure scholastic. The great 

thoughts of his master—or perhaps indeed rather Leibnitz's 

secondary thoughts—are dried and pressed by him, labelled 

and catalogued. Monadology drops out of Wolff's teaching. 

Pre-established harmony drops out—except that it is used 

to explain the union of soul and body. Wolff tells us 

that six Latin works contain his system:—Ontology, General 

Cosmology, Empirical Psychology, Rational Psychology, Natural 

Theology, i; Natural Theology, ii. In the volume on 

Empirical Psychology, Wolff discusses free will. He decides 

that human actions are caused or determined by the nature 

of the agent, but that, as man is not a necessary being, 
his actions are contingent. This view seems to preserve 
all that is questionable in Libertarianism, while omitting its 

moral meaning. The Rational Psychology formulates immor-

tality on the ground that the immaterial soul has no parts to 
suffer decay—the argument which Kant's Critique of Pure 

Reason "refutes" with special reference to the statement of it 

by Moses Mendelssohn. The earlier of the two volumes on 

Natural Theology relies on the cosmological argument; the 

later—obviously an afterthought—tries to vindicate the onto-

logical argument as an alternative basis for theism, but 

awkwardly and with manifest uneasiness. In the end, this 

volume diverges into the Attributes, construing God in the 

likeness of man via eminence.1 No writer can be less intrinsi-

cally worthy of study than Wolff. But he is immortal as the 

man against whom Kant directed his tremendous battery; 

and he is also tolerably characteristic in outlook. He is no 

intuitionist; but he is a drily common-sense mind, piling up 
in heaps the ruinous fragments of an idealist system. 

In England, empiricist thought found a prophet in Bacon. 
He draws no inferences to theology, whether friendly or 
hostile, from his new positions. He takes the line 
of separating the things of God from those of Caesar, 
and defends the traditional Protestant theology with obvious 
simplicity. Thomas Hobbes, a rough and unassuming but vigor-

ous thinker, is the fountainhead of a more formidable 

empiricism. He is almost a materialist. In ethics, 

he is a hard determinist and hedonist, though not without 

qualifications (man's boundless desire for "gain and glory") and 

peculiarities. He saves himself theologically by affirming 

that the good citizen will be of the same faith as the government 

— which had been a monarchy. In that sense, living under a 

professedly Christian ruler, Hobbes himself is a Christian. 

John Locke, the real father of English philosophy, 

philosopher for what he regarded as Descartes's 

impossible programme of "Innate Ideas."2 But Locke is a double-minded or half-hearted philosopher. He admits two 

sources of knowledge—sensation and reflection; and God is to 

him the Great First Cause, especially of our own existence (or 

of the existence of finite minds). This is a form of the 

cosmological argument, and ought to go with an intuitionist not 

an empiricist doctrine of causality. On ethics, Locke says very 

little, although that little is hedonist and determinist. But 

once again in his political writings he breaks away from emp-

ricism in appealing to natural law—an intuitionist or con-

servative and idealist tradition, that is a sensualist and 

empiristic, but incompletely, and without perfect coherence. 

His suggestions led to different developments. In France, 

through Condillac, the inconsistencies were purged out, 

and materialism was ready for the next comer to 

affirm—though it may be said with R. Flint that 

while materialism requires sensationalist psychology, yet 

the psychology in question allows no valid inference to 

matter, and therefore destroys materialism. Bishop George 

Berkeley, afraid of materialistic developments from a 

philosophical field against what he regarded as Descartes's 

system: to recur, took refuge in immaterialism. Locke had treated ideas as testifying to the existence of matter. But can they? The inference seemed unwarrantable. Why should not God, a spirit like our own, though greater, speak to us in this language? In 

Athism or the Minute Philosopher Berkeley gives the fullest 

statement of this argument, while adding more commonplace attacks on the pettiness of religious scepticism. David Hume, 

following up Berkeley's leading suggestion, pointed out 

that the inference to God is as precarious as the 

inference to matter, and that the assertion of a continuous or 

immaterial mind in man also goes beyond the immediate facts. 

The truth is, that all truth is uncertain! Scepticism, with 

which P. Bayle had played as a historian—he amused himself 

too, with praising the Manichaean solution of the riddle of 

the universe—became a serious power in the history of philosophy 

with the advent of David Hume. Still, it may be doubted how 

far Hume was in earnest. Nay, it may be questioned how far 

it is either psychologically or logically possible to turn general 

scepticism into a coherent doctrine. The Dialogues Concerning 

Natural Religion constitute Hume's formal profession of re-

ligious faith. The existence of God was no doubt probable; but 

what a number of difficulties there were! Still, one would 

not dispute whether God existed; but what he was—that was 

the hard question. This treatise must not be confused with the 

Natural History of Religion, in which Hume acts as a pioneer 

for comparative religion, with its study of facts. Even in that 

book Hume is able to play with sceptical solutions. Religion 

began in fear—as if it were no more than a lying superstition. 

Of course once more Hume saves himself by strong professions of 

admiration for rational or natural religion. It was not yet 

socially safe to be a confessed religious sceptic. 

1 And against similar views in Lord Herbert of Cherbury.

12
THEISM

Samuel Clarke, who defended Newton's view of the world against Leibniz's strictures, is perhaps chiefly interesting to us as one of the authorities of Bishop Joseph Butler. It is Clarke's defence of free will, Clarke's idealistic theory of eternal "fitness" as the basis of ethical distinctions, perhaps Clarke's teaching on immortality, that Butler regards as "the common foundation of all the modern philosophies," in the region of philosophy or Natural Theism. Butler himself occupies a peculiar position in more respects than one. He has profoundly influenced British thinking, but is little known abroad. He is difficult to classify. We may be helped in assigning him his proper place if we observe that, almost invariably, he accepts certain beliefs which he forbears to press. Thus in his most important contribution to ethics, the Three Sermons on Human Nature—i., ii., iii. of the Sermons—he grants the validity of an appeal to nature upon the lines of a sort of Stoical idealism, but for his own part he prefers the humbler appeal to human nature. He makes the issue, as far as possible, a question of fact. We, from the altered modern point of view, may doubt whether Butler's curious account of the mechanism of moral psychology is a simple report of facts. There are (a) given instinctive "propensities"; (b) a part of higher principles, "benevolence" and "rational self-love," equally valid with each other, though at times they may seem to conflict; (c) there is the master principle of conscience, which judges between motives, but does not itself constitute a motive to action. Butler is opposing the psycho-biologist; but he is not doing the work of an experience that man necessarily acts at the dictation of selfish motives. But Butler—for reasons satisfactory to himself, and eminently characteristic of the man; he hoped to conciliate his age—dwells so much upon the rewards of goodness, as bribes (we must almost say) to rational self-love, that some have called Butler himself an ethical hedonist; though his sermon on the "Love of God" ought surely to free him from that charge. In all this, Butler was convinced that he was giving a simple statement of facts. Any one introspectively apprehending the facts must grant, he thought, that benevolence was an integral part of human nature and that conscience was rightfully supreme. This reveals the empiricist temper, and points to an attempted empiricist solution of great problems. Butler holds that more ambitious philosophies are valid, but he shrinks from their use. The same thing is seen again in the Analogy. Butler divests himself in this book of the principles of "liberty" and "moral fitness" in which personally he believes.

Part i. of this book shows the "Analogy" of "Natural Religion" to the "Constitution and Course of Nature." Probably "Nature" is here employed in a more familiar or humber sense than in the passages of the Analogy means by "nature," indisputable human experience. Deists believed in a God of unmingled benevolence: Butler's contention is that justice, punishment, hell-fire itself are credible in their similarity to the known experiences of man's life upon earth. What the Three Sermons sought to find written small within—a law of inflexible justice or righteousness—part i. of the Analogy seeks to discover written in large characters without us. Butler is charged by Sir Leslie Stephen with arguing illegitimately—professing to make no appeal to "moral fitness," and yet contending that the facts of human life show (the beginnings of) moral retribution for good and evil. Assuredly Butler is met on this ground, but his right to their use is based on his claim about moral evil and good when he waived the "high priori" method of vindicating their real existence. Yet it is a very grave question whether the idea of God's moral government admits of being argued as pure matter of fact. Butler tries to do this. You call it unjust, he says in effect, that you should be punished. You argue, for example, that you have no free will. Well, what of that? Does it not look very much as though you were being punished? It does not seem to treat you as if you had free will. One thing is clear, however: you will not hear any formal argument for the truth of theism. He will not waste time upon triflers who deny what he thinks, in the light of the (empiricist!) Design, is morally true. On the other hand, Butler in personal conviction is an intuitionalist appealing towards the idealism of his age; but in argument he is an empiricist, trying to reason every question as one of given facts. Natural Theism, in this respect, has no appeal to facts—it is the depth and purity of Butler's moral nature—which fascinates the reader, and wins praise from Matthew Arnold or Goldwin Smith or even Leslie Stephen. Precisely because the facts are not the best evidence of any large systems, as of scripture or of a person, the hearer is left to himself. On the other hand, no Christian, and perhaps no theist, is interested in maintaining that Butler grasps the whole shape of the matter: he might say this. If theism is a growing doctrine, Butler in England like Kant in Germany stands for a fresh ethical opportunity.

Stephen accuses Butler of reasoning in a circle. The things which make for our ultimate welfare are the things we call morally good. No wonder if they prove to involve happiness; that is their definition! But is it? Does not Stephen himself rather say that morally good things are conditions of social, not personal welfare? Butler's argument is that the individual sullies (and feels that he suffers deservedly) from neglecting these. If George Elliot is guilty, of a platitudinous when she says that "consequences are un pitying," then Butler's argument is empty: but not otherwise.

Butler on the soul may be studied in chap. i. of the Analogy—where we observe the old assumption of an immaterial and so immortal soul, which is in truth the basis and in fact the main idea of all Butler's thought. Moral postulates make their presence felt, Butler's doctrine of man, as of God, leaps into new vigour.

It is more important that Clarke's Demonstration of the Being and Attributes of God is really a priori. Clarke appeals to the immensity of time and space as involving infinity in God. A modification of his views is the starting-point of W. H. Gillespie's able Argument a priori for the Being and Attributes of the Godhead, published part by part 1833-1872. We find something curiously similar in James Martineau's Study of Religion ("Implicit Attributes of God as Cause," sub fac.). One might also compare F. A. H. Martineau's Valiant Witness: the Life and Work of a personal God—and F. Max Müller's Goff Proceedings. Dismissing his earlier intuitionalism, in order, like Butler, to conciliate an empiricist age, Müller tried to base even sense experience on the immensity of time and space, and the im- of the idea of God. He therefore appealed to the Indian goddess Aditi or Immensity, a deity connected with a set of personal gods called Adityas. Looking into the immensity of space, man also looks into the depths of godhead. Whatever one may think of the cogency of such arguments, it seems safe to conclude that thinkers, who dislike constructive idealism, but accept time and space, find it easier, though perhaps not more satisfying, to believe in the God of Aditi. We have already spoken of Kant's peculiar philosophical positions. One result of these is a very damaging attack upon traditional theism. Kant puts together, as belonging to Kant as to "Rational Theology," three arguments—he is fond of triads, though they have not the significance of their parts. But he has been better known to him which they came to have for the Hegel. Then he attacks the arguments, one after another. Is there anything fresh in the attack? Or is it simply a reiteration of his sceptical contrast between phenomena and noumena, and of his confidence of (valid) knowledge to the former? Perhaps the attack on cause as used in the cosmological argument is independent of Kant's philosophical peculiarities. The argument affirms a first cause, or uncaused cause. Does it not then deny rather than assert universal creation? But that special criticism is a question of detail. A more entirely novel and more general principle of Kant's attack upon theism is the challenge of our right to build up the idea of God bit by bit out of different arguments. The arguments had been regarded as alternative or else as cumulative proofs, all pointing to one conclusion—God exists. Kant insists that they are incompatible with each other.

1 Analogy, part i. chap. i. ("the natural and moral proofs of a future life commonly insisted upon"); last sentence of part i. Conclusion ("the proper proofs of natural religion from our moral nature"); part ii. chap. viii. sub fac., "the proof" of religion, not out of the two . . . principles of liberty and moral fitness.

2 These useful distinctions are stated and well explained in W. R. Sorley's Ethics of Naturalism. Analogy, iii. chap. viii. following S. Clarke?

4 Part ii. of the Analogy tries similarly to establish Christianity as a credible matter of fact, sufficiently analogous to the facts of (empiricist!) Design, to any moral "value judgments" (as Ritschlian might say).

5 See (e.g.) ii. chap. ix. The Three Sermons also point to a moral argument for theism, but forbear to press it (Sermons ii. when the third sense of the word "Nature" is being explained).
other. They offer alternative and mutually exclusive conceptions of God. If the God of the cosmological argument is the "Great First Cause," we have no right to identify him with the "Most real being" of the Ontological argument. If the God of the Design argument seems a limited being, working as an artist upon given materials, he is hardly God at all. Kant takes for granted that we cannot sum up these imperfect conceptions in a wider reconciling truth. It is a shrewd criticism, but needs arguing out. A great deal of popular theism is undoubtedly hard hit by it; for popular theism is apt to throw its arguments together in very random fashion.

It is no more characteristic of Kant's whole speculative philosophy that he should think the Ontological argument the one which comes nearest to success (yet the Ontological argument is held to prove—or rather to point out—not that God must exist, but that we think of him as necessary if we think of him as existing at all). As a result of this, Kant is metaphysically a sort of pantheist. The God whom all our thinking feels after is the all-inclusive system of reality. On the other hand, Kant's religion is of a type which requires a sort of deistic God, standing outside the world and constraining it into moral paths, or standing outside our moral struggles and rewarding our goodness. Butler fears profoundly that there must be a just God who will punish us. Kant hopes, with tolerable strength of conviction, that there may be a just God who will reward us.

The main line in pure philosophy runs on from Kant's wavering and sceptical idealism to the all-including gnosia of Hegel.2

Hegel on the theological arguments.

Hegel inherits from Kant the three arguments, and takes them as stages in one developing process of thought. The cosmological argument points to nature-pantheism, with the religions—especially those of India—which embody that attitude of mind. This involves a re-interpretation of the Cosmological argument, or a criticism of the view ordinarily taken of it. Trace out the clue of causation to the end, says Hegel in effect, and it introduces you, not to a single first cause beyond nature, but to the totality of natural process—a substance, as it were, in which all causes inhere. This is a suggestion which deserves to be well weighed. The Design argument is held to give a contrasted view. It suggests in every deed a personal but limited God, or a number of Gods—"Religions of spiritual Individuality," including, along with "Judaism," the anthropomorphic religions of Greece and Rome. Finally the Ontological argument sums up the truth in the two previous arguments, and gives it worthier utterance in its vision of the philosophical Absolute. This is the last word of religious truth, though pure philosophy stands still higher. And, in some sense not clearly explained, Hegel identifies this final religion with Christianity.

The theism of Hegel is ambiguous.3 Later theists may be grouped according as their thought has been remoulded or not by the influences of Kant. The distinguished writers, whom we have to regard as repeating in essence pre-Kantian theories, generally know Kant, and frequently show traces of him in detail. But it is a plain finding of history that he has brought no "Copernican revolution"4 to their minds. Empiricism is restated by Paley, who is Kant's younger contemporary as a man and also on the whole as a writer. Doubtless the archdeacon knew nothing of the German professor, and would have cared nothing for him however well he had known him. A much more significant figure is that of J. S. Mill in the tentative approach to theism found in his posthumous volume (Three Essays on Religion; 1874).

Mill directs his attention to the Design argument. The inference that organized bodies are due to an intelligent cause is only reached by the "Method of Agreement"—a full inductive proof requiring, according to Mill's Logic, the "Method of Difference." Still, the Design argument is a good sample of a proof by means of the inferior method. Although nothing more than probability is established, it is a high probability.5 Unfortunately, however, the method of agreement is liable to be baffled by plurality of causes. In this instance it may happen that the work of intelligence has only been mimicked in nature by blind forces which have accidentally produced organic life; and Mill is disposed to hold that if the evolution of species should be clearly established as due to natural law—if there has been no creation by special interposition the argument falls to the ground and theism (apparently) is lost.6 A further point is of some interest. If Mill's theism holds, what is it? The belief in a God of limited power. That is what Kant contended that the Design argument pointed to, and Mill, proceeding on the Design argument, claims nothing more for his conclusion. Of course that was not Mill's special or conscious motive for denying divine omnipotence. His extreme sensitiveness and hatred of pain constrained Mill to hold that, if a good God exists, he cannot possess infinite power. Yet the correspondence between Mill's conclusion and what Kant had alleged to be implied in the underlying metaphysical position is very striking indeed.

Intuitionism also has its restatements of theistic reasoning little modified by Kant. R. Flint's theism carefully excludes the early random talk (e.g. Cicero) of an intuitive or innate knowledge of God. What is self-evident, Flint justly remarks, neither needs nor admits of argument.

We have intuitions of cause, of infinity, of good and evil. The Cosmological argument proves, with the help of the first-named intuition, that there is one great First Cause; and the Design argument shows the First Cause to be intelligent or personal. The Ontological argument, though not wholly rejected as a proof, is taken rather as pointing to God's attribute of infinity; thought rather than experience making affirmation that the intuition in question must be attached to God. The moral argument, relying upon the third intuition named, certifies us of a good God. In this way, the attributes are suggestively allotted among the four traditional proofs; but we miss an explicit rebutting of Kant's hostile assumption, that it is incompetent for us to take the thought of God piecemeal. Martineau's Study of Religion is also essentially Intuitionist. It has two parts: "God as cause" and "God as perfection." The Design argument comes in as a special illustration or intensification of the former of these, i.e. of the cosmological proof; but Martineau follows a side modification of intuitionism (Maine de Biran, &c.) in identifying cause with will. This involves a very high doctrine of Libertarianism. The only ultimate cause is God. Nature exists over against Him; but its forces or processes are His own power in immediate exercise, except in so far as God has delegated freedom to human wills; and there follows a theodicy, repeating Leibnitz in more modern form. Martineau's two main proofs yield two sets of attributes; those known as "natural" and "moral," R. Browning's "power" and "love." In "God as perfection" Martineau handles the basis of ethics without reference to his own modification of the intuitionist form of "cosmological Theism," according to which "God" is the better or the best. We may infer that, whatever the merits of that modification, it does not affect the theistic problem. Martineau's Study also includes a section upon Immortality. The Ontological argument is omitted; but we have already observed that there is a discussion of divine

1 The Design argument has mainly to do with living bodies. Might one suggest that organisms seem at least to be a working up of inorganic matter for new ends, viz. those of life?
2 The idealisms of Fichte and Schelling made contributions to Hegel's thought; Krause and the Roman Catholic Baader represent a parallel in French lines of idealism.
3 Equally so the Hegelian attitude towards personal immortality.
4 Such as Kant claimed to effect: Critique of Pure Reason, preface to 2nd ed.

1 Paul Janet's Final Causes seems to follow Mill in this ("the fact of Finality"), but without naming him.
2 Janet naturally is in opposition here. Ultimately, he argues, if man is immediately oriented to his rational cause to account for so rational an effect. But again of course Mill is not named.
3 The three which Kant criticized, with the addition of the moral argument, which he favoured.
infinity in relation to time and space which from one point of view is parallel to the Ontological argument.

Definite theism, bearing the mark of Kant's thought throughout, is found in Hermann Lotze. From the point of view of our grouping, he is an idealist of anomalous type. He begins as an empiricist or realist, with given matter-of-fact; but from time to time (e.g. in his Microcosmus) he makes readjustments without perhaps very clearly realizing that he is being done, and in the end he is unmistakably idealist. While a pronounced theist—though not a church Christian—he is hardly less an asistant of traditional theism than Kant (e.g. his Outline [Lecture headings] on Philosophy of Religion). He dissents as a realist from the Cosmological argument in the form in which it concludes from "contingent" to "necessary" being. We do not wish to find our way to a being who "must be." That is an idle dream. We must keep to real and assured facts, Lotze was a man of considerable attainments in special science; perhaps he reveals here the bias of the scientific mind, possibly even its limitations. He regards the Ontological argument strictly so-called as having been exploded by Kant. Still it has a value for him if taken not as an argument, but rather as the expression of an immediate conviction; viz. the highest must exist. This is an intuitionalist touch, or a parallel to intuitionism, and has called forth a gibe from that very confident ratiocinator, J. E. MacTaggart; Lotze's immediate convictions are matters of interest to a biographer but to no one else. The Design argument elicits from Lotze the criticism that some things look purposeful, but others decidedly purposeless. The only solid nucleus he finds in it is the fact that there is a great deal of beauty in this world. Obviously this writer is harder to focus than Kant or Hegel. He is not all of one piece. He holds—on grounds of fact and science—to the mechanical orderliness of nature, but claims that the Wollen-schauung thus suggested may be reinterpreted in view of those undying human aspirations which MacTaggart dismisses to instant execution (unless they can dress themselves in syllogism). Thus, for Lotze, free will is possible; the consequences of action proceed regularly a parte post, and there is no such chaos as the critics of Libertarianism have pretended it would involve. Similarly, miracles—absolute new beginnings—are possible on God's side, if they are not mere anomalies but acts promotive of the general meaning or tendency of things, and of the divine plan of the universe. But this appeal to "values" is only half of Lotze's constructive work. For the other half he falls back on ratiocination. All existences must be individuals, with an inner life (cf. Leibnitz). Since they interact, they must be elements in the life of one supreme being (cf. Spinoza: the Spinozistic affinities of Leibnitz are not so marked as Lotze's). God can be personal and doubtless is (though he has no Non-eGo to define himself against) through contrast of passing conscious states with the abiding Ego. It is reasonable to hold that the supreme personality is the only fully personal being, while ours is a broken and imperfect personality, hindered by the Non-eGo which in other ways helps it. Lotze resolves space into "ideal space"; and finally, in the philosophy of religion, or in view of the thought of God (in his Metaphysics), he denies the objective existence of time. God sees all history neither as future nor as present but as actual.

Besides the stream of tendency which flowed from Kant in the direction of idealism, two other streams emerged from him, often but not always blending. There was a new scepticism—at the very least a doctrine of limitation in human knowledge; but in its extremity forms an absolute agnosticism. And there was the positive ethical element in Kant's theism.

Ancient scepticism was frankly opposed to religious belief. Later, the emergence of a great body of doctrine attributed to divine revelation and of a great institution like the Christian church suggested the possibility of enlisting scepticism in the service of dogmatic faith. In a sense (see Apologetics) this was done in the middle ages, and possibly repeated by Pascal after the Reformation. We now find Kant's intellectual scepticism borrowed by W. Hamilton and H. L. Mansel, both of them, as J. S. Mill complained, "bringing back under the name of "themselves" the devil whom they repudiated as knowledge." The therapist found a melodious echo in Tennyson's InMemoria, a great hymn of God, Freedom and Immortality on a basis of speculative agnosticism. "We have but faith we cannot know, For knowledge is of things we see;" but the moral element which Mansel despised is dominant in Tennyson. "The heart Stood up and answered, I have felt." If there is a reading of the new theories of evolution in nature which revives rather than darkens hope in immortality and faith in God, Tennyson gave an early sketch of that tentative modern theism.

R. Browning has been charged by H. Jones with partial agnosticism. But at least we may say that agnosticism is much less clear in Browning than in Tennyson. Browning reasons as far as he can; if reasoning fails him, he gives a leap of faith. Jones, almost as merciless as MacTaggart, calls this procedure by the hard names of agnosticism and dualism. Another who "got the seed" and "grew the flower" was Herbert Spencer. He quotes pages from Mansel's Bampton Lectures in favour of his own type of agnosticism, which is to make peace between religion and science by permanently silencing the former. Religion may "feel," like Tennyson's "man in wrath," and may expatiate in an undefined awe; science alone is to possess the "knowledge." This yields a characteristic type of pantheism, in the theory of the Unknowable which—rather paradoxically—is offered us. Alongside of this there are other elements in Spencer's composite system of "Naturalism and Agnosticism" (J. Ward's expression, see his Gifford Lecture). The element of naturalism stands for science with a leaning towards materialism ("explanation in terms of matter and motion"). The element of agnosticism tends rather towards pantheism, just as Indian pantheism long ago tended towards agnosticism. John Fiske, however, an able interpreter of Spencer, reached what he called "Cosmic Theism." He rejected all that is anthropomorphic in Theism, but gave a positive note and negative interpretation to Spencer's scientific generalizations, and broke away from pantheism—perhaps also from naturalism—when, like Tennyson, he pleaded for human immortality as the climax of evolutionary progress.

[The name agnosticism (q.v.) is T. H. Huxley's. Modern doubt does not say there is no God; it says, We don't know. Popular scepticism—perhaps even Charles Darwin's; Huxley himself was a student of Hume—understands by agnosticism that science is certain while philosophy and theology are baseless. Leslie Stephen gave this popular agnosticism its finest literary expression. Spencer goes much further in rejection of human knowledge: "The man of science more than any other truly knows that in its ultimate essence nothing can be known."]

An interesting manifesto of agnosticism, with a religious conclusion, is A. J. Balfour's Foundations of Belief, welcomed in Germany by Julius Kaftan (see below). In "Some Consequences of (naturalistic) Belief," Balfour argues that the results of "naturalism" are unbearable. In "Some Reasons for Belief," the author institutes a rapid destructive criticism of all possible philosophies. In "Some Causes of Belief," he tries, standing outside the psychological process, to show how beliefs grow up under every kind of influence except that of genuine evidence. His constructive theory comes at the end, and seems to argue thus: Since (r) there is no discoverable reason why we

\(^{1}\) Stated and criticized by Kant.

\(^{2}\) Lotze is not to be understood as guaranteeing the actuality of Bible miracles. Such things are philosophically possible—that is all.

\(^{3}\) Mansel's theism (or natural theology), and the revelation he believes in, seem both of them pure matters of assertion on his part, without evidence, or even in the teeth of the evidence as he conceives it.

\(^{4}\) Examination of Sir Wm. Hamilton's Philosophy, chap. v.

\(^{5}\) First Principles, p. 67.
If we try to bring the contents of theism under Kant's three traditional arguments, then moral and aesthetic considerations—the "values"—fall under the Design argument or the study of teleology; albeit there is a great gap between Paley's supernatural watchmaker and any moral argument or appeal to the beautiful. It might be argued that beauty bears witness against materialism, and moral values against pantheism; although such an anomalous type as ethical pantheism has its representatives—J. G. Fichte, Matthew Arnold, perhaps H. Höfding. Kant's reliance on the moral argument alone goes with his scepticism. Giving that argument the highest place seems to solve, (Mill) said, a dash of theother scepticism.

The arguments, as already noted, may be differentiated combined. (1) Usually they are alternatives or else cumulative. (2) Flint places out the proof (and the attributes) among them. (3) Hegel regards them as phases.

V. What are the alternative conclusions to theism? The extremest form of antagonism is pure scepticism or pure agnosticism, the assertion that nothing can be known. Empiricism may lead to this conclusion; or it may lead to materialism. True materialism includes both anticlerical atheism, and is probably the only coherent type of atheism. Pantheism further brings with it an extreme or "hard" determinism; and, denying the soul's separate existence in any sense, it naturally denies immortalitry. Once again, empiricism may lead to any qualified and restricted form of agnosticism, religious or anti-religious. If pantheism is to be seriously defended at all, the basis must be empiricism. Intuitionism in its turn may harden out of "natural" dualism into moral dualism; either a literally Manichaean scheme—a god good impelled by an evil personality or principle (Bayle)—or belief in a good god and a supreme evil (Spinoza). And idealism in some cases may interpret itself in favour of pantheism rather than of theism. Pantheism does not favour free will or immortalitry, and may move indefinitely near to materialism. Out of pantheism again pessimism develops. If the principle of the universe is impersonal or unconscious, personal consciousness in finite spirits comes to wear the appearance of a blunder. Conversely, if God cares for men, despair is impossible. For another systematic grouping, see A. C. Fraser's Gifford Lectures. Wolf's list is of some historical importance—atheism, deism (a God with limited powers (Mill)); pure empiricism (Locke); empiricism and deism (Mill); empirical (Popper, Hume); and, lastly, against materialism, idealism (non-existence of matter); paganism (polytheism); Manichaicism, Spinozism, Epicureanism. R. Flint has dealt with the following antitheistic theories: atheism, materialism, positivism, secularism, pessimism, pantheism (and in a separate volume) agnosticism. It is hard to be certain that any systematic grouping will anticipate all the suggestions that may occur to a restlessly and recklessly inquiring age.

LITERATURE.—Two sets of writers have been considered: first, the greater philosophers, who have incidentally furthered theism (Socrates, Plato, Aristotle, the Stoics, Descartes, Locke, Kant, etc.); and, secondly, the critics (Mill, Hegel, Mill, Spencer); and, secondly, the deliberate champions of theism—Cicero (especially in the De Natura Deorum), Philo, Raymond of Fossem (in a sense), Wolff, Butler (in a sense), Paley, and a host of English and German 18th-century authors, who chiefly handle the Design argument; then recent writers like R. Flint, Theism, Antitheistic Theories, Agnosticism—all with valuable notes and references, and J. Martineau—especially in A Study of Religion. The theistic writers are usually intuitionists; but it has been urged above that a fruitful study of theism must in each case inquire what is the writer's philosophical basis. The Bridgewater treatises have little more than historical interest to-day. A certain historical interest also attaches to the Burnett prize essays on theism: 1815, 1st prize, W. L. Bruce, 2nd J. B. Sumner, afterwards archbishop; 1855, 1st R. A. Thompson, 2nd J. Talloch. All of the Gifford Lectures are supposed to be strictly appropriated to Natural Theology; yet subjects and

1 Son of A. Ritschl. The younger theologian has accepted determinism. 2 Dr MacTaggart's beliefs once more present themselves as an unexpected modern type (Studies in Hegelian Cosmology, chap. iii.). 3 Yet cf. once more MacTaggart's society of eternal spirits with no divine head.

THEISS (Hungarian, Tissa; Lat., Tisia or Tissius), a large affluent of the Danube, next to which it is the greatest river of Hungary. It rises in the north-eastern part of the Carpathian mountains, in the county of Máramaros, at a height of above 630 ft., and is formed by the confluence of two branches, the Black Theiss (Fekete Tisa), and the White Theiss (Fehér Tisa), which unite at about 20 m. E. of Máramaros-Szat-he. The Theiss then follows a north-westerly direction until it leaves its mountainous valley, then runs west, and after a great curve to the north, takes a south-westerly direction and enters the great plain of Hungary (Alföld). From Szolnok the river runs in an almost parallel course with that of the Danube, from which it is separated by a distance of about 60 m., and flows into the Danube near the village of Titel, 20 m. E. of Ujvidék. Its length from source to mouth is, as the crow flies, only about 340 m., but its windings make its course about 870 m. long. The Theiss is clear and swift in its course through the mountains, but in the plain it becomes slow, somewhat muddy and very tortuous. Its basin covers an area of 56,600 sq. m., and comprises the whole eastern part of Hungary, and the greater part of Lower Austria, and collects all the rivers descending from the Carpathian westward.

The Theiss is navigable for rafts almost everywhere, but for steamers only from Szolnok downwards, a distance of about 200 m., where the breadth of the river is 450 to 750 ft. The depth of the river is generally 7 to 20 ft., but at certain points it is 33 ft., and at Titel, near its mouth, it is 11 ft. At Titel, the river is 500, and at Marosu, 20 m. E. of Titel, 31 ft. at Titel, near its mouth, while the difference between the low-water mark and the high-water mark is as high as 25 to 35 ft. During its course through the great Hungarian plain the Theiss flows between flat, low-lying banks, which are the cause of the periods of drought and sometimes disastrous inundations and of extensive marshes. Therefore extensive works have been undertaken for the regulation and canalization of the river, which is now strongly dammed in many parts. At these works large tracts of marsh have been transformed into productive ground. Its chief tributaries are the Szamos, Körös, Maros, Latorcza, and the Sajó. In its lower course it is joined by the Sajó, the upper Danube, and by the Bega canal, while it is also united with Temesvár by the Bega canal.

THEMIS, in Greek mythology, the personification of justice. In Homer them is used both as a common and as a proper noun. As a common noun (plural òmówn, òmówn, òmówn, òmówn), it is the body of rules and precedents established at the beginning of the world, as a guarantee of its order and harmony (see GREEK LAW); personified, Themis is the servant or companion of Zeus, her chief function being to summon the assemblies of both gods and men (Odyssey, i. 68). In the Hesiodic theogony, she is the daughter of Uranus and Gaea, and according to Pindar the wife of Zeus, by whose side she sits, assisting him with her advice, and being better than the Muses, Justitia is the mother of the Horae and of the Moirae (Fates), an indication of her influence in the physical and moral world. She is the representative of divine justice in all its relations to men, and takes special cognizance of the rights of hospitality. Her opposite is Hybris (Hubris), insolent encroachment upon the rights of others, on whose track she follows to punish, like Nemesis. In this aspect both Themis and Nemesis are called Hesperia (Hesperos, track). In the lexicon of Festus, Themis is described as the goddess who prescribes that which is right in moral law (cf. Eclogues 6). Daedalus is her son, and is identical with this divine law. She is also a prophetic divinity, as on one occasion there was a tradition that the oracle at Delphi had first been in the hands of Gaia, who transferred it to Themis (sometimes identified with her) by whom it was handed over to Apollo (Aeschylus, Eumenides, 2; Euripides, Iphig. in T. 1). Orphic poetry makes her a daughter of Helios, whose eye is all-seeing (Panóskos) and penetrates all mysteries. She was especially honoured at Athens, Delphi, Thebes, Aegina, and Troezen, where there was an altar dedicated to a triad of Themises (on the analogy of the triads of Hera, Charles, Moirae). In art she was represented in the form of a dignified and comely figure, with cornucopia (symbolizing the blessings resulting from order) and a pair of scales.

See article "Justice" by J. A. Hild in Darmberg and Saglio's Dict. des Antiquités; H. Ahrens, Die Göttin Themis (1862); R. Hirzel, Themis, Diis, and Verwandten (1907).

THEMISTIUS (317-737), named ἐφραῖος ("eloquent"), statesman, rhetorician, and philosopher, was born in Paphlagonia and taught at Constantinople, where, after a short sojourn in Rome, he resided during the rest of his life. Though we have been able to know little of his life, he was as noted for his learning as for his oratory. It was prefixed to Constantine in 384 on the nomination of Theodosius. His paraphrases of Aristotle's Posterior Analytics, Physics and De Anima are valuable; but the orations in which he panegyrizes successive emperors, comparing them to Plato's "true philosopher," and even to the "idea" itself, are servile and unworthy. Against this, however, should be set the description given by Boetius, "disertissimus scriptor ac lucidus, et omnia ad facilitatem intellectualem resecans," and that of Gregory Nazianzen—"with whom Themistius corresponded—"hanc liceat nequum." Themistius's paraphrases of the De Coelo and of book A of the metaphysics have been preserved only through Hebrew versions. In philosophy Themistius was an eclectic. He held that Plato and Aristotle were in substantial agreement, that God has made men free to adopt the mode of worship they prefer, and that Christianity and Hellenism were merely two forms of the one universal religion.

The first edition of Themistius's works (Venice, 1534) included the paraphrases and eight of the orations. Nineteen orations were known to Petavius, whose editions appeared in 1519 and 1618; Hardouin (Paris, 1684) gives thirty-three. Another oration was discovered by Angelo Mai, and published at Milan in 1816. The most recent editions are W. Dindorf's of the orations (Leipzig, 1832), and L. Spengel's of the paraphrases (Leipzig, 1866). The Latin translations of the Hebrew versions of the paraphrases of the De Coelo and book A of the Metaphysics have been published at Paris, 1874 and 1858 respectively. A new edition of the latter by S. Landauer appeared in 1903. See Fabricius, Bibliotheca Graeca, vi. 790 seq.; E. Zeller, History of Greek Phil.; E. Baret, De Themisti, sophista (Paris, 1853); Jourdan's Recherches critiques sur le "travers" d' Origène (1854); see NEOPLATONISM. For Themistius's Commentaries on Aristotle, see Commentaria in Aristotelis Graeca (Berlin), and also Themisti paraphrases Aristotelis libros quae supersunt, ed. L. Spengel (1866), Teubner series.

THEMISTOCLES (c. 514-449 B.C.), Athenian soldier and statesman in some respects probably the ablest and most far-sighted whom Greece produced in the first half of the 5th century. He was the son of Neocles, an Athenian of no distinction and moderate means, his mother being a Carian or a Thracian. Hence according to the Periclean law Ἰ σὰμβων ἄρταν he would not have been a free Athenian at all (see PERICLES). Thucydides properly brings out the fact that, though he lacked that education which was the peculiar glory of the Periclean age, he displayed the intellectual power of an able and a complex intellect, together with a genius for rapid action. Plutarch similarly enlarges on his consuming ambition for power both
personal and national, and the unscrupulous ability with which he pursued his ends. In all these points he is the antithesis of his great rival Aristides (q.v.). Of his early years little is known. He may have been strategus of his tribe at Marathon (Plut. Arist. 5) and we are told that he deeply envied the glory which Miltiades earned. At all events the death of Miltiades left the stage to Aristides and Themistocles. It is sufficiently clear that their rivalry, terminated in 483-82 by the ostracism of Aristides, turned largely on the fact that Themistocles was the advocate of a policy of naval expansion, while Aristides was under the influence of Athens and indeed to Greece. Athens was faced by the equal if not superior power of Aegina, while the danger of a renewed Persian invasion loomed large on the horizon. Themistocles therefore persuaded his countrymen to put in hand the building of 200 triremes, and—what was of even greater importance—to fortify the three natural harbours of Peiraeus (see E. Gardner, Ancient Athens, 562 f.) in place of the open roadstead of Phalerum. For the building of the ships Themistocles persuaded the Athenians to allocate 100 talents obtained from the new silver mines at Laurium (Arist. Pol. xi. 22) which were not bequeathed to the citizens (10 drachmae each). One hundred of the proposed 200 were built.

According to the Ath. Pol, it would seem that Themistocles was archon in 493-82 at the time when this naval programme began. Dionysius of Halicarnassus places his archonship in 493-92, in favour of which are several considerations. In 487 the office lost much of its importance owing to the substitution of the lot for election: the chance that the lot would at the particular crisis of 493 fall on Themistocles was obviously remote; and the Ath. Pol. is generally wrong about Themistocles. In any case the year prior to the invasion of Xerxes found Themistocles the chief man in Athens if not in Greece. Though the Greek fleet was nominally under the control of the Spartan Eurybiades, it was Themistocles who caused the Greeks to fight the indecisive battle of Artemisium, and still more it was he who, by his threat that he would lead the Athenian army to found a new home in the West, and by his treacherous message to Xerxes, precipitated the engagement at Salamis (q.v.). The retirement of the Persians left the Athenians free to restore their ruined city (see Athens). Sparta, nominally at war with Athens, did not enter the lists; and that it was dangerous to Greece that there should be any citadel north of the Isthmus which an invader might hold, urged that this should not be done, but Themistocles by means of diplomatic delays and subterfuges enabled the work to be carried sufficiently near to completion to make the walls defensible. He also carried out his original plan of making Peiraeus a real harbour and fortress for Athens. Athens thus became the finest trade centre in Greece, and this fact, coupled with Themistocles' remission of the alien's tax (µετοχαπ), induced many foreign business men to settle in Athens.

After the crisis of the Persian invasion Themistocles and Aristides appear to have composed their differences. But Themistocles soon began to lose the confidence of the people, partly owing to his boastfulness (it is said that he built near his own house a sanctuary to Artemis Aristoboule "of good counsel") and partly to his alleged readiness to take bribes. Diodorus (xi. 54) and Plutarch (Themist. 23) both refer to some accusation levelled against him, and some time between 476 and 471 he was ostracized. He retired to Argos, but the Spartans further accused him of treasonable intrigues with Persia, and he fled to Corcyra, thence to Admetus, king of the Molossians, and finally to Asia Minor. He was proclaimed a traitor at Athens and his property was confiscated, though his friends saved him some portion of it. He was well received by the Persians and was allowed to settle in Magnesia on the Maeander. The revenues (50 talents) of this town were assigned to him for bread, those of Myus for condiments, those of Lampascus for wine. He died at Magnesia at the age of sixty-five, and a splendid memorial was raised by the people of the town, though it is said that his bones were secretly transferred to Attica. He was worshipped by the Magnesians as a god, as we find from a coin on which he is shown with a patera in his hand and a slain bull at his feet (hence perhaps the legend that he died from drinking bull's blood: cf. Aristoph. Eq. 83; Dio. xi. 58; Plut. Them. 31).

Though his end was discreditable, though his great wealth can hardly have been obtained by loyal public service, there is no doubt that his services to Athens and to Greece were great. He led the Athenian fleet and with it the possibility of the Delian League (q.v.), previously a mere formality in Ionia, and there are many indications (e.g. his well-attested plan of expansion in the west) that the later imperialist ideal originated in his fertile brain.

There are monographs by Bauer (Mersburg, 1881) and Wecklein (Munich, 1882); but the best discussions of his career will be found in the chief Greek histories e.g. Busolt; on the difficult chronology of his later years see Grote, History of Greece (and the one-vol. ed. by Mitchell and Caspari, 1907, p. 283, note 1, with the authorities there quoted); on the Magnesian coin, Rhousopoulos, in Athen. Mitt. (1896), p. 22. On the walls, see Ed. Meyer in Hermes, xl. (1905), pp. 561-569.

THÉNARD, LOUIS JACQUES (1777—1857), French chemist, was born on the 4th of May 1777 at Loupiâtre, near Nogent-sur-Seine, Aube. His father, a poor peasant, managed to have him educated at the academy of Sens, and sent him at the age of sixteen to study pharmacy in Paris. There he attended the lectures of A. F. Fourcroy and L. N. Vauquelin, and succeeded in gaining admission, in a humble capacity, to the latter's laboratory. But his progress was so rapid that in two or three years he was able to take his master's place at the lecture-table, and Fourcroy and Vauquelin were so satisfied with his performance that they procured for him a school appointment in 1799 as teacher of chemistry, and in 1798 one as répétiteur at the École Polytechnique. In 1804 Vauquelin resigned his professorship at the Collège de France and successfully used his influence to obtain the appointment for Thénard, who six years later, after Fourcroy's death, was further elected to the chairs of chemistry at the École Polytechnique and the Faculté des Sciences. He also succeeded Fourcroy as member of the Academy. In 1812 he received the title of laron from Charles X., and in 1832 Louis Philippe made him a peer of France. From 1831 to 1857 he represented the chamber of deputies, and as vice-president of the conseil supérieur de l'instruction publique, he exercised a great influence on scientific education in France. He died in Paris on the 21st of June 1857. A statue was erected to his memory at Sens in 1861, and in 1865 the name of his native village was changed to Loupiâtre-Thénard.

Above all things Thénard was a teacher; as he himself said, the professor, the assistants, the laboratory—everything must be sacrificed to the students. Like most great teachers he published text-book, and his Traité de Chimie élémentaire, théorique et pratique (4 vols., Paris, 1813-16), which served as a standard for a quarter of a century, perhaps did even more for the advance of chemistry than his numerous original discoveries. Soon after his appointment as répétiteur at the École Polytechnique he began a lifelong friendship with J. L. Gay-Lussac, and the two carried out many researches together. Careful analysis led him to dispute some of C. L. Berthollet's theoretical views regarding the composition of the metallic oxides, and he also showed Berthollet's "zoonic acid" to be impure acetic acid (1802); but Berthollet (q.v.), so far from resenting these corrections, made him a member of the Société d'Arcueil. Thénard's first original paper (1799) was on the compound of arsenic and antimony with oxygen and sulphur, and of his other separate investigations one of the most important was that on the compound ethers, begun in 1807. His researches on sebacic acid (1802) and on bile (1807), and his discovery of peroxide of hydrogen (1818) also deserve mention. The substance known as Thénard's blue, he prepared in 1799 in response to a peremptory demand by J. A. Chaptal for a cheap colouring matter, as
THEOBALD—THEOCRITUS

760

bright as ultra-marine and capable of standing the heat of the porcelain furnace.

Most of Thénard's memoirs, a list of which may be found in the Royal Society's Catalogue of Scientific Papers, were published in the Annales de Chimie et de Physique, the Mémóires d'Arcueil, the Comptes Rendus and the Mémoires of the Academy of Sciences.

THEOBALD (d. 1161), archbishop of Canterbury, was of Norman parentage, but the date of his birth is unknown. Early in life he entered the great abbey of Bec, of which he became prior in 1127 and abbot ten years later. In 1138 he was selected by Stephen, king of England, to fill the vacant see of Canterbury. Apparently he owed this advancement to his character for meekness, and as archbishop he behaved with a moderation which is in striking contrast to the conduct of his rival, Henry of Blois, bishop of Winchester. During the struggle between Stephen and Matilda it was Bishop Henry who fought for the privileges of the Church; Theobald, while showing a preference for Stephen's title, made it his rule to support the de facto sovereign. But as Stephen's case gained ground the archbishop showed greater independence. He refused to consecrate the king's nephew to the see of York, and in 1148 attended the papal council of Reims in defiance of a royal prohibition. This quarrel was ended by the intercession of the queen, Matilda of Boulogne, but another, of a more serious character, was provoked by Theobald's refusal to crown Count Eustace, the eldest son of Louis VII, king of France, to be pope. Physically the pope plighted the pope's word as the excuse for this contumacy. He was banished from the kingdom, but Pope Eugenius tried Stephen into a reversal of the sentence. In 1153 Theobald succeeded in reconciling Stephen with Henry of Anjou, and in securing for the latter the succession to the throne. On the accession of Henry in 1154, Theobald naturally became his trusted counsellor; but ill-health prevented the archbishop from using his influence to its full extent. He placed the interests of the Church in the hands of Thomas Becket, his archdeacon, whom he induced Henry to elevate to the see of Canterbury. Theobald died on the 18th of April 1161. He is said to have recommended Becket as his successor.

In history Theobald lives chiefly as the patron of three eminent men: Becket, who began life as a clerk in his household; Master Vacarius, the Italian jurist, who was the first to teach Roman law in England; and John of Salisbury, the most learned scholar of the age. Theobald's household was a university in little; and in it were trained not a few of the leading prelates of the next generation.

THEOBALD, LEWIS (1688-1744), English man of letters, playwright and Shakespearian commentator, the son of an attorney, was born at Sissinghurst, Kent, and was baptized on the 2nd of April 1688. He was educated under a clergyman named Ellis at Iselworth, and became a good classical scholar. He followed his father's profession, but soon abandoned it for literature. In 1713 he translated the Phaedo of Plato, and entered into a contract with Bernard Lintot the publisher to translate a number of the comedies of Aeschylus. He seems to have made other promises not carried out, but in 1714 and 1715 appeared versions of the Electra, the Ajax, and the Oedipus Rex of Sophocles, and the Plutus and the Clouds of Aristophanes. He became a regular hack-writer, contributing to Mist's Journal, and producing plays and poems of very small merit. The publication of his play The Perfidious Brother (acted 1715; printed 1710) involved Theobald in considerable difficulty. He apparently received a rough draft of the play from Henry Meystayer, a London watchmaker, with a commission to arrange it for the stage. Theobald brought it out as his own work. In the next year Meystayer produced a version, and charged Theobald with plagiarism, but there is no means of ascertaining the exact rights of the case. His poverty compelled him to produce rapidly. He translated the first book of the Odyssey (1716), wrote tragi-comedies, operas and masques, and helped John Rich in the production of pantomimes, then an innovation at Drury Lane. But in 1726 he produced Shakespeare Restored, or a Specimen of the many Errors as well Committed as Unnamed by Mr Pope in his late edition of this Poet; designed not only to correct the said Edition, but to restore the true Reading of Shakespeare in all the Editions ever published (1726). However ill Theobald may have succeeded as a poet and dramatist, he showed great discrimination as a textual editor. Some of his happiest emendations are to be found in this work, which conclusively proved Pope's incompetence as a Shakespearian editor. Two years later a second edition of Pope's work appeared. In it he stated that he had incorporated some of Theobald's readings, in all amounting to about twenty-five words, and that he added the rest which could "at worst but spoil half a sheet of paper that chances to be left vacant here." He also insinuated that Theobald had maliciously kept back his emendations during the progress of the edition. All this was a gross misstatement of fact. He had in reality incorporated the majority of Theobald's best emendations. In the first edition of the Dunciad (1728) Theobald figured as the hero, and he occupied the place of chief victim until replaced by Colley Cibber in 1741. In spite of the critics, Theobald's work was appreciated by the public. In 1731 he undertook to edit Shakespeare for Tonson the publisher. The work appeared in seven volumes in 1734, and completely superseded Pope's edition. From 1729 to the date of its publication Theobald had been engaged in correspondence on the subject with Warburton, who after his friend's death published an estimate of Shakespeare's work, in the preface of which he asserted that Theobald owed his best corrections to him. Study of the correspondence proves, however, that the indebtedness was on Warburton's side. Subsequent editors reaped, in most cases without acknowledgment or with actual scorn, the fruit of Theobald's pains-taking labour, his wide learning and his critical genius. But Pope's satire, as Johnson justly remarked, blasted the characters that it touched. Theobald remained the type of the dry-as-dust commentator. His merits obtained a tardy recognition on the publication of a detailed study of his critical work by Mr. Churton Collins in an essay entitled "The Person of Shakespearian Criticism" (Essays and Studies, 1895). Theobald gave proof of the same happy gift in classical scholarship in some emendations of Aeschylus, Euripides, Atheneaus and others, contributed to a learned journal started by John Jortin in 1731. He was a candidate for the laureateship in 1730, but Cibber gained the coveted post. His last years were harassed by poverty and disease. He began a critical edition of the plays of Beaumont and Fletcher, completed by Seward and Parnell after his death, which took place on the 18th of September 1744.

His correspondence with Matthew Concanen, Styan Thirlby and William Warburton is to be found in Nichols's Illustrations of Literature (ii. 204-654), which also gives the fullest account of his life.

THEOCRACY (Gr. θεοκρατία, the rule of God, from θεός, god, and -κρατία, κράτος, to rule), a term applied to a form of government or to a state ruled by such a form of government, (a dopoligarchy of the gods). There were several definitions of this term. The one most generally adopted is that of civil power, and the divine commandments regarded as the laws of the community. The typical example of such a state is that of the Jews till the establishment of the kingship under Saul (see JEWS).

THEOCRITUS, the creator of pastoral poetry, flourished in the 3rd century b.c. Little is known of him beyond what can be inferred from his writings. We must, however, handle these with some caution, since some of the poems ("Idyls") commonly attributed to him have little claim to authenticity. It is clear that at a very early date two collections were made, one of which included a number of doubtful poems and formed a corpus of bucolic poetry, while the other was confined to those works which were considered to be by Theocritus himself. The record of these recensions is preserved by two epigrams, one of which proceeds from Artemidorus, a grammarian, who

"
the fledgelings of the Muse,
veteran poet of Cos, and criticizes
who cackle against the Chian bard and find their labour lost." 4
Other persons mentioned are Nicias, a physician of Miletus, whose
name occurs in other poems, and Aratus, whom the Scholiast
identifies with the author of the Phenomena.
The other bucolic poems need not be further discussed. Several
of them consist of a singing-match, conducted according to the
rules of amoebean poetry, in which the second singer takes the
subject chosen by the first and contributes a variation in the same
air.
It may be noted that the peasants of Theocritus differ greatly
in refinement.
Those in v. are low fellows who indulge in coarse
abuse. This Idyll and iv. are laid in the neighbourhood of Croton,
and we may infer that Theocritus was personally acquainted with
Magna Graecia. Suspicion has been cast upon poems yiii. and ix.
on various grounds. An extreme view holds that in ix. we have
two genuine Theocritean fragments, 11. 7-13 and 15-20, describing
the joys of summer and winter respectively, which have been
provided with a clumsy preface, 11. 1-6, while an early editor of a
bucolic collection has appended an epilogue in which he takes
leave of the Bucolic Muses. 6 On the other hand, it is clear that
both poems were in Virgil's Theocritus, and that they passed the
scrutiny of the editor who formed the short collection of Theocritean Bucolics.

are three in number, viz., ii., xiv., xv. In ii. Simaetha,
deserted by Delphis, tells the story of her love to the moon; in
xiv. Aeschines narrates his quarrel with his sweetheart, and is
advised to go to Egypt and enlist in the army of Ptolemy Philadelphus; in xv. Gorgo and Praxinoe go to the festivaj of Adonis.
It may be noticed that in the best MSS. ii. comes immediately
before xiv., an arrangement which is obviously right, since it places
the three mimes together. The second
in the MSS. is occupied
place
"

These three mimes are wonderby Idyll vii., the Harvest Feast.
fully natural and lifelike. There is nothing in ancient literature so
vivid and real as the chatter of Gorgo and Praxinofi, and the voces
populi in xv.
It will be convenient to add to the Bucolics and Mimes three
poems which cannot be brought into any other class, viz. xii. (Aln^),
a poem to a beautiful youth; xviii., the marriage-song of Helen
The
('EjTiflaXd/uos) ; and xxvi., the murder of Pentheus (Aijvat).
genuineness of the last has been attacked by U. von WilamowitzMollendorff on account of the crudity of the language, which
sometimes degenerates into doggerel. It is, however, likely that
Theocritus intentionally used realistic language for the sake of
dramatic effect, and the MSS. evidence is in favour of the poem.
Eustathius quotes from it as the work of Theocritus.
II. Epics.
Three of these are Hymns, viz., xvi., xvii. and xxii.
In xvi. the poet praises Hiero II. of
Syracuse, in xvii. Ptolemy
The other poems are
Philadelphus, and in xxii. the Dioscuri.
xiii., the story of Hylas and the Nymphs, and
xxiy. the youthful
Heracles.
It cannot be said that Theocritus exhibits signal merit
in his Epics.
xiii.
In
he shows some skill in word-painting, in xvi.
there is some delicate" fancy in the description of his poems as
"
"
Graces
(XAputs), and a passage at the end, where he foretells
the joys of peace after the enemy have been driven out of Sicily,
has the true bucolic ring. The most that can be said of xxii. and
xxiv. is that they are very dramatic.
Otherwise they differ little
from work done by other poets, such as Callimachus and Apollonius
Rhodius. The flattery heaped upon Ptolemy is somewhat nauseous.
From another point of view, however, these two poems xvi. and
xvii. are supremely interesting, since they are the only ones which
can be dated. In xvii. Theocritus celebrates the incestuous marriage
of Ptolemy Philadelphus with his sister Arsinoe. This marriage
is
hejd to have taken place in 277 B.C., and a recently discovered
inscription shows that Arsinoe died in 270, in the fifteenth year
of her brother's reign. * This poem, therefore, together with xv.,
which Theocritus wrote to please Arsinoe (Schol. xapifo/w'w TJ}
must fall within this period. The encomium upon
f3atri\U>i)
Hiero II. would from internal reasons seem prior to that upon
since
in it Theocritus is a hungry poet seeking for a

Longanus and his election as King
(/SoaiXeCu),
ascribed to 270 B.C., had not yet taken place. If so, xvii. and xv.
can only have been written within 275 and 270.
III. Lyrics.
Two of these are certainly by Theocritus, viz.,
xxviii. and xxix.
The first is a very graceful poem presented
together with a distaff to Theugenis, wife of Nicias, a doctor of
Miletus, on the occasion of a voyage thither undertaken by the
poet. The theme of xxix. is similar to that of xii.
very corrupt
poem, only found in one very late MS., was discovered by Ziegler
in 1864.
As the subject and style very closely resemble that of
xxix., it is assigned to Theocritus by recent editors.
IV. The Epigrams do not call for detailed notice.
They do not
possess any special merit, and their authenticity is often doubtful.
It remains to notice the poems which are now generally considered
to be spurious. They are as follows
"

poem consisting of two episodes, viz. the interview of Heracles with the balsam of Auges and his recital to Phyleus, son of Auges, of the story of the Nemean lion. The composition is not unworthy of Theocritus. It is, however, anonymous in the MSS. and comes next to 

in Megara in the works of the pupil of Theocritus. It is probable from some metrical and linguistic peculiarities that xxv. and the "Megara" are both by the same author.

Daphnis and Chloé ( Libyan) is also anonymous. It contains imitations of Theocritus, but the tone and the language betray a later writer.

We have no sure facts as to the life of Theocritus beyond those supplied by Idylls xvi. and xvii. It is quite uncertain whether the bucolic poems were written in the pleasant isle of Cos among a circle of poets and students, or in Alexandria and meant for dwellers in streets. The usual view is that Theocritus went first from Syracuse to Cos, and then, after suing in vain for the favour of Hiero, took up his residence permanently in Egypt. Some have supposed on very flimsy evidence that he quarrelled with the Egyptian court and retired to Cos, and would assign various poems to the "later-Coan period." Wilmovitz-Möllendorff, laying stress on the fact that in the best MS. the poem to Ptolemy (xvii.) comes before that to Hiero (xvi.), very ingeniously puts the Egyptian period first and supposes it to have been of very short duration (i.e. 277 to 275), and then makes the poet, after his unsuccessful appeal to Hiero, retire to Cos for the rest of his life. This view would enable us to see a reference to Ptolemy in vii. 93, and even to the young Apollonios Rhodius in 47-48 of the same poem.

The stylis of Theocritus (Idylle vii. 1 alludet) by the grammarians. The word is a diminutive from idos, and is supposed to mean "little poems." The use of idos in the sense of "poem" is somewhat doubtful, and so some have referred idella to idos in its usual sense of "form" or "type." Thus idos bukolikos, etikoi, lirikoi might be used to classify various kinds of poetry, and these poems might be called idella, since they include so many types.

Language and Metre.—Theocritus wrote in various dialects according to the subject. The Lyrics xxviii., xlix. (and xxx.) are in Aeolic, and being the traditional dialect for the poems of Theocritus. Two Idylls, xii. (Aetrus) and xxii. (to Castor and Pollux), were written in Ionic, as is stated in titles prefixed to them, though a number of Doric forms have been inserted by the scribes. The epics in general show a mixture of Homeric, Ionic and Doric forms. The Bucolics, Mimes, and the "Marriage-song of Helen" (xviii.) are in Doric, with occasional forms from other dialects.

Theocritus in the Bucolics and Mimes, as well as in the Epics, is the dactylic hexameter. His treatment of this may be compared both with Homeric usage and that of other Alexandrian poets, e.g. Callimachus. It was the tendency of these writers to prefer to a series of end rhymes with a view to lightness and rapidity. This tendency shows itself most in the third foot, the favourite caesura being the trochaic, i.e. after the second syllable. In the Bucolics, however, the Alexandrines have admitted a spondee in the fifth foot, especially when the verse ends with a quadrisyllable. Theocritus in the Epics conforms to the new technique in both these respects: in the Bucolics his practice agrees with that of Homer. The feature in his versification which has attracted most attention is the so-called bucolic caesura. The rule is that, if there is a pause at the end of the fourth foot, this foot must be a dactyl. This pause is no new invention, being exceedingly common in Homer. Theocritus uses it so frequently in the Bucolics that it has become a mannerism. In the Epics his practice agrees with that of Homer.

Theocritus, the first original poet, and as the "inventor of bucolic poetry" he deserves this reputation. At the same time he had no scruple about borrowing from predecessors or contemporaries; in fact he did so in the most open manner. Traditions, of course, were the storehouse of the Alexandrines of the fourth century B.C., and of points out, with words used by Aratus at the beginning of the Phenomena. The love of the Cyclops for Galatea had been treated by Philocleon, and from his poems fragments quoted from this show that Theocritus copied some of his phrases closely. In the Bucolics Theocritus appears to have made great use of Sophron. Idyll ii. is modelled upon a mimic of this writer which began in a very similar way.1

1 The chief argument is that in xii. 5 the poet says—

δια βουκολικος τροφεος τριγματος γανατων. As Arsinöe had been married three times, it is thought that she may have been widowed by this work.

2 οιον οιον οιον αλιματα. From Sophron's mimic with πει γαρ αδολαλος; Theocritus' begins with πει μοι κα οδαλος;

The Scholiast thought that Theocritus showed want of taste in making Thystylis a persona muta, instead of giving her a share in the dialogue as Sophron had done. The famous poem about Gorgo of Praxinos, ascribed by some to Theocritus, and modelled on one of Macrobius about women looking on at the Disputations of Menaechmus (τιμοποιησεις του Μεναημηνου), and fragments quoted from this are closely imitated by Theocritus. It is extremely interesting to find a similar poem in the so-called compositions of Thysistrates, the fourth of which is termed "Women making offerings to Aceplamius" (Αθηναηος άναθημας κατ' θρησκευαντα).

The relation of Theocritus to Horondas is a subject of great interest. Herondas must have been acquainted with Ptolemy, as Ptolemy was a native of Cos, so that he and Theocritus must have been acquainted. There are some curious parallels in the language and idioms of the two poets, but which of them copied the other it is impossible to determine.

Manuscripts.—The oldest authority for any part of Theocritus is a papyrus discovered by B. P. Grenfell and A. S. Hunt at Oxyrhynchus, in the second century after Christ. It was written in the Juntine edition (1515) from a codex Ptolemaios now lost. The only existing MS. of any value in which it is found is in Paris (2726), and was written in the 14th century. These two collections are divided into Homeric and non-Homeric, and both go beyond xx. In the English translation (edit. 1901; xxxi. 29.) it is sometimes noticed that xxv. and a portion of xxii. are found both in φ and π. In these poems there are constant divergences, and π appears to give the better reading.

There are important Scholia to Theocritus, or rather to that part of the poems (i.-xxiv., and xxvii.) which is found in the best MSS. The most valuable of those are those contained by Ambros. 229 (K.). They are written by the two most distinguished scholiasts, Atticorum, the editor of Theocritus. It is, therefore, suggested that Theon formed the shorter collection of Theocritian poems, furnished them with scholia, and wrote the second epigram quoted at the beginning of this article. The other sections which possess no scholia and have come down to us from the other collections, would, according to this ingenious theory, be those which appeared in the larger collection of Artemidorus but were excluded by Theon. (G. S.)

Theocritus (c. 380-330 B.C.). Greek rhetorician and tragic poet, of Phaselis in Lycia, pupil of Isocrates and Plato, and an intimate friend of Aristotle. He at first wrote speeches for the law courts, but subsequently composed tragedies with success. He spent most of his life at Athens, and was buried on the sacred road to Eleusis. The inhabitants of Phaselis honoured him with a statue, which was decorated with garlands by Alexander the Great on his way to the East. In the contests arranged by Artemisia, queen of Caria, at the funeral of Mausolus, Theocritus gained the prize with his tragedy Mausolus (extant in the 2nd century A.D.), but was defeated by Theopompus in oratory. According to the inscription on his tomb, he was

1 30, θεοι θεονομένοι τον ἀλατά καταστάντον, ἀπαθίμων. 
2 Οὐκώτας ἐν τῷ ἀκροβράτῳ ὁμορίθῃς, Εὐμενίδας τιμήμων , ἐτίμαν τε ἐν i. 39: θεοὶ οἱ ἀπερίβολοι, ἐτίμαν τε ἐν iv. 5: Αθ. ii. p. xxvii.
eight times victorious in thirteen dramatic contests. Of his tragic poems (fifty in number, thirteen titles and some fragments remain, (A. Nauck, Tragicorum Graecorum Fragmata, 1887). His treatise on the art of rhetoric (according to Suidas written in verse) and his speeches are lost. The names of two of the latter—Socrates and Nomos (referring to a law proposed by Theodectes for the reform of the mercenary service)—are preserved by Aristotle (Rhetoric, ii. 23, 13, 17). The Theodecteans (Aristotle, Rhe. iii. 9, 9) was probably not by Theodectes, but an earlier work of Aristotle, which was superseded by the extant Rhetorica.

See a monograph by C. F. Mürck (Berlin, 1835). There is a lengthy article on Theodectes in Smith's Dictionary of Greek and Roman Biography, in which the connexion of the tragedy with the Artemision contest is disputed.

THEODOLITE, a surveying instrument consisting of two graduated circles placed at right angles to each other, for the measurement of horizontal and vertical angles, a telescope, which turns on axes mounted centrally to the circles, and an alidade for each circle, which carries two or more verniers. The whole is supported by a pedestal resting on footscrews, which are also employed to level the instrument. The size varies from a minimum with circles 3 in. in diameter to a maximum with a 36-in. horizontal and an 18-in. vertical circle.

Theodolites are designed to measure horizontal angles with greater accuracy than vertical, because it is on the former that the most important work of a survey depends; measures of vertical angles are liable to be much impaired by atmospheric refraction, more particularly on long lines, so that when heights have to be determined with much accuracy the theodolite must be discarded for a levelling instrument. When truly adjusted the theodolite measures the horizontal angle between any two objects, however much they may differ in altitude, as the pole star and any terrestrial object.

The instrument is made in three forms—the Y pattern, the Everest and the transit. Certain parts are common to all the forms in use and to the level. The stand is generally made circular in section, each of the three legs being shod at the lower extremity with steel. Their upper ends are hinged to a flat plate provided with a screwed collar of large diameter (fig. 1). To the legs is screwed a plate OO, which supports the lower side of the plate PP. This receives the ends of the screws SS by which the instrument is levelled, its annular portion being larger than the collar in OO, so that, until clamped by the screwed plate above it, the whole of the instrument except the legs can be moved horizontally in any direction to the extent of 4 in. This facilitates centring over a point. The upper plate PP is bored centrally to receive a parallel or conical pillar which supports the lower circle of the theodolite or the arm of the level which carries the telescope, and on the theodolite the edge of the prism is free-bevelled and divided into 360 or 400 degrees, and to half degrees, or to 20 minutes or 10 minutes, according to the size of the instrument. A clamp is provided, which, when tightened on the vertical axis, otherwise free to move, holds it rigidly in position with respect to the plate PP. To this collar is attached a slow-motion screw, working against a reaction spring, by which the plate rr can be rotated through a small arc. The upper plate carrying two, three or four verniers vv is attached to a vertical coned pillar passing through the centre of the larger pillar and rotating in it; this plate can be clamped to the lower plate by means of the screw C, and can be rotated with respect to it by the slow-motion screw d. On the upper plate are placed two small levelling bubbles, and two standards b are attached to the upper side of the plate for supporting the trunnions of the telescope T. The bearings for receiving these trunnions are V-shaped; the V on one side is fixed, while the other is cut through and can be narrowed or made wider, thus lifting or lowering the trunnion by means of two capstan-headed screws. To the telescope the vertical circle for reading angles in the vertical circle. When it is desired to read a line in the reverse direction the telescope is lifted out of the cradle, turned end for end, and replaced in the Y bearings of the cradle again. In the Everest theodolite the supports are low and the telescope cannot be transitted. The instrument is similar to that described above, except that the vertical circle is not continuous, but is formed of two arcs in the supports for the telescope are low, that the telescope rests in a cradle the trunnions of which rest on the supports, and that a segment of a circle attached to the cradle replaces

1 This word has been a puzzle to etymologists. Various ingenious explanations have been given, all based on the apparent Greek etymology: theorein means "to view"; the o has been derived from the Greek θεό, way, and λοίδον, smooth, plain; from θαύρ, to run, and δοξολοίδον, long, and in other ways equally fanciful. Another imaginary origin has been suggested in a corruption of the O deleted, i.e. crossed out. It has been shown by Thomsen that this is not correct: others have found in it a corruption of "the alidade." (g.v.). It would appear, however, to be taken from the O. Fr. theodole or theodolite, a term never in use for a theodolite, but a treatise by one Theodolus, probably a mathematician (see Notes and Queries, 3rd series, vii. 337, 428; &c. Skeat, Etym. Dict., 1910).

FIG. 1.
Theodora, the wife of the emperor Justinian (q.v.), was born probably in Constantinople, though according to some in Cyprus, in the early years of the 6th century, and died in 547. According to Procopius, our chief, but by no means a trustworthy authority for her life, she was the daughter of Acacius, a certain wealthy patrician, and was brought up in the palace at Constantinople. Procopius says that her father, who had already caused to be raised to the patriciate, they were some time after (537) admitted by Justin to a share in the sovereignty; and, on his death four months later, Justinian and Theodora became sole rulers of the Roman world. He was then about forty-four years of age, and she some twenty years younger. Procopius relates in his unpublished history (Ἄξιόδορα) many repulsive tales regarding Theodora's earlier life, but his evident hatred of her, though she had been more than ten years dead when the Anecdota were written, and the extravagances which the book contains, oblige us to regard him as a very doubtful witness. Some confirmation of the reported opposition of the imperial family to the marriage has been found in the story regarding the conduct of Justinian's own mother Vigilantia, which Nicholas Alemanni, the first editor of the Anecdota, in his notes to that book, quotes from a certain "Life of Justinian" by Theophilius, to which he frequently refers, without saying where he found it. Mr Bryce, however, discovered in Rome what is believed to be the only MS. of this so-called Life of Justinian; and his examination of its contents makes him think it worthless as an authority (see Theophilius).

Theodora speedily acquired unbounded influence over her husband. He consulted her in everything, and allowed her to interfere directly, as and when she pleased, in the government of the empire. She had a right to interfere, for she was not merely his consort, but empress regnant, and as such entitled equally with himself to the exercise of all prerogatives. In the most terrible crisis of Justinian's reign, the great Nika insurrection of 532, her courage and firmness in refusing to fly when the rebels were attacking the palace saved her husband's crown, and no doubt strengthened her command over his mind. Officials took an oath of allegiance to her as well as to the emperor (Nov., viii.). She even corresponded with foreign ambassadors, and instructed Belisarius how to deal with the popes. Procopius describes her as acting with harshness, seizing on trivial pretences persons who had offended her, stripping some of their property, and throwing others into dungeons, where they were cruelly tortured or kept for years without the knowledge of their friends. The city was full of her spies, who reported to her everything said against herself or the administration. She had decked herself with ceremonial pomp, and required all who approached to abase themselves in a manner new even to that half-Oriental court. She was an incessant and tyrannical match-maker, forcing men to accept wives and women to accept husbands at her caprice. She constituted herself the protectress of faithless wives against outraged husbands, yet professed great zeal for the moral reformation of the city, enforcing severely the laws against vice, and immuring in a "house of repentance" on the Asiatic side of the Bosphorus five hundred courtiers whom she had swept out of the streets of Constantinople. Her conduct and actions in the case of determining, for it rests on the sole word of Procopius. But there are slight indications in other writers that she had a reputation for severity.

In the religious strife which distracted the empire Theodora took part with the Monophysites, and her coterie usually contained several leading prelates and monks of that party. As Justinian was a warm upholder of the decrees of Chalcedon, this difference of the royal pair excited much remark and indeed much suspicion. Many saw in it a design to penetrate the secrets of both ecclesiastical factions, and so to rule more securely. In other matters also the wife spoke and acted very differently from her husband; but their differences do not seem to have disturbed either his affection or his confidence. The maxim in Constantinople was that the empress was a stronger and a safer friend than the emperor; for, while he abandoned his favourites to her wrath, she stood by her protégés, and never failed to punish anyone whose heedless tongue had assailed her character.

Theodora bore to Justinian no son, but one daughter—at least it would seem that her grandson, who is twice mentioned, was the offspring of a legitimate daughter, but we have, however, no information. According to Procopius, she had before her marriage become the mother of a son, who when grown up returned from Arabia, revealed himself to her, and forthwith disappeared for ever; but this is a story to be received with distrust. That her behaviour as a wife was irreproachable may be gathered from the fact that Procopius mentions only one scandal affecting it, the case of Arobinus. Even he does not seem to believe this case, for, while referring to it as a mere rumour, the only proof he gives is that, suspecting Arobinus of some offence, she had tortured applied to this supposed paramour. Her health was delicate, and, though she took all possible care of it, frequently quitting the capital for the seclusion of her villas on the Asiatic shore, she died comparatively young. Theodora was small in stature and rather pale, but with a graceful figure, beautiful features, and a piercing glance. There remains in the apse of the famous church of S. Vitale at Ravenna a contemporaneous mosaic portrait of her, to which the artist, notwithstanding the stiffness of the material, has succeeded in giving some character.

The above account is in substance that which historians of the two centuries and a half prior to 1885 accepted and maintained regarding this famous empress. But it must be admitted to be open to serious doubts. Everything relating to the early career of Theodora, the faults of her girlhood, the charges of cruelty and improvidence in her government, are found in her own conduct and in the sole authority of the Anecdota of Procopius—a book whose credit is shaken by its bitterness and extravagance. If we reject it, little is left against the charge of course that action in ecclesiastical affairs which excited the wrath of Belisarius, who had denounced her before the Anecdota was published.

In favour of the picture which Procopius gives of the empress it
THEODORA—THEODORE (TSARS) 765

may be argued (1) that she certainly did interfere constantly and arbitrarily in the administration of public affairs, and showed herself therein the kind of person who would be cruel and unscrupulous in her choice of means, and (2) that we gather from other writers as well as from her own statements that, harsh as, for instance, from the references to her in the lives of the popes in the Liber Pontificalis (which used to pass under the name of Anastasius, the patriarch of Jerusalem, in the early Middle Ages), and the references which were added to bring Vigilius to her was "nisio hce fercers, Per Venetiam in saeculo excorlari te faciam." Much of what we find in these lives is legendary, but they are some evidence of Theodora's reputation. Among the sciences that Theodora was said to have controlled are those that related to astronomy. Though we are not informed as to what the Byzantine stage was (as appears even by the statute in question), her life cannot have been irreproachable.

In addition to Theodora, with such confirmations as have been indicated, there is to be set the silence of other writers, contemporaries like Agathias and Evagrius, as well as such later historians as Theophanes, none of whom repeat the charges as to Theodora's life before her marriage. The condition of her great weight need be attached.

It is difficult to establish any view of the controversy without a long and minute examination of the text of the two works, in particular of the Anecdota. But the most probable conclusion must seem to be that, though details which Procopius gives, and which Gibbon did not blush to copy, deserve no more weight than would be given nowadays to the modern scandal sheets, her are not, in our judgment, a final or decisive picture of Theodora. For instance, where scandal is all the blacker because it is propagated in secret; (2) that apparently she was an actress and a courtesan, and impossibly conspicuous in both those characters; and (3) that it is certain, just as we know from his own sayings how fast the courts were burdened with charges of corruption and oppression brought against her by Procopius deserve credence.

We are not bound to accept them, for they are uncorroborated; yet the attacks of Justinian's government given in the Anecdota agree in too many respects with what we know almost to enable us to reject them altogether; and it must be admitted that there is a certain internal consistency in the whole picture which the Anecdota present of the empress, both as to her personal and public character; and, the imperial order of Theodora there can be no doubt, for as to these all our authorities agree. She was evidently an extraordinary person, born to shine in any station of life. She was indeed admired. Among the later serious works dealing with them may be mentioned M. Antonin Débourdou's L'Empératrice Theodora: Étude Critique (Paris, 1889), which endeavours to vindicate her from the aspersions of Procopius; and among more imaginative writings are Sir Henry Pottinger's interesting romance Blue and Green (London, Hurst and Blackett, 1879), M. Rangabe's tragedy Odysseia (Leipzig, 1884), and M. Sarcey's novel Théodore, produced in Paris in 1884. See also Dr F. Dahn's Procopios von Vassaros (1866), and, in addition, the works cited under Justinian.

THEODORA, wife of the Roman emperor Theophilus. In the last year of her husband's reign (842) she overrode his ecclesiastical policy and summoned a council under the patriarch Methodius, in which the worship of images was finally restored and the iconoclastic clergy dismissed. Appointed guardian of her infant son, Michael III., she carried on the government with a firm and judicious hand; she replenished the treasury and deterred the Bulgarians from an attempt at invasion. In order to perpetuate her power she purposely neglected her son's education, and therefore must be held responsible for the voluptuous character which he developed under the influence of his uncle Bardas. Theodora endeavoured in vain to combat Bardas's authority; in 855 she was displaced from her regency at his prompting, and being subsequently convicted of intrigues against him was relegated to a monastery. She was spared in recompense for her zeal on behalf of image-worship.

THEODORA (d. 1057), daughter of the emperor Constantine VIII. Possessed of a strong and austere character, she refused the hand of the heir-presumptive, Romanus, who was manufacturing himself for the succession. She married her sister Zoe (1053). Though living in retirement she excited Zoe's jealousy, and on a pretexts, on which suspicions were founded in a monastery. In 1042 the popular movement which caused the dethronement of Michael V. also led to Theodora's instalment as joint-empress with her sister. After two months of active participation in government she allowed herself to be virtually superseded by Zoe's new husband, Constantine IX. Upon his death in 1054, in spite of her seventy years, she reassessed her dormant rights with vigour, and frustrated an attempt to supersede her on behalf of the general Nicephoros Bryennius. By her firm administration she controlled the unruly nobles, and checked numerous abuses; but she marred her reputation by excessive severity towards private enemies and the undue employment of menials for advisers. She died suddenly in 1057.

THEODOR, the name of two popes. Theodore I. pope from November 642 till May 649, succeeded John IV. He was the son of a bishop, and was born in Jerusalem. A zealous opponent of monotheilism, in the course of the protracted controversy he in a Roman synod excommunicated Pyrrhus, patriarch of Constantinople, and signed the document with ink mingled with consecrated wine. Theodore II. had a pontificate of only twenty days (Nov.–Dec. 897).

THEODORE (Rus. Fedor, or Feodor), the name of three tsars of Russia.

Theodore I. (1557–1568), tsar of Russia, the son of Ivan the Terrible and Anastasia Romanova, nominally succeeded his father in 1584, but being of weak intellect was governed throughout his reign by the boyar, Boris Godunov, whose sister Irene he married in 1580. On his death-bed he is said to have left the throne to his consort, with the Patriarch Joh, Boris Godunov, and Theodore I. he afterwards the Patriarch Philaret, as his chief counsellors. Irene, however, retired into a monastery and her brother Boris stepped into her place.

See S. M. Solovoy, History of Russia (Rus., vol. viii.) (Petersburg, 1895, &c.).

Theodore II. (1589–1605), tsar of Russia, was the son of Tsar Boris Godunov and one of the daughters of Malyuta-Skuratov, the infamous favourite of Ivan the Terrible. Passionately beloved by his father, he received the best available education for those days, and from childhood was initiated into all the minstrelcies of government, besides sitting regularly in the council and receiving the foreign envoys. He seems also to have been remarkably precocious and intelligent, and the first map of Russia by a native, still preserved, is by his hand. On the sudden death of Boris he was proclaimed tsar (13th of April 1605). Though his father had taken the precaution to surround him with powerful friends, he lived from the first moment of his reign in an atmosphere of treachery. On the 1st of July the envoys of Pseudo-Demetrius I. arrived at Moscow to demand his removal, and the letters which they read publicly in the Red Square decided his fate. On the 20th of July he was most foully murdered in his apartments in the Kremlin.

See D. I. Ilovaisky, The Anarchical Period in the Realm of Moscow (Rus.) (Moscow, 1894).

Theodore III. (1661–1683), tsar of Russia, was the eldest surviving son of Tsar Alexius and Maria Miloslavskaya. In 1676 he succeeded his father on the throne. He was endowed with a fine intellect and a noble disposition; he had received an excellent education at the hands of Simeon Polotsky, the most learned Slavonic monk of the day, knew Polish, and even possessed the unusual accomplishment of Latin; but, horribly disfigured and half paralyzed by a mysterious disease, supposed to be scurvy, he had been a hopeless invalid from the day of his birth. In 1679 he married his first cousin Agatha and assumed the sceptre. His native energy, though crippled, was not crushed by his terrible disabilities; and he soon showed that he was as thorough and devoted a reformer as a man incompetent to lead armies and obliged to issue his orders from his bed-chamber, by possibly the. The atmosphere of the court ceased to be oppressive; the light of a new liberalism shone in the highest places; and the severity of the penal laws was considerably mitigated. He founded the academy of sciences in the Zaanenospassky monastery, where everything not expressly forbidden by the orthodox church, including Slavonic, Greek, Latin and Polish, was to be taught by competent professors. The chief difference between the
THEODORE - THEODORE OF MOPSUESTIA

Theodorean and the later Petrine reforms was that while the former were primarily, though not exclusively, for the benefit of the church, the latter were primarily for the benefit of the state. The most notable reform of Theodore III, however, was the abolition, at the suggestion of Vasily Golitsyn, of *Mysterinekestos*, or "place priority," which had paralyzed the whole civil and military administration of Muscovy for generations (see Golitsyn). Henceforth all appointments to the civil and military services were to be determined by merit and the will of the sovereign. Theodore's consort, Agatha, shared his progressive views. She was the first to advocate beard-shaving. On her death (4th of July 681) Theodore married Martha Apraksina. He died on the 27th of April 682, without issue.

See M. P. Pogodin, *The First Seventeen Years of the Life of Peter the Great* (Moscow, 1875). (R. N. B.)

THEODORE (602—690), seventh archbishop of Canterbury, was born at Tarsus in Cilicia in 602. On the death of Wigheard, who had been sent to Pope Vitalian by Ecgbereht of Kent and Oswiu of Northumbria in 667, apparently for consecration as archbishop, Theodore, who had become prominent in the Eastern work of the church, was recommended by Hadrian of Nitridianum to fill the vacant throne. He was consecrated at Nicaea on 688 on condition that Hadrian, afterwards abbot of St Peter's, Canterbury, should go with him. Hadrian was detained for some time by Ebroin, the Neustrian mayor of the palace, but Theodore reached England in May 669. According to Bede's account he made a tour of the whole of Anglo-Saxon England, reforming abuses and giving instruction as to the monastic rule and the canonical Easter. Bede also declares that he was the first archbishop to whom all the "church of the Angles" submitted. From the first he seems to have ignored the scheme for a separate province of York, but he reorganized the episcopal diocese assigning Bish to East Anglia, Putta to Rochester, Hlothhere to Wessex, and Ceadda after consecration to Mercia. He brought the monastic education up to date by introducing literary, metrical and musical studies. In 673 Theodore presided at the first synod of the clergy in England which was held at Hertford. Various disciplinary regulations were emphasized, and an annual meeting arranged at a place called Cloveshoe. After this council Theodore revived the East Saxons bishopric, to which he appointed Eaccornwald. Soon after the first expulsion of Wilfrid in 678 he divided the Northumbrian diocese assigning Trinhamel to the Bishop of the Picts. This led to a quarrel with Wilfrid which was finally settled until 686—687. In 679 Theodore intervened to make peace between Ecgbereht of Northumbria and Aethelred of Mercia. He presided at other synods held in 680 at Hatfield and in 684 at Twyford, and died in 690. A penitential composed under Theodore's direction is still extant.

THEODORE LASCARIS (d. 1222), emperor of Nicaea, was born a noble Byzantine family. He became the son-in-law of the Emperor Alexius III. and distinguished himself during the sieges of Constantinople by the Latins (1203—4). After the capture of the city he gathered a band of fugitives in Bithynia and established himself in the town of Nicaea, which became the chief rallying-point for his countrymen. Relieved of the danger of invasion by a Latin force which had defeated him in 1204 but was recalled to Europe by a Bulgarian invasion, he set to work to form a new Byzantine state in Asia Minor, and in 1206 assumed the title of emperor. During the next years Theodore was beset by enemies on divers sides. He maintained himself stubbornly in defensive campaigns against the Latin emperor Henry, defeated his rival Alexius Comnenus of Trebizond, and carried out a successful counter-attack upon Gayath-ed-din, the sultan of Kitab, who had been instigated to war by the deposed Alexius III. Theodore's crowning victory was gained in 1210, when in a battle near Psidian Antioc he captured Alexius and wrested the town itself from the Turks. At the end of his reign he ruled over a territory roughly coterminous with the old Roman provinces of Asia and Bithynia. Though there is no proof of higher qualities of statesmanship in him, by his courage and military skill he enabled the Byzantine nation not merely to survive, but ultimately to beat back the Latin invasion.

Theodore's grandson, Theodore II. (Lascaris), emperor from 1254 to 1258, is chiefly noticeable for two brilliant campaigns by which he recovered Thrace from the Bulgarians (1255—56). His ill-health and early death prevented his making full use of his ability as a ruler.

IRENE LASCARIS, daughter of Theodore I. (Lascaris), was first married to the great Andronicus Palaeologus, and after his death became the wife of Theodore's successor, John Vatatzes (q.v.), and mother of Theodore II. She is much praised by history for her learning and moderation. She wrote five books on the moral and religious subject, and seems to have been rather an example of remarkable industry than of the example of a considerable improvement in the morals of her nation. She died several years before her husband.

THEODORE OF MOPSUESTIA (c. 350—428), early Christian theologian, the most eminent representative of the so-called school of Antioc, was born at Antioc about the middle of the 4th century and was a friend of John Chrysostom; in rhetoric the celebrated Libanius was his teacher. Soon, however, he attached himself to the school of the great exegete and ascetic, Diodorus, a presbyter in Antioc, and with only a transitory qualification for the latter, he was made a presbyter and consecrated archbishop. He remained faithful to the theology and ascetic discipline of this master. Under Diodorus he became a skilful exegete, and ultimately outstripped his master in biblical learning. About 383 Theodore became a presbyter in Antioc, and began to write against Eunomius the Arius and against the christology of Apollinaris. Soon after 392 he became bishop of Mopsuestia in Cilicia (the modern Missis near Adana). As such he was held in great respect, and took part in several synods, with a reputation for orthodoxy that was never questioned. It was greatly to his advantage that in the Eastern Church the period between 411 and 412 was a era of comparative peace. He was on friendly terms even with Cyril of Alexandria. He died in 428 or 429, just at the beginning of the Nestorian controversy.

Theodore was a very prolific writer, but, before all, an exegete. He wrote commentaries on almost every book of the Old and New Testaments, of which, however, only a small proportion is now extant, as at a later period he lost credit in the church. We still possess in Greek his commentary on the Minor Prophets, in a Syriac version his commentary on St John, and, in Latin translations, commentaries on the shorter Pauline epistles, besides very many fragments, especially on the epistle to the Romans. Theodore's importance as an exegete lies in two characteristics: (1) in opposition to the allegorical method he insists on getting at the literal meaning, and adheres to it when found; (2) in his interpretation of the Scriptures he takes into account the historical circumstances in which they were produced, and substitutes the historical-typological for the pneumatico-christiologist interpretations of prophecy; in other words, he interprets all Old Testament passages historically in the first instance, and sees the fulfilment of Old Testament prophecy in the history of Christ and His church only in so far as the entire Old Testament is a "shadow of things to come." Following his master Diodorus, he wrote a treatise *Tis devpore teorías kal allograpous*, Theodore also was the author of a special dissertation against the allegorists, i.e., against Origen and his followers, which, however, has unfortunately perished. The conservative freedom of opinion of inspiration is also noteworthy. He discriminates between historical, prophetic and didactic writings, and in accordance with this distinction assumes varying degrees of inspiration. Finally, he entertained very bold opinions about the canon and several of the books included in it.

1 Ed. P. B. Chabot (Paris, 1897).
Theodoret, a prominent Church Father, was known for his extensive commentary work on the New Testament. His contributions were not only extensive but also influential, shaping Christian thought and theology. The following text provides insights into Theodoret's life and work:

Theodoret was born in Cilicia and became a prominent theologian, known for his extensive commentary work on the New Testament. His insights and interpretations were widely influential and are still studied today. He was a key figure in the development of Christian thought and theology, particularly in the areas of dogmatics and ecclesiastical history. His works, which include commentaries on the New Testament and other religious texts, are still studied and appreciated for their depth and insight. Theodoret's life and work continue to be celebrated as a testament to the impact of his thought on Christian scholarship and doctrine.
THEODORIC, king of the Ostrogoths (c. 454–526). Referring to the article Gorns for a general statement of the position of this greatest ruler of the Gothic nation produced, we add here some details of a more personal kind. Theodoric was born about the year 454, and was the son of Theudemir, one of three brothers who reigned over the East Goths, at that time settled in Pannonia. The day of his birth coincided with the arrival of the news of a victory of his uncle Walamir over the sons of Attila. The name of Theodoric's mother was Ereliëva, and she is called the concubine of Theudemir. The Byzantine historians generally call him son of Walamir, apparently because the latter was the best known member of the royal fraternity. At the age of seven he was sent as a hostage to the court of Constantinople, and spent ten years of his life, which doubtless exercised a most important influence on his career. Soon after his return to his father (about 471) he secretly, with a comitatus of 10,000 men, attacked the king of the Sarmatians, and wrested from him the important city of Singidunum (Belgrade). In 473 Theudemir, now chief king of the Ostrogoths, invaded Moesia and Macedonia, and obtained a permanent settlement for his people near Thessalonica. Theodoric took the chief part in this expedition, the result of which was to remove the Ostrogoths from the now barbarous province, and to settle them as foederati in the heart of the empire. About 474 Theodoric relived, another Theodoric, son of Triarius. In 488 he set out at the head of his people to win Italy from Odoacer. There is no doubt that he had for this enterprise the sanction of the emperor, only too anxious to be rid of so troublesome a guest. But the precise nature of the relation which was to unite the two powers in the event of Theodoric's success was, perhaps, left open. A year or two after this campaign, during which he spent ten complete practical independence, combined with a great show of sovereignty, had given the empire, reminds us somewhat of the relation of the old East India Company to the Mogul dynasty at Delhi, but the Ostrogoths was sometimes actually at war with his imperial friend. The invasion and conquest of Italy occupied more than four years (488–493). Theodoric, who marched round the head of the Venetian Gulf, had to fight a fierce battle with the Gepidae, probably in the valley of the Save. At the Sontius (Isonzo) he found his passage barred by Odoacer, over whom he gained a complete victory (28th of August 496). A yet more decisive victory followed on the 30th September at Verona. Odoacer fled to Ravenna, and it seemed as if the conquest of Italy was complete. It was delayed, however, for three years by the treachery of Tufa, an officer who had deserted from the service of Odoacer, and of Frederic the Rugian, one of the companions of Theodoric, as well as by the intervention of the Burgundians on behalf of Odoacer. A sally was made from Ravenna by the besieged king, who was defeated in a bloody battle in the Pine Wood. At length (26th of February 493) the long and severe blockade of Ravenna was ended by a capitulation, the terms of which Theodoric subsequently violated by slaying Odoacer with his own hand (15th of March).

Leid. Fl. Theod. III. 485 (484); Staudlin, Gesch. u. Lit. der Kirchengesch. (Hanover, 1827); Kihn, Die Bedeutung der antith. Schule (1866); Dietzel, Das A. T. in der christl. Kirche (Jena, 1896); Specht, Theodor v. Mospensta

1 Roman Catholic writers vary greatly in their estimate of Theodoric's chrestology and of his general orthodoxy. On Bertram's essay on this subject (Theodori, Episcopi Cyrenis, Doctrina Christioglogiae, Hildesheim, 1883), see Theol. Lit.-Ztg. (1883), 563 seq.

2 In one of the intervals of friendship with the emperor in 483 Theodoric was made master of the household troops and in 484 consul.
venality of the Roman officials and the turbulence of the Gothic nobles were sternly repressed. Marshes were drained, harbours formed, the burden of the taxes lightened, and the state of agriculture so much improved that Italy, from a corn-importing country, became a corn-exporting country. Moreover Theodoric, though adhering to the Arian creed of his forefathers, was during the greater part of his reign so conspicuously impartial in religious matters that a legend which afterwards became current represented him as actually putting to death a Catholic deacon who had turned Arian in order to win his favour. At the time of the contested papal election between Symmachus and Laurentius (496-502), Theodoric's mediation was welcomed by both contending parties. Unfortunately, at the very close of his reign (524), the Emperor Justin's persecution of the Arians led him into a policy of reprisals. He forced Pope John to undertake a mission to Constantinople to plead for toleration, and on his return threw him into prison, where he died. Above all, he sullied his fame by the execution of Boetius and Symmachus (see BOETIUS). It should be observed, however, that the motive for these acts of violence was probably political rather than religious. Theodoric, who was in the imperial court rather than zeal on behalf of the Arian confession. Theodoric's death, which is said to have been hastened by remorse for the execution of Symmachus, occurred on the 30th of August 526. He was buried in the mausoleum which is still one of the marvels of Ravenna (q.v.), and his grandson Athalaric, a boy of ten years, succeeded him, under the regency of his mother Amalasuntha.

**Authorities.**—The authorities for the life of Theodoric are very imperfect. Jordanes, Procopius, and the curious fragment named as Anonymus Valens (printed at the end of Ammianus Marcellinus) are the chief and most important sources of narrative, but for the most important indirect source is the Variae (state-papers) of Cassiodorus, chief minister of Theodoric. Malchus furnishes some interesting particulars as to his early life, and it is possible to extract a little information from the turgid panegyric of Ennodius. Among German scholars F. Dahn (Könige der Germanen, ii, iii, and iv.), J. K. F. Manso (Geschichte des Ostgotischen Reichs in Italien, 1824), and Sauri (Versuch über die Regierung der Ostgoten, 1848) have done most to illustrate Theodoric's principles of government. The English reader may consult Gibbon's Decline and Fall, chap. xxxix., and Hodgkin, Italy and her Neighbours (1864), his introduction to the Letters of Cassiodorus (1886) and Theodoric the Goth (London and New York, 1891). For the legends connected with the name of Theodoric see the article DIETRICH OF BERN. (T. H.)

**Theodorus, Flavius Mallius.** Roman consul a.d. 399, author of an extant treatise on metres, one of the best of its kind (H. Kell, Grammataleitique, vi.). He also studied philology and geometry, and wrote works on those subjects, which, together with his consulship, formed the subject of a panegyric by Claudian.

**Theodorus Studita.** (A.D. 750-826), Greek theological writer, abbot of the monastery of Studium, was born at Constantinople. In 794 he succeeded his uncle Plato, who had persuaded him to become a monk some ten years before, as head of the monastery of Saccudium in Bithynia. Soon afterwards he was banished to Thessalonica for having excommunicated Constantine VI., who had divorced his wife Maria in order to marry Theodotè. After the emperor's death in 797 he was recalled with every mark of favour, and removed with his monks to the monastery of Studium in Constantinople, where he carried on a vigorous campaign in favour of asceticism and monastic reform. In 809 he was again banished in consequence of his refusal to hold communion with the patriarch Nicephorus, who had pardoned the priest Joseph for his part in the marriage of Constantine and Theodotè. In 811 he was recalled by Michael Rangabes, and again banished in 814 for his resistance to the edict of Leo the Armenian, which forbade Christian images. Liberated at the request of the Emperor Michael the Stammerer (Balbus), he soon got into trouble again. In 824 he violently attacked Michael for showing too great leniency towards the iconoclasts and even favoured an insurrection against him. When the attempt failed, Theodorus found it prudent to leave Constantinople. He lived at various monasteries in Bithynia, on Chalcitis (one of the Princes' Islands) and on the peninsula of Tryphon, near the promontory of Acrita, where he died on the 11th of November 826. He was buried at Chalcis, but his body was afterwards (24th of January 844) removed to Studium. He subsequently received the honours of canonization. Of his extant works there are the following:—Letters, which are of considerable value as giving an insight into the life and character of the writer, and throwing light upon the ecclesiastical disputes in which he was involved; Catechises (divided into Magna and Parva), two collections of addresses to his monks on various subjects connected with the spiritual life; funeral orations on his mother and his uncle Flato; various polemical discourses connected with the question of image-worship. He was also the author of epigrams on various subjects, which show considerable originality, and of some church hymns. Like all the monks of Studium, Theodorus was famous for his calligraphy and industry in copying MSS.

**Bibliography.**—General edition of his works in J. P. Migne, Patrologia Graeca, xcix., to be supplemented (for the Letters) by A. Mai's Patrum Nova Bibliotheca, viii. (1871) and (for the Catechises) by ib., ix. (1888), which contains the Greek text of the Perna (also ed. separately by E. Avray, 1891); hymns in J. B. Pitra, Analecta Sacra, i. (1876). See also Alice Gardner, Theodore of Studium: his Life and Times (1905), containing specimens of English translation and an account of his published works; C. Theodor, Theodor von Studion und sein Zeiseler (1892); G. A. Schneider, Theodor von Studion, in "Kirchengeschichtliche Studien," v. 3 (Münster, 1900); S. Schiwez, De Sancto Thoedori Studita (Halle, 1890); E. Monat, Studia Theodori (1897); C. Schwarzkose, Der Billestretze (1890); A. Tougard, La Persécution iconoclaste d'après la correspondance de saint Théodore Studite (1891). Some of the hymns have been translated by E. Leigh, The East Church. For further bibliographical details see C. Krumbacher, Gesch. der byz. Litt. (2nd ed., 1897) and article by Von Dobisch in Herzog-Hauck's Realencyclopadie für protestantische Theologie, xix. (1907). On his relation to Theophanes Confessor (q.v.), see J. Fargue, 'Saint Théophane le Chronographe et ses rapports avec saint Théodore Studite" in Béatrice Novara, ix. (St. Petersburg, 1902).

**Theodosis,** formerly Kaffa, a seaport and watering-place of South Russia, on the east coast of the Crimea, 66 m. E.N.E. of Simferopol and 72 m. by a branch line from the Sebastopol-Ekaterinoslav railway. It has an excellent modern harbour, and its roadstead, which is never frozen, is well protected from east and west winds, and partly also from the south, but its depth is only 11 to 14 ft., reaching 35 ft. in the middle. The population was 10,800 in 1881, and 27,236 in 1897. Among the minority population of Russians, Tatars, Armenians, Germans and Greeks are several hundred Qaraite Jews. Few remnants of its former importance exist, the chief being the Citadel built by the Genoese and still showing Latin inscriptions on some of its towers, the one or two detached towers left when the town walls were pulled down, and two or three mosques, formerly Genoese churches. The town also possesses a museum of antiquities and a picture gallery containing the works of the marine painter Ayvazovsky. Theodoisia is an episcopal see of the Orthodox Greek Church. Gardening is one of the leading industries; fishing, a few manufactures, and agriculture are...
THEODOSIUS (EMPERORS)

THEODOSIUS, after reorganizing the army at Thessalonica, carried on a successful campaign of skirmishes along the Danube and induced numerous Gothic bands to give in their allegiance; his lieutenant Modares, a Gothic refugee, defeated the invaders severely in Thrace. At the end of the year Theodosius went to Constantinople to be crowned. Returning to Thessalonica in 380 he was kept out of the town for some time by a serious illness. In this year or the next he was called upon to meet two armies of invaders. He conducted in person the war against the Visigoths under Fritigern (in Macedonia and Epirus), and on one occasion was nearly betrayed into the enemy's hands; this campaign, in which Gratian's general Arbogast eventually lent help, was ended by Fritigern's death. The defence of the Danube against the Ostrogoths under Alatheus and Sahrax was entrusted to the general Promontus, who severely defeated the enemy in an attempt to cross the river. Theodosius attained even greater successes by his diplomacy. He persuaded the fugitive Visigoth king Athanaric to enter his service, and enlisted 40,000 of his former enemies as foederati, providing them with settlements in various parts of the realm. Though this kindness towards the Germanic tribes was resented by the Romans, and in some cases ill required, yet it may be said that it not only averted a great danger to the empire, but considerably strengthened Theodosius' army. In 382 the pacification of the Balkans was complete. In 386 Promontus checked a new attempt at invasion on the Danube.

In 385 Theodosius created his eldest son Arcadius Augustus. Theodosius, however, was not quite satisfied with his eldest son, and the victory seemed to him a sufficient justification of his policy. For five years Theodosius consented to accept the usurper as his colleague; but when Maximus attempted a few years later to make himself master of Italy Theodosius advanced against the invader and overthrew him near Aquileia (July 28, 388). This victory was followed by the murder of Maximus and his son Victor, after whose death Theodosius conferred upon Valentinian II. all that part of the empire which his father had held. After celebrating a triumph in Rome (386) he stayed to arrange the government of Italy for another two years. If we here trust the evidence of Zosimus, from the end of the year 388 Theodosius resigned himself to gluttony and voluptuous living, from which he was only roused by the news that in the Western empire Arbogast had slain the young Emperor Valentinian and set up the grammarian Eugenius in his stead (May 15, 392).

Theodosius made extensive levies and with a force partly composed of barbarian auxiliaries marched out against Eugenius. The armies met near the river Frigidus, some thirty-six miles distant from Aquileia. On the first day Theodosius' barbarians, engaging with those of the hostile army, were almost destroyed, and the victory seemed to belong to Eugenius. After a night of prayer, towards cockcrow the emperor was cheered by a vision of St Philip and St John, who, mounted on white steeds, promised him success. On the second day the issue was doubtful till, if we may trust the contemporary testimony of all the contemporary church historians, a sudden gust of wind blew back the enemy's arrows on themselves. This was the turning-point of the battle: Eugenius was slain by the soldiers; and two days later Arbogast committed suicide (September 5–9, 394). From the north-eastern parts of Italy Theodosius passed to Rome, where he had his son Honorius proclaimed emperor under the guardianship of Stilicho. Thence he retired to Milan, where he died of dropsy (January 17, 395), leaving the empire to be divided between his two sons Honorius and Arcadius.

Important as the reign of Theodosius was from the political point of view, it is perhaps still more so from the theological. Theodosius' parents were both orthodox Christians, and according to the creed sanctioned by the council of Nicæa. It was not, however, till his illness at Thessalonica that the emperor received baptism at the hands of Bishop Achilles, whereupon, says the same historian, he issued a decree (February 380) in favour of the faith of St Peter and Pope Damasus of Rome. This was to be the true Catholic faith; the adherents of other creeds were to be reckoned as heretics and punished. The great council of
THEODOSIUS OF TRIPOLIS

Constantinople, consisting of 150 orthodox and 36 Macedonian bishops, met in the following year, confirmed the Nicene faith, ordained the emperor...he declared the bishop of Constantinople to rank next to the bishop of Rome. The emperor cannot be acquitted of the intolerance which marks edicts such as that depriving apostatizing Christians of the right of bequest. It was not until 300 that he issued orders for the destruction of the great image of Scarpis at Alexandria. Other edicts of an earlier or later date forbade the unorthodox to hold assemblies in the towns, enjoined the surrender of all churches to the cathedral bishop of Alexandria as the "hearth of the world." During the reign of Theodosius Gregory of Nazianzos was made bishop of Constantinople. In 383 Theodosius called a new council for the discussion of the true faith. The orthodox, the Arians, the Eunomians and the Macedonians all sent champions to maintain their special tenets before the emperor, who finally decided in favour of the orthodox party. He seems to have suffered the Greek mathematician Pappus of Alexandria at his hands. The most remarkable incident in the life of Theodosius from a personal point of view is the incident of his submission to the reprimands of Ambrose, who dared to rebuke him and refused to admit him to the Eucharist till he had done public penance for prosecuting a riot in Thessalonica by a wholesale massacre of the populace. Equally praiseworthy is the generous pardon that the emperor, after much intercession, granted to the seditious people of Antioch, who, out of anger at the growing imports, had beaten down the imperial statues of their city (387). When the Christians in the eastern part of the empire destroyed a Jewish synagogue and a church belonging to the Manichaeans in Persia, the emperor ordered the offenders to make reparation. Such impartial conduct drew forth a remonstrance from Ambrose, who, where the interests of his creed were concerned, was a man of common principles. Theodosius was twice married—(1) to Aelia Flaccilla, the mother of Arcadius (377-408) and Honorius (384-423); (2) to Galia (d. 394), the daughter of Valentinian I.

The chief authorities for the age of Theodosius are Ammianus Marcellinus, Zosimus, Eunapius and the ecclesiastical historians (Socrates, Sozomen, Theodoret). Much information may also be gleaned from the writings of St Ambrose, St Gregory of Nazianzos, Iaodare of Seville, and the oratoro Pacatus, Libianus, Theodoret. Among modern authorities see: E. Gibbon, The Decline and Fall of the Roman Empire (ed. Bury, London, 1896), chaps. 25, 27, 29, 48, and The Christian Empire (chap. 8-11); A. Gildenepenning and J. Iland, Der Kaiser Theodosius der Grosse (Halle, 1878); G. R. Sievers, Studien zur Geschichte der römischen Kaiser (Berlin, 1870), pp. 233-333.

THEODOSIUS II. (404-450) succeeded his father Arcadius as emperor of the East in 408. During his minority the empire was ably ruled by the praetorian prefect Anthemius and Pulcheria, who became her brother's guardian in 414. Under his sister's care the young emperor was trained in divers accomplishments which won him the name of Calligraphus ("the Penman"), but grew up in a weak though amiable character. Through his generals Arbodurus and Agatho, the emperor was fairly successful in wars against the Persians (421 and 441), and after the failure of one expedition (431) by means of a gigantic fleet put an end to the piracies of the Vandal Genesric. A Hunsish invasion in 408 was skilfully repelled, but from 441 the Balkan country was repeatedly overrun by the armies of Attila, whose invasions Theodosius feebly attempted to buy off with ever-increasing payments of tribute. His internal administration, though not sufficiently rigorous to check abuses, was upright and thoughtful. Among its chief events may be mentioned the endowment of the university of Constantinople (429), the commission (463) and the publication (468) of the Codex Theodosianus (438), a collection of imperial constitutions for the benefit of public officials, which is our chief source of information about the government of the empire in the 5th century. In 450 Theodosius died of injuries sustained through a fall from his horse.

THEODOSIUS III, emperor of the East (716-717), was a financial officer whom a Byzantine army rebelling against Anastasius III, unexpectedly proclaimed monarch in his stead. He captured Constantinople after a six months' siege and deposed Anastasius, but in the following year was himself forced to resign by a new usurper, Leo III. (q.v.). Theodosius ended his life in a monastery.

(M. O. B. C.)

THEODOSIUS OF TRIPOLIS.

Greek geometran and astronomer, three of whose works were contained in the collection of lesser writings named δ μῦροι ἀστρονομικοί (sc. τότο), or δ μῦροι ἀστροφόι.1 Such erroneous identifies him with a sceptical philosopher of the same name who lived in the second half of the 2nd century A.D. or later, but, on the other hand, distinguishes him from a native of Tripol in who wrote a poem on spring. He is doubtless the same as Theodosius the mathematician, who is mentioned by Strabo amongst the natives of Bithynia distinguished for their learning, and whose sons were also mathematicians, the same as the inventor of a universal sun-dial (horologium ποσάν κύλλων). If that name which is praised by Vitruvius (De Architectura, ix. 9). His date, therefore, could not have been later than the 1st century B.C.; he may, however, have lived in the preceding century, inasmuch as the names mentioned by Strabo in the passage referred to above are, as far as we know, arranged chronologically, and Theodosius immediately follows Hipparchus, who made astronomical observations between 161 and 126 B.C. and precedes Asclepiades the physician, who lived at Rome at the beginning of the 1st century B.C.

His chief work—σφαιρικόν, in three books—is a tolerably complete treatise on the physical geometry of the surface of a sphere, and was still the classical book on the subject in Pappus's time. It does not contain (except for a faint suggestion in iii. 11-12) any trace of spherical trigonometry, which, on the other hand, was the special subject of the work having the same title and in the same collection, of Menelaus of Alexandria, who lived at the end of the 1st century.

A. Nolck (Uber die Sphrikis des Theodosii Karlruhe, 1857), Herodianergericht der Studien über Euklid, pp. 445-450 (Leipzig, 1882), and Hultsch (Jahrbücher für classische Philologie, 1885, pp. 415-420, and Antiquitates; Leipzig, 1885) have proved that as the title of the work having the same title and in the same collection, of Menelaus of Alexandria, who lived at the end of the 1st century. The Spherkis of Theodosius was translated into Arabic at the beginning of the 10th century, and from the Arabic into Latin in the 12th century by Plato of Tivoli (Tiburtinus). This translation was published in 1518 at Venice, but was found so faulty by J. Vogelius that he published a new Latin version, together with additions from the Arabic commentator (Vienna, 1520, 460); another Latin translation by B. C. Clavus (Rome, 1586, 460); and by Barrow under the title, Theodosii Sphaerica, methodo nova illustrata et successice demonstrata (London, 1675, 140). The Greek text was first published, and with it a Latin translation, by J. Pena (Paris, 1558, 460); it has been edited since by Joseph Hunt (Oxford, 1707), and by E. Nizze (Berlin, 1832), but these two editions are accompanied with valuable notes and an appendix containing additions from Vogelius and others.

His other works of Theodosius which have come down to us have not as yet been published in the original. The propositions, without demonstrations, in the work τῶν ἐστίν καὶ ἐκτιθῶν (On Days and Nights), in two books, were given by Dasypodius, in Greek (1588, in his Athenaeum, ed. J. Pena, Paris, 1558; fol.), by C. Clavis (Rome, 1586, 460); and by Barrow under the title, Theodosii Sphaerica, methodo nova illustrata et successice demonstrata (London, 1675, 140). The Greek text was first published, and with it a Latin translation, by J. Pena (Paris, 1558, 460); it has been edited since by Joseph Hunt (Oxford, 1707), and by E. Nizze (Berlin, 1832), but these two editions are accompanied with valuable notes and an appendix containing additions from Vogelius and others.

1 This collection contained, according to Fabricius, Bibliotheca Graeci, ed. Halles, iv. p. 16, the following books:—Theodosi Tripli, De Habitationibus et Notibus ac Dioecibus; Theodosi Tripli, De Habitationibus et Notibus ac Dioecibus; theodosi Tripli, De Habitationibus et Notibus ac Dioecibus; and Libri ii.; Autolyci Pitanai, De Spihera Mota, et Libri ii. and Libri ii. et tertii alque Occasii Stellarum Errantium; Aristarchi Sarici, De Magnis et Medianis ac Dioecibus de Distributione Astrorum, et Arabocardi, De Ascensionibus; Menelai, Sphaerica, libri iii. Euclidis Data is, however, wrongly included, for Pappus, vii., makes it part of analysis (δ αρκαδοφρα νόμον).
THEODULF—THEOLOGY

first book of this work of Theodosius. His work onel onachelen
(On Habitation) also was published by Auria (Rome, 1588). It
gives an account of how, for every inhabitant of the earth from
the equator to the pole, the starry firmament presents itself in
the course of a year. The propositions in it were also given by Dusay-
bozidus in his work mentioned above.

(T. L. H.)

THEODULF, bishop of Orleans, was born about the middle
of the 8th century, of a noble family of Gothic extraction, pro-

abate of Fleury and of Saint-Aignan, and in 781 became
bishop of Orleans. He was a staunch supporter of Charle-
magne's principles of government and educational reforms;
he established schools, and by his own literary achievements showed
himself a worthy member of the learned circle which graced the
Court of Charlemagne. He is likelier to have been chaplain or
able administrator of his diocese; he encouraged the reforma-
tion of the clergy and the monasteries. In 798 he was appointed
missis dominicus, and two years later performed so great
services for Leo III. as judge in the cause between the pope and
his enemies, that he returned from Rome with the pallium.

After the death of Alcuin he became the foremost councillor
to the king on theological matters: it was he who made, on
Charlemagne's request, a collection of the opinions of the fathers
on the much-disputed point of the procession of the Holy Ghost.
Theodulf borrowed the influence of his culture and temper of
judges. He asserted his innocence to the end, and no proof of his guilt
has come down to us; in fact, from what we know of the bishop's
life and political principles we should presuppose his innocence.

He died in prison, probably from poison, in 821.

Theodulf was called Poetics in the glosses of Charlemagne.
For that reason, in Latin literature, whether Christian or pagan, and a friend
of the arts, he was himself one of the best writers of the period.
His prose works include sermons, treatises on vices and on baptism,
a penitential, capitularies and exhortations to bishops, priests and
judges. His poems are his best work, and afford us a vivid picture
of the times. Theodulf was the author of at least part of the
hymn for Palm Sunday, the Gloria laus. The complete works of
The best edition of his poetry is that of E. Dümmler in the Mon.

See C. Cruissard, Theodulf, the Poet of the Carolingian Age, su et ses crear. (Orleans, 1892), a critical study of the writings by M. Mantin in
Neues Arch. der Ges. für d. deutsche Gesch. xi. (1886).

THEOGENIS OF MEGARA (6th century B.C.), Greek poet.
More than half the elegiac poetry of Greece before the Alex-

iernan period is included in the 1400 lines ascribed to Theogenis.
This collection contains several poems acknowledged to have
been composed by Tyrtaeus, Minnemus and Solon; with two
exceptions (T. W. Allen in Classical Review, Nov. 1905, and
E. Harrison) modern critics unanimously regard these elegies
as intruders, that is, not admitted into his works by Theogenis
himself; for this and other reasons they assume the existence
of further interpolations which we can no longer safely detect.

Generations of students have exhausted their ingenuity in vain
efforts to sift the true from the false and to account for the
origin and date of the Theognidea as we possess them; the
question is fully discussed in the works of Harrison and Hudson-

The best-attested elegies are those addressed to Cyrus, the
young friend to whom Theognis imparts instruction in the
ways of life, bidding him be true to the "good" cause, eschew the
company of "evil" men (democrats), be loyal to his city, and
be the "good" citizen. Theognis lived at Megara on the Isthmus of Corinth during the democratic re-

olution in the 6th century B.C.; some critics hold that he
witnessed the "Persian terror" of 590 and 580; others, in-
cluding the present writer, place his floruit in 545 B.C.
We know little about his life; few of the details usually given in
text-books are capable of proof; we are not certain, for in-
stance, that the poem (783-88) which mentions a visit to Sicily,
Sparta and Euboea comes from the hand of Theognis himself;
but that is of little concern, for we know the man. Whether,
with Harrison, we hold that 'Theognis' is the "all or nearly all
of the poems which are extant under his name" or follow the
most ruthless of the higher critics (Sitzler) in rejecting all but
330 lines, there is abundant and unmistakable evidence to show
what Theognis himself was. However much extraneous matter
could have warped its way into the collection, he still remains
the one main personality, and stands clearly before us, a living
soul, quivering with passion and burning with political hate,
the very embodiment of the faction-spirit (stasis) and all it
implied in the tense city-state life of the ancient Greek.

To publish "theognidea" was neither an easy nor sublime poetry in the
work of Theognis; but it is full of splendid collection embodied
in exquisitely simple, concise and well-balanced verse.
As York Powell said, "Theognis was a great and wise man"
and was an able exponent of that intensely practical wisdom which we associate with the "seven sages of Greece." Had
he lived a century later, he would probably have published his
thoughts in prose; in his day verse was the recognized vehicle
for political and ethical discussion, and the gnostic poets
were in many ways the precursors of the philosophers and
the sophists; who indeed oftenhide their discourse turn on points
raised by Theognis and his fellow-poets.

No treatment of the much-debated question "Can virtue be taught?"
was regarded as complete without a reference to Theognis 35-36
which appears in Plato, Xenophon, Aristotle, Musonius and
Clement of Alexandria, who aptly compares it with Psalm xviii.

26. Another famous couplet is 177-78: "In poverty, dear Cyrus
we forego | Freedom in word and deed—body and mind, |
Action and thought, are fitter'd and confirm'd" (trans. Freere). This
discussed by Aristotle, mercilessly criticized by Lucian and the
Soics, and warmly commended by Ammianus Marcellinus,
who introduces the author as "Theognis poetae vetus et prudens." For
many generations Theognis was to the Greeks the model
par excellence; Isocrates says that Hesiod, Theognis and
Phocylides were admitted to be the best teachers of practical
morality; and the Emperor Julian in his defence of paganism
asks whether "the most wise Solomon is equal to Phocylides
or Theognis or Isocrates."

Besides the elegies to Cyrus the Theognidea comprise many
maxims, laments on the degeneracy of the age and the woes
doing, personal admonitions and challenges, invocations of
the gods, songs for convivial gatherings and much else that
makes it a "devout work," as Harrision calls it. The second
section ("Musa Paedica") deals with the love of boys, and,
with the exceptions already noted, scholars are at one in reject-
ing its claim to authenticity. Although some critics assign
many elegies to a very late date, a careful examination of the
language, vocabulary, versification and general trend of thought
has convinced the present writer that practically the whole
80 collection was composed before the Alexandrian age.

Editions.—Imn. Bekker (1815, 2nd ed. 1827); F. G. Welcker
(1826); both these are epoch-making books which no serious
student can ignore; Th. Bergk (1843, 4th ed. 1882; re-edited by
E. Hiller, 1890, and O. Crusius, 1897); J. Sitzler (1886); E. Harri-
son (1902); T. Hudson-Williams (1910). For further bibliographical
works on the Theognidea see the various translations. There is a prose
translation by J. Banks in Bohn's Classical Library (1850), which
also includes verse translations by J. Hookham Freere.

THEOLOGY, literally the science which deals with God or
the gods. The word is Greek (Oös, God; λόγος, theory).
But doctrine counted for less in Greek or Roman religion than
in Christianity, and forms of worship for more. In the oldest
usages θεολογία were those who dealt in myths, like Hesiod
and like the supposed Orpheus, the θεολογία par excellence.
Paul Natorp1 contends that θεολογία in Plato's Republic
refers wholly to the control of myths. He further denies that
Aristotle identified his First Philosophy with a "theology,"
holding the text of the Metaphysics to be out of order and

1 Philosophische Monatsshefte (1888), Heft 1 and 2. See also
THEISM.
corrupted, though from a very early period. He regards the Stoics as having initiated a philosophical theology, and gives numerous references for the "three theologies" which they divide: Christian Theology, Jewish Theology (the Talmud), and Greek philosophy. It is possible that the epithet theologia for St John may go back as far as Papias. This is the first appearance of the term upon Christian ground. The primitive application of theologia to the poets and myth-fanciers meets us again in Church writers; but there is also a tendency to use the name for a philosophical theology based on the doctrine of the Logos. In this sense Gregory Nazianzus also receives the title theologia. His περὶ θεολογίας is a dissertation on the knowledge of God.1 Many centuries later Abelard generalized the expression in books which came to be known as the titles Theologia Christiana and Introductio ad Theologiam. (Abelard speaks himself of "theologia nostra." 2) It is of interest to note that even in these books the Trinity and Christology are the topics of outstanding importance. In the Summa Theologica of Thomas Aquinas the technical sense is fully established. Except in special circumstances which generally explain themselves, e.g. "Homerian Theology" (a book by Nægelsbach), Old Testament Theology, Comparative Theology, Natural Theology, the word in modern languages means the theology of the Christian Church. What follows is devoted to that subject.

While the word points to God as the special theme of the theologian, other topics inevitably find entrance. Theistic philosophy thinks of God as the absolute being; and every monothelite religion insists, not indeed that the knowledge of God includes all knowledge, but that this supremely important knowledge throws fresh light upon everything. So, with an added Christian intensity, St Paul declares: "If any man is in Christ, he is a new creature; the old things are passed away; behold, they are become new. But all things are of God, who reconciled us to himself through Christ" (2 Cor. 5:17). A minimum division might be threefold—Gottesbegriff, Solsbeurmarkt, Waldenschock.3 But historically it is more important to note that Christian theology has developed as a doctrine concerning Christ: his relation to God, our relation to God in or through him. For Christ is viewed as bringing redemption—a conception of importance in many religions, but in none so important as in Christianity. Indeed, another possibility opens here. Instead of being mainly a doctrine concerning God, or one concerning Christ, theology may be construed as being mainly the theory here will be experience. Most schools of theology will concur, however, in giving the complementary point of view and making their systems a study of Divine revelation. Even if they accept Natural Theology, they generally hold that Christian theology, properly so called, begins at a further point. Those who deny this were formerly called Naturalists, i.e. deniers of supernatural revelation; those who extend the province of reason in theology, and push back the frontier of revelation, are often called Rationalists.4 Such being the usual point of view, it is plain that the claim of theology to be a science, or a group of sciences, is legitimate.

In so far as theology is orderly, coherent, systematic, and seeks to rest upon grounds of some sort, it may be called a science. But, in so far as it claims to deal with special revelation, it lifts itself out of the circle of the sciences, and turns away from natural knowledge towards what it regards as more intimate messages from God.

Two special usages should be noted: (1) a medieval use of theology for mystical or intuitive knowledge of God, as in the well-known book called Theologia Germanica; (2) "theology proper," in Protestant systems, is the portion of theology which deals directly with the doctrine of God.

Another characteristic of theology is its secondary and reflective character. Religion, therefore, is earlier than theology. Or the theology which religion contains is in a state of solution—vaguely defined and suffused with emotion; important practically, but intellectually unsatisfying. Scientific theology contrasts with this. History may soften the contrast by discovering transitional forms, and by showing the religious interest at work in theology as well as the scientific interest affecting early utterances of religion. Still, this contrast enters into the meaning of divines when they say that they are at work upon a science. A religious man need no more be a theologian than a poet need have a theory of aesthetics.

Where, then, are we to look for Christian theology? It is not the trash it may seem if we reply that we are to find it in the writings of theologians. As authorities control of work, theologians may name the Bible, or tradition, or the consciousness of the Church, or some combination of these. But the Bible is not systematic, and the authority of consciousness is vague; while the creeds into which Church tradition crystallizes emerge out of long theological discussions. Ordinarily, doctrine has been in close connexion not only with edification but with controversy. Anselm of Canterbury stands almost alone among the great theological masters in working purely from a scientific interest; this holds alike of his contribution to theism and of his doctrine of Atonement. Among the earlier theological statements are catechetical books, e.g. Cyril of Jerusalem. These books record doctrinal instruction, for example, in practical ends, to laymen of adult years who were candidates for baptism. The interested discussions by experts for experts is medieval rather than primitive. Modern catechisms in the form of question and answer for the instruction of baptized children are sometimes convenient if dry summaries of doctrine (e.g. the Westminster Assembly's Shorter Catechism); but sometimes they have the glow of religious tenderness, like Luther's Lesser Catechism, or the Heidelberg Catechism. They generally expound (1) the Apostles' Creed, (2) the Ten Commandments, (3) the Lord's Prayer. Medieval theologians had an appearance of keeping in touch with the Apostles' Creed when it divides the substance of doctrine into (usually) twelve "articles"—not always the same twelve—a reminiscence of the legendary composition of the Creed in twelve sections by the twelve apostles. This treatment, however, has little real influence upon the structure of medieval theology. German Protestant writers, again, following their catechisms, often distinguish three articles—of the Father, of the Son, and of the Holy Spirit. This, too, is no more than convenient phraseology.

Before the Christian age, there had been a good deal of reflective thinking in the Jewish schools, though the interest there was legal rather than speculative. To some extent Christianity inherited this Jewish theology. True, Jesus Christ sprang from the people. He was a "layman" (Paul Wernle), with out technical Jewish lore. The great attainment of the Old Testament, ethical monothelism, had become the common property of the nation; it occurs in Christianity as a simple presupposition. Early Christian writers find it well necessary to prove what no one dreams of questioning. Along with this great doctrine there pass into Christianity the slowly attained hope of resurrection and the dreadful doctrine of future punishment for the wicked. Leading thoughts in the Gospels of Jesus, are the Fatherhood of God—new at last in the central place given to the image of the "kingdom" or judgment of God, and Jesus' own place as Messiah, i.e. as king (and as judge). The "second founder" of Christian thought Paul of Tarsus was an inductee. His own from Judaism is all the more intense because of St Paul. The special intellectual presuppositions which he continues to share with Judaism. In many respects, Pauline Christianity is the obverse of the Pharisaic creed. Modern Christians are
tempted to charge the seeming extravagance of St. Paul's thought upon his Jewish inheritance, while modern Jews are tempted to charge St. Paul's disloyalty to Judaism upon his gentile inheritance. They have both, probably, a point.

According to one Jewish and one Christian interpretation, the difference between the New Testament and the Old is identical. Probably both are right, and both wrong. The germs were Jewish; but, transported to a new soil, and watered with a new enthusiasm, they assumed new forms. These cannot claim the character of correctives, but they are not corrections.

The New Testament is, at the same time, what it is not. At the same time, they employ all the resources of dialectic, and have, therefore, taken quite half the journey from primary religion to theology. But the dislocation of religious thinking, when Christianity ceased to be a Jewish faith and found a home with Gentiles, destroyed the continuity of Paulinism and of Jewish thought working through St. Paul. In later times, when Paulinism revolved in the New Testament book for themselves, though there were not always correctly understood. It should be added that, according to A. Harnack, Hellenistic Judaism had worked out the principles of a theology which simply passed on into the Greek-speaking Christian Church.

Theological

Besides the teaching of Jesus (best preserved in the first three gospels) and the teaching of Paul (in six, ten, or thirteen epistles), the recent "science" of New Testament theology finds other types of doctrine. The Epistle to the Hebrews is a parallel to Paulinism, working out its superiority to the Old Testament. The Johannine Gospel and Epistles are later than Paulinism, and presuppose its leading or least startling positions. Whatever historical elements may be preserved in Christ's discourses as given in the Fourth Gospel, these discourses fit into the author's type of theology; and he may have been far from the authority of the church that had been transformed. 1 Peter is good independent Paulinism. The Epistle of James may breathe a Christianized Jewish legalism, or, as others hold, it may breathe the legalism (not untouched by Jewish influences) of popular Gentile-Christian thought. The Johannine Apocalypse is chiefly interesting as an apocalyptic. F. C. Baur and his school interpreted it as a manifesto of anti-Pauline Jewish Christianity; on the contrary, it closely approaches Paul's doctrine of the Atonement and his Christology. Other writings are of less importance. Acts is indeterminate in one sense as the book of the theocratic kingdom, in another as a book which writer wishes to reproduce his great master's thought, but his Paulinism is simplified and cut down. Possibly the Pastoral Epistles show the same process. When we go outside the New Testament, this involuntary lack of grasp becomes even more marked.

Neither the theory of infallible inspiration, with its assertion of absolute uniformity in the New Testament, nor Baur's criticism, with its denial of Paul's authorship, is based on any facts. The New Testament is many-sided, but it has a predominant spiritual unity. Only in minor details do contradictions emerge. It is to be remembered that criticism has broken up the historical unity of the New Testament collection and placed many of its thoughts, without that understanding or that feeling, which has been transformed. 1 Peter is good independent Paulinism. Modern Christians generally trust this development; and all of them must admit that it seeks to answer a question arising out of the elements of New Testament belief. There is one God; but also there is a Christ. The claim that can be put forward for the doctrine of the Trinity is that it is loyal to Christ without being disloyal to the Divine unity. Consequently it holds that, by reason of its critical or philosophical interest, and some to prefer to Trinitarianism as a reconciliation of the personality with the infinity of God. But the biblical materials worked up in the doctrine betray little sign of any except a religious intuition. Yet it is to be said that the current of modern Christology, as we will see, is all the more convincing that it is from the Gospel, and it is the Gospel itself. To refer, for example, to the Fourth Gospel in this connexion, and it is doubtful whether Matt. xv. 27 will bear such weight as it puts upon it. Of course, we might make this the ground of a further argument of Christ. But without pedantic ultra-Protestant devotion to written scripture, one may distrust on scientific grounds the attempt to reconstruct tradition by a process of inference. If such records as John vi. 55, and xii. 27 can be taken as historical, we may feel certain that Jesus taught his pre-existence. If not, modern Christian minds will hardly regard the doctrine as more than a speculation. Yet we should mention another element of weight. There is the suggestion that, among any Jewish criticisms challenged St Paul's Christology. This may point to its being the Christology of the whole Church. If so, who could first teach it except the one Master? Moreover, it has been suggested that the "Son of Man" (Dan. vii. 13), used by Jesus, may have come to imply for all early Christians personal pre-existence. W. Wrede and others have more boldly conjectured that the Christ's pre-existence had become an accepted element in the prophetic teaching of the OT before the time of Jesus. It is possible that the Book of Enoch included a Christology, and that Paul merely transferred to Jesus a doctrine which he had held while in the Jewish religion, but not as part of their scriptural ancestry. But the pre-existence of Christ's Sonship has not been free of use of the title as a metaphorical honour, and we have no proof that any Jewish school interpreted the phrase differently.

The rival type of early theology is known as Adoptionism or Adoptionismism (q.v.). According to it, the man Jesus was exalted Adoptionismto Messianic or divine rank. It has been argued that the Chrestos baptism points to a Adoptionist derivation of this belief. Whatever role Joseph? may have had in the development of the Christ, it is clear that the Nazarene tradition of the Virgin birth (Matthew, Luke) is an intermediate stage in Christology. When pre-existence is clearly taught (Paul, John), the virgin birth is suggested, loses its importance; another theory of the Virgin birth has established itself. This trenchant analysis is, however, not universally admitted. Further development of doctrine need not be attributed to the last traces of Adoptionist belief, though Christ's exaltation continued to be taught in correlation to His humiliation (Phil. ii. 8), and became in due time a dogmatic locus in Protestantism.

The lineaments of Greek Christian theology show themselves more clearly in Justin Martyr than in the other Apologists, but still more plainly in Irenaeus, who, with little speculative power, keeps the same mark of the Augustinian influence as the Western church in the Middle Ages. He was a lawyer as a curious coincidence, nothing more, and those legal concepts which show themselves strongly in him have done much to mould the Western type of Christian theology. He had great influence on the course of Latin theology, partly through his own writings, but still more through the spell he cast upon Cyprian. At Alexandria, Clement and his great pupil Origen state Christian in terms of philosophy. Origen's treatise, De Principiis, is the first and in some respects the greatest theological work in the whole of Church history. The Catechetical School was primarily oriental in its influence and inquirers into Christianity. But it had attained the rank of a Christian university; and in this treatise Origen does not fertilize for milk for babies; he writes for himself and for like-minded friends. Wildly conjectural as it may seem, his thinking—though partly Greek and only in part biblical—is completely fused together in his own mind. Nor does it ever suffer from lack of thoroughness. It may be summed up in one word as the theology of free will.

Unfeathering use made of that conception as a key to all religious and moral problems. Usually, apologists and divines are hampered by the Arian position, that the Logos is a creature of God, and regarded as separable moral units. A new world, after death, may be called in to redress the balance of the old; but anomalies which make it in a future immortality does not touch. Origen called in the Logos as a being more great than the angelic, and thus created with equal privilege; all fell, save one, who steadily clung to the Logos, and thus merited to become in due time the human likeness of Jesus Christ. No higher function could be given to free will; unless by an extraneous, some say, pre-existent Logos of God. But there is a sense in which the Almighty Himself had merited His sovereignty by the virtuous use of freedom. On the other hand, a shadow is cast upon the future by Origen's fear that incoetllectable free will may again depart from God. Human birth in a grossly material body is partly due to the pre-temporal fall of souls; here we see in Origen the Greek, the dualist (mind and matter), the ascetic, and to some extent the kinism of the Gnostics. But he breaks away again when he asserts that God ever wills to do good, and is seeking each lost soul until He find it. Even Satan must repent and live.

It was not possible that this brilliant tour de force should become the theology of Christendom. Origen contributed one or two points to the central development of thought; e.g. the Son of God is "eternally" begotten in a continuous process. But while to Origen creation was a continuous process, an unspeculative orthodoxy struck out the latter point as inconceivable. But history and biographical method was of his great price. The eternal generation of the Divine Son adds a more distinctive glory to the Logos when it is no longer balanced by an eternal creation. While the Church thus lived upon fragments of Origen's wisdom, lovers of the great scholar and thinker, who had dominated his age, and reconciled many a hetero to his own version of orthodoxy, must submit to have him branded as a heretic in later days, when all freedom of thought was falling under suspicion.

For a time, freedom in scholarship lingered in the younger rival of Alexandria, the school of Antioch; though speculation never so strong there. Alexandria, on the other hand, tended to be unduly speculative and allegorizing even in its scholarship. The antagonism of the two schools governs much of the history of doctrine; and behind it we can trace in part the contrast between Church Platonism and what churchmen called Aristotelianism.

Arius, a Libyan by birth, of Antioch by training (though earlier than the greatest days of that theological school), and a presbyter of Alexandria, represents the work of Arianism. Arius' chief claim to fame is his advocacy of the Son of God as the greatest, if not the greatest Christian, if Origen is the greatest thinker, among all the Greek fathers. Few will deny that Athanasius stood for the single issue, that the supreme and divine chamber of the Logos, was used to believe in a divine redemption. According to Harnack, Athanasius simplified the faith of his time by fasting on the essential point—human immortality or "deification through the Incarnation of the Logos. Cosmic theories of the work of a Logos subordinate to the Father fell into the background. Origen, successfully discredited earlier as a Sabellian formula by Paul of Samosata, was now found to be the one unambiguously which assured the Gnostics of Origen, and the Logos of Christ was truly God (Council of Nicaea, A.D. 325 and Tertullian (Lact. Persona) became the technical name for each of the Divine Three. Trinitarianism, himself tried to draw a distinction between affirming the Son υἱός and calling Him μωρον. Yet it seems plain that he considered Sabellianizing reduction of the Divine Persons to phases or modes in the unity a lesser evil than regarding the Logos (with Arius) as a creature, however dignified. This was made plain by the fact that Athanasius and his followers were excommunicated. Marcellus. Marcellus and Marcellus. In those days there was no word for "Person" as modern philo-

Of course this does not mean that Harnack considers monophysism nearer the historic truth, or nearer the normal type of Christian thought.

On these lines modern Trinitarianism maintains the doctrine of the Trinity. It seeks to prove its case by asserting first the divinity of Christ, and secondly the personality of the Holy Spirit. The modern idea of personality, though with doubtful fairness, helps the change.

The first great supplement of the doctrine of the Logos or Son was the more explicit doctrine of the Holy Spirit. Macedonius, who defended the semi-Arian or Homoioanenisian position that the Spirit was merely a Divine in the duality rather than an entity against Nicene, and his faith ultimately conquered the Catholic Church. There is only this to notice, that it conquered under the great Cappadocians (Basil, Gregory Nazianzen, Gregory of Nyssa), in somewhat different type of teaching. The Trinity in Unity stood firm; but, instead of recognizing God as one yet in some sense three, men now began to recognize these divine beings, somewhat definitely distinguished in rank each from each and yet in some sense one. Arians' piety is thus brought into association with the details of Logos speculation. The new type passed on into the West through Augustine, and the so-called Athenian creed, which was an Augustian version of Greek dogma. There is indeed one immense change. Subordinationism is blotted out, more even than by Athanasius. On these lines modern Trinitarianism has developed.

Augustine's Trinitarianism.

Doctrine of the Holy Spirit.

The monophysite view, developed out of the Alexandrian tradition ("Eutychianism is simply Cyprianism run mad," A. B. Bruce). The Council of Chalcedon (431) rejected the Alexandrian extreme in its turn, guided by Leo of Rome's celebrated letter, which put the emphasis on the unity in Christ's person. Another grave and lasting schism was the result. Two great doctrinal traditions had thus been anathematized; the narrow line of orthodoxy sought still to keep the middle track. Was there at least unity of will in Jesus? No, said orthodoxy; He had two independent faculties of will, divine and human. The Manories of Syria, reconciled to the see of Rome in 1189, probably represent the Monothelite schism. John of Damascus' theory of Enhydrastasia (Christ's manhood not impersonal, but made personal only through union with His Godhead) is held by some to be the copemone of this great dogmatic development.

In the Trinity the problem is to combine independence and unity; in Christology, to combine duality of nature with the unity of the person. Verbally this is done; is it done substantially? The question, Who is Jesus Christ? has been pushed to the very end, and authoritatively answered in the definitions of Church orthodoxy. With these the Orthodox Greek Churches—and with their divergent decisions the various non-Orthodox Eastern Churches, Coptic, Armenian, &c.—desire to rest satisfied; theology has finished its work, unless in so far as it is to be codified. It is never true while men live that thought is at a standstill; but, as nearly as it may be true, Eastern theology has made it so. In the West the decisions of the great councils have been accepted as a datum. They enter into the basis of theology; results attained by long struggles in the East are simply presented, if not even confirmed, to the West. While that independent interest attaches to them in the Western world.

They are taken as involved in redemption from sin—the Atonement, or in the sacraments. Belief in the Trinity is almost unbroken. Western Christendom wishes to call Christ God; even the Ritschlian school uses the wonted language in the light of its own definitions. For others, the Trinity is the accepted way of making that confession. It becomes of practical importance, according to T. S. Coleridge, in connexion with Redemption. It passes, therefore, as a datum of revelation. In Christology the tradition has been more frequently challenged since the Reformation.

Harnack criticizes the doctrinal development. He considers that Christianity is best defended on the basis of the doctrine that Christ is a man chosen and equipped for his task by God. But in the Eastern Church the religious interest, as he thinks, points to something which is not mere humanity in Christ. It is that which makes Christianity, or thrown it upon inferior forms of piety. Of course this does not mean that Harnack considers monophysism nearer the historic truth, or nearer the normal type of Christian thought. The Modern Schismatic, and Antioch more nearly reaches the real historical manhood of Jesus. But if it be presupposed that the purpose of Christ's mission was to be fulfilled by the Godhead of Christ, it may be assumed, first, Christ's essential Godhead, and, secondly, the fusion of His divine and human natures. Whatever be the truth in the assertion that death rather than sin is the enemy dreaded by Eastern Christianity, and imperfection rather than forgiveness the blessing craved, it is difficult to take the talk about deification as anything more than rhetoric. Did they not start from belief in one God? Was not polytheism still a living enemy? It is a more obvious, if perhaps a more vulgar, criticism of the great development in the East—its intellectual—seeking clear-cut definitions and dogmas without measuring the resources at the command of Christians or the urgency of their need for such things. We are sometimes told that the councils simply denied error after error, affirming little or nothing. But the Trinity and the Hypostatic Union are vast speculative constructions reared upon slender foundations. The whole Schism of a theological adversary is a recognized move in the game; it may commonly be played in good faith; it proves little or nothing. The facts appear to be, that the Church embarked confidently on the task of monophysitism, and much of it was achieved. Biblical exegesis in these minds in that age as a rational (i.e. neo-platonic) construction, but that in Christology the data or the methods proved less tractable. Now two natures, or two wills, or two persons, or what can the humanity be except one drop in the ocean of divine power, wisdom, goodness? The biblical authorities plainly set forth the man Christ Jesus," but theological science failed to explain how Godhead and manhood came together in unity. East and theory sprang asunder; for theory had done its utmost, and was baffled. Another admission ought to be made. Western contributions to the prolonged debate constantly tended to take the form of asserting truths of faith rather than theories. Yet was the whole process but a colossal theory? 4

One perplexity connected with theology is the question, How far does Christianity succeed in embodying its essential interests in its doctrines? The Orthodox Eastern Church might seem to have succeeded beyond all others. Facets of lay-folk, who quarrelled furiously over shades of opinion never heard of in the West, and scarcely intelligible to Western minds even if expounded, might seem to have placed their sincerity beyond all question. And yet there were at least two other developments which were important in the history of the Church in the East—the legal development and the sacramental. The name "Catholic" is one which Protestant Christians may well

1 Harnack and F. Loofs describe them as belonging to the Homoioanenisian party—believers in the Son's "likeliness of essence to the Father's". "Identity of essence." Bethune Baker vehemently denies that these great leaders were contented with Homoioanenisianism. Anyway, we must remember that radical theology had been to much greater extremes in denial (Anamnoence—the Son unlike the Father) if it was not by any means exclusively the "battle of a diphthong."

2 Spanish Adoptionism breaks up the unity almost without disguise.

3 Cf. Aids to Reflection, Aphorism 2, Comment.

4 A. M. Fairbairn takes the rather unusual view that Greek Christian theology was the climax of the process of Greek philosphy, and so far alien to piety, although he is far from banishing speculation out of theology. Christ in Modern Theol., pp. 81, 90, 183.

Further elements in Catho- B. H.
hesitate to resign to their rivals. Yet there is convenience and no small significance in connecting the terms with a certain characteristic and un-Protestant type of the Christian mind. Catholicism is not dogma only, but dogmas plus law plus sacrament. From very early days Christianity was hailed as the "new law"; and the suppression of the rigorist sects, by definitely giving law supremacy over enthusiasm, aggrandized it, but at the same time aggrandized the sacraments. The Western Christian must needs hold that the Eastern development was incomplete. It laid these things side by side; it did not work them into a unity. The latter task was accomplished with no little power by the Western Church in the period of its independent development. The Greek, and the Roman Catholic Churches stand united against Protestantism in the general theory of law and of sacraments; but a Protestant can hardly doubt that, if Catholicism is to be accepted, a Catholic organization, and doctrine are better furnished by the Western Church than by the arrested development of its rival.

The theory of asceticism had also to be more fully worked out and better harmonized with Church authority. The priesthood had successive rivals to face. First in the period of "enthusiasm," the prophets; then the martyrs and confessors; finally the ascetics. The leading published forms are the permanent elements of Catholicism; and the rivalries of these "regular" clergy with their "seemly" or parochial brethren continue to this day. Hence the whole intrinsic morality that not every one is called to, that the call is imperious when it comes, and that asceticism must be developed under Church control—all this is common to East and West. But, in the utilization of the materials to the best of the Church's forces, the Western Church far surpasses the East, where meditation rather than practical activity is the monastic ideal. In the West, "enthusiasm," in the transformation under which it survives, is not merely bridled but harnessed and set to work.

The new developments of the West could not grow directly out of Eastern or even out of early Western conditions. They grew out of the influence of Ambrose of Milan, but far more of Augustine of Hippo; and behind the latter to no small degree there is the greater influence of St. Paul. Intellectual developments do not go straight onward; there are sharp and sudden reactions. Pelagianism, the rival and contradiction of Augustinianism, represents a mode of thought which appeared early in Christianity and which could count upon sympathizers both in East and in West. But, when the Christian world was faced with the clear-cut questions, Was this, then, how it conceived man's relation to God? and Did it mean this by merit? Augustine without much difficulty secured the answer "No." In the East (Council of Ephesus, 431) he was helped by the entanglement of Pelagianism with Nestorianism, just as in the West the ruin of Nestorian prospects was occasioned partly by dislike for the better known system of Pelagianism. In Augustine's own case, reaction against Pelagianism was not needed in order to make his position clear. He may have left a vulnerable frontier in his earlier dealings with the same thorny problem of free will. Certainly his polemic as a Christian against the Manicheism of his youth constitutes a curious preface to his vehement rejection of Pelagian libertarianism. Once again, a narrow track of orthodoxy midway between the obvious landmarks! But Augustine had a deeply religious nature, and passed through deep personal experience; these things above all gave him his power. He was also genius and scholar and churchman, transmitting uncriticized the dogmas of Athanasianism and the philosophy of ancient Greece, according to his understanding of them. Without forgetting that Augustine was partly a symptom and only in part a cause—without committing ourselves to the one-sidedness of the great-man method of construing history—we must do justice to his supreme greatness. If earlier times lived upon fragments of Origen, the generations of the West since Augustine have largely lived upon fragments of his thought and experience. On the other hand, not even the authority of Paul and of Augustine has been able to keep alive the belief in unconditional predestination. If in the West Augustinianism is a datum, but unexamined, and not valued for its own sake, Augustinianism is a bold interpretation of the essential piety of the West, but an interpretation which not even piety can long endure—morally burdensome if religiously impressive. The clock is wound up at the great crises of history, but proceeds to run down, and does so even more rapidly in Protestantism than in Catholicism. It may be held by hostile critics that the whole thing is a delusion. More sympathetic judgments will divine unquenchable vitality in a faith whose dogmas rise and grow as a result of Augustine's (erroneous) interpretation of the Millennium (Rev. xx.), as a parable of the Church's historic triumph, stands for the final eradication of primitive "enthusiasm" in the great Church, though of course millennialism has had many revivals in special circles.

Even if the Augustinian stream is the main current of Western piety, there are feeders and also side-currents. Ambrose, Augustine, Jerome, Gregory the Great are known as the four Latin Fathers. But the Church is a great and not a small affair, as a Catholic historian would say. Perhaps two side-currents of piety should be named. There is an ethical rationalism which can never be wholly suppressed in the Christian Church by the Pauline or Augustinian soteriology. One thinks of it, though held down by other influences, in the whole of medieval theology, and notably in Abelard. It disengages itself in the 17th century as Socinianism and in the 18th as Rationalism or Deism. Secondly there is a strong side-current in the mystical tradition, which we may perhaps treat as the modified form under which the philosophical theology of the Greek Church maintained its life in the medieval West. If so, Mysticism includes in itself a prophecy of modern Christian Platonism or idealism, with its cry of "Back to Alexandria!"

A Western echo of the Christological controversies of the East is found in the Adoptionism of Spain (755-818). These Adoptionists do not hold that Christ the person is adopted (He is God by birth), but his human nature may be. There might be need of this, indeed, if the Adoptionists' theory of redemption were to stand, according to which Christ had taken to Himself a sinful human nature, and had washed it clean. This extreme assertion of duality as against Christological unity was naturally marked as heretical.

Great advance is made in organizing Catholic theology by the fuller theory of sacraments. The East had a tentative hesitating doctrine of transubstantiation; the West defines it with absolute precision (cf. Paschasius Radbertus against Ratramnus; the fourth Lateran Council, 1215). But the medieval Church and modern Catholics regard the Eucharist as the principal sacrament, Protestants can hardly keep from assigning the supreme place, in the medieval system, to the sacrament of penance. If early enthusiasm conceived the Christian as almost entirely free from acts of sin, and if Protestant Paulinism conceives the child of God as justified by faith once for all, the full Catholic theory, representing one development of Augustinianism, views the Christian as an invalid, perpetually dependent on the good offices of the Church. The number of sacraments is fixed at seven, first by Peter Lombard, and the essence of the three sacraments which do not allow of repetition—baptism, confirmation, orders—is defined as a "character" impressed on the soul and never capable of being lost. We must mark the advance in formal completeness. Theology is not merely the doctrine of the Divine nature or of Christ's person; it is also a

---

1 Loofs declares that the very conception of a means of grace is medieval.

2 The term Adoptionist arose at this time. Modern theologians carry it back to much earlier views.

3 Until indeed, in the later times, Greek theology accepted the Western term and definition.

4 This, too, has been adopted in modern Greek theology.

5 Augustine already has this conception (Loc. 20); the critic might say that the conception affirms the absolute worth of sacraments while absolutely declining to say what they accomplish.
THEOLOGY

theory of how the Christian salvation is conveyed through sacraments to sinful men. On the other hand, a theology which is mainly sacramental is overtaken pretty soon by dumbness. It is of the essence of a sacrament to be an inscrutable process.

Theories of legal merit, amount of debt, supererogatory good-
ness, and ascetic claim—representing the aspect of Catholicism as law—are more and more worked out. The occasion of the formal separation of East and West—the Western doctrine of the twofold process of the divine Spirit, incorporated in the

identified Nicodemus creed itself ("filioque")—is of complete
real theological importance. The schism was due to race rivalries, and to dislike for the ever-growing claims of the see of Rome.

An important contribution to doctrine is contained in the Cur Deus Homo of Anselm of Canterbury. The doctrine of Anselm, Atone-ment, destined to be the focus of Protestant evangelicalism, has remained undefined in Catholic circles, an implicit or presupposition, but no part of the explicit and authorized creeds. When treated in the early centuries, it was frequently explained by saying that Christ's sufferings bought off the devil's claim to sinful man, and some of the greatest theologians (e.g. Gregory of Nysse) added that the devil was finely outwitted—contracted by the halt of Christ's humanity, but caught by the hidden hook of His divinity. Anselm holds that it was best for the injured honour of God to receive from a substitute what the sinner was personally in no condition to offer. Whatever other elements in suggestions are present, the atmosphere of the medieval world, and its sense of personal claims, are unmistakable. With Anselm Ritschl takes Abelard, who explains the Atonement simply by God's love, and thus is the forerunner of "moral" or "subjective" modern theories as Anselm is of the objective or "forensic" theory. It must be admitted, however, that he is not the original in Abelard's time, that he was not Anselm. He does not even deal with the doctrine as a specialist, in a monograph, but only as an exegete.

Contemporaneously with the new and vivid intellectual life of an Anselm or an Abelard, the "freezing up" of traditionalism is evidenced by the preparation of volumes of Sentences from Scripture and the Fathers. One of the earliest of such collections is that of Isidore (q.e.) of Seville (560–636), who, from this mass of writings, retrenched the few chapters of unconvoked ancient learning to the middle ages. His Sentences are selected almost (though not quite) exclusively from Augustine and Gregory the Great. Direct influence from the Greek Fathers on the West is manifest in the Gregorianism is forgotten. The great outburst of Sentences at a later time has been referred to the consternation produced by Abelard's Sic et Non. The modern reader can readily banish the impression that Abelard writes in the spirit of mere schiffiness. Probably it would be truer to say that he rots in the pleasures of discussion, and in setting tasks to other irresponsible and ingenious spirits. He does not fear to contrast authority with authority, upon each point in succession; the harder the task, the greater the achievement when harmony is reached! In regard to Scripture alone does he maintain that seeming error or discrepancy must be due to our misinterpreta-

tion. If throughout the middle ages Scripture is treated as the ultimate authority in doctrine, yet Abelard seems to stand alone in definitely contrasting Scripture with later authorities. Moderns will question the possibility of asserting Bible infallibility a priori, but it is more really startling and noteworthy that Abelard should preserve a living sense of fallibility outside the Bible.

There are many great collections of Sentences, notably by Hugh of St Victor and Pierre Lombard. The last-named—though with more continuity of texture than Isidore—quotes largely from the Bible and the Latin Fathers. If Abelard stands for the intel-
llectual daring of scholasticism, Lombard represents its other pole—interest and piety—within the Church. He is almost timidity cautious. He does not open up difficulties like Abelard, but smooths them over. This suits the coming age. The great writer of his time was a scholar's and men's writer not in the breadth of their treatment but in a theological penmanum. And the characteristic task for living theologians was to consist in writing commentaries on the Lombard's Sentences; for a time these were the only ones that existed, and men's minds were not in the breadth of their treatment but in a theological penmanum. And the characteristic task for living theologians was to consist in writing commentaries on the Lombard's Sentences; for a time these were the only ones that existed, and men's minds were not in the breadth of their treatment but in a theological penmanum.

Had this been all, Western theology might have sunk into a purely Chinese devotion to ancient classics. But the medi-

eval world had not one authority but two. Thin and turbid, the stream of classical tradition had flowed on through Cassiodorus or Boethius or Isidore; through these, at second-hand, it made itself known and did its work. But before the great outburst of scholasticism, ancient literature found a somewhat less inadequate channel in Arabic and partly even in Jewish scholarship. Aristotle was no longer strained through the meshes of Boethius; and the new light inspired Roscellinus with hery. The Medieval must be separated from the scholastic. There was no genuine renaissance of civilization, such as marked the dawn of modern history. The medieval world did not copy the free scientific spirit of Aristotle; it made him, so far as known, a sort of philosophical Bible side by side with the theo-
litical Bible. But it was a very great matter to have two authorities rather than one. And if any man was to be put in the preposterous position of a secular Bible, no writer was fitter for it than Aristotle. The middle ages did their best in this grouping; only here and there a rare spirit like Roger Bacon did something more, something altogether superior to his age, something that could find the fault with the scholasticism every-thing was not quite extinct. It is possible to exaggerate the influence of the revived knowledge of Aristotle; but, so far as one can trace causes in the mysterious intellectual life of mankind, that influence gave scholasticism its vigour. (See ARABIAN PHILOSOPHY, SCHOLASTICISM.)

With the new knowledge and impulse, there came a new method. Alexander of Hales is the first to adopt it, in place of the "rhetori-
cal" method of previous theologians. Everything is now matter of debate and argument. The Sentences method was adopted with increasing enthusiasm; with scholasticism each topic dissolves into a string of arguments for and against. These arguments are made up of "ratiocines" and "argumenta" ("proofs") which are held together by ar-

tories. They are as litigious as a lawsuit—without any summing up; it all comes in a moment with a text of Scripture or an utterance by one of the great Fathers. Once such a dictum has been cited, the rest of the discussion is treated by as by and goes for nothing. "I am a transmitter," Confucius is reported to have said. The great schoolmen were transmitters—putting in order, stating clearly and consecutively, conclusions reached by their predecessors. But the scholastics have failed to pe-

ant? Their guarantee is the tireless criticism carried on by rival systems. No parallel display of debating acuteness has ever been carried through in the schools. Moderns are driven by their need to keep their minds bright and clear. The schol-

men. Indolence in every age escapes difficulties by shirking them, but the schoolmen's activity raised innumerable awkward questions. On the other hand, they possessed to perfection the scholastic method of "under-estimation." They worked in the doctrinal foundations of the Church, it will be a tacet under-

standing among the schoolmen that such questions are not to be pressed. Above all, one must not look to a schoolman to speak "a piercing and a reconciling word." There is no revision of the premises in debate from a higher or even from a detached and independent point of view. The premises from which he may select are fixed; many of the conclusions to be reached are also fixed. He speaks, most cleverly, to his brief, but he will not go outside it. He may argue as he likes so long as he respects the Church's decisions and reaches her conclusions.

That schoolmen always sat in glory above the schoolmen. And their rank above their contemporaries upon the Lombard's Sentences, as the greatest of all systems of theology. Especially is that honour due to St Thomas Aquinas's larger Summa Theologica. A we may briefly remark that he is called to his inferior, and in a way best. He is not an Augustine, still less perhaps an Aristotle, but he is the Aristotle and the Augustine of his age, the normal thinker of the present and the lawyer of the future. He teaches the medieval Platonic realism, but he accepts the Aristotelian philo-

sophy of his day, marking off certain truths as proved and under-

stood by the light of nature, and stamping those which are not so proved as not understood or understandable, i.e. as "myster-

ies."
necessarily. To use technical language, Calvinism holds that sacraments are needful ex ratione praecepti, (merely) because they are needful; in this sense, they are needful, for baptism and the Lord's Supper are both necessary to teach baptismal regeneration and consubstantiation, as well as justification by faith. It is hard to see how the positions harmonize. Zwingle and Calvin, developing a hint of Hus, introduce a distinction of the sacrament of the Eucharist; the former repudiates but later Lutheranism adopts. The Articles of the Church of England (19, 26) speak of the visible Church, but unless by inference do not assert a Church invisible. Upon most points Anglicanism seeks for a via media between Calvinist and Protestant in early days and even Calvinistic, it yielded to the suggestions of its episcopal constitution and sacramental liturgies; and to its theologians range from Calvinism at one extreme and Catholicism at the other. Historically, great issues have hung upon the dislike by which High Lutheranism and High Anglicanism, those two midway fortresses between Rome and Geneva, have been estranged from each other.

It is thus plain that the stream of Protestantism was very early split up into separate channels. Did any of these theologies do justice to the great master thought of grace given to faith? Antecedently to their separation from each other the Reformers took over the theology of Greek orthodoxy as a whole. Complaints against that theology may be quoted from early writings of every Reformer, even Calvin. They knew well that the centre of gravity in their own belief lay elsewhere than in the elaborately detailed scheme of relations within the Godhead or in the Theanthropic person. But ultimately they persuaded themselves to accept these definitions as normal and biblical, and made them the presupposition of Christ's saving work. The decision had immense results, both for orthodoxy and for theology. Nor did the unity of Protestant theology—Lutheran and Calvinist—confuse itself to the period before the great divergence. Men of the second or third generation—often called the "Protestant Scholastics"—worked together upon two characteristic doctrines which the fathers of Protestantism left vague. The Reformers hold that the doctrine of Atonement, with St Anselm, in making God the guarantor of a system of public law rather than of His private or personal honour. This conception came to be more fully defined. Christ's twofold obedience, (a) active and (b) passive, produces jointly a twofold result, (r) satisfaction to the moral law, (a) merit, securing eternal life to Christ's people. There is no such full and careful theory of Atonement in any Catholic theology, and, according to so unbiased a judge as A. Ritschl, it represents the last word in doctrine along the lines laid down by the Reformers. Could Catholics adopt it? Hardly; for the Protestant assertion of Christ's merit is shadowed, if any doctrine of merit in the Christian is brought in. Yet the very words remind us of the legal piety which characterizes Western popular religion through its history. We now find "merit" confined to Christ, and the usual application ruled out, somewhat as St Paul's intense use of Pharisaic conceptions destroyed instead of confirming the idea of righteousness by works. But it is by no means clear that this Protestant doctrine of Atonement is a unity. "Merit" is an intruder in that region of more strict and majestic law; yet Christ's "merit" is the only form under which the positive contents and promises of the Christian Gospel are there represented. Even the most requisite modern orthodoxy usually tried to modify this doctrine. They break with the past, which no revival or reaction can quite conceal. Again, the Reformation had drawn a line round the canon—sharply in Calvinism, less sharply in Lutheranism which also gave a quasi normative position to its Confessions of Faith. Anglicanism once more resembles Lutheranism with differences.

Few Lutheran churches possess bishops. In Germany the "episcopal system" is a right claimed on behalf of the civil government. The doctrine is not fully formulated even in the Lutheran Formula of Concord, nor yet in the Calvinistic canons of Dort and Confession of Westminster, though these and other Protestant creeds have various instalments of the finished doctrine. One might add a still further distinction of the Protestant scholasticism. The Amyrtium imparts to the believer (a) forgiveness, (b) positive acceptance. Actual renewal is, of course, something beyond either of these.
it enjoins public reading of certain lessons from the Apocrypha and uses in worship even the "Athenian" as well as the two more ancient creeds. On the basis of belief in inspiration we find, during the days of Protestant scholasticism, the most reckless and insane assertions of scriptural perfection. Even in our own time, popular Protestant evangelicalism joins with the new emphasis upon conversion the two great early Prot- estant appeals—to Atonement and to infallible Scripture. But the Protestant Church is by no means alone in making such assertions. Other Churches make them too, though they overlay and disguise them with appeals to tradition and to the authority of the Church itself, or the Fathers. The definite and limited burden had to be more definitely dealt with; hence these Protestant extravagances.

The first great rival to Protestant orthodoxy, apart from its old enemy of Rome, was Socinianism, guided by Laelius Socinus. Socinus's doctrine was, more or less, by his nephew Faustus Socinus. Thoroughly intellectualist, and rational, and supernaturalist, it has no one to champion it to-day, yet its influence is everywhere. Jesus, a teacher who sealed His testimony with His blood, and, raised from the dead, was exalted or adopted to divine glory, thus giving to men for the first time the certainty that God's favour could be won and eternal life enjoyed—such is the scheme. There is no natural theology; the teachings so described are really part, or rather are the essence, of the revelation of Jesus. Atonement is a dream, and an immoral dream. Supernatural sacraments of course drop out. The Lord's Supper is a simple memorial. Baptism were better disputed, though Faustus will leave the matter to each Christian man's discretion. There is not in all Church history any statement of doctrine better knit together. Socinus's church is a school—a school of enlightenment. He was also—like Calvin, if on more narrowly common-sense lines—an admirable exegete. Harnack ranks his system with Tridentine and post-Tridentine theology on the one hand, and with Protestantism on the other hand, as the third great outcome of the history of dogma. Nevertheless the judgment of history declares that this brilliant, most brilliant, was entirely eccentric, and could only in indirect ways subserve theological study. Those to-day who are nearest the Socini in belief are as far as any from their fashion of approaching and justifying their chosen version of Christian doctrine.

Even after the loss of the Protestants and the suppression or expulsion of the Jansenists, the doctrinal history of the Church of Rome is described as governed by discus- sions in regard to Thomist Augustinianism. The Molinists (i.e. followers of Louis Molina the Jesuit, not Michael Molinos the mystic) are the leading representatives of a different theology. Harnack, a keenly hostile critic, draws attention to a change in the region of moral theology, not dogmatics. After long controversy, St. Alfonso Liguori's doctrine of Predestination (originated by Molina), definitely triumphed everywhere. Conduct is considered lawful if any good Church authority holds it to be defensible; and "probability" warrants the confessors in taking a lenient view of sins which he himself, and authorities of weight in the Church, may regard as blanks in the extreme. From Harnack's point of view, the theory destroys Augustinianism, whatever honour may still be paid to that name. Another important change in Roman Catholic theology has been the increasing personal power of the pope. This was significantly foreshadowed when Pius IV, put forward by his own act what is known as the creed of the Council of Trent; and, after the coldness of the 18th century and the evil days of the French Revolution, an Ultramontane revival, relying with enthusiasm on the papacy, grew more and more strong until it became all-powerful under Pius IX. It gained a notable victory when that pope, acting on his own authority, defined (1854) as of faith a doctrine which had been long and hotly discussed—the Immaculate or absolutely sinless Conception (deeper than mere sinlessness in act and life) of the Blessed Virgin. The second and decisive victory followed at the Vatican Council (1870), which, at the cost of a small secession of distinguished men, declared the pope personally infallible (see Infallibility) and irrefutable as often as he rules ex cathedra points of faith or morals. This once again seems to be the last word in a long development. Uncertainty as to the authorities determining religious belief—Scripture, tradition, Fathers, Doctors—is now, at least poten- tially, at an end; the pope can rule every point definitely, if he chooses to do so.

The theory of Development (J. A. Möhler, J. H. Newman), which throws so new a light upon the meaning of tradition, is a valuable support of the conception of a sovereign pontiff drawing out dogmas from implicit into explicit form. Still, new and obscure questionings may still arise. When is the pope ruling faith and morals from his throne? When may the Church be assured that the infallible guidance is being given? As startling a development is suggested by Harnack, who vehemently dismissed it as impossible by a former Protestant scholar, H. M. Gwatkin. May a reforming or innovating pope arise? He would find, in theory at least, that he possessed a weapon of matchless power and precision. But hitherto Roman Catholic theology has refused to conceive of any development except by enlargement of the Church's creed. Much may be added to formulated belief; it is not admitted that anything has been or can be withdrawn. Brilliant Modernist scholars like A. Loisy may have successors who will champion theories of evolutionary transformation. But at the present hour a repre- sentative of the writer maintains the traditional Catholic view in his commend of the Assumption of the Virgin. Perhaps we may say, the Assumption has lost a dogma hastening towards definition. Is the theory or tradition correct, that, after death and burial, Mary was bodily received into heaven and her grave left empty? Such problems engage the official theologians of the Church of Rome.

It is natural that the "variations" with which Bossuet re- approached the Protestants should demand more space. The Christological problem seems to require separate treat- ment. In regard to the Trinity, Protestantism has nothing very new to say, though "Sabellianism" is revived by Swedenborg and Schleiermacher. But in regard to Christology opinion takes fresh forms as early as Luther himself. While this became conspicuous in connexion with the doctrine of the Eucharist and the doctrine of the Resurrection, it appears that he had a genuine speculative interest in the matter. Communio idiomatum was well known in the schools as an affair of terminology. You might say correctly that God has died (meaning the Godman), or that a man is to be worshipped—Christ Jesus. According to Luther, however, it is not merely in words that the attributes of the Godhead qualify Christ's human nature. That takes place in fact; and so the human glorified body of Christ is, or may become under conditions which please Him, e.g. at the Enchurist, ubiquitous. This new quasi-monophysitism directed the Lutherans to make much of Christ's human nature; St. John's human nature is formed, partly from the scholarly tradition of Calvin, partly from the polemical laid great emphasis on the manhood. A. Ritschl even speaks of the Reformed as teaching Kenosis in the modern sense; but it is to be feared they rather taught alternately the manhood and the Godhead than made a serious effort to show the compati- bility of divine and human predicates in one person. Christ as man was one of the Elect (and their head); He needed grace; He depended upon the Holy Spirit. On the other hand, as God, He was the very source of grace. The Lutherans held that the Incarnate One possessed all divine attributes, but still bound to observe the doctrine of the Incarnation in the Lutheran school of Thübingen in the 17th century; or concealed their working; the latter was the doctrine of the Giessen school.

A theory which flickers through Church history in the train of mystical influence proceeding from the pseudo-Dionysius Areopagita has become more prominent in modern times—that Christ would have become Incarnate even had man not sinned. Rejected by Thomas, it is patronized by Duns—not, one thinks, that he loved rational certainties more, but that he loved redemptive necessities

---

1 According to I. A. Dorner.
2 To be sure, human predestination are not held to modify the Divine nature, except by modern Kenotists, who therefore, when they are Lutherans, claim to be completing Luther's theory.
THEOLOGY

less. In a sense this theory puts the coping-stone upon Christological development. If we are warranted in regarding the Second Person of the Godhead as in very deed "Himself vouchsafing to be made," that great Becoming cannot well be suspended upon a contingency which might or might not arise; and theologians in general regard the sin of man as such a contingent event. Incarnation almost demands to be speculatively interpreted as necessary, and self-manifestation and self-importing of God. Yet interest in man's moral necessities threatens to be lost amid this cosmological wisdom. Theology pushed too far may overlap itself. Those who shrink from the old confident assertion, "Christ would not have become incarnate but for man's sin," might claim to say, from reverence and not from evasiveness, ignoramus. On the other hand, the type of thought which would perfect Christianity in the form of a philosophy, and subordinates Atonement to Incarnation, is pledged to this doctrine that Incarnation was a rational necessity. Such speculative views are associated with the revival of another traditional piece of mysticism—the Holy Spirit the Cepula or bond of union in the Godhead. There is no such assertion anywhere in the New Testament.

For modern German theories of Kenosis among Luther and Reformed, see A. B. Bruce's *Humiliation of Christ*. Basing on the language of Phil. ii. 7, they teach, in different forms, that Christ was humbled because he surrendered the operations of conception at birth, and resumed divine predicates at His exaltation. It might be put in this way—a real human being, a really human experience. Such as are the terms of Phil. ii. 7, so we choose that St Paul had a metaphysical theory of Christ's person in view. In Great Britain and America many have adopted this theory. It is often taught, e.g. that Christ's statements on Old Testament literature are to be interpreted in the light of the Kenosis. The enemies of the theory insist that, while it safeguards the unity of Christ's personal experience at any one point, it breaks up by absolute guile the continuity of experience and destroys the identity of the person. Indeed, those forms of the theory, which give us a Logos in heaven (John iii. 13) along with the humbled or Incarnate Christ on earth, an over-riding canonicity even at the point of excision. Other suggestions in explanation of the mystery have been: a gradual Incarnation, the process not being complete until Christ's exaltation (I. A. Dorner's earlier view); impersonal pre-existence of the Logos, who became personal—compare and contrast Marcellus of Ancyra—at the Incarnation (W. Böschlag's earlier view, practically adopted by Dorner in his later days); Jesus the man who was absolutely filled with the consciousness of God (Schleiermacher); Jesus not to be defined in terms of 'nature,' either human or divine, but as the perfect fulfiller of God's absolute purpose (E. Lohse in later days, partly); the absolute (Böschlag). The orthodoxy which refuses all new theories may look for help to the pathological dissociation of personality, or at least (e.g. J. O. Dykes in *Expository Times*, Jan. 1906; Sunday Churchman May 1906) of the soul itself among those who song of the soul is in part modulated by the knowledge that a person has a soul even as a bird or a flower has a flower or a bird. We are not here concerned with the question of the sort of pre-existence which Christ had before the world was.
Protestantism has two principles: a "formal principle," the authority of Scripture, and a "material principle," the doctrine of justification by faith. We have already indicated that some such pair of principles was prominent when historic Protestantism pulled itself together for defense during its scholastic age. But surely serious thought cannot acquiesce in dual control. Pneumatically inspired systems have always believed to continue in power, there seems no hope of making theology a living unity, which will claim respect from the modern age.

One great attempt at unifying Christian theology came from the side of philosophy. Kant's scheme, which in religious theory as well as in chronology may be regarded as a link between the 18th and the 19th centuries, led on to the modern school of Hegel; and the latter system began almost at once to influence Church doctrine.

D. F. Strauss (gest) applied it with explosive effect to the study of the life of Jesus. P. C. Baur, assisted by able colleagues, if hardly less revolutionary, was much more in touch with theology than had been. The Hegelian threefold rhythm was to run through all history, especially for Baur through the history of the Christian Church and of its doctrine. Baur maintained a thorough-going evolutionary optimism. "The real was the rational" from first to last. However biased, this a priori study had its merits. It was not a theory but a method, and this it was which made Hegel, and less exclusively, but still as much, was Hegelian philosophy as a whole.

Influence of Hegelianism.

The orthodox wing of idealists take as their watchword Incarnation; Christianity is the religion of the Incarnation (sub-title of Hegel's "Theosophy of Religion"). B. F. Westcott, a typical representative of this philosophical view, consists in that Hegel's thought, which brings it into harmony with the philosophical scheme, is found in E. Erdmann and the theologians P. K. Marheineke and Karl Daub. Influences from Hegel are also to be traced in Richard Rothe, J. A. Dorner, A. M. Fabricius, and others. The second and last of the three great theologians Hegelianism has widely affected British theology. Schleiermacher him towards a post-historic interpretation of the New Testament.

Schleiermacher set himself to explain what is distinctive in religion. What is the relation of religion from philosophy as looked in contrast with thought; but when he has done that (Reden über die Religion, 1799) he has little to add. Any type of highly wrought feeling may make a man religious, some of them believe the whole spirit of Romanticism, Schleiermacher puts a peculiarly high estimate upon the pantheistic type. What else can we expect from a thinker who was so passionately in favor of the "soul"? Here his Gläubenschaft (1811) Schleiermacher had become much more of a Christian churchman. "Christianity is one of the theological pieties," and has as its peculiarity "that in everything is referred to the redemption accomplished through Jesus of Nazareth." But it is doubtful whether the elements of his final synthesis really interpenetrate. He tells us (Kurze Darstellung des theologischen Studiums, 1811) that the theologian, while himself loyal to Church, must expound, as a historian, the beliefs actually held in the church of which he represents. Oil and water do not mix. Do the unchecked individual enthusiasm of the Reden, and the loyal and enlightened philosophy of the system, combine to form a living theology? It is little wonder if Schleiermacher attains a compromise rather than a unity. He has been one of the great fermenters in modern Protestant doctrine both of the Right and of the Left. His position at between his general positions more nearly than any other. But there is no Schleiermacher church. W. Herrmann, from his own point of view, has quoted J. C. K. Hofmann and F. R. Frank as making important additions. (Die Philosophie der Religion, 1832.) In the last chapter of his "The Philosophy of Religion," he says laid down by Schleiermacher, while J. S. Clandish, representing a moderate Scottish Calvinism, was half inclined to welcome the rededication of the Church to the ideas of Jesus Christ, and to the influence of the church. J. T. Beck, and the Dutchman, J. j. van Oosterzee, i.e. Scripture the true source of doctrine, but the religious consciousness its ordering principle.

1 Hence R. B. Haldane, in the Scottish Church lawyer of 1904, is found telling the House of Lords that Justin Martlar had a grasp of speculative truth which was impossible to St Augustine. 2 Or the Dutchman, J. j. Scholten.
THEOLOGY

assumed a tainted human nature and washed it clean, thus making it a promise and potency of the world's redemption.

Even if we accept the programme of reconstructing theology from a single point of view, we may desire to criticize not merely Ritschl's execution of the scheme, but his selection of the ruling principle. Is it enough to extricate the spirit of Protestantism from the imperfect letter of its early creeds? Yes, one set of difficulties is raised by the progress of science. No Protestant can deny that it is a duty for Christianity to come to terms with scientific discoveries, and few Catholics will care to deny it. Anxious negotiations thus arise, which colour all modern schemes of theology. But with a certain school theory became central and dominant. I hope to place this position from the new emphasis on Christology, whether churchly or radical. Those who find a gospel in philosophy are ready to dictate terms to outsiders; but those who wait upon science for its verdicts supplant terms of peace. Just as much of Christianity is to survive as science will spare. Often the theologians in question look to psychology as the permanent basis of religion; who is to deny that religion is a psychological fact, and the natural expression of something in man's constitution? This strain may be recognized, mingled with other ideas. Scammel, for example, was interested in the contributions of H. J. Holtmann and Ernst Troeltsch to the volume dealing with Christianity in Die Kultur der Gegenwart. Christ is confessed as the greatest figure of the past, and as one of no small importance still for the present and future. But, with entire decision, Christianity is called to the bar of modern culture. From that tribunal there is to be no appeal, whether to a higher revelation or to a deeper experience. This view stands in connexion with the study of comparative religion. One of the main tasks of very Ritschl school, which began by despising all religions except those of the Bible, has developed the religionsgeschichtlich method, which dissolves Christianity in the wider stream. Such a policy is at the opposite pole to Ritschl's; he desired to interpret Christianity in the light of its own central thought. If Christians can find in their faith new resources to meet the new needs, they may hope to command the future. Theology if it is to live must be henceforth at once more Christian and more scientific than it has ever yet been.

A less threatening yet important possibility of modification arises out of the scientific study of the New Testament. Augustine, in his ecclesiastical revival, went back to St Paul; can Christianity not dig deeper by going back to Jesus? A Protestant has to view the past history of doctrine very much as a succession of declensions and revivals, the latter more than counteracting the former. He does not claim to have regained the inspiration of a Paul; but he holds that Augustine was more Christian than the sub-apostolic age, and Luther more Christian than Augustine. That is the hopeful feature in the past. The task for the present, with its unequalled scientific resources, is to get nearer than ever to the heart of the Gospel. Must Pauline categories always be supreme? The Ritschl school, and others too, have made an earnest effort to incorporate Christ's words in Dogmatic and no longer shunt them into systems of "Christian Ethics." They have not idolized Paulinism; but have they not idolized Luther? They seem to take for granted that the spirit—though not the letter—of that great man was a definitive statement of the Christian principle. To interpret Christianity out of itself is one thing; to interpret it out of Luther, even out of a distillate of Luther, is possibly a lower thing. The theology of the future may draw more equally from several sources, the types of doctrines. The scheme that includes most may be the successful scheme. Unity may be safeguarded in the confession of Christ, and theology indeed prove "Christocentric." Above all, the social message of Jesus may well prove a gospel to our materially prosperous

1 Thomasius and H. B. Smith are quoted as holding the "Christocentric" ideal. A. M. Fairbairn, mindful of the vast importance of the conception of God, amends the programme. Theology is to be formally Christocentric, materially Theocentric (Fatherhood of God), but inwardly sorrowful age. Any school of thought which despires that hope has small right to call itself Christian.

Casting a backward glance once more over the evolution of Christian theology, we may say very roughly that at first it recognized as natural or rational truth the being of the Logos, and as special fact of revelation the Incarnation of the Word in Jesus Christ. In medieval times the basis was altered. What had been rational truth now claimed acceptance as supernatural mystery. Modern idealists, ill at ease with this inheritance, try to show that Christ's Incarnation no less than His eternal divine being is a natural and rational truth. But, when this programme is carried out, there is no small danger lest the relations traced out between God and men should collapse into dust; of Christ transform themselves into symbols, and the idealistic theology of the right wheel to the left.

Again, Western theology, very roughly summarized, while accepting the earlier doctrinal tradition, has broken new ground for itself, in affirning as rational necessity that God must punish sin (this is at least latent in Aquinas's doctrine of natural law), but as contingent fact of revelation that God has in Christ combined the punishment of sin with the salvation of sinners; this is the Reformation's quasi- Reformation thought. Here again the question is raised: Is His mercy not as inherent as His justice? If so, must He not redeem? For, if He mayly redeem but must punish, then His greatest deeds on our behalf wear an aspect of caprice, or suggest unknown if not unknowable motives. The doctrine of penal substitution in the Atone- ment, as usually conceived, seems to point in the same direction as predestinarianism. Behind superificial manifestations of grace there is a dark background, almost like the Greek Fate. The ultimate source of God's actions is something either unintelligible or unfathomable. From this we conclude that in such a day especially it must seek to light up every doctrine with the genuine Christian belief in God's Fatherhood. And yet here again incautious advance may seem to overlap itself. If it should come to be held that with so kind a God no redemption at all is necessary, the significance of Christ is immensely curtailed if not blotted out. Even if He should still be taken as the prophet of the divine good will, yet the loss of any serious estimate of sin makes good nature on God's part a matter of course. Christianity of such a type is likely to be feeble and precarious. Perhaps more is third and best possibility by aiming at a scientific understanding of God, either limited or unlimited. Perhaps what concerns the Christian is rather the assured revelation that God is acting in character, like Himself, and yet acting wonderfully by methods which we could not predict but must adore. The free life of personal beings is no more to be mastered by a formula than it is to be assigned to caprice. A God who is love will act neither from wilfulness nor from what is called rational but might more correctly be called physical necessity. He will act in and from character. Always wise, always holy, always unsearchable, the Christian God is that heavenly Father who has His full image and revelation in Jesus Christ.

While the greatest of all theological systems, the Summae of the middle ages, include everything in the one treatise, it has been the business of post-Reformation learning to effect a formal improvement by distributing theological studies among a definite number of headings. The new theory lived and grew throughout the 18thcentury Age of Enlightenment (e.g. J. S. Semler), connecting Protestant scholasticism with modern thought, and stringing the continuity of scientific in spite of great revo- lutionary changes. The beginning is ascribed to A. Hyperius (Gerhard of Ypres), a professor at Marburg, and, it seems, a conciliatory Lutheran, not, as sometimes said, a Reformed (1521-64). He published Four Books on the Study of Theo- logy (1556). Book iv. is said to be the first appearance of Practical Theology—Liturgies, Pastoral Theology, &c. In virtue of another work (De Formandis Concionibus, 1553),

THEOLOGY

Hyperius has been further termed the father of Homiletics. L. Danaeus (Danae), a French Protestant, has the merit of publishing for the first time on Christian Ethics (1577). It has been supposed that the Reformed divinity here set itself to remedy the dogmatic dryness of Protestant scholasticism, fifty years before the Lutheran G. Calixtus moved in the matter (Theol. Moralis, 1634). Too much has been made of this. Danaeus hardly represents at all what moderns mean by Christian ethics. He does not contrast the Christian outlook upon ethics with all others, but dwells chiefly upon the super-eminence of the Ten Commandments as a summary of duty. Of his distinguished opponent J. T. Gabler, wrote in 1877 De Justo Discipline Theologicae Bibliicae et Dogmaticae. Biblical Theology is a historical statement of the different Bible teachings, not a dogmatic statement of what the writer holds for truth, qua truth. Again, P. K. Marheineke is named as the first writer (1810) on Symbolics, the comparative study of creeds and confessions of faith. In 1764 the introductory study of theology as a whole, which Hyperius invented, had been given by S. Murisima the name it has since undergone, and come to be assigned to the branch Encyclopaedias have been "material," i.e. connected treatises, giving a brief outline of theology as a whole; not, of course, alphabetic indexes or dictionaries. The most famous of all, however—Schleiermacher's Kurz Darstellung des theologischen Studiums (1st ed. 1811)—belongs to the class of "formal" encyclopaedias. It states how theology should be divided, but does not profess to give a bird's-eye view of results.

Schleiermacher's treatise is highly individual. Theology is viewed as essentially a branch of church administration. True, in the theologian's proper—so called the scientific interest is strong; where the religious or practical interest is stronger, he gets church rulers or administrators in a narrower sense. Still, even to the theologian the practical interest in church welfare is vital. Theology loses its savour when studied in a spirit of merely scientific curiosity; and it does not concern the lay Christian.

In spite of what may be deemed eccentric in this standpoint, Schleiermacher's summary is full of interest. He divides as follows:—I. Philosophical Theology; A. Apologetics; B. Polemics. II. Historical Theology: A. Exegetical—Including the determination of the canon; B. Church History proper; C. The depicting of the present state of the Church; (1) its faith—Dogmaties; the behavior and life of Church and Churchmen; (2) Statistics; these should be universal. Symbolics is to be a branch of statistics. Biblical "Dogmaties" also is said to be nearer this than it is to Dogmaties proper. III. Practical Theology: A. the service of the Church; B. History, the moral, political, and Church Government of the (national or international) Church; questions of relation to the State, &c. The reader will note Schleiermacher's peculiar way of dealing with Dogmatic as the belief of the Church—an unproven statement, according to A. Kirschl—and his requiring that belief to be reported qua historical fact.

It is singular that Schleiermacher on the whole sums up in the Kurz Darstellung against the separation of Christian Ethics from Dogmaties. But he grants that much may be said on both sides of that question, and in his own Glaubenslehre he follows ordinary usage and as far as possible banishes Ethics to a Christliche Sittenlehre, a book which has caused him to be regarded by Protestants as the founder of modern Christian Ethics. There are therefore three parallel studies, on all of which Schleiermacher published—Dogmatic or Glaubenslehre, Christian Ethics, Philosophical Ethics.

Curiously enough, it is from Schleiermacher's philosophical ethics that a threefold division—the Chief Good, Virtues, and Duty or the Law—passed into almost all textbooks of Christian Ethics, till recently a rebellion rose against it on the ground that books of this sort should not be included in the curriculum of the Kingdom of God, which Paulinized dogmatic systems were slow to admit. It should also be noted that Schleiermacher's place for Apologetics is by no means undisputed. Many dislike the subject; some would thrust it into practical theology. Again, the new study of the religions of the world is seeking its place in the curriculum of Christian theology, just as it is seeking—in some way—to modify Christian thought. The recognized place, the assured results, have not yet been attained further details must be sought in textbooks. But it may be affirmed that Dogmatic must remain the vital centre; and so far we may set Flint's censure of the British School of thoughtlessness which has called that study by the name "systematic theology." Systems of ethics and apologetics are welcome to the theologian; "encyclopaedia" is a new and broader-based "systematic theology" in itself; but none of these is central as Dogmatic is. One may also venture to declare that Dogmatic rests upon philosophical and historical studies, and exists for practical uses. Thus a triple or fourfold division of theological sciences seems natural.
